Writing Device Drivers
Contents

Preface 17

1 Solaris Kernel and Device Tree 23
   What Is the Kernel? 23
      Multithreaded Execution Environment 25
      Virtual Memory 25
      Devices as Special Files 25
      DDI/DKI Interfaces 26
   Overview of the Device Tree 27
      Device Tree Components 27
      Displaying the Device Tree 28
      Binding a Driver to a Device 30

2 Overview of Solaris Device Drivers 35
   What Is a Device Driver? 35
   Types of Device Drivers 36
      Block Device Drivers 36
      Character Device Drivers 36
      STREAMS Drivers 37
   Driver Module Entry Points 37
      Loadable Module Entry Points 38
      Autoconfiguration Entry Points 38
      Character and Block Driver Entry Points 39
      Power Management Entry Point 39
   Device Driver Design Considerations 39
3  Multithreading  45
  Locking Primitives  45
  Storage Classes of Driver Data  45
  Mutual-Exclusion Locks  46
  Readers/Writer Locks  47
  Semaphores  48
  Thread Synchronization  48
  Condition Variables in Thread Synchronization  48
  cv_wait() and cv_timedwait() Functions  50
  cv_wait_sig() Function  51
  cv_timedwait_sig() Function  52
  Choosing a Locking Scheme  52
  Potential Locking Pitfalls  53

4  Properties and Events  55
  Device Properties  55
  Device Property Names  56
  Creating and Updating Properties  56
  Looking up Properties  56
  prop_op() Entry Point  58
  Events  59
  How Drivers Track Events: ddi_log_sysevent()  60
  Event Name-Value Pairs  62

5  Driver Autoconfiguration  65
  Driver Loading and Unloading  65
  Data Structures Required for Drivers  66
  modlinkage Structure  66
  modldriv Structure  67
  dev_ops Structure  67

4  Writing Device Drivers • May 2002
cb_ops Structure 68
Loadable Driver Interfaces 69
  _init() Example 70
  _fini() Example 71
  _info() Example 71
Device Configuration Concepts 72

Index 439
Writing Device Drivers provides information on developing device drivers for character-oriented devices, block-oriented devices, and small computer system interface (SCSI) target devices. This book discusses the development of a dynamically loadable and unloadable, multithreaded re-entrant device driver applicable to all architectures that conform to the Solaris 9™ DDI/DKI. A common driver programming approach is taken so that drivers can be written without concern for platform-specific issues, such as endianness and data ordering.

Who Should Use This Book

The audience for this book is UNIX® programmers familiar with UNIX device drivers. Several overview chapters at the beginning of the book provide background information for the detailed technical chapters that follow, but they are not intended as a general tutorial on device drivers.

Note – The Solaris operating environment runs on two types of hardware, or platforms—SPARC™ and IA. The Solaris operating environment also runs on both 64-bit and 32-bit address spaces. The information in this document pertains to both platforms and address spaces unless called out in a special chapter, section, note, bullet, figure, table, example, or code example.
How This Book Is Organized

This book is organized into the following chapters.

- Chapter 1 provides an overview of the Solaris kernel and the manner in which it represents devices as nodes in a device tree.
- Chapter 2 gives an outline of the kinds of device drivers and their basic structure. It points out the common data access routines and concludes with an illustrated roadmap of common driver entry points and structures.
- Chapter 3 describes the mechanisms of the Solaris multithreaded kernel that are of interest to driver writers.
- Chapter 4 describes the set of interfaces used to read an update device node properties. It also contains information on events and name-value pairs.
- Chapter 5 explains the support a driver must provide for autoconfiguration.
- Chapter 6 describes the interfaces and methodologies for drivers to use to access (read or write) device memory.
- Chapter 7 describes the interrupt handling mechanisms. These include registering, servicing, and removing interrupts.
- Chapter 8 describes direct memory access (DMA) and the DMA interfaces.
- Chapter 9 explains the interfaces for Power Management™, a framework designed to regulate and reduce the power consumed by computer systems and devices.
- Chapter 10 describes the structure and functions of a driver for a character-oriented device.
- Chapter 11 describes the structure and functions of a driver for a block-oriented device.
- Chapter 12 describes the set of interfaces that enable device drivers to manage access to memory, control the context of user processes accessing a device, and take advantage of large data transfers using new MMU hardware.
- Chapter 13 describes the set of interfaces that enable device drivers to manage user access to devices.
- Chapter 14 outlines the Sun Common SCSI Architecture and describes the additional requirements of SCSI target drivers.
- Chapter 15 explains how to write a SCSI Host Bus Adapter (HBA) driver using the Sun Common SCSI Architecture (SCSA).
- Chapter 16 describes the Generic LAN driver (GLD), which is used for Solaris network drivers. GLD uses STREAMS technology, along with the Data Link Provider Interface (DLPI) for communicating with network protocol stacks.
- Chapter 17 provides information on compiling and linking a driver, and for installing it in the system.
Chapter 18 gives hints, a simple mdb/kadb tutorial, and some hints on testing the driver.

Chapter 19 describes the recommended coding practices for writing drivers.

Appendix A discusses multi-platform hardware issues related to device drivers.

Appendix B summarizes, by topic, the kernel functions that device driver can use.

Appendix C provides guidelines for updating a device driver to run in a 64-bit environment.

Related Books and Papers

For detailed reference information about the device driver interfaces, see the man page sections 9, 9E (entry points), 9F (functions), and 9S (structures). For information on hardware and other driver-related issues, the following books might be helpful.

From Sun Microsystems:

From other sources:

Note – In this document, the term “IA” refers to the Intel 32-bit processor architecture, which includes the Pentium, Pentium Pro, Pentium II, Pentium II Xeon, Celeron, Pentium III, Pentium III Xeon, and Pentium 4 processors, and compatible microprocessor chips made by AMD and Cyrix.
Accessing Sun Documentation Online

The docs.sun.comSM Web site enables you to access Sun technical documentation online. You can browse the docs.sun.com archive or search for a specific book title or subject. The URL is http://docs.sun.com.

Typographic Conventions

The following table describes the typographic changes used in this book.

A device driver needs to work transparently as an integral part of the operating environment. Understanding how the kernel works is a prerequisite for learning about device drivers. This chapter provides an overview of the Solaris kernel and device tree. For an overview of how device drivers work, see Chapter 2.

This chapter provides information on the following subjects:

- “What Is the Kernel?” on page 23
- “Multithreaded Execution Environment” on page 25
- “Virtual Memory” on page 25
- “Devices as Special Files” on page 25
- “DDI/DKI Interfaces” on page 26
- “Device Tree Components” on page 27
- “Displaying the Device Tree” on page 28
- “Binding a Driver to a Device” on page 30

What Is the Kernel?

The Solaris kernel is a program that manages system resources. It insulates applications from the system hardware and provides them with essential system services such as input/output (I/O) management, virtual memory, and scheduling. The kernel consists of object modules that are dynamically loaded into memory when needed.

One way to look at the Solaris kernel is to divide it into two parts: the first part, referred to as the kernel, manages file systems, scheduling, and virtual memory. The second part, referred to as the I/O subsystem, manages the physical components.
The kernel provides a set of interfaces for applications to use that are accessible through system calls. System calls are documented in the Solaris 9 Reference Manual Collection (see Intro(2)). Some system calls are used to invoke device drivers to perform I/O. Device drivers are loadable kernel modules that manage data transfers while insulating the rest of the kernel from the device hardware. To be compatible with the operating environment, device drivers need to be able to accommodate such features as multithreading, virtual memory addressing, and both 32-bit and 64-bit operation.

The following figure illustrates the kernel, with the kernel modules handling system calls from application programs and the I/O modules communicating with hardware.

**FIGURE 1–1 The Solaris Kernel**

The kernel provides access to device drivers through:

- **Device-to-driver mapping** — The kernel maintains the *device tree*. Each node in the tree represents a virtual or a physical device. The kernel binds each node to a driver by matching the device node name with the set of drivers installed in the system. The device is made accessible to applications only if there is a driver binding.
DDI/DDK interfaces — DDI/DDK stands for Device Driver Interface Driver-Kernel Interface. The DDI/DKI interfaces standardize interactions between the driver and the kernel, the device hardware, and the boot/configuration software. Use of these interfaces keeps the driver independent from the kernel and improves its portability across successive releases of the operating environments on a particular machine.

Multithreaded Execution Environment

The Solaris kernel is multithreaded. On a multiprocessor machine, multiple kernel threads can be running kernel code, and can do so concurrently. Kernel threads can also be preempted by other kernel threads at any time.

The multithreading of the kernel imposes some additional restrictions on device drivers. For more information on multithreading considerations, see Chapter 3. Device drivers must be coded to run as needed at the request of many different threads. For each thread, it must handle contention problems from overlapping I/O requests.

Virtual Memory

A complete overview of the Solaris virtual memory system is beyond the scope of this book, but two virtual memory terms of special importance are used when discussing device drivers: virtual address and address space.

- Virtual address — A virtual address is an address that is mapped by the memory management unit (MMU) to a physical hardware address. All addresses directly accessible by the driver are kernel virtual addresses; they refer to the kernel address space.
- Address space — An address space is a set of virtual address segments, each of which is a contiguous range of virtual addresses. Each user process has an address space called the user address space. The kernel has its own address space called the kernel address space.

Devices as Special Files

Devices are treated as files. They are represented in the file system by special files. In the Solaris operating environment these files reside in the /devices directory hierarchy.

Special files can be of type block or character. The type indicates which kind of device driver operates the device. Drivers can be implemented to operate on both types. For example, disk drivers export a character interface for use by the fsck(1) and mkfs(1) utilities, and a block interface for use by the file system.
Associated with each special file is a device number \( (\text{dev}_t) \). This consists of a major number and a minor number. The major number identifies the device driver associated with the special file. The minor number is created and used by the device driver to further identify the special file. Usually, the minor number is an encoding that identifies the device instance the driver should access and the type of access to perform. The minor number, for example, could identify a tape device used for backup and also specify whether the tape needs to be rewound when the backup operation is complete.

**DDI/DKI Interfaces**

In System V Release 4 (SVR4), the interface between device drivers and the rest of the UNIX kernel was standardized as the DDI/DKI. The Solaris 9 DDI/DKI is documented in Section 9 of the Solaris 9 Reference Manual Collection. This section documents driver entry points, driver-callable functions, and kernel data structures used by device drivers.

The Solaris 9 DDI/DKI, like its SVR4 counterpart, is intended to standardize and document all interfaces between device drivers and the rest of the kernel. In addition, the Solaris 9 DDI/DKI allows source compatibility for drivers on any machine running the Solaris 9 operating environment, regardless of the processor architecture (such as SPARC or IA). It is also intended to provide binary compatibility for drivers running on any Solaris 9-based processor, regardless of the specific platform architecture. Drivers using only kernel facilities that are part of the Solaris 9 DDI/DKI are known as Solaris 9 DDI/DKI-compliant device drivers.

The Solaris 9 DDI/DKI allows platform-independent device drivers to be written for Solaris 9 based machines. These shrink-wrapped (binary compatible) drivers enable third-party hardware and software to be more easily integrated into Solaris 9-based machines. The Solaris 9 DDI/DKI is designed to be architecture independent and enable the same driver to work across a diverse set of machine architectures.

Platform independence is accomplished by the design of DDI in Solaris 9 DDI/DKI. The following main areas are addressed:

- Dynamic loading and unloading of modules
- Power management
- Interrupt handling
- Accessing the device space from the kernel or a user process (register mapping and memory mapping)
- Accessing kernel or user process space from the device (DMA services)
- Managing device properties
Overview of the Device Tree

Devices in Solaris are represented as a tree of interconnected device information nodes.

Device Tree Components

The system builds a tree structure that contains information about the devices connected to the machine at boot time. The device tree can also be modified by dynamic reconfiguration operations while the system is in normal operation.

The tree begins at the “root” device node, which represents the platform. Below the root node are “branches” of the device tree, where a branch consists of one or more bus nexus devices and a terminating leaf device.

A bus nexus device provides bus mapping and translation services to devices that are subordinate to it in the device tree. PCI - PCI bridges, PCMCIA adapters, and SCSI HBAs are all example of nexus devices. The discussion of writing drivers for nexus devices is limited to that of developing SCSI HBA drivers (see Chapter 15).

Leaf devices are typically peripheral devices such as disks, tapes, network adapters, frame buffers, and so forth. Drivers for these devices export the traditional character and block driver interfaces for use by user processes to read and write data to storage or communication devices.

Each driver exports a device operations structure dev_ops(9S) that defines the operations that the device driver can perform. The device operations structure contains function pointers for generic operations such as attach(9E), detach(9E), and getinfo(9E). It also contains a pointer to a set of operations specific to bus nexus drivers and a pointer to a set of operations specific to leaf drivers.

The tree structure creates a parent-child relationship between nodes. This parent-child relationship is the key to architectural independence. When a leaf or bus nexus driver requires a service that is architecturally dependent in nature, it requests its parent to provide the service. This approach enables drivers to function regardless of the architecture of the machine or the processor. A typical device tree is shown in the following figure.
The nexus nodes may have one or more children, and the leaf nodes represent individual devices.

Displaying the Device Tree

The device tree can be displayed in three ways:

- The **libdevinfo** library provides interfaces to access the contents of the device tree programmatically.
- The **prtconf**(1M) command displays the complete contents of the device tree.
- The **/devices** hierarchy is a representation of the device tree; use **ls**(1) to view it.

**Note** – **/devices** displays only devices that have drivers configured into the system. **prtconf**(1M) shows all device nodes regardless of whether a driver for the device exists on the system.

The **libdevinfo** Library

The **libdevinfo** library provides interfaces for accessing all public device configuration data. See the **libdevinfo**(3DEVINFO) man page for a list of interfaces.
The `prtconf` Command

The `prtconf(1M)` command (excerpted example follows) displays all the devices in the system:

```
System Configuration: Sun Microsystems sun4u
Memory size: 128 Megabytes
System Peripherals (Software Nodes):

SUNW, Ultra-5_10
  packages (driver not attached)
  terminal-emulator (driver not attached)
  deblocker (driver not attached)
  obp-tftp (driver not attached)
  disk-label (driver not attached)

```

Binding a Driver to a Device

In addition to constructing the device tree, the kernel also determines the drivers that will be used to manage the devices.
Binding a driver to a device refers to the process by which the system selects a driver to manage a particular device. The driver binding name is the name that links a driver to a unique device node in the device information tree. For each device in the device tree, the system attempts to choose a driver from a list of installed drivers.

Each device node has a *name* property associated with it. This property can be assigned either from an external agent, such as the PROM, during system boot or from a *driver.conf* configuration file. In either case, the *name* property represents the node name assigned to a device in the device tree. The node name is the name visible in `/devices` and listed in the `prtconf(1M)` output.

![Diagram of device node names](image)

**FIGURE 1-3 Device Node Names**

A device node can also have a *compatible* property associated with it. The *compatible* property (if it exists) contains an ordered list of one or more possible driver names or driver aliases for the device.

The system uses both the *compatible* and the *name* properties to select a driver for the device. The system first attempts to match the contents of the *compatible* property (if the *compatible* property exists) to a driver on the system. Beginning with the first driver name on the *compatible* property list, the system attempts to match the driver name to a known driver on the system. It processes each entry on the list until either a match is found or the end of the list is reached.

If the contents of either the *name* property or the *compatible* property match a driver on the system, then that driver is bound to the device node. If no match is found, no driver is bound to the device node.
Generic Device Names

Some devices specify a *generic* device name as the value for the `name` property. Generic device names describe the function of a device without actually identifying a specific driver for the device. For example, a SCSI host bus adapter might have a generic device name of `scsi`. An Ethernet device might have a generic device name of `ethernet`.

The `compatible` property allows the system to determine alternate driver names (like `glm` for `scsi` HBA device drivers or `hme` for `ethernet` device drivers) for devices with a generic device name.

Devices with generic device names are required to supply a `compatible` property.

---

**Note** – For a complete description of *generic device names*, see the IEEE 1275 Open Firmware Boot Standard.

---

Figure 1–4 and Figure 1–5 show two device nodes: one node uses a specific device name and the other uses a generic device name. For the device node with a specific device name, the driver binding name `SUNW,ffb` is the same name as the device node name.

**Device Node A**

| name = SUNW,ffb |
| binding name = SUNW,ffb |

/devices/SUNW,ffb@le,0:ffb0

**FIGURE 1–4** Specific Driver Node Binding

For the device node with the generic device name `display`, the driver binding name `SUNW,ffb` is the first name on the `compatible` property driver list that matches a driver on the system driver list. In this case, `display` is a generic device name for frame buffers.
Device Node B

```plaintext
name = display
compatible = fast_fb
           SUNW,ffb
           slow_fb
binding name = SUNW,ffb
```

/devices/display@le,0:ffb0

**FIGURE 1-5** Generic Driver Node Binding
Overview of Solaris Device Drivers

This chapter gives an overview of Solaris device drivers. It provides information on the following subjects:

- “What Is a Device Driver?” on page 35
- “Types of Device Drivers” on page 36
- “Driver Module Entry Points” on page 37
- “Device Driver Design Considerations” on page 39

What Is a Device Driver?

A device driver is a kernel module responsible for managing low-level I/O operations for a particular hardware device. Device drivers can also be software-only, emulating a device that exists only in software, such as a RAM disk or a pseudo-terminal.

A device driver contains all the device-specific code necessary to communicate with a device and provides a standard set of interfaces to the rest of the system. This interface protects the kernel from device specifics just as the system call interface protects application programs from platform specifics. Application programs and the rest of the kernel need little (if any) device-specific code to address the device. In this way, device drivers make the system more portable and easier to maintain.
Types of Device Drivers

There are several kinds of device drivers, each handling a different kind of I/O. Block device drivers manage devices with physically addressable storage media, such as disks. All other devices are considered character devices. Two types of character device drivers are standard character device drivers and STREAMS device drivers.

Block Device Drivers

Devices that support a file system are known as block devices. Drivers written for these devices are known as block device drivers. Block device drivers take a file system request, in the form of a buf(9S) structure, and issue the I/O operations to the disk to transfer the specified block. The main interface to the file system is the strategy(9E) routine. See Chapter 11 for more information.

Block device drivers can also provide a character driver interface that allows utility programs to bypass the file system and access the device directly. This device access is commonly referred to as the raw interface to a block device.

Character Device Drivers

Character device drivers normally perform I/O in a byte stream. Examples of devices using character drivers include tape drives and serial ports. Character device drivers can also provide additional interfaces not present in block drivers, such as I/O control (ioctl) commands, memory mapping, and device polling. See Chapter 10 for more information.

Byte-Stream I/O

The main task of any device driver is to perform I/O, and many character device drivers do what is called byte-stream or character I/O. The driver transfers data to and from the device without using a specific device address. This is in contrast to block device drivers, where part of the file system request identifies a specific location on the device.

The read(9E) and write(9E) entry points handle byte-stream I/O for standard character drivers. See “I/O Request Handling” on page 156 for more information.
Memory Mapped Devices

For certain devices, such as frame buffers, application programs having direct access to device memory is more efficient than byte-stream I/O. Applications can map device memory into their address spaces using the `mmap(2)` system call. To support memory mapping, device drivers implement `segmap(9E)` and `devmap(9E)` entry points. For information on `devmap(9E)`, see Chapter 12. For information on `segmap(9E)`, see Chapter 10.

Drivers that define the `devmap(9E)` entry point usually do not define `read(9E)` and `write(9E)` entry points, as application programs perform I/O directly to the devices after calling `mmap(2)`.

STREAMS Drivers

STREAMS is a separate programming model for writing a character driver. Devices that receive data asynchronously (such as terminal and network devices) are suited to a STREAMS implementation. STREAMS device drivers must provide the loading and autoconfiguration support described in Chapter 5. See the Streams Programming Guide for additional information on how to write STREAMS drivers.

Driver Module Entry Points

Each device driver defines a standard set of functions called *entry points*, which are listed in `Intro(9E)`. These entry points are called by the Solaris kernel to load and unload the driver, autoconfigure devices, and provide the character, block, or STREAMS driver I/O services. Drivers for different types of devices have different sets of entry points according to the kinds of operations the devices perform. A driver for a memory-mapped character-oriented device, for example, supports a `devmap(9E)` entry point, while a block driver does not support this entry.

dev_ops(9S)

Character/block driver entry points

cb_ops(9S)

FIGURE 2-1 Device Driver Overview

Some operations are common to all drivers, such as the functions that are required for module loading (_init(9E), _info(9E), and _fini(9E)), and the required autoconfiguration entry points attach(9E), detach(9E), and getinfo(9E). Drivers also support the optional autoconfiguration entry point for probe(9E). Most leaf drivers have open(9E) and close(9E) entry points to control access to their devices.

Traditionally, all driver function and variable names have some prefix added to them. Usually this is the name of the driver, such as xxopen() for the open(9E) routine of driver xx. In subsequent examples, xx is used as the driver prefix.

Note – In the Solaris 9 operating environment, only the loadable module routines must be visible outside the driver object module. Other routines can have the storage class static.

Loadable Module Entry Points

All drivers are required to implement the loadable module entry points _init(9E), _fini(9E), and _info(9E) to load, unload, and report information about the driver module.

Drivers should allocate and initialize any global resources in _init(9E) and release their resources in _fini(9E).

Autoconfiguration Entry Points

Drivers are required to implement the attach(9E), detach(9E), and getinfo(9E) entry points for device autoconfiguration. Drivers might need to implement probe(9E) if the driver supports devices that are not self identifying, such as SCSI target devices. See Chapter 5 for more information on these routines.
Character and Block Driver Entry Points

Drivers for character and block devices export a cb_ops(9S) structure, which defines the driver entry points for block device access and character device access. Both types of drivers are required to support open(9E) and close(9E). Block drivers are required to support strategy(9E), while character drivers can choose to implement whatever mix of read(9E), write(9E), ioctl(9E), mmap(9E), or devmap(9E) entry points as appropriate for the type of device. Character drivers can also support a polling interface through chpoll(9E), as well as asynchronous I/O through aread(9E) and awrite(9E).

For information on character driver entry points, see Chapter 10. For information on block driver entry points, see Chapter 11.

Power Management Entry Point

Drivers for hardware devices that provide Power Management functionality can support the optional power(9E) entry point. See Chapter 9 for details about this entry point.

Device Driver Design Considerations

Device driver must be compatible with the Solaris operating environment, both as a consumer and provider of services. This section discusses the following issues which should be considered in device driver design:

- “DDI/DKI Facilities” on page 39
- “Driver Context” on page 42
- “Returning Errors” on page 42
- “Dynamic Memory Allocation” on page 43
- “Hotplugging” on page 43
- “Driver Layout” on page 44

DDI/DKI Facilities

This section discusses design considerations necessary for using the DDI/DKI interfaces.
Device IDs

The Solaris DDI provides interfaces that allow drivers to provide a persistent, unique identifier for a device. The device ID can be used to identify or locate a device and is independent of the device’s name or number (dev_t). Applications can use the functions defined in libdevid(3LIB) to read and manipulate the device IDs registered by the drivers.

Device Properties

The attributes of a device or device driver are specified by properties. A property is a name-value pair. The name is a string that identifies the property with an associated value. Properties can be defined by the FCode of a self-identifying device, by a hardware configuration file (see the driver.conf(4) man page), or by the driver itself using the ddi_prop_update(9F) family of routines.

Interrupt Handling

The Solaris 9 DDI/DKI addresses these aspects of device interrupt handling:

- Registering device interrupts with the system
- Removing device interrupts
- Dispatching interrupts to interrupt handlers

Device interrupt sources are contained in a property called interrupt, which is either provided by the PROM of a self-identifying device, in a hardware configuration file, or by the booting system on the IA platform.

Callback Functions

Certain DDI mechanisms provide a callback mechanism. DDI functions provide a mechanism for scheduling a callback when a condition is met. Conditions for which callback functions are used include:

- When a transfer has completed
- When a resource might have become available
- When a time-out period has expired

In some sense, callback functions are similar to entry points—interrupt handlers, for example. DDI functions that allow callbacks expect the callback function to perform certain tasks. In the case of DMA routines, a callback function must return a value indicating whether the callback function needs to be rescheduled in case of a failure. Callback functions execute as a separate interrupt thread and must handle all the usual multithreading issues.
Note – A driver must cancel all scheduled callback functions before detaching a device.

Software State Management

To assist device driver writers in allocating state structures, the Solaris 9 DDI/DKI provides a set of memory management routines called the software state management routines (also known as the soft state routines). These routines dynamically allocate, retrieve, and destroy memory items of a specified size, and hide the details of list management. An instance number is used to identify the desired memory item; this number can be (and usually is) the instance number assigned by the system.

Routines are provided to:

- Initialize a driver’s soft state list
- Allocate space for an instance of a driver’s soft state
- Retrieve a pointer to an instance of a driver’s soft state
- Free the memory for an instance of a driver’s soft state
- Finish using a driver’s soft state list

See “Loadable Driver Interfaces” on page 69 for an example of how to use these routines.

Programmed I/O Device Access

Programmed I/O device access is the act of reading and writing of device registers or device memory by the host CPU. The Solaris DDI provides interfaces for mapping a device’s registers or memory by the kernel as well as interfaces for reading and writing to device memory from the driver. These interfaces are designed to enable drivers to be developed that are platform and bus independent, by automatically managing any difference in device and host endianness as well as enforcing any memory-store ordering requirements imposed by the device.

Direct Memory Access (DMA)

Solaris defines a high-level, architecture-independent model for supporting DMA-capable devices. The Solaris DDI is designed to shield drivers from platform-specific details, which enables a common driver to be developed that runs across multiple platforms and architectures.
Driver and Device Statistics

Solaris provides a rich set of interfaces for maintaining and exporting kernel-level statistics, or *kstats*. Drivers are free to use these interfaces to export driver and device statistics that can be used by user applications to observe the internal state of the driver. See the `kstat_create(9F)` and `kstat(3KSTAT)` man pages for additional information.

Driver Context

The driver context determines which kernel routines the driver is permitted to call. There are four contexts in which driver code executes:

- **User context** – A driver entry point has *user context* if it was directly invoked because of a user thread. For example, the `read(9E)` entry point of the driver, invoked by a `read(2)` system call, has user context.
- **Kernel context** – A driver function has *kernel context* if it was invoked by some other part of the kernel. In a block device driver, the `strategy(9E)` entry point can be called by the pageout daemon to write pages to the device. Because the page daemon has no relation to the current user thread, `strategy(9E)` has kernel context in this case.
- **Interrupt context** – *Interrupt context* is a more restrictive form of kernel context. Driver interrupt routines operate in interrupt context and have an interrupt level associated with them. Callback routines also operate in an interrupt context. See Chapter 7 for more information.
- **High-level interrupt context** – *High-level interrupt context* is a more restricted form of interrupt context. If `ddi_intr_hilevel(9F)` indicates that an interrupt is high level, the driver interrupt handler will run in high-level interrupt context. See Chapter 7 for more information.

The manual pages in section 9F document the allowable contexts for each function. For example, in kernel context the driver must not call `copyin(9F)`.

Returning Errors

Device drivers do not usually print messages, except for unexpected errors such as data corruption. Instead, the driver entry points should return error codes so that the application can determine how to handle the error. If the driver must print a message, it should use `cmn_err(9F)` to do so. This is similar to the C function `printf(3C)`, which prints to the console, to the message buffer, or both.

The format string specifier interpreted by `cmn_err(9F)` is similar to the `printf(3C)` format string, with the addition of the format `%b`, which prints bit fields. Callers to `cmn_err(9F)` also specify the `level`, which indicates the label to be printed. The first character of the format string is treated specially. See the `cmn_err(9F)` man page for more details.
The level `CE_PANIC` has the side effect of crashing the system. This level should be used only if the system is in such an unstable state that to continue would cause more problems. It can also be used to get a system core dump when debugging. It should not be used in production device drivers.

Dynamic Memory Allocation

Device drivers must be prepared to simultaneously handle all attached devices that they claim to drive. There should be no driver limit on the number of devices that the driver handles, and all per-device information must be dynamically allocated.

```c
void *kmem_alloc(size_t size, int flag);
```

The standard kernel memory allocation routine is `kmem_alloc(9F)`. It is similar to the C library routine `malloc(3C)`, with the addition of the `flag` argument. The `flag` argument can be either `KM_SLEEP` or `KM_NOSLEEP`, indicating whether the caller is willing to block if the requested size is not available. If `KM_NOSLEEP` is set, and memory is not available, `kmem_alloc(9F)` returns `NULL`.

`kmem_zalloc(9F)` is similar to `kmem_alloc(9F)`, but also clears the contents of the allocated memory.

**Note** – Kernel memory is a limited resource, not pageable, and competes with user applications and the rest of the kernel for physical memory. Drivers that allocate a large amount of kernel memory can cause system performance to degrade.

```c
void kmem_free(void *cp, size_t size);
```

Memory allocated by `kmem_alloc(9F)` or by `kmem_zalloc(9F)` is returned to the system with `kmem_free(9F)`. This is similar to the C library routine `free(3C)`, with the addition of the `size` argument. Drivers *must* keep track of the size of each object they allocate in order to call `kmem_free(9F)` later.

Hotplugging

In general, this manual does not highlight hotplugging information; following the rules and suggestions for writing device drivers given in this book should enable any driver to handle hotplugging. In particular, you should ensure that autoconfiguration works (see Chapter 5) and always include a working `detach(9E)` routine in any driver. Writers of drivers with power management issues should also follow the information given in Chapter 9. SCSI HBA drivers may need to add a `cb_ops` structure to their `dev_ops` structure (see Chapter 15) to take advantage of hotplugging capabilities.
Previous versions of the Solaris operating system required hotpluggable drivers to include a `DT_HOTPLUG` property, but such a property is no longer required. (Driver writers are free, however, to include it and have routines make use of it as they see fit.)

For more information, visit http://sldc.sun.com/developer/support/driver/notes/scsi-hotplug.html, which contains links to hotplugging whitepapers.

**Driver Layout**

Driver code is usually divided into the following files:

- Headers (.h files)
- Source files (.c files)
- Optional configuration files (driver.conf file)

**Header Files**

Header files define data structures specific to the device (such as a structure representing the device registers), data structures defined by the driver for maintaining state information, defined constants (such as those representing the bits of the device registers), and macros (such as those defining the static mapping between the minor device number and the instance number).

Some of this information, such as the state structure, may only be needed by the device driver. This information should go in `private` headers. These header files are included only by the device driver itself.

Any information that an application might require, such as the I/O control commands, should be in `public` header files. These are included by the driver and any applications that need information about the device.

There is no standard for naming private and public files. One possible convention is to name the private header file `xximpl.h` and the public header file `xxio.h`.

**Source Files**

A .c file for a device driver contains the data declarations and the code for the entry points of the driver. It contains the #include statements the driver needs, declares extern references, declares local data, sets up the `cb_ops` and `dev_ops` structures, declares and initializes the module configuration section, makes any other necessary declarations, and defines the driver entry points.

**Configuration Files**

Information for configuration files used with device drivers can be found in `driver.conf(4), sbus(4), pci(4),` and `isa(4).`
Multithreading

This chapter describes the locking primitives and thread synchronization mechanisms of the Solaris multithreaded kernel. Device drivers should be designed to take advantage of multithreading. This chapter provides information on the following subjects:

- “Locking Primitives” on page 45
- “Thread Synchronization” on page 48
- “Choosing a Locking Scheme” on page 52

Locking Primitives

In traditional UNIX systems, every section of kernel code runs until it explicitly gives up the processor by calling sleep(1) or is interrupted by hardware. This is not true in the Solaris operating environment. A kernel thread can be preempted at any time to run another thread. Because all kernel threads share kernel address space and often need to read and modify the same data, the kernel provides a number of locking primitives to prevent threads from corrupting shared data. These mechanisms include mutual exclusion locks (or mutex), readers/writer locks, and semaphores.

Storage Classes of Driver Data

The storage class of data is a guide to whether the driver might need to take explicit steps to control access to the data. The three types of data storage classes are:

- **Automatic (stack) data** – Every thread has a private stack, so drivers never need to lock automatic variables.
- **Global and static data** – Global and static data can be shared by any number of threads in the driver; the driver might need to lock this type of data at times.
**Kernel heap data** – Any number of threads in the driver might share kernel heap data, such as data allocated by `kmem_alloc(9F)`. If this data is shared, the driver needs to protect it at times.

### Mutual-Exclusion Locks

A mutual-exclusion lock, or mutex, is usually associated with a set of data and regulates access to that data. Mutexes provide a way to allow only one thread at a time access to that data.

**TABLE 3-1 Mutex Routines**

</tr>
</tbody>
</table>

### Setting Up Mutexes

Device drivers usually allocate a mutex for each driver data structure. The mutex is typically a field in the structure and is of type `kmutex_t`. `mutex_init(9F)` is called to prepare the mutex for use. This is usually done at `attach(9E)` time for per-device mutexes and `_init(9E)` time for global driver mutexes.

For example,

```c
struct xxstate *xsp;
...
mutex_init(&xsp->mu, NULL, MUTEX_DRIVER, NULL);
...
```

For a more complete example of mutex initialization, see Chapter 5.

The driver must destroy the mutex with `mutex_destroy(9F)` before being unloaded. This is usually done at `detach(9E)` time for per-device mutexes and `_fini(9E)` time for global driver mutexes.
Using Mutexes

Every section of the driver code that needs to read or write the shared data structure must do the following:

- Acquire the mutex
- Access the data
- Release the mutex

The scope of a mutex—the data it protects—is entirely up to the programmer. A mutex protects some particular data structure because the programmer chooses to do so and uses it accordingly. A mutex protects a data structure only if every code path that accesses the data structure does so while holding the mutex.

Readers/Writer Locks

A readers/writer lock regulates access to a set of data. The readers/writer lock is so called because many threads can hold the lock simultaneously for reading, but only one thread can hold it for writing.

Most device drivers do not use readers/writer locks. These locks are slower than mutexes and provide a performance gain only when protecting data that is not frequently written but is commonly read by many concurrent threads. In this case, contention for a mutex could become a bottleneck, so using a readers/writer lock might be more efficient. The readers/writer functions are summarized in the following table. See the rwlock(9F) man page for detailed information.

**TABLE 3-2 Readers/Writer Locks**

Thread Synchronization

In addition to protecting shared data, drivers often need to synchronize execution among multiple threads.

Condition Variables in Thread Synchronization

Condition variables are a standard form of thread synchronization. They are designed to be used with mutexes. The associated mutex is used to ensure that a condition can be checked atomically, and that the thread can block on the associated condition variable without missing either a change to the condition or a signal that the condition has changed.

Table 3-4 lists the `condvar(9F)` interfaces.

### Initializing Condition Variables

Declare a condition variable (type `kcondvar_t`) for each condition. Usually, this is done in the driver's soft-state structure. Use `cv_init(9F)` to initialize each one. Similar to mutexes, condition variables are usually initialized at `attach(9E)` time. For example:

```c
cv_init(&xsp->cv, NULL, CV_DRIVER, NULL);
```

For a more complete example of condition variable initialization see Chapter 5.

### Waiting for the Condition

To use condition variables, follow these steps in the code path waiting for the condition:

1. Acquire the mutex guarding the condition.
2. Test the condition.
3. If the test results do not allow the thread to continue, use `cv_wait(9F)` to block the current thread on the condition. `cv_wait(9F)` releases the mutex before blocking. Upon return from `cv_wait(9F)` (which will reacquire the mutex before returning), repeat the test.
4. Once the test allows the thread to continue, set the condition to its new value. For example, set a device flag to busy.
5. Release the mutex.

### Signaling the Condition

Follow these steps in the code path signaling the condition:

1. Acquire the mutex guarding the condition.
2. Set the condition.
3. Signal the blocked thread with `cv_broadcast(9F)`.
4. Release the mutex.

Example 3–1 uses a busy flag along with mutex and condition variables to force the `read(9E)` routine to wait until the device is no longer busy before starting a transfer.

**EXAMPLE 3-1 Using Mutexes and Condition Variables**

```c
static int
xxread(dev_t dev, struct uio *uiop, cred_t *credp)
{
    struct xxstate *xsp;
    ...
    mutex_enter(&xsp->mu);
    while (xsp->busy)
        cv_wait(&xsp->cv, &xsp->mu);
    xsp->busy = 1;
    mutex_exit(&xsp->mu);
    /* perform the data access */
}

static uint_t
xxintr(caddr_t arg)
{
    struct xxstate *xsp = (struct xxstate *)arg;
    mutex_enter(&xsp->mu);
    xsp->busy = 0;
    cv_broadcast(&xsp->cv);
    mutex_exit(&xsp->mu);
}
```

**cv_wait() and cv_timedwait() Functions**

If a thread blocks on a condition with `cv_wait(9F)`, and that condition does not occur, it can wait forever. For that reason, it is often preferable to use `cv_timedwait(9F)`, which depends upon another thread to perform a wakeup. `cv_timedwait(9F)` takes an absolute wait time as an argument and returns `-1` if the time is reached and the event has not occurred. It returns a positive value if the condition is met.

cv_timedwait(9F) requires an absolute wait time expressed in clock ticks since the system was last rebooted. This can be determined by retrieving the current value with `ddi_get_lbolt(9F)`. The driver usually has a maximum number of seconds or microseconds to wait, so this value is converted to clock ticks with `drv_usec_tohz(9F)` and added to the value from `ddi_get_lbolt(9F)`.

Example 3–2 shows how to use `cv_timedwait(9F)` to wait up to five seconds to access the device before returning EIO to the caller.

**EXAMPLE 3-2 Using cv_timedwait()**

```c
clock_t cur_ticks, to;
mutex_enter(&xsp->mu);
while (xsp->busy) {
```
EXAMPLE 3-2 Using cv_timedwait() (Continued)

```c
cur_ticks = ddi_get_lbolt();
to = cur_ticks + drv_usec2hz(5000000); /* 5 seconds from now */
if (cv_timedwait(&xsp->cv, &xsp->mu, to) == -1) {
    /*
    * The timeout time 'to' was reached without the
    * condition being signalled.
    */
    /* tidy up and exit */
    mutex_exit(&xsp->mu);
    return (EIO);
}
}
xsp->busy = 1;
mutex_exit(&xsp->mu);
```

Although device driver writers generally find it preferable to use `cv_timedwait(9F)` over `cv_wait(9F)`, there are situations in which `cv_wait(9F)` is a better choice. For example, `cv_wait(9F)` would be better when a driver is waiting on:

- Internal driver state changes, where such a state change may require some command to be executed, or a set amount of time to pass.
- Something the driver needs to single-thread.
- Some situation that is already managing a possible timeout, as when “A” depends on “B,” and “B” itself is using `cv_timedwait(9F)`.

**cv_wait_sig() Function**

There is always the possibility that either the driver accidentally waits for a condition that will never occur or that the condition will not happen for a long time. In either case, the user can abort the thread by sending it a signal. Whether the signal causes the driver to wake up depends upon the driver.

`cv_wait_sig(9F)` allows a signal to unblock the thread. This enables the user to break out of potentially long waits by sending a signal to the thread with `kill(1)` or by typing the interrupt character. `cv_wait_sig(9F)` returns zero if it is returning because of a signal, or nonzero if the condition occurred.

Example 3-3 shows how to use `cv_wait_sig(9F)` to allow a signal to unblock the thread.

EXAMPLE 3-3 Using cv_wait_sig()
```
mutex_enter(&xsp->mu);
while (xsp->busy) {
    if (cv_wait_sig(&xsp->cv, &xsp->mu) == 0) {
        /* Signalled while waiting for the condition */
    }
}
```
EXAMPLE 3-3 Using cv_wait_sig()  (Continued)

        /* tidy up and exit */
        mutex_exit(&xsp->mu);
        return (EINTR);
    }
    xsp->busy = 1;
    mutex_exit(&xsp->mu);

cv_timedwait_sig() Function

cv_timedwait_sig(9F) is similar to cv_timedwait(9F) and cv_wait_sig(9F), except that it returns -1 without the condition being signaled after a timeout has been reached, or 0 if a signal (for example, kill(2)) is sent to the thread.

For both cv_timedwait(9F) and cv_timedwait_sig(9F), time is measured in absolute clock ticks since the last system reboot.

Choosing a Locking Scheme

The locking scheme for most device drivers should be kept straightforward. Using additional locks allows more concurrency but increases overhead. Using fewer locks is less time consuming but allows less concurrency. Generally, use one mutex per data structure, a condition variable for each event or condition the driver must wait for, and a mutex for each major set of data global to the driver. Avoid holding mutexes for long periods of time.

- Use the multithreading semantics of the entry point to your advantage.
- Make all entry points re-entrant and reduce the amount of shared data by changing static variable to automatic.
- If your driver acquires multiple mutexes, acquire and release the mutexes in the same order in all code paths.
- Hold and release locks within the same functional space.
- Avoid holding driver mutexes when calling DDI interfaces which can block, for example, kmem_alloc(9F) with KM_SLEEP.

To look at lock usage, use lockstat(1M). lockstat(1M) monitors all kernel lock events, gathers frequency and timing data about the events, and displays the data.

See the Multithreaded Programming Guide for more details on multithreaded operations.
Potential Locking Pitfalls

Mutexes are not re-entrant by the same thread. If you already own the mutex, attempting to claim it again leads to this panic:

`panic: recursive mutex_enter. mutex %x caller %x`

Releasing a mutex that the current thread does not hold causes this panic:

`panic: mutex_adaptive_exit: mutex not held by thread`

The following panic occurs only on uniprocessors:

`panic: lock_set: lock held and only one CPU`

It indicates that a spin mutex is held and will spin forever, because there is no other CPU to release it. This could happen because the driver forgot to release the mutex on one code path, or blocked while holding it.

A common cause of this panic is that the device’s interrupt is high-level and is calling a routine that blocks the interrupt handler while holding a spin mutex. This is obvious if the driver explicitly calls `cv_wait(9F)`, but might not be so if the driver is blocking while grabbing an adaptive mutex with `mutex_enter(9F)`.
Properties and Events

Properties and events are user-defined, name-value pair structures that are managed using the DDI/DKI interfaces. This chapter provides information on the following subjects:

- “Device Property Names” on page 56
- “Creating and Updating Properties” on page 56
- “Looking up Properties” on page 56
- “prop_op() Entry Point” on page 58
- “How Drivers Track Events: ddi_log_sysevent()” on page 60
- “Event Name-Value Pairs” on page 62

Device Properties

Device attribute (or device-related) information can be represented by a name-value pair notation called a property.

A reg property, for example, represents device registers and onboard memory. The reg property is a software abstraction that describes device hardware registers; its value encodes the device register address location and size. Drivers use the reg property to access device registers.

Another example is the interrupt property. An interrupt property represents the device interrupt. Its value encodes the device-interrupt PIN number.

The value of a property can be one of five types:

- A byte array that has an arbitrary length and whose value is a series of bytes
- An integer property whose value is an integer
- An integer array property whose value is an array of integers
- A string property whose value is a NULL-terminated string
A string array property whose value is a list of NULL-terminated strings.

A property that has no value is known as a Boolean property. It is considered to be true if it exists and false if it doesn’t exist.

Device Property Names

Strictly speaking, DDI/DKI software property names are not restricted in any way; however, there are certain recommended uses. As defined in IEEE 1275-1994 (the Standard for Boot Firmware), a property “is a human readable text string consisting of one to thirty-one printable characters. Property names shall not contain upper case characters or the characters "/", ",", ",[, "]," and ")@”. Property names beginning with the character "+" are reserved for use by future revisions of IEEE 1275-1994.” By convention, underscores are not used in property names; use a hyphen (-) instead. Also by convention, property names ending with the question mark character (auto-boot?) contain values that are strings, typically TRUE or FALSE.

Predefined property names are listed in publications of the IEEE 1275 Working Group. See http://playground.sun.com/1275 for information on how to obtain these publications. For a discussion of adding properties in driver configuration files, see driver.conf(4). The pm(9P) and pm-components(9P) man pages shows how properties are used in power management. Read the sd(7D) man page as an example of how properties should be documented in device driver man pages.

Creating and Updating Properties

To create a property for a driver, or to update an existing property, use one of the DDI driver update interfaces, such as ddi_prop_update_int(9F) or ddi_prop_update_string(9F), with the appropriate type for the property you want to create. (See Table 4-1 for a list of available property interfaces.) These interfaces are typically called from the driver’s attach(9E) entry point. In this example, the attach() routine creates a string property called pm-hardware-state and gives it the value needs-suspend-resume:

```c
/* The following code is to tell cpr that this device * needs to be suspended and resumed. */
(void) ddi_prop_update_string(device, dip,
   "pm-hardware-state", "needs-suspend-resume");
```

Looking up Properties

A driver can request a property from its parent, which in turn might ask its parent. The driver can control whether the request can go higher than its parent.
For example, the example driver below, “esp,” maintains an integer property for each target called \texttt{targetx-sync-speed}, where “\(x\)” is the target number. The \texttt{prtconf(1M)} command in its verbose mode displays driver properties. The following example shows a partial listing for the “esp” driver.

\[
\texttt{\% prtconf -v} \\
\texttt{...} \\
\texttt{esp, instance #0} \\
\texttt{Driver software properties:} \\
\texttt{\hspace{1em} name <target2-sync-speed> length <4>} \\
\texttt{\hspace{1em} value <0x00000fa0>}. \\
\texttt{...}
\]

The following table provides a summary of the property interfaces.

<table>
<thead>
<tr>

</tbody>
</table>
Whenever possible, use 64–bit versions of int property interfaces (such as ddi_prop_update_int64(9F)) instead of 32–bit versions (such as ddi_prop_update_int(9F)).

**prop_op() Entry Point**

ddi_prop_op(9F) can be used as a device driver’s prop_op(9E) entry point when ddi_prop_op() is defined within the driver’s cb_ops(9S) structure. ddi_prop_op() allows leaf devices to search for and obtain a property value from the device’s property list.

It is sometimes useful for a device driver to define a driver-specific prop_op() routine within cb_ops rather than invoking ddi_prop_op(). For example, this is appropriate if a driver maintains a property whose value changes frequently. Changing such a value with ddi_prop_update() would not be efficient. In this case, the driver is responsible for updating the property value and should maintain a copy of the property value either within its soft state structure or in a driver variable.

The prop_op(9E) entry point reports the values of certain driver or device properties to the system. In many cases, the ddi_prop_op(9F) routine may be used as the driver’s prop_op() entry point in the cb_ops(9S) structure. ddi_prop_op() performs all of the required processing and is sufficient for drivers that do not need to perform any special processing when handling a device property request.

However, there are cases when the driver must provide a prop_op() entry point. For example, if a driver maintains a property whose value changes frequently, updating the property with ddi_prop_update(9F) each time the value changes may not be efficient. Instead, the driver can maintain a local copy of the property in the instance’s soft state. The driver updates the shadow copy in the soft state when the value of the property changes and does not call one of the ddi_prop_update() routines. In this case, the prop_op() entry point would need to intercept requests for this property and call one of the ddi_prop_update() routines to update the value of the property before passing the request to ddi_prop_op() to process the property request.
In Example 4–1, prop_op() intercepts requests for the temperature property. The driver updates a variable in the state structure whenever the property changes but only updates the property when a request is made. It then uses the system routine ddi_prop_op() to process the property request. If the property request is not specific to a device, the driver does not intercept the request. This is indicated when the value of the dev parameter is equal to DDI_DEV_T_ANY (the wildcard device number).

**EXAMPLE 4–1 prop_op(9E) Routine**

```c
static int xxprop_op(dev_t dev, dev_info_t *dip, ddi_prop_op_t prop_op, int flags, char *name, caddr_t valuep, int *lengthp)
{
    minor_t instance;
    struct xxstate *xsp;
    if (dev != DDI_DEV_T_ANY) {
        return (ddi_prop_op(dev, dip, prop_op, flags, name,
                             valuep, lengthp));
    }
    instance = getminor(dev);
    xsp = ddi_get_soft_state(statep, instance);
    if (xsp == NULL)
        return (DDI_PROP_NOTFOUND);
    if (strcmp(name, "temperature") == 0) {
        ddi_prop_update_int(dev, dip, name, temperature);
    }
    /* other cases */
}
```

Events

A system often needs to respond to an external state change in some device. For example, it may issue a warning when a component begins to overheat, or start a movie player when a DVD is inserted into a drive.
How Drivers Track Events:

**ddi_log_sysevent()**

Device drivers use the `ddi_log_sysevent(9F)` interface to generate and log an event with the system; an event tells the system what has just occurred to the device. The system, in turn, queues events and passes them to the `syseventd()` daemon outside of kernel process space. `syseventd()` then passes the events on to an appropriate event-handling process, as shown in Figure 4–1.

![Event Plumbing Diagram](image)

**FIGURE 4–1 Event Plumbing**

`ddi_log_sysevent()` takes the following arguments:

- **dip** A pointer to the `dev_info` node for this driver.
- **vendor** A pointer to a string defining the driver’s vendor. Third-party drivers should use their company’s stock symbol or a similarly enduring identifier. Sun-supplied drivers use `DDI_VENDOR_SUNW`.
- **class** A pointer to a string defining the event’s class. This is a driver-specific value. An example of a class might be a string representing a set of environmental conditions affecting a device. This value must be intelligible to the event consumer.
subclass

Also a driver-specific string, this parameter represents a subset of the class argument. For example, within a class representing environmental conditions, an event subclass might refer to the device's temperature. This value must be intelligible to the event consumer.

attr_list

A pointer to an nvlist_t structure, listing name-value attributes associated with the event. Name-value attributes, like class and subclass, are driver-defined; they refer to some specific attribute or condition of the device. For example, a device that reads both CD-ROMs and DVDs may create a string name-value pair in which the name is disc_type and the value is either cd_rom or dvd. As with class and subclass, the driver handle (outside of kernel process space) must be able to interpret name-value pairs and respond to them in an appropriate manner.

For more on name-value pairs and the nvlist_t structure, see “Event Name-Value Pairs” on page 62, as well as nvlist_alloc(9F)

If there are no such attributes for an event, then this argument should be set to NULL.

eidp

The address of a sysevent_id_t structure. The sysevent_id_t structure is used to provide a unique identification for the event. ddi_log_sysevent(9F) returns this structure with a system-provided event sequence number and timestamp. See the ddi_log_sysevent(9F) page for more information on the sysevent_id_t structure.

sleep_flag

This flag indicates how a caller will handle the possibility of resources not being available. If sleep_flag is DDI_NOSLEEP, then it does not matter if allocation fails or the queue is full; the caller will handle such a failure appropriately. If sleep_flag is set to DDI_SLEEP, the caller will have allocation and queuing routines wait for resources to become available.

The following example demonstrates how ddi_log_sysevent() is used.

```
char *vendor_name = "DDI_VENDOR_JGJG"
char *my_class = "EC_ENVIRONMENT";
char *my_subclass = "ESC_TEMPERATURE";
vlist_t *nvl;
...

nvl = create_nvlist();

/* an event occurs... */...
if (ddi_log_sysevent(dip, vendor_name, my_class,
                   my_subclass, nvl, NULL, DDI_SLEEP)!= DDI_SUCCESS)
    cmn_err(CE_WARN, "error logging system event");
```
Event Name-Value Pairs

For interfaces such as ddi_log_sysevent(9F), the Solaris DDI provides a way to store information in name-value pairs. Name-value pairs are retained in an nvlist_t structure, which is opaque to the driver.

The value for a name-value pair may be a boolean, an int (16, 32, and 64-bit, signed or unsigned), a string, or an array of ints, bytes, or strings.

The steps in creating a list of name-value pairs are as follows.

1. Create an nvlist_t structure with nvlist_alloc(9F).

   The nvlist_alloc(9F) interface takes three arguments. The first is a pointer to an nvlist_t structure.

   The second is a flag relating to the uniqueness of the names of the pairs. If this flag is set to NV_UNIQUE_NAME_TYPE, any existing pair in the list will be removed if a new pair with the same name and type is added. If the flag is set to NV_UNIQUE_NAME, then any existing pair with the same name as one being added will be removed, regardless of its type. Specifying NV_UNIQUE_NAME_TYPE allows a list to contain two or more pairs with the same name, as long as their types are different, whereas with NV_UNIQUE_NAME only one instance of a pair name can be in the list. If neither value is used, then no uniqueness checking is done, and the consumer of the list must parse it in such a way as to ensure that any pair retrieved is the one wanted.

   The third argument relates to kernel memory allocation policy. If it is set to KM_SLEEP, then the driver will block until the requested memory is available for allocation. KM_SLEEP allocations may sleep but are guaranteed to succeed. KM_NOSLEEP allocations are guaranteed not to sleep but may fail (return NULL) if no memory is currently available.

2. Populate the nvlist with name-value pairs. For example, to add a string, use nvlist_add_string(9F); to add an array of 32-bit integers, use nvlist_add_int32_array(9F). The nvlist_add_boolean(9F) man page contains a complete list of interfaces for adding pairs.

To deallocate a list, use nvlist_free(9F).

EXAMPLE 4-2 Creating and Populating a Name-Value Pair List

```c
nvlist_t*
create_nvlist()
{
    int err;
    char *str = "child";
    int32_t ints[] = {0, 1, 2};
    nvlist_t *nvl;
    err = nvlist_alloc(&nvl, 0); /* allocate list */
    if (err)
        return (NULL);
    /* name="child" & prop={0, 1, 1} */
```
EXAMPLE 4-2 Creating and Populating a Name-Value Pair List  (Continued)

if ((nvlist_add_string(nvl, "name", str) != 0) ||
    (nvlist_add_int32_array(nvl, "prop", ints, 3) != 0)) {
    nvlist_free(nvl);
    return (NULL);
}
return (nvl);

Drivers can retrieve the elements of an nvlist by using a lookup function for that type, such as nvlist_lookup_int32_array(9F), which takes as its arguments the name and type of the pair being searched for. Note, however, that these interfaces will only work if either NV_UNIQUE_NAME or NV_UNIQUE_NAME_TYPE was specified when nvlist_alloc(9F) was called.

Name-value lists can be placed in contiguous memory (for example, to pass them to another process or send them to another host). To do so, first get the size of the memory block needed for the list with nvlist_size(9F), and then pack the list into the buffer with nvlist_pack(9F). The consumer receiving the buffer’s content can unpack the buffer with nvlist_unpack(9F).
Autoconfiguration is the process of getting the driver’s code and static data loaded into memory and registered with the system. It also involves configuring (attaching) individual device instances that are controlled by the driver.

This chapter provides information on the following subjects:

- “Driver Loading and Unloading” on page 65
- “Data Structures Required for Drivers” on page 66
- “Loadable Driver Interfaces” on page 69
- “Device Configuration Concepts” on page 72
- “Using Device IDs” on page 85

Driver Loading and Unloading

The system loads driver binary modules from the `drv` subdirectory of the kernel module directory for autoconfiguration (see “Copying the Driver to a Module Directory” on page 327). Once a module is read into memory with all symbols resolved, the system will call the `init()` entry point for that module. Upon successful completion of `init()`, the driver is properly registered with the system, or “loaded.” At this point, the driver is not actively managing any device; that will happen as part of device configuration.

The system unloads driver binary modules either to conserve system memory or at the explicit request of a user. Before deleting the driver code and data from memory, the `fini()` entry point of the driver is invoked. The driver is unloaded if and only if `fini()` returns success.
Figure 5–1 illustrates a structural overview of a device driver. The shaded area of this figure highlights the driver data structures and entry points. The upper half of the shaded area contains data structures and entry points supporting driver loading and unloading; the lower half, driver configuration.

**Modlinkage (9S)**

- `_info()`
- `_fini()`
- `_init()`

**Modldrv (9S)**

- `attach(9E)`
- `detach(9E)`
- `getinfo(9E)`
- `probe(9E)`
- `power(9E)`

**Dev_ops (9S)**

**Cb_ops (9S)**

**FIGURE 5–1 Module Loading and Autoconfiguration Entry Points**

Data Structures Required for Drivers

Drivers are required to statically initialize a number of data structures to support autoconfiguration. These structures include `modlinkage(9S)`, `modldrv(9S)`, `dev_ops(9S)`, and `cb_ops(9S)`.

The data structures illustrated in Figure 5-1 must be provided and initialized correctly for the driver to load and for its routines to be called. If an operation is not supported by the driver, the address of the routine `nodev(9F)` can be used to fill it in. If the driver supports the entry point, but does not need to do anything except return success, the address of the routine `nulldev(9F)` can be used.

**Note** – These structures should be initialized at compile-time. They should not be accessed or changed by the driver at any other time.

**Modlinkage Structure**

```c
static struct modlinkage xxmodlinkage = {
    MODREV_1,    /* ml_rev */
    &xxmodldrv,  /* ml_linkage[] */
```

---

66  Writing Device Drivers • May 2002
The first field is the version number of the module loading subsystem and should be MODREV_1. The second field points to driver’s modldrv structure defined next. The last element of the structure should always be NULL.

### modldrv Structure

```c
static struct modldrv xxmodldrv = {
    &mod_driverops, /* drv_modops */
    "generic driver v1.1", /* drv_linkinfo */
    &xx_dev_ops /* drv_dev_ops */
};
```

This structure describes the module in more detail. The first field provides information on how to install and uninstall the module. It should be set to &mod_driverops for driver modules. The second field is a string to be displayed by modinfo(1M). It should contain sufficient information for identifying the version of source code that generated the driver binary. The last field points to the driver’s dev_ops structure defined in the following section.

### dev_ops Structure

```c
static struct dev_ops xx_dev_ops = {
    DEVO_REV, /* devo_rev, */
    0, /* devo_refcnt */
    xxgetinfo, /* getinfo(9E) */
    nulldev, /* identify(9E) */
    xxprobe, /* probe(9E) */
    xxattach, /* attach(9E) */
    xxdetach, /* detach(9E) */
    nodev, /* devo_reset */
    &xx_cb_ops, /* devo_cb_ops */
    NULL, /* devo_bus_ops */
    &xxpower /* power(9E) */
};
```

The dev_ops(9S) structure enables the kernel to find the autoconfiguration entry points of the device driver. The devo_rev field identifies the revision number of the structure itself, and must be set to DEVO_REV. The devo_refcnt field must be initialized to zero. The function address fields should be filled in with the address of the appropriate driver entry point. The exceptions are:

- If a probe(9E) routine is not needed, set the devo_probe field to nulldev(9F).
- identify(9E) is obsolete and no longer required. Set this field to nulldev(9F).
- Set devo_reset to nodev(9F).
- Drivers for devices that provide Power Management functionality must have a power(9E) entry point. If a power(9E) routine is not needed, set this field to NULL.
The `devo_cb_ops` member should include the address of the `cb_ops(9S)` structure. The `devo_bus_ops` field must be set to NULL.

### `cb_ops` Structure

```c
static struct cb_ops xx_cb_ops = {
    xxopen,  /* open(9E) */
    xxclose, /* close(9E) */
    xxstrategy, /* strategy(9E) */
    xxprint,  /* print(9E) */
    xxdump,  /* dump(9E) */
    xxread,   /* read(9E) */
    xxwrite,  /* write(9E) */
    xxioctl,  /* ioctl(9E) */
    xxdevmap, /* devmap(9E) */
    nodev,    /* mmap(9E) */
    xxsegmap, /* segmap(9E) */
    xxchpoll, /* chpoll(9E) */
    xxprop_op, /* prop_op(9E) */
    NULL,    /* streamtab(9S) */
    D_MP | D_64BIT, /* cb_flag */
    CB_REV,   /* cb_rev */
    xxaread,  /* aread(9E) */
    xxawrite  /* awrite(9E) */
};
```

The `cb_ops(9S)` structure contains the entry points for the character and block operations of the device driver. Any entry points the driver does not support should be initialized to `nodev(9F)`. For example, character device drivers should set all the block-only fields, such as `cb_strategy`, to `nodev(9F)`. Note that the `mmap(9E)` entry point is maintained for compatibility with previous releases, and drivers should use the `devmap(9E)` entry point for device memory mapping. If `devmap(9E)` is supported, set `mmap(9E)` to `nodev(9F)`.

The `streamtab` field indicates whether this is a STREAMS-based driver. The device drivers discussed in this book (with the exception of Chapter 16) are not STREAMS based. For a non-STREAMS-based driver, the `streamtab` field must be set to NULL.

The `cb_flag` member contains the following flags:

- The `D_MP` flag indicates that the driver is safe for multi-threading. Solaris 9 operating environment only supports thread safe drivers, so `D_MP` must be set.
- If the driver properly handles 64-bit offsets, it should set the `D_64BIT` flag in the `cb_flag` field. This specifies that the driver will use the `uio_loffset` field of the `uio(9S)` structure.
- If the driver supports the `devmap(9E)` entry point, it should set the `D_DEVMAP` flag. For information on `devmap(9E)`, see Chapter 12.

`cb_rev` is the `cb_ops(9S)` structure revision number. This field must be set to `CB_REV`.
Loadable Driver Interfaces

Device drivers must be dynamically loadable and should be unloadable to help conserve memory resources. Drivers that can be unloaded are also easier to test, debug, and patch.

Each device driver is required to implement _init(9E), _fini(9E), and _info(9E) entry points to support driver loading and unloading. Example 5–1 shows a typical implementation of loadable driver interfaces.

**EXAMPLE 5–1 Loadable Interface Section**

```c
static void *statep; /* for soft state routines */
static struct cb_ops xx_cb_ops; /* forward reference */
static struct dev_ops xx_ops = {
    DEVO_REV,
    0,
    xxgetinfo,
    nulldev,
    xxprobe,
    xxattach,
    xxdetach,
    xxreset,
    nodev,
    &xx_cb_ops,
    NULL,
    xxpower
};

static struct modldr modldr = {
    &mod_driverops,
    "xx driver v1.0",
    &xx_ops
};

static struct modlinkage modlinkage = {
    MODREV_1,
    &modldr,
    NULL
};

int _init(void)
{
    int error;
    ddi_soft_state_init(&statep, sizeof (struct xxstate),
                        estimated number of instances);
    further per-module initialization if necessary
    error = mod_install(&modlinkage);
    if (error != 0) {
        undo any per-module initialization done earlier
```
EXAMPLE 5-1 Loadable Interface Section  (Continued)

ddi_soft_state_fini(&statep);
}
return (error);

int
_fini(void)
{
    int error;
    error = mod_remove(&modlinkage);
    if (error == 0) {
        release per-module resources if any were allocated
        ddi_soft_state_fini(&statep);
    }
    return (error);
}

int
_info(struct modinfo *modinfop)
{
    return (mod_info(&modlinkage, modinfop));
}

_init() Example

Example 5-2 shows a typical _init(9E) interface.

EXAMPLE 5-2 _init()

static void *xxstatep;
int
_init(void)
{
    int error;
    const int max_instance = 20; /* estimated max device instances */
    ddi_soft_state_init(&xxstatep, sizeof (struct xxstate), max_instance);
    error = mod_install(&xxmodlinkage);
    if (error != 0) {
        /* Cleanup after a failure */
        ddi_soft_state_fini(&xxstatep);
    }
    return (error);
}

The driver should perform any one-time resource allocation or data initialization
during driver loading in _init(). For example, it should initialize any mutexes
global to the driver in this routine. The driver should not, however, use _init(9E) to
allocate or initialize anything that has to do with a particular instance of the device. Per-instance initialization must be done in `attach(9E)`. For example, if a driver for a printer can handle more than one printer at the same time, it should allocate resources specific to each printer instance in `attach(9E)`.

---

**Note** – Once `_init(9E)` has called `mod_install(9F)`, the driver should not change any of the data structures attached to the `modlinkage(9S)` structure, as the system may make copies of them or change them.

---

**_fini() Example**

The following example demonstrates the `_fini(9E)` routine.

```c
int _fini(void)
{
    int error;
    error = mod_remove(&modlinkage);
    if (error != 0) {
        return (error);
    }
    /*
    * Cleanup resources allocated in _init()
    */
    ddi_soft_state_fini(&xxstatep);
    return (0);
}
```

Similarly, in `_fini()`, the driver should release any resources that were allocated in `_init()` and must remove itself from the system module list.

**Note** – `_fini()` may be called when the driver is attached to hardware instances. In this case, `mod_remove(9F)` returns failure. Therefore, driver resources should not be released until `mod_remove(9F)` returns success.

---

**_info() Example**

The following example demonstrates the `_info(9E)` routine.

```c
int _info(struct modinfo *modinfop)
{
    return (mod_info(&xxmodlinkage, modinfop));
}
```
The driver is called to return module information. The entry point should be implemented as shown above.

Device Configuration Concepts

For each node in the kernel device tree, the system selects a driver for the node based on the node name and the compatible property (see “Binding a Driver to a Device” on page 30). The same driver may bind to multiple device nodes; the driver can differentiate different nodes by instance numbers assigned by the system.

Once a driver is selected for a device node, the driver’s probe(9E) entry point is called to determine the presence of device on the system. If probe(9E) is successful, the driver’s attach(9E) entry point is invoked to set up and manage the device. The device can be opened if and only if attach(9E) returns success (see “The attach() Entry Point” on page 76).

A device may be unconﬁgured to conserve system memory resources or to allow device to be hot removed. To allow device to be unconﬁgured, the system ﬁrst checks if the device instance is referenced. This check involves calling the driver’s getinfo(9E) entry point to obtain information known only to the driver (see “The getinfo() Entry Point” on page 83). If the device instance is not referenced, the driver’s detach(9E) routine is invoked to unconﬁgure the device (see “The detach() Entry Point” on page 82).

In short, each driver must deﬁne the following entry points that are used by the kernel for device conﬁguration:

- probe(9E)
- attach(9E)
- detach(9E)
- getinfo(9E)

Note that attach(), detach(), and getinfo() are required. probe() is only required for non self-identifying devices. For self-identifying devices, an explicit probe() routine may be provided, or nulldev(9E) may be speciﬁed in the dev_ops structure for the probe() entry point.

Device Instances and Instance Numbers

The system assigns an instance number to each device. The driver may not reliably predict the value of the instance number assigned to a particular device. The driver should retrieve the particular instance number that has been assigned by calling ddi_get_instance(9F).
Instance numbers represent the system’s notion of devices. Each dev_info (that is, each node in the device tree) for a particular driver is assigned an instance number by the kernel. Furthermore, instance numbers provide a convenient mechanism for indexing data specific to a particular physical device. The most common usage for this is ddi_get_soft_state(9F), which uses an instance number to retrieve soft state data for a particular physical device.

**Caution** – For pseudo devices (children of the pseudo nexus), the instance numbers are defined in the driver.conf(4) file via the instance property. If the driver.conf(4) file does not contain the instance property, the behavior is undefined. For hardware device nodes, the system assigns instance numbers when the device is first seen by the OS. The instance numbers persist across system reboots and OS upgrades.

---

**Minor Nodes and Minor Numbers**

Drivers are responsible for managing their minor number name space. For example, the sd driver needs to export 16 minor nodes (8 character, 8 block) to the file system for each disk. Each represents a different piece of the same disk, or a different interface to the same data (character/block). However, the driver still needs to be able to retrieve the instance number of the device in order to get soft state, and so forth. The getinfo(9E) entry point informs the system about the mapping from minor number to device instance (see “The getinfo() Entry Point” on page 83).

---

**The probe() Entry Point**

For non-self-identifying devices, this entry point should determine whether the hardware device is present on the system.

For probe(9E) to determine whether the instance of the device is present, probe(9E) may need to do many of the things also commonly done by attach(9E). In particular, it may need to map the device registers.

Probing the device registers is device-specific. The driver often has to perform a series of tests of the hardware to assure that the hardware is really there. The test criteria must be rigorous enough to avoid misidentifying devices. For example, a device may appear to be present when in fact it is not, because a different device seems to behave like the expected device.

The test returns:

DDI_PROBE_SUCCESS if the probe was successful

DDI_PROBE_FAILURE if the probe failed
DDI_PROBE_DONTCARE if the probe was unsuccessful yet attach(9E) should still be called.

DDI_PROBE_PARTIAL if the instance is not present now, but may be present in the future.

For a given device instance, attach(9E) will not be called before probe(9E) has succeeded at least once on that device.

probe(9E) must free all the resources that it allocates, because it may be called multiple times; however, attach(9E) will not necessarily be called even if probe(9E) succeeds.

ddi_dev_is_sid(9F) may be used in a driver’s probe(9E) routine to determine if the device is self-identifying. This is useful in drivers written for self-identifying and non-self-identifying versions of the same device.

Example 5-3 is a sample probe(9E) routine.

**EXAMPLE 5-3** probe(9E) Routine

```c
static int
xxprobe(dev_info_t *dip)
{
    ddi_acc_handle_t dev_hdl;
    ddi_device_acc_attr_t dev_attr;
    Pio_csr *csrp;
    uint8_t csrval;

    /*
     * if the device is self identifying, no need to probe
     */
    if (ddi_dev_is_sid(dip) == DDI_SUCCESS)
        return (DDI_PROBE_DONTCARE);

    /*
     * Initialize the device access attributes and map in
     * the devices CSR register (register 0)
     */
    dev_attr.devacc_attr_version = DDI_DEVICE_ATTR_V0;
    dev_attr.devacc_attr_endian_flags = DDI_STRUCTURE_LE_ACC;
    dev_attr.devacc_attr_dataorder = DDI_STRICTORDER_ACC;
    if (ddi_regs_map_setup(dip, 0, (caddr_t *)&csrp, 0, sizeof (Pio_csr),
                                &dev_attr, &dev_hdl) != DDI_SUCCESS)
        return (DDI_PROBE_FAILURE);

    /*
     * Reset the device
     * Once the reset completes the CSR should read back
     * (PIO_DEV_READY | PIO_IDLE_INTR)
     */
    ddi_put8(dev_hdl, csrp, PIO_RESET);
}```
When the driver’s `probe` routine is called, it does not know whether the device being probed exists on the bus. Therefore, it is possible that the driver may attempt to access device registers for a nonexistent device. A bus fault may be generated on some buses as a result.

Example 5-4 shows a `probe` routine that uses `ddi_poke8` to check for the existence of the device. `ddi_poke8` cautiously attempts to write a value to a specified virtual address, using the parent nexus driver to assist in the process where necessary. If the address is not valid, or the value cannot be written without an error occurring, an error code is returned. See also `ddi.peek`.

In this example, `ddi_regs_map_setup` is used to map the device registers.

**EXAMPLE 5-4 probe Routine Using ddi_poke8**

```c
static int xxprobe(dev_info_t *dip)
{
    ddi_acc_handle_t dev_hdl;
    ddi_device_acc_attr_t dev_attr;
    Pio_csr *csrp;
    uint8_t csrval;

    /*
     * if the device is self identifying, no need to probe
     */
    if (ddi_dev_is_sid(dip) == DDI_SUCCESS) 
        return (DDI_PROBE_DONTCARE);

    /* Initialize the device access attributes and map in
     * the devices CSR register (register 0)
     */
    dev_attr.devacc_attr_version = DDI_DEVICE_ATTR_V0;
    dev_attr.devacc_attr_endian_flags = DDI_STRUCTURE_LE_ACC;
    dev_attr.devacc_attr_dataorder = DDI_STRICTORDER_ACC;

    /* tear down the mappings and return probe success/failure */
    ddi_regs_map_free(&dev_hdl);
    if ((csrval & 0xff) == (PIO_DEV_READY | PIO_IDLE_INTR))
        return (DDI_PROBE_SUCCESS);
    else
        return (DDI_PROBE_FAILURE);
}
```
EXAMPLE 5-4  probe(9E) Routine Using ddi_poke8(9F)  (Continued)

if (ddi_regs_map_setup(dip, 0, (caddr_t *)&csrp, 0, sizeof (Pio_csr),
    &dev_attr, &dev_hdl) != DDI_SUCCESS)
     return (DDI_PROBE_FAILURE);

/*
 * The bus can generate a fault when probing for devices which
 * do not exist. Use ddi_poke8(9f) to handle any faults which
 * may occur.
 *
 * Reset the device. Once the reset completes the CSR should read
 * back (PIO_DEV_READY | PIO_IDLE_INTR)
 */
if (ddi_poke8(dip, csrp, PIO_RESET) != DDI_SUCCESS) {
    ddi_regs_map_free(&dev_hdl);
    return (DDI_FAILURE);
}

csrval = ddi_get8(dev_hdl, csrp);
/*
 * tear down the mappings and return probe success/failure
 */
  ddi_regs_map_free(&dev_hdl);
if ((csrval & 0xff) == (PIO_DEV_READY | PIO_IDLE_INTR))
     return (DDI_PROBE_SUCCESS);
else
     return (DDI_PROBE_FAILURE);
}

The attach() Entry Point

The kernel calls a driver’s attach(9E) entry point to attach an instance of a device or
to resume operation for an instance of a device that has been suspended or shut down
by the power management framework. This section discusses only the operation of
attaching device instances; the power management discussion is left to Chapter 9.

A driver’s attach(9E) entry point is called to attach each instance of a device that is
bound to the driver. The entry point is called with the instance of the device node to
attach, with DDI_ATTACH specified as the cmd argument to attach(9E). The attach
entry point will typically include the following types of processing:

- Allocating a soft state structure for the device instance
- Initializing per-instance mutexes and condition variables
- Registering the device’s interrupts
- Mapping the registers and memory of the device instance
- Creating minor device nodes for the device instance
- Reporting that the device instance has attached
Driver Soft State Management

To assist device driver writers in allocating state structures, the Solaris 9 DDI/DKI provides a set of memory management routines called software state management routines (also known as the soft state routines). These routines dynamically allocate, retrieve, and destroy memory items of a specified size, and hide the details of list management. An instance number identifies the desired memory item. This number can be (and usually is) the instance number assigned by the system.

Drivers will typically allocate a soft state structure for each device instance that attaches to the driver by calling ddi_soft_state_zalloc(9F), passing the instance number of the device. Because there cannot be two device nodes with the same instance number, ddi_soft_state_zalloc(9F) will fail if an allocation already exists for a given instance number.

A driver’s character or block entry point (cb_ops(9S)) will reference a particular soft state structure by first decoding the device’s instance number from the dev_t argument that is passed to the entry point function. The driver then calls ddi_get_soft_state(9F), passing the per-driver soft state list and the instance number that was derived. If ddi_get_soft_state(9F) returns a NULL value, the driver should treat this as if the device does not exist and return the appropriate code.

See “Creating Minor Device Nodes” on page 77 for additional information on how instance numbers and device numbers, or dev_t’s, are related.

Lock and Conditional Variable Initialization

Drivers should initialize any per-instance locks and condition variables during attach. The initialization of any locks which are acquired by the driver’s interrupt handler must be initialized prior to adding any interrupt handlers. See Chapter 3 for a description of lock initialization and usage. See Chapter 7 for a discussion of the issues surrounding interrupt handler and locks.

Creating Minor Device Nodes

An important part of the attach process is the creation of minor nodes for the device instance. A minor node contains the information exported by the device and the DDI framework which the system uses to create a special file for the minor node under /devices.

Minor nodes are created when the driver calls ddi_create_minor_node(9F). The driver supplies a minor number, a minor name, a minor node type, and whether the minor node represents a block or character device.
Drivers can choose to create any number of minor nodes for a device. The Solaris DDI/DDK expects certain classes of devices to have minor nodes created in a particular format. For example, disk drivers are expected to create 16 minor nodes for each physical disk instance attached; 8 minor nodes are created, representing the a-h block device interfaces, with an additional 8 minor nodes for the a, raw-h, raw character device interfaces.

The minor number passed to `ddi_create_minor_node(9F)` is defined wholly by the driver itself. The minor number is usually an encoding of the device’s instance number with a minor node identifier. Taking the above example, the driver creates minor numbers for each of the minor nodes by taking the devices instance number, shifting it left 3 bits, and OR’ing in the minor node index whose values range from 0 to 7. Note that minor nodes a and a, raw share the same minor number. They are distinguished by the `spec_type` argument passed to `ddi_create_minor_node()`. The minor node type passed to `ddi_create_minor_node(9F)` classifies the type of device, such as disks, tapes, network interfaces, frame buffers, and so forth. Table 5–1 lists the types of possible nodes that may be created.

### Table 5-1 Possible Node Types

<table>
<thead>
<tr>
<th>Constant</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>DDI_NT_SERIAL</td>
<td>Serial port</td>
</tr>
<tr>
<td>DDI_NT_SERIAL_DO</td>
<td>Dialout ports</td>
</tr>
<tr>
<td>DDI_NT_BLOCK</td>
<td>Hard disks</td>
</tr>
<tr>
<td>DDI_NT_BLOCK_CHAN</td>
<td>Hard disks with channel or target numbers</td>
</tr>
<tr>
<td>DDI_NT_CD</td>
<td>ROM drives (CD-ROM)</td>
</tr>
<tr>
<td>DDI_NT_CD_CHAN</td>
<td>ROM drives with channel or target numbers</td>
</tr>
<tr>
<td>DDI_NT_FD</td>
<td>Floppy disks</td>
</tr>
<tr>
<td>DDI_NT_TAPE</td>
<td>Tape drives</td>
</tr>
<tr>
<td>DDI_NT_NET</td>
<td>Network devices</td>
</tr>
<tr>
<td>DDI_NT_DISPLAY</td>
<td>Display devices</td>
</tr>
<tr>
<td>DDI_NT_MOUSE</td>
<td>Mouse</td>
</tr>
<tr>
<td>DDI_NT_KEYBOARD</td>
<td>Keyboard</td>
</tr>
<tr>
<td>DDI_NT_AUDIO</td>
<td>Audio Device</td>
</tr>
<tr>
<td>DDI_PSEUDO</td>
<td>General pseudo devices</td>
</tr>
</tbody>
</table>

The node types `DDI_NT_BLOCK, DDI_NT_BLOCK_CHAN, DDI_NT_CD, and DDI_NT_CD_CHAN` cause `devfsadm(1M)` to identify the device instance as a disk and to create names in the `/dev/dsk` or `/dev/rdsk` directory.
The node type DDI_NT_TAPE causes devfsadm(1M) to identify the device instance as a tape and to create names in the /dev/rmt directory.

The node types DDI_NT_SERIAL and DDI_NT_SERIAL_DO causes devfsadm(1M) to identify the device instance as a serial port and to create names in the /dev/term and /dev/cua directories and to add entries in /etc/inittab.

Vendor-supplied strings should include an identifying value to make them unique, such as their name or stock symbol (if appropriate). The string can be used in conjunction with devfsadm(1M) and devlink.tab(4) to create logical names in /dev.

Deferred Attach

open(9E) might be called on a minor device before attach(9E) has succeeded on the corresponding instance. open() must then return ENXIO, which will cause the system to attempt to attach the device. If the attach succeeds, the open is retried automatically.

EXAMPLE 5–5 Example attach(9E) Entry Point

/*
 * Attach an instance of the driver. We take all the knowledge we
 * have about our board and check it against what has been filled in for
 * us from our FCode or from our driver.conf(4) file.
 */
static int
xxattach(dev_info_t *dip, ddi_attach_cmd_t cmd)
{
  int instance;
  Pio *pio_p;
  ddi_device_acc_attr_t da_attr;
  static int pio_validate_device(dev_info_t *);

  switch (cmd) {
    case DDI_ATTACH:
      /*
       * first validate the device conforms to a configuration this driver
       * supports
       */
      if (pio_validate_device(dip) == 0)
        return (DDI_FAILURE);

      /*
       * Allocate a soft state structure for this device instance
       * Store a pointer to the device node in our soft state structure
       * and a reference to the soft state structure in the device
       * node.
       */
      instance = ddi_get_instance(dip);
      if (ddi_soft_state_zalloc(pio_softstate, instance) != 0)
        return (DDI_FAILURE);
EXAMPLE 5–5 Example attach(9E) Entry Point  (Continued)

```c
pio_p = ddi_get_soft_state(pio_softstate, instance);
ddi_set_driver_private(dip, (caddr_t)pio_p);
pio_p->dip = dip;

/*
 * Before adding the interrupt, get the interrupt block
 * cookie associated with the interrupt specification to
 * initialize the mutex used by the interrupt handler.
 */
if (ddi_get_iblock_cookie(dip, 0, &pio_p->iblock_cookie) !=
    DDI_SUCCESS) {
    ddi_soft_state_free(pio_softstate, instance);
    return (DDI_FAILURE);
}
mutex_init(&pio_p->mutex, NULL, MUTEX_DRIVER, pio_p->iblock_cookie);

/*
 * Now that the mutex is initialized, add the interrupt itself.
 */
if (ddi_add_intr(dip, 0, NULL, NULL, pio_intr, (caddr_t)instance) !=
    DDI_SUCCESS) {
    mutex_destroy(&pio_p->mutex);
    ddi_soft_state_free(pio_softstate, instance);
    return (DDI_FAILURE);
}

/*
 * Initialize the device access attributes for the register
 * mapping
 */
dev_acc_attr.devacc_attr_version = DDI_DEVICE_ATTR_V0;
dev_acc_attr.devacc_attr_endian_flags = DDI_STRUCTURE_LE_ACC;
dev_acc_attr.devacc_attr_dataorder = DDI_STRICTORDER_ACC;

/*
 * Map in the csr register (register 0)
 */
if (ddi_regs_map_setup(dip, 0, (caddr_t *)&(pio_p->csr), 0,
    sizeof (Pio_csr), &dev_acc_attr, &pio_p->csr_handle) !=
    DDI_SUCCESS) {
    ddi_remove_intr(pio_p->dip, 0, pio_p->iblock_cookie);
    mutex_destroy(&pio_p->mutex);
    ddi_soft_state_free(pio_softstate, instance);
    return (DDI_FAILURE);
}

/*
 * Map in the data register (register 1)
 */
if (ddi_regs_map_setup(dip, 1, (caddr_t *)&(pio_p->data), 0,
    sizeof (uchar_t), &dev_acc_attr, &pio_p->data_handle) !=
    DDI_SUCCESS) {
    ddi_remove_intr(pio_p->dip, 0, pio_p->iblock_cookie);
    mutex_destroy(&pio_p->mutex);
    ddi_soft_state_free(pio_softstate, instance);
    return (DDI_FAILURE);
}
```

Writing Device Drivers • May 2002
Example attach(9E) Entry Point (Continued)

```c
DDI_SUCCESS) {
    ddi_remove_intr(pio_p->dip, 0, pio_p->iblock_cookie);
    ddi_regs_map_free(&pio_p->csr_handle);
    mutex_destroy(&pio_p->mutex);
    ddi_soft_state_free(pio_softstate, instance);
    return (DDI_FAILURE);
}

/*
 * Create an entry in /devices for user processes to open(2)
 * This driver will create a minor node entry in /devices
 * of the form: /devices/..../pio@X,Y:pio
 */
if (ddi_create_minor_node(dip, ddi_get_name(dip), S_IFCHR,
    instance, DDI_PSEUDO, 0) == DDI_FAILURE) {
    ddi_remove_intr(pio_p->dip, 0, pio_p->iblock_cookie);
    ddi_regs_map_free(&pio_p->csr_handle);
    ddi_regs_map_free(&pio_p->data_handle);
    mutex_destroy(&pio_p->mutex);
    ddi_soft_state_free(pio_softstate, instance);
    return (DDI_FAILURE);
}

/*
 * reset device (including disabling interrupts)
 */
    ddi_put8(pio_p->csr_handle, pio_p->csr, PIO_RESET);

/*
 * report the name of the device instance which has attached
 */
    ddi_report_dev(dip);
    return (DDI_SUCCESS);
}

case DDI_RESUME:
    return (DDI_SUCCESS);

default:
    return (DDI_FAILURE);
}
```

**Note** – The attach(9E) routine must not make any assumptions about the order of invocations on different device instances. The system may invoke attach(9E) concurrently on different device instances. The system may also invoke attach(9E) and detach(9E) concurrently on different device instances.
The detach() Entry Point

The kernel calls a driver’s detach(9E) entry point to detach an instance of a device or to suspend operation for an instance of a device by power management. This section discusses the operation of detaching device instances. Refer to Chapter 9 for a discussion of power management issues.

A driver’s detach() entry point is called to detach an instance of a device that is bound to the driver. The entry point is called with the instance of the device node to detach and DDI_DETACH specified as the cmd argument to the entry point.

A driver is required to cancel or wait for any time-outs or callbacks to complete, then release any resources that are allocated to the device instance before returning. If for some reason a driver cannot cancel outstanding callbacks for free resources, the driver is required to return the device to its original state and return DDI_FAILURE from the entry point, leaving the device instance in the attached state.

There are two types of callback routines: those that can be canceled and those that cannot. timeout(9F) and bufcall(9F) callbacks can be atomically cancelled by the driver during detach(9E). Other types of callbacks such as scsi_init_pkt(9F) and ddi_dma_buf_bind_handle(9F) cannot be canceled, requiring the driver to either block in detach() until the callback completes or to fail the request to detach.

EXAMPLE 5-6 detach(9E) Routine

```c
static int xxdetach(dev_info_t *dip, ddi_detach_cmd_t cmd)
{
    Pio *pio_p;
    int instance;

    switch (cmd) {
        case DDI_DETACH:
            instance = ddi_get_instance(dip);
            pio_p = ddi_get_soft_state(pio_softstate, instance);

            /*
             * turn off the device
             * free any resources allocated in attach
             */
            ddi_put8(pio_p->csr_handle, pio_p->csr, PIO_RESET);

            ddi_remove_minor_node(dip, NULL);
            ddi_regs_map_free(&pio_p->csr_handle);
            ddi_regs_map_free(&pio_p->data_handle);
            ddi_remove_intr(pio_p->dip, 0, pio_p->iblock_cookie);
            mutex_destroy(&pio_p->mutex);
            ddi_soft_state_free(pio_softstate, instance);
    }
    return DDI_OK;
}
```
EXAMPLE 5-6 detach(9E) Routine  (Continued)

    return (DDI_SUCCESS);

    case DDI_SUSPEND:
      default:
        return (DDI_FAILURE);
    }
}

The getinfo() Entry Point

The system calls getinfo(9E) to obtain configuration information that only the driver knows. The mapping of minor numbers to device instances is entirely under the control of the driver. The system sometimes needs to ask the driver which device a particular dev_t represents.

getinfo() can take one of two commands as its infocmd argument:
DDI_INFO_DEVT2INSTANCE, which asks for a device’s instance number, and
DDI_INFO_DEVT2DEVINFO, which asks for pointer to the device’s dev_info structure.

In the DDI_INFO_DEVT2INSTANCE case, arg is a dev_t, and getinfo() must translate the minor number in dev_t to an instance number. In the following example, the minor number is the instance number, so getinfo() simply passes back the minor number. In this case, the driver must not assume that a state structure is available, since getinfo() may be called before attach(9E). The mapping that the driver defines between the minor device number and the instance number does not necessarily follow the mapping shown in the example. In all cases, however, the mapping must be static.

In the DDI_INFO_DEVT2DEVINFO case, arg is again a dev_t, so getinfo() first decodes the instance number for the device. It then passes back the dev_info pointer saved in the driver’s soft state structure for the appropriate device. This is shown in Example 5-7.

EXAMPLE 5-7 getinfo(9E) Routine
/*
 * getinfo(9e)
 * Return the instance number or device node given a dev_t
 */
static int
xxgetinfo(dev_info_t *dip, ddi_info_cmd_t infocmd, void *arg, void **result)
{
    int error;
    Pio *pio_p;
    int instance = getminor((dev_t)arg);
EXAMPLE 5–7 \texttt{getinfo(9E)} Routine \textit{(Continued)}

```c
switch (infocmd) {

    /*
     * return the device node if the driver has attached the
     * device instance identified by the dev_t value which was passed
     */
    case DDI_INFO_DEVT2DEVINFO:
        pio_p = ddi_get_soft_state(pio_softstate, instance);
        if (pio_p == NULL) {
            *result = NULL;
            error = DDI_FAILURE;
        } else {
            mutex_enter(&pio_p->mutex);
            *result = pio_p->dip;
            mutex_exit(&pio_p->mutex);
            error = DDI_SUCCESS;
        }
        break;

    /*
     * the driver can always return the instance number given a dev_t
     * value, even if the instance is not attached.
     */
    case DDI_INFO_DEVT2INSTANCE:
        *result = (void *)instance;
        error = DDI_SUCCESS;
        break;
    default:
        *result = NULL;
        error = DDI_FAILURE;
    }

    return (error);
}
```

\textbf{Note} – The \texttt{getinfo()} routine must be kept in sync with minor nodes that the driver creates. Failure to do so may cause failure of hotplug operations and result in system panics.
Using Device IDs

The Solaris DDI interfaces allow drivers to provide a persistent unique identifier for a device, a device ID, which can be used to identify or locate a device and which is independent of the /devices name or device number (dev_t). Applications can use the functions defined in libdevid(3LIB) to read and manipulate the device IDs registered by the drivers.

Before a driver can export a device ID, it needs to verify that the device is capable of either providing a unique ID, such as a WWN (world-wide number), or is capable of storing a host-generated unique ID in an area not accessible through normal operations, such as device NVRAM, reserved sectors, etc.

Registering Device IDs

Drivers will typically initialize and register device IDs in the drivers attach(9E) handler. As mentioned above, the driver is responsible for registering a device ID which is persistent. As such, the driver may be required to handle both devices which can provide a unique ID directly (WN), and devices where fabricated IDs are written to and read from stable storage.

Registering a Device-Supplied ID

If the device can supply the driver with an identifier that is unique, the driver can simply initialize the device ID with this identifier and register the ID with the Solaris DDI.

/*
 * The device provides a guaranteed unique identifier,
 * in this case a SCSI3-WWN. The WWN for the device has been
 * stored in the devices soft state.
 */
if (ddi_devid_init(dip, DEVID_SCSI3_WWN, un->un_wwn_len, un->un_wwn, 
 &un->un_devid) != DDI_SUCCESS)
    return (DDI_FAILURE);
(void) ddi_devid_register(dip, un->un_devid);

Registering a Fabricated ID

A driver may also register device IDs for devices which do not directly supply a unique ID. If the device is capable of storing and retrieving a small amount of data in a reserved area, the driver can create a fabricated device ID and write it to the reserved area.
/*
 * the device doesn't supply a unique ID, attempt to read
 * a fabricated ID from the device's reserved data.
 */

if (xxx_read_deviceid(un, &devid_buf) == XXX_OK) {
    if (ddi_devid_valid(devid_buf) == DDI_SUCCESS) {
        devid_sz = ddi_devi_sizeof(devid_buf);
        un->un_devid = kmem_alloc(devid_sz, KM_SLEEP);
        bcopy(devid_buf, un->un_devid, devid_sz);
        ddi_devid_register(dip, un->un_devid);
        return (XXX_OK);
    }
}

/*
 * we failed to read a valid device ID from the device
 * fabricate an ID, store it on the device, and register
 * it with the DDI
 */

if (ddi_devid_init(dip, DEVID_FAB, 0, NULL, &un->un_devid) == DDI_FAILURE) {
    return (XXX_FAILURE);
}

if (xxx_write_deviceid(un) != XXX_OK) {
    ddi_devid_free(un->un_devid);
    un->un_devid = NULL;
    return (XXX_FAILURE);
}

ddi_devid_register(dip, un->un_devid);
return (XXX_OK);

Unregistering Device IDs

Drivers will typically unregister and free any device IDs they allocated as part of the detach(9E) handling. The driver will first call ddi_devid_unregister(9F) to unregister the device ID for the device instance. The driver must then free the device ID handle itself by calling ddi_devid_free(9F), passing the handle which had been returned by ddi_devid_init(9F). The driver is responsible for managing any space allocated for WWN or Serial Number data.
Device Access — Programmed I/O

The Solaris operating environment provides driver developers with a comprehensive set of interfaces for accessing device memory. These interfaces are designed to shield the driver from platform-specific dependencies by handling mismatches between processor and device endianness as well as enforcing any data ordering dependencies the device might have. By using these interfaces, a single source driver can be developed that runs on both that SPARC and IA (Intel architecture) processor architectures as well as the various platforms from each respective processor family.

This chapter provides information on the following subjects:
- “Managing Differences in Device and Host Endianness” on page 88
- “Managing Data Ordering Requirements” on page 88
- “ddi_device_acc_attr Structure” on page 88
- “Mapping Device Memory” on page 89
- “Mapping Setup Example” on page 90
- “Alternate Device Access Interfaces” on page 92

Device Memory

Devices that support programmed I/O are assigned one or more regions of bus address space that map to addressable regions of the device. These mappings are described as pairs of values in the reg property associated with the device. Each value pair describes a segment of a bus address.

Drivers identify a particular bus address mapping by specifying the register number, or regspec, which is an index into the device’s reg property that identifies a (busaddr, size) pair. Drivers pass the register number when making calls to DDI functions such as ddi_regs_map_setup(9F). Drivers can determine how many mappable regions have been assigned to the device by calling ddi_dev_nregs(9F).
Managing Differences in Device and Host Endianness

The data format of the host can have different endian characteristics than the data format of the device. If this is the case, data transferred between the host and device needs to be byte swapped to conform to the data format requirements of the destination location. Other devices can have the same endian characteristics of the host and require no byte swapping of the data.

Drivers specify the endian characteristics of the device by setting the appropriate flag in the ddi_device_acc_attr(9S) structure that is passed to ddi_regs_map_setup(9F). The DDI framework then performs any required byte swapping when the driver calls a ddi_getX routine (such as ddi_get8(9F)) or a ddi_putX routine (such as ddi_put16(9F)) to read or write device memory.

Managing Data Ordering Requirements

Platforms can choose to reorder loads and stores of data to optimize performance of the platform. Because reordering might not be allowed by certain devices, the driver is required to specify the device’s ordering requirements when setting up mappings to the device.

ddi_device_acc_attr Structure

This structure describes the endian and data ordering requirements of the device. The driver is required to initialize and pass one of these structures as an argument to ddi_regs_map_setup(9F).

```c
typedef struct ddi_device_acc_attr {
    ushort_t devacc_attr_version;
    uchar_t devacc_attr_endian_flags;
    uchar_t devacc_attr_dataorder;
} ddi_device_acc_attr_t;
```

- **devacc_attr_version**
  - Specifies DDIDEVICEATTR_V0
- **devacc_attr_endian_flags**
  - Describes the endian characteristics of the device. Specified as a bit value whose possible values are:
    - DDI_NEVERSWAP_ACC – Never swap data
    - DDI_STRUCTURE_BE_ACC – The device data format is big-endian
    - DDI_STRUCTURE_LE_ACC – The device data format is little-endian
devacc_attr_dataorder

Describes the order in which the CPU must reference data as required by the device. Specified as an enumerated value, where data access restrictions are ordered from most to least strict.

- DDI_STRICTORDER_ACC – The host must issue the references in order, as specified by the programmer. This is the default behavior.
- DDI_UNORDERED_OK_ACC – The host is allowed to reorder loads and stores to device memory.
- DDI_MERGING_OK_ACC – The host is allowed to merge individual stores to consecutive locations. This setting also implies reordering.
- DDI_LOADCACHING_OK_ACC – The host is allowed to read data from the device until a store occurs.
- DDI_STORECACHING_OK_ACC – The host is allowed to cache data written to the device and defer writing it to the device until some future time.

Note – The system can access data more strictly than the driver specified in devacc_attr_dataorder. The restriction to the host diminishes while moving from strict data ordering to cache storing in terms of data accesses by the driver.

Mapping Device Memory

Drivers typically map all regions of a device during attach(9E). The driver maps a region of device memory by calling ddi_regs_map_setup(9F), specifying the register number of the region to map, the device access attributes for the region, an offset, and size. The DDI framework sets up the mappings for the device region and returns an opaque handle to the driver. This data access handle is passed as an argument to the ddi_get8(9F) or ddi_put8(9F) family of routines when reading or writing data to that region of the device.

The driver verifies that the shape of the device mappings match what the driver is expecting by checking the number of mappings exported by the device. It calls ddi_dev_nregs(9F) and then verifies the size of each mapping by calling ddi_dev_regsize(9F).
Mapping Setup Example

Example 6–1 is a simple example demonstrating the setup and use of the DDI data access interfaces. This driver is for a fictional little endian device that accepts one character at a time and generates an interrupt when ready for another. This device implements two register sets: the first is an 8-bit CSR register, and the second is an 8-bit data register.

EXAMPLE 6-1 Mapping Setup

```c
#define CSR_REG 0
#define DATA_REG 1

/*
 * Initialize the device access attributes for the register
 * mapping
 */
dev_acc_attr.devacc_attr_version = DDI_DEVICE_ATTR_V0;
dev_acc_attr.devacc_attr_endian_flags = DDI_STRUCTURE_LE_ACC;
dev_acc_attr.devacc_attr_dataorder = DDI_STRICTORDER_ACC;

/*
 * Map in the csr register (register 0)
 */
if (ddi_regs_map_setup(dip, CSR_REG, (caddr_t *)&(pio_p->csr), 0,
                     sizeof (Pio_csr), &dev_acc_attr, &pio_p->csr_handle) != DDI_SUCCESS) {
    mutex_destroy(&pio_p->mutex);
    ddi_soft_state_free(pio_softstate, instance);
    return (DDI_FAILURE);
}

/*
 * Map in the data register (register 1)
 */
if (ddi_regs_map_setup(dip, DATA_REG, (caddr_t *)&(pio_p->data), 0,
                     sizeof (uchar_t), &dev_acc_attr, &pio_p->data_handle) != DDI_SUCCESS) {
    mutex_destroy(&pio_p->mutex);
    ddi_regs_map_free(&pio_p->csr_handle);
    ddi_soft_state_free(pio_softstate, instance);
    return (DDI_FAILURE);
}
```

90  Writing Device Drivers • May 2002
Device Access Functions

Drivers use the `ddi_get8(9F)` and `ddi_put8(9F)` family of routines in conjunction with the handle returned by `ddi_regs_map_setup(9F)` to transfer data to and from a device. The DDI framework automatically handles any byte swapping that is required to meet host or device endian formats, and enforces any store-ordering constraints the device might have.

The DDI provides interfaces for transferring data in 8, 16, 32, and 64 bit quantities, as well as interfaces for transferring multiple values repeatedly. See the man pages for the `ddi_get8(9F)`, `ddi_put8(9F)`, `ddi_rep_get8(9F)` and `ddi_rep_put8(9F)` families of routines for a complete listing and description of these interfaces.

Example 6–2 builds on Example 6–1 where the driver mapped the device’s CSR and data registers. Here, the driver’s `write(9E)` entry point, when called, will write a buffer of data to the device one byte at a time.

**EXAMPLE 6–2**

```c
static int
pio_write(dev_t dev, struct uio *uiop, cred_t *credp)
{
    int retval;
    int error = OK;
    Pio *pio_p = ddi_get_soft_state(pio_softstate, getminor(dev));

    if (pio_p == NULL)
        return (ENXIO);
    mutex_enter(&pio_p->mutex);
    /*
    * enable interrupts from the device by setting the Interrupt
    * Enable bit in the devices CSR register
    */
    ddi_put8(pio_p->csr_handle, pio_p->csr,
             (ddi_get8(pio_p->csr_handle, pio_p->csr) | PIO_INTR_ENABLE));

    while (uiop->uio_resid > 0) {
        /*
        * this device issues an IDLE interrupt when it is ready
        * to accept a character; the interrupt can be cleared
        * by setting PIO_INTR_CLEAR. The interrupt is reasserted
        * after the next character is written or the next time
        * PIO_INTR_ENABLE is toggled on.
        *
        * wait for interrupt (see pio_intr)
        */
        cv_wait(&pio_p->cv, &pio_p->mutex);
    }

    return (error);
}
```

Chapter 6 • Device Access — Programmed I/O 91
Alternate Device Access Interfaces

While having a driver implement all device accesses using the `ddi_get8(9F)` and `ddi_put8(9F)` family of interfaces, Solaris provides interfaces specific to particular bus implementations. While these functions are more efficient on some platforms, use of these routines can limit the ability of the driver to remain portable across different bus versions of the device.

Memory Space Access

With memory mapped access, device registers appear in memory address space. The `ddi_getX` family of routines (such as `ddi_get16(9F)`) and the `ddi_putX` family (such as `ddi_put8(9F)`) are available for use by drivers as an alternative to the standard device access interfaces.
I/O Space Access

With I/O space access, the device registers appear in I/O space, where each addressable element is called an I/O port. The ddi_io_get8(9F) and ddi_io_put8(9F) family of routines is available for use by drivers as an alternative to the standard device access interfaces.

PCI Configuration Space Access

To access PCI configuration space without using the normal device access interfaces, a driver is required to map PCI configuration space by calling pci_config_setup(9F) in place of ddi_regs_map_setup(9F). The driver can then call the pci_config_get8(9F) and pci_config_put8(9F) family of interfaces to access PCI configuration space.
Interrupt Handlers

This chapter describes interrupt handling mechanisms, such as registering, servicing, and removing interrupts. This chapter provides information on the following subjects:

- “Interrupt Handler Overview” on page 95
- “Device Interrupts” on page 96
- “Registering Interrupts” on page 98
- “Interrupt Handler Responsibilities” on page 99
- “Handling High-Level Interrupts” on page 101

Interrupt Handler Overview

An interrupt is a hardware signal from a device to a CPU. It tells the CPU that the device needs attention and that the CPU should stop performing what it is doing and respond to the device. If a CPU is available (it is not performing a task with higher priority), it suspends the current thread and eventually invokes the interrupt handler for that device. The job of the interrupt handler is to service the device and stop it from interrupting. Once the handler returns, the CPU resumes what it was doing before the interrupt occurred.

The DDI/DKI provides interfaces for registering and servicing interrupts.

Interrupt Specification

The interrupt specification is information the system uses to bind a device interrupt source with a specific device interrupt handler. The specification describes the information provided by the hardware to the system when making an interrupt request. Because an interrupt specification is bus specific, the information it contains varies from bus to bus.
Interrupt specifications typically include a bus-interrupt level. For vectored interrupts the specifications include an interrupt vector. On IA platforms the interrupt specification defines the relative interrupt priority of the device. Because interrupt specifications are bus specific, see the man pages for `isa(4)`, `eisa(4)`, `sbus(4)`, and `pci(4)` for information on interrupt specifications for these buses.

**Interrupt Number**
When registering interrupts the driver must provide the system with an interrupt number. This interrupt number identifies the interrupt specification for which the driver is registering a handler. Most devices have one interrupt: interrupt number 0. However, there are devices that have different interrupts for different events. A communications controller may have one interrupt for receive ready and one for transmit ready. The device driver normally knows how many interrupts the device has, but if the driver has to support several variations of a controller, it can call `ddi_dev_nintrs(9F)` to find out the number of device interrupts.

**Interrupt Block Cookies**
An `iblock` cookie is an opaque data structure that represents the information the system needs to block interrupts and is returned from `ddi_get_iblock_cookie(9F)` or `ddi_get_soft_iblock_cookie(9F)`. This interface uses an interrupt number to return the `iblock` cookie associated with a specific interrupt source. The value of the `iblock` cookie (not the address) must be passed to `mutex_init(9F)` when initializing driver mutexes that will be used in the interrupt routine. The value of the `iblock` cookie is obtained by passing the address of the cookie to `ddi_get_iblock_cookie()` or `ddi_get_soft_iblock_cookie()`. For example:

```c
  ddi_get_soft_iblock_cookie(dip, DDI_SOFTINT_HI, &xsp->low_iblock_cookie)
  mutex_init(&xsp->low_mu, NULL, MUTEX_DRIVER, (void *)xsp->low_iblock_cookie);
```

**Device Interrupts**
There are two common ways in which buses implement interrupts: *vectored* and *polled*. Both methods commonly supply a bus-interrupt priority level. However, vectored devices also supply an interrupt vector; polled devices do not.
High-Level Interrupts

Buses prioritize device interrupts at one of several bus-interrupt levels. These bus interrupt levels are then mapped to different processor-interrupt levels. A bus interrupt level that maps to a CPU interrupt priority level above the scheduler priority level is called a high-level interrupt. High-level interrupt handlers are restricted in what DDI interfaces they can call. In particular, the only DDI routines that high-level interrupt handlers are allowed to call are:

- `mutex_enter(9F)` and `mutex_exit(9F)` on a mutex initialized with an `iblock` cookie associated with the high-level interrupt
- `ddi_trigger_softintr(9F)`
- the `ddi_getX/ddi_putX` families of routines (such as `ddi_get8(9F)`)  

A bus-interrupt level by itself does not determine whether a device interrupts at high level: a given bus-interrupt level may map to a high-level interrupt on one platform, but map to an ordinary interrupt on another platform.

The driver can choose whether to support devices that have high-level interrupts, but it always has to check—it cannot assume that its interrupts are not high level. The function `ddi_intr_hilevel(9F)`, given an interrupt number, returns a value indicating whether the interrupt is high level.

Normal Interrupts

The only information the system has about a device interrupt is either the bus interrupt priority level (IPL, on an SBus in a SPARC machine, for example) or the interrupt request number (IRQ on an ISA bus in an IA machine, for example).

When an interrupt handler is registered, the system adds the handler to a list of potential interrupt handlers for each IPL or IRQ. Once the interrupt occurs, the system must determine which device, of all the devices associated with a given IPL or IRQ, actually interrupted. It does this by calling all the interrupt handlers for the designated IPL or IRQ, until one handler claims the interrupt.

The SBus, ISA, EISA, and PCI buses are capable of supporting polled interrupts.

Software Interrupts

The Solaris 9 DDI/DKI supports software interrupts, also known as soft interrupts. Soft interrupts are initiated by software, rather than by a hardware device. Handlers for these interrupts must also be added to and removed from the system. Soft interrupt handlers run in interrupt context and therefore can be used to do many of the tasks that belong to an interrupt handler.
Hardware interrupt handlers are supposed to perform their tasks quickly, since they may suspend other system activity while running. This is particularly true for high-level interrupt handlers, which operate at priority levels greater than that of the system scheduler. High-level interrupt handlers mask the operations of all lower-priority interrupts—including those of the system clock. Consequently, the interrupt handler must avoid involving itself in an activity (such as acquiring a mutex) that might cause it to sleep.

If the handler sleeps, then the system may hang because the clock is masked and incapable of scheduling the sleeping thread. For this reason, high-level interrupt handlers normally perform a minimum amount of work at high-priority levels and delegate remaining tasks to software interrupts, which run below the priority level of the high-level interrupt handler. Because software interrupt handlers run below the priority level of the system scheduler, they can do the work that the high-level interrupt handler was incapable of doing.

Registering Interrupts

Before a device driver can receive and service interrupts, it must register an interrupt handler with the system by calling ddi_add_intr(9F). Registering interrupts provides the system with a way to associate an interrupt handler with an interrupt specification. The interrupt handler is called when the device might have been responsible for the interrupt. The handler has the responsibility of determining if it should handle the interrupt and, if so, of claiming it.

Caution – There is a potential race condition between adding the interrupt handler and initializing mutexes. The interrupt routine is eligible to be called as soon as ddi_add_intr(9F) returns, as another device might interrupt and cause the handler to be invoked. This may result in the interrupt routine being called before any mutexes have been initialized with the returned interrupt block cookie. If the interrupt routine acquires the mutex before it has been initialized, undefined behavior may result. To ensure that this race condition does not occur, always initialize mutexes and any other data used in the interrupt handler before adding the interrupt.

To register a driver’s interrupt handler, the driver usually performs the following steps in attach(9E).

1. Test for high-level interrupts by calling ddi_intr_hilevel(9F) to find out if the interrupt specification maps to a high-level interrupt. If it does, one possibility is to post a message to that effect and return DDI_FAILURE. See Example 7–1.
2. Get the iblock cookie by calling ddi_get_iblock_cookie(9F).
3. Initialize any associated mutexes with the iblock cookie by calling 
   \texttt{mutex\_init}(9F).

4. Register the interrupt handler by calling \texttt{ddi\_add\_intr}(9F).

Example 7–1 shows how to install an interrupt handler.

\textbf{EXAMPLE 7–1} \texttt{attach}(9E) Routine Installing an Interrupt Handler

\begin{verbatim}
static int
xxattach(dev_info_t *dip, ddi_attach_cmd_t cmd)
{
    struct xxstate *xsp;
    switch (cmd) {
    case DDI_ATTACH:
        ...
        if (ddi_intr_hilevel(dip, inumber) != 0) {
            cmn_err(CE_CONT,
            "xx: high-level interrupts are not supported\n");
            return (DDI_FAILURE);
        }
        ddi_get_iblock_cookie(dip, inumber, &xsp->iblock_cookie);
        mutex_init(&xsp->mu, NULL, MUTEX_DRIVER,
                (void *)xsp->iblock_cookie);
        cv_init(&xsp->cv, NULL, CV_DRIVER, NULL);
        if (ddi_add_intr(dip, inumber, NULL, NULL, xxintr,
                (caddr_t)xsp) != DDI_SUCCESS) {
            cmn_err(CE_WARN, "xx: cannot add interrupt handler.");
            goto failed;
        }
        return (DDI_SUCCESS);
    case DDI_RESUME:
        For information, see Chapter 9
        default:
            return (DDI_FAILURE);
    }
failed:
    remove interrupt handler if necessary, destroy mutex and condition variable
    return (DDI_FAILURE);
}
\end{verbatim}

\textbf{Interrupt Handler Responsibilities}

The interrupt handler has a set of responsibilities to perform. Some are required by the 
framework, and some are required by the device. All interrupt handlers are required 
to do the following:

- Determine if the device is interrupting and possibly reject the interrupt.
The interrupt handler must first examine the device and determine if it has issued the interrupt. If it has not, the handler must return DDI_INTR_UNCLAIMED. This step allows the implementation of device polling: it tells the system whether this device, among a number of devices at the given interrupt priority level, has issued the interrupt.

- **Inform the device that it is being serviced.**
  This is a device-specific operation, but it is required for the majority of devices. For example, SBus devices are required to interrupt until the driver tells them to stop. This guarantees that all SBus devices interrupting at the same priority level will be serviced.

- **Perform any I/O request-related processing.**
  Devices interrupt for different reasons, such as transfer done or transfer error. This step may involve using data access functions to read the device’s data buffer, examine the device’s error register, and set the status field in a data structure accordingly. Interrupt dispatching and processing are relatively time consuming.

- **Do any additional processing that could prevent another interrupt.**
  For example, read the next item of data from the device.

- **Return** DDI_INTR_CLAIMED.

The following example shows an interrupt routine.

**EXAMPLE 7-2 Interrupt Example**

```c
static uint_t
xxintr(caddr_t arg)
{
    struct xxstate *xsp = (struct xxstate *)arg;
    uint8_t status;
    volatile uint8_t temp;

    /* Claim or reject the interrupt. This example assumes that the device's CSR includes this information. */
    mutex_enter(&xsp->high_mu);
    /* use data access routines to read status */
    status = ddi_get8(xsp->data_access_handle, &xsp->regp->csr);
    if (!(status & INTERRUPTING)) {
        mutex_exit(&xsp->high_mu);
        return (DDI_INTR_UNCLAIMED); /* dev not interrupting */
    }

    /* Inform the device that it is being serviced, and re-enable interrupts. The example assumes that writing to the CSR accomplishes this. The driver must ensure that this data access operation makes it to the device before the interrupt service routine returns. For example, using the data access functions to read the CSR, if it does not result in unwanted effects, can ensure this. */
```

100 Writing Device Drivers • May 2002
EXAMPLE 7-2 Interrupt Example  (Continued)

    ddi_put8(xsp->data_access_handle, &xsp->regp->csr,
        CLEAR_INTERRUPT | ENABLE_INTERRUPTS);
    /* flush store buffers */
    temp = ddi_get8(xsp->data_access_handle, &xsp->regp->csr);

    mutex_exit(&xsp->mu);
    return (DDI_INTR_CLAIMED);
}

Most of the steps performed by the interrupt routine depend on the specifics of the
device itself. Consult the hardware manual for the device to determine the cause of the
interrupt, detect error conditions, and access the device data registers.

Handling High-Level Interrupts

High-level interrupts are those that interrupt at the level of the scheduler and above.
This level does not allow the scheduler to run; therefore, high-level interrupt handlers
cannot be preempted by the scheduler, nor can they rely on the scheduler (that is, they
cannot block because of the scheduler)—they can only use mutual exclusion locks for
locking.

Because of this, the driver must use ddi_intr_hilevel(9F) to determine if it is
using high-level interrupts. If ddi_intr_hilevel(9F) returns true, the driver can fail
to attach, or it can use a two-level scheme to handle interrupts.

The suggested method is to add a high-level interrupt handler, which simply triggers
a lower-priority software interrupt to handle the device. The driver should allow more
concurrency by using a separate mutex for protecting data from the high-level
handler.

High-level Mutexes

A mutex initialized with the interrupt block cookie that represents a high-level
interrupt is known as a high-level mutex. While holding a high-level mutex, the driver
is subject to the same restrictions as a high-level interrupt handler.
High-Level Interrupt Handling Example

In the example presented in Example 7-3, the high-level mutex (xsp->high_mu) is used only to protect data shared between the high-level interrupt handler and the soft interrupt handler. This includes a queue that the high-level interrupt handler appends data to (and the low-level handler removes data from), and a flag that indicates the low-level handler is running. A separate low-level mutex (xsp->low_mu) protects the rest of the driver from the soft interrupt handler.

**EXAMPLE 7-3** attach(9E) Routine Handling High-Level Interrupts

```c
static int
xxattach(dev_info_t *dip, ddi_attach_cmd_t cmd)
{
    struct xxstate *xsp;
    ...
    if (ddi_intr_hilevel(dip, inumber)) {
        ddi_get_iblock_cookie(dip, inumber,
            &xsp->high_iblock_cookie);
        mutex_init(&xsp->high_mu, NULL, MUTEX_DRIVER,
            (void *)&xsp->high_iblock_cookie);
        if (ddi_add_intr(dip, inumber, &xsp->high_iblock_cookie,
            &xsp->high_device_cookie, xxhighintr, (caddr_t)xsp)
            != DDI_SUCCESS)
            goto failed;
        ddi_get_soft_iblock_cookie(dip, DDI_SOFTINT_HI,
            &xsp->low_iblock_cookie)
        mutex_init(&xsp->low_mu, NULL, MUTEX_DRIVER,
            (void *)&xsp->low_iblock_cookie);
        if (ddi_add_softintr(dip, DDI_SOFTINT_HI, &xsp->id,
            &xsp->low_iblock_cookie, NULL,
            xxlowintr, (caddr_t)xsp) != DDI_SUCCESS)
            goto failed;
    } else {
        // add normal interrupt handler
    }
    cv_init(&xsp->cv, NULL, CV_DRIVER, NULL);
    ...
    return (DDI_SUCCESS);
failed:
    free allocated resources, remove interrupt handlers
    return (DDI_FAILURE);
}
```

The high-level interrupt routine services the device, and enqueues the data. The high-level routine triggers a software interrupt if the low-level routine is not running, as Example 7-4 demonstrates.

**EXAMPLE 7-4** High-level Interrupt Routine

```c
static uint_t
xxhighintr(caddr_t arg)
{
```
EXAMPLE 7–4 High-level Interrupt Routine  (Continued)

```c
struct xxstate *xsp = (struct xxstate *)arg;
uint8_t status;
volatile uint8_t temp;
int need_softint;

mutex_enter(&xsp->high_mu);
/* read status */
status = ddi_get8(xsp->data_access_handle, &xsp->regp->csr);
if (!(status & INTERRUPTING)) {
    mutex_exit(&xsp->high_mu);
    return (DDI_INTR_UNCLAIMED); /* dev not interrupting */
}

ddi_put8(xsp->data_access_handle, &xsp->regp->csr,
        CLEAR_INTERRUPT | ENABLE_INTERRUPTS);
/* flush store buffers */
temp = ddi_get8(xsp->data_access_handle, &xsp->regp->csr);
read data from device and queue the data for the low-level interrupt handler;
if (xsp->softint_running)
    need_softint = 0;
else {
    xsp->softint_count++;
    need_softint = 1;
}
mutex_exit(&xsp->high_mu);
/* read-only access to xsp->id, no mutex needed */
if (need_softint)
    ddi_trigger_softintr(xsp->id);
return (DDI_INTR_CLAIMED);
```

The low-level interrupt routine is started by the high-level interrupt routine triggering a software interrupt. Once running, it should continue to do so until there is nothing left to process, as Example 7–5 shows.

EXAMPLE 7–5 Low-level Interrupt Routine

```c
static uint_t xxlowlintr(caddr_t arg)
{
    struct xxstate *xsp = (struct xxstate *)arg;
    ....
    mutex_enter(&xsp->low_mu);
    mutex_enter(&xsp->high_mu);
    if (xsp->softint_count > 1) {
        xsp->softint_count--;
        mutex_exit(&xsp->high_mu);
        mutex_exit(&xsp->low_mu);
        return (DDI_INTR_CLAIMED);
    }
    if (queue empty) {
```
EXAMPLE 7-5 Low-level Interrupt Routine  (Continued)

mutex_exit(&xsp->high_mu);
mutex_exit(&xsp->low_mu);
return (DDI_INTR_UNCLAIMED);
}

xsp->softint_running = 1;
while (data on queue) {
    ASSERT(mutex_owned(&xsp->high_mu);
    dequeue data from high-level queue;
    mutex_exit(&xsp->high_mu);
    normal interrupt processing
    mutex_enter(&xsp->high_mu);
}

xsp->softint_running = 0;
xsp->softint_count = 0;
mutex_exit(&xsp->high_mu);
mutex_exit(&xsp->low_mu);
return (DDI_INTR_CLAIMED);
}
Direct Memory Access (DMA)

Many devices can temporarily take control of the bus and perform data transfers to (and from) main memory or other devices. Because the device is doing the work without the help of the CPU, this type of data transfer is known as direct memory access (DMA). DMA transfers can be performed between two devices, between a device and memory, or between memory and memory. This chapter explains transfers between a device and memory only.

This chapter provides information on the following subjects:
- “DMA Model” on page 105
- “Types of Device DMA” on page 106
- “Managing DMA Resources” on page 113
- “DMA Software Components: Handles, Windows, and Cookies” on page 108
- “DMA Operations” on page 108
- “Managing DMA Resources” on page 113
- “DMA Windows” on page 125

DMA Model

The Solaris Device Driver Interface/Driver-Kernel Interface (DDI/DKI) provides a high-level, architecture-independent model for DMA. This allows the framework (the DMA routines) to hide such architecture-specific details as:

- Setting up DMA mappings
- Building scatter-gather lists
- Ensuring that I/O and CPU caches are consistent

There are several abstractions that are used in the DDI/DKI to describe aspects of a DMA transaction. These include:

- DMA object – Memory that is the source or destination of a DMA transfer.
- **DMA handle** – An opaque object returned from a successful `ddi_dma_alloc_handle(9F)` call. The DMA handle can be used in subsequent DMA subroutine calls to refer to such DMA objects.

- **DMA cookie** – A `ddi_dma_cookie(9S)` structure (`ddi_dma_cookie_t`) describes a contiguous portion of a DMA object that is entirely addressable by the device. It contains DMA addressing information required to program the DMA engine.

Rather than knowing that a platform needs to map an object (typically a memory buffer) into a special DMA area of the kernel address space, device drivers instead allocate DMA resources for the object. The DMA routines then perform any platform-specific operations needed to set the object up for DMA access. The driver receives a DMA handle to identify the DMA resources allocated for the object. This handle is opaque to the device driver; the driver must save the handle and pass it in subsequent calls to DMA routines, but should not interpret it in any way.

Operations are defined on a DMA handle that provide the following services:

- Manipulating DMA resources
- Synchronizing DMA objects
- Retrieving attributes of the allocated resources

---

### Types of Device DMA

Devices perform one of the following three types of DMA:

- “Bus-Master DMA” on page 106
- “Third-party DMA” on page 106
- “First-party DMA” on page 107

#### Bus-Master DMA

If the device is capable of acting as a true bus master (where the DMA engine resides on the device board), the driver should program the device’s DMA registers directly. The transfer address and count are obtained from the DMA cookie and given to the device.

#### Third-party DMA

Third-party DMA utilizes a system DMA engine resident on the main system board, which has several DMA channels available for use by devices. The device relies on the system’s DMA engine to perform the data transfers between the device and memory.
The driver uses DMA engine routines (see ddi_dmae(9F)) to initialize and program the DMA engine. For each DMA data transfer, the driver programs the DMA engine and then gives the device a command to initiate the transfer in cooperation with that engine.

First-party DMA

Under first-party DMA, the device drives its own DMA bus cycles using a channel from the system’s DMA engine. The ddi_dmae_1stparty(9F) function is used to configure this channel in a cascade mode so that the DMA engine will not interfere with the transfer.

Types of Host Platform DMA

The platform that the device operates on provides one of two types of memory access: direct memory access (DMA) or direct virtual memory access (DVMA).

On platforms that support DMA, the system provides the device with a physical address in order to perform transfers. In this case, the transfer of a DMA object can actually consist of a number of physically discontiguous transfers. An example of this occurs when an application transfers a buffer that spans several contiguous virtual pages that map to physically discontiguous pages. To deal with the discontiguous memory, devices for these platforms usually have some kind of scatter-gather DMA capability. Typically, IA systems provide physical addresses for direct memory transfers.

On platforms that support DVMA, the system provides the device with a virtual address to perform transfers. In this case, the underlying platform provides some form of memory management unit (MMU) that translates device accesses to these virtual addresses into the proper physical addresses. The device transfers to and from a contiguous virtual image that can be mapped to discontiguous physical pages. Devices that operate in these platforms don’t need scatter-gather DMA capability. Typically, SPARC platforms provide virtual addresses for direct memory transfers.
DMA Software Components: Handles, Windows, and Cookies

A DMA handle is an opaque pointer representing an object (usually a memory buffer or address) where a device can perform DMA transfers. Several different calls to DMA routines use the handle to identify the DMA resources allocated for the object.

An object represented by a DMA handle is completely covered by one or more DMA cookies. A DMA cookie represents a contiguous piece of memory to or from which the DMA engine can transfer data. The system uses the information in a DMA attribute ddi_dma_attr(9S) structure provided by the driver, as well as the memory location and alignment of the target object, to decide how to divide an object into multiple cookies.

If the object is too big to fit the request within system resource limitations, it has to be broken up into multiple DMA windows. Only one window is activated at one time and has resources allocated. The ddi_dma_getwin(9F) function is used to position between windows within an object. Each DMA window consists of one or more DMA cookies. For more information, see “DMA Windows” on page 125.

Some DMA engines can accept more than one cookie. Such engines perform scatter-gather I/O without the help of the system. In this case, it is most efficient if the driver uses ddi_dma_nextcookie(9F) to get as many cookies as the DMA engine can handle and program them all into the engine. The device can then be programmed to transfer the total number of bytes covered by all these DMA cookies combined.

DMA Operations

The steps involved in a DMA transfer are similar among the types of DMA. The sections below present methods for performing DMA transfers.

Note – You do not have to ensure the DMA object is locked in memory in block drivers for buffers coming from the file system, as the file system has already locked the data in memory.

Performing Bus-Master DMA Transfers

In general, the driver should perform the following steps for bus-master DMA.
1. Describe the DMA attributes. This enables the routines to ensure that the device will be able to access the buffer.

2. Allocate a DMA handle.

3. Ensure that the DMA object is locked in memory (see `physio(9F)` or `ddi_umem_lock(9F)`).

4. Allocate DMA resources for the object.

5. Program the DMA engine on the device and start it (this is device specific). When the transfer is complete, continue the bus master operation.

6. Perform any required object synchronizations.

7. Release the DMA resources.

8. Free the DMA handle.

Performing First-Party DMA Transfers

In general, the driver should perform the following steps for first-party DMA.

1. Allocate a DMA channel.

2. Configure the channel with `ddi_dmae_1stparty(9F)`.

3. Ensure that the DMA object is locked in memory (see `physio(9F)` or `ddi_umem_lock(9F)`).

4. Allocate DMA resources for the object.

5. Program the DMA engine on the device and start it (this is device specific). When the transfer is complete, continue the bus-master operation.

6. Perform any required object synchronizations.

7. Release the DMA resources.

8. Deallocate the DMA channel.

Performing Third-Party DMA Transfers

In general, the driver should perform these steps for third-party DMA.

1. Allocate a DMA channel.

2. Retrieve the system’s DMA engine attributes with `ddi_dmae_getattr(9F)`.

3. Lock the DMA object in memory (see `physio(9F)` or `ddi_umem_lock(9F)`).

4. Allocate DMA resources for the object.

5. Program the system DMA engine to perform the transfer with `ddi_dmae_prog(9F)`.

6. Perform any required object synchronizations.

7. Stop the DMA engine with `ddi_dmae_stop(9F)`.
8. Release the DMA resources.
9. Deallocate the DMA channel.

Certain hardware platforms restrict DMA capabilities in a bus-specific way. Drivers should use `ddi_slaveonly(9F)` to determine if the device is in a slot in which DMA is possible.

**DMA Attributes**

DMA attributes describe the built-in attributes and limits of a DMA engine, including:

- Limits on addresses the device can access
- Maximum transfer count
- Address alignment restrictions

To ensure that DMA resources allocated by the system can be accessed by the device's DMA engine, device drivers must inform the system of their DMA engine limitations using a `ddi_dma_attr(9S)` structure. The system might impose additional restrictions on the device attributes, but it never removes any of the driver-supplied restrictions.

**ddi_dma_attr Structure**

The DMA attribute structure has the following members:

```c
typedef struct ddi_dma_attr {
    uint_t dma_attr_version; /* version number */
    uint64_t dma_attr_addr_lo; /* low DMA address range */
    uint64_t dma_attr_addr_hi; /* high DMA address range */
    uint64_t dma_attr_count_max; /* DMA counter register */
    uint64_t dma_attr_align; /* DMA address alignment */
    uint_t dma_attr_burstsizes; /* DMA burstsizes */
    uint32_t dma_attr_minxfer; /* min effective DMA size */
    uint64_t dma_attr_maxxfer; /* max DMA xfer size */
    uint64_t dma_attr_seg; /* segment boundary */
    int dma_attr_sgllen; /* s/g length */
    uint32_t dma_attr_granular; /* granularity of device */
    uint_t dma_attr_flags; /* Bus specific DMA flags */
} ddi_dma_attr_t;
```

- `dma_attr_version` : Version number of the attribute structure. It should be set to `DMA_ATTR_V0`.
- `dma_attr_addr_lo` : Lowest bus address that the DMA engine can access.
- `dma_attr_addr_hi` : Highest bus address that the DMA engine can access.
- `dma_attr_count_max` : Specifies the maximum transfer count that the DMA engine can handle in one cookie. The limit is expressed as the maximum count minus one. It is used as a bit mask, so it must also be one less than a power of two.
dma_attr_align  Specifies additional alignment requirements for any allocated DMA resources. This field can be used to force more restrictive alignment than implicitly specified by other DMA attributes, such as alignment on a page boundary.

dma_attr_burstsizes  Specifies the burst sizes that the device supports. (A burst size is the amount of data the device can transfer before relinquishing the bus.) This member is a binary encoding of burst sizes, assumed to be powers of two. For example, if the device is capable of doing 1-, 2-, 4-, and 16-byte bursts, this field should be set to 0x17. The system also uses this field to determine alignment restrictions.

dma_attr_minxfer  Minimum effective transfer size the device can perform. It also influences alignment and padding restrictions.

dma_attr_maxxfer  Describes the maximum number of bytes that the DMA engine can transmit or receive in one I/O command. This limitation is only significant if it is less than (dma_attr_count_max + 1) * dma_attr_sgllen.

dma_attr_seg  Upper bound of the DMA engine’s address register. This is often used where the upper 8 bits of an address register are a latch containing a segment number, and the lower 24 bits are used to address a segment. In this case, dma_attr_seg would be set to 0xFFFFFF, which prevents the system from crossing a 24-bit segment boundary when allocating resources for the object.

dma_attr_sgllen  Specifies the maximum number of entries in the scatter-gather list. It is the number of cookies that the DMA engine can consume in one I/O request to the device. If the DMA engine has no scatter-gather list, this field should be set to one.

dma_attr_granular  This field describes the granularity of the device’s DMA transfer ability, in units of bytes. This value is used to specify, for example, the sector size of a mass storage device. DMA requests will be broken into multiples of this value. If there is no scatter-gather capability, then the size of each DMA transfer will be a multiple of this value. If there is scatter-gather capability, then a single segment will not be smaller than the minimum transfer value, but can be less than the granularity; however the total transfer length of the scatter-gather list will be a multiple of the granularity value.
This field can be set to DDI_DMA_FORCE_PHYSICAL, which indicates that the system should return physical rather than virtual I/O addresses if the system supports both. If the system does not support physical DMA, the return value from ddi_dma_alloc_handle(9F) will be DDI_DMA_BADATTR. In this case, the driver has to clear DDI_DMA_FORCE_PHYSICAL and retry the operation.

SBus Example

A DMA engine on an SBus in a SPARC machine has the following attributes:
- It can access only addresses ranging from 0xFF000000 to 0xFFFFFFFF.
- It has a 32-bit DMA counter register.
- It can handle byte-aligned transfers.
- It supports 1-, 2- and 4-byte burst sizes.
- It has a minimum effective transfer size of 1 byte.
- It has a 32-bit address register.
- It doesn’t have a scatter-gather list.
- The device operates on sectors only (for example a disk).

The resulting attribute structure is:

```c
static ddi_dma_attr_t attributes = {
    DMA_ATTR_V0, /* Version number */
    0xFF000000, /* low address */
    0xFFFFFFFF, /* high address */
    0xFFFFFFFF, /* counter register max */
    1, /* byte alignment */
    0x7, /* burst sizes: 0x1 | 0x2 | 0x4 */
    0x1, /* minimum transfer size */
    0xFFFFFFFF, /* max xfer size */
    0xFFFFFFFF, /* address register max */
    1, /* no scatter-gather */
    512, /* device operates on sectors */
    0, /* attr flag: set to 0 */
};
```

ISA Bus Example

A DMA engine on an ISA bus in an IA machine has the following attributes:
- It accesses only the first 16 megabytes of memory.
- It cannot cross a 1 megabyte boundary in a single DMA transfer.
It has a 16-bit counter register.
It can handle byte-aligned transfers.
It supports 1-, 2- and 4-byte burst sizes.
It has a minimum effective transfer size of 1 byte.
It can hold up to 17 scatter-gather transfers.
The device operates on sectors only (for example a disk).

The resulting attribute structure is:

```c
static ddi_dma_attr_t attributes = {
    DMA_ATTR_V0,    /* Version number */
    0x00000000,    /* low address */
    0x00FFFFFF,    /* high address */
    0xFFFF,        /* counter register max */
    1,             /* byte alignment */
    0x7,           /* burst sizes */
    0x1,           /* minimum transfer size */
    0xFFFFFFFFFF,  /* max xfer size */
    0x0000FFFF,    /* address register max */
    17,            /* scatter-gather */
    512,           /* device operates on sectors */
    0,             /* attr flag: set to 0 */
};
```

Managing DMA Resources

This section describes how to manage DMA resources.

Object Locking

Before allocating the DMA resources for a memory object, the object must be prevented from moving. Otherwise, the system can remove the object from memory while the device is writing to it, causing the data transfer to fail, and possibly corrupting the system. The process of preventing memory objects from moving during a DMA transfer is known as locking down the object.

The following object types do not require explicit locking:

- Buffers coming from the file system through strategy(9E). These buffers are already locked by the file system.
- Kernel memory allocated within the device driver, such as that allocated by ddi_dma_mem_alloc(9F).
For other objects (such as buffers from user space), `physio(9F)` or `ddi_umem_lock(9F)` must be used to lock down the objects. This is usually performed in the `read(9E)` or `write(9E)` routines of a character device driver. See "Data Transfer Methods" on page 159 for an example.

### Allocating a DMA Handle

A DMA handle is an opaque object that is used as a reference to subsequently allocated DMA resources. It is usually allocated in the driver’s attach entry point using `ddi_dma_alloc_handle(9F)`. `ddi_dma_alloc_handle(9F)` takes the device information referred to by `dip` and the device’s DMA attributes described by a `ddi_dma_attr(9S)` structure as parameters. `ddi_dma_alloc_handle(9F)` has the following syntax:

```c
int ddi_dma_alloc_handle(dev_info_t *dip,
                      ddi_dma_attr_t *attr, int (*callback)(caddr_t),
                      caddr_t arg, ddi_dma_handle_t *handlep);
```

- `dip` Pointer to the device’s `dev_info` structure
- `attr` Pointer to a `ddi_dma_attr(9S)` structure as described in “DMA Attributes” on page 110
- `callback` Address of the callback function for handling resource allocation failures
- `arg` Argument to be passed to the callback function
- `handlep` Pointer to a DMA handle to store the returned handle

### Allocating DMA Resources

Two interfaces allocate DMA resources:

- `ddi_dma_buf_bind_handle(9F)` – Used with `buf(9S)` structures
- `ddi_dma_addr_bind_handle(9F)` – Used with virtual addresses

DMA resources are usually allocated in the driver’s `xxstart()` routine, if one exists. See “Asynchronous Data Transfers (Block Drivers)” on page 191 for discussion of `xxstart`. These two interfaces have the following syntax:

```c
int ddi_dma_addr_bind_handle(ddi_dma_handle_t handle,
                        struct as *as, caddr_t addr,
                        size_t len, uint_t flags, int (*callback)(caddr_t),
                        caddr_t arg, ddi_dma_cookie_t *cookiep, uint_t *ccountp);

int ddi_dma_buf_bind_handle(ddi_dma_handle_t handle,
                        struct buf *bp, uint_t flags,
                        int (*callback)(caddr_t), caddr_t arg,
```
ddi_dma_cookie_t *cookiep, uint_t *ccountp);

The following arguments are common to both ddi_dma_addr_bind_handle(9F) and ddi_dma_buf_bind_handle(9F):

- **handle** DMA handle and the object for allocating resources.
- **flags** Set of flags indicating the transfer direction and other attributes. DDI_DMA_READ indicates a data transfer from device to memory. DDI_DMA_WRITE indicates a data transfer from memory to device. See the ddi_dma_addr_bind_handle(9F) or ddi_dma_buf_bind_handle(9F) man pages for a complete discussion of the allowed flags.
- **callback** Address of callback function for handling resource allocation failures. See the ddi_dma_addr_bind_handle(9F) man page.
- **arg** Argument to pass to the callback function.
- **cookiep** Pointer to the first DMA cookie for this object.
- **ccountp** Pointer to the number of DMA cookies for this object.

- For ddi_dma_addr_bind_handle(9F), the object is described by an address range, where as is a pointer to an address space structure (this must be NULL), addr is the base kernel address of the object, and len is the length of the object in bytes.
- For ddi_dma_buf_bind_handle(9F), the object is described by a buf(9S) structure pointed to by bp.

## Device Register Structure

DMA capable devices have more registers than have been used in previous examples. This section adds the following fields to the device register structure to support DMA-capable device examples.

For DMA engines without scatter-gather support:

```c
uint32_t dma_addr; /* starting address for DMA */
uint32_t dma_size; /* amount of data to transfer */
```

For DMA engines with scatter-gather support:

```c
struct sglentry {
    uint32_t dma_addr;
    uint32_t dma_size;
} sglist[SGLLEN];

caddr_t iopb_addr; /* When written informs device of the next */
/* command's parameter block address. */
/* When read after an interrupt, contains */
/* the address of the completed command. */
```
DMA Callback Example

In Example 8-1, `xxstart()` is used as the callback function and the per-device state structure is given as its argument. `xxstart()` attempts to start the command. If the command cannot be started because resources are not available, `xxstart()` is scheduled to be called sometime later, when resources might be available.

Because `xxstart()` is used as a DMA callback, it must follow these rules imposed on DMA callbacks:

- It must not assume that resources are available (it must try to allocate them again).
- It must indicate to the system whether allocation succeeded by returning `DDI_DMA_CALLBACK_RUNOUT` if it fails to allocate resources (and needs to be called again later) or `DDI_DMA_CALLBACK_DONE` indicating success (so no further callback is necessary).

**EXAMPLE 8-1 DMA Callback Example**

```c
static int xxstart(caddr_t arg)
{
    struct xxstate *xsp = (struct xxstate *)arg;
    struct device_reg *regp;
    int flags;
    mutex_enter(&xsp->mu);
    if (xsp->busy) {
        /* transfer in progress */
        mutex_exit(&xsp->mu);
        return (DDI_DMA_CALLBACK_RUNOUT);
    }
    xsp->busy = 1;
    regp = xsp->regp;
    if (transfer is a read) {
        flags = DDI_DMA_READ;
    } else {
        flags = DDI_DMA_WRITE;
    }
    mutex_exit(&xsp->mu);
    if (ddi_dma_buf_bind_handle(xsp->handle,xsp->bp,flags,
        xxstart,
        (caddr_t)xsp, &cookie, &ccount) != DDI_DMA_MAPPED) {
        /* really should check all return values in a switch */
        mutex_enter(&xsp->mu);
        xsp->busy=0;
        mutex_exit(&xsp->mu);
        return (DDI_DMA_CALLBACK_RUNOUT);
    }
    ...
    program the DMA engine
    ...
    return (DDI_DMA_CALLBACK_DONE);
}
```

116 Writing Device Drivers • May 2002
Determining Maximum Burst Sizes

Drivers specify the DMA burst sizes that their device supports in the dma_attr_burstsizes field of the ddi_dma_attr(9S) structure. This is a bitmap of the supported burst sizes. However, when DMA resources are allocated, the system might impose further restrictions on the burst sizes that might be actually used by the device. The ddi_dma_burstsizes(9F) routine can be used to obtain the allowed burst sizes. It returns the appropriate burst size bitmap for the device. When DMA resources are allocated, a driver can ask the system for appropriate burst sizes to use for its DMA engine.

EXAMPLE 8-2 Determining Burst Size

```c
#define BEST_BURST_SIZE 0x20 /* 32 bytes */
if (ddi_dma_buf_bind_handle(xsp->handle,xsp->xp, flags, xxstart,
    (caddr_t)xsp, &cookie, &ccount) != DDI_DMA_MAPPED) {
    /* error handling */
}
burst = ddi_dma_burstsizes(xsp->handle);
/* check which bit is set and choose one burstsize to */
/* program the DMA engine */
if (burst & BEST_BURST_SIZE) {
    program DMA engine to use this burst size
} else {
    other cases
}
```

Allocating Private DMA Buffers

Some device drivers might need to allocate memory for DMA transfers to or from a device, besides doing transfers requested by user threads and the kernel. Examples of this are setting up shared memory for communication with the device and allocating intermediate transfer buffers. Use ddi_dma_mem_alloc(9F) to allocate memory for DMA transfers.

```c
int ddi_dma_mem_alloc(ddi_dma_handle_t handle, size_t length,
    ddi_device_acc_attr_t *accattrp, uint_t flags,
    int (*waitfp)(caddr_t), caddr_t arg, caddr_t *kaddrp,
    size_t *real_length, ddi_acc_handle_t *handlep);

handle DMA handle
length Length in bytes of the desired allocation
accattrp Pointer to a device access attribute structure
flags Data transfer mode flags; possible values are: DDI_DMA_CONSISTENT and DDI_DMA_STREAMING
waitfp Address of callback function for handling resource allocation failures. See the ddi_dma_mem_alloc(9F) man page
```
Argument to pass to the callback function

Pointer (on a successful return) that contains the address of the allocated storage

Length in bytes that was allocated

Pointer to a data access handle

flags should be set to DDI_DMA_CONSISTENT if the device accesses in a nonsequential fashion, or if synchronization steps using ddi_dma_sync(9F) should be as lightweight as possible (because of frequent use on small objects). This type of access is commonly known as consistent access. I/O parameter blocks that are used for communication between a device and the driver are set up this way.

On the IA platform, to allocate memory for DMA using physically contiguous pages, set the length of the scatter/gather list dma_attr_sgllen in the ddi_dma_attr(9S) structure to 1, and do not specify DDI_DMA_PARTIAL which would otherwise permit partial resource allocation.

Example 8-3 shows how to allocate IOPB memory and the necessary DMA resources to access it. DMA resources must still be allocated, and the DDI_DMA_CONSISTENT flag must be passed to the allocation function.

EXAMPLE 8-3 Using ddi_dma_mem_alloc(9F)

```c
if (ddi_dma_mem_alloc(xsp->iopb_handle, size, &accattr,
        DDI_DMA_CONSISTENT, DDI_DMA_SLEEP, NULL, &xsp->iopb_array,
        &real_length, &xsp->acchandle) != DDI_SUCCESS) {
    error handling
    goto failure;
}
if (ddi_dma_addr_bind_handle(xsp->iopb_handle, NULL, 
        xsp->iopb_array, real_length, 
        DDI_DMA_READ | DDI_DMA_CONSISTENT, DDI_DMA_SLEEP, 
        NULL, &cookie, &count) != DDI_DMA_MAPPED) {
    error handling
    ddi_dma_mem_free(&xsp->acchandle);
    goto failure;
}
```

flags should be set to DDI_DMA_STREAMING if the device is doing sequential, unidirectional, block-sized and block-aligned transfers to or from memory. This type of access is commonly known as streaming access.

For example, if an I/O transfer can be sped up by using an I/O cache, which at a minimum transfers (flushes) one cache line, ddi_dma_mem_alloc(9F) will round the size to a multiple of the cache line to avoid data corruption.
ddi_dma_mem_alloc(9F) returns the actual size of the allocated memory object. Because of padding and alignment requirements, the actual size might be larger than the requested size. ddi_dma_addr_bind_handle(9F) requires the actual length.

ddi_dma_mem_free(9F) is used to free the memory allocated by ddi_dma_mem_alloc(9F).

**Note** – If the memory is not properly aligned, the transfer will succeed but the system will choose a different (and possibly less efficient) transfer mode that requires fewer restrictions. For this reason, ddi_dma_mem_alloc(9F) is preferred over kmem_alloc(9F) when allocating memory for the device to access.

### Handling Resource Allocation Failures

The resource-allocation routines provide the driver with several options when handling allocation failures. The *waitfp* argument indicates whether the allocation routines will block, return immediately, or schedule a callback, as shown in Table 8–1.

**TABLE 8–1** Resource Allocation Handling

<table>
<thead>
<tr>
<th><em>waitfp</em> value</th>
<th>Indicated Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>DDI_DMA_DONTWAIT</td>
<td>Driver does not want to wait for resources to become available</td>
</tr>
<tr>
<td>DDI_DMA_SLEEP</td>
<td>Driver is willing to wait indefinitely for resources to become available</td>
</tr>
<tr>
<td>Other values</td>
<td>The address of a function to be called when resources are likely to be available</td>
</tr>
</tbody>
</table>

### Programming the DMA Engine

When the resources have been successfully allocated, the device must be programmed. Although programming a DMA engine is device specific, all DMA engines require a starting address and a transfer count. Device drivers retrieve these two values from the *DMA cookie* returned by a successful call from ddi_dma_addr_bind_handle(9F), ddi_dma_buf_bind_handle(9F), or ddi_dma_getwin(9F). These functions all return the first DMA cookie and a cookie count indicating whether the DMA object consists of more than one cookie. If the cookie count N is greater than 1, ddi_dma_nextcookie(9F) has to be called N-1 times to retrieve all the remaining cookies.

A cookie is of type ddi_dma_cookie(9S) and has the following fields:
uint64_t _dmac_ll; /* 64-bit DMA address */
uint32_t _dmac_la[2]; /* 2 x 32-bit address */
size_t _dmac_size; /* DMA cookie size */
uint_t _dmac_type; /* bus specific type bits */

The _dmac_1address specifies a 64-bit I/O address appropriate for programming the device's DMA engine. If a device has a 64-bit DMA address register, a driver should use this field to program the DMA engine. The _dmac_address field specifies a 32-bit I/O address that should be used for devices that have a 32-bit DMA address register. _dmac_size contains the transfer count. Depending on the bus architecture, the _dmac_type field in the cookie might be required by the driver. The driver should not perform any manipulations, such as logical or arithmetic, on the cookie.

**EXAMPLE 8-4 ddi_dma_cookie(9S) Example**

ddi_dma_cookie_t cookie;

if (ddi_dma_buf_bind_handle(xsp->handle, xsp->bp, flags, xxstart, (caddr_t)xsp, &cookie, &xsp->ccount) != DDI_DMA_MAPPED) {
    /* error handling */
}

sglp = regp->sglist;
for (cnt = 1; cnt <= SGLLEN; cnt++, sglp++) {
    /* store the cookie params into the S/G list */
    ddi_put32(xsp->access_hdl, &sglp->dma_size, (uint32_t)cookie.dmac_size);
    ddi_put32(xsp->access_hdl, &sglp->dma_addr, cookie.dmac_address);
    /* Check for end of cookie list */
    if (cnt == xsp->ccount)
        break;
    /* Get next DMA cookie */
    (void) ddi_dma_nextcookie(xsp->handle, &cookie);
} /* start DMA transfer */

ddi_put8(xsp->access_hdl, &regp->csr, ENABLE_INTERRUPTS | START_TRANSFER);

**Note** — ddi_dma_addr_bind_handle(9F) and ddi_dma_buf_bind_handle(9F) can return more DMA cookies than fit into the scatter-gather list. In this case, the driver has to continue the transfer in the interrupt routine and reprogram the scatter-gather list with the remaining DMA cookies. You must handle _sglllen_ cookies at a time.

**Freeing the DMA Resources**

After a DMA transfer is completed (usually in the interrupt routine), the driver can release DMA resources by calling ddi_dma_unbind_handle(9F).
As described in “Synchronizing Memory Objects” on page 123, `ddi_dma_unbind_handle(9F)` calls `ddi_dma_sync(9F)`, eliminating the need for any explicit synchronization. After calling `ddi_dma_unbind_handle(9F)`, the DMA resources become invalid, and further references to them have undefined results. Example 8–5 shows how to use `ddi_dma_unbind_handle(9F).

**EXAMPLE 8–5** Freeing DMA Resources

```c
static uint_t
xxintr(caddr_t arg)
{
    struct xxstate *xsp = (struct xxstate *)arg;
    uint8_t status;
    volatile uint8_t temp;
    mutex_enter(&xsp->mu);
    /* read status */
    status = ddi_get8(xsp->access_hdl, &xsp->regp->csr);
    if (!(status & INTERRUPTING)) {
        mutex_exit(&xsp->mu);
        return (DDI_INTR_UNCLAIMED);
    }
    ddi_put8(xsp->access_hdl, &xsp->regp->csr, CLEAR_INTERRUPT);
    /* for store buffers */
    temp = ddi_get8(xsp->access_hdl, &xsp->regp->csr);
    ddi_dma_unbind_handle(xsp->handle);
    ...
    /* check for errors */
    ...
    xsp->busy = 0;
    mutex_exit(&xsp->mu);
    if (pending transfers) {
        (void) xxstart((caddr_t)xsp);
    }
    return (DDI_INTR_CLAIMED);
}
```

The DMA resources should be released and reallocated if a different object will be used in the next transfer. However, if the same object is always used, the resources can be allocated once and continually reused as long as there are intervening calls to `ddi_dma_sync(9F).

**Freeing the DMA Handle**

When the driver is detached, the DMA handle must be freed. `ddi_dma_free_handle(9F)` destroys the DMA handle and any residual resources the system is caching on the handle. Any further references of the DMA handle will have undefined results.
Canceling DMA Callbacks

DMA callbacks cannot be canceled. This requires some additional code in the drivers
detach(9E) routine, as it must not return DDI_SUCCESS if there are any outstanding
callbacks. (See Example 8–6.) When DMA callbacks occur, the detach(9E) routine
must wait for the callback to run and must prevent it from rescheduling itself. This can
be done using additional fields in the state structure, as shown below.

**EXmLE 8-6 Cmrmling DMA Callbacks**

```c
static int
xxdetach(dev_info_t *dip, ddi_detach_cmd_t cmd)
{
    ...
    mutex_enter(&xsp->callback_mutex);
    xsp->cancel_callbacks = 1;
    while (xsp->callback_count > 0) {
        cv_wait(&xsp->callback_cv, &xsp->callback_mutex);
    }
    mutex_exit(&xsp->callback_mutex);
    ...
}

static int
xxstrategy(struct buf *bp)
{
    ...
    mutex_enter(&xsp->callback_mutex);
    xsp->bp = bp;
    error = ddi_dma_buf_bind_handle(xsp->handle, xsp->bp, flags,
         xxmacallback, (caddr_t)xsp, &cookie, &ccount);
    if (error == DDI_DMA_NORESOURCES)
         xsp->callback_count++;
    mutex_exit(&xsp->callback_mutex);
    ...
}

static int
xxdmacallback(caddr_t callbackarg)
{
    struct xxstate *xsp = (struct xxstate *)callbackarg;
    ...
    mutex_enter(&xsp->callback_mutex);
    if (xsp->cancel_callbacks) {
        /* do not reschedule, in process of detaching */
        xsp->callback_count--; 
        if (xsp->callback_count == 0)
            cv_signal(&xsp->callback_cv);
        mutex_exit(&xsp->callback_mutex);
        return (DDI_DMA_CALLBACK_DONE); /* don't reschedule it */
    }
    /*
    * Presumably at this point the device is still active
    * and will not be detached until the DMA has completed.
    */
    ...
```
EXAMPLE 8-6 Canceling DMA Callbacks  (Continued)

* A return of 0 means try again later
*/
error = ddi_dma_buf_bind_handle(xsp->handle, xsp->bp, flags,
       DDI_DMA_DONTWAIT, NULL, &cookie, &ccount);
if (error == DDI_DMA_MAPPED) {
    /* program the DMA engine */
    ...
    xsp->callback_count--;
    mutex_exit(&xsp->callback_mutex);
    return (DDI_DMA_CALLBACK_DONE);
}
if (error != DDI_DMA_NORESOURCES) {
    xsp->callback_count--;
    mutex_exit(&xsp->callback_mutex);
    return (DDI_DMA_CALLBACK_DONE);
}
mutex_exit(&xsp->callback_mutex);
return (DDI_DMA_CALLBACK_RUNOUT);
}

Synchronizing Memory Objects

At various points when the memory object is accessed (including the time of removal
of the DMA resources), the driver might need to synchronize the memory object with
respect to various caches. This section gives guidelines on when and how to
synchronize memory objects.

Cache

Cache is a very high-speed memory that sits between the CPU and the system’s main
memory (CPU cache), or between a device and the system’s main memory (I/O
cache), as shown in Figure 8–1.
When an attempt is made to read data from main memory, if the associated cache determines whether it contains the requested data, it quickly satisfies the request. If the cache does not have the data, it retrieves the data from main memory, passes the data on to the requestor, and saves the data in case that data is requested again.

Similarly, on a write cycle, the data is stored in the cache quickly and the CPU or device is allowed to continue executing (transferring). This takes much less time than if the CPU or device had to wait for the data to be written to memory.

With this model, after a device transfer has been completed, the data can still be in the I/O cache but not yet in main memory. If the CPU accesses the memory, it might read the wrong data from the CPU cache. To ensure a consistent view of the memory for the CPU, the driver must call a synchronization routine to flush the data from the I/O cache and update the CPU cache with the new data. Similarly, a synchronization step is required if data modified by the CPU is to be accessed by a device.

There might also be additional caches and buffers between the device and memory, such as caches associated with bus extenders or bridges. Use `ddi_dma_sync(9F)` to synchronize all applicable caches.

`ddi_dma_sync(9F)`

If a memory object has multiple mappings—such as for a device (through the DMA handle) and for the CPU—and one mapping is used to modify the memory object, the driver needs to call `ddi_dma_sync(9F)` to ensure that the modification of the memory object is complete before accessing the object through another mapping. `ddi_dma_sync(9F)` can also inform other mappings of the object that any cached references to the object are now stale. Additionally, `ddi_dma_sync(9F)` flushes or invalidates stale cache references as necessary.
Generally, the driver has to call `ddi_dma_sync(9F)` when a DMA transfer completes. The exception to this is that deallocating the DMA resources with `ddi_dma_unbind_handle(9F)`, does an implicit `ddi_dma_sync(9F)` on behalf of the driver.

```c
int ddi_dma_sync(ddi_dma_handle_t handle, off_t off,
                 size_t length, uint_t type);
```

If the object is going to be read by the DMA engine of the device, the device’s view of the object must be synchronized by setting `type` to `DDI_DMA_SYNC_FORDEV`. If the DMA engine of the device has written to the memory object, and the object is going to be read by the CPU, the CPU’s view of the object must be synchronized by setting `type` to `DDI_DMA_SYNC_FORCPU`.

Here is an example of synchronizing a DMA object for the CPU:

```c
if (ddi_dma_sync(xsp->handle, 0, length, DDI_DMA_SYNC_FORCPU)
    == DDI_SUCCESS) {
    /* the CPU can now access the transferred data */
    ...
} else {
    error handling
}
```

If the only mapping that concerns the driver is one for the kernel (such as memory allocated by `ddi_dma_mem_alloc(9F)`), the flag `DDI_DMA_SYNC_FORKERNEL` can be used. If the system can synchronize the kernel’s view faster than the CPU’s view, it will do so; otherwise, it acts the same as `DDI_DMA_SYNC_FORCPU`.

---

**DMA Windows**

The system might be unable to allocate resources for a large object. If this occurs, the transfer must be broken into a series of smaller transfers. The driver can either do this itself, or it can let the system allocate resources for only part of the object, thereby creating a series of DMA *windows*. Allowing the system to allocate resources is the preferred solution, as the system can manage the resources more effectively than the driver.

A DMA window has attributes `offset` (from the beginning of the object) and `length`. After a partial allocation, only a range of `length` bytes starting at `offset` has resources allocated for it.

A DMA window is requested by specifying the `DDI_DMA_PARTIAL` flag as a parameter to `ddi_dma_buf_bind_handle(9F)` or `ddi_dma_addr_bind_handle(9F)`. Both functions return `DDI_DMA_PARTIAL_MAP`.
if a window can be established. However, the system might allocate resources for the entire object (less overhead), in which case DDI_DMA_MAPPED is returned. The driver should check the return value (see Example 8–7) to determine whether DMA windows are in use.

**EXAMPLE 8–7 Setting Up DMA Windows**

```c
static int xxstart (caddr_t arg)
{
    struct xxstate *xsp = (struct xxstate *)arg;
    struct device_reg *regp = xsp->reg;
    ddi_dma_cookie_t cookie;
    int status;
    mutex_enter(&xsp->mu);
    if (xsp->busy) {
        /* transfer in progress */
        mutex_exit(&xsp->mu);
        return (DDI_DMA_CALLBACK_RUNOUT);
    }
    xsp->busy = 1;
    mutex_exit(&xsp->mu);
    if (transfer is a read) {
        flags = DDI_DMA_READ;
    } else {
        flags = DDI_DMA_WRITE;
    }
    flags |= DDI_DMA_PARTIAL;
    status = ddi_dma_buf_bind_handle(xsp->handle, xsp->bp,
        flags, xxstart, (caddr_t)xsp, &cookie, &ccount);
    if (status != DDI_DMA_MAPPED &&
        status != DDI_DMA_PARTIAL_MAP)
        return (DDI_DMA_CALLBACK_RUNOUT);
    if (status == DDI_DMA_PARTIAL_MAP) {
        ddi_dma_numwin(xsp->handle, &xsp->nwin);
        xsp->partial = 1;
        xsp->windex = 0;
    } else {
        xsp->partial = 0;
    }
...  
    return (DDI_DMA_CALLBACK_DONE);
}
```

Two functions operate with DMA windows. The first, *ddi_dma_numwin*(9F), returns the number of DMA windows for a particular DMA object. The other function, *ddi_dma_getwin*(9F), allows repositioning (reallocation of system resources) within the object. It shifts the current window to a new window within the object. Because *ddi_dma_getwin*(9F) reallocates system resources to the new window, the previous window becomes invalid.
Caution – Do not move the DMA windows with a call to `ddi_dma_getwin(9F)` before transfers into the current window are complete. Wait until the transfer to the current window is complete (when the interrupt arrives) then call `ddi_dma_getwin(9F)` or data will be corrupted.

`ddi_dma_getwin(9F)` is normally called from an interrupt routine (see Example 8–8). The first DMA transfer is initiated as a result of a call to the driver. Subsequent transfers are started from the interrupt routine.

The interrupt routine examines the status of the device to determine if the device completed the transfer successfully. If not, normal error recovery occurs. If the transfer was successful, the routine must determine if the logical transfer is complete (the entire transfer specified by the `buf(9S)` structure) or if only one DMA window was moved. If it was only one window, the interrupt routine moves the window with `ddi_dma_getwin(9F)`, retrieves a new cookie, and starts another DMA transfer.

If the logical request has been completed, the interrupt routine checks for pending requests and starts a transfer, if necessary. Otherwise, it returns without invoking another DMA transfer. Example 8–8 illustrates the usual flow control.

**EXAMPLE 8-8 Interrupt Handler Using DMA Windows**

```c
static uint_t
xxintr(caddr_t arg)
{
    struct xxstate *xsp = (struct xxstate *)arg;
    uint8_t status;
    volatile uint8_t temp;
    mutex_enter(&xsp->mu);
    /* read status */
    status = ddi_get8(xsp->access_hdl, &xsp->regp->csr);
    if (!((status & INTERRUPTING))) {
        mutex_exit(&xsp->mu);
        return (DDI_INTR_UNCLAIMED);
    }
    ddi_put8(xsp->access_hdl, &xsp->regp->csr, CLEAR_INTERRUPT);
    /* for store buffers */
    temp = ddi_get8(xsp->access_hdl, &xsp->regp->csr);
    if (an error occurred during transfer) {
        bioerror(xsp->bp, EIO);
        xsp->partial = 0;
    } else {
        xsp->bp->b_resid -= amount transferred;
    }
    if (xsp->partial && (++xsp->windex < xsp->nwin)) {
        /* device still marked busy to protect state */
        mutex_exit(&xsp->mu);
        (void) ddi_dma_getwin(xsp->handle, xsp->windex,
            &offset, &len, &cookie, &ccount);
    }
}
```
EXAMPLE 8–8 Interrupt Handler Using DMA Windows  (Continued)

    program the DMA engine with the new cookie(s)
    ...
    return (DDI_INTR_CLAIMED);
}

ddi_dma_unbind_handle(xsp->handle);
biodone(xsp->bp);
xsp->busy = 0;
xsp->partial = 0;
mutex_exit(&xsp->mu);
if (pending transfers) {
    (void) xxstart((caddr_t)xsp);
}
return (DDI_INTR_CLAIMED);
Power Management

Power management provides the ability to control and manage the electrical power usage of a computer system or device. Power management enables systems to conserve energy by using less power when idle and by shutting down completely when not in use. For example, desktop computer systems can use a significant amount of power, and often (particularly at night) are left idle. Power management software can detect that the system is not being used and power it or some of its components down.

This chapter provides information on the following subjects:

- “Power Management Framework” on page 129
- “Device Power Management Model” on page 131
- “System Power Management Model” on page 139
- “Power Management Device Access Example” on page 145
- “Power Management Flow of Control” on page 146

Power Management Framework

The Solaris Power Management framework depends on device drivers to implement device-specific power management functionality. The framework is implemented in two parts:

- Device power management – Automatically turns off unused devices to reduce power consumption
- System power management – Automatically turns off the computer when the entire system is idle
Device Power Management

The framework allows devices to reduce their energy consumption after a specified idle time interval. To perform effective device power management, system software monitors the different devices and determines when they are not in use. Since only device drivers are able to determine when a device is idle, and only device drivers are able to reduce power consumption of a device, the Power Management framework exports interfaces to enable communication between the system software and the device driver.

The Solaris Power Management framework provides the following:

- A device-independent model for power-manageable devices.
- \texttt{dtpower(1M)}, a graphical user interface for workstation power management. (Power management can also be implemented through the \texttt{power.conf(4)} and \texttt{/etc/default/power} files.)
- A set of DDI interfaces for the device driver to notify the framework if the device can be power managed, and when it is idle or busy.

System Power Management

System power management consists of turning off the entire computer after saving its state so that it can be returned to the same state immediately when it is turned back on.

To shut down an entire system and later return it to the state it was in prior to the shutdown:

- Stop (and later restart) kernel threads and user processes.
- Save the hardware state of all devices on the system to disk (and later restore it).

\textbf{SPARC only} – System power management is currently implemented only on some SPARC systems supported by the Solaris 9 operating environment.

The Solaris operating environment System Power Management framework provides the following:

- A platform-independent model of system idleness
- \texttt{dtpower(1M)}, a graphical user interface for workstation power management. (Power management can also be implemented through the \texttt{power.conf(4)} and \texttt{/etc/default/power} files.)
- A set of interfaces for the device driver to override the method for determining which drivers have hardware state
A set of interfaces to allow the framework to call into the driver to save and restore the device state

A mechanism for notifying processes that a resume operation has occurred

Device Power Management Model

The following sections describe the details of the device power management model. This model includes the following elements:

- Components
- Idleness
- Power levels
- Dependency
- Policy
- Device power management interfaces
- Power management entry points

Power Management Components

A device is power manageable if the power consumption of the device can be reduced when it is idle. Conceptually, a power manageable device consists of a number of power-manageable hardware units called components.

The device driver notifies the system of the existence of device components and the power levels that they support by creating a pm-components(9P) property in its attach(9E) entry point as part of driver initialization.

Most devices that are power manageable implement only a single component. An example of a single-component, power-manageable device is a disk whose spindle motor can be stopped to save power when the disk is idle.

If a device has multiple power-manageable units that are separately controllable, it should implement multiple components.

An example of a two-component, power-manageable device is a frame buffer card with a monitor connected to it. Frame buffer electronics is the first component [component 0]. Its power consumption can be reduced when not in use. The monitor is the second component [component 1], which can also enter a lower power mode when not in use. The combination of frame buffer electronics and monitor is considered by the system as one device with two components.
Multiple Power Management Components

To the power management framework, all components are considered equal and completely independent of each other. If this is not true for a particular device, the device driver must ensure that undesirable state combinations do not occur. For example, with a frame buffer/monitor card with a monitor attached to it, for each possible power state of the monitor (On, Standby, Suspend, Off) there are states of the frame buffer electronics (D0, D1, D2, D3) that are not allowed if the device is to work properly. If the monitor is On, then the frame buffer must be at D0 (full on), so if the frame buffer driver gets a request to power up the monitor to On while the frame buffer is D3, it must ask the system to bring the frame buffer back up (by calling pm_raise_power(9F)) before setting the monitor On. If the frame buffer driver gets a request from the system to lower the power of the frame buffer while the monitor is On, it must fail that request.

Power Management States

Each component of a device may be in one of two states: busy or idle. The device driver notifies the framework of changes in the device state by calling pm_busy_component(9F) and pm_idle_component(9F). When components are initially created, they are considered idle.

Power Levels

From the pm-components property exported by the device, the Device Power Management framework knows what power levels the device supports. Power level values must be positive integers. The interpretation of power levels is determined by the device driver writer, but they must be listed in monotonically increasing order in the pm-components property, and a power level of 0 is interpreted by the framework to mean off. When the framework must power up a device because of a dependency, it will bring each component to its highest power level.

Example 9–1 is an example pm-components entry from the .conf file of a driver that implements a single power-managed component consisting of a disk spindle motor. The disk spindle motor is component 0 and it supports 2 power levels, which represent stopped and spinning full speed.

**Example 9–1 Sample pm-component Entry**

```
pm-components="NAME=Spindle Motor", "0=Stopped", "1=Full Speed";
```

Example 9–2 shows an example of how Example 9–1 could be implemented in the attach() routine of the driver.

**Example 9–2 attach(9E) Routine With pm-components Property**

```
static char *pmcomps[] = {
  "NAME=Spindle Motor",
```

132 Writing Device Drivers • May 2002
EXAMPLE 9-2 attach(9E) Routine With pm-components Property  (Continued)

    "0=Stopped",
    "1=Full Speed"
};

...
xxattach(dev_info_t *dip, ddi_attach_cmd_t cmd)
{
...
    if (ddi_prop_update_string_array(DDI_DEV_T_NONE, dip,
        "pm-components", &pmcomp[0],
        sizeof(pmcomps) / sizeof(char *)) != DDI_PROP_SUCCESS)
        goto failed;
...

Example 9–3 shows a frame buffer that implements two components. Component 0 is the frame buffer electronics that support four different power levels. Component 1 represents the state of power management of the attached monitor.

EXAMPLE 9-3 Multiple Component pm-components Entry

pm-components="NAME=Frame Buffer", "0=Off", "1=Suspend", 
    "2=Standby", "3=On",
    "NAME=Monitor", "0=Off", "1=Suspend", "2=Standby", "3=On";

When a device driver is first attached, the framework does not know the power level of the device. A power transition may occur when:

- The driver calls pm_raise_power(9F) or pm_lower_power(9F).
- The framework has lowered the power level of a component because it has exceeded its threshold time.
- Another device has changed power, and there is a dependency between the two devices. See “Power Management Dependencies” on page 134.

Once a power transition has occurred or the driver has informed the framework of the power level, the framework tracks the current power level of each component of the device. The driver can inform the framework of a power level change by calling pm_power_has_changed(9F).

The system calculates a default threshold for each possible transition from one power level to the next lower level, based on the system idleness threshold. These default thresholds can be overridden using dtpower(1M) or power.conf(4). Another default threshold based on the system idleness threshold is used when the component power level is unknown.
Power Management Dependencies

Some devices should be powered down only when other devices are also powered down. For example, if removable-media devices such as CD-ROM drives or Zip drives are allowed to power down by themselves, functionality associated with their current state, such as the ability to eject a CD or to respond when a new Zip disk is inserted, may be lost.

One way to prevent a device from powering down independently is to make the device dependent on another device that is likely to remain powered on while its functionality is required. Typically, the device is made dependent upon a frame buffer, because a monitor is generally on whenever a user is utilizing a system.

The `power.conf(4)` file specifies the dependencies among devices. (A parent node in the device tree implicitly depends upon its children. This dependency is handled automatically by the power management framework.) You can specify a particular dependency with a `power.conf(4)` entry of this form:

```
device-dependency dependent_phys_path phys_path
```

where `dependent_phys_path` is the device that is kept powered up (such as the CD-ROM drive) and `phys_path` is the device whose power state it depends on (such as the frame buffer).

Because it would be burdensome to add an entry to `power.conf` for every new device plugged into the system, another syntax enables you to indicate dependency in a more general fashion:

```
device-dependency-property property phys_path
```

Such an entry mandates that any device that exports the property `property` will be dependent upon the device named by `phys_path`. Because this dependency applies especially to removable-media devices, `/etc/power.conf` includes the following line by default:

```
device_dependent-property removable-media /dev/fb
```

to signal that any device exporting the `removable-media` property will not be powered down unless the console frame buffer is also powered down.

For more information, see the `power.conf(4)` and `removable-media(9P)` man pages.
Automatic Power Management for Devices

If automatic power management is enabled by `dtpower(1M)` or `power.conf(4)`, then all devices with a `pm-components(9P)` property automatically will be power managed. After each component has been idle for a default period, it will be automatically brought to its next lowest power level. The default period is calculated by the power management framework to set the entire device to its lowest power state within the system idleness threshold.

**Note** – By default automatic power management is enabled on all SPARC desktop systems first shipped after July 1, 1999. This feature is disabled by default for all other systems. To determine if automatic power management is enabled on your machine, refer to the `power.conf(4)` man page for instructions.

`dtpower(1M)` or `power.conf(4)` may be used to override the defaults calculated by the framework.

Device Power Management Interfaces

A device driver that supports a device with power-manageable components must notify the system of the existence of these components and the power levels that they support by creating a `pm-components(9P)` property. This is typically done from the driver's `attach(9E)` entry point by calling `ddi_prop_update_string_array(9F)`, but may be done from a `driver.conf(4)` file instead. See the `pm-components(9P)` man page for details.

Busy-Idle State Transitions

The driver must keep the framework informed of device state transitions from idle to busy or busy to idle. Where these transitions happen is entirely device-specific. The transitions from idle to busy and from busy to idle depend on the nature of the device and the abstraction represented by the specific component. For example, SCSI disk target drivers typically export a single component, which represents whether the SCSI target disk drive is spun up or not. It is marked busy whenever there is an outstanding request to the drive and idle when the last queued request finishes. Some components are created and never marked busy (components created by `pm-components(9P)` are created in an idle state).

The `pm_busy_component(9F)` and `pm_idle_component(9F)` interfaces notify the power management framework of busy-idle state transitions. The syntax for `pm_busy_component(9F)` is:

```c
int pm_busy_component(dev_info_t *dip, int component);
```
pm_busy_component(9F) marks component as busy. While the component is busy, it will not be powered off. If the component is already powered off, then marking it busy doesn’t change its power level. The driver needs to call pm_raise_power(9F) for this purpose. Calls to pm_busy_component(9F) are cumulative and require a corresponding number of calls to pm_idle_component(9F) to idle the component.

The syntax for pm_idle_component(9F) is:

```c
int pm_idle_component(dev_info_t *dip, int component);
```

pm_idle_component(9F) marks component as idle. An idle component is subject to being powered off. pm_idle_component(9F) must be called once for each call to pm_busy_component(9F) in order to idle the component.

**Device Power State Transitions**

A device driver can call pm_raise_power(9F) to request that a component be set to at least a given power level. This is necessary before using a component that has been powered off. For example, a SCSI disk target driver’s read(9E) or write(9E) routine might need to spin up the disk before completing the read or write, if the disk has already been powered off. pm_raise_power(9F) requests the power management framework to initiate a device power state transition to a higher power level. Normally, reductions in component power levels are initiated by the framework. However, a device driver should call pm_lower_power(9F) when detaching, in order to reduce the power consumption of unused devices as much as possible.

Powering down can pose risks for some devices. For example, some tape drives damage tapes when power is removed; likewise, some disk drives have a limited tolerance for power cycles, since each cycle results in a head landing. Such devices should export the no-involuntary-power-cycles(9P) property to notify the system that all power cycles for the device must be under control of a device driver. This prevents power from being removed from a device while the device driver is detached, unless the device was powered off by a driver’s call to pm_lower_power(9F).

pm_raise_power(9F) is called when the driver discovers that a component needed for some operation is at a power level less than is needed for that operation. This interface arranges for the driver to be called to raise the current power level of the component at least to the level specified in the request. All the devices that depend on this device are also brought back to full power by this call.

pm_lower_power(9F) is called when the device is detaching, once access to the device is no longer needed. It should be called for each component to set each component to its lowest power so that the device uses as little power as possible while it is not in use. The syntax for pm_lower_power(9F) is the same as that for pm_raise_power(9F).
pm_power_has_changed(9F) is called to notify the framework when a device has made a power transition on its own, or to inform the framework of the power level of a device, for example, after a suspend-resume operation. The syntax for pm_power_has_changed(9F) is the same as that for pm_raise_power(9F).

**power() Entry Point**

The power management framework uses the power(9E) entry point.

The syntax for power(9E) is:

```c
int power(dev_info_t *dip, int component, int level);
```

The system calls the power(9E) entry point (either directly or as a result of a call to pm_raise_power(9F) or pm_lower_power(9F)) when it determines that a component’s current power level needs to be changed. The action taken by this entry point is device driver specific. In the example of the SCSI target disk driver mentioned previously, setting the power level to 0 results in sending a SCSI command to spin down the disk, while setting the power level to the full power level results in sending a SCSI command to spin up the disk.

If a power transition will cause the device to lose state, then the driver must ensure that any necessary state is saved in memory so that it can be restored when it is needed again. If a power transition will require that saved state be restored before the device can be used again, then the driver must restore that state. The framework makes no assumptions about what power transactions cause the loss of or require the restoration of state for automatically power-manage devices. Example 9–4 shows a sample power(9E) routine.

**EXAMPLE 9–4 power(9E) Routine for Single-Component Device**

```c
int xxpower(dev_info_t *dip, int component, int level)
{
    struct xxstate *xsp;
    int instance;

    instance = ddi_get_instance(dip);
    xsp = ddi_get_soft_state(statep, instance);
    /*
     * Make sure the request is valid
     */
    if (!xx_valid_power_level(component, level))
        return (DDI_FAILURE);
    mutex_enter(&xsp->mu);
    /*
     * If the device is busy, don’t lower its power level
     */
    if (xsp->xx_busy[component] &&
        xsp->xx_power_level[component] > level) {
        /*
         * Lower the power level
         */
        xsp->xx_power_level[component] = level;
        /*
         * Notify the framework
         */
        pm_power_has_changed(9F);
    }
    mutex_exit(&xsp->mu);
    return (DDI_SUCCESS);
}
```
EXAMPLE 9-4 power(9E) Routine for Single-Component Device  (Continued)

mutex_exit(&xsp->mu);
return (DDI_FAILURE);

if (xsp->xx_power_level[component] != level) {
    /*
     * device- and component-specific setting of power level
     * goes here
     */
    ...
    xsp->xx_power_level[component] = level;
} mutex_exit(&xsp->mu);
return (DDI_SUCCESS);

Example 9-5 is a power(9E) routine for a device with two components, where component 0 must be on when component 1 is on.

EXAMPLE 9-5 power(9E) Routine for Multiple Component Device

int
xxpower(dev_info_t *dip, int component, int level)
{
    struct xxstate *xsp;
    int instance;

    instance = ddi_get_instance(dip);
    xsp = ddi_get_soft_state(statep, instance);
    /*
    * Make sure the request is valid
    */
    if (!xx_valid_power_level(component, level))
        return (DDI_FAILURE);
    mutex_enter(&xsp->mu);
    /*
    * If the device is busy, don’t lower its power level
    */
    if (xsp->xx_busy[component] &&
        xsp->xx_power_level[component] > level) {
        mutex_exit(&xsp->mu);
        return (DDI_FAILURE);
    }
    /*
    * This code implements inter-component dependencies:
    * If we are bringing up component 1 and component 0
    * is off, we must bring component 0 up first, and if
    * we are asked to shut down component 0 while component
    * 1 is up we must refuse
    */
    if (component == 1 && level > 0 && xsp->xx_power_level[0] == 0) {
        /*
         * device- and component-specific setting of power level
         * goes here
         */
         ...
         xsp->xx_power_level[0] = level;
    }
    mutex_exit(&xsp->mu);
    return (DDI_SUCCESS);
}
EXAMPLE 9–5  power(9E) Routine for Multiple Component Device  (Continued)

```c
xsp->xx_busy[0]++;  
if (pm_busy_component(dip, 0) != DDI_SUCCESS) {
    /*
     * This can only happen if the args to
     * pm_busy_component() are wrong, or pm-components property was not
     * exported by the driver.
     */
    xsp->xx_busy[0]--;  
    mutex_exit(&xsp->mu);  
    cmn_err(CE_WARN, "xspower pm_busy_component() failed");  
    return (DDI_FAILURE);
}
mutex_exit(&xsp->mu);  
if (pm_raise_power(dip, 0, XX_FULL_POWER_0) != DDI_SUCCESS)  
    return (DDI_FAILURE);  
mutex_enter(&xsp->mu);
}
if (component == 0 && level == 0 && xsp->xx_power_level[1] != 0)  
    mutex_exit(&xsp->mu);  
    return (DDI_FAILURE);
}
if (xsp->xx_power_level[component] != level) {
    /*
     * device- and component-specific setting of power level
     * goes here
     */
    ...
    xsp->xx_power_level[component] = level;
}  
mutex_exit(&xsp->mu);  
    return (DDI_SUCCESS);
}
```

### System Power Management Model

This section describes the details of the System Power Management model. The model includes the following components:

- Autoshutdown threshold
- Busy state
- Hardware state
- Policy
- Power management entry points
Autoshutdown Threshold

The system may be shut down (powered off) automatically after a configurable period of idleness. This period is known as the autoshutdown threshold. This behavior is enabled by default for SPARC desktop systems first shipped after October 1, 1995 and before July 1, 1999. It may be overridden using dtpower(1M) or power.conf(4).

Busy State

There are several ways to measure the busy state of the system. The currently supported built-in metrics are keyboard characters, mouse activity, tty characters, load average, disk reads, and NFS requests. Any one of these may make the system busy. In addition to the built-in metrics, an interface is defined for running a user-specified process that may indicate that the system is busy.

Hardware State

Devices that export a reg property are considered to have hardware state that must be saved prior to shutting down the system. A device that does not have a reg property is considered to be stateless. However, this consideration can be overridden by the device driver.

A device that has hardware state but no reg property (such as a SCSI target driver, which has hardware at the other end of the SCSI bus), is called to save and restore its state if it exports a pm-hardware-state property with the value needs-suspend-resume. Otherwise, the lack of a reg property is taken to mean that the device has no hardware state. For information on device properties, see Chapter 4.

A device that has a reg property but no hardware state may export a pm-hardware-state property with the value no-suspend-resume to keep the framework from calling into the driver to save and restore that state. For more information on power management properties, see the pm-components(9P) man page.

Automatic Power Management for Systems

The system will be shut down if the following conditions apply:

- Autoshutdown is enabled by dtpower(1M) or power.conf(4).
- The system has been idle for autoshutdown threshold minutes.
- All the metrics specified in power.conf(4) have been satisfied.
Entry Points Used by System Power Management

System power management passes the command DDI_SUSPEND to the detach(9E) driver entry point to request the driver to save the device hardware state. It passes the command DDI_RESUME to the attach(9E) driver entry point to request the driver to restore the device hardware state.

`detach()` Entry Point

The syntax for `detach(9E)` is as follows:

```c
int detach(dev_info_t *dip, ddi_detach_cmd_t cmd);
```

If a device has a `reg` property or a `pm-hardware-state` property with a value of `needs-suspend-resume`, then the framework calls into the driver's `detach(9E)` entry point to allow the driver to save the hardware state of the device to memory so that it can be restored after the system power returns. To process the DDI_SUSPEND command, `detach(9E)` must do the following:

- Block further operations from being initiated until the device is resumed (except for `dump(9E)` requests).
- Wait until outstanding operations have completed (or abort them if they can be restarted).
- Cancel pending timeouts and callbacks.
- Save any volatile hardware state to memory. The state includes the contents of device registers, and may also include downloaded firmware.

If for some reason the driver is not able to suspend the device and save its state to memory, then it must return `DDI_FAILURE`, and the framework aborts the system power management operation.

In some cases, powering down a device involves certain risks. For example, if a tape drive is powered off with a tape inside it, the tape can be damaged. In such a case, `attach(9E)` should:

- Call `ddi_removing_power(9F)` to determine if a DDI_SUSPEND command may cause power to be removed from the device.
- Determine if power removal will cause problems.

If both of these are true, the DDI_SUSPEND request should be rejected. Example 9–6 shows an example of an `attach(9E)` routine using `ddi_removing_power(9F)` to check whether a DDI_SUSPEND causes problems.

Dump requests must be honored. The framework uses the `dump(9E)` entry point to write out the state file containing the contents of memory. See the `dump(9E)` man page for restrictions imposed on the device driver when using this entry point.
If the device implements power-manageable components, the device may have had its state saved and powered off when its detach(9E) entry point is called with the DDI_SUSPEND command. In this case the driver should cancel pending timeouts and suppress the call to pm_raise_power(9F) (except for dump(9E) requests) until the device is resumed by a call to attach(9E) with a command of DDI_RESUME. The driver must keep sufficient track of its state to be able to deal appropriately with this possibility. Example 9–6 shows an example of a detach(9E) routine with the DDI_SUSPEND command implemented.

Example 9–6 detach(9E) Routine Implementing DDI_SUSPEND

```c
int xxdetach(dev_info_t *dip, ddi_detach_cmd_t cmd)
{
    struct xxstate *xsp;
    int instance;

    instance = ddi_get_instance(dip);
    xsp = ddi_get_soft_state(statep, instance);

    switch (cmd) {
        case DDI_DETACH:
            ...
        case DDI_SUSPEND:
            /*
             * We do not allow DDI_SUSPEND if power will be removed and
             * we have a device that damages tape when power is removed
             * We do support DDI_SUSPEND for Device Reconfiguration.
             */
            if (ddi_removing_power(dip) && xxdamages_tape(dip))
                return (DDI_FAILURE);

            mutex_enter(&xsp->mu);
            xsp->xx_suspended = 1; /* stop new operations */

            /*
             * Sleep waiting for all the commands to be completed
             */
            ...

            /*
             * If a callback is outstanding which cannot be cancelled
             * then either wait for the callback to complete or fail the
             * suspend request
             */
            ...

            /*
             * This section is only needed if the driver maintains a
             * running timeout
             */
            if (xsp->xx_timeout_id) {
```
EXAMPLE 9-6 detach(9E) Routine Implementing DDI_SUSPEND  (Continued)

timeout_id_t temp_timeout_id = xsp->xx_timeout_id;

xsp->xx_timeout_id = 0;
mutex_exit(&xsp->mu);
untimeout(temp_timeout_id);
mutex_enter(&xsp->mu);
}

if (!xsp->xx_state_saved) {
    /*
    * Save device register contents into
    * xsp->xx_device_state
    */
    ...
}
mutex_exit(&xsp->mu);
return (DDI_SUCCESS);

default:
    return (DDI_FAILURE);
}

attach() Entry Point

The syntax for attach(9E) is as follows:

    int attach(dev_info_t *dip, ddi_attach_cmd_t cmd);

When power is restored to the system, each device with a reg property or with a pm-hardware-state property of value needs-suspend-resume has its attach(9E) entry point called with a command value of DDI_RESUME. If the system shutdown was aborted for some reason, each driver that was suspended is called to resume, even though the power has not been shut off. Consequently, the resume code in attach(9E) must make no assumptions about the state of the hardware; it may or may not have lost power.

The power management framework considers the power level of the components to be unknown at DDI_RESUME time. Depending on the nature of the device, the driver writer has two choices:

- If the driver can determine the actual power level of the components of the device without powering them up (by reading a register, for example), then the driver should notify the framework of the power level of each component by calling pm_power_has_changed(9F).
- If it cannot determine the power levels of the components, then the driver should mark each component internally as unknown and call pm_raise_power(9F) before the first access to each one.
Example 9–7 shows an example of an attach(9E) routine with the DDI_RESUME command.

EXAMPLE 9–7 attach(9E) Routine Implementing DDI_RESUME

```c
int
xxattach(devinfo_t *dip, ddi_attach_cmd_t cmd)
{
    struct xxstate *xsp;
    int instance;

    instance = ddi_get_instance(dip);
    xsp = ddi_get_soft_state(statep, instance);

    switch (cmd) {
    case DDI_ATTACH:
        ...
    case DDI_RESUME:
        mutex_enter(&xsp->mu);
        if (xsp->xx_pm_state_saved) {
            /*
             * Restore device register contents from
             * xsp->xx_device_state
             */
            ...
        }
        /*
         * This section is optional and only needed if the
         * driver maintains a running timeout
         */
        xsp->xx_timeout_id = timeout(...);
        xsp->xx_suspended = 0; /* allow new operations */
        cv_broadcast(&xsp->xx_suspend_cv);
        /* If it is possible to determine in a device-specific
         * way what the power levels of components are without
         * powering the components up,
         * then the following code is recommended
         */
        for (i = 0; i < num_components; i++) {
            xsp->xx_power_level[i] = xx_get_power_level(dip, i);
            if (xsp->xx_power_level[i] != XX_LEVEL_UNKNOWN)
                (void) pm_power_has_changed(dip, i,
                xsp->xx_power_level[i]);
        }
        mutex_exit(&xsp->mu);
        return(DDI_SUCCESS);
    default:
        return(DDI_FAILURE);
    }
}
```
Note – The detach(9E) and attach(9E) interfaces may also be used to resume a system that has been quiesced.

Power Management Device Access Example

If power management is supported, and detach(9E) and attach(9E) have code such as shown in the previous examples, the code fragment in Example 9–8 can be used where device access is about to be made to the device from user context (for example, in read(2), write(2), ioctl(2)).

The following example assumes that the operation about to be performed requires a component that is operating at power level level.

EXAMPLE 9–8 Device Access

```c
mutex_enter(&xsp->mu);
/*
 * Block command while device is susped via DDI_SUSPEND
 */
while (xsp->xx_suspended)
    cv_wait(&xsp->xx_suspend_cv, &xsp->mu);
/*
 * Mark component busy so power() will reject attempt to lower power
 */
xsp->xx_busy[component]++;
if (pm_busy_component(dip, component) != DDI_SUCCESS) {
    xsp->xx_busy[component]--;
    /*
     * Log error and abort
     */
    ....
}
if (xsp->xx_power_level[component] < level) {
    mutex_exit(&xsp->mu);
    if (pm_raise_power(dip, component, level) != DDI_SUCCESS) {
        /*
         * Log error and abort
         */
        ....
    }
    mutex_enter(&xsp->mu);
```
The code fragment in Example 9–9 can be used when device operation completes (for example, in the device’s interrupt handler).

EXAMPLE 9–9 Device Operation Completion

```c
/*
 * For each command completion, decrement the busy count and unstack
 * the pm_busy_component() call by calling pm_idle_component(). This
 * will allow device power to be lowered when all commands complete
 * (all pm_busy_component() counts are unstacked)
 */
xx_busy[component]--;
if (pm_idle_component(dip, component) != DDI_SUCCESS) {
    xx_busy[component]++;
    /*
     * Log error and abort
     */
    ...
}
/*
 * If no more outstanding commands, wake up anyone (like DDI_SUSPEND)
 * waiting for all commands to be completed
 */
...
```

Power Management Flow of Control

Figure 9–1 illustrates the flow of control in the power management framework.

When a component’s activity is complete, a driver can call pm_idle_component() to mark the component as idle. When the component has been idle for its threshold time, the framework may lower the power of the component to its next lower level. The framework does this by calling the power() function to set the power level of the component to its next lower supported power level (if any). The driver’s power() function should reject any attempt to lower the power level of a component when it is busy. The driver’s power() function should also save any state that will be lost as a result of the transition to the lower power level before making that transition.
When the component is needed again at a higher power level, the driver calls `pm_busy_component(9F)` to keep the framework from lowering the power still further, and then calls `pm_raise_power(9F)` on the component. The framework then calls `power(9E)` to raise the power of the component (before the call to `pm_raise_power(9F)` returns). The driver’s `power(9E)` code must restore any state that was lost in the lower level but is needed in the higher level after making the power transition.
When a driver is detaching, it should call `pm_lower_power(9F)` for each component to lower its power to its lowest level. The framework may then call into the driver’s `power(9E)` routine (before the call to `pm_lower_power(9F)` returns) to lower the power of the component.

![Diagram of power management states](image)

**Note:**
9E routines are always called by the framework.
9F routines are always called by the driver.

**FIGURE 9-1** Power Management Conceptual State Diagram
Changes to Power Management Interfaces

Previous to the Solaris 8 release, power management of devices was not automatic. It was necessary to add an entry to `/etc/power.conf` for each device that was to be power managed.

The framework assumed that all devices supported only two power levels: 0 and full (“normal”) power.

There was an implied dependency of all other components on component 0. Whenever component 0 changed to or from level 0, a call was made into the driver’s `detach(9E)` or `attach(9E)` routine with commands `DDI_PM_SUSPEND` and `DDI_PM_RESUME` respectively to save and restore hardware state.

The old interfaces (including `ddi_dev_is_needed(9F)`, `pm_create_components(9F)`, `pm_destroy_components(9F)`, `pm_get_normal_power(9F)`, `pm_set_normal_power(9F)`, `DDI_PM_SUSPEND` and `DDI_PM_RESUME`) are still supported for binary compatibility, but are obsolete.

As of the Solaris 8 release, devices which export the `pm-components` property are automatically power managed (if autopm is enabled).

The framework now knows from the `pm-components` property which power levels are supported by each device.

The framework makes no assumptions about dependencies among the different components of a device. The device driver is responsible for saving and restoring hardware state as needed when changing power levels.

These changes allow the power management framework to deal with emerging device technology, and result in greater power savings (since the framework can detect automatically which devices can save power, and can use intermediate power states of the devices), and allows the system to meet energy consumption goals without the entire system being powered down or functionality being lost.

Drivers for Character Devices

Character devices are devices that do not have physically addressable storage media, such as tape drives or serial ports, where I/O is normally performed in a byte stream. This chapter describes the structure of a character device driver, focusing in particular on character driver entry points. In addition, this chapter describes the use of physio(9F) (in read(9E) and write(9E)) and aphysio(9F) (in aread(9E) and awrite(9E)) in the context of synchronous and asynchronous I/O transfers.

This chapter provides information on the following subjects:

- “Character Driver Structure Overview” on page 151
- “Character Device Autoconfiguration” on page 152
- “Device Access (Character Drivers)” on page 154
- “I/O Request Handling” on page 156
- “Mapping Device Memory” on page 165
- “Multiplexing I/O on File Descriptors” on page 166
- “Miscellaneous I/O Control” on page 169
- “32-bit and 64-bit Data Structure Macros” on page 174

Character Driver Structure Overview

Figure 10–1 shows data structures and routines that define the structure of a character device driver. Device drivers typically include the following:

- Device-loadable driver section
- Device configuration section
- Character driver entry points
The shaded device access section in Figure 10–1 illustrates character driver entry points.

Associated with each device driver is a dev_ops(9S) structure, which in turn refers to a cb_ops(9S) structure. These structures contain pointers to the driver entry points. Note that some of these entry points can be replaced with nodev(9F) or nulldev(9F) as appropriate.

**Character Device Autoconfiguration**

The attach(9E) routine should perform the common initialization tasks that all devices require. Typically, these tasks include:

- Allocating per-instance state structures
- Registering device interrupts
- Mapping the device’s registers
- Initializing mutex and condition variables
Creating power-manageable components
Creating minor nodes

See “The attach() Entry Point” on page 76 for code examples of these tasks.

Character device drivers create minor nodes of type S_IFCHR. This causes a character special file representing the node to eventually appear in the /devices hierarchy.

Example 10–1 shows a sample attach(9E) routine. It is common to declare any properties associated with the device in an attach() routine; in this example, it is the predefined Size property. Size is the equivalent of the Nblocks property used for getting the size of partition in a block device. If, for example, you are doing character I/O on a disk device, you might use Size to get the size of a partition. Since Size is a 64–bit property—the 32–bit version is size—you must use a 64–bit property interface, in this case ddi_prop_update_int64(9E) See “Device Properties” on page 55 for more on properties.

EXAMPLE 10–1 Character Driver attach(9E) Routine

```c
static int
xxattach(dev_info_t *dip, ddi_attach_cmd_t cmd)
{
    int instance = ddi_get_instance(dip);
    switch (cmd) {
    case DDI_ATTACH:
        allocate a state structure and initialize it.
        map the device's registers.
        add the device driver's interrupt handler(s).
        initialize any mutexes and condition variables.
        create power manageable components.
        
        /*
         * Create the device's minor node. Note that the node_type
         * argument is set to DDI_NT_TAPE.
         */
        if (ddi_create_minor_node(dip, "minor_name", S_IFCHR,
                                   instance, DDI_NT_TAPE, 0) == DDI_FAILURE) {
            free resources allocated so far.
            /* Remove any previously allocated minor nodes */
            ddi_remove_minor_node(dip, NULL);
            return (DDI_FAILURE);
        }
        
        /*
         * Create driver properties like "Size." Use "Size"
         * instead of "size" to ensure the property works
         * for large bytecounts.
         */
        xsp->Size = size of device in bytes;
        maj_number = ddi_driver_major(dip);
        if (ddi_prop_update_int64(makedevice(maj_number, instance),
                                   dip, "Size", xsp->Size) != DDI_PROP_SUCCESS) {
            cmn_err(CE_CONT, "%s: cannot create Size property\n",
                    ddi_get_name(dip));
            free resources allocated so far
            return (DDI_FAILURE);
        }
    }
}

Chapter 10 • Drivers for Character Devices  153
Device Access (Character Drivers)

Access to a device by one or more application programs is controlled through the open(9E) and close(9E) entry points. The open(9E) routine of a character driver is always called whenever an open(2) system call is issued on a special file representing the device. For a particular minor device, open(9E) can be called many times, but the close(9E) routine is called only when the final reference to a device is removed. If the device is accessed through file descriptors, the final call to close(9E) may occur as a result of a close(2) or exit(2) system call. If the device is accessed through memory mapping, the final call to close(9E) may occur as a result of a munmap(2) system call.

open() Entry Point (Character Drivers)

The syntax for open(9E) is as follows:

```
int xxopen(dev_t *devp, int flag, int otyp, cred_t *credp);
```

The primary function of open() is to verify that the open request is allowed. devp is a pointer to a device number. The open(9E) routine is passed a pointer so that the driver can change the minor number. This enables drivers to dynamically create minor instances of the device. An example of this might be a pseudo-terminal driver that creates a new pseudo-terminal whenever the driver is opened. A driver that dynamically chooses the minor number, normally creates only one minor device node in attach(9E) with ddi_create_minor_node(9F), then changes the minor number component of *devp using makedevice(9F) and getmajor(9F):

```
*devp = makedevice(getmajor(*devp), new_minor);
```

It is not necessary to call ddi_create Minor_node(9F) for the new minor. A driver may not change the major number of *devp. The driver must keep track of available minor numbers internally.
otyp indicates how open(9E) was called. The driver must check that the value of otyp is appropriate for the device. For character drivers, otyp should be OTYP_CHR (see the open(9E) manual page).

flag contains bits indicating whether the device is being opened for reading (FREAD), writing (FWRITE), or both. User threads issuing the open(2) system call can also request exclusive access to the device (FEXCL) or specify that the open should not block for any reason (FNDELAY), but the driver must enforce both cases. A driver for a write-only device such as a printer might consider an open(9E) for reading invalid.

credp is a pointer to a credential structure containing information about the caller, such as the user ID and group IDs. Drivers should not examine the structure directly, but should instead use drv_priv(9F) to check for the common case of root privileges. In this example, only root is allowed to open the device for writing.

Example 10–2 shows a character driver open(9E) routine.

**EXAMPLE 10–2 Character Driver open(9E) Routine**

```c
static int
xxopen(dev_t *devp, int flag, int otyp, cred_t *credp)
{
    minor_t instance;
    if (getminor(*devp) is invalid)
        return (EINVAL);
    instance = getminor(*devp); /* one-to-one example mapping */
    /* Is the instance attached? */
    if (ddi_get_soft_state(statep, instance) == NULL)
        return (ENXIO);
    /* verify that otyp is appropriate */
    if (otyp != OTYP_CHR)
        return (EINVAL);
    if ((flag & FWRITE) && drv_priv(credp) == EPERM)
        return (EPERM);
    return (0);
}
```

close() Entry Point (Character Drivers)

The syntax for close(9E) is as follows:

```c
int xxclose(dev_t dev, int flag, int otyp, cred_t *credp);
```

close() should perform any cleanup necessary to finish using the minor device, and prepare the device (and driver) to be opened again. For example, the open routine might have been invoked with the exclusive access (FEXCL) flag. A call to close(9E) would allow further open routines to continue. Other functions that close(9E) might perform are:

- Waiting for I/O to drain from output buffers before returning.
I/O Request Handling

This section gives the details of I/O request processing: from the application to the kernel, the driver, the device, the interrupt handler, and back to the user.

User Addresses

When a user thread issues a `write(2)` system call, it passes the address of a buffer in user space:

```c
char buffer[] = "python";
count = write(fd, buffer, strlen(buffer) + 1);
```

The system builds a `uioc(9S)` structure to describe this transfer by allocating an `iov(9S)` structure and setting the `iov_base` field to the address passed to `write(2)`, in this case, `buffer`. The `uioc(9S)` structure is passed to the driver `write(9E)` routine (see “Vectored I/O” on page 156 for more information about the `uioc(9S)` structure).

The address in the `iov(9S)` is in user space, not kernel space, and so is not guaranteed to be currently in memory. It is not even guaranteed to be a valid address. In either case, accessing a user address directly from the device driver or from the kernel could crash the system, so device drivers should never access user addresses directly. Instead, they should always use one of the data transfer routines in the Solaris 9 DDI/DKI that transfer data into or out of the kernel. These routines are able to handle page faults, either by bringing the proper user page in and continuing the copy transparently, or by returning an error on an invalid access.

Two routines commonly used are `copyout(9F)` to copy data from kernel space to user space and `copyin(9F)` to copy data from user space to kernel space. `ddi_copyout(9F)` and `ddi_copyin(9F)` operate similarly but are to be used in the `ioctl(9E)` routine. `copyin(9F)` and `copyout(9F)` can be used on the buffer described by each `iov(9S)` structure, or `uiomove(9F)` can perform the entire transfer to or from a contiguous area of driver (or device) memory.

Vectored I/O

In character drivers, transfers are described by a `uioc(9S)` structure. The `uioc(9S)` structure contains information about the direction and size of the transfer, plus an array of buffers for one end of the transfer (the other end is the device).
The uio(9S) structure contains the following members:

```c
iovec_t *uio_iov; /* base address of the iovec */
/* buffer description array */
int uio_iovcnt; /* the number of iovec structures */
off_t uio_offset; /* 32-bit offset into file where */
/* data is transferred from or to */
offset_t uio_loffset; /* 64-bit offset into file where */
/* data is transferred from or to */
uio_seg_t uio_segflg; /* identifies the type of I/O */
/* transfer: */
/* UIO_SYSSPACE: kernel <-> kernel */
/* UIO_USERSPACE: kernel <-> user */
short uio_fmode; /* file mode flags (not driver setable) */
daddr_t uio_limit; /* 32-bit ulimit for file (maximum */
/* block offset). not driver setable. */
diskaddr_t uio_llimit; /* 64-bit ulimit for file (maximum block */
/* block offset). not driver setable. */
int uio_resid; /* amount (in bytes) not */
/* transferred on completion */
```

A uio(9S) structure is passed to the driver read(9E) and write(9E) entry points. This structure is generalized to support what is called gather-write and scatter-read. When writing to a device, the data buffers to be written do not have to be contiguous in application memory. Similarly, when reading from a device into memory, the data comes off the device in a contiguous stream but can go into noncontiguous areas of application memory. See the readv(2), writev(2), pread(2), and pwrite(2) man pages for more information on scatter-gather I/O.

Each buffer is described by an iovec(9S) structure. This structure contains a pointer to the data area and the number of bytes to be transferred.

```c
caddr_t iov_base; /* address of buffer */
int iov_len; /* amount to transfer */
```

The uio structure contains a pointer to an array of iovec(9S) structures. The base address of this array is held in uio_iov, and the number of elements is stored in uio_iovcnt.

The uio_offset field contains the 32-bit offset into the device at which the application needs to begin the transfer. uio_loffset is used for 64-bit file offsets. If the device does not support the notion of an offset, these fields can be safely ignored. The driver should interpret either uio_offset or uio_loffset (but not both). If the driver has set the D_64BIT flag in the cb_ops(9S) structure, it should use uio_loffset.

The uio_resid field starts out as the number of bytes to be transferred (the sum of all the iov_len fields in uio_iov) and must be set by the driver to the number of bytes not transferred before returning. The read(2) and write(2) system calls use the return value from the read(9E) and write(9E) entry points to determine if the transfer failed (and then return -1). If the return value indicates success, the system
calls return the number of bytes requested minus uio_resid. If uio_resid is not changed by the driver, the read(2) and write(2) calls will return 0 (indicating end-of-file), even though all the data was transferred.

The support routines uiomove(9F), physio(9F), and aphysio(9F) update the uio(9S) structure directly, updating the device offset to account for the data transfer. When used with a seekable device, for which the concept of position is relevant, the driver does not need to adjust either the uio_offset or uio_loffset fields. I/O performed to a device in this manner is constrained by the maximum possible value of uio_offset or uio_loffset. An example of such a usage is raw I/O on a disk.

When performing I/O on a device on which the concept of position has no relevance, the driver can save uio_offset or uio_loffset, perform the I/O operation, then restore uio_offset or uio_loffset to the field's initial value. I/O performed to a device in this manner is not constrained by the maximum possible value of uio_offset or uio_loffset. An example of such a usage is I/O on a serial line.

The following example shows one way to preserve uio_loffset in the read(9E) function.

```c
static int
xxread(dev_t dev, struct uio *uio_p, cred_t *cred_p)
{
    offset_t off;
    ...

    off = uio_p->uio_loffset; /* save the offset */
    /* do the transfer */
    uio_p->uio_loffset = off; /* restore it */
}
```

## Synchronous Versus Asynchronous I/O

Data transfers can be synchronous or asynchronous depending on whether the entry point scheduling the transfer returns immediately or waits until the I/O has been completed.

The read(9E) and write(9E) entry points are synchronous entry points; they must not return until the I/O is complete. Upon return from the routines, the process knows whether the transfer has succeeded.

The aread(9E) and awrite(9E) entry points are asynchronous entry points. They schedule the I/O and return immediately. Upon return, the process issuing the request knows that the I/O has been scheduled and that the status of the I/O must be determined later. In the meantime, the process can perform other operations.

When an asynchronous I/O request is made to the kernel by a user process, the process is not required to wait while the I/O is in process. A process can perform multiple I/O requests and let the kernel handle the data transfer details. This is useful
in applications such as transaction processing where concurrent programming methods can take advantage of asynchronous kernel I/O operations to increase performance or response time. Any performance boost for applications using asynchronous I/O, however, comes at the expense of greater programming complexity.

Data Transfer Methods

Data can be transferred using either programmed I/O or DMA. These data transfer methods can be used by either synchronous or asynchronous entry points, depending on the capabilities of the device.

Programmed I/O Transfers

Programmed I/O devices rely on the CPU to perform the data transfer. Programmed I/O data transfers are identical to other device register read and write operations. Various data access routines are used to read or store values to device memory.

`uiomove(9F)` can be used to transfer data to some programmed I/O devices. `uiomove(9F)` transfers data between the user space (defined by the `uio(9S)` structure) and the kernel. `uiomove(9F)` can handle page faults, so the memory to which data is transferred need not be locked down. It also updates the `uio_resid` field in the `uio(9S)` structure. Example 10–3 shows one way to write a ramdisk `read(9E)` routine. It uses synchronous I/O and relies on the presence of the following fields in the ramdisk state structure:

```c
    caddr_t  ram;  /* base address of ramdisk */
    int      ramsize;  /* size of the ramdisk */
```

**EXAMPLE 10–3 Ramdisk read(9E) Routine Using uiomove(9F)**

```c
static int
rd_read(dev_t dev, struct uio *uiop, cred_t *credp)
{
    rd_devstate_t  *rsp;

    rsp = ddi_get_soft_state(rd_statep, getminor(dev));
    if (rsp == NULL)
        return (ENOMEM);
    if (uiop->uio_offset >= rsp->ramsize)
        return (EINVAL);
    /*
    * uiomove takes the offset into the kernel buffer,
    * the data transfer count (minimum of the requested and
    * the remaining data), the UIO_READ flag, and a pointer
    * to the uio structure.
    */
    return (uiomove(rsp->ram + uiop->uio_offset,
```
EXAMPLE 10–3 Ramdisk read(9E) Routine Using uiomove(9F) (Continued)

min(uiop->uio_resid, rsp->ramsize - uiop->uio_offset),
UIO_READ, uiop));

Another example of programmed I/O might be a driver writing data one byte at a time directly to the device’s memory. Each byte is retrieved from the uio(9S) structure using uwritec(9F), then sent to the device. read(9E) can use ureadc(9F) to transfer a byte from the device to the area described by the uio(9S) structure.

EXAMPLE 10–4 Programmed I/O write(9E) Routine Using uwritec(9F)

static int
xxwrite(dev_t dev, struct uio *uiop, cred_t *cred)
{
    int value;
    struct xxstate *xsp;

    xsp = ddi_get_soft_state(statep, getminor(dev));
    if (xsp == NULL)
        return (ENXIO);
    if (the device implements a power manageable component, do this:
        pm_busy_component(xsp->dip, 0);
        if (xsp->pm_suspended)
            ddi_dev_is_needed(xsp->dip, normal power);
    while (uiop->uio_resid > 0) {
        /*
         * do the programmed I/O access
         */
        value = uwritec(uiop);
        if (value == -1)
            return (EFAULT);
        ddi_put8(xsp->data_access_handle, &xsp->regp->data,
            (uint8_t)value);
        ddi_put8(xsp->data_access_handle, &xsp->regp->csr,
            START_TRANSFER);
        /*
         * this device requires a ten microsecond delay
         * between writes
         */
        drv_usecwait(10);
    }
    pm_idle_component(xsp->dip, 0);
    return (0);
}

DMA Transfers (Synchronous)

Most character drivers use physio(9F) to do most of the setup work for DMA transfers in read(9E) and write(9E), as is shown in Example 10–5.
int physio(int (*strat)(struct buf *), struct buf *bp, 
    dev_t dev, int rw, void (*mincnt)(struct buf *), 
    struct uio *uiop);

physio(9F) requires the driver to provide the address of a strategy(9E) routine. 
physio(9F) ensures that memory space is locked down (cannot be paged out) for the 
duration of the data transfer. This is necessary for DMA transfers because they cannot 
handle page faults. physio(9F) also provides an automated way of breaking a larger 
transfer into a series of smaller, more manageable ones. See “minphys() Entry Point” 
on page 163 for more information.

EXAMPLE 10-5 read(9E) and write(9E) Routines Using physio(9F)

static int
xxread(dev_t dev, struct uio *uiop, cred_t *credp)
{
    struct xxstate *xsp;
    int ret;

    xsp = ddi_get_soft_state(statep, getminor(dev));
    if (xsp == NULL)
        return (ENXIO);
    ret = physio(xxstrategy, NULL, dev, B_READ, xxminphys, uiop);
    return (ret);
}

static int
xxwrite(dev_t dev, struct uio *uiop, cred_t *credp)
{
    struct xxstate *xsp;
    int ret;

    xsp = ddi_get_soft_state(statep, getminor(dev));
    if (xsp == NULL)
        return (ENXIO);
    ret = physio(xxstrategy, NULL, dev, B_WRITE, xxminphys, uiop);
    return (ret);
}

In the call to physio(9F), xxstrategy() is a pointer to the driver strategy routine. 
Passing NULL as the buf(9S) structure pointer tells physio(9F) to allocate a buf(9S) 
structure. If the driver must provide physio(9F) with a buf(9S) structure, 
getrbuf(9F) should be used to allocate one. physio(9F) returns zero if the transfer 
completes successfully, or an error number on failure. After calling strategy(9E), 
physio(9F) calls biowait(9F) to block until the transfer is completed or fails. The 
return value of physio(9F) is determined by the error field in the buf(9S) structure 
set by bioerror(9F).
DMA Transfers (Asynchronous)

Character drivers supporting aread(9E) and awrite(9E) use aphysio(9F) instead of physio(9F).

```c
int aphysio(int (*strat)(struct buf *), int (*cancel)(struct buf *),
    dev_t dev, int rw, void (*mincnt)(struct buf *),
    struct aio_req *aio_req);
```

**Note** – The address of anocancel(9F) is the only value that can currently be passed as the second argument to aphysio(9F).

aphysio(9F) requires the driver to pass the address of a strategy(9E) routine. aphysio(9F) ensures that memory space is locked down (cannot be paged out) for the duration of the data transfer. This is necessary for DMA transfers because they cannot handle page faults. aphysio(9F) also provides an automated way of breaking a larger transfer into a series of smaller, more manageable ones. See “minphys() Entry Point” on page 163 for more information. Example 10–5 and Example 10–6 demonstrate that the aread(9E) and awrite(9E) entry points differ only slightly from the read(9E) and write(9E) entry points; the difference lies mainly in their use of aphysio(9F) instead of physio(9F).

**EXAMPLE 10–6 aread(9E) and awrite(9E) Routines Using aphysio(9F)**

```c
static int
xxaread(dev_t dev, struct aio_req *aiop, cred_t *cred_p)
{
    struct xxstate *xsp;

    xsp = ddi_get_soft_state(statep, getminor(dev));
    if (xsp == NULL)
        return (ENXIO);
    return (aphysio(xxstrategy, anocancel, dev, B_READ,
        xxminphys, aiop));
}

static int
xxawrite(dev_t dev, struct aio_req *aiop, cred_t *cred_p)
{
    struct xxstate *xsp;

    xsp = ddi_get_soft_state(statep, getminor(dev));
    if (xsp == NULL)
        return (ENXIO);
    return (aphysio(xxstrategy, anocancel, dev, B_WRITE,
        xxminphys, aiop));
}
```
In the call to aphysio(9F), xxstrategy() is a pointer to the driver strategy routine. aiop is a pointer to the aio_req(9S) structure and is also passed to aread(9E) and awrite(9E). aio_req(9S) describes where the data is to be stored in user space. aphysio(9F) returns zero if the I/O request is scheduled successfully or an error number on failure. After calling strategy(9E), aphysio(9F) returns without waiting for the I/O to complete or fail.

**minphys() Entry Point**

xxminphys() is a pointer to a function to be called by physio(9F) or aphysio(9F) to ensure that the size of the requested transfer does not exceed a driver-imposed limit. If the user requests a larger transfer, strategy(9E) will be called repeatedly, requesting no more than the imposed limit at a time. This is important because DMA resources are limited. Drivers for slow devices, such as printers, should be careful not to tie up resources for a long time.

Usually, a driver passes the address of the kernel function minphys(9F), but the driver can define its own xxminphys() routine instead. The job of xxminphys() is to keep the b_bcount field of the buf(9S) structure below a driver limit. There might be additional system limits that the driver should not circumvent, so the driver xxminphys() routine should call the system minphys(9F) routine after setting the b_bcount field and before returning.

**EXAMPLE 10–7 minphys(9F) Routine**

```c
#define XXMINVAL (512 << 10) /* 512 KB */
static void xxminphys(struct buf *bp)
{
    if (bp->b_bcount > XXMINVAL)
        bp->b_bcount = XXMINVAL
    minphys(bp);
}
```

**strategy() Entry Point**

The strategy(9E) routine originated in block drivers and is so called because it can implement a strategy for efficient queuing of I/O requests to a block device. A driver for a character-oriented device can also use a strategy(9E) routine. In the character I/O model presented here, strategy(9E) does not maintain a queue of requests, but rather services one request at a time.

In Example 10–8, the strategy(9E) routine for a character-oriented DMA device allocates DMA resources for synchronous data transfer and starts the command by programming the device register (see Chapter 8 for a detailed description).
Note – strategy(9E) does not receive a device number (dev_t) as a parameter; instead, this is retrieved from the b_edev field of the buf(9S) structure passed to strategy(9E).

EXAMPLE 10–8 strategy(9E) Routine

```c
static int
xxstrategy(struct buf *bp)
{
    minor_t instance;
    struct xxstate *xsp;
    ddi_dma_cookie_t cookie;

    instance = getminor(bp->b_e dev);
    xsp = ddi_get_soft_state(statep, instance);
    ...
    if the device has power manageable components
    mark the device busy with pm_busy_components(9F),
    and then ensure that the device
    is powered up by calling ddi_dev_is_needed(9F).

    set up DMA resources with ddi_dma_alloc_handle(9F) and
    ddi_dma_buf_bind_handle(9F).
    xsp->bp = bp; /* remember bp */
    program DMA engine and start command
    return (0);
}
```

Note – Although strategy(9E) is declared to return an int, it must always return zero.

On completion of the DMA transfer, the device generates an interrupt, causing the interrupt routine to be called. In Example 10–9, xxintr() receives a pointer to the state structure for the device that might have generated the interrupt.

EXAMPLE 10–9 Interrupt Routine

```c
static u_int
xxintr(caddr_t arg)
{
    struct xxstate *xsp = (struct xxstate *)arg;
    if (device did not interrupt) {
        return (DDI_INTR_UNCLAIMED);
    }
    if (error) {
        error handling
    }
}
```
EXAMPLE 10–9 Interrupt Routine (Continued)

release any resources used in the transfer, such as DMA resources
ddi_dma_unbind_handle(9F) and ddi_dma_free_handle(9F)
	/* notify threads that the transfer is complete */
biodone(xsp->bp);
	return (DDI_INTR_CLAIMED);
}

The driver indicates an error by calling bioerror(9F). The driver must call biodone(9F) when the transfer is complete or after indicating an error with bioerror(9F).

Mapping Device Memory

Some devices, such as frame buffers, have memory that is directly accessible to user threads by way of memory mapping. Drivers for these devices typically do not support the read(9E) and write(9E) interfaces. Instead, these drivers support memory mapping with the devmap(9E) entry point. A typical example is a frame buffer driver that implements the devmap(9E) entry point to allow the frame buffer to be mapped in a user thread.

 segmap() Entry Point

int xxsegmap(dev_t dev, off_t off, struct as *asp, caddr_t *addrp,
            off_t len, unsigned int prot, unsigned int maxprot,
            unsigned int flags, cred_t *credp);

segmap(9E) is the entry point responsible for actually setting up a memory mapping requested by the system on behalf of an mmap(2) system call. Drivers for many memory-mapped devices will use ddi_devmap_segmap(9F) as the entry point rather than defining their own segmap(9E) routine.

If a driver wants to check mapping permissions or allocate private mapping resources before setting up the mapping, the driver can provide its own segmap(9E) entry point. segmap(9E) must call devmap_setup(9F) before returning.

In Example 10–10, the driver controls a frame buffer that allows write-only mappings. The driver returns EINVAL if the application tries to gain read access and then calls devmap_setup(9F) to set up the user mapping.

EXAMPLE 10–10 segmap (9E) Routine

static int
xxsegmap(dev_t dev, off_t off, struct as *asp, caddr_t *addrp,
EXAMPLE 10-10 segmap(9E) Routine  (Continued)

    off_t len, unsigned int prot, unsigned int maxprot,
    unsigned int flags, cred_t *credp)
    {
        if (prot & PROT_READ)
            return (EINVAL);
        return (devmap_setup(dev, (offset_t)off, as, addrp,
                          (size_t)len, prot, maxprot, flags, cred));
    }

devmap() Entry Point

int xxdevmap(dev_t dev, devmap_cookie_t handle, offset_t off,
              size_t len, size_t *maplen, uint_t model);

This entry point is called to export device memory or kernel memory to user
applications. devmap(9E) is called from devmap_setup(9F) inside segmap(9E) or on
behalf of ddi_devmap_segmap(9F). See Chapter 12 and Chapter 13 for details.

Multiplexing I/O on File Descriptors

A thread sometimes needs to handle I/O on more than one file descriptor. One
example is an application program that needs to read the temperature from a
temperature-sensing device and then report the temperature to an interactive display.
If the program makes a read request and there is no data available, it should not block
waiting for the temperature before interacting with the user again.

The poll(2) system call provides users with a mechanism for multiplexing I/O over a
set of file descriptors that reference open files. poll(2) identifies those file descriptors
on which a program can send or receive data without blocking, or on which certain
events have occurred.

To allow a program to poll a character driver, the driver must implement the
chpoll(9E) entry point. Its syntax is:

    int xxchpoll(dev_t dev, short events, int anyget, short *reventsp,
                 struct pollhead **phpp);

The system calls chpoll(9E) when a user process issues a poll(2) system call on a
file descriptor associated with the device. The chpoll(9E) entry point routine is used
by non-STREAMS character device drivers that need to support polling.

In chpoll(9E), the driver must follow these rules:
Implement the following algorithm when the chpoll(9E) entry point is called:

```c
if (events are satisfied now) {  
  *reventsp = mask of satisfied events;
} else {  
  *reventsp = 0;
  if (!anyyet)  
    *phpp = & local pollhead structure;
}
return (0);
```

xxchpoll() should check to see if certain events have occurred; see the chpoll(9E) man page. It should then return the mask of satisfied events by setting the return events in *reventsp.

If no events have occurred, the return field for the events is cleared. If the anyyet field is not set, the driver must return an instance of the pollhead structure. It is usually allocated in a state structure and should be treated as opaque by the driver. None of its fields should be referenced.

Call pollwakeup(9F) whenever a device condition of type events, listed in Example 10–11, occurs. This function should be called only with one event at a time. pollwakeup(9F) might be called in the interrupt routine when the condition has occurred.

Example 10–11 and Example 10–12 show how to implement the polling discipline and how to use pollwakeup(9F).

**EXAMPLE 10–11 chpoll(9E) Routine**

```c
static int  
xxchpoll(dev_t dev, short events, int anyyet,  
    short *reventsp, struct pollhead **phpp)  
{  
    uint8_t status;  
    short revent;  
    struct xxstate *xsp;

    xsp = ddi_get_soft_state(statep, getminor(dev));  
    if (xsp == NULL)  
        return (ENXIO);  
    revent = 0;
    /*  
     * Valid events are:
     * POLLIN | POLLOUT | POLLPRI | POLLHUP | POLLERR
     * This example checks only for POLLIN and POLLERR.
     */  
    status = ddi_get8(xsp->data_access_handle, &xsp->regp->csr);  
    if ((events & POLLIN) && /* data available to read */  
        revent |= POLLIN;  
    }
    if ((events & POLLERR) && (status & DEVICE_ERROR)) {  
        revent |= POLLERR;
    }
}
```
EXAMPLE 10–11 chpoll(9E) Routine  (Continued)

    /* if nothing has occurred */
    if (revent == 0) {
        if (!anyyet) {
            *phpp = &xsp->pollhead;
        }
    }
    *reventsp = revent;
    return (0);
}

In Example 10–12, the driver can handle the POLLIN and POLLERR events. The driver first reads the status register to determine the current state of the device. The parameter events specifies which conditions the driver should check. If the appropriate conditions have occurred, the driver sets that bit in *reventsp. If none of the conditions have occurred and anyyet is not set, the address of the pollhead structure is returned in *phpp.

EXAMPLE 10–12 Interrupt Routine Supporting chpoll(9E)

static u_int
xxintr(caddr_t arg)
{
    struct xxstate *xsp = (struct xxstate *)arg;
    uint8_t status;
    normal interrupt processing...

    status = ddi_get8(xsp->data_access_handle, &xsp->regp->csr);
    if (status & DEVICE_ERROR) {
        pollwakeup(&xsp->pollhead, POLLERR);
    }
    if (just completed a read) {
        pollwakeup(&xsp->pollhead, POLLIN);
    }
    ...
    return (DDI_INTRCLAIMED);
}

pollwakeup(9F) is usually called in the interrupt routine when a supported condition has occurred. The interrupt routine reads the status from the status register and checks for the conditions. It then calls pollwakeup(9F) for each event to possibly notify polling threads that they should check again. Note that pollwakeup(9F) should not be called with any locks held, as it could cause the chpoll(9E) routine to be entered, resulting in deadlock if that routine tries to grab the same lock.
Miscellaneous I/O Control

The ioctl(9E) routine is called when a user thread issues an ioctl(2) system call on a file descriptor associated with the device. The I/O control mechanism is a catchall for getting and setting device-specific parameters. It is frequently used to set a device-specific mode, either by setting internal driver software flags or by writing commands to the device. It can also be used to return information to the user about the current device state. In short, it can do whatever the application and driver need it to do.

ioctl() Entry Point (Character Drivers)

```c
int xxioctl(dev_t dev, int cmd, intptr_t arg, int mode,
            cred_t *credp, int *rvalp);
```

The cmd parameter indicates which command ioctl(9E) should perform. By convention, I/O control commands indicate the driver they belong to in bits 8-15 of the command (usually given by the ASCII code of a character representing the driver), and the driver-specific command in bits 0-7. They are usually created in the following way:

```c
#define XXIOC ('x' << 8) /* 'x' is a character representing */
             /* device xx */
#define XX_GET_STATUS (XXIOC | 1) /* get status register */
#define XX_SET_CMD (XXIOC | 2) /* send command */
```

The interpretation of arg depends on the command. I/O control commands should be documented (in the driver documentation or a manual page) and defined in a public header file, so that applications can determine the names, what they do, and what they accept or return as arg. Any data transfer of arg (into or out of the driver) must be performed by the driver.

Certain classes of devices such as frame buffers or disks must support standard sets of I/O control requests. These standard I/O control interfaces are documented in the Solaris 8 Reference Manual Collection. For example, fbio(7I) documents the I/O controls that frame buffers must support, and dkio(7I) documents standard disk I/O controls. See “Miscellaneous I/O Control” on page 169 for more information on I/O control.

Drivers must use ddi_copyin(9F) to transfer arg data from the userland application to the kernel and ddi_copyout(9F) from kernel to userland. Failure to use ddi_copyin(9F) or ddi_copyout(9F) will result in panics on architectures that separate kernel and user address spaces, or if the user address has been swapped out.

ioctl(9E) is usually a switch statement with a case for each supported ioctl(9E) request.
EXAMPLE 10-13 ioctl(9E) Routine

```c
static int
xxioctl(dev_t dev, int cmd, intptr_t arg, int mode,
    cred_t *credp, int *rvalp)
{
    uint8_t csr;
    struct xxstate *xsp;

    xsp = ddi_get_soft_state(statep, getminor(dev));
    if (xsp == NULL) {
        return (ENXIO);
    }
    switch (cmd) {
    case XX_GET_STATUS:
        csr = ddi_get8(xsp->data_access_handle, &xsp->regp->csr);
        if (ddi_copyout(&csr, (void *)arg,
            sizeof (uint8_t), mode) != 0) {
            return (EFAULT);
        }
        break;
    case XX_SET_CMD:
        if (ddi_copyin((void *)arg, &csr,
            sizeof (uint8_t), mode) != 0) {
            return (EFAULT);
        }
        ddi_put8(xsp->data_access_handle, &xsp->regp->csr, csr);
        break;
    default:
        /* generic "ioctl unknown" error */
        return (ENOTTY);
    }
    return (0);
}
```

The `cmd` variable identifies a specific device control operation. If `arg` contains a user virtual address, `ioctl(9E)` must call `ddi_copyin(9F)` or `ddi_copyout(9F)` to transfer data between the data structure in the application program pointed to by `arg` and the driver. In Example 10–13, for the case of an `XX_GET_STATUS` request the contents of `xsp->regp->csr` are copied to the address in `arg`. When a request succeeds, `ioctl(9E)` can store in `*rvalp` any integer value to be the return value of the `ioctl(2)` system call that made the request. Negative return values, such as -1, should be avoided, as they usually indicate the system call failed, and many application programs assume that negative values indicate failure.

An application that uses the I/O controls discussed above could look like Example 10–14.

EXAMPLE 10–14 Using ioctl(9E)

```c
#include <sys/types.h>
#include "xxio.h" /* contains device’s ioctl cmds and args */
```

```
int
```
EXAMPLE 10–14 Using ioctl(9E)  (Continued)

main(void)
{
    uint8_t     status;
    ...

    /*
     * read the device status
     */
    if (ioctl(fd, XX_GET_STATUS, &status) == -1) {
        error handling
    }
    printf("device status %x\n", status);
    exit(0);
}

I/O Control Support for 64-Bit Capable Device Drivers

The Solaris kernel runs in 64-bit mode on suitable hardware and supports both 32-bit and 64-bit applications. A 64-bit device driver is required to support I/O control commands from 32-bit and 64-bit user mode programs. The difference between a 32-bit program and a 64-bit program is its C language type model: a 32-bit program is ILP32 and a 64-bit program is LP64. See Appendix C for information on C data type models.

Any data that flows between programs and the kernel and vice versa (for example using ddi_copyin(9F) or ddi_copyout(9F)) will either need to be identical in format regardless of the type model of the kernel and application, or the device driver should be able to handle a model mismatch between it and the application and adjust the data format accordingly.

To determine if there is a model mismatch, the ioctl(9E) mode parameter passes the data model bits to the driver. As Example 10–15 shows, the mode parameter is then passed to ddi_model_convert_from(9F) to determine if any model conversion is necessary.

The data model is passed to the ioctl(9E) routine using a flag subfield of the mode argument. The flag will be set to one of:

- DATAMODEL_ILP32
- DATAMODEL_LP64

with FNATIVE conditionally defined to match the data model of the kernel implementation. The flag should be extracted from the mode argument using the FMODELS mask. The driver can then determine the data model explicitly to work out how to copy the application data structure.
The DDI function ddi_model_convert_from(9F) is a convenience routine that can assist some drivers with their ioctl() calls. The function takes the data type model of the user application as an argument and returns one of the following values:

- **DDI_MODEL_ILP32** — Convert from ILP32 application
- **DDI_MODEL_NONE** — No conversion needed

DDI_MODEL_NONE is returned if no data conversion is necessary. This is the case when the application and driver have the same data model. DDI_MODEL_ILP32 is returned if the driver is compiled to the LP64 data model and is communicating with a 32-bit application.

In the following example, the driver copies a data structure that contains a user address. Because the data structure changes size from ILP32 to LP64, the 64-bit driver uses a 32-bit version of the structure when communicating with a 32-bit application.

**EXAMPLE 10-15 ioctl(9E) Routine to Support 32-bit and 64-bit Applications**

```c
struct args32 {
    uint32_t addr; /* 32-bit address in LP64 */
    int len;
}
struct args {
    caddr_t addr; /* 64-bit address in LP64 */
    int len;
}

static int
xxioctl(dev_t dev, int cmd, intptr_t arg, int mode, 
    cred_t *credp, int *rvalp)
{
    struct xxstate *xsp;
    struct args a;
    xsp = ddi_get_soft_state(statep, getminor(dev));
    if (xsp == NULL) {
        return (ENXIO);
    }
    switch (cmd) {
    case XX_COPYIN_DATA:
        switch(ddi_model_convert_from(mode)) {
        case DDI_MODEL_ILP32:
            {
            struct args32 a32;
            /* copy 32-bit args data shape */
            if (ddi_copyin((void *)arg, &a32,
                sizeof (struct args32), mode) != 0) {
                return (EFAULT);
            }
            /* convert 32-bit to 64-bit args data shape */
            a.addr = a32.addr;
            a.len = a32.len;
            break;
            }
        172

```
Handling `copyout()` Overflow

Sometimes a driver needs to copy out a native quantity that no longer fits in the 32-bit sized structure. In this case, the driver should return `EOVERFLOW` to the caller as an indication that the data type in the interface is too small to hold the value to be returned, as shown in Example 10–16.

**Example 10–16: Handling `copyout()` Overflow**

```c
int xxioctl(dev_t dev, int cmd, intptr_t arg, int mode,
            cred_t *cr, int *rval_p)
{
    struct resdata res;
    ... body of driver code ...

    switch (ddi_model_convert_from(mode & FMODELS)) {
        case DDI_MODEL_ILP32: {
            struct resdata32 res32;
            if (res.size > UINT_MAX)
                return (EOVERFLOW);
            res32.size = (size32_t)res.size;
            res32.flag = res.flag;
            if (ddi_copyout(&res32,
                             (void *)arg, sizeof (res32), mode))
                return (EFAULT);
        }
        break;
    }
    return (0);
}
```
32–bit and 64–bit Data Structure Macros

While the method shown in the previous example works well for many drivers, an alternate scheme is to use the data structure macros provided in `<sys/model.h>` to move data between the application and the kernel. These macros make the code less cluttered and behave identically, from a functional perspective.

**EXAMPLE 10–17 Using Data Structure Macros to Move Data**

```c
int
xxioctl(dev_t dev, int cmd, intptr_t arg, int mode,
    cred_t *cr, int *rval_p)
{
    STRUCT_DECL(opdata, op);
    if (cmd != OPONE)
        return (ENOTTY);
    STRUCT_INIT(op, mode);
    if (copyin((void *)arg,
        STRUCT_BUF(op), STRUCT_SIZE(op)))
        return (EFAULT);
    if (STRUCT_FGET(op, flag) != XXACTIVE ||
        STRUCT_FGET(op, size) > XXSIZE)
        return (EINVAL);
    xxdowork(device_state, STRUCT_FGET(op, size));
    return (0);
}
```

**How Do the Structure Macros Work?**

In a 64-bit device driver, these macros do all that is necessary to use the same piece of kernel memory as a buffer for the contents of the native form of the data structure (that is, the LP64 form), and for the ILP32 form of the same structure. This usually
means that each structure access is implemented by a conditional expression. When compiled as a 32-bit driver, only one data model is supported and only the native form exists, so no conditional expression is used.

The 64-bit versions of the macros depend on the definition of a shadow version of the data structure that describes the 32-bit interface using fixed-width types. The name of the shadow data structure is formed by appending “32” to the name of the native data structure. For convenience, place the definition of the shadow structure in the same file as the native structure to ease future maintenance costs.

The macros take arguments such as:

- `structname`: The structure name (as would appear after the `struct` keyword) of the native form of the data structure
- `umodel`: A flag word containing the user data model, such as `FILP32` or `FLP64`, extracted from the mode parameter of `ioctl(9E)`
- `handle`: The name used to refer to a particular instance of a structure that is manipulated by these macros
- `fieldname`: The name of the field within the structure

**When to Use Structure Macros**

Macros enable you to make in-place references only to the fields of a data item. They do not provide a way to take separate code paths based on the data model. They should be avoided if the number of fields in the data structure is large or the frequency of references to these fields is high.

Because the macros hide many of the differences between data models in the implementation of the macros, code written with this interface is generally easier to read. When compiled as a 32-bit driver, the resulting code is compact without needing clumsy `#ifdef`s, but still preserves type checking.

**Declaring and Initializing Structure Handles**

`STRUCT_DECL(9F)` and `STRUCT_INIT(9F)` can be used to declare and initialize a handle and space for decoding an ioctl on the stack. `STRUCT_HANDLE(9F)` and `STRUCT_SET_HANDLE(9F)` declare and initialize a handle without allocating space on the stack. The latter macros can be useful if the structure is very large, or is contained in some other data structure.
Note – Because the `STRUCT_DECL(9F)` and `STRUCT_HANDLE(9F)` macros expand to
data structure declarations, they should be grouped with such declarations in C code.

`STRUCT_DECL(structname, handle)`
Declares a `structure` handle called `handle` for a struct `structname` data structure, and
allocates space for its native form on the stack. The native form is assumed to be
larger than or equal to the ILP32 form of the structure.

`STRUCT_INIT(handle, umodel)`
Initializes the data model for `handle` to `umodel`. This macro must be invoked before
any access is made to a structure handle declared with `STRUCT_DECL(9F)`.

`STRUCT_HANDLE(structname, handle)`
Declares a `structure` handle called `handle`. Contrast with `STRUCT_DECL(9F)`.

`STRUCT_SET_HANDLE(handle, umodel, addr)`
Initializes the data model for `handle` to `umodel`, and sets `addr` as the buffer used for
subsequent manipulation. Invoke this macro before accessing a structure handle
declared with `STRUCT_DECL(9F)`.

Operations on Structure Handles

`size_t STRUCT_SIZE(handle)`
Returns the size of the structure referred to by `handle`, according to its embedded
data model.

`typedef fieldname STRUCT_FGET(handle, fieldname)`
Returns the indicated field (non-pointer type) in the data structure referred to by
`handle`.

`typedef fieldname STRUCT_FGETP(handle, fieldname)`
Returns the indicated field (pointer type) in the data structure referred to by `handle`.

`STRUCT_FSET(handle, fieldname, val)`
Sets the indicated field (non-pointer type) in the data structure referred to by `handle`
to value `val`. The type of `val` should match the type of `fieldname`.

`STRUCT_FSETP(handle, fieldname, val)`
Sets the indicated field (pointer type) in the data structure referred to by `handle` to
value `val`.

`typedef fieldname *STRUCT_FADDR(handle, fieldname)`
Returns the address of the indicated field in the data structure referred to by `handle`.

`struct structname *STRUCT_BUF(handle)`
Returns a pointer to the native structure described by `handle`.
Other Operations

\texttt{size_t SIZEOF_STRUCT(struct\_name, datamodel)}

Returns the size of \textit{struct\_name} based on the given data model.

\texttt{size_t SIZEOF\_PTR(datamodel)}

Returns the size of a pointer based on the given data model.
Drivers for Block Devices

This chapter describes the structure of block device drivers. The kernel views a block device as a set of randomly accessible logical blocks. The file system buffers the data blocks between a block device and the user space using a list of buf(9S) structures. Only block devices can support a file system.

This chapter provides information on the following subjects:

- “Block Driver Structure Overview” on page 179
- “File I/O” on page 180
- “Block Device Autoconfiguration” on page 181
- “Controlling Device Access” on page 183
- “Synchronous Data Transfers (Block Drivers)” on page 187
- “Asynchronous Data Transfers (Block Drivers)” on page 191
- “Miscellaneous Entry Points” on page 194
- “Disk Device Drivers” on page 195

Block Driver Structure Overview

Figure 11–1 shows data structures and routines that define the structure of a block device driver. Device drivers typically include the following:

- Device-loadable driver section
- Device configuration section
- Device access section

The shaded device access section in Figure 11–1 illustrates block driver entry points.
Associated with each device driver is a `dev_ops(9S)` structure, which in turn refers to a `cb_ops(9S)` structure. See Chapter 5, for details regarding driver data structures.

**Note** – Some of the entry points can be replaced by `nodev(9F)` or `nulldev(9F)` as appropriate.

---

**File I/O**

A file system is a tree-structured hierarchy of directories and files. Some file systems, such as the UNIX File System (UFS), reside on block-oriented devices. File systems are created by `format(1M)` and `newfs(1M)`.

When an application issues a `read(2)` or `write(2)` system call to an ordinary file on the UFS file system, the file system can call the device driver `strategy(9E)` entry point for the block device on which the file system resides. The file system code can call `strategy(9E)` several times for a single `read(2)` or `write(2)` system call.

The file system code determines the logical device address, or **logical block number**, for each ordinary file block and builds a block I/O request in the form of a `buf(9S)` structure directed at the block device. The driver `strategy(9E)` entry point then interprets the `buf(9S)` structure and completes the request.
Block Device Autoconfiguration

`attach(9E)` should perform the common initialization tasks for each instance of a device. Typically, these tasks include:

- Allocating per-instance state structures
- Mapping the device’s registers
- Registering device interrupts
- Initializing mutex and condition variables
- Creating power manageable components
- Creating minor nodes

Block device drivers create minor nodes of type `S_IFBLK`. This causes a block special file representing the node to eventually appear in the `/devices` hierarchy.

Logical device names for block devices appear in the `/dev/dsk` directory, and consist of a controller number, bus-address number, disk number, and slice number. These names are created by the `devfsadm(1M)` program if the node type is set to `DDI_NT_BLOCK` or `DDI_NT_BLOCK_CHAN`. `DDI_NT_BLOCK_CHAN` should be specified if the device communicates on a channel (a bus with an additional level of addressability), such as SCSI disks, and causes a bus-address field (`tN`) to appear in the logical name. `DDI_NT_BLOCK` should be used for most other devices.

For each minor device (which corresponds to each partition on the disk), the driver must also create an `nblocks` or `Nblocks` property. This is an integer property giving the number of blocks supported by the minor device expressed in units of `DEV_BSIZE` (512 bytes). The file system uses the `nblocks` and `Nblocks` properties to determine device limits; `Nblocks` is the 64-bit version of `nblocks` and should be used with storage devices with over 1 Tbyte of storage per disk.). See “Device Properties” on page 55 for more information.

Example 11–1 shows a typical `attach(9E)` entry point with emphasis on creating the device’s minor node and the `Nblocks` property. Note that because this example uses `Nblocks` and not `nblocks`, it calls `ddi_prop_update_int64(9F)` instead of `ddi_prop_update_int(9F)`.

As a side note, this example shows the use of `makedevice(9F)` to create a device number for `ddi_prop_update_int64(9F)`. `makedevice(9F)` itself makes use of `ddi_driver_major(9F)`, which generates a major number from a pointer to a `dev_info_t` structure, just as `getmajor(9F)` does with a `dev_t` structure pointer.

**EXAMPLE 11–1 Block Driver `attach(9E)` Routine**

```c
static int
xxattach(dev_info_t *dip, ddi_attach_cmd_t cmd)
{
    int instance = ddi_get_instance(dip);
    switch (cmd) {
```
example 11–1 Block Driver attach(9E) Routine (Continued)

    case DDI_ATTACH:
        allocate a state structure and initialize it
        map the devices registers
        add the device driver’s interrupt handler(s)
        initialize any mutexes and condition variables
        read label information if the device is a disk
        create power manageable components
        /*
         * Create the device minor node. Note that the node_type
         * argument is set to DDI_NT_BLOCK.
         */
        if (ddi_create_minor_node(dip, "minor_name", S_IFBLK,
            instance, DDI_NT_BLOCK, 0) == DDI_FAILURE) {
            free resources allocated so far
            /* Remove any previously allocated minor nodes */
            ddi_remove_minor_node(dip, NULL);
            return (DDI_FAILURE);
        }
        /*
         * Create driver properties like "Nblocks". If the device
         * is a disk, the Nblocks property is usually calculated from
         * information in the disk label. Use "Nblocks" instead of
         * "nblocks" to ensure the property works for large disks.
         */
        xsp->Nblocks = size of device in 512 byte blocks;
        maj_number = ddi_driver_major(dip);
        if (ddi_prop_update_int64(makedevice(maj_number, instance), dip,
            "Nblocks", xsp->Nblocks) != DDI_PROP_SUCCESS) {
            cmn_err(CE_CONT, "%s: cannot create Nblocks property\n",
                ddi_get_name(dip));
            free resources allocated so far
            return (DDI_FAILURE);
        }
        xsp->open = 0;
        xsp->nlayered = 0;
        ...
        return (DDI_SUCCESS);
    case DDI_RESUME:
        For information, see Chapter 9
        default:
            return (DDI_FAILURE);
        }
    }
Controlling Device Access

This section describes aspects of the `open()` and `close()` entry points that are specific to block device drivers. See Chapter 10 for more information on `open(9E)` and `close(9E).

open() Entry Point (Block Drivers)

The `open(9E)` entry point is used to gain access to a given device. The `open(9E)` routine of a block driver is called when a user thread issues an `open(2)` or `mount(2)` system call on a block special file associated with the minor device, or when a layered driver calls `open(9E)`. See “File I/O” on page 180 for more information.

The `open(9E)` entry point should check for the following:

- The device can be opened; for example, it is online and ready.
- The device can be opened as requested; the device supports the operation, and the device’s current state does not conflict with the request.
- The caller has permission to open the device.

Example 11–2 demonstrates a block driver `open(9E)` entry point.

**EXAMPLE 11–2 Block Driver open(9E) Routine**

```c
static int
xxopen(dev_t *devp, int flags, int otyp, cred_t *credp)
{
    minor_t instance;
    struct xxstate *xsp;

    instance = getminor(*devp);
    xsp = ddi_get_soft_state(statep, instance);
    if (xsp == NULL)
        return (ENXIO);
    mutex_enter(&xsp->mu);
    /*
    * only honor FEXCL. If a regular open or a layered open
    * is still outstanding on the device, the exclusive open
    * must fail.
    */
    if ((flags & FEXCL) && (xsp->open || xsp->nlayered)) {
        mutex_exit(&xsp->mu);
        return (EAGAIN);
    }
    switch (otyp) {
        case OTYP_LYR:
            xsp->nlayered++;
```
EXAMPLE 11–2 Block Driver open(9E) Routine  (Continued)

```c
break;
case OTYP_BLK:
   xsp->open = 1;
break;
default:
   mutex_exit(&xsp->mu);
   return (EINVAL);
}
mutex_exit(&xsp->mu);
return (0);
}
```

The `otyp` argument is used to specify the type of open on the device. OTYP_BLK is the typical open type for a block device. A device can be opened several times with `otyp` set to OTYP_BLK, although `close`(9E) will be called only once when the final close of type OTYP_BLK has occurred for the device. `otyp` is set to OTYP_LYR if the device is being used as a layered device. For every open of type OTYP_LYR, the layering driver issues a corresponding close of type OTYP_LYR. The example keeps track of each type of open so the driver can determine when the device is not being used in `close`(9E).

### `close()` Entry Point (Block Drivers)

The arguments of the `close`(9E) entry point are identical to arguments of `open`(9E), except that `dev` is the device number, as opposed to a pointer to the device number.

The `close`(9E) routine should verify `otyp` in the same way as was described for the `open`(9E) entry point. In Example 11–3, `close`(9E) must determine when the device can really be closed based on the number of block opens and layered opens.

EXAMPLE 11–3 Block Device close(9E) Routine

```c
static int
xxclose(dev_t dev, int flag, int otyp, cred_t *credp)
{
    minor_t instance;
    struct xxstate *xsp;

    instance = getminor(dev);
    xsp = ddi_get_soft_state(statep, instance);
    if (xsp == NULL)
        return (ENXIO);
    mutex_enter(&xsp->mu);
    switch (otyp) {
        case OTYP_LYR:
            xsp->nlayered--;
            break;
        case OTYP_BLK:
            xsp->open = 0;
```
strategy() Entry Point

The strategy(9E) entry point is used to read and write data buffers to and from a block device. The name strategy refers to the fact that this entry point might implement some optimal strategy for ordering requests to the device.

strategy(9E) can be written to process one request at a time (synchronous transfer), or to queue multiple requests to the device (asynchronous transfer). When choosing a method, the abilities and limitations of the device should be taken into account.

The strategy(9E) routine is passed a pointer to a buf(9S) structure. This structure describes the transfer request, and contains status information on return. buf(9S) and strategy(9E) are the focus of block device operations.

buf Structure

The following buf structure members are important to block drivers:

<table>
<thead>
<tr>
<th>Member</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>b_flags</td>
<td>int</td>
<td>Buffer Status</td>
</tr>
<tr>
<td>av_forw</td>
<td>struct buf</td>
<td>Driver work list link</td>
</tr>
<tr>
<td>av_back</td>
<td>struct buf</td>
<td>Driver work list link</td>
</tr>
<tr>
<td>b_count</td>
<td>size_t</td>
<td># of bytes to transfer</td>
</tr>
<tr>
<td>b_addr</td>
<td>caddr_t</td>
<td>Buffer’s virtual address</td>
</tr>
<tr>
<td>b_blkno</td>
<td>daddr_t</td>
<td>Block number on device</td>
</tr>
<tr>
<td>b_lblkno</td>
<td>diskaddr_t</td>
<td>Expanded block number on device</td>
</tr>
<tr>
<td>b_resid</td>
<td>size_t</td>
<td># of bytes not transferred</td>
</tr>
</tbody>
</table>

Example 11-3 Block Device close(9E) Routine (Continued)

break;
default:
    mutex_exit(&xsp->mu);
    return (EINVAL);
}

if (xsp->open || xsp->nlayered) {
    /* not done yet */
    mutex_exit(&xsp->mu);
    return (0);
}

/* cleanup (rewind tape, free memory, etc.) */
/* wait for I/O to drain */
mutex_exit(&xsp->mu);

return (0);
}
b_flags contains status and transfer attributes of the buf structure. If B_READ is set, the buf structure indicates a transfer from the device to memory; otherwise, it indicates a transfer from memory to the device. If the driver encounters an error during data transfer, it should set the B_ERROR field in the b_flags member and provide a more specific error value in b_error. Drivers should use bioerror(9F) rather than setting B_ERROR.

---

**Caution** – Drivers should never clear b_flags.

---

av_forw and av_back

Pointers that the driver can use to manage a list of buffers by the driver. See “Asynchronous Data Transfers (Block Drivers)” on page 191 for a discussion of the av_forw and av_back pointers.

b_bcount

Specifies the number of bytes to be transferred by the device.

b_un.b_addr

The kernel virtual address of the data buffer. Only valid after bp_mapin(9F) call.

b_blkno

The starting 32-bit logical block number on the device for the data transfer, expressed in DEV_BSIZE (512 bytes) units. The driver should use either b_blkno or b_lblkno, but not both.

b_lblkno

The starting 64-bit logical block number on the device for the data transfer, expressed in DEV_BSIZE (512 bytes) units. The driver should use either b_blkno or b_lblkno, but not both.

b_resid

Set by the driver to indicate the number of bytes that were not transferred because of an error. See Example 11–8 for an example of setting b_resid. The b_resid member is overloaded: it is also used by dissort(9F).

b_error

Set to an error number by the driver when a transfer error occurs. It is set in conjunction with the b_flags B_ERROR bit. See Intro(9E) for details regarding error values. Drivers should use bioerror(9F) rather than setting b_error directly.
b_private
For exclusive use by the driver to store driver-private data.

b_edev
Contains the device number of the device involved in the transfer.

bp_mapin Structure
When a buf structure pointer is passed into the device driver’s strategy(9E) routine, the data buffer referred to by b_un.b_addr is not necessarily mapped in the kernel’s address space. This means that the driver cannot directly access the data. Most block-oriented devices have DMA capability, and therefore do not need to access the data buffer directly. Instead, they use the DMA mapping routines to allow the device’s DMA engine to do the data transfer. For details about using DMA, see Chapter 8.

If a driver needs to directly access the data buffer (as opposed to having the device access the data), it must first map the buffer into the kernel’s address space using bp_mapin(9F). bp_mapout(9F) should be used when the driver no longer needs to access the data directly.

Caution – bp_mapout(9F) should only be called on buffers that have been allocated and are owned by the device driver. It must not be called on buffers passed to the driver through the strategy(9E) entry point (for example a file system). Because bp_mapin(9F) does not keep a reference count, bp_mapout(9F) will remove any kernel mapping that a layer above the device driver might rely on.

Synchronous Data Transfers (Block Drivers)

This section presents a simple method for performing synchronous I/O transfers. It assumes that the hardware is a simple disk device that can transfer only one data buffer at a time using DMA, and that the disk can be spun up and spun down by software command. The device driver’s strategy(9E) routine waits for the current request to be completed before accepting a new one. The device interrupts when the transfer is complete or when an error occurs.

1. Check for invalid buf(9S) requests.
Check the buf(9S) structure passed to strategy(9E) for validity. All drivers should check that:
The request begins at a valid block. The driver converts the b_blkno field to the correct device offset and then determines if the offset is valid for the device.

- The request does not go beyond the last block on the device.
- Device-specific requirements are met.

If an error is encountered, the driver should indicate the appropriate error with bioerror(9F) and complete the request by calling biodone(9F). biodone(9F) notifies the caller of strategy(9E) that the transfer is complete (in this case, because of an error).

2. **Check whether the device is busy.**

Synchronous data transfers allow single-threaded access to the device. The device driver enforces this by maintaining a busy flag (guarded by a mutex), and by waiting on a condition variable with cv_wait(9F) when the device is busy.

If the device is busy, the thread waits until a cv_broadcast(9F) or cv_signal(9F) from the interrupt handler indicates that the device is no longer busy. See Chapter 3 for details on condition variables.

When the device is no longer busy, the strategy(9E) routine marks it as busy and prepares the buffer and the device for the transfer.

3. **Set up the buffer for DMA.**

Prepare the data buffer for a DMA transfer by allocating a DMA handle using ddi_dma_alloc_handle(9F) and binding the data buffer to the handle using ddi_dma_buf_bind_handle(9F). See Chapter 8 for information on setting up DMA resources and related data structures.

4. **Begin the transfer.**

At this point, a pointer to the buf(9S) structure is saved in the state structure of the device. The interrupt routine can then complete the transfer by calling biodone(9F).

The device driver then accesses device registers to initiate a data transfer. In most cases, the driver should protect the device registers from other threads by using mutexes. In this case, because strategy(9E) is single-threaded, guarding the device registers is not necessary. (See Chapter 3 for details about data locks.)

Once the executing thread has started the device’s DMA engine, the driver can return execution control to the calling routine, as shown in Example 11–4:

**EXAMPLE 11-4 Synchronous Block Driver strategy(9E) Routine**

```c
static int
xxstrategy(struct buf *bp)
{
    struct xxstate *xsp;
    struct device_reg *regp;
    minor_t instance;
    ddi_dma_cookie_t cookie;
    instance = getminor(bp->b_edev);
    xsp = ddi_get_soft_state(statep, instance);
    if (xsp == NULL) {
```

```c
```
EXAMPLE 11-4 Synchronous Block Driver strategy(9E) Routine  (Continued)

```c
bioerror(bp, ENXIO);
biodone(bp);
return (0);
}
/* validate the transfer request */
if ((bp->b_blkno >= xsp->Nblocks) || (bp->b_blkno < 0)) {
    bioerror(bp, EINVAL);
biodone(bp);
return (0);
}
/* Hold off all threads until the device is not busy. */
mutex_enter(&xsp->mu);
while (xsp->busy) {
    cv_wait(&xsp->cv, &xsp->mu);
}
xsp->busy = 1;
mutex_exit(&xsp->mu);

if the device has power manageable components (see Chapter 9),
mark the device busy with pm_busy_components(9F),
and then ensure that the device
is powered up by calling ddi_dev_is_needed(9F).

Set up DMA resources with ddi_dma_alloc_handle(9F) and ddi_dma_buf_bind_handle(9F).

xsp->bp = bp;
regp = xsp->regp;
ddi_put32(xsp->data_access_handle, &regp->dma_addr,
    cookie.dmac_address);
ddi_put32(xsp->data_access_handle, &regp->dma_size,
    (uint32_t)cookie.dmac_size);
ddi_put8(xsp->data_access_handle, &regp->csr,
    ENABLE_INTERRUPTS | START_TRANSFER);
return (0);
}

5. Handle the interrupting device.

When the device finishes the data transfer it generates an interrupt, which eventually
results in the driver’s interrupt routine being called. Most drivers specify the state
structure of the device as the argument to the interrupt routine when registering
interrupts (see the ddi_add_intr(9F) man page and “Registering Interrupts”
on page 98). The interrupt routine can then access the buf(9S) structure being
transferred, plus any other information available from the state structure.

The interrupt handler should check the device’s status register to determine if the
transfer completed without error. If an error occurred, the handler should indicate the
appropriate error with bioerror(9F). The handler should also clear the pending
interrupt for the device and then complete the transfer by calling biodone(9F).
```
As the final task, the handler clears the busy flag and calls `cv_signal(9F)` or `cv_broadcast(9F)` on the condition variable, signaling that the device is no longer busy. This allows other threads waiting for the device (in `strategy(9E)`) to proceed with the next data transfer.

**EXAMPLE 11-5 Synchronous Block Driver Interrupt Routine**

```c
static u_int
xxintr(caddr_t arg)
{
    struct xxstate *xsp = (struct xxstate *)arg;
    struct buf *bp;
    uint8_t status;
    mutex_enter(&xsp->mu);
    status = ddi_get8(xsp->data_access_handle, &xsp->regp->csr);
    if (!(status & INTERRUPTING)) {
        mutex_exit(&xsp->mu);
        return (DDI_INTR_UNCLAIMED);
    }
    /* Get the buf responsible for this interrupt */
    bp = xsp->bp;
    xsp->bp = NULL;
    /*
    * This example is for a simple device which either
    * succeeds or fails the data transfer, indicated in the
    * command/status register.
    */
    if (status & DEVICE_ERROR) {
        /* failure */
        bp->b_resid = bp->b_bcount;
        bioerror(bp, EIO);
    } else {
        /* success */
        bp->b_resid = 0;
    }
    ddi_put8(xsp->data_access_handle, &xsp->regp->csr,
             CLEAR_INTERRUPT);
    /* The transfer has finished, successfully or not */
    biodone(bp);
    if (the device has power manageable components that were marked busy in strategy(9F).
        mark them idle now with pm_idle_component(9F)
        release any resources used in the transfer, such as DMA resources (ddi_dma_unbind_handle(9F) and
        ddi_dma_free_handle(9F)).
    }
    /* Let the next I/O thread have access to the device */
    xsp->busy = 0;
    cv_signal(&xsp->cv);
    mutex_exit(&xsp->mu);
    return (DDI_INTR_CLAIMED);
}
```

190  Writing Device Drivers • May 2002
Asynchronous Data Transfers (Block Drivers)

This section presents a method for performing asynchronous I/O transfers. The driver queues the I/O requests and then returns control to the caller. Again, the assumption is that the hardware is a simple disk device that allows one transfer at a time. The device interrupts when a data transfer has completed or when an error occurs.

1. **Check for invalid buf(9S) requests.**
   As in the synchronous case, the device driver should check the `buf(9S)` structure passed to `strategy(9E)` for validity. See “Synchronous Data Transfers (Block Drivers)” on page 187 for more details.

2. **Enqueue the request.**
   Unlike synchronous data transfers, a driver does not wait for an asynchronous request to complete. Instead, it adds the request to a queue. The head of the queue can be the current transfer, or a separate field in the state structure can be used to hold the active request (as in Example 11–6). If the queue was initially empty, then the hardware is not busy, and `strategy(9E)` starts the transfer before returning. Otherwise, whenever a transfer completes and the queue is non-empty, the interrupt routine begins a new transfer. This example actually places the decision of whether to start a new transfer into a separate routine for convenience.

   The driver can use the `av_forw` and the `av_back` members of the `buf(9S)` structure to manage a list of transfer requests. A single pointer can be used to manage a singly linked list, or both pointers can be used together to build a doubly linked list. The device hardware specification specifies which type of list management (such as insertion policies) will optimize the performance of the device. The transfer list is a per-device list, so the head and tail of the list are stored in the state structure.

   Example 11–6 allows multiple threads access to the driver shared data, so you must identify any such data (such as the transfer list) and protect it with a mutex. (See Chapter 3 for more details about mutex locks.)

**EXAMPLE 11–6** Asynchronous Block Driver `strategy(9E)` Routine

```c
static int
xxstrategy(struct buf *bp)
{
    struct xxstate *xsp;
    minor_t instance;
    instance = getminor(bp->b_edev);
    xsp = ddi_get_soft_state(statep, instance);
    ...
    validate transfer request
    ...
    Add the request to the end of the queue. Depending on the device, a sorting algorithm, such as
```
EXAMPLE 11-6  Asynchronous Block Driver strategy(9E) Routine  (Continued)

    disksort(9F)
    may be used if it improves the performance of the device.
    mutex_enter(&xsp->mu);
    bp->av_forw = NULL;
    if (xsp->list_head) {
        /* Non-empty transfer list */
        xsp->list_tail->av_forw = bp;
        xsp->list_tail = bp;
    } else {
        /* Empty Transfer list */
        xsp->list_head = bp;
        xsp->list_tail = bp;
    }
    mutex_exit(&xsp->mu);
    /* Start the transfer if possible */
    (void) xxstart((caddr_t)xsp);
    return (0);
}

3. Start the first transfer.

Device drivers that implement queuing usually have a start() routine. start() dequeues the next request and starts the data transfer to or from the device. In this example, start() processes all requests, regardless of the state of the device (busy or free).

Note – start() must be written so that it can be called from any context, because it can be called by both the strategy routine (in kernel context) and the interrupt routine (in interrupt context).

start() is called by strategy(9E) every time it queues a request so that an idle device can be started. If the device is busy, start() returns immediately.

start() is also called by the interrupt handler before it returns from a claimed interrupt so that a nonempty queue can be serviced. If the queue is empty, start() returns immediately.

Because start() is a private driver routine, it can take any arguments and return any type. Example 11-7 is written as if it will also be used as a DMA callback (although that portion is not shown), so it must take a caddr_t as an argument and return an int. See “Handling Resource Allocation Failures” on page 119 for more information about DMA callback routines.

EXAMPLE 11-7  Block Driver start() Routine

static int
xxstart(caddr_t arg)
{

EXAMPLE 11–7 Block Driver start() Routine  (Continued)

```c
struct xxstate *xsp = (struct xxstate *)arg;
struct buf *bp;
mutex_enter(&xsp->mu);
/*
 * If there is nothing more to do, or the device is
 * busy, return.
 */
if (xsp->list_head == NULL || xsp->busy) {
    mutex_exit(&xsp->mu);
    return (0);
}
xsp->busy = 1;
/* Get the first buffer off the transfer list */
bp = xsp->list_head;
/* Update the head and tail pointer */
xsp->list_head = xsp->list_head->av_forw;
if (xsp->list_head == NULL)
    xsp->list_tail = NULL;
bp->av_forw = NULL;
mutex_exit(&xsp->mu);
if the device has power manageable components (see
Chapter 9),
mark the device busy with pm_busy_components, and then ensure that the device
is powered up by calling ddi_dev_is_needed.
Set up DMA resources with ddi_dma_alloc_handle(9F) and
ddi_dma_buf_bind_handle(9F).
xsp->bp = bp;
    ddi_put32(xsp->data_access_handle, &xsp->regp->dma_addr,
        cookie.dmac_address);
    ddi_put32(xsp->data_access_handle, &xsp->regp->dma_size,
        (uint32_t)cookie.dmac_size);
    ddi_put8(xsp->data_access_handle, &xsp->regp->csr,
        ENABLE_INTERRUPTS | START_TRANSFER);
    return (0);
}
```

4. Handle the interrupting device.
The interrupt routine is similar to the asynchronous version, with the addition of the
call to start() and the removal of the call to cv_signal(9F).

EXAMPLE 11–8 Asynchronous Block Driver Interrupt Routine

```c
static u_int
xxintr(caddr_t arg)
{
    struct xxstate *xsp = (struct xxstate *)arg;
    struct buf *bp;
    uint8_t status;
    mutex_enter(&xsp->mu);
```
status = ddi_get8(xsp->data_access_handle, &xsp->regp->csr);
if (!(status & INTERRUPTING)) {
    mutex_exit(&xsp->mu);
    return (DDI_INTR_UNCLAIMED);
}
/* Get the buf responsible for this interrupt */
bp = xsp->bp;
xsp->bp = NULL;
/*
 * This example is for a simple device which either
 * succeeds or fails the data transfer, indicated in the
 * command/status register.
 */
if ((status & DEVICE_ERROR) {
    /* failure */
    bp->b_resid = bp->b_bcount;
    bioerror(bp, EIO);
} else {
    /* success */
    bp->b_resid = 0;
}
ddi_put8(xsp->data_access_handle, &xsp->regp->csr,
          CLEAR_INTERRUPT);
/* The transfer has finished, successfully or not */
biodone(bp);
    if (the device has power manageable components that were marked busy in strategy(9F)
(9E), mark them idle now with pm_idle_component(9F)
release any resources used in the transfer, such as DMA resources
ddi_dma_unbind_handle(9F) and
ddi_dma_free_handle(9F)
/* Let the next I/O thread have access to the device */
xsp->busy = 0;
mutex_exit(&xsp->mu);
(void) xxstart((caddr_t)xsp);
return (DDI_INTR_CLAIMED);

---

**Miscellaneous Entry Points**

This section discusses the dump(9E) and print(9E) entry points.
dump() Entry Point (Block Drivers)

The dump(9E) entry point is used to copy a portion of virtual address space directly to the specified device in the case of a system failure. It is also used to copy the state of the kernel out to disk during a checkpoint operation (see the cpr(7) and dump(9E) man pages). It must be capable of performing this operation without the use of interrupts, since they are disabled during the checkpoint operation.

```c
int dump(dev_t dev, caddr_t addr, daddr_t blkno, int nblk)
```

dev is the device number of the device to dump to, addr is the base kernel virtual address at which to start the dump, blkno is the first block to dump to, and nblk is the number of blocks to dump. The dump depends upon the existing driver working properly.

print() Entry Point (Block Drivers)

```c
int print(dev_t dev, char *str)
```

The print(9E) entry point is called by the system to display a message about an exception it has detected. print(9E) should call cmn_err(9F) to post the message to the console on behalf of the system. Here is an example:

```c
static int
xxprint(dev_t dev, char *str)
{
    cmn_err(CE_CONT, "xx: %s\n", str);
    return (0);
}
```

Disk Device Drivers

Disk devices represent an important class of block device drivers.

Disk ioctls

Solaris disk drivers need to support a minimum set of ioctl commands specific to Solaris disk drivers. These I/O controls are specified in the dkio(7) manual page. Disk I/O controls transfer disk information to or from the device driver. A Solaris disk device is one that is supported by disk utility commands such as format(1M) and newfs(1M). Table 11–1 lists the mandatory Sun disk I/O controls.
**TABLE 11–1 Mandatory Solaris Disk ioctl s**

</tbody>
</table>

**Disk Performance**

The Solaris DDI/DKI provides facilities to optimize I/O transfers for improved file system performance. It supports a mechanism to manage the list of I/O requests so as to optimize disk access for a file system. See “Asynchronous Data Transfers (Block Drivers)” on page 191 for a description of enqueuing an I/O request.

The `diskhd` structure is used to manage a linked list of I/O requests.

```c
struct diskhd {
    long   b_flags;  /* not used, needed for consistency*/
    struct buf *b_forw,  *b_back;  /* queue of unit queues */
    struct buf *av_forw,  *av_back; /* queue of bufs for this unit */
    long   b_bcount;    /* active flag */
};
```

The `diskhd` data structure has two `buf` pointers that the driver can manipulate. The `av_forw` pointer points to the first active I/O request. The second pointer, `av_back`, points to the last active request on the list.

A pointer to this structure is passed as an argument to `disksort(9F)`, along with a pointer to the current `buf` structure being processed. The `disksort(9F)` routine is used to sort the `buf` requests in a fashion that optimizes disk seek and then inserts the `buf` pointer into the `diskhd` list. The `disksort(9F)` program uses the value that is in `b_resid` of the `buf` structure as a sort key. The driver is responsible for setting this value. Most Sun disk drivers use the cylinder group as the sort key. This tends to optimize the file system read-ahead accesses.

Once data has been added to the `diskhd` list, the device needs to transfer the data. If the device is not busy processing a request, the `xxstart()` routine pulls the first `buf` structure off the `diskhd` list and starts a transfer.
If the device is busy, the driver should return from the `xxstrategy()` entry point. Once the hardware is done with the data transfer, it generates an interrupt. The driver’s interrupt routine is then called to service the device. After servicing the interrupt, the driver can then call the `start()` routine to process the next `buf` structure in the `diskhd` list.
Mapping Device and Kernel Memory

Some device drivers allow applications to access device or kernel memory using `mmap(2)`. Examples are frame buffer drivers, which allow the frame buffer to be mapped into a user thread, or a pseudo driver that communicates with an application using a shared kernel memory pool. This chapter provides information on the following subjects:

- “Memory Mapping Operation Overview” on page 199
- “Exporting the Mapping” on page 199
- “Associating Device Memory With User Mappings” on page 201
- “Associating Kernel Memory With User Mappings” on page 203

### Memory Mapping Operation Overview

In general, the steps a driver must take to export device or kernel memory are:

1. Set the `D_DEVMAP` flag in the `cb_flag` flag of the `cb_ops(9S)` structure.
2. Define a `devmap(9E)` driver entry point to export the mapping.
3. Use `devmap_devmem_setup(9F)` to set up user mappings to a device. To set up user mappings to kernel memory, use `devmap_umem_setup(9F)`.

### Exporting the Mapping

The `devmap(9E)` entry point is called as a result of the `mmap(2)` system call. `devmap(9E)` is used to:

- Validate the user mapping to the device or kernel memory.
Translate the logical offset within the application mapping to the corresponding offset within the device or kernel memory.

Pass the mapping information to the system for setting up the mapping.

```c
int devmap(dev_t dev, devmap_cookie_t handle, offset_t off,
            size_t len, size_t *maplen, uint_t model);
```

where:

- `dev` Device whose memory is to be mapped
- `handle` Device-mapping handle that the system creates and uses to describe a mapping to contiguous device or kernel memory
- `off` Logical offset within the application mapping that has to be translated by the driver to the corresponding offset within the device or kernel memory
- `len` Length (in bytes) of the memory being mapped
- `maplen` Allows driver to associate different kernel memory regions or multiple physically discontiguous memory regions with one contiguous user application mapping
- `model` Data model type of the current thread

The system creates multiple mapping handles in one `mmap(2)` system call (for example, if the mapping contains multiple physically discontiguous memory regions).

Initially `devmap(9E)` is called with parameters `off` and `len`, which were passed by the application to `mmap(2)`. `devmap(9E)` sets `maplen` to the length from `off` to the end of a contiguous memory region. `maplen` must be rounded up to a multiple of a page size. If `maplen` is set to less than the original mapping length `len`, the system will repeatedly call `devmap(9E)` with a new mapping handle and adjusted `off` and `len` parameters until the initial mapping length is satisfied.

If a driver supports multiple application data models, `model` has to be passed to `ddi_model_convert_from(9F)` to determine whether there is a data model mismatch between the current thread and the device driver. The device driver might have to adjust the shape of data structures before exporting them to a user thread that supports a different data model. See the Appendix C man page for more details.

`devmap(9E)` must return `-1` if the logical offset, `off`, is out of the range of memory exported by the driver.
Associating Device Memory With User Mappings

devmap_devmem_setup(9F) is provided to export device memory to user applications.

**Note** – devmap_devmem_setup(9F) has to be called from the driver’s devmap(9E) entry point.

The syntax for devmap_devmem_setup() follows:

```c
int devmap_devmem_setup(devmap_cookie_t handle, dev_info_t *dip,
  struct devmap_callback_ctl *callbacks, uint_t rnumber,
  offset_t roff, size_t len, uint_t maxprot, uint_t flags,
  ddi_device_acc_attr_t *accattrp);
```

where:

- **handle**  
  Opaque device-mapping handle that the system uses to identify the mapping

- **dip**  
  Pointer to the device’s `dev_info` structure

- **callbacks**  
  Pointer to a `devmap_callback_ctl(9S)` structure that allows the driver to be notified of user events on the mapping

- **rnumber**  
  Index number to the register address space set

- **roff**  
  Offset into the device memory

- **len**  
  Length in bytes that is exported

- **maxprot**  
  Allows the driver to specify different protections for different regions within the exported device memory

- **flags**  
  Must be set to `DEVMAP_DEFAULTS`

- **accattrp**  
  Pointer to a `ddi_device_acc_attr(9S)` structure

`roff` and `len` describe a range within the device memory specified by the register set `rnumber`. The register specifications referred to by `rnumber` are described by the `reg` property. For devices with only one register set, pass zero for `rnumber`. The range described by `roff` and `len` are made accessible to the user’s application mapping at the offset passed in by the `devmap(9E)` entry point. Usually the driver passes the `devmap(9E)` offset directly to `devmap_devmem_setup(9F)`. The return address of `mmap(2)` then maps to the beginning address of the register set.
maxprot allows the driver to specify different protections for different regions within the exported device memory. For example, one region might not allow write access by setting only PROT_READ and PROT_USER.

Example 12-1 shows how to export device memory to an application. The driver first determines whether the requested mapping falls within the device memory region. The size of the device memory is determined using ddi_dev_regsize(9F). The length of the mapping is rounded up to a multiple of a page size using ptob(9F) and btopr(9F), and devmap_devmem_setup(9F) is called to export the device memory to the application.

EXAMPLE 12-1 devmap_devmem_setup(9F) Routine

```c
static int
xxdevmap(dev_t dev, devmap_cookie_t handle, offset_t off, size_t len,
        size_t *maplen, uint_t model)
{
    struct xxstate *xsp;
    int    error, rnumber;
    off_t regsize;

    /* Set up data access attribute structure */
    struct ddi_device_acc_attr xx_acc_attr = {
        DDI_DEVICE_ATTR_V0,
        DDI_NEVERSWAP_ACC,
        DDI_STRICTORDER_ACC
    };
    xsp = ddi_get_soft_state(statep, getminor(dev));
    if (xsp == NULL)
        return (-1);
    /* use register set 0 */
    rnumber = 0;
    /* get size of register set */
    if (ddi_dev_regsize(xsp->dip, rnumber, &regsize) != DDI_SUCCESS)
        return (-1);
    /* round up len to a multiple of a page size */
    len = ptob(btopr(len));
    if (off + len > regsize)
        return (-1);
    /* Set up the device mapping */
    error = devmap_devmem_setup(handle, xsp->dip, NULL, rnumber, off, len, PROT_ALL, DEVMAP_DEFAULTS, &xx_acc_attr);
    /* acknowledge the entire range */
    *maplen = len;
    return (error);
}
```
Associating Kernel Memory With User Mappings

Some device drivers might need to allocate kernel memory that is made accessible to user programs by using `mmap(2)`. Examples of this are setting up shared memory for communication between two applications or between driver and application.

In general, the steps for exporting kernel memory to user applications are:

1. Allocate kernel memory using `ddi_umem_alloc(9F)`.
2. Export the memory using `devmap_umem_setup(9F)`.
3. Free the memory using `ddi_umem_free(9F)` when no longer needed.

Allocating Kernel Memory for User Access

`ddi_umem_alloc(9F)` is provided to allocate kernel memory that is exported to applications. The syntax for `ddi_umem_alloc()` is:

```c
void *ddi_umem_alloc(size_t size, int flag, ddi_umem_cookie_t *cookiep);
```

- **size**: Number of bytes to allocate
- **flag**: Used to determine the sleep conditions and the memory type
- **cookiep**: Pointer to a kernel memory cookie

`ddi_umem_alloc(9F)` allocates page-aligned kernel memory and returns a pointer to the allocated memory. The initial contents of the memory is zero-filled. The number of bytes allocated is a multiple of the system page size (roundup of `size`). The allocated memory can be used in the kernel and can be exported to applications. `cookiep` is a pointer to the kernel memory cookie that describes the kernel memory being allocated. It is used in `devmap_umem_setup(9F)` when the driver exports the kernel memory to a user application.

The `flag` argument indicates whether `ddi_umem_alloc(9F)` will block or return immediately, and whether the allocated kernel memory is pageable. Table 12-1 lists the values for `flag`.

<td>Driver allows memory to be paged out. If not set, the memory is locked down.</td>
</tr>
</tbody>
</table>

Example 12-2 shows how to allocate kernel memory for application access. The driver exports one page of kernel memory, which is used by multiple applications as a shared memory area. The memory is allocated in segmap(9E) when an application maps the shared page the first time. An additional page is allocated if the driver has to support multiple application data models (for example a 64-bit driver exporting memory to 64-bit and 32-bit applications). 64-bit applications share the first page, and 32-bit applications share the second page.

**Example 12-2 ddi_umem_alloc(9F) Routine**

```c
static int xxsegmap(dev_t dev, off_t off, struct asp *asp, caddr_t *addrp, off_t len,
                     unsigned int prot, unsigned int maxprot, unsigned int flags,
                     cred_t *credp)
{
    int error;
    minor_t instance = getminor(dev);
    struct xxstate *xsp = ddi_get_soft_state(statep, instance);

    size_t mem_size;
    /* 64-bit driver supports 64-bit and 32-bit applications */
    switch (ddi_mmap_get_model()) {
        case DDI_MODEL_LP64:
            mem_size = ptob(2);
            break;
        case DDI_MODEL_ILP32:
            mem_size = ptob(1);
            break;
    }

    mutex_enter(&xsp->mu);
    if (xsp->umem == NULL) {
        /* allocate the shared area as kernel pageable memory */
        xsp->umem = ddi_umem_alloc(mem_size,
                                   DDI_UMEM_SLEEP | DDI_UMEM_PAGEABLE, &xsp->ucookie);
    }
    mutex_exit(&xsp->mu);
    /* Set up the user mapping */
    error = devmap_setup(dev, (offset_t)off, asp, addrp, len,
                          prot, maxprot, flags, credp);

    return (error);
}
```

204 Writing Device Drivers • May 2002
Exporting Kernel Memory to Applications

devmap_umem_setup(9F) is provided to export kernel memory to user applications. devmap_umem_setup() must be called from the driver’s devmap(9E) entry point. The syntax for devmap_umem_setup() is as follows:

```c
int devmap_umem_setup(devmap_cookie_t handle, dev_info_t *dip,
                      struct devmap_callback_ctl *callbackops, ddi_umem_cookie_t cookie,
                      offset_t koff, size_t len, uint_t maxprot, uint_t flags,
                      ddi_device_acc_attr_t *accattrp);
```

- **handle**: Opaque structure used to describe the mapping
- **dip**: Pointer to the device’s dev_info structure
- **callbackops**: Pointer to a devmap_callback_ctl(9S) structure
- **cookie**: Kernel memory cookie returned by ddi_umem_alloc(9F)
- **koff**: Offset into the kernel memory specified by cookie
- **len**: Length in bytes that is exported
- **maxprot**: Specifies the maximum protection possible for the exported mapping
- **flags**: Must be set to DEVMAP_DEFAULTS
- **accattrp**: Pointer to a ddi_device_acc_attr(9S) structure

*handle* is a device-mapping handle that the system uses to identify the mapping. It is passed in by the devmap(9E) entry point. *dip* is a pointer to the device’s dev_info structure. *callbackops* allows the driver to be notified of user events on the mapping. Most drivers set *callbackops* to NULL when kernel memory is exported.

*koff* and *len* specify a range within the kernel memory allocated by ddi_umem_alloc(9F). This range will be made accessible to the user’s application mapping at the offset passed in by the devmap(9E) entry point. Usually the driver will pass the devmap(9E) offset directly to devmap_umem_setup(9F). The return address of mmap(2) will then map to the kernel address returned by ddi_umem_alloc(9F). *koff* and *len* must be page-aligned.

*maxprot* enables the driver to specify different protections for different regions within the exported kernel memory. For example, one region might not allow write access by only setting PROT_READ and PROT_USER.

Example 12–3 shows how to export kernel memory to an application. The driver first checks if the requested mapping falls within the allocated kernel memory region. If a 64-bit driver receives a mapping request from a 32-bit application, the request is redirected to the second page of the kernel memory area. This ensures that only applications compiled to the same data model will share the same page.
EXAMPLE 12-3  devmap_umem_setup(9F) Routine

    static int
    xxdevmap(dev_t dev, devmap_cookie_t handle, offset_t off, size_t len,
             size_t *maplen, uint_t model)
    {
        struct xxstate *xsp;
        int    error;

        /* round up len to a multiple of a page size */
        len = ptob(btopr(len));
        /* check if the requested range is ok */
        if (off + len > ptob(1))
            return (ENXIO);
        xsp = ddi_get_soft_state(statep, getminor(dev));
        if (xsp == NULL)
            return (ENXIO);
        if (ddi_model_convert_from(model) == DDI_MODEL_ILP32)
            /* request from 32-bit application. Skip first page */
            off += ptob(1);

        /* export the memory to the application */
        error = devmap_umem_setup(handle, xsp->dip, NULL, xsp->ucookie,
                                   off, len, PROT_ALL, DEVMAP_DEFAULTS, NULL);
        *maplen = len;
        return (error);
    }

Freeing Kernel Memory Exported for User Access

When the driver is unloaded, the memory that was allocated by
ddi_umem_alloc(9F) must be freed by calling ddi_umem_free(9F).

    void ddi_umem_free(ddi_umem_cookie_t cookie);

    cookie is the kernel memory cookie returned by ddi_umem_alloc(9F).
Some device drivers, such as those for graphics hardware, provide user processes with direct access to the device. These devices often require that only one process at a time accesses the device.

This chapter describes the set of interfaces that allow device drivers to manage access to such devices. It provides information on the following subjects:

- “Introduction to Device Context” on page 207
- “Context Management Model” on page 207
- “Context Management Operation” on page 209

Introduction to Device Context

This section introduces device context and the context management model.

What Is a Device Context?

The context of a device is the current state of the device hardware. The device driver manages the device context for a process on behalf of the process. It must maintain a separate device context for each process that accesses the device. The device driver has the responsibility to restore the correct device context when a process accesses the device.

Context Management Model

An accelerated frame buffer is an example of a device that allows user processes (such as graphics applications) to directly manipulate the control registers of the device through memory-mapped access. Because these processes are not using the traditional
I/O system calls (read(2), write(2), and ioctl(2)), the device driver is no longer called when a process accesses the device. However, the device driver must be notified when a process is about to access a device so that it can restore the correct device context and provide any needed synchronization.

To resolve this problem, the device context management interfaces enable a device driver to be notified when a user process accesses memory-mapped regions of the device, and to control accesses to the device’s hardware. Synchronization and management of the various device contexts are responsibilities of the device driver. When a user process accesses a mapping, the device driver must restore the correct device context for that process.

A device driver will be notified whenever a user process:

- Accesses a mapping
- Duplicates a mapping
- Frees a mapping
- Creates a mapping

Figure 13–1 shows multiple user processes that have memory-mapped a device. The driver has granted process B access to the device, and process B no longer notifies the driver of accesses. However, the driver is still notified if either process A or process C accesses the device.

At some point in the future, process A accesses the device. The device driver is notified of this and blocks future access to the device by process B. It then saves the device context for process B, restores the device context of process A, and grants access to process A, as illustrated in Figure 13–2. At this point, the device driver will be notified if either process B or process C accesses the device.
On a multiprocessor machine, multiple processes could be attempting to access the device at the same time. This can cause thrashing. Some devices require a longer time to restore a device context. To prevent more CPU time from being used to restore a device context than to actually use that device context, the minimum time that a process needs to have access to the device can be set using `devmap_set_ctx_timeout(9F).

The kernel guarantees that once a device driver has granted access to a process, no other process will be allowed to request access to the same device for the time interval specified by `devmap_set_ctx_timeout(9F).

## Context Management Operation

In general, the steps for performing device context management are:

1. Define a `devmap_callback_ctl(9S) structure.
2. Allocate space to save device context if necessary.
3. Set up user mappings to the device and driver notifications with `devmap_devmem_setup(9F).
4. Manage user access to the device with `devmap_load(9F) and `devmap_unload(9F).
5. Free the device context structure, if needed.

## devmap_callback_ctl Structure

The device driver must allocate and initialize a `devmap_callback_ctl(9S) structure to inform the system of its device context management entry point routines. This structure contains the following fields:
struct devmap_callback_ctl {
    int devmap_rev;
    int (*devmap_map)(devmap_cookie_t dhp, dev_t dev,
        uint_t flags, offset_t off, size_t len, void **pvtp);
    int (*devmap_access)(devmap_cookie_t dhp, void *pvtp,
        offset_t off, size_t len, uint_t type, uint_t rw);
    int (*devmap_dup)(devmap_cookie_t dhp, void *pvtp,
        devmap_cookie_t new_dhp, void **new_pvtp);
    void (*devmap_unmap)(devmap_cookie_t dhp, void *pvtp,
        offset_t off, size_t len, devmap_cookie_t new_dhp1,
        void **new_pvtp1, devmap_cookie_t new_dhp2,
        void **new_pvtp2);
};

devmap_rev The version number of the devmap_callback_ctl structure. It must be set to DEVMAP_OPS_REV.
devmap_map Must be set to the address of the driver’s devmap_map() entry point.
devmap_access Must be set to the address of the driver’s devmap_access() entry point.
devmap_dup Must be set to the address of the driver’s devmap_dup() entry point.
devmap_unmap Must be set to the address of the driver’s devmap_unmap() entry point.

Device Context Management Entry Points

The following device driver entry points are used to manage device context:

- devmap(9E)
- devmap_access(9E)
- devmap_contextmgt(9E)
- devmap_dup(9E)
- devmap_unmap(9E)

devmap() Entry Point

The syntax for devmap(9E) is:

```c
int xxdevmap_map(devmap_cookie_t handle, dev_t dev, uint_t flags,
    offset_t offset, size_t len, void **new_devprivate);
```
This entry point is called after the driver returns from its `devmap()` entry point and the system has established the user mapping to the device memory. The `devmap()` entry point enables a driver to perform additional processing or to allocate mapping specific private data. For example, in order to support context switching, the driver has to allocate a context structure and associate it with the mapping.

The system expects the driver to return a pointer to the allocated private data in `new_devprivate`. The driver must store `offset` and `len`, which define the range of the mapping, in its private data. Later, when the system calls `devmap_unmap(9E)`, the driver will use `offset` and `len` stored in `new_devprivate` to check if the entire mapping, or just a part of it, is being unmapped.

`flags` indicates whether the driver should allocate a private context for the mapping. For example, a driver can allocate a memory region to store the device context if `flags` is set to `MAP_PRIVATE`, or it might return a pointer to a shared region if `MAP_SHARED` is set.

Example 13–1 shows an example of a `devmap()` entry point. The driver allocates a new context structure and saves relevant parameters passed in by the entry point. Then the mapping is assigned a new context by either allocating a new one or attaching it to an already existing shared context. The minimum time interval that the mapping should have access to the device is set to one millisecond.

**EXAMPLE 13–1 devmap(9E) Routine**

```c
static int
int xxdevmap_map(devmap_cookie_t handle, dev_t dev, uint_t flags,
                  offset_t offset, size_t len, void **new_devprivate)
{
    struct xxstate *xsp = ddi_get_soft_state(statep,
                                              getminor(dev));
    struct xxctx *newctx;
    /* create a new context structure */
    newctx = kmem_alloc(sizeof (struct xxctx), KM_SLEEPS);
    newctx->xsp = xsp;
    newctx->handle = handle;
    newctx->offset = offset;
    newctx->flags = flags;
    newctx->len = len;
    mutex_enter(&xsp->ctx_lock);
    if (flags & MAP_PRIVATE) {
        /* allocate a private context and initialize it */
        newctx->context = kmem_alloc(XXCTX_SIZE, KM_SLEEPS);
        xxctxinit(newctx);
    } else {
        /* set a pointer to the shared context */
        newctx->context = xsp->ctx_shared;
    }
    mutex_exit(&xsp->ctx_lock);
    /* give at least 1 ms access before context switching */
    devmap_set_ctx_timeout(handle, drv_usectohz(1000));
}
```
EXAMPLE 13–1 devmap(9E) Routine (Continued)

    /* return the context structure */
    *new_devprivate = newctx;
    return(0);
}

devmap_access() Entry Point

The syntax for devmap_access(9E) is:

    int xxdevmap_access(devmap_cookie_t handle, void *devprivate,
                        offset_t offset, size_t len, uint_t type, uint_t rw);

This entry point is called when an access is made to a mapping whose translations are invalid. Mapping translations are invalidated when the mapping is created with devmap_devmem_setup(9F) in response to mmap(2), duplicated by fork(2), or explicitly invalidated by a call to devmap_unload(9F).

- **handle**: Mapping handle of the mapping that was accessed by a user process.
- **devprivate**: Pointer to the driver private data associated with the mapping.
- **offset**: Offset within the mapping that was accessed.
- **len**: Length in bytes of the memory being accessed.
- **type**: Type of access operation.
- **rw**: Specifies the direction of access.

The system expects devmap_access(9E) to call either devmap_do_ctxmgt(9F) or devmap_default_access(9F) to load the memory address translations before it returns. For mappings that support context switching, the device driver should call devmap_do_ctxmgt(9F). This routine is passed all parameters from devmap_access(9E), as well as a pointer to the driver entry point devmap_contextmgt(9E), which handles the context switching. For mappings that do not support context switching, the driver should call devmap_default_access(9F), whose only purpose is to call devmap_load(9F) to load the user translation.

Example 13–2 shows an example of a devmap_access(9E) entry point. The mapping is divided into two regions. The region starting at offset OFF_CTXMG with a length of CTXMGTL_SIZE bytes supports context management. The rest of the mapping supports default access.

EXAMPLE 13–2 devmap_access(9E) Routine

```c
#define OFF_CTXMG 0
#define CTXMGTL_SIZE 0x20000
```
static int
xxdevmap_access(devmap_cookie_t handle, void *devprivate,
    offset_t off, size_t len, uint_t type, uint_t rw)
{
    offset_t diff;
    int error;
    if ((diff = off - OFF_CTXMG) >= 0 && diff < CTXMGT_SIZE) {
        error = devmap_do_ctxmgt(handle, devprivate, off,
            len, type, rw, xxdevmap_contextmgt);
    } else {
        error = devmap_default_access(handle, devprivate,
            off, len, type, rw);
    }
    return (error);
}

devmap_contextmgt() Entry Point

The syntax for devmap_contextmgt(9E) is:

int xxdevmap_contextmgt(devmap_cookie_t handle, void *devprivate,
    offset_t offset, size_t len, uint_t type, uint_t rw);

In general, devmap_contextmgt() should call devmap_unload(9F), with the
handle of the mapping that currently has access to the device, to invalidate the
translations for that mapping. This ensures that a call to devmap_access(9E) occurs
for the current mapping the next time it is accessed. To validate the mapping
translations for the mapping that caused the access event to occur, the driver must
restore the device context for the process requesting access and call devmap_load(9F)
on the handle of the mapping that generated the call to this entry point.

Accesses to portions of mappings that have had their mapping translations validated
by a call to devmap_load() do not generate a call to devmap_access(). A
subsequent call to devmap_unload() invalidates the mapping translations and
allows devmap_access() to be called again.

If either devmap_load() or devmap_unload() returns an error,
devmap_contextmgt() should immediately return that error. If the device driver
encounters a hardware failure while restoring a device context, a -1 should be
returned. Otherwise, after successfully handling the access request,
devmap_contextmgt() should return zero. A return of other than zero from
devmap_contextmgt() will cause a SIGBUS or SIGSEGV to be sent to the process.

Example 13-3 shows how to manage a one-page device context.
**Note** – `xxctxsave()` and `xxctxrestore()` are device-dependent context save and restore functions. `xxctxsave()` reads data from the registers using the Solaris 9 DDI/DKI data access routines and saves it in the soft state structure. `xxctxrestore()` takes data saved in the soft state structure and writes it to device registers using the Solaris 9 DDI/DKI data access routines.

---

**EXAMPLE 13-3** `devmap_contextmgt(9E)` Routine

```c
static int
xxdevmap_contextmgt(devmap_cookie_t handle, void *devprivate,
    offset_t off, size_t len, uint_t type, uint_t rw)
{
    int error;
    struct xxctx *ctxp = devprivate;
    struct xxstate *xsp = ctxp->xsp;
    mutex_enter(&xsp->ctx_lock);
    /* unload mapping for current context */
    if (xsp->current_ctx != NULL) {
        if ((error = devmap_unload(xsp->current_ctx->handle,
            off, len)) != 0) {
            xsp->current_ctx = NULL;
            mutex_exit(&xsp->ctx_lock);
            return (error);
        }
    }
    /* Switch device context - device dependent */
    if (xxctxsave(xsp->current_ctx, off, len) < 0) {
        xsp->current_ctx = NULL;
        mutex_exit(&xsp->ctx_lock);
        return (-1);
    }
    if (xxctxrestore(ctxp, off, len) < 0) {
        xsp->current_ctx = NULL;
        mutex_exit(&xsp->ctx_lock);
        return (-1);
    }
    xsp->current_ctx = ctxp;
    /* establish mapping for new context and return */
    error = devmap_load(handle, off, len, type, rw);
    if (error)
        xsp->current_ctx = NULL;
    mutex_exit(&xsp->ctx_lock);
    return (error);
}
```

---

**devmap_dup()** Entry Point

The syntax for `devmap_dup(9E)` is:
int xxdevmap_dup(devmap_cookie_t handle, void *devprivate,
                devmap_cookie_t new_handle, void **new_devprivate);

This entry point is called when a device mapping is duplicated, for example, by a user process calling fork(2). The driver is expected to generate new driver private data for the new mapping.

handle 
Mapping handle of the mapping being duplicated

new_handle 
Mapping handle of the mapping that was duplicated

devprivate 
Pointer to the driver private data associated with the mapping being duplicated

*new_devprivate 
Should be set to point to the new driver private data for the new mapping

Mappings created with devmap_dup() will, by default, have their mapping translations invalidated. This will force a call to the devmap_access(9E) entry point the first time the mapping is accessed.

Example 13–4 shows a devmap_dup() routine.

EXAMPLE 13–4 devmap_dup(9E) Routine

static int
xxdevmap_dup(devmap_cookie_t handle, void *devprivate,
          devmap_cookie_t new_handle, void **new_devprivate)
{
    struct xxctx *ctxp = devprivate;
    struct xxstate *xsp = ctxp->xsp;
    struct xxctx *newctx;
    /* Create a new context for the duplicated mapping */
    newctx = kmem_alloc(sizeof (struct xxctx), KM_SLEEP);
    newctx->xsp = xsp;
    newctx->handle = new_handle;
    newctx->offset = ctxp->offset;
    newctx->flags = ctxp->flags;
    newctx->len = ctxp->len;
    mutex_enter(&xsp->ctx_lock);
    if (ctxp->flags & MAP_PRIVATE) {
        newctx->context = kmem_alloc(XXCTX_SIZE, KM_SLEEP);
        bcopy(ctxp->context, newctx->context, XXCTX_SIZE);
    } else {
        newctx->context = xsp->ctx_shared;
    }
    mutex_exit(&xsp->ctx_lock);
    *new_devprivate = newctx;
    return(0);
}
devmap_unmap() Entry Point

The syntax for devmap_unmap() is as follows:

```c
void xxdevmap_unmap(devmap_cookie_t handle, void *devprivate,
    offset_t off, size_t len, devmap_cookie_t new_handle1,
    void **new_devprivate1, devmap_cookie_t new_handle2,
    void **new_devprivate2);
```

This entry point is called when a mapping is unmapped. This can be caused by a user process exiting or calling the munmap(2) system call.

- **handle**: Mapping handle of the mapping being freed.
- **devprivate**: Pointer to the driver private data associated with the mapping.
- **off**: Offset within the logical device memory at which the unmapping begins.
- **len**: Length in bytes of the memory being unmapped.
- **new_handle1**: Handle that the system uses to describe the new region that ends at `off - 1`. `new_handle1` may be `NULL`.
- **new_devprivate1**: Pointer to be filled in by the driver with the driver-private mapping data for the new region that ends at `off - 1`. It is ignored if `new_handle1` is `NULL`.
- **new_handle2**: Handle that the system uses to describe the new region that begins at `off + len`. `new_handle2` may be `NULL`.
- **new_devprivate2**: Pointer to be filled in by the driver with the driver-private mapping data for the new region that begins at `off + len`. It is ignored if `new_handle2` is `NULL`.

The devmap_unmap() routine is expected to free any driver private resources that were allocated when this mapping was created, either by devmap_map(9E) or by devmap_dup(9E). If only a part of the mapping is being unmapped, the driver must allocate a new private data for the remaining mapping before freeing the old private data. There is no need to call devmap_unload(9F) on the handle of the mapping being freed, even if it is the mapping with the valid translations. However, to prevent future problems in devmap_access(9E), the device driver should make sure that its representation of the current mapping is set to "no current mapping".

Example 13-5 shows an example of a devmap_unmap() routine.

**EXAMPLE 13-5 devmap_unmap(9E) Routine**

```c
static void
xxdevmap_unmap(devmap_cookie_t handle, void *devprivate,
    offset_t off, size_t len, devmap_cookie_t new_handle1,
    void **new_devprivate1, devmap_cookie_t new_handle2,
    void **new_devprivate2)
{
```
EXAMPLE 13-5 devmap_unmap() Routine  (Continued)

```c
struct xxctx *ctxp = devprivate;
struct xxstate *xsp = ctxp->xsp;
mutex_enter(&xsp->ctx_lock);

/*
 * If new_handle1 is not NULL, we are unmapping
 * at the end of the mapping.
 */
if (new_handle1 != NULL) {
    /* Create a new context structure for the mapping */
    newctx = kmem_alloc(sizeof (struct xxctx), KM_SLEEP);
    newctx->xsp = xsp;
    if (ctxp->flags & MAP_PRIVATE) {
        /* allocate memory for the private context */
        /* and copy it */
        newctx->context = kmem_alloc(XXCTX_SIZE, KM_SLEEP);
        bcopy(ctxp->context, newctx->context, XXCTX_SIZE);
    } else {
        /* point to the shared context */
        newctx->context = xsp->ctx_shared;
    }
    newctx->handle = new_handle1;
    newctx->offset = ctxp->offset;
    newctx->len = off - ctxp->offset;
    *new_devprivate1 = newctx;
}

/*
 * If new_handle2 is not NULL, we are unmapping
 * at the beginning of the mapping.
 */
if (new_handle2 != NULL) {
    /* Create a new context for the mapping */
    newctx = kmem_alloc(sizeof (struct xxctx), KM_SLEEP);
    newctx->xsp = xsp;
    if (ctxp->flags & MAP_PRIVATE) {
        newctx->context = kmem_alloc(XXCTX_SIZE, KM_SLEEP);
        bcopy(ctxp->context, newctx->context, XXCTX_SIZE);
    } else {
        newctx->context = xsp->ctx_shared;
    }
    newctx->handle = new_handle2;
    newctx->offset = off + len;
    newctx->flags = ctxp->flags;
    newctx->len = ctxp->len - (off + len - ctxp->off);
    *new_devprivate2 = newctx;
}
if (xsp->current_ctx == ctxp)
    xsp->current_ctx = NULL;
mutex_exit(&xsp->ctx_lock);
if (ctxp->flags & MAP_PRIVATE)
    kmem_free(ctxp->context, XXCTX_SIZE);
    kmem_free(ctxp, sizeof (struct xxctx));
```

Chapter 13 • Device Context Management  217
Associating User Mappings With Driver Notifications

When a user process requests a mapping to a device with mmap(2), the driver’s segmap(9E) entry point is called. The driver must use ddi_devmap_segmap(9F) or devmap_setup(9F) when setting up the memory mapping if it needs to manage device contexts. Both functions will call the driver’s devmap(9E) entry point, which uses devmap_devmem_setup(9F) to associate the device memory with the user mapping. See Chapter 12 for details on how to map device memory.

For the driver to get notifications on accesses to the user mapping, it has to inform the system of the devmap_callback_ctl(9S) entry points. It does this by providing a pointer to a devmap_callback_ctl(9S) structure to devmap_devmem_setup(9F). A devmap_callback_ctl(9S) structure describes a set of context management entry points that are called by the system to notify a device driver to manage events on the device mappings.

The system associates each mapping with a mapping handle. This handle is passed to each of the context management entry points. The mapping handle can be used to invalidate and validate the mapping translations. If the driver invalidate(s) the mapping translations, it will be notified of any future access to the mapping. If the driver validate(s) the mapping translations, it will no longer be notified of accesses to the mapping. Mappings are always created with the mapping translations invalidated so that the driver will be notified on first access to the mapping.

Example 13–6 shows how to set up a mapping using the device context management interfaces.

EXAMPLE 13–6 devmap(9E) Entry Point With Context Management Support

```c
static struct devmap_callback_ctl xx_callback_ctl = {
    DEVMAP_OPS_REV, xxdevmap_map, xxdevmap_access,
    xxdevmap_dup, xxdevmap_unmap
};

static int
xxdevmap(dev_t dev, devmap_cookie_t handle, offset_t off,
    size_t len, size_t *maplen, uint_t model)
{
    struct xxstate *xsp;
    uint_t rnumber;
    int error;
```
EXAMPLE 13–6 devmap(9E) Entry Point With Context Management Support  (Continued)

```c
/* Setup data access attribute structure */
struct ddi_device_acc_attr xx_acc_attr = {
    DDI_DEVICE_ATTR_V0,
    DDI_NEVERSWAP_ACC,
    DDI_STRICTORDER_ACC
};
xsp = ddi_get_soft_state(statep, getminor(dev));
if (xsp == NULL)
    return (ENXIO);
len = ptob(btopr(len));
rnumber = 0;
/* Set up the device mapping */
error = devmap_devmem_setup(handle, xsp->dip, &xx_callback_ctl,
rnumber, off, len, PROT_ALL, 0, &xx_acc_attr);
*maplen = len;
return (error);
```

Managing Mapping Accesses

The device driver is notified when a user process accesses an address in the memory-mapped region that does not have valid mapping translations. When the access event occurs, the mapping translations of the process that currently has access to the device must be invalidated. The device context of the process requesting access to the device must be restored, and the translations of the mapping of the process requesting access must be validated.

The functions `devmap_load(9F)` and `devmap_unload(9F)` are used to validate and invalidate mapping translations.

**devmap_load() Entry Point**

The syntax for `devmap_load(9F)` is:

```c
int devmap_load(devmap_cookie_t handle, offset_t offset,
    size_t len, uint_t type, uint_t rw);
```

`devmap_load()` validates the mapping translations for the pages of the mapping specified by handle, offset, and len. By validating the mapping translations for these pages, the driver is telling the system not to intercept accesses to these pages of the mapping and to allow accesses to proceed without notifying the device driver.
devmap_load() must be called with the offset and the handle of the mapping that generated the access event for the access to complete. If devmap_load(9F) is not called on this handle, the mapping translations will not be validated, and the process will receive a SIGBUS.

devmap_unload() Entry Point

The syntax for devmap_unload(9F) is:

```c
int devmap_unload(devmap_cookie_t handle, offset_t offset, size_t len);
```

devmap_unload() invalidates the mapping translations for the pages of the mapping specified by handle, offset, and len. By invalidating the mapping translations for these pages, the device driver is telling the system to intercept accesses to these pages of the mapping and notify the device driver the next time these pages of the mapping are accessed by calling the devmap_access(9E) entry point.

For both functions, requests affect the entire page containing the offset and all pages up to and including the entire page containing the last byte, as indicated by offset + len. The device driver must ensure that for each page of device memory being mapped only one process has valid translations at any one time.

Both functions return zero if they are successful. If, however, there was an error in validating or invalidating the mapping translations, that error is returned to the device driver. The device driver must return this error to the system.
SCSI Target Drivers

The Solaris DDI/DKI divides the software interface to SCSI devices into two major parts: target drivers and host bus adapter (HBA) drivers. Target refers to a driver for a device on a SCSI bus, such as a disk or a tape drive. Host bus adapter refers to the driver for the SCSI controller on the host machine. SCSA defines the interface between these two components. This chapter discusses target drivers only. See Chapter 15 for information on host bus adapter drivers.

Note – The terms “host bus adapter” or “HBA” used in this manual are equivalent to the phrase “host adapter” defined in SCSI specifications.

This chapter provides information on the following subjects:

- “Introduction to Target Drivers” on page 221
- “Sun Common SCSI Architecture Overview” on page 222
- “Hardware Configuration File” on page 225
- “Declarations and Data Structures” on page 226
- “Autoconfiguration for SCSI Target Drivers” on page 229
- “Resource Allocation” on page 234
- “Building and Transporting a Command” on page 237
- “SCSI Options” on page 244

Introduction to Target Drivers

Target drivers can be either character or block device drivers, depending on the device. Drivers for tape drives are usually character device drivers, while disks are handled by block device drivers. This chapter describes how to write a SCSI target driver and discusses the additional requirements that SCSA places on block and character drivers for SCSI target devices.
The following reference documents provide supplemental information needed by the designers of target drivers and host bus adapter drivers.

Also refer to the SCSI command specification for the target device, provided by the hardware vendor.

### Sun Common SCSI Architecture Overview

The Sun Common SCSI Architecture (SCSA) is the Solaris DDI/DKI programming interface for the transmission of SCSI commands from a target driver to a host bus adapter driver. This interface is independent of the type of host bus adapter hardware, the platform, the processor architecture, and the SCSI command being transported across the interface.

By conforming to the SCSA, the target driver can pass any SCSI command to a target device without knowledge of the hardware implementation of the host bus adapter.

The SCSA conceptually separates building the SCSI command (by the target driver) from transporting the SCSI command and data across the SCSI bus. The architecture defines the software interface between high-level and low-level software components. The higher level software component consists of one or more SCSI target drivers, which translate I/O requests into SCSI commands appropriate for the peripheral device. Figure 14–1 illustrates the SCSI architecture.
The lower-level software component consists of a SCSA interface layer and one or more host bus adapter drivers. The target driver is responsible for the generation of the proper SCSI commands required to execute the desired function and for processing the results.

**General Flow of Control**

Assuming no transport errors occur, the following steps describe the general flow of control for a read or write request.

1. The target driver's read(9E) or write(9E) entry point is invoked. physio(9F) is used to lock down memory, prepare a **buf** structure, and call the strategy routine.

2. The target driver's strategy(9E) routine checks the request and allocates a **scsi_pkt**(9S) using scsi_init_pkt(9F). The target driver initializes the packet and sets the SCSI command descriptor block (CDB) using the scsi_setup_cdb(9F) function. The target driver also specifies a timeout and provides a pointer to a callback function, which is called by the host bus adapter driver on completion of the command. The **buf**(9S) pointer should be saved in the SCSI packet's target-private space.

3. The target driver submits the packet to the host bus adapter driver using scsi_transport(9F). The target driver is then free to accept other requests. The target driver should not access the packet while it is in transport. If either the host bus adapter driver or the target supports queueing, new requests can be submitted while the packet is in transport.
4. As soon as the SCSI bus is free and the target not busy, the host bus adapter driver selects the target and passes the CDB. The target executes the command and performs the requested data transfers.

5. After the target sends completion status and the command completes, the host bus adapter driver notifies the target driver by calling the completion function that was specified in the SCSI packet. At this time the host bus adapter driver is no longer responsible for the packet, and the target driver has regained ownership of the packet.

6. The SCSI packet’s completion routine analyzes the returned information and determines whether the SCSI operation was successful. If a failure has occurred, the target driver retries the command by calling `scsi_transport(9F)` again. If the host bus adapter driver does not support auto request sense, the target driver must submit a request sense packet to retrieve the sense data in the event of a check condition.

7. If either the command was completed successfully or cannot be retried, the target driver calls `scsi_destroy_pkt(9F)`, which synchronizes the data and frees the packet. If the target driver needs to access the data before freeing the packet, it calls `scsi_sync_pkt(9F)`.

8. Finally, the target driver notifies the application program that originally requested the read or write that the transaction is complete, either by returning from the `read(9E)` entry point in the driver (for a character device) or indirectly through `biodone(9F)`.

SCSA allows the execution of many of such operations, both overlapped and queued, at various points in the process. The model places the management of system resources on the host bus adapter driver. The software interface enables the execution of target driver functions on host bus adapter drivers using SCSI bus adapters of varying degrees of sophistication.

**SCSA Functions**

SCSA defines functions to manage the allocation and freeing of resources, the sensing and setting of control states, and the transport of SCSI commands. These functions are listed in Table 14–1.

Note – If your driver needs to work with a SCSI-1 device, use the makecom(9F) function.

Hardware Configuration File

Because SCSI devices are not self-identifying, a hardware configuration file is required for a target driver (see driver.conf(4) and scsi(4) for details). A typical configuration file looks like this:

    name="xx" class="scsi" target=2 lun=0;

The system reads the file during autoconfiguration and uses the class property to identify the driver’s possible parent. The system then attempts to attach the driver to any parent driver that is of class scsi. All host bus adapter drivers are of this class. Using the class property rather than the parent property enables the target driver to be attached to any host bus adapter driver that finds the expected device at the specified target and lun IDs. The target driver is responsible for verifying this in its probe(9E) routine.
Declarations and Data Structures

Target drivers must include the header file `<sys/scsi/scsi.h>`.

SCSI target drivers must use the following command to generate a binary module:

```bash
ld -r xx xx.o -N"misc/scsi"
```

**scsi_device Structure**

The host bus adapter driver allocates and initializes a `scsi_device(9S)` structure for the target driver before either the `probe(9E)` or `attach(9E)` routine is called. This structure stores information about each SCSI logical unit, including pointers to information areas that contain both generic and device-specific information. There is one `scsi_device(9S)` structure for each logical unit attached to the system. The target driver can retrieve a pointer to this structure by calling `ddi_get_driver_private(9F)`.

---

**Caution** – Because the host bus adapter driver uses the private field in the target device’s `dev_info` structure, target drivers must not use `ddi_set_driver_private(9F)`.

---

The `scsi_device(9S)` structure contains the following fields:

```c
struct scsi_device {
    struct scsi_address sd_address; /* opaque address */
    dev_info_t *sd_dev; /* device node */
    kmutex_t sd_mutex;
    void *sd_reserved;
    struct scsi_inquiry *sd_inq;
    struct scsi_extended_sense *sd_sense;
    caddr_t sd_private;
};
```

- `sd_address` Data structure that is passed to the SCSI resource allocation routines.
- `sd_dev` Pointer to the target’s `dev_info` structure.
- `sd_mutex` Mutex for use by the target driver. This is initialized by the host bus adapter driver and can be used by the target driver as a per-device mutex. Do not hold this mutex across a call to `scsi_transport(9F)` or `scsi_poll(9F)`. See Chapter 3 for more information on mutexes.
sd_inq  Pointer for the target device’s SCSI inquiry data. The 
scsi_probe(9F) routine allocates a buffer, fills it in with inquiry 
data, and attaches it to this field.

sd_sense  Pointer to a buffer to contain SCSI request sense data from the 
device. The target driver must allocate and manage this buffer itself; 
see “attach() Entry Point (SCSI Target Drivers)” on page 231.

sd_private  Pointer field for use by the target driver. It is commonly used 
to store a pointer to a private target driver state structure.

**scsi_pkt Structure**

The scsi_pkt structure contains the following fields:

```c
struct scsi_pkt {
    opaque_t pkt_ha_private; /* private data for host adapter */
    struct scsi_address pkt_address; /* destination packet is for */
    opaque_t pkt_private; /* private data for target driver */
    void (*pkt_comp)(struct scsi_pkt *); /* completion routine */
    uint_t pkt_flags; /* flags */
    int pkt_time; /* time allotted to complete command */
    uchar_t *pkt_scbp; /* pointer to status block */
    uchar_t *pkt_cdbp; /* pointer to command block */
    ssize_t pkt_resid; /* data bytes not transferred */
    uint_t pkt_state; /* state of command */
    uint_t pkt_statistics; /* statistics */
    uchar_t pkt_reason; /* reason completion called */
};
```

pkt_address  Target device’s address set by scsi_init_pkt(9F).

pkt_private  Place to store private data for the target driver. It is commonly 
used to save the buf(9S) pointer for the command.

pkt_comp  Address of the completion routine. The host bus adapter driver 
calls this routine when it has transported the command. This does 
not mean that the command succeeded; the target might have been 
busy or might not have responded before the time-out time 
elapsed (see the description for pkt_time field). The target driver 
must supply a valid value in this field, though it can be NULL if the 
driver does not want to be notified.

**Note**—There are two different SCSI callback routines. The pkt_comp field identifies a 
completion callback routine, which is called when the host bus adapter completes its 
processing. There is also a resource callback routine, called when currently unavailable 
resources are likely to be available (as in scsi_init_pkt(9F)).
**pkt_flags**  Provides additional control information, for example, to transport the command without disconnect privileges (FLAG_NODISCON) or to disable callbacks (FLAG_NOINTR). See the scsi_pkt(9S) man page for details.

**pkt_time**  Time-out value (in seconds). If the command is not completed within this time, the host bus adapter calls the completion routine with pkt_reason set to CMD_TIMEOUT. The target driver should set this field to longer than the maximum time the command might take. If the timeout is zero, no timeout is requested. Timeout starts when the command is transmitted on the SCSI bus.

**pkt_scbp**  Pointer to the SCSI status completion block; this is filled in by the host bus adapter driver.

**pkt_cdbp**  Pointer to the SCSI command descriptor block, the actual command to be sent to the target device. The host bus adapter driver does not interpret this field. The target driver must fill it in with a command that the target device can process.

**pkt_resid**  Residual of the operation. When allocating DMA resources for a command scsi_init_pkt(9F), pkt_resid indicates the number of bytes for which DMA resources could not be allocated because of DMA hardware scatter-gather or other device limitations. After command transport, pkt_resid indicates the number of data bytes not transferred; this is filled in by the host bus adapter driver before the completion routine is called.

**pkt_state**  Indicates the state of the command. The host bus adapter driver fills in this field as the command progresses. One bit is set in this field for each of the five following command states:

- **STATE_GOT_BUS** – Acquired the bus
- **STATE_GOT_TARGET** – Selected the target
- **STATE_SENT_CMD** – Sent the command
- **STATE_XFERRED_DATA** – Transferred data (if appropriate)
- **STATE_GOT_STATUS** – Received status from the device

**pkt_statistics**  Contains transport-related statistics set by the host bus adapter driver.

**pkt_reason**  Gives the reason the completion routine was called. The main function of the completion routine is to decode this field and take the appropriate action. If the command completed—in other words, if there were no transport errors—this field is set to CMD_CMPLT; other values in this field indicate an error. After a command is completed, the target driver should examine the pkt_scbp field for a check condition status. See the scsi_pkt(9S) man page for more information.
Autoconfiguration for SCSI Target Drivers

SCSI target drivers must implement the standard autoconfiguration routines
_init(9E), _fini(9E), and _info(9E). See “Loadable Driver Interfaces” on page 69
for more information.

probe(9E), attach(9E), detach(9E), and getinfo(9E) are also required, but they
must perform SCSI (and SCSA) specific processing.

probe() Entry Point (SCSI Target Drivers)

SCSI target devices are not self-identifying, so target drivers must have a probe(9E)
routine. This routine must determine whether the expected type of device is present
and responding.

The general structure and return codes of the probe(9E) routine are the same as those
of other device drivers. SCSI target drivers must use the scsi_probe(9F) routine in
their probe(9E) entry point. scsi_probe(9F) sends a SCSI inquiry command to the
device and returns a code indicating the result. If the SCSI inquiry command is
successful, scsi_probe(9F) allocates a scsi_inquiry(9S) structure and fills it in
with the device's inquiry data. Upon return from scsi_probe(9F), the sd_inq field
of the scsi_device(9S) structure points to this scsi_inquiry(9S) structure.

Because probe(9E) must be stateless, the target driver must call scsi_unprobe(9F)
before probe(9E) returns, even if scsi_probe(9F) fails.

Example 14-1 shows a typical probe(9E) routine. It retrieves its scsi_device(9S)
structure from the private field of its dev_info structure. It also retrieves the device's
SCSI target and logical unit numbers so that it can print them in messages. The
probe(9E) routine then calls scsi_probe(9F) to verify that the expected device (a
printer in this case) is present.

If scsi_probe(9F) succeeds, it has attached the device's SCSI inquiry data in a
scsi_inquiry(9S) structure to the sd_inq field of the scsi_device(9S) structure.
The driver can then determine if the device type is a printer (reported in the
inq_dtype field). If it is, the type is reported with scsi_log(9F), using
scsi_dname(9F) to convert the device type into a string.

EXAMPLE 14-1 SCSI Target Driver probe(9E) Routine

            break;
        case SCSIPROBE_EXISTS:
            /*
            * There is a device at the target/lun address. Check
            * inq_dtype to make sure that it is the right device
            * type. See scsi_inquiry(9S)for possible device types.
            */
            switch (sdp->sd_inq->inq_dtype) {
                case DTYPE_PRINTER:
                    scsi_log(sdp, "xx", SCSI_DEBUG,
                        "found %s device at target%d, lun%d\n",
                        scsi_dname((int)sdp->sd_inq->inq_dtype),
                        target, lun);
                    rval = DDI_PROBE_SUCCESS;
                    break;
                case DTYPE_NOTPRESENT:
                    default:
                        rval = DDI_PROBE_FAILURE;
                        break;
            }  
    }
}
```
EXAMPLE 14–1 SCSI Target Driver probe(9E) Routine  

(Continued)

    
    }
    scsi_unprobe(sdp);
    return (rval);
}

A more thorough probe(9E) routine could also check other fields of the 
scsi_inquiry(9S) structure as necessary to make sure that the device is of the type 
expected by a particular driver.

attach() Entry Point (SCSI Target Drivers)

After the probe(9E) routine has verified that the expected device is present, 
attach(9E) is called. This routine allocates and initializes any per-instance data, 
creates minor device node information, and restores the hardware state of a device 
when the device or the system has been suspended. (See “The attach() Entry Point” 
on page 76 for details.) In addition to these steps, a SCSI target driver again calls 
scsi_probe(9F) to retrieve the device’s inquiry data and also creates a SCSI request 
sense packet. If the attach is successful, the attach() function should not call 
scsi_unprobe(9F).

Three routines are used to create the request sense packet: 
scsi_alloc_consistent_buf(9F), scsi_init_pkt(9F), and 
scsi_setup_cdb(9F). scsi_alloc_consistent_buf(9F) allocates a buffer 
suitable for consistent DMA and returns a pointer to a buf(9S) structure. The 
advantage of a consistent buffer is that no explicit synchronization of the data is 
required. In other words, the target driver can access the data after the callback. The 
sd_sense element of the device’s scsi_device(9S) structure must be initialized 
with the address of the sense buffer. scsi_init_pkt(9F) creates and partially 
initializes a scsi_pkt(9S) structure. scsi_setup_cdb(9F) creates a SCSI command 
descriptor block, in this case creating a SCSI request sense command.

Note that since a SCSI device is not self-identifying and does not have a reg property, 
the driver must set the pm-hardware-state property to inform the framework that 
this device needs to be suspended and resumed.

Example 14–2 shows the SCSI target driver’s attach() routine.

sdp->sd_private = (caddr_t)xsp;
xsp->sdp = sdp;
/*
call scsi_probe(9F) again to get and validate inquiry data
*/
bp = scsi_alloc_consistent_buf(&sdp->sd_address, NULL, SENSE_LENGTH, B_READ, NULL_FUNC, NULL);
if (bp == NULL)
    goto failed;
/*
* Create a Request Sense scsi_pkt(9S) structure.
*/
rqpkt = scsi_init_pkt(&sdp->sd_address, NULL, bp, CDB_GROUP0, 1, 0, PKT_CONSISTENT, NULL_FUNC, NULL);
if (rqpkt == NULL)
    goto failed;
/*
* scsi_alloc_consistent_buf(9F) returned a buf(9S) structure.  
* The actual buffer address is in b_un.b_addr.
*/
sdp->sd_sense = (struct scsi_extended_sense *)bp->b_un.b_addr;
/*
* Create a Group0 CDB for the Request Sense command
*/
if (scsi_setup_cdb((union scsi_cdb *)rqpkt->pkt_cdbp, SCMD_REQUEST_SENSE, 0, SENSE_LENGTH, 0) == 0)
    goto failed;
EXAMPLE 14-2  SCSI Target Driver attach(9E) Routine  (Continued)

* Fill in the rest of the scsi_pkt structure.
* xxcallback() is the private command completion routine.
*/
rgpkt->pkt_comp = xxcallback;
rgpkt->pkt_time = 30; /* 30 second command timeout */
rgpkt->pkt_flags |= FLAG_SENSING;
xsp->rqs = rgpkt;
xsp->rqsbuf = bp;
    create minor nodes, report device, and do any other initialization
/*
* Since the device does not have the 'reg' property,
* cpr will not call its DDI_SUSPEND/DDI_RESUME entries.
* The following code is to tell cpr that this device
* needs to be suspended and resumed.
*/
(void) ddi_prop_update_string(device, dip,
    "pm-hardware-state", "needs-suspend-resume");
xsp->open = 0;
return (DDI_SUCCESS);
failed:
if (bp)
    scsi_free_consistent_buf(bp);
if (rgpkt)
    scsi_destroy_pkt(rgpkt);
sdp->sd_private = (caddr_t)NULL;
sdp->sd_sense = NULL;
scsi_unprobe(sdp);
    free any other resources, such as the state structure
return (DDI_FAILURE);
}

detach()  Entry Point (SCSI Target Drivers)

The detach(9E) entry point is the inverse of attach(9E); it must free all resources
that were allocated in attach(). If successful, the detach should call
scsi_unprobe(9F). Example 14–3 shows a target driver detach() routine.

EXAMPLE 14-3  SCSI Target Driver detach(9E) Routine

static int
xxdetach(dev_info_t *dip, ddi_detach_cmd_t cmd)
{
    struct xxstate *xsp;
    switch (cmd) {
    case DDI_DETACH:
        normal detach(9E) operations, such as getting a
        pointer to the state structure
        ...
        scsi_free_consistent_buf(xsp->rqsbuf);
EXAMPLE 14–3 SCSI Target Driver detach(9E) Routine  (Continued)

```c
scsi_destroy_pkt(xsp->rqs);
xsp->sd->sd_private = (caddr_t)NULL;
xsp->sd->sd_sense = NULL;
scci_unprobe(xsp->sd);
  remove minor nodes
  free resources, such as the state structure and properties
  return (DDI_SUCCESS);

case DDI_SUSPEND:
  For information, see Chapter 9
default:
  return (DDI_FAILURE);
```

getinfo() Entry Point (SCSI Target Drivers)

The getinfo(9E) routine for SCSI target drivers is much the same as for other drivers (see “The getinfo() Entry Point” on page 83 for more information on DDI_INFO_DEVT2INSTANCE case). However, in the DDI_INFO_DEVT2DEVINFO case of the getinfo() routine, the target driver must return a pointer to its dev_info node. This pointer can be saved in the driver state structure or can be retrieved from the sd_dev field of the scsi_device(9S) structure. Example 14–4 shows an alternative SCSI target driver getinfo() code fragment.

EXAMPLE 14–4 Alternative SCSI Target Driver getinfo(9E) Code Fragment

```c
... case DDI_INFO_DEVT2DEVINFO:
  dev = (dev_t)arg;
  instance = getminor(dev);
  xsp = ddi_get Soft_state(statep, instance);
  if (xsp == NULL)
    return (DDI_FAILURE);
  *result = (void *)xsp->sd->sd_dev;
  return (DDI_SUCCESS);
...```

Resource Allocation

To send a SCSI command to the device, the target driver must create and initialize a scsi_pkt(9S) structure and pass it to the host bus adapter driver.
scsi_init_pkt() Function

The scsi_init_pkt(9F) routine allocates and zeros a scsi_pkt(9S) structure; it also sets pointers to pkt_private, *pkt_scbp, and *pkt_cdbp. Additionally, it provides a callback mechanism to handle the case where resources are not available. This function has the following syntax:

```c
struct scsi_pkt *scsi_init_pkt(struct scsi_address *ap,  
   struct scsi_pkt *pktp, struct buf *bp, int cmdlen,  
   int statuslen, int privatelen, int flags,  
   int (*callback)(caddr_t), caddr_t arg)
```

- **ap**
  Pointer to a scsi_address structure. This is the sd_address field of the device’s scsi_device(9S) structure.

- **pktp**
  Pointer to the scsi_pkt(9S) structure to be initialized. If this is set to NULL, a new packet is allocated.

- **bp**
  Pointer to a buf(9S) structure. If this is non-NULL and contains a valid byte count, DMA resources are allocated.

- **cmdlen**
  Length of the SCSI command descriptor block in bytes.

- **statuslen**
  Required length of the SCSI status completion block in bytes.

- **privatelen**
  Number of bytes to allocate for the pkt_private field.

- **flags**
  Set of flags. Possible bits include:
  ```
  • PKT_CONSISTENT – This bit must be set if the DMA buffer was allocated using scsi_alloc_consistent_buf(9F). In this case, the host bus adapter driver guarantees that the data transfer is properly synchronized before performing the target driver’s command completion callback.
  • PKT_DMA_PARTIAL – This bit can be set if the driver accepts a partial DMA mapping. If set, scsi_init_pkt(9F) allocates DMA resources with the DDI_DMA_PARTIAL flag set. The pkt_resid field of the scsi_pkt(9S) structure can be returned with a nonzero residual, indicating the number of bytes for which scsi_init_pkt(9F) was unable to allocate DMA resources.
  ```

- **callback**
  Specifies the action to take if resources are not available. If set to NULL_FUNC, scsi_init_pkt(9F) returns immediately (returning NULL). If set to SLEEP_FUNC, it does not return until resources are available. Any other valid kernel address is interpreted as the address of a function to be called when resources are likely to be available.

- **arg**
  Parameter to pass to the callback function.

The scsi_init_pkt() routine synchronizes the data prior to transport. If the driver needs to access the data after transport, it should call scsi_sync_pkt(9F) to flush any intermediate caches. The scsi_sync_pkt() routine can be used to synchronize any cached data.
scsi_sync_pkt() Function

If the target driver needs to resubmit the packet after changing the data, `scsi_sync_pkt(9F)` must be called before calling `scsi_transport(9F)`. However, if the target driver does not need to access the data, there is no need to call `scsi_sync_pkt()` after the transport.

scsi_destroy_pkt() Function

The `scsi_destroy_pkt(9F)` routine synchronizes any remaining cached data associated with the packet, if necessary, and then frees the packet and associated command, status, and target driver-private data areas. This routine should be called in the command completion routine.

scsi_alloc_consistent_buf() Function

For most I/O requests, the data buffer passed to the driver entry points is not accessed directly by the driver; it is just passed on to `scsi_init_pkt(9F)`. If a driver sends SCSI commands that operate on buffers that the driver itself examines (such as the SCSI request sense command), the buffers should be DMA consistent. The `scsi_alloc_consistent_buf(9F)` routine allocates a `buf(9S)` structure and a data buffer suitable for DMA-consistent operations. The HBA will perform any necessary synchronization of the buffer before performing the command completion callback.

---

**Caution** – `scsi_alloc_consistent_buf(9F)` uses scarce system resources; use it sparingly.

---

scsi_free_consistent_buf() Function

`scsi_free_consistent_buf(9F)` releases a `buf(9S)` structure and the associated data buffer allocated with `scsi_alloc_consistent_buf(9F)`. See “attach() Entry Point (SCSI Target Drivers)” on page 231 and “detach() Entry Point (SCSI Target Drivers)” on page 233 for examples.
Building and Transporting a Command

The host bus adapter driver is responsible for transmitting the command to the device and handling the low-level SCSI protocol. The `scsi_transport(9F)` routine hands a packet to the host bus adapter driver for transmission. The target driver has the responsibility to create a valid `scsi_pkt(9S)` structure.

Building a Command

The routine `scsi_init_pkt(9F)` allocates space for a SCSI CDB, allocates DMA resources if necessary, and sets the `pkt_flags` field, as shown in this example:

```c
pkt = scsi_init_pkt(&sdp->sd_address, NULL, bp,
                    CDB_GROUP0, 1, 0, 0, SLEEP_FUNC, NULL);
```

This example creates a new packet and allocates DMA resources as specified in the passed `buf(9S)` structure pointer. A SCSI CDB is allocated for a Group 0 (6-byte) command, the `pkt_flags` field is set to zero, but no space is allocated for the `pkt_private` field. This call to `scsi_init_pkt(9F)`, because of the `SLEEP_FUNC` parameter, waits indefinitely for resources if none are currently available.

The next step is to initialize the SCSI CDB, using the `scsi_setup_cdb(9F)` function:

```c
if (scsi_setup_cdb((union scsi_cdb *)pkt->pkt_cdbp,
                   SCMD_READ, bp->b_blkno, bp->b_bcount >> DEV_BSHIFT, 0) == 0)
    goto failed;
```

This example builds a Group 0 command descriptor block and fills in the `pkt_cdbp` field as follows:

- The command itself (byte 0) is set from the parameter (`SCMD_READ`).
- The address field (bits 0-4 of byte 1 and bytes 2 and 3) is set from `bp->b_blkno`.
- The count field (byte 4) is set from the last parameter. In this case it is set to `bp->b_bcount >> DEV_BSHIFT`, where `DEV_BSHIFT` is the byte count of the transfer converted to the number of blocks.

**Note** – `scsi_setup_cdb(9F)` does not support setting a target device’s logical unit number (LUN) in bits 5-7 of byte 1 of the SCSI command block, as defined by SCSI-1. For SCSI-1 devices requiring the LUN bits set in the command block, use `makecom_g0(9F)` (or equivalent) rather than `scsi_setup_cdb(9F)`.
After initializing the SCSI CDB, initialize three other fields in the packet and store as a pointer to the packet in the state structure.

```c
pkt->pkt_private = (opaque_t)bp;
pkt->pkt_comp = xxcallback;
pkt->pkt_time = 30;
xsp->pkt = pkt;
```

The `buf(9S)` pointer is saved in the `pkt_private` field for later use in the completion routine.

## Setting Target Capabilities

The target drivers use `scsi_ifsetcap(9F)` to set the capabilities of the host adapter driver. A `cap` is a name-value pair whose name is a null terminated character string and whose value is an integer. The current value of a capability can be retrieved using `scsi_ifgetcap(9F)`. `scsi_ifsetcap(9F)` allows capabilities to be set for all targets on the bus.

In general, however, setting capabilities of targets that are not owned by the target driver is not recommended and is not universally supported by HBA drivers. Some capabilities (such as disconnect and synchronous) can be set by default by the HBA driver but others might need to be set explicitly by the target driver (wide-xfer or tagged-queueing, for example).

## Transporting a Command

After creating and filling in the `scsi_pkt(9S)` structure, the final step is to hand it to the host bus adapter driver using `scsi_transport(9F):

```c
if (scsi_transport(pkt) != TRAN_ACCEPT) {
    bp->b_resid = bp->b_bcount;
    bioerror(bp, EIO);
    biodone(bp);
}
```

The other return values from `scsi_transport(9F)` are:

- **TRAN_BUSY** – There is already a command in progress for the specified target.
- **TRAN_BADPKT** – The DMA count in the packet was too large, or the host adapter driver rejected this packet for other reasons.
- **TRAN_FATAL_ERROR** – The host adapter driver is unable to accept this packet.
Caution – The mutex sd_mutex in the scsi_device(9S) structure must not be held across a call to scsi_transport(9F).

If scsi_transport(9F) returns TRAN_ACCEPT, the packet is the responsibility of the host bus adapter driver and should not be accessed by the target driver until the command completion routine is called.

**Synchronous scsi_transport() Function**

If FLAG_NOINTR is set in the packet, then scsi_transport(9F) will not return until the command is complete, and no callback will be performed.

Note – Do not use FLAG_NOINTR in interrupt context.

**Command Completion**

Once the host bus adapter driver has done all it can with the command, it invokes the packet’s completion callback routine, passing a pointer to the scsi_pkt(9S) structure as a parameter. The completion routine decodes the packet and takes the appropriate action.

Example 14–5 presents a simple completion callback routine. This code checks for transport failures and gives up rather than retrying the command. If the target is busy, extra code is required to resubmit the command at a later time.

If the command results in a check condition, the target driver needs to send a request sense command unless auto request sense has been enabled.

Otherwise, the command succeeded. If this is the end of processing for the command, it destroys the packet and calls biodone(9F).

In the event of a transport error (such as a bus reset or parity problem), the target driver can resubmit the packet using scsi_transport(9F). There is no need to change any values in the packet prior to resubmitting.

Example 14–5 does not attempt to retry incomplete commands.

Note – Normally, the target driver’s callback function is called in interrupt context. Consequently, the callback function should never sleep.
EXAMPLE 14-5 SCSI Driver Completion Routine

```c
static void
xxcallback(struct scsi_pkt *pkt) {
    struct buf      *bp;
    struct xxstate  *xsp;
    minor_t          instance;
    struct scsi_status *ssp;
    /*
      * Get a pointer to the buf(9S) structure for the command
      * and to the per-instance data structure.
      */
    bp = (struct buf *)pkt->pkt_private;
    instance = getminor(bp->b_edev);
    xsp = ddi_get_soft_state(statep, instance);
    /*
      * Figure out why this callback routine was called
      */
    if (pkt->pkt_reason != CMP_CMPLT) {
        bp->b_resid = bp->b_bcount;
        bioerror(bp, EIO);
        scsi_destroy_pkt(pkt);    /* release resources */
        biodone(bp);               /* notify waiting threads */
    } else { /* Command completed, check status.
              * See scsi_status(9S)
              */
        ssp = (struct scsi_status *)pkt->pkt_scbp;
        if (ssp->sta_busy) {
            error, target busy or reserved
        } else if (ssp->sta_chk) {    /* send a request sense command */
            /*packet completed OK */
            scsi_destroy_pkt(pkt);
            biodone(bp);
        } else {
            bp->b_resid = pkt->pkt_resid;
        }
    }
}
```

Reuse of Packets

A target driver can reuse packets in the following ways:

- Resubmit the packet unchanged.
- Use `scsi_sync_pkt(9F)` to synchronize the data, then process the data in the driver and resubmit.
Free DMA resources, using scsi_dmfree(9F), and pass the pkt pointer to scsi_init_pkt(9F) for binding to a new bp. The target driver is responsible for reinitializing the packet. The CDB has to have the same length as the previous CDB.

If partial DMA was allocated during the first call to scsi_init_pkt(9F), subsequent calls to scsi_init_pkt(9F) can be made for the same packet and bp to adjust the DMA resources to the next portion of the transfer.

Auto-Request Sense Mode

Auto-request sense mode is most desirable if tagged or untagged queuing is used. A contingent allegiance condition is cleared by any subsequent command and, consequently, the sense data is lost. Most HBA drivers will start the next command before performing the target driver callback. Other HBA drivers can use a separate and lower-priority thread to perform the callbacks, which might increase the time needed to notify the target driver that the packet completed with a check condition. In this case, the target driver might not be able to submit a request sense command in time to retrieve the sense data.

To avoid this loss of sense data, the HBA driver, or controller, should issue a request sense command as soon as a check condition has been detected; this mode is known as auto-request sense mode. Note that not all HBA drivers are capable of auto-request sense mode, and some can only operate with auto-request sense mode enabled.

A target driver enables auto-request-sense mode by using scsi_ifsetcap(9F). Example 14–6 shows enabling auto request sense.

**EXAMPLE 14-6 Enabling Auto Request Sense**

```c
static int
xxattach(dev_info_t *dip, ddi_attach_cmd_t cmd)
{
    struct xxstate *xsp;
    struct scsi_device *sdp = (struct scsi_device *)
        ddi_get_driver_private(dip);
    ...
    /*
     * enable auto-request-sense; an auto-request-sense cmd may
     * fail due to a BUSY condition or transport error. Therefore,
     * it is recommended to allocate a separate request sense
     * packet as well.
     * Note that scsi_ifsetcap(9F) may return -1, 0, or 1
     */
    xsp->sdp_arq_enabled =
        ((scsi_ifsetcap(ROUTE, "auto-rqsense", 1, 1) == 1) ? 1 : 0);
    /*
     * if the HBA driver supports auto request sense then the
     */
```
EXAMPLE 14–6 Enabling Auto Request Sense (Continued)

```c
* status blocks should be sizeof (struct scsi_arq_status);
else
* one byte is sufficient
 */
xsp->sdp_cmd_stat_size = (xsp->sdp_arq_enabled ?
    sizeof (struct scsi_arq_status) : 1);
...
```

When a packet is allocated using `scsi_init_pkt(9F)` and auto request sense is desired on this packet, then the target driver must request additional space for the status block to hold the auto request sense structure. The sense length used in the request sense command is `sizeof (struct scsi_extended_sense)`. Auto request sense can be disabled per individual packet by just allocating `sizeof (struct scsi_status)` for the status block.

The packet is submitted using `scsi_transport(9F)` as usual. When a check condition occurs on this packet, the host adapter driver takes the following steps:

- Issues a request sense command if the controller doesn’t have auto-request-sense capability
- Obtains the sense data
- Fills in the `scsi_arq_status` information in the packet’s status block
- Sets `STATE_ARQ_DONE` in the packet’s `pkt_state` field
- Calls the packet’s callback handler (`pkt_comp( )`)

The target driver’s callback routine should verify that sense data is available by checking the `STATE_ARQ_DONE` bit in `pkt_state`, which implies that a check condition has occurred and a request sense has been performed. If auto-request-sense has been temporarily disabled in a packet, there is no guarantee that the sense data can be retrieved at a later time.

The target driver should then verify whether the auto request sense command completed successfully and decode the sense data.

**Dump Handling**

The `dump(9E)` entry point is used to copy a portion of virtual address space directly to the specified device in the case of system failure or checkpoint operation. See the `cpr(7)` and `dump(9E)` man pages. The `dump(9E)` entry point must be capable of performing this operation without the use of interrupts.
The arguments for `dump()` are as follows. `dev` is the device number of the dump device, `addr` is the kernel virtual address at which to start the dump, `blkno` is the first destination block on the device, and `nblk` is the number of blocks to dump.

**EXAMPLE 14-7** dump(9E) Routine

```c
static int
xxdump(dev_t dev, caddr_t addr, daddr_t blkno, int nblk)
{
    struct xxstate *xsp;
    struct buf *bp;
    struct scsi_pkt *pkt;
    int rval;
    int instance;

    instance = getminor(dev);
    xsp = ddi_get_soft_state(statep, instance);

    if (tgt->suspended) {
        (void) ddi_dev_is_needed(DEVINFO(tgt), 0, 1);
    }

    bp = getrbuf(KM_NOSLEEP);
    if (bp == NULL) {
        return (EIO);
    }

    Calculate block number relative to partition

    bp->b_un.b_addr = addr;
    bp->b_ehev = dev;
    bp->b_bcount = nblk * DEV_BSIZE;
    bp->b_flags = B_WRITE | B_BUSY;
    bp->b_blkno = blkno;

    pkt = scsi_init_pkt(ROUTE(tgt), NULL, bp, CDB_GROUP1,
                          sizeof (struct scsi_arg_status),
                          sizeof (struct bst_pkt_private), 0, NULL_FUNC, NULL);
    if (pkt == NULL) {
        freerbuf(bp);
        return (EIO);
    }

    (void) scsi_setup_cdb((union scsi_cdb *)pkt->pkt_cdbp,
                          SCMD_WRITE_G1, blkno, nblk, 0);

    /*
     * while dumping in polled mode, other cmds might complete
     * and these should not be resubmitted. we set the
     * dumping flag here which prevents requeueing cmds.
     */
    tgt->dumping = 1;
    rval = scsi_poll(pkt);
    tgt->dumping = 0;
```

Chapter 14 • SCSI Target Drivers  243
EXAMPLE 14–7 dump(9E) Routine  (Continued)

    scsi_destroy_pkt(pkt);
    freerbuf(bp);

    if (rval != DDI_SUCCESS) {
        rval = EIO;
    }

    return (rval);
}

SCSI Options

SCSA defines a global variable, scsi_options, which can be used for debug and control. The defined bits in scsi_options can be found in the file <sys/scsi/conf/autoconf.h>. The following table describes the use of these bits.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SCSI_OPTIONS_DR</td>
<td>Enables global disconnect/reconnect</td>
</tr>
<tr>
<td>SCSI_OPTIONS_SYNC</td>
<td>Enables global synchronous transfer capability</td>
</tr>
<tr>
<td>SCSI_OPTIONS_LINK</td>
<td>Enables global link support</td>
</tr>
<tr>
<td>SCSI_OPTIONS_PARITY</td>
<td>Enables global parity support</td>
</tr>
<tr>
<td>SCSI_OPTIONS_TAG</td>
<td>Enables global tagged queuing support</td>
</tr>
<tr>
<td>SCSI_OPTIONS_FAST</td>
<td>Enables global FAST SCSI support: 10 Mbytes/sec transfers, as opposed to 5 Mbytes/sec</td>
</tr>
<tr>
<td>SCSI_OPTIONS_FAST20</td>
<td>Enables global FAST20 SCSI support: 20 Mbytes/sec transfers</td>
</tr>
<tr>
<td>SCSI_OPTIONS_FAST40</td>
<td>Enables global FAST40 SCSI support: 40 Mbytes/sec transfers</td>
</tr>
<tr>
<td>SCSI_OPTIONS_FAST80</td>
<td>Enables global FAST80 SCSI support: 80 Mbytes/sec transfers</td>
</tr>
<tr>
<td>SCSI_OPTIONS_WIDE</td>
<td>Enables global WIDE SCSI</td>
</tr>
</tbody>
</table>
**Note** – The setting of `scsi_options` affects all host adapter and target drivers present on the system (as opposed to `scsi_ifsetcap(9F)`). Refer to the `scsi_hba_attach(9F)` man page for information on controlling these options for a particular host adapter.
SCSI Host Bus Adapter Drivers

This chapter contains information on creating SCSI host bus adapter (HBA) drivers and provides sample code illustrating the structure of a typical HBA driver and showing the use of the HBA driver interfaces provided by the Sun Common SCSI Architecture (SCSA). This chapter provides information on the following subjects:

- “Introduction to Host Bus Adapter Drivers” on page 247
- “SCSI Interface” on page 248
- “SCSA HBA Interfaces” on page 250
- “HBA Driver Dependency and Configuration Issues” on page 260
- “SCSA HBA Entry Points” on page 267
- “SCSI HBA Driver Specific Issues” on page 295
- “Support for Queuing” on page 298

Introduction to Host Bus Adapter Drivers

As described in Chapter 14, the Solaris 9 DDI/DKI divides the software interface to SCSI devices into two major parts:

- Target devices and drivers
- Host bus adapter devices and drivers

Target device refers to a device on a SCSI bus, such as a disk or a tape drive. Target driver refers to a software component installed as a device driver. Each target device on a SCSI bus is controlled by one instance of the target driver.
Host bus adapter device refers to HBA hardware, such as an SBus or PCI SCSI adapter card. Host bus adapter driver refers to a software component installed as a device driver, such as the esp driver on a SPARC machine or the ncrs driver on an IA machine, and the isp driver, which works on both. An instance of the HBA driver controls each of its host bus adapter devices configured in the system.

The Sun Common SCSI Architecture (SCSA) defines the interface between these target and HBA components.

**Note** – Understanding SCSI target drivers is an essential prerequisite to writing effective SCSI HBA drivers. For information on SCSI target drivers, see Chapter 14. Target driver developers can also benefit from reading this chapter.

The host bus adapter driver is responsible for:

- Managing host bus adapter hardware
- Accepting SCSI commands from the SCSI target driver
- Transporting the commands to the specified SCSI target device
- Performing any data transfers that the command requires
- Collecting status
- Handling auto-request sense (optional)
- Informing the target driver of command completion (or failure)

### SCSI Interface

SCSA is the Solaris 9 DDI/DKI programming interface for the transmission of SCSI commands from a target driver to a host adapter driver. By conforming to the SCSA, the target driver can pass any combination of SCSI commands and sequences to a target device without knowledge of the hardware implementation of the host adapter. SCSA conceptually separates the building of a SCSI command (by the target driver) from the transporting of the command to and data to and from the SCSI bus (by the HBA driver) for the appropriate target device. SCSA manages the connections between the target and HBA drivers through an HBA transport layer, as shown in the following figure.
The **HBA transport layer** is a software and hardware layer responsible for transporting a SCSI command to a SCSI target device. The HBA driver provides resource allocation, DMA management, and transport services in response to requests made by SCSI target drivers through SCSA. The host adapter driver also manages the host adapter hardware and the SCSI protocols necessary to perform the commands. When a command has been completed, the HBA driver calls the target driver’s SCSI `pkt` command completion routine.

Figure 15–2 illustrates this flow, with emphasis placed on the transfer of information from target drivers to SCSA to HBA drivers. The following figure also shows typical transport entry points and function calls.
SCSA HBA Interfaces

SCSA HBA interfaces include HBA entry points, HBA data structures, and an HBA framework.

SCSA HBA Entry Point Summary

SCSA defines a number of HBA driver entry points, listed in the following table. These entry points are called by the system when configuring a target driver instance connected to the HBA driver, or when the target driver makes a SCSA request. See “SCSA HBA Entry Points” on page 267 for more information.

### SCSA HBA Data Structures

SCSA defines data structures to enable the exchange of information between the target and HBA drivers. These data structures include:

- `scsi_hba_tran(9S)`
- `scsi_address(9S)`
- `scsi_device(9S)`
- `scsi_pkt(9S)`

### `scsi_hba_tran(9S)` Structure

Each instance of an HBA driver must allocate a `scsi_hba_tran(9S)` structure using `scsi_hba_tran_alloc(9F)` in the `attach(9E)` entry point. `scsi_hba_tran_alloc(9F)` initializes the `scsi_hba_tran(9S)` structure before it returns. The HBA driver must initialize specific vectors in the transport structure to point to entry points within the HBA driver. Once initialized, the HBA driver exports the transport structure to SCSA by calling `scsi_hba_attach_setup(9F)`. 
Caution – Because SCSA keeps a pointer to the transport structure in the driver-private field on the devinfo node, HBA drivers must not use ddi_set_driver_private(9F). They can, however, use ddi_get_driver_private(9F) to retrieve the pointer to the transport structure.

The scsi_hba_tran(9S) structure contains the following fields:

```c
struct scsi_hba_tran {
    dev_info_t *tran_hba_dip; /* HBA softstate */
    void *tran_hba_private; /* HBA softstate */
    void *tran_tgt_private; /* target-specific info */
    struct scsi_device *tran_sd;
    int (*tran_tgt_init)();
    int (*tran_tgt_probe)();
    void (*tran_tgt_free)();
    int (*tran_start)();
    int (*tran_reset)();
    int (*tran_abort)();
    int (*tran_getcap)();
    int (*tran_setcap)();
    void (*tran_setcap)();
    struct scsi_pkt *(*tran_init_pkt)();
    void (*tran_destroy_pkt)();
    void (*tran_dmafree)();
    void (*tran_sync_pkt)();
    int (*tran_reset_notify)();
    int (*tran_quiesce)();
    int (*tran_unquiesce)();
    int (*tran_bus_reset)();
};
```

Note – Code fragments presented subsequently in this chapter use these fields to describe practical HBA driver operations. See “SCSA HBA Entry Points” on page 267 for more information.

where:

- **tran_hba_dip**
  - Pointer to the HBA device instance dev_info structure. The function scsi_hba_attach_setup(9F) sets this field.

- **tran_hba_private**
  - Pointer to private data maintained by the HBA driver. Usually, tran_hba_private contains a pointer to the state structure of the HBA driver.

- **tran_tgt_private**
  - Pointer to private data maintained by the HBA driver when using cloning. By specifying SCSI_HBA_TRAN_CLONE when calling scsi_hba_attach_setup(9F), the
scsi_hba_tran(9S) structure is cloned once per target, permitting the HBA to initialize this field to point to a per-target instance data structure in the tran_tgt_init(9E) entry point. If SCSI_HBA_TRAN_CLONE is not specified, tran_tgt_private is NULL and must not be referenced. See “Transport Structure Cloning” on page 257 for more information.

**tran_sd**

Pointer to a per-target instance scsi_device(9S) structure used when cloning. If SCSI_HBA_TRAN.Clone is passed to scsi_hba_attach_setup(9F), tran_sd is initialized to point to the per-target scsi_device structure before any HBA functions are called on behalf of that target. If SCSI_HBA_TRAN_CLONE is not specified, tran_sd is NULL and must not be referenced. See “Transport Structure Cloning” on page 257 for more information.

**tran_tgt_init**

Pointer to the HBA driver entry point called when initializing a target device instance. If no per-target initialization is required, the HBA can leave tran_tgt_init set to NULL.

**tran_tgt_probe**

Pointer to the HBA driver entry point called when a target driver instance calls scsi_probe(9F) to probe for the existence of a target device. If no target probing customization is required for this HBA, the HBA should set tran_tgt_probe to scsi_hba_probe(9F).

**tran_tgt_free**

Pointer to the HBA driver entry point called when a target device instance is destroyed. If no per-target deallocation is necessary, the HBA can leave tran_tgt_free set to NULL.

**tran_start**

Pointer to the HBA driver entry point called when a target driver calls scsi_transport(9F).

**tran_reset**

Pointer to the HBA driver entry point called when a target driver calls scsi_reset(9F).

**tran_abort**

Pointer to the HBA driver entry point called when a target driver calls scsi_abort(9F).

**tran_getcap**

Pointer to the HBA driver entry point called when a target driver calls scsi_ifgetcap(9F).

**tran_setcap**

Pointer to the HBA driver entry point called when a target driver calls scsi_ifsetcap(9F).

**tran_init_pkt**

Pointer to the HBA driver entry point called when a target driver calls scsi_init_pkt(9F).
tran_destroy_pkt  Pointer to the HBA driver entry point called when a target driver calls scsi_destroy_pkt(9F).

tran_dmafree  Pointer to the HBA driver entry point called when a target driver calls scsi_dmafree(9F).

tran_sync_pkt  Pointer to the HBA driver entry point called when a target driver calls scsi_sync_pkt(9F).

tran_reset_notify  Pointer to the HBA driver entry point called when a target driver calls tran_reset_notify(9E).

scsi_address Structure

The scsi_address(9S) structure provides transport and addressing information for each SCSI command allocated and transported by a target driver instance.

The scsi_address structure contains the following fields:

```c
struct scsi_address {
    struct scsi_hba_tran *a_hba_tran; /* Transport vectors */
    ushort_t a_target; /* Target identifier */
    uchar_t a_lun; /* Lun on that Target */
    uchar_t a_sublun; /* Sublun on that Lun */
};
```

- **a_hba_tran**  Pointer to the scsi_hba_tran(9S) structure, as allocated and initialized by the HBA driver. If SCSI_HBA_TRAN_CLONE was specified as the flag to scsi_hba_attach_setup(9F), a_hba_tran points to a copy of that structure.

- **a_target**  Identifies the SCSI target on the SCSI bus.

- **a_lun**  Identifies the SCSI logical unit on the SCSI target.

scsi_device Structure

The HBA framework allocates and initializes a scsi_device(9S) structure for each instance of a target device before calling an HBA driver's tran_tgt_init(9E) entry point. This structure stores information about each SCSI logical unit, including pointers to information areas that contain both generic and device-specific information. There is one scsi_device(9S) structure for each target device instance attached to the system.

If the per-target initialization is successful (in other words, if either tran_tgt_init(9E) returns success or the vector is NULL), the HBA framework will set the target driver's per-instance private data to point to the scsi_device(9S) structure, using ddi_set_driver_private(9F).
The `scsi_device(9S)` structure contains the following fields:

```c
struct scsi_device {
    struct scsi_address sd_address; /* routing information */
    dev_info_t *sd_dev; /* device dev_info node */
    kmutex_t sd_mutex; /* mutex used by device */
    void *sd_reserved;
    struct scsi_inquiry *sd_inq;
    struct scsi_extended_sense *sd_sense;
    caddr_t sd_private; /* for driver’s use */
};
```

- `sd_address` Data structure that is passed to the SCSI resource allocation routines.
- `sd_dev` Pointer to the target’s dev_info structure.
- `sd_mutex` Mutex for use by the target driver. This is initialized by the HBA framework and can be used by the target driver as a per-device mutex. This mutex should not be held across a call to `scsi_transport(9F)` or `scsi_poll(9F)`. See Chapter 3 for more information on mutexes.
- `sd_inq` Pointer for the target device’s SCSI inquiry data. The `scsi_probe(9F)` routine allocates a buffer, fills it in, and attaches it to this field.
- `sd_sense` Pointer to a buffer to contain Request Sense data from the device. The target driver must allocate and manage this buffer itself. See the target driver’s `attach(9E)` routine in “The `attach()` Entry Point” on page 76 for more information.
- `sd_private` Pointer field for use by the target driver. It is commonly used to store a pointer to a private target driver state structure.

### `scsi_pkt` Structure

To execute SCSI commands, a target driver must first allocate a `scsi_pkt(9S)` structure for the command, specifying its own private data area length, the command status, and the command length. The HBA driver is responsible for implementing the packet allocation in the `tran_init_pkt(9E)` entry point. The HBA driver is also responsible for freeing the packet in its `tran_destroy_pkt(9E)` entry point. See `scsi_pkt(9S)` in Chapter 14, for more information.

The `scsi_pkt(9S)` structure contains these fields:

```c
struct scsi_pkt {
    opaque_t pkt_ha_private; /* private data for host adapter */
    struct scsi_address pkt_address; /* destination address */
    opaque_t pkt_private; /* private data for target driver */
    void (*pkt_comp)(struct scsi_pkt *); /* completion routine */
};
```
struct pkt {
    uint_t pkt_flags; /* flags */
    int pkt_time; /* time allotted to complete command */
    uchar_t *pkt_scbp; /* pointer to status block */
    uchar_t *pkt_cdbp; /* pointer to command block */
    ssize_t pkt_resid; /* data bytes not transferred */
    uint_t pkt_state; /* state of command */
    uint_t pkt_statistics; /* statistics */
    uchar_t pkt_reason; /* reason completion called */
};

pkt_ha_private Pointer to per-command HBA-driver private data.
pkt_address Pointer to the scsi_address(9S) structure providing address information for this command.
pkt_private Pointer to per-packet target-driver private data.
pkt_comp Pointer to the target driver completion routine called by the HBA driver when the transport layer has completed this command.
pkt_flags Flags for the command.
pkt_time Specifies the completion timeout in seconds for the command.
pkt_scbp Pointer to the status completion block for the command.
pkt_cdbp Pointer to the command descriptor block (CDB) for the command.
pkt_resid Count of the data bytes not transferred when the command has been completed or the amount of data for which resources have not been allocated. The HBA must modify this field during transport.
pkt_state State of the command. The HBA must modify this field during transport.
pkt_statistics Provides a history of the events the command experienced while in the transport layer. The HBA must modify this field during transport.
pkt_reason Reason for command completion. The HBA must modify this field during transport.

Per-Target Instance Data

An HBA driver must allocate a scsi_hba_tran(9S) structure during attach(9E) and initialize the vectors in this transport structure to point to the required HBA driver entry points. This scsi_hba_tran(9S) structure is then passed into scsi_hba_attach_setup(9F).

The scsi_hba_tran(9S) structure contains a tran_hba_private field, which can be used to refer to the HBA driver’s per-instance state.
Each `scsi_address(9S)` structure contains a pointer to the `scsi_hba_tran(9S)` structure and also provides the target (`a_target`) and logical unit (`a_lun`) addresses for the particular target device. Because every HBA driver entry point is passed a pointer to the `scsi_address(9S)` structure, either directly or indirectly through the `scsi_device(9S)` structure, the HBA driver can reference its own state and can identify the target device being addressed.

The following figure illustrates the HBA data structures for transport operations.

![HBA Transport Structures](image)

**FIGURE 15-3 HBA Transport Structures**

**Transport Structure Cloning**

Cloning can be useful if an HBA driver needs to maintain per-target private data in the `scsi_hba_tran(9S)` structure, or if it needs to maintain a more complex address than is provided in the `scsi_address(9S)` structure.

When cloning, the HBA driver must still allocate a `scsi_hba_tran` structure at `attach(9E)` time and initialize the `tran_hba_private` soft state pointer and HBA entry point vectors as before. The difference occurs when the framework begins to connect an instance of a target driver to the HBA driver. Before calling the HBA driver's `tran_tgt_init(9E)` entry point, the framework duplicates (clones) the `scsi_hba_tran` structure associated with that instance of the HBA. This means
that each `scsi_address(9S)` structure, allocated and initialized for a particular target device instance, points to a per-target instance `copy` of the `scsi_hba_tran` structure, not to the `scsi_hba_tran` structure allocated by the HBA driver at `attach(9E)` time.

Two important pointers that an HBA driver can use when it has specified cloning are contained in the `scsi_hba_tran` structure. The first pointer is the `tran_tgt_private` field, which the driver can use to point to per-target HBA private data. This is useful, for example, if an HBA driver needs to maintain a more complex address than the `a_target` and `a_lun` fields in the `scsi_address(9S)` structure allow. The second pointer is the `tran_sd` field, which is a pointer to the `scsi_device(9S)` structure referring to the particular target device.

When specifying cloning, the HBA driver must allocate and initialize the per-target data and initialize the `tran_tgt_private` field to point to this data during its `tran_tgt_init(9E)` entry point. The HBA driver must free this per-target data during its `tran_tgt_free(9E)` entry point.

When cloning, the framework initializes the `tran_sd` field to point to the `scsi_device(9S)` structure before the HBA driver `tran_tgt_init(9E)` entry point is called. The driver requests cloning by passing the `SCSI_HBA_TRAN_CLONE` flag to `scsi_hba_attach_setup(9F)`. Figure 15-4 illustrates the HBA data structures for cloning transport operations.
SCSA HBA Functions

SCSA also provides a number of functions, listed in Table 15–2, for use by HBA drivers.

**TABLE 15-2 SCSA HBA Functions**

HBA Driver Dependency and Configuration Issues

In addition to incorporating SCSA HBA entry points, structures, and functions into a driver, HBA driver developers must also concern themselves with issues surrounding driver dependency and configuration. These issues involve configuration properties, dependency declarations, state structure and per-command structure, module initialization entry points, and autoconfiguration entry points.

Declarations and Structures

HBA drivers must include the following header files:

```
#include <sys/scsi/scsi.h>
#include <sys/ddi.h>
#include <sys/sunddi.h>
```

To inform the system that the module depends on SCSA routines (see “SCSA HBA Interfaces” on page 250 for more information), the driver binary must be generated with the following command:

```
% ld -r xx.o -o xx -N "misc/scsi"
```

The code samples are derived from a simplified isp driver for the QLogic Intelligent SCSI Peripheral device. The isp driver supports WIDE SCSI, with up to 15 target devices and 8 logical units (LUNs) per target.
Per-Command Structure

An HBA driver will usually need to define a structure to maintain state for each command submitted by a target driver. The layout of this per-command structure is entirely up to the device driver writer and needs to reflect the capabilities and features of the hardware and the software algorithms used in the driver.

The following structure is an example of a per-command structure. The remaining code fragments of this chapter use this structure to illustrate the HBA interfaces.

```c
struct isp_cmd {
    struct isp_request cmd_isp_request;
    struct isp_response cmd_isp_response;
    struct scsi_pkt *cmd_pkt;
    struct isp_cmd *cmd_forw;
    uint32_t cmd_dmacount;
    ddi_dma_handle_t cmd_dmahandle;
    uint_t cmd_cookie;
    uint_t cmd_ncookies;
    uint_t cmd_cookiecnt;
    uint_t cmd_nwin;
    uint_t cmd_curwin;
    off_t cmd_dma_offset;
    uint_t cmd_dma_len;
    ddi_dma_cookie_t cmd_dmacookies[ISP_NDATASEGS];
    u_int cmd_flags;
    u_short cmd_slot;
    u_int cmd_cdblen;
    u_int cmd_scblen;
};
```

Module Initialization Entry Points

Drivers for different types of devices have different sets of entry points, depending on the operations they perform. Some operations, however, are common to all drivers, such as the `as_init(9E)`, `_info(9E)`, and `_fini(9E)` entry points for module initialization. This section describes only those entry points associated with operations performed by SCSI HBA drivers.

The following code for a SCSI HBA driver illustrates a representative `dev_ops(9S)` structure. The driver must initialize the `devo_bus_ops` field in this structure to NULL. A SCSI HBA driver can provide leaf driver interfaces for special purposes, in which case the `devo_cb_ops` field might point to a `cb_ops(9S)` structure. In this example, no leaf driver interfaces are exported, so the `devo_cb_ops` field is initialized to NULL.

```
_init() Entry Point (SCSI HBA Drivers)
```

The `_init(9E)` function initializes a loadable module and is called before any other routine in the loadable module.
In a SCSI HBA, the _init() function must call scsi_hba_init(9F) to inform the framework of the existence of the HBA driver before calling mod_install(9F). If scsi_hba_init() returns a nonzero value, _init() should return this value. Otherwise, _init() must return the value returned by mod_install(9F).

The driver should initialize any required global state before calling mod_install(9F).

If mod_install() fails, the _init() function must free any global resources allocated and must call scsi_hba_fini(9F) before returning.

Example 15–1 uses a global mutex to show how to allocate data that is global to all instances of a driver. The code declares global mutex and soft-state structure information. The global mutex and soft state are initialized during _init().

_fini() Entry Point (SCSI HBA Drivers)

The _fini(9E) function is called when the system is about to try to unload the SCSI HBA driver. The _fini() function must call mod_remove(9F) to determine if the driver can be unloaded. If mod_remove() returns 0, the module can be unloaded, and the HBA driver must deallocate any global resources allocated in _init(9E) and must call scsi_hba_fini(9F).

_fini() must return the value returned by mod_remove().

Note – The HBA driver must not free any resources or call scsi_hba_fini(9F) unless mod_remove(9F) returns 0.

Example 15–1 shows SCSI HBA module initialization.

**EXAMPLE 15–1** SCSI HBA Module Initialization

```c
static struct dev_ops isp_dev_ops = {
    DEVO_REV, /* devo_rev */
    0, /* refcnt */
    isp_getinfo, /* getinfo */
    nulldev, /* probe */
    isp_attach, /* attach */
    isp_detach, /* detach */
    nodev, /* reset */
    NULL, /* driver operations */
    NULL, /* bus operations */
    isp_power, /* power management */
};

/*
 * Local static data
 */
static kmutex_t isp_global_mutex;
```
EXAMPLE 15–1 SCSI HBA Module Initialization  (Continued)

static void *isp_state;

int _init(void)
{
    int err;

    if ((err = ddi_soft_state_init(&isp_state,
            sizeof (struct isp), 0)) != 0) {
        return (err);
    }

    if ((err = scsi_hba_init(&modlinkage)) == 0) {
        mutex_init(&isp_global_mutex, "isp global mutex",
                MUTEX_DRIVER, NULL);
        if ((err = mod_install(&modlinkage)) != 0) {
            mutex_destroy(&isp_global_mutex);
            scsi_hba_fini(&modlinkage);
            ddi_soft_state_fini(&isp_state);
        }
    }
    return (err);
}

int _fini(void)
{
    int err;

    if ((err = mod_remove(&modlinkage)) == 0) {
        mutex_destroy(&isp_global_mutex);
        scsi_hba_fini(&modlinkage);
        ddi_soft_state_fini(&isp_state);
    }
    return (err);
}

Autoconfiguration Entry Points

Associated with each device driver is a dev_ops(9S) structure, which allows the kernel to locate the autoconfiguration entry points of the driver. A complete description of these autoconfiguration routines is given in Chapter 5. This section describes only those entry points associated with operations performed by SCSI HBA drivers. These include attach(9E) and detach(9E).
attach() Entry Point (SCSI HBA Drivers)

The `attach(9E)` entry point for a SCSI HBA driver must perform a number of tasks to configure and attach an instance of the driver for the device. For a typical driver of real devices, the following operating system and hardware concerns must be addressed:

- Soft-state structure
- DMA
- Transport structure
- Attaching an HBA driver
- Register mapping
- Interrupt specification
- Interrupt handling
- Create power manageable components
- Report attachment status

**Soft State Structure**

The driver should allocate the per-device-instance soft state structure, being careful to clean up properly if an error occurs.

**DMA**

The HBA driver must describe the attributes of its DMA engine by properly initializing the `ddi_dma_attr_t` structure.

```c
static ddi_dma_attr_t isp_dma_attr = {
    DMA_ATTR_V0, /* ddi_dma_attr version */
    0, /* low address */
    0xffffffff, /* high address */
    0x00ffffff, /* counter upper bound */
    1, /* alignment requirements */
    0x3f, /* burst sizes */
    1, /* minimum DMA access */
    0xffffffff, /* maximum DMA access */
    (1<<24)-1, /* segment boundary restrictions */
    1, /* scatter/gather list length */
    512, /* device granularity */
    0 /* DMA flags */
};
```

The driver, if providing DMA, should also check that its hardware is installed in a DMA-capable slot:

```c
if (ddi_slaveonly(dip) == DDI_SUCCESS) {
    return (DDI_FAILURE);
}
```
Transport Structure

The driver should further allocate and initialize a transport structure for this instance. The `tran_hba_private` field is set to point to this instance’s soft-state structure. `tran_tgt_probe` can be set to NULL to achieve the default behavior, if no special probe customization is needed.

```c
tran = scsi_hba_tran_alloc(dip, SCSI_HBA_CANSLEEP);
isp->isp_tran = tran;
isp->isp_dip = dip;
tran->tran_hba_private = isp;
tran->tran_tgt_private = NULL;
tran->tran_tgt_init = scsi_hba_probe;
tran->tran_tgt_probe = scsi_hba_probe;
tran->tran_tgt_free = (void (*)(()))NULL;
tran->tran_start = isp_scsi_start;
tran->tran_abort = isp_scsi_abort;
tran->tran_reset = isp_scsi_reset;
tran->tran_getcap = isp_scsi_getcap;
tran->tran_setcap = isp_scsi_setcap;
tran->tran_init_pkt = isp_scsi_init_pkt;
tran->tran_destroy_pkt = isp_scsi_destroy_pkt;
tran->tran_dmafree = isp_scsi_dmafree;
tran->tran_sync_pkt = isp_scsi_sync_pkt;
tran->tran_reset_notify = isp_scsi_reset_notify;
tran->tran_bus_quiesce = isp_tran_bus_quiesce;
tran->tran_bus_unquiesce = isp_tran_bus_unquiesce;
tran->tran_bus_reset = isp_tran_bus_reset;
```

Attaching an HBA Driver

The driver should attach this instance of the device, and perform error cleanup if necessary.

```c
i = scsi_hba_attach_setup(dip, &isp_dma_attr, tran, 0);
if (i != DDI_SUCCESS) {
    do error recovery
    return (DDI_FAILURE);
}
```

Register Mapping

The driver should map in its device’s registers, specifying the index of the register set, the data access characteristics of the device and the size of the register set to be mapped.

```c
ddi_device_acc_attr_t dev_attributes;

dev_attributes.devacc_attr_version = DDI_DEVICE_ATTR_V0;
```
dev_attributes.devacc_attr_dataorder = DDI.StrictOrder_ACC;
dev_attributes.devacc_attr_endian_flags = DDI.Structure_LE_ACC;

if (ddi_regs_map_setup(dip, 0, (caddr_t *)&isp->isp_reg,
                      0, sizeof (struct ispregs), &dev_attributes,
                      &isp->isp_acc_handle) != DDI_SUCCESS) {
    do error recovery
    return (DDI_FAILURE);
}

Adding an Interrupt Handler

The driver must first obtain the iblock cookie to initialize mutexes used in the driver
handler. Only after those mutexes have been initialized can the interrupt handler be
added.

    i = ddi_get_iblock_cookie(dip, 0, &isp->iblock_cookie);
    if (i != DDI_SUCCESS) {
        do error recovery
        return (DDI_FAILURE);
    }

    mutex_init(&isp->mutex, "isp_mutex", MUTEX_DRIVER,
               (void *)isp->iblock_cookie);
    i = ddi_add_intr(dip, 0, &isp->iblock_cookie,
                     0, isp_intr, (caddr_t)isp);
    if (i != DDI_SUCCESS) {
        do error recovery
        return (DDI_FAILURE);
    }

The driver should determine if a high-level interrupt handler is required. If a
high-level handler is required and the driver is not coded to provide one, rewrite the
driver to include either a high-level interrupt or fail the attach. See “Handling
High-Level Interrupts” on page 101 for a description of high-level interrupt handling.

Create Power Manageable Components

If the host bus adapter hardware supports power management, and the host bus
adapter only needs to be powered down when all of the target adapters are power
manageable and are at power level 0, then the host bus adapter driver only needs to
provide a power(9E) entry point as described in Chapter 9 and create a
pm-components(9P) property that describes the components that the device
implements.

Nothing more is necessary, since the components will default to idle, and the power
management framework’s default dependency processing will ensure that the host
bus adapter will be powered up whenever an target adapter is powered up and will
automatically power down the host bus adapter whenever all of the target adapters
are powered down (provided that automatic power management is enabled).
Report Attachment Status

Finally, the driver should report that this instance of the device is attached and return success.

    ddi_report_dev(dip);
    return (DDI_SUCCESS);

detach() Entry Point (SCSI HBA Drivers)

The driver should perform standard detach operations, including calling scsi_hba_detach(9F).

SCSA HBA Entry Points

For an HBA driver to work with target drivers using the SCSA interface, each HBA driver must supply a number of entry points, callable through the scsi_hba_tran(9S) structure. These entry points fall into five functional groups:

- Target driver instance initialization
- Resource allocation and deallocation
- Command transport
- Capability management
- Abort and reset handling
- Dynamic reconfiguration

Table 15–3 lists the SCSA HBA entry points arranged by function groups.

### Target Driver Instance Initialization

The following sections explain target entry points.

**tran_tgt_init()** Entry Point

The `tran_tgt_init(9E)` entry point enables the HBA to allocate and/or initialize any per-target resources. It also enables the HBA to qualify the device’s address as valid and supportable for that particular HBA. By returning `DDI_FAILURE`, the instance of the target driver for that device will not be probed or attached.

This entry point is not required, and if none is supplied, the framework will attempt to probe and attach all possible instances of the appropriate target drivers.

```c
static int
isp_tran_tgt_init(
    dev_info_t *hba_dip,
    dev_info_t *tgt_dip,
    scsi_hba_tran_t *tran,
    struct scsi_device *sd)
```

268 Writing Device Drivers • May 2002
tran_tgt_probe() Entry Point

The `tran_tgt_probe(9E)` entry point enables the HBA to customize the operation of `scsi_probe(9F)`, if necessary. This entry point is called only when the target driver calls `scsi_probe(9F)`.

The HBA driver can retain the normal operation of `scsi_probe(9F)` by calling `scsi_hba_probe(9F)` and returning its return value.

This entry point is not required, and if not needed, the HBA driver should set the `tran_tgt_probe` vector in the `scsi_hba_tran(9S)` structure to point to `scsi_hba_probe(9F)`.

`scsi Probe(9F)` allocates a `scsi_inquiry(9S)` structure and sets the `sd_inq` field of the `scsi_device(9S)` structure to point to the data in `scsi_inquiry(9S)`. `scsi_hba_probe(9F)` handles this automatically. `scsi_unprobe(9F)` then frees the `scsi_inquiry(9S)` data.

Other than during the allocation of `scsi_inquiry(9S)` data, normally handled by `scsi_hba_probe(9F)`, `tran_tgt_probe(9E)` must be stateless, as the same SCSI device might call it multiple times.

Note – The allocation of the `scsi_inquiry(9S)` structure is handled automatically by `scsi_hba_probe(9F)`. This is only of concern if you want custom `scsi_probe(9F)` handling.

```c
static int
isp_tran_tgt_probe(
    struct scsi_device *sd,
    int (*callback)())
{
    Perform any special probe customization needed. /*
    * Normal probe handling
    */
    return (scsi_hba_probe(sd, callback));
}
```

tran_tgt_free() Entry Point

The `tran_tgt_free(9E)` entry point enables the HBA to perform any deallocation or clean-up procedures for an instance of a target. This entry point is optional.

```c
static void
isp_tran_tgt_free(
```
dev_info_t *hba_dip,
dev_info_t *tgt_dip,
scsi_hba_tran_t *hba_tran,
struct scsi_device *sd)
{
    Undo any special per-target initialization done
    earlier in tran_tgt_init(9F) and tran_tgt_probe(9F)
}

Resource Allocation

The following sections discuss resource allocation.

tran_tgt_pkt() Entry Point

The tran_init_pkt(9E) entry point is the HBA driver function that allocates and
initializes, on behalf of the target driver, a scsi_pkt(9S) structure and DMA
resources for a target driver request.

The tran_init_pkt(9E) entry point is called when the target driver calls the SCSA
function scsi_init_pkt(9F).

Each call of the tran_init_pkt(9E) entry point is a request to perform one or more
of three possible services:
- Allocation and initialization of a scsi_pkt(9S) structure
- Allocation of DMA resources for data transfer
- Reallocation of DMA resources for the next portion of the data transfer

Allocation and Initialization of a scsi_pkt(9S) Structure

The tran_init_pkt(9E) entry point must allocate a scsi_pkt(9S) structure if pkt
is NULL through scsi_hba_pkt_alloc(9F).

scsi_hba_pkt_alloc(9F) allocates the following:
- scsi_pkt(9S)
- SCSI CDB of length cmdlen
- SCSI status completion area of length statuslen
- Per-packet target driver private data area of length tgtlen
- Per-packet HBA driver private data area of length hbalen
The `scsi_pkt(9S)` structure members, as well as `pkt` itself, must be initialized to zero except for the following members: `pkt_scbp` (status completion), `pkt_cdbp` (CDB), `pkt_ha_private` (HBA driver private data), `pkt_private` (target driver private data). These members are pointers to memory space where the values of the fields are stored, as illustrated in Figure 15-5. For more information, refer to “scsi_pkt Structure” on page 255.

![Figure 15-5 scsi_pkt(9S) Structure Pointers](image)

Example 15–2 provides an example of allocation and initialization of a `scsi_pkt(9S)` structure.

**EXAMPLE 15–2 HBA Driver Initialization of a SCSI Packet Structure**

```c
static struct scsi_pkt *
isp_scsi_init_pkt(
    struct scsi_address *ap,
    struct scsi_pkt *pkt,
    struct buf *bp,
    int cmdlen,
    int statuslen,
    int tgtlen,
    int flags,
    int (*callback)(),
    caddr_t arg)
{
    struct isp_cmd *sp;
    struct isp *isp;
    struct scsi_pkt *new_pkt;

    ASSERT(callback == NULL_FUNC || callback == SLEEP_FUNC);

    isp = (struct isp *)ap->a_hba_tran->tran_hba_private;
```
EXAMPLE 15-2 HBA Driver Initialization of a SCSI Packet Structure  
(Continued)

/*
 * First step of isp_scsi_init_pkt: pkt allocation
 */
if (pkt == NULL) {
    pkt = scsi_hba_pkt_alloc(isp->isp_dip, ap, cmdlen,
                           statuslen, tgtlen, sizeof (struct isp_cmd),
                           callback, arg);
    if (pkt == NULL) {
        return (NULL);
    }
    sp = (struct isp_cmd *)pkt->pkt_ha_private;
    /*
     * Initialize the new pkt
     */
    sp->cmd_pkt = pkt;
    sp->cmd_flags = 0;
    sp->cmd_scblen = statuslen;
    sp->cmd_cdblen = cmdlen;
    sp->cmd_dmahandle = NULL;
    sp->cmd_ncookies = 0;
    sp->cmd_cookie = 0;
    sp->cmd_cookiecnt = 0;
    sp->cmd_nwin = 0;
    pkt->pkt_address = *ap;
    pkt->pkt_comp = (void (*)())NULL;
    pkt->pkt_flags = 0;
    pkt->pkt_time = 0;
    pkt->pkt_resid = 0;
    pkt->pkt_statistics = 0;
    pkt->pkt_reason = 0;
    new_pkt = pkt;
} else {
    sp = (struct isp_cmd *)pkt->pkt_ha_private;
    new_pkt = NULL;
}

/*
 * Second step of isp_scsi_init_pkt: dma allocation/move
 */
if (bp && bp->b_bcount != 0) {
    if (sp->cmd_dmahandle == NULL) {
        if (isp_i_dma_alloc(isp, pkt, bp,
                          flags, callback) == 0) {
            if (new_pkt) {
                scsi_hba_pkt_free(ap, new_pkt);
            }
            return ((struct scsi_pkt *)NULL);
        }
    } else {

    }
}
EXAMPLE 15-2 HBA Driver Initialization of a SCSI Packet Structure

(Continued)

```
ASSERT(new_pkt == NULL);
if (isp_i_dma_move(isp, pkt, bp) == 0) {
    return ((struct scsi_pkt *)NULL);
}
}
return (pkt);
```

Allocation of DMA Resources

If `bp` is not NULL and `bp->b_bcount` is not zero and DMA resources have not yet been allocated for this `scsi_pkt(9S)`, the `tran_init_pkt(9E)` entry point must allocate DMA resources for a data transfer. The HBA driver needs to keep track of whether DMA resources have been allocated for a particular command with a flag bit or a DMA handle in the per-packet HBA driver private data.

By setting the `PKT_DMA_PARTIAL` flag in the `pkt`, the target driver indicates it can accept breaking up the data transfer into multiple SCSI commands to accommodate the complete request. This might be necessary if the HBA hardware scatter-gather capabilities or system DMA resources are insufficient to accommodate the complete request in a single SCSI command.

If the `PKT_DMA_PARTIAL` flag is set, the HBA driver can set the `DDI_DMA_PARTIAL` flag when allocating DMA resources (using, for example, `ddi_dma_buf_bind_handle(9F)`) for this SCSI command. The DMA attributes used when allocating the DMA resources should accurately describe any constraints placed on the ability of the HBA hardware to perform DMA. If the system can only allocate DMA resources for part of the request, `ddi_dma_buf_bind_handle(9F)` will return `DDI_DMA_PARTIAL_MAP`.

The `tran_init_pkt(9E)` entry point must return the amount of DMA resources not allocated for this transfer in the field `pkt_resid`.

A target driver can make one request to `tran_init_pkt(9E)` to simultaneously allocate both a `scsi_pkt(9S)` structure and DMA resources for that `pkt`. In this case, if the HBA driver is unable to allocate DMA resources, it must free the allocated `scsi_pkt(9S)` before returning. The `scsi_pkt(9S)` must be freed by calling `scsi_hba_pkt_free(9F)`.

The target driver might first allocate the `scsi_pkt(9S)` and allocate DMA resources for this `pkt` at a later time. In this case, if the HBA driver is unable to allocate DMA resources, it must not free `pkt`. The target driver in this case is responsible for freeing the `pkt`. 
EXAMPLE 15-3 HBA Driver Allocation of DMA Resources

```c
static int
isp_i_dma_alloc(
    struct isp *isp,
    struct scsi_pkt *pkt,
    struct buf *bp,
    int flags,
    int (*callback)()
) {
    struct isp_cmd *sp = (struct isp_cmd *)pkt->pkt_ha_private;
    int dma_flags;
    ddi_dma_attr_t tmp_dma_attr;
    int (*cb)(caddr_t);
    int i;

    ASSERT(callback == NULL_FUNC || callback == SLEEP_FUNC);

    if (bp->b_flags & B_READ) {
        sp->cmd_flags &= ~CFLAG_DMASEND;
        dma_flags = DDI_DMA_READ;
    } else {
        sp->cmd_flags |= CFLAG_DMASEND;
        dma_flags = DDI_DMA_WRITE;
    }

    if (flags & PKT_CONSISTENT) {
        sp->cmd_flags |= CFLAG_CMDIOPB;
        dma_flags |= DDI_DMA_CONSISTENT;
    }

    if (flags & PKT_DMA_PARTIAL) {
        dma_flags |= DDI_DMA_PARTIAL;
    }

    tmp_dma_attr = isp_dma_attr;
    tmp_dma_attr.dma_attr_burstsizes = isp->isp_burst_size;

    cb = (callback == NULL_FUNC) ? DDI_DMA_DONTWAIT : DDI_DMA_SLEEP;

    if ((i = ddi_dma_alloc_handle(isp->isp_dip, &tmp_dma_attr,
        cb, 0, &sp->cmd_dmahandle)) != DDI_SUCCESS) {
        switch (i) {
            case DDI_DMA_BADATTR:
                bioerror(bp, EFAULT);
                return (0);
            case DDI_DMA_NORESOURCES:
                bioerror(bp, 0);
                return (0);
        }
    }

    i = ddi_dma_buf_bind_handle(sp->cmd_dmahandle, bp, dma_flags,
        cb, 0, &sp->cmd_dmacookies[0], &sp->cmd_ncookies);
```

274  Writing Device Drivers • May 2002
switch (i) {

}

ddi_dma_free_handle(&sp->cmd_dmahandle);
sp->cmd_dmahandle = NULL;
sp->cmd_flags &= -CFLAG_DMAVALID;
return (0);
}

Reallocation of DMA Resources for Data Transfer

For a previously allocated packet with data remaining to be transferred, the tran_init_pkt(9E) entry point must reallocate DMA resources when the following conditions apply:

- Partial DMA resources have already been allocated.
- A non-zero pkt_resid was returned in the previous call to tran_init_pkt(9E).
- bp is not NULL.
- bp->b_bcount is not zero.

When reallocating DMA resources to the next portion of the transfer, tran_init_pkt(9E) must return the amount of DMA resources not allocated for this transfer in the field pkt_resid.

If an error occurs while attempting to move DMA resources, tran_init_pkt(9E) must not free the scsi_pkt(9S). The target driver in this case is responsible for freeing the pkt.

If the callback parameter is NULL_FUNC, the tran_init_pkt(9E) entry point must not sleep or call any function that might sleep. If the callback parameter is SLEEP_FUNC and resources are not immediately available, the tran_init_pkt(9E) entry point should sleep until resources are available, unless the request is impossible to satisfy.

EXAMPLE 15-4 HBA Driver DMA Resource Reallocation

static int
isp_i_dma_move(
    struct isp *isp,
    struct scsi_pkt *pkt,
    struct buf *bp)
{
    struct isp_cmd *sp = (struct isp_cmd *)pkt->pkt_ha_private;
    int i;

    /* DDI_DMA_INUSE impossible
*/

    default:
        cmn_err(CR_PANIC, "ddi_dma_buf_bind_handle:
            " 0x%x impossible
", i);
    }

    ddi_dma_free_handle(&sp->cmd_dmahandle);
    sp->cmd_dmahandle = NULL;
    sp->cmd_flags &= -CFLAG_DMAVALID;
    return (0);
}
EXAMPLE 15-4 HBA Driver DMA Resource Reallocation (Continued)

```c
ASSERT(sp->cmd_flags & CFLAG_COMPLETED);
sp->cmd_flags &= ~CFLAG_COMPLETED;

/*
 * If there are no more cookies remaining in this window,
 * must move to the next window first.
 */
if (sp->cmd_cookie == sp->cmd_ncookies) {
    /*
    * For small pkts, leave things where they are
    */
    if (sp->cmd_curwin == sp->cmd_nwin && sp->cmd_nwin == 1)
        return (1);

    /*
    * At last window, cannot move
    */
    if (++sp->cmd_curwin >= sp->cmd_nwin)
        return (0);

    if (ddi_dma_getwin(sp->cmd_dmahandle, sp->cmd_curwin,
                        &sp->cmd_dma_offset, &sp->cmd_dma_len,
                        &sp->cmd_dmacookies[0], &sp->cmd_ncookies) ==
     DDI_FAILURE)
        return (0);

    sp->cmd_cookie = 0;
} else {
    /*
    * Still more cookies in this window - get the next one
    */
    ddi_dma_nextcookie(sp->cmd_dmahandle,
                        &sp->cmd_dmacookies[0]);
}

/*
 * Get remaining cookies in this window, up to our maximum
 */
i = 0;
for (;;) {
    sp->cmd_dmacount += sp->cmd_dmacookies[i++].dmac_size;
    sp->cmd_cookie++;
    if (i == ISP_NDATASEGS ||
        sp->cmd_cookie == sp->cmd_ncookies)
        break;
    ddi_dma_nextcookie(sp->cmd_dmahandle,
                        &sp->cmd_dmacookies[i]);
}
sp->cmd_cookiecnt = i;

pkt->pkt_resid = bp->b_bcount - sp->cmd_dmacount;
return (1);
```
tran_destroy_pkt() Entry Point

The tran_destroy_pkt(9E) entry point is the HBA driver function that deallocates scsi_pkt(9S) structures. The tran_destroy_pkt() entry point is called when the target driver calls scsi_destroy_pkt(9F).

The tran_destroy_pkt() entry point must free any DMA resources allocated for the packet. Freeing the DMA resources causes an implicit DMA synchronization if any cached data remained after the completion of the transfer. The tran_destroy_pkt() entry point frees the SCSI packet itself by calling scsi_hba_pkt_free(9F).

EXAMPLE 15-5 HBA Driver tran_destroy_pkt(9E) Entry Point

```c
static void isp_scsi_destroy_pkt(  
    struct scsi_address *ap,  
    struct scsi_pkt *pkt)  
{  
    struct isp_cmd *sp = (struct isp_cmd *)pkt->pkt_ha_private;  
    
    /*  
       * Free the DMA, if any  
       */  
    if (sp->cmd_flags & CFLAG_DMAVALID) {  
        sp->cmd_flags &= ~CFLAG_DMAVALID;  
        (void) ddi_dma_unbind_handle(sp->cmd_dmahandle);  
        ddi_dma_free_handle(&sp->cmd_dmahandle);  
        sp->cmd_dmahandle = NULL;  
    }  
    /*  
       * Free the pkt  
       */  
    scsi_hba_pkt_free(ap, pkt);  
}
```

tran_sync_pkt() Entry Point

The tran_sync_pkt(9E) entry point is the HBA driver function that synchronizes the DMA object allocated for the scsi_pkt(9S) structure before or after a DMA transfer. The tran_sync_pkt() entry point is called when the target driver calls scsi_sync_pkt(9F).

If the data transfer direction is a DMA read from device to memory, tran_sync_pkt() must synchronize the CPU’s view of the data. If the data transfer direction is a DMA write from memory to device, tran_sync_pkt() must synchronize the device’s view of the data.
EXAMPLE 15-6 HBA Driver tran_sync_pkt(9E) Entry Point

static void
isp_scsi_sync_pkt(
    struct scsi_address *ap,
    struct scsi_pkt *pkt)
{
    struct isp_cmd *sp = (struct isp_cmd *)pkt->pkt_ha_private;

    if (sp->cmd_flags & CFLAG_DMAVALID) {
        (void)ddi_dma_sync(sp->cmd_dmahandle, sp->cmd_dma_offset,
                           sp->cmd_dma_len,
                           (sp->cmd_flags & CFLAG_DMASEND) ?
                           DDI_DMA_SYNC_FORDEV : DDI_DMA_SYNC_FORCPU);
    }
}

tran_dmafree() Entry Point

The tran_dmafree(9E) entry point is the HBA driver function that deallocates DMA resources allocated for a scsi_pkt(9S) structure. The tran_dmafree() entry point is called when the target driver calls scsi_dmafree(9F).

tran_dmafree() must free only DMA resources allocated for a scsi_pkt(9S) structure, not the scsi_pkt(9S) itself. Freeing the DMA resources implicitly performs a DMA synchronization.

Note – The scsi_pkt(9S) will be freed in a separate request to tran_destroy_pkt(9E). Because tran_destroy_pkt() must also free DMA resources, the HBA driver must keep accurate note of whether scsi_pkt() structures have DMA resources allocated.

EXAMPLE 15-7 HBA Driver tran_dmafree(9E) Entry Point

static void
isp_scsi_dmafree(
    struct scsi_address *ap,
    struct scsi_pkt *pkt)
{
    struct isp_cmd *sp = (struct isp_cmd *)pkt->pkt_ha_private;

    if (sp->cmd_flags & CFLAG_DMAVALID) {
        sp->cmd_flags &= ~CFLAG_DMAVALID;
        (void)ddi_dma_unbind_handle(sp->cmd_dmahandle);
        ddi_dma_free_handle(sp->cmd_dmahandle);
        sp->cmd_dmahandle = NULL;
    }
}
Command Transport

As part of command transport, the HBA driver accepts a command from the target driver, issues the command to the device hardware, services any interrupts that occur, and manages timeouts.

tran_start() Entry Point

The tran_start(9E) entry point for a SCSI HBA driver is called to transport a SCSI command to the addressed target. The SCSI command is described entirely within the scsi_pkt(9S) structure, which the target driver allocated through the HBA driver's tran_init_pkt(9E) entry point. If the command involves a data transfer, DMA resources must also have been allocated for the scsi_pkt(9S) structure.

The tran_start() entry point is called when a target driver calls scsi_transport(9F).

tran_start() should perform basic error checking along with whatever initialization the command requires. If the flag FLAG_NOINTR is not set in the pkt_flags field of the scsi_pkt(9S) structure, tran_start() must queue the command for execution on the hardware and return immediately. Upon completion of the command, the HBA driver should call the pkt() completion routine.

For commands with the FLAG_NOINTR bit set in the pkt_flags field of the scsi_pkt(9S) structure, tran_start(9E) should not return until the command has been completed, and the HBA driver should not call the pkt() completion routine.

Example 15–8 demonstrates how to handle the tran_start(9E) entry point. The ISP hardware provides a queue per-target device. For devices that can manage only one active outstanding command, the driver itself is typically required to manage a per-target queue and starts up a new command upon completion of the current command in a round-robin fashion.

EXAMPLE 15–8 HBA Driver tran_start(9E) Entry Point

static int
isp_scsi_start( ...
    sp = (struct isp_cmd *)pkt->pkt_ha_private;
    isp = (struct isp *)ap->a_hba_tran->tran_hba_private;
    u_long cur_lbolt;
    cur_lbolt = ...
    ...
sp->cmd_flags = (sp->cmd_flags & ~CFLAG_TRANFLAG) | CFLAG_IN_TRANSPORT;
pkt->pkt_reason = CMD_CMPLT;

/*
 * set up request in cmd_isp_request area so it is ready to
 * go once we have the request mutex
 */
req = &sp->cmd_isp_request;

req->req_header.cq_entry_type = CQ_TYPE_REQUEST;
req->req_header.cq_entry_count = 1;
req->req_header.cq_flags = 0;
req->req_header.cq_seqno = 0;
req->req_reserved = 0;
req->req_token = (opaque_t)sp;
req->req_target = TGT(sp);
req->req_lun_trn = LUN(sp);
req->req_time = pkt->pkt_time;
ISP_SET_PKT_FLAGS(pkt->pkt_flags, req->req_flags);

/*
 * Set up dma transfers data segments.
 */
if (sp->cmd_flags & CFLAG_DMAVALID) {
    if (sp->cmd_flags & CFLAG_CMDIOPB) {
        (void) ddi_dma_sync(sp->cmd_dmahandle,
                             sp->cmd_dma_offset, sp->cmd_dma_len,
                             DDI_DMA_SYNC_FORDEV);
    }

    ASSERT(sp->cmd_cookiecnt > 0 &&
           sp->cmd_cookiecnt <= ISP_NDATASEGS);
    xfercount = 0;
    req->req_seg_count = sp->cmd_cookiecnt;
    for (i = 0; i < sp->cmd_cookiecnt; i++) {
        req->req_dataseg[i].d_count =
            sp->cmd_dmacookies[i].dmac_size;
        req->req_dataseg[i].d_base =
            sp->cmd_dmacookies[i].dmac_address;
        xfercount +=
            sp->cmd_dmacookies[i].dmac_size;
}

    for (; i < ISP_NDATASEGS; i++) {
        req->req_dataseg[i].d_count = 0;
        req->req_dataseg[i].d_base = 0;
    }
}

pkt->pkt_resid = xfercount;
EXAMPLE 15-8 HBA Driver tran_start(9E) Entry Point  (Continued)

```c
if (sp->cmd_flags & CFLAG_DMASEND) {
    req->req_flags |= ISP_REQ_FLAG_DATA_WRITE;
} else {
    req->req_flags |= ISP_REQ_FLAG_DATA_READ;
}
else {
    req->req_seg_count = 0;
    req->req_dataseg[0].d_count = 0;
}

/*
 * Set up cdb in the request
 */
req->req_cdblen = sp->cmd_cdblen;
bcopy((caddr_t)pkt->pkt_cdbp, (caddr_t)req->req_cdb,
     sp->cmd_cdblen);

/*
 * Start the cmd. If NO_INTR, must poll for cmd completion.
 */
if ((pkt->pkt_flags & FLAG_NOINTR) == 0) {
    mutex_enter(ISP_REQ_MUTEX(isp));
    rval = isp_i_start_cmd(isp, sp);
    mutex_exit(ISP_REQ_MUTEX(isp));
} else {
    rval = isp_i_polled_cmd_start(isp, sp);
}
return (rval);
```

Interrupt Handler and Command Completion

The interrupt handler must check the status of the device to be sure the device is generating the interrupt in question. It must also check for any errors that have occurred and service any interrupts generated by the device.

If data was transferred, the hardware should be checked to determine how much data was actually transferred, and the pkt_resid field in the scsi_pkt(9S) structure should be set to the residual of the transfer.

For commands marked with the PKT_CONSISTENT flag when DMA resources were allocated through tran_init_pkt(9E), the HBA driver must ensure that the data transfer for the command is correctly synchronized before the target driver’s command completion callback is performed.

Once a command has completed, there are two requirements:

- Start a new command (if one is queued up) on the hardware as quickly as possible.
Call the command completion callback as set up in the `scsi_pkt(9S)` structure by the target driver to notify the target driver that the command is now complete.

Start a new command on the hardware, if possible, before calling the `PKT_COMP` command completion callback. The command completion handling can take considerable time, as the target driver will typically call functions such as `biodone(9F)` and possibly `scsi_transport(9F)` to begin a new command.

The interrupt handler must return `DDI_INTR_CLAIMED` if this interrupt is claimed by this driver; otherwise, the handler returns `DDI_INTR_UNCLAIMED`.

Example 15-9 shows an interrupt handler for the SCSI HBA `isp` driver. The `caddr_t` argument is the parameter set up when the interrupt handler was added in `attach(9E)` and is typically a pointer to the state structure allocated per instance.

**EXAMPLE 15-9 HBA Driver Interrupt Handler**

```c
static u_int
isp_intr(caddr_t arg)
{
    struct isp_cmd *sp;
    struct isp_cmd *head, *tail;
    u_short response_in;
    struct isp_response *resp;
    struct isp *isp = (struct isp *)arg;
    struct isp_slot *isp_slot;
    int n;

    if (ISP_INT_PENDING(isp) == 0) { return (DDI_INTR_UNCLAIMED);
    }

    do {
        again:
        /*
         * head list collects completed packets for callback later
         */
        head = tail = NULL;

        /*
         * Assume no mailbox events (e.g. mailbox cmds, async
         * events, and isp dma errors) as common case.
         */
        if (ISP_CHECK_SEMAPHORE_LOCK(isp) == 0) {
            mutex_enter(ISP_RESP_MUTEX(isp));

            /*
             * Loop through completion response queue and post
             * completed pkts. Check response queue again
             * afterwards in case there are more
             */
            isp->isp_response_in = 
                response_in = ISP_GET_RESPONSE_IN(isp);
```
/ * Calculate the number of requests in the queue */
 n = response_in - isp->isp_response_out;
 if (n < 0) {
   n = ISP_MAX_REQUESTS - isp->isp_response_out + response_in;
 }
 while (n-- > 0) {
   ISP_GET_NEXT_RESPONSE_OUT(isp, resp);
   sp = (struct isp_cmd *)resp->resp_token;
   /*
   * copy over response packet in sp
   */
   isp_i_get_response(isp, resp, sp);
 }
 if (head) {
   tail->cmd_forw = sp;
   tail = sp;
   tail->cmd_forw = NULL;
 } else {
   tail = head = sp;
   sp->cmd_forw = NULL;
 }
 ISP_SET_RESPONSE_OUT(isp);

 mutex_exit(ISP_RESP_MUTEX(isp));
 if (head) {
   isp_i_call_pkt_comp(isp, head);
 } else {
   if (isp_i_handle_mbox_cmd(isp) != ISP_AEN_SUCCESS) {
     return (DDI_INTR_CLAIMED);
   }
   /*
   * if there was a reset then check the response
   * queue again
   */
   goto again;
 }
 while (ISP_INT_PENDING(isp));
 return (DDI_INTR_CLAIMED);

static void
EXAMPLE 15-9 HBA Driver Interrupt Handler (Continued)

```c
isp_i_call_pkt_comp(
    struct isp *isp,
    struct isp_cmd *head)
{
    struct isp *isp;
    struct isp_cmd *sp;
    struct scsi_pkt *pkt;
    struct isp_response *resp;
    u_char status;

    while (head) {
        sp = head;
        pkt = sp->cmd_pkt;
        head = sp->cmd_forw;

        ASSERT(sp->cmd_flags & CFLAG_FINISHED);

        resp = &sp->cmd_isp_response;

        pkt->pkt_scbp[0] = (u_char)resp->resp_scb;
        pkt->pkt_state = ISP_GET_PKT_STATE(resp->resp_state);
        pkt->pkt_statistics = (u_long)ISP_GET_PKT_STATS(resp->resp_status_flags);
        pkt->pkt_resid = (long)resp->resp_resid;

        /*
         * if data was xferred and this is a consistent pkt,
         * we need to do a dma sync
         */
        if ((sp->cmd_flags & CFLAG_CMDIOPB) &&
            (pkt->pkt_state & STATE_XFERRED_DATA)) {
            (void) ddi_dma_sync(sp->cmd_dmahandle,
                                sp->cmd_dma_offset, sp->cmd_dma_len,
                                DDI_DMA_SYNC_FORCPU);
        }

        sp->cmd_flags = (sp->cmd_flags & ~CFLAG_IN_TRANSPORT) |
                        CFLAG_COMPLETED;

        /*
         * Call packet completion routine if FLAG_NOINTR is not set.
         */
        if (((pkt->pkt_flags & FLAG_NOINTR) == 0) &&
            pkt->pkt_comp) {
            (*pkt->pkt_comp)(pkt);
        }
    }
}
```
Timeout Handler

The HBA driver should be prepared to time out the command if it is not complete within a specified time unless a zero timeout was specified in the `scsi_pkt(9S)` structure.

When a command times out, the HBA driver should mark the `scsi_pkt(9S)` with `pkt_reason` set to `CMD_TIMEOUT` and `pkt_statistics` OR’d with `STAT_TIMEOUT`. The HBA driver should also attempt to recover the target and/or bus and, if this recovery can be performed successfully, mark the `scsi_pkt(9S)` with `pkt_statistics` OR’d with either `STAT_BUS_RESET` or `STAT_DEV_RESET`.

Once the command has timed out and the target and bus recovery attempt has completed, the HBA driver should call the command completion callback.

---

**Note** – If recovery was unsuccessful or not attempted, the target driver might attempt to recover from the timeout by calling `scsi_reset(9F)`.

---

The ISP hardware manages command timeout directly and returns timed-out commands with the necessary status, so the `isp` sample driver timeout handler checks active commands for timeout state only once every 60 seconds.

The `isp` sample driver uses the `timeout(9F)` facility to arrange for the kernel to call the timeout handler every 60 seconds. The `caddr_t` argument is the parameter set up when the timeout is initialized at `attach(9E)` time. In this case, the `caddr_t` argument is a pointer to the state structure allocated per driver instance.

If the driver discovers timed-out commands that have not been returned as timed-out by the ISP hardware, the hardware is not functioning correctly and needs to be reset.

Capability Management

The following sections discuss capability management.

**tran_getcap()** Entry Point

The `tran_getcap(9E)` entry point for a SCSI HBA driver is called when a target driver calls `scsi_ifgetcap(9F)` to determine the current value of one of a set of SCSA-defined capabilities.

The target driver can request the current setting of the capability for a particular target by setting the `whom` parameter to nonzero. A `whom` value of 0 means the request is for the current setting of the capability for the SCSI bus or for adapter hardware in general.
tran_getcap() should return -1 for undefined capabilities or the current value of the requested capability.

The HBA driver can use the function scsi_hba_lookup_capstr(9F) to compare the capability string against the canonical set of defined capabilities.

**EXAMPLE 15–10 HBA Driver tran_getcap(9E) Entry Point**

```c
static int isp_scsi_getcap(
    struct scsi_address *ap,
    char *cap,
    int whom)
{
    struct isp *isp;
    int rval = 0;
    u_char tgt = ap->a_target;

    /*
     * We don't allow getting capabilities for other targets
     */
    if (cap == NULL || whom == 0) {
        return (-1);
    }
    isp = (struct isp *)ap->a_hba_tran->tran_hba_private;
    ISP_MUTEX_ENTER(isp);
    switch (scsi_hba_lookup_capstr(cap)) {
    case SCSI_CAP_DMA_MAX:
        rval = 1 < 24; /* Limit to 16MB max transfer */
        break;
    case SCSI_CAP_MSG_OUT:
        rval = 1;
        break;
    case SCSI_CAP_DISCONNECT:
        if (((isp->isp_target_scsi_options[tgt] & SCSI_OPTIONS_DR) == 0) {
            break;
        } else if {
            (isp->isp_cap[tgt] & ISP_CAP_DISCONNECT) == 0) {
                break;
            }
        rval = 1;
        break;
    case SCSI_CAP_SYNCHRONOUS:
        if (((isp->isp_target_scsi_options[tgt] & SCSI_OPTIONS_SYNC) == 0) {
            break;
        } else if {
            (isp->isp_cap[tgt] & ISP_CAP_SYNC) == 0) {
                break;
            }
        }
    }
```
EXAMPLE 15–10 HBA Driver tran_getcap(9E) Entry Point (Continued)

rval = 1;
break;
case SCSI_CAP_WIDE_XFER:
    if ((isp->isp_target_scsi_options[tgt] &
        SCSI_OPTIONS_WIDE) == 0) {
        break;
    } else if (isp->isp_cap[tgt] & ISP_CAP_WIDE) == 0) {
        break;
    } rval = 1;
break;
case SCSI_CAP_TAGGED_QING:
    if ((isp->isp_target_scsi_options[tgt] &
        SCSI_OPTIONS_DR) == 0 ||
        (isp->isp_target_scsi_options[tgt] &
        SCSI_OPTIONS_TAG) == 0) {
        break;
    } else if (isp->isp_cap[tgt] & ISP_CAP_TAG) == 0) {
        break;
    } rval = 1;
break;
case SCSI_CAP_UNTAGGED_QING:
    rval = 1;
break;
case SCSI_CAP_PARITY:
    if (isp->isp_target_scsi_options[tgt] &

break;
case SCSI_CAP_GEOMETRY:
    rval = (64 << 16) | 32;
break;

default:
    rval = -1;
break;
tran_setcap() Entry Point

The tran_setcap(9E) entry point for a SCSI HBA driver is called when a target driver calls scsi_ifsetcap(9F) to change the current one of a set of SCSA-defined capabilities.

The target driver might request that the new value be set for a particular target by setting the whom parameter to nonzero. A whom value of 0 means the request is to set the new value for the SCSI bus or for adapter hardware in general.

tran_setcap() should return -1 for undefined capabilities, 0 if the HBA driver cannot set the capability to the requested value, or 1 if the HBA driver is able to set the capability to the requested value.

The HBA driver can use the function scsi_hba_lookup_capstr(9F) to compare the capability string against the canonical set of defined capabilities.

```
EXAMPLE 15–11 HBA Driver tran_setcap(9E) Entry Point

static int
isp_scsi_setcap(
    struct scsi_address *ap,
    char *cap,
    int value,
    int whom)
{
    struct isp *isp;
    int rval = 0;
    u_char tgt = ap->a_target;
    int update_isp = 0;

    ISP_MUTEX_ENTER(isp);
    ISP_MUTEX_EXIT(isp);

    return (rval);
}
```

Abort and Reset Management

The following sections discuss the abort and reset entry points for SCSI HBA.

**tran_abort() Entry Point**

The `tran_abort()` entry point for a SCSI HBA driver is called to abort one or all the commands currently in transport for a particular target. This entry point is called when a target driver calls `scsi_abort()`. The `tran_abort()` entry point should attempt to abort the command denoted by the `pkt` parameter. If the `pkt` parameter is NULL, `tran_abort()` should attempt to abort all outstanding commands in the transport layer for the particular target or logical unit.

Each command successfully aborted must be marked with `pkt_reason CMD_ABORTED` and `pkt_statistics OR'd with STAT_ABORTED`.

**tran_reset() Entry Point**

The `tran_reset()` entry point for a SCSI HBA driver is called to reset either the SCSI bus or a particular SCSI target device. This entry point is called when a target driver calls `scsi_reset()`. The `tran_reset()` entry point must reset the SCSI bus if `level` is `RESET_ALL`. If `level` is `RESET_TARGET`, just the particular target or logical unit must be reset.

Active commands affected by the reset must be marked with `pkt_reason CMD_RESET`, and with `pkt_statistics OR'd with either STAT_BUS_RESET or STAT_DEV_RESET`, depending on the type of reset.

Commands in the transport layer, but not yet active on the target, must be marked with `pkt_reason CMD_RESET`, and `pkt_statistics OR'd with STAT_ABORTED`.

**tran_bus_reset() Entry Point**

The `tran_bus_reset()` entry point should attempt to abort all commands currently in transport for a particular target. This entry point is called when a target driver calls `scsi_abort()`. The `tran_bus_reset()` entry point should attempt to abort all outstanding commands in the transport layer for the particular target or logical unit.

Each command successfully aborted must be marked with `pkt_reason CMD_ABORTED` and `pkt_statistics OR'd with STAT_ABORTED`.

Include `<sys/scsi/scsi.h>`

```c
#include <sys/scsi/scsi.h>

int tran_bus_reset(dev_info_t *hba_dip, int level);
```

Where `level` must be the following:

- `RESET_BUS` Reset the SCSI bus only, not the targets

The `tran_bus_reset()` vector in the `scsi_hba_tran(9S)` structure should be initialized during the HBA driver's `attach(9E)` to point to an HBA entry point to be called when a user initiates a bus reset.
Implementation is hardware specific. If it cannot reset the SCSI bus without affecting the targets, the HBA driver should fail RESET_BUS or not initialize this vector.

**tran_reset_notify() Entry Point**

The `tran_reset_notify` entry point for a SCSI HBA driver is called to request that the HBA driver notify the target driver by callback when a SCSI bus reset occurs.

```c
EXAMPLE 15–12 HBA Driver tran_reset_notify(9E) Entry Point

```isp_scsi_reset_notify(`
  struct scsi_address *ap,
  int flag,
  void (*callback)(caddr_t),
  caddr_t arg)
{
  struct isp *isp;
  struct isp_reset_notify_entry *p, *beforep;
  int rval = DDI_FAILURE;

  isp = (struct isp *)ap->a_hba_tran->tran_hba_private;

  mutex_enter(ISP_REQ_MUTEX(isp));
  /*
   * Try to find an existing entry for this target
   */
  p = isp->isp_reset_notify_listf;
  beforep = NULL;
  while (p) {
    if (p->ap == ap)
      break;
    beforep = p;
    p = p->next;
  }
  if (((flag & SCSI_RESET_CANCEL) && (p != NULL)) {
    if (beforep == NULL) {
      isp->isp_reset_notify_listf = p->next;
    } else {
      beforep->next = p->next;
      }
    kmem_free((caddr_t)p, sizeof (struct
      isp_reset_notify_entry));
    rval = DDI_SUCCESS;
  } else if (((flag & SCSI_RESET_NOTIFY) && (p == NULL)) {
    p = kmem_zalloc(sizeof (struct isp_reset_notify_entry),
      KM_SLEEP);
    p->ap = ap;
    p->callback = callback;
  }
```
EXAMPLE 15.12 HBA Driver tran_reset_notify(9E) Entry Point  (Continued)

```c
    p->arg = arg;
p->next = isp->isp_reset_notify_listf;
isp->isp_reset_notify_listf = p;
rval = DDI_SUCCESS;
"

mutex_exit(ISP_REQ_MUTEX(isp));
return (rval);
```

Dynamic Reconfiguration

To support the minimal set of hot-plugging operations, drivers might need to implement support for bus *quiesce*, bus *unquiesce*, and bus *reset*. The *scsi_hba_tran(9S)* structure supports these operations. If *quiesce/unquiesce/reset* is not required by hardware, no driver changes are needed.

The *scsi_hba_tran* structure includes the following fields:

```c
    int (*tran_quiesce)(dev_info_t *hba_dip);
    int (*tran_unquiesce)(dev_info_t *hba_dip);
    int (*tran_bus_reset)(dev_info_t *hba_dip, int level);
```

These interfaces quiesce and unquiesce a SCSI bus.

```c
#include <sys/scsi/scsi.h>

int prefixtran_quiesce(dev_info_t *hba_dip);
int prefixtran_unquiesce(dev_info_t *hba_dip);
```

*tran_quiesce(9E)* and *tran_unquiesce(9E)* must be implemented by an HBA driver to support dynamic reconfiguration (DR) of SCSI devices on buses that were not designed to support hot-plugging.

The *tran_quiesce(9E)* and *tran_unquiesce(9E)* vectors in the *scsi_hba_tran(9S)* structure should be initialized during the HBA driver’s *attach(9E)* to point to HBA entry points so they are called when a user initiates quiesce and unquiesce operations.

*tran_quiesce(9E)* is called by the SCSA framework to stop all activity on a SCSI bus prior to and during the reconfiguration of devices attached to the SCSI bus. *tran_unquiesce(9E)* is called by the SCSA framework to resume activity on the SCSI bus after the reconfiguration operation has been completed.
HBA drivers are required to handle `tran_quiesce(9E)` by waiting for all outstanding commands to complete before returning success. After the HBA has quiesced the bus, it must queue any new I/O requests from target drivers until the SCSA framework calls the corresponding `tran_unquiesce(9E)` entry point.

HBA drivers handle calls to `tran_unquiesce(9E)` by starting any target driver I/O requests that were queued by the HBA during the time the bus was quiesced.

---

**SCSI HBA Driver Specific Issues**

The section covers issues specific to SCSI HBA drivers.

**Installing HBA Drivers**

A SCSI HBA driver is installed like a leaf driver (see Chapter 17), except that the `add_drv(1M)` command must specify the driver class as SCSI, such as:

```
# add_drv -m" * 0666 root root" -i"pci1077,1020" -c scsi isp
```

**HBA Configuration Properties**

When attaching an instance of an HBA device, `scsi_hba_attach_setup(9F)` creates a number of SCSI configuration parameter properties for that HBA instance. A particular property is created only if there is no existing property of the same name already attached to the HBA instance, permitting a default property value to be overridden in an HBA configuration file.

An HBA driver must use `ddi_prop_get_int(9F)` to retrieve each property. The HBA driver then modifies (or accepts the default value of) the properties to configure its specific operation.

**scsi-reset-delay Property**

The `scsi-reset-delay` property is an integer specifying the SCSI bus or device reset delay recovery time in milliseconds.
**scsi-options Property**

The `scsi-options` property is an integer specifying a number of options through individually defined bits. The bits in `scsi_options` are:

- **SCSI_OPTIONS_DR (0x008)** – If not set, the HBA should not grant disconnect privileges to a target device.
- **SCSI_OPTIONS_LINK (0x010)** – If not set, the HBA should not enable linked commands.
- **SCSI_OPTIONS_SYNC (0x020)** – If not set, the HBA should not negotiate synchronous data transfer, and should reject any attempt to negotiate synchronous data transfer initiated by a target.
- **SCSI_OPTIONS_PARITY (0x040)** – If not set, the HBA should run the SCSI bus without parity.
- **SCSI_OPTIONS_TAG (0x080)** – If not set, the HBA should not operate in Command Tagged Queuing mode.
- **SCSI_OPTIONS_FAST (0x100)** – If not set, the HBA should not operate the bus in FAST SCSI mode.
- **SCSI_OPTIONS_WIDE (0x200)** – If not set, the HBA should not operate the bus in WIDE SCSI mode.

**Per-target scsi-options**

An HBA driver might support a per-target `scsi-options` feature in the following format:

```
target<n>-scsi-options=<hex value>
```

In this example, `<n>` is the target ID. If the per-target `scsi-options` property is defined for a particular target, the HBA driver uses the value of the per-target `scsi-options` property for that target rather than the per-HBA driver instance `scsi-options` property. This can provide more precise control if, for example, synchronous data transfer needs to be disabled for just one particular target device. The per-target `scsi-options` property can be defined in the `driver.conf` file.

Here is an example of a per-target `scsi-options` property definition to disable synchronous data transfer for target device 3:

```
target3-scsi-options=0x2d8
```

**IA Target Driver Configuration Properties**

Some IA SCSI target drivers (such as the `cmdk` disk target driver) use the following configuration properties:
When using the `cmdk` sample driver to write an HBA driver for an IA platform, one or more of these properties (as appropriate to the HBA driver and hardware) need to be defined in the `driver.conf` file.

**Note** – These property definitions should appear only in an HBA driver's `driver.conf` file. The HBA driver itself should not inspect or attempt to interpret these properties in any way. These properties are advisory only and serve as an adjunct to the `cmdk` driver. They should not be relied upon in any way. The property definitions might or might not be used in future releases.

The disk property can be used to define the type of disk supported by `cmdk`. For a SCSI HBA, the only possible value for the disk property is:

- `disk="scdk"` – Disk type is a SCSI disk

The queue property defines how the disk driver sorts the queue of incoming requests during strategy(9E). There are two possible values:

- `queue="qsort"` – One-way elevator queuing model, provided by `disksort`(9F)
- `queue="qfifo"` – FIFO (first in, first out) queuing model

The flow_control property defines how commands are transported to the HBA driver. There are three possible values:

- `flow_control="dsngl"` – Single command per HBA driver
- `flow_control="dmult"` – Multiple commands per HBA driver—when the HBA queue is full, the driver returns `TRAN_BUSY`
- `flow_control="duplx"` – The HBA can support separate read and write queues, with multiple commands per queue. FIFO ordering is used for the write queue; the queuing model used for the read queue is described by the queue property. When an HBA queue is full, the driver returns `TRAN_BUSY`

Here is an example of a `driver.conf` file for use with an IA HBA PCI device designed for use with the `cmdk` sample driver:

```bash
# config file for ISP 1020 SCSI HBA driver
#
flow_control="dsngl" queue="qsort" disk="scdk"
scsi-initiator-id=7;
```
Support for Queuing

For a definition of tagged queuing, refer to the SCSI-2 specification. To support tagged queuing, first check the `scsi_options` flag `SCSI_OPTIONS_TAG` to see if tagged queuing is enabled globally. Next, check to see if the target is a SCSI-2 device and whether it has tagged queuing enabled. If this is all true, attempt to enable tagged queuing by using `scsi_ifsetcap(9F)`.

If tagged queuing fails, you can attempt to set untagged queuing. In this mode, you submit as many commands as you think necessary or optimal to the host adapter driver. Then the host adapter queues the commands to the target one at a time (as opposed to tagged queuing, where the host adapter submits as many commands as it can until the target indicates that the queue is full).
Drivers for Network Devices

Solaris network drivers are STREAMS-based. These types of drivers are covered in depth in *STREAMS Programming Guide*. This chapter discusses the Generic LAN driver (GLD), which is a kernel module encapsulating features common to most network drivers. The GLD implements much of the STREAMS and Data Link Provider Interface (DLPI) functionality for a Solaris network driver.

This chapter provides information on the following subjects:

- “Generic LAN Driver Overview” on page 299
- “Declarations and Data Structures” on page 309
- “GLD Arguments” on page 314
- “GLD Entry Points” on page 315
- “GLD Service Routines” on page 319

For more information on GLDs, see the `gld(7D)`, `dlpi(7P)`, `gld(9E)`, `gld(9F)`, `gld_mac_info(9S)`, `gld_stats(9S)` man pages.

Generic LAN Driver Overview

GLD is a multi-threaded, clonable, loadable kernel module providing support for Solaris local area network device drivers. Local area network (LAN) device drivers in Solaris are STREAMS-based drivers that use DLPI to communicate with network protocol stacks. These protocol stacks use the network drivers to send and receive packets on a local area network. A network device driver must implement and conform to the requirements imposed by the DDI/DKI specification, STREAMS specification, DLPI specification, and programmatic interface of the device itself.
GLD implements most STREAMS and DLPI functionality required of a Solaris LAN driver. Several Solaris network drivers are implemented using GLD.

A Solaris network driver implemented using GLD is made up of two distinct parts: a generic component that deals with STREAMS and DLPI interfaces, and a device-specific component that deals with the particular hardware device. The device-specific module indicates its dependency on the GLD module (which is found at /kernel/misc/gld) and registers itself with GLD from within the driver’s attach(9E) function. After it is successfully loaded, the driver is DLPI-compliant. The device-specific part of the driver calls gld(9F) functions when it receives data or needs some service from GLD. GLD makes calls into the gld(9E) entry points of the device-specific driver through pointers provided to GLD by the device-specific driver when it registered itself with GLD. The gld_mac_info(9S) structure is the main data interface between GLD and the device-specific driver.

The GLD facility currently supports devices of type DL_ETHER (ISO 8802-3, IEEE 802.3 protocol), DL_TPR (IEEE 802.5, Token Passing Ring), and DL_FDDI (ISO 9314-2, Fibre Distributed Data Interface). GLD drivers are expected to process fully formed MAC-layer packets and should not perform logical link control (LLC) handling.

In some cases, you might need or want to implement a full DLPI-compliant driver without using the GLD facility. This is true for devices that are not ISO 8802-style (IEEE 802) LAN devices, or where you need a device type or DLPI service not supported by GLD.

**Type DL_ETHER: Ethernet V2 and ISO 8802-3 (IEEE 802.3)**

For devices designated type DL_ETHER, GLD provides support for both Ethernet V2 and ISO 8802-3 (IEEE 802.3) packet processing. Ethernet V2 enables a data link service user to access and use any of a variety of conforming data link service providers without special knowledge of the provider’s protocol. A service access point (SAP) is the point through which the user communicates with the service provider.

Streams bound to SAP values in the range [0-255] are treated as equivalent and denote that the user wants to use 8802-3 mode. If the value of the SAP field of the DL_BIND_REQ is within this range, GLD computes the length (not including the 14-byte media access control (MAC) header) of each subsequent DL_UNITDATA_REQ message on that Stream and transmits 8802-3 frames having those lengths in the MAC frame header type fields. Such lengths never exceed 1500.

All frames received from the media that have a type field in the range [0-1500] are assumed to be 8802-3 frames and are routed up all open Streams that are in 8802-3 mode (those Streams bound to a SAP value in the [0-255] range). If more than one Stream is in 8802-3 mode, the incoming frame is duplicated and routed up each such Stream.
Streams bound to SAP values greater than 1500 (Ethernet V2 mode) receive incoming packets whose Ethernet MAC header type value exactly matches the value of the SAP to which the Stream is bound.

**Types DL_TPR and DL_FDDI: SNAP Processing**

For media types DL_TPR and DL_FDDI, GLD implements minimal SNAP (Sub-Net Access Protocol) processing for any Stream bound to a SAP value greater than 255. SAP values in the range [0-255] are LLC SAP values and are carried naturally by the media packet format. SAP values greater than 255 require a SNAP header, subordinate to the LLC header, to carry the 16-bit Ethernet V2-style SAP value.

SNAP headers are carried under LLC headers with destination SAP 0xAA. For outgoing packets with SAP values greater than 255, GLD creates an LLC+SNAP header that always looks like:

```
AA AA 03 00 00 00 XX XX
```

where “XX XX” represents the 16-bit SAP, corresponding to the Ethernet V2 style “type.” This is the only class of SNAP header supported—non-zero OUI (organizational unique identifier) fields and LLC control fields other than 03 are considered to be LLC packets with SAP 0xAA. Clients wanting to use SNAP formats other than this one must use LLC and bind to SAP 0xAA.

Incoming packets are examined to ascertain whether they conform to the format shown above. Packets that conform to this format are matched to any Streams bound to the packet’s 16-bit SNAP type, as well as being considered to match the LLC SNAP SAP 0xAA.

Packets received for any LLC SAP are passed up all Streams that are bound to an LLC SAP, as described for media type DL_ETHER.

**Type DL_TPR: Source Routing**

For type DL_TPR devices, GLD implements minimal support for source routing. Source routing enables a station that is sending a packet across a bridged medium to specify (in the packet MAC header) routing information that determines the route that the packet will take through the network.

Functionally, the source routing support provided by GLD learns routes, solicits and responds to requests for information about possible multiple routes, and selects among available routes. It adds *Routing Information Fields* to the MAC headers of outgoing packets and recognizes such fields in incoming packets.

GLD’s source routing support does not implement the full *Route Determination Entity* (RDE) specified in Section 9 of *ISO 8802-2 (IEEE 802.2)*. However, it can interoperate with any such implementations that might exist in the same (or a bridged) network.
Style 1 and Style 2 DLPI Providers

GLD implements both Style 1 and Style 2 DLPI providers. A physical point of attachment (PPA) is the point at which a system attaches itself to a physical communication medium. All communication on that physical medium funnels through the PPA. The Style 1 provider attaches the Stream to a particular PPA based on the major/minor device that has been opened. The Style 2 provider requires the DLS (data link service) user to explicitly identify the desired PPA using DL_ATTACH_REQ. In this case, open(9E) creates a Stream between the user and GLD, and DL_ATTACH_REQ subsequently associates a particular PPA with that Stream. Style 2 is denoted by a minor number of zero. If a device node whose minor number is not zero is opened, Style 1 is indicated and the associated PPA is the minor number minus 1. In both Style 1 and Style 2 opens, the device is cloned.

Implemented DLPI Primitives

GLD implements several DLPI primitives. The DL_INFO_REQ primitive requests information about the DLPI Stream. The message consists of one M_PROTO message block. GLD returns device-dependent values in the DL_INFO_ACK response to this request, based on information the GLD-based driver specified in the gldm_mac_info(9S) structure passed to gld_register(). However, GLD returns the following values on behalf of all GLD-based drivers:

- Version is DL_VERSION_2
- Service mode is DL_CLDLS — GLD implements connectionless-mode service
- Provider style is DL_STYLE1 or DL_STYLE2, depending on how the Stream was opened
- No optional Quality of Service (QOS) support is present and the QOS fields are zero

*Note* — Contrary to the DLPI specification, GLD returns the device’s correct address length and broadcast address in DL_INFO_ACK even before the Stream has been attached to a PPA.

The DL_ATTACH_REQ primitive is used to associate a PPA with a Stream. This request is needed for Style 2 DLS providers to identify the physical medium over which the communication will transpire. Upon completion, the state changes from DL_UNATTACHED to DL_UNBOUND. The message consists of one M_PROTO message block. This request is not permitted when using the driver in Style 1 mode; Streams opened using Style 1 are already attached to a PPA by the time the open completes.

The DL_DETACH_REQ primitive requests to detach the PPA from the Stream. This is only allowed if the Stream was opened using Style 2.
The DL_BIND_REQ and DL_UNBIND_REQ primitives bind and unbind a DLSAP (data link service access point) to the Stream. The PPA associated with a Stream will have completed initialization before completion of the processing of the DL_BIND_REQ on that Stream. Binding multiple Streams to the same SAP is allowed; each such Stream receives a copy of any packets received for that SAP.

The DL_ENABMULTI_REQ and DL_DISABMULTI_REQ primitives enable and disable reception of individual multicast group addresses. An application or other DLS user is permitted to create or modify a set of multicast addresses on a per-Stream basis by iterative use of these primitives. The Stream must be attached to a PPA for these primitives to be accepted.

The DL_PROMISCON_REQ and DL_PROMISCOFF_REQ primitives enable and disable promiscuous mode on a per-Stream basis, either at a physical level or at the SAP level. The DL Provider routes all received messages on the media to the DLS user until either a DL_DETACH_REQ or a DL_PROMISCOFF_REQ is received or the Stream is closed. You can specify physical level promiscuous reception of all packets on the medium or of multicast packets only.

**Note** – The Stream must be attached to a PPA for these promiscuous mode primitives to be accepted.

The DL_UNITDATA_REQ primitive is used to send data in a connectionless transfer. Because this is an unacknowledged service, there is no guarantee of delivery. The message consists of one M_PROTO message block followed by one or more M_DATA blocks containing at least one byte of data.

The DL_UNITDATA_IND type is used when a packet is received and is to be passed upstream. The packet is put into an M_PROTO message with the primitive set to DL_UNITDATA_IND.

The DL_PHYS_ADDR_REQ primitive requests the MAC address currently associated with the PPA attached to the Stream. The address is returned by the DL_PHYS_ADDR_ACK primitive. When using Style 2, this primitive is only valid following a successful DL_ATTACH_REQ.

The DL_SET_PHYS_ADDR_REQ primitive changes the MAC address currently associated with the PPA attached to the Stream. This primitive affects all other current and future Streams attached to this device. Once changed, all Streams currently or subsequently opened and attached to this device will obtain this new physical address. The new physical address remains in effect until this primitive is used to change the physical address again or the driver is reloaded.

**Note** – The superuser is allowed to change the physical address of a PPA while other Streams are bound to the same PPA.
The DL_GET_STATISTICS_REQ primitive requests a DL_GET_STATISTICS_ACK response containing statistics information associated with the PPA attached to the Stream. Style 2 Streams must be attached to a particular PPA using DL_ATTACH_REQ before this primitive can succeed.

### Implemented ioctl Functions

GLD implements the ioctl ioctl command described below. If GLD receives an ioctl command that it does not recognize, it passes it to the device-specific driver’s gldm_ioctl() routine, as described in gld(9E).

The DLIOCRAW ioctl function is used by some DLPI applications, most notably the snoop(1M) command. The DLIOCRAW command puts the Stream into a raw mode, which causes the driver to pass full MAC-level incoming packets upstream in M_DATA messages instead of transforming them into the DL_UNITDATA_IND form that is normally used for reporting incoming packets. Packet SAP filtering is still performed on Streams that are in raw mode. If a Stream user wants to receive all incoming packets, it must also select the appropriate promiscuous mode or modes. After successfully selecting raw mode, the application is also allowed to send fully formatted packets to the driver as M_DATA messages for transmission. DLIOCRAW takes no arguments. Once enabled, the Stream remains in this mode until closed.

### GLD Driver Requirements

GLD-based drivers must include the header file <sys/gld.h>.

GLD-based drivers must be linked with the -N"misc/gld" option:

```
%ld -r -N"misc/gld" xx.o -o xx
```

GLD implements the open(9E) and close(9E) functions and the required STREAMS put(9E) and srv(9E) functions on behalf of the device-specific driver. GLD also implements the getinfo(9E) function for the driver.

The mi_idname element of the module_info(9S) structure is a string specifying the name of the driver. This must exactly match the name of the driver module as it exists in the file system.

The read-side qinit(9S) structure should specify the following elements:

- **qi_putp**: NULL
- **qi_srvp**: gld_rsrv
- **qi_qopen**: gld_open
- **qi_qclose**: gld_close

The write-side qinit(9S) structure should specify these elements:
qi_putp gld_wput
glq_qopen NULL
qi_qclose NULL

The devo_getinfo element of the dev_ops(9S) structure should specify gld_getinfo as the getinfo(9E) routine.

The driver's attach(9E) function does all the work of associating the hardware-specific device driver with the GLD facility and preparing the device and driver for use.

The attach(9E) function allocates a gld_mac_info(9S) ("macinfo") structure using gld_mac_alloc(). The driver usually needs to save more information per device than is defined in the macinfo structure. It should allocate the additional required data structure and save a pointer to it in the gldm_private member of the gld_mac_info(9S) structure.

The attach(9E) routine must initialize the macinfo structure as described in gld_mac_info(9S) and then call gld_register() to link the driver with the GLD module. The driver should map registers if necessary and be fully initialized and prepared to accept interrupts before calling gld_register(). The attach(9E) function should add interrupts but not enable the device to generate them. The driver should reset the hardware before calling gld_register() to ensure it is quiescent. The device must not be started or put into a state where it might generate an interrupt before gld_register() is called. That will be done later when GLD calls the driver's gldm_start() entry point, described in the gld(9E) man page. After gld_register() succeeds, the gld(9E) entry points might be called by GLD at any time.

The attach(9E) routine should return DDI_SUCCESS if gld_register() succeeds. If gld_register() fails, it returns DDI_FAILURE, and the attach(9E) routine should deallocate any resources it allocated before calling gld_register() and then also return DDI_FAILURE. Under no circumstances should a failed macinfo structure be reused; it should be deallocated using gld_mac_free().

The detach(9E) function should attempt to unregister the driver from GLD by calling gld_unregister() (described in gld(9F) man page). The detach(9E) routine can get a pointer to the needed gld_mac_info(9S) structure from the device's private data using ddi_get_driver_private(9F). gld_unregister() checks certain conditions that could require that the driver not be detached. If the checks fail, gld_unregister() returns DDI_FAILURE, in which case the driver's detach(9E) routine must leave the device operational and return DDI_FAILURE.

If the checks succeed, gld_unregister() ensures that the device interrupts are stopped (calling the driver's gldm_stop() routine if necessary), unlinks the driver from the GLD framework, and returns DDI_SUCCESS. In this case, the detach(9E)
routine should remove interrupts, deallocate any data structures allocated in the attach(9E) routine (using gld_mac_free() to deallocate the macinfo structure), and return DDI_SUCCESS. The routine must remove the interrupt before calling gld_mac_free().

Network Statistics

Solaris network drivers must implement statistics variables. GLD itself tallies some network statistics, but other statistics must be counted by each GLD-based driver. GLD provides support for GLD-based drivers to report a standard set of network driver statistics. Statistics are reported by GLD using the kstat(7D) and kstat(9S) mechanisms. The DL_GET_STATISTICS_REQ DLPI command can also be used to retrieve the current statistics counters. All statistics are maintained as unsigned, and all are 32 bits unless otherwise noted.

GLD maintains and reports the following statistics.

- **rbytes64**: Total bytes successfully received on the interface (64 bits)
- **rbytes**: Total bytes successfully received on the interface
- **obytes64**: Total bytes requested to be transmitted on the interface (64 bits)
- **obytes**: Total bytes requested to be transmitted on the interface
- **ipackets64**: Total packets successfully received on the interface (64 bits)
- **ipackets**: Total packets successfully received on the interface
- **opackets64**: Total packets requested to be transmitted on the interface (64 bits)
- **opackets**: Total packets requested to be transmitted on the interface
- **multircv**: Multicast packets successfully received, including group and functional addresses (long)
- **multixmt**: Multicast packets requested to be transmitted, including group and functional addresses (long)
- **brdcstrcv**: Broadcast packets successfully received (long)
- **brdcstxmt**: Broadcast packets requested to be transmitted (long)
- **unknowns**: Valid received packets not accepted by any Stream (long)
The device-dependent driver counts the following statistics, keeping track of them in a private per-instance structure. When GLD is asked to report statistics, it calls the driver's `gldm_get_stats()` entry point (as described in the `gldm_get_stats(9E)` man page) to update the device-specific statistics in the `gld_stats(9S)` structure. GLD then reports the updated statistics using the named statistics variables shown below.

- `ifspeed`: Current estimated bandwidth of the interface in bits per second (64 bits)
- `media`: Current media type in use by the device (string)
- `intr`: Times interrupt handler was called and claimed the interrupt (long)
- `norcvbuf`: Number of times a valid incoming packet was known to have been discarded because no buffer could be allocated for receive (long)
- `ierrors`: Total packets received that could not be processed because they contained errors (long)
- `oerrors`: Total packets that were not successfully transmitted because of errors (long)
- `missed`: Packets known to have been dropped by the hardware on receive (long)
- `uflo`: Times FIFO underflowed on transmit (long)
- `oflo`: Times receiver overflowed during receive (long)

The following group of statistics applies to networks of type `DL_ETHER`. These statistics are maintained by device-specific drivers of that type, as shown previously.

- `align_errors`: Packets received with framing errors (not an integral number of octets) (long)
- `fcs_errors`: Packets received with CRC errors (long)
- `duplex`: Current duplex mode of the interface (string)
carrier_errors  Number of times carrier was lost or never detected on a transmission attempt (long)
collisions  Ethernet collisions during transmit (long)
ex_collisions  Frames where excess collisions occurred on transmit, causing transmit failure (long)
tx_late_collisions  Number of times a transmit collision occurred late (after 512 bit times) (long)
defer_xmts  Packets without collisions where first transmit attempt was delayed because the medium was busy (long)
first_collisions  Packets successfully transmitted with exactly one collision
multi_collisions  Packets successfully transmitted with multiple collisions
sqe_errors  Number of times SQE test error was reported
macxmt_errors  Packets encountering transmit MAC failures, except carrier and collision failures
macrcv_errors  Packets received with MAC errors, except align_errors, fcs_errors, and tolong_errors
toolong_errors  Packets received larger than the maximum permitted length
runt_errors  Packets received smaller than the minimum permitted length (long)

The following group of statistics applies to networks of type DL_TPR; these are maintained by device-specific drivers of that type, as shown above.

line_errors  Packets received with non-data bits or FCS errors
burst_errors  Number of times an absence of transitions for five half-bit timers was detected
signal_losses  Number of times loss of signal condition on the ring was detected
ace_errors  Number of times an AMP or SMP frame, in which A is equal to C is equal to 0, was followed by another such SMP frame without an intervening AMP frame
internal_errors  Number of times the station recognized an internal error
lost_frame_errors  Number of times the TRR timer expired during transmit

**Declarations and Data Structures**

This section describes the `gld_mac_info(9S)` and `gld_stats` structures.

**gld_mac_info Structure**

The GLD MAC information (`gld_mac_info`) structure is the main data interface between the device-specific driver and GLD. It contains data required by GLD and a pointer to an optional additional driver-specific information structure.
Allocate the gld_mac_info structure using gld_mac_alloc() and deallocate it using gld_mac_free(). Drivers must not make any assumptions about the length of this structure, which might vary in different releases of Solaris, GLD, or both. Structure members private to GLD, not documented here, should not be set or read by the device-specific driver.

The gld_mac_info(9S) structure contains the following fields.

```
caddr_t gldm_private;       /* Driver private data */
int  (*gldm_reset)();       /* Reset device */
int  (*gldm_start)();       /* Start device */
int  (*gldm_stop)();        /* Stop device */
int  (*gldm_set_mac_addr)();/* Set device phys addr */
int  (*gldm_set_multicast)();/* Set/delete multicast addr */
int  (*gldm_set_promiscuous)();/* Set/reset promiscuous mode */
int  (*gldm_send)();        /* Transmit routine */
uint_t (*gldm_intr)();      /* Interrupt handler */
int  (*gldm_get_stats)();   /* Get device statistics */
char *gldm_ident;           /* Device type */
uint32_t gldm_type;         /* Minimum packet size */
uint32_t gldm_minpkt;       /* Maximum packet size */
uint32_t gldm_maxpkt;       /* Physical address length */
int32_t gldm_addrlen;       /* Physical address length */
unsigned char *gldm广播_addr; /* Physical broadcast addr */
unsigned char *gldm_vendor_addr; /* Factory MAC address */
t_uscalar_t glldm_ppa;      /* Physical Point of */
dev_info_t *gldm_devinfo;   /* Pointer to device's */
                           /* dev_info node */
                     ddi_iblock_cookie_t gldm_cookie; /* Device’s interrupt */
                           /* block cookie */
```

The gldm_private structure member is visible to the device driver; it is also private to the device-specific driver and is not used or modified by GLD. Conventionally, this is used as a pointer to private data, pointing to a driver-defined and driver-allocated per-instance data structure.

The following group of structure members must be set by the driver before calling gld_register(), and should not thereafter be modified by the driver. Because gld_register() might use or cache the values of some of these structure members, changes made by the driver after calling gld_register() might cause unpredictable results.

```
gldm_reset Pointer to driver entry point; see the glld(9E) man page.

gldm_start Pointer to driver entry point; see the glld(9E) man page.
```

</tbody>
</table>
address in a DLSAP address. See Appendix A.2, “Message DL_INFO_ACK,” in the DLPI specification for more details.

**gldm_broadcast_addr**

Pointer to an array of bytes of length `gldm_addrlen` containing the broadcast address to be used for transmit. The driver must provide space to hold the broadcast address, fill it in with the appropriate value, and set `gldm_broadcast_addr` to point to it. For Ethernet, Token Ring, and FDDI, the broadcast address is normally `0xFF-FF-FF-FF-FF`.

**gldm_vendor_addr**

Pointer to an array of bytes of length `gldm_addrlen` containing the vendor-provided network physical address of the device. The driver must provide space to hold the address, fill it in with information read from the device, and set `gldm_vendor_addr` to point to it.

**gldm_ppa**

PPA number for this instance of the device. This should always be set to the instance number returned from `ddi_get_instance(9F)`.

**gldm_devinfo**

Pointer to the `dev_info` node for this device.

**gldm_cookie**

Interrupt block cookie returned by
`ddi_get_iblock_cookie(9F), ddi_add_intr(9F), ddi_get_soft_iblock_cookie(9F),` or `ddi_add_softintr(9F)`. This must correspond to the device's receive-interrupt, from which `gld_recv()` is called.

---

**gld_stats Structure**

The GLD statistics (`gld_stats`) structure communicates statistics and state information from a GLD-based driver to GLD when returning from a driver's `gldm_get_stats()` routine, as discussed in the `gld(9E)` and `gld(7D)` man pages. The members of this structure, filled in by the GLD-based driver, are used when GLD reports the statistics. In the tables below, the name of the statistics variable reported by GLD is noted in the comments. See the `gld(7D)` man page for a more detailed description of the meaning of each statistic.

Drivers must not make any assumptions about the length of this structure, which might vary in different releases of the Solaris operating environment, GLD, or both. Structure members private to GLD, not documented here, should not be set or read by the device-specific driver.

The following structure members are defined for all media types:
uint64_t glds_speed;    /* ifspeed */
uint32_t glds_media;   /* media */
uint32_t glds_intr;    /* intr */
uint32_t glds_norcvbuf; /* norcvbuf */
uint32_t glds_errrcv;  /* errors */
uint32_t glds_errxmt;  /* errors */
uint32_t glds_missed;  /* missed */
uint32_t glds_underflow; /* uflo */
uint32_t glds_overflow; /* oflo */

The following structure members are defined for media type DL_ETHER:

uint32_t glds_frame;    /* align_errors */
uint32_t glds_crc;      /* fcs_errors */
uint32_t glds_duplex;   /* duplex */
uint32_t glds_nocarrier; /* carrier_errors */
uint32_t glds_collisions; /* collisions */
uint32_t glds_excoll;   /* ex_collisions */
uint32_t glds_xmtlatecoll; /* tx_late_collisions */
uint32_t glds_defer;    /* defer_xmts */
uint32_t glds_dot3_first_coll; /* first_collisions */
uint32_t glds_dot3_multi_coll; /* multi_collisions */
uint32_t glds_dot3_sge_error; /* sge_errors */
uint32_t glds_dot3_mac_xmt_error; /* macxmt_errors */
uint32_t glds_dot3_mac_rcv_error; /* macrcv_errors */
uint32_t glds_dot3_frame_too_long; /* toolong_errors */
uint32_t glds_short;  /* runt_errors */

The following structure members are defined for media type DL_TPR:

uint32_t glds_dot5_line_error /* line_errors */
uint32_t glds_dot5_burst_error /* burst_errors */
uint32_t glds_dot5_signal_loss /* signal_losses */
uint32_t glds_dot5_ace_error /* ace_errors */
uint32_t glds_dot5_internal_error /* internal_errors */
uint32_t glds_dot5_lost_frame_error /* lost_frame_errors */
uint32_t glds_dot5_frame_copied_error /* frame_copied_errors */
uint32_t glds_dot5_token_error /* token_errors */
uint32_t glds_dot5_freq_error /* freq_errors */

The following structure members are defined for media type DL_FDDI:

uint32_t glds_fddi_mac_error; /* mac_errors */
uint32_t glds_fddi_mac_lost; /* mac_lost_errors */
uint32_t glds_fddi_mac_token; /* mac_tokens */
uint32_t glds_fddi_mac_tvx_expired; /* mac_tvx_expired */
uint32_t glds_fddi_mac_late; /* mac_late */
uint32_t glds_fddi_mac_ring_op; /* mac_ring_ops */

Most of the above statistics variables are counters denoting the number of times the particular event was observed. Exceptions are:

gl_ds_speed Estimate of the interface’s current bandwidth in bits per second. For interfaces that do not vary in...
bandwidth or for those where no accurate estimation can be made, this object should contain the nominal bandwidth.

glds_media

Type of media (wiring) or connector used by the hardware. Currently supported media names include GLDM_AUI, GLDM_BNC, GLDM_TP, GLDM_10BT, GLDM_100BT, GLDM_100BTX, GLDM_100BT4, GLDM_RING4, GLDM_RING16, GLDM_FIBER, and GLDM_PHYMII. GLDM_UNKNOWN is also permitted.

glds_duplex

Current duplex state of the interface. Supported values are GLD_DUPLEX_HALF and GLD_DUPLEX_FULL. GLD_DUPLEX_UNKNOWN is also permitted.

GLD Arguments

The following arguments are used by the GLD routines.

macinfo

Pointer to a gld_mac_info(9S) structure.

macaddr

Pointer to the beginning of a character array containing a valid MAC address. The array will be of the length specified by the driver in the gldm_addrlen element of the gld_mac_info(9S) structure.

multicastaddr

Pointer to the beginning of a character array containing a multicast, group, or functional address. The array will be of the length specified by the driver in the gldm_addrlen element of the gld_mac_info(9S) structure.

multiflag

Flag indicating whether reception of the multicast address is to be enabled or disabled. This argument is specified as GLD_MULTI_ENABLE or GLD_MULTI_DISABLE.

promiscflag

Flag indicating what type of promiscuous mode, if any, is to be enabled. This argument is specified as GLD_MAC_PROMISC_PHYS, GLD_MAC_PROMISC_MULTI, or GLD_MAC_PROMISC_NONE.

mp

gld_ioctl() uses mp as a pointer to a STREAMS message block containing the ioctl to be executed. gldm_send() uses it as a pointer to a STREAMS message block containing the packet to be transmitted. gld_recv() uses it as a pointer to a message block containing a received packet.

stats

Pointer to a gld_stats(9S) structure to be filled in with the current values of statistics counters.
Pointer to the queue(9S) structure to be used in the reply to the ioctl.

dip  Pointer to the device’s dev_info structure.

name  Device interface name.

GLD Entry Points

Entry points must be implemented by a device-specific network driver designed to interface with GLD.

As described in the gld(7D) man page, the main data structure for communication between the device-specific driver and the GLD module is the gld_mac_info(9S) structure. Some of the elements in that structure are function pointers to the entry points described here. The device-specific driver must, in its attach(9E) routine, initialize these function pointers before calling gld_register().

gldm_reset() Entry Point

```c
int prefix_reset(gld_mac_info_t * macinfo);
gldm_reset() resets the hardware to its initial state.
```

**gldm_start() Entry Point**

```c
int prefix_start(gld_mac_info_t * macinfo);
gldm_start() enables the device to generate interrupts and prepares the driver to call gld_recv() for delivering received data packets to GLD.
```

**gldm_stop() Entry Point**

```c
int prefix_stop(gld_mac_info_t * macinfo);
gldm_stop() disables the device from generating any interrupts and stops the driver from calling gld_recv() for delivering data packets to GLD. GLD depends on the gldm_stop() routine to ensure that the device will no longer interrupt, and it must do so without fail. This function should always return GLD_SUCCESS.
```
gldm_set_mac_addr() Entry Point

```
int prefx_set_mac_addr(gld_mac_info_t * macinfo, unsigned char * macaddr);
```

`gldm_set_mac_addr()` sets the physical address that the hardware is to use for receiving data. This function enables the device to be programmed via the passed MAC address `macaddr`. If sufficient resources are currently not available to carry out the request, it should return GLD_NORESOURCES. If the requested function is not supported, it should return GLD_NOTSUPPORTED.

---

**gldm_set_multicast() Entry Point**

```
int prefx_set_multicast(gld_mac_info_t * macinfo,
                        unsigned char * multicastaddr, int multilflag);
```

`gldm_set_multicast()` enables and disables device-level reception of specific multicast addresses. If the third argument `multilflag` is set to GLD_MULTI_ENABLE, then the function sets the interface to receive packets with the multicast address pointed to by the second argument. If `multilflag` is set to GLD_MULTI_DISABLE, the driver is allowed to disable reception of the specified multicast address.

This function is called whenever GLD wants to enable or disable reception of a multicast, group, or functional address. GLD makes no assumptions about how the device does multicast support and calls this function to enable or disable a specific multicast address. Some devices might use a hash algorithm and a bitmask to enable collections of multicast addresses; this procedure is allowed, and GLD filters out any superfluous packets. If disabling an address could result in disabling more than one address at the device level, the device driver should keep whatever information it needs in order to avoid disabling an address that GLD has enabled but not disabled.

`gldm_set_multicast()` will not be called to enable a particular multicast address that is already enabled, nor will it be called to disable an address that is not currently enabled. GLD keeps track of multiple requests for the same multicast address and only calls the driver’s entry point when the first request to enable, or the last request to disable, a particular multicast address is made. If sufficient resources are currently not available to carry out the request, the function should return GLD_NORESOURCES. The function should return GLD_NOTSUPPORTED if the requested function is not supported.

---

**gldm_set_promiscuous() Entry Point**

```
int prefx_set_promiscuous(gld_mac_info_t * macinfo, int promiscflag);
```

---

316 Writing Device Drivers • May 2002
gldm_set_promiscuous() enables and disables promiscuous mode. This function is called whenever GLD wants to enable or disable the reception of all packets on the medium, or of all multicast packets on the medium. If the second argument promiscflag is set to the value of GLD_MAC_PROMISC_PHYS, then the function enables physical-level promiscuous mode, resulting in the reception of all packets on the medium. If promiscflag is set to GLD_MAC_PROMISC_MULTI, then reception of all multicast packets will be enabled. If promiscflag is set to GLD_MAC_PROMISC_NONE, then promiscuous mode is disabled.

In the case of a request for promiscuous multicast mode, drivers for devices that have no multicast-only promiscuous mode must set the device to physical promiscuous mode to ensure that all multicast packets are received. In this case the routine should return GLD_SUCCESS. The GLD software filters out any superfluous packets. If sufficient resources are currently not available to carry out the request, the function should return GLD_NORESOURCES. It should return GLD_NOTSUPPORTED if the requested function is not supported.

For forward compatibility, gldm_set_promiscuous() routines should treat any unrecognized values for promiscflag as though they were GLD_MAC_PROMISC_PHYS.

**gldm_send() Entry Point**

```c
int prefix_send(gld_mac_info_t * macinfo, mblk_t * mp);
```

gldm_send() queues a packet to the device for transmission. This routine is passed a STREAMS message containing the packet to be sent. The message might include multiple message blocks, and the send routine must traverse all the message blocks in the message to access the entire packet to be sent. The driver should be prepared to handle and skip over any zero-length message continuation blocks in the chain. The driver should check that the packet does not exceed the maximum allowable packet size, and it must pad the packet, if necessary, to the minimum allowable packet size. If the send routine successfully transmits or queues the packet, it should return GLD_SUCCESS.

The send routine should return GLD_NORESOURCES if it cannot immediately accept the packet for transmission; in this case GLD will retry it later. If gldm_send() ever returns GLD_NORESOURCES, the driver must, at a later time when resources have become available, call gld_sched(). This call to gld_sched() informs GLD that it should retry packets that the driver previously failed to queue for transmission. (If the driver’s gldm_stop() routine is called, the driver is absolved from this obligation until it later again returns GLD_NORESOURCES from its gldm_send() routine. However, extra calls to gld_sched() will not cause incorrect operation.)

If the driver’s send routine returns GLD_SUCCESS, then the driver is responsible for freeing the message when the driver and the hardware no longer need it. If the send routine copied the message into the device, or into a private buffer, then the send
routine is permitted to free the message after the copy is made. If the hardware uses
DMA to read the data directly out of the message data blocks, then the driver must not
free the message until the hardware has completed reading the data. In this case the
driver will probably free the message in the interrupt routine, or in a buffer reclaim
operation at the beginning of a future send operation. If the send routine returns
anything other than GLD_SUCCESS, then the driver must not free the message. Return
GLD_NOLINK if gldm_send() is called when there is no physical connection to the
network or link partner.

gldm_intr() Entry Point

int prefix_intr(gld_mac_info_t * macinfo);

gldm_intr() is called when the device might have interrupted. Because interrupts
can be shared with other devices, the driver must check the device status to determine
whether it actually caused an interrupt. If the device that the driver controls did not
cause the interrupt, then this routine must return DDI_INTR_UNCLAIMED. Otherwise,
it must service the interrupt and should return DDI_INTR_CLAIMED. If the interrupt
was caused by successful receipt of a packet, this routine should put the received
packet into a STREAMS message of type M_DATA and pass that message to
gld_recv().

gld_recv() will pass the inbound packet upstream to the appropriate next layer of
the network protocol stack. The routine must correctly set the b_rptr and b_wptr
members of the STREAMS message before calling gld_recv().

The driver should avoid holding mutex or other locks during the call to gld_recv().
In particular, locks that could be taken by a transmit thread must not be held during a
call to gld_recv(): the interrupt thread that calls gld_recv() will in some cases
carry out processing that includes sending an outgoing packet, resulting in a call to the
driver’s gldm_send() routine. If the gldm_send() routine were to try to acquire a
mutex being held by the gldm_intr() routine at the time it calls gld_recv(), a
panic occurs due to recursive mutex entry. If other driver entry points attempt to
acquire a mutex that the driver holds across a call to gld_recv(), deadlock can
result.

The interrupt code should increment statistics counters for any errors. This includes
failure to allocate a buffer needed for the received data and any hardware-specific
errors, such as CRC errors or framing errors.

gldm_get_stats() Entry Point

int prefix_get_stats(gld_mac_info_t * macinfo, struct gld_stats * stats);
gldm_get_stats() gathers statistics from the hardware, driver private counters, or both, and updates the gld_stats(9S) structure pointed to by stats. This routine is called by GLD when it gets a request for statistics, and provides the mechanism by which GLD acquires device-dependent statistics from the driver before composing its reply to the statistics request. See the gld_stats(9S) and gld(7D) man page for a description of the defined statistics counters.

**gldm_ioctl() Entry Point**

```c
int prefix_ioctl(gld_mac_info_t * macinfo, queue_t * q, mblk_t * mp);
```

`gldm_ioctl()` implements any device-specific ioctl commands. This element is allowed to be NULL if the driver does not implement any ioctl functions. The driver is responsible for converting the message block into an ioctl reply message and calling the qreply(9F) function before returning GLD_SUCCESS. This function should always return GLD_SUCCESS; any errors the driver might want to report should be returned by the message passed to qreply(9F). If the gldm_ioctl element is specified as NULL, GLD returns a message of type M_IOCNAK with an error of EINVAL.

**GLD Return Values**

In addition to the return values described above, and subject to the restrictions above, some of the GLD entry point functions can return these values:

- **GLD_BADARG**
  - If the function detected an unsuitable argument, for example, a bad multicast address, a bad MAC address, or a bad packet or packet length
- **GLD_FAILURE**
  - On hardware failure
- **GLD_SUCCESS**
  - On success

**GLD Service Routines**

This section provides the syntax and description for the GLD service routines.

**gld_mac_alloc() Function**

```c
gld_mac_info_t * gld_mac_alloc(dev_info_t * dip);
```
**gld_mac_alloc()** allocates a new `gld_mac_info(9S)` structure and returns a pointer to it. Some of the GLD-private elements of the structure might be initialized before `gld_mac_alloc()` returns; all other elements are initialized to zero. The device driver must initialize some structure members, as described in the `gld_mac_info(9S)` man page, before passing the pointer to the `gld_mac_info` structure to `gld_register()`.

**gld_mac_free()** Function

```c
void gld_mac_free(gld_mac_info_t * macinfo);
```

`gld_mac_free()` frees a `gld_mac_info(9S)` structure previously allocated by `gld_mac_alloc()`.

**gld_register()** Function

```c
int gld_register(dev_info_t * dip, char * name, gld_mac_info_t * macinfo);
```

`gld_register()` is called from the device driver's `attach(9E)` routine and is used to link the GLD-based device driver with the GLD framework. Before calling `gld_register()`, the device driver's `attach(9E)` routine must first use `gld_mac_alloc()` to allocate a `gld_mac_info(9S)` structure, and initialize several of its structure elements. See `gld_mac_info(9S)` for more information. A successful call to `gld_register()` performs the following actions:

- Links the device-specific driver with the GLD system
- Sets the device-specific driver's private data pointer (using `ddi_set_driver_private(9F)`) to point to the `macinfo` structure
- Creates the minor device node
- Returns `DDI_SUCCESS`

The device interface name passed to `gld_register()` must exactly match the name of the driver module as it exists in the file system.

The driver's `attach(9E)` routine should return `DDI_SUCCESS` if `gld_register()` succeeds. If `gld_register()` does not return `DDI_SUCCESS`, the `attach(9E)` routine should deallocate any resources it allocated before calling `gld_register()`, and then return `DDI_FAILURE`.

**gld_unregister()** Function

```c
int gld_unregister(gld_mac_info_t * macinfo);
```
gld_unregister() is called by the device driver’s detach(9E) function, and if successful, performs the following tasks:

- Ensures that the device’s interrupts are stopped, calling the driver’s gldm_stop() routine if necessary
- Removes the minor device node
- Unlinks the device-specific driver from the GLD system
- Returns DDI_SUCCESS

If gld_unregister() returns DDI_SUCCESS, the detach(9E) routine should deallocate any data structures allocated in the attach(9E) routine, using gld_mac_free() to deallocate the macinfo structure, and return DDI_SUCCESS. If gld_unregister() does not return DDI_SUCCESS, the driver’s detach(9E) routine must leave the device operational and return DDI_FAILURE.

### gld_recv() Function

```c
void gld_recv(gld_mac_info_t * macinfo, mblk_t * mp);
```

gld_recv() is called by the driver’s interrupt handler to pass a received packet upstream. The driver must construct and pass a STREAMS M_DATA message containing the raw packet. gld_recv() determines which STREAMS queues, if any, should receive a copy of the packet, duplicating it if necessary. It then formats a DL_UNITDATA_IND message, if required, and passes the data up all appropriate Streams.

The driver should avoid holding mutex or other locks during the call to gld_recv(). In particular, locks that could be taken by a transmit thread must not be held during a call to gld_recv(): the interrupt thread that calls gld_recv() will in some cases carry out processing that includes sending an outgoing packet, resulting in a call to the driver’s gldm_send() routine. If the gldm_send() routine were to try to acquire a mutex being held by the gldm_intr() routine at the time it calls gld_recv(), this would result in a panic caused by a recursive mutex entry. If other driver entry points attempt to acquire a mutex that the driver holds across a call to gld_recv(), deadlock can result.

### gld_sched() Function

```c
void gld_sched(gld_mac_info_t * macinfo);
```

gld_sched() is called by the device driver to reschedule stalled outbound packets. Whenever the driver’s gldm_send() routine has returned GLD_NORESOURCES, the driver must later call gld_sched() to inform the GLD framework that it should retry the packets that previously could not be sent. gld_sched() should be called as soon...
as possible after resources are again available, to ensure that GLD resumes passing outbound packets to the driver’s gldm_send() routine in a timely way. (If the driver’s gldm_stop() routine is called, the driver is absolved from this obligation until it later again returns GLD_NORESOURCES from its gldm_send() routine; however, extra calls to gld_sched() will not cause incorrect operation.)

gld_intr() Function

uint_t gld_intr(caddr_t);

gld_intr() is GLD’s main interrupt handler. Normally, gld_intr() is specified as the interrupt routine in the device driver’s call to ddi_add_intr(9F). The argument to the interrupt handler (specified as int_handler_arg in the call to ddi_add_intr(9F)) must be a pointer to the gld_mac_info(9S) structure. gld_intr() will, when appropriate, call the device driver’s gldm_intr() function, passing that pointer to the gld_mac_info(9S) structure. However, if the driver uses a high-level interrupt, it must provide its own high-level interrupt handler and trigger a soft interrupt from within that. In this case, gld_intr() would normally be specified as the soft interrupt handler in the call to ddi_add_softintr(). gld_intr() will return a value appropriate for an interrupt handler.
Compiling, Loading, Packaging, and Testing Drivers

This chapter describes the procedure for driver development, including code layout, compilation, packaging, and testing. The chapter provides information on the following subjects:

- “Driver Code Layout Structure” on page 323
- “Preparing for Driver Installation” on page 324
- “Installing, Updating, and Removing Drivers” on page 326
- “Loading and Unloading Drivers” on page 328
- “Driver Packaging” on page 329
- “Testing Drivers” on page 331

Driver Code Layout Structure

The code for a device driver is usually divided into the following files:

- Header files (.h files)
- Source files (.c files)
- Optional configuration file (driver.conf file)

Header Files

Header files define:

- Data structures specific to the device, such as a structure representing the device registers
- Data structures defined by the driver for maintaining state information
- Defined constants, such as those representing the bits of the device registers
Macros, such as those defining the static mapping between the minor device number and the instance number:

Some of the header file definitions, such as the state structure, might be needed only by the device driver. This information should go in private header files that are only included by the device driver itself.

Any information that an application might require, such as the I/O control commands, should be in public header files. These are included by the driver and any applications that need information about the device.

While there is no standard for naming private and public files, one convention is to name the private header file `xximpl.h` and the public header file `xxio.h`.

`.c Files`

A `.c` file for a device driver contains the data declarations and the code for the entry points of the driver. It contains the `#include` statements the driver needs, declares extern references, declares local data, sets up the `cb_ops` and `dev_ops` structures, declares and initializes the module configuration section (the `modlinkage(9S)` and `modldr(9S)` structures), makes any other necessary declarations, and defines the driver entry points.

`driver.conf Files`

`driver.conf` files are required for devices that are not self-identifying. Entries in the `driver.conf` file specify possible device instances the driver will probe for existence. For more information, see the `scsi(4)` and `driver.conf(4)` man pages. Driver global properties can also be set by entries in the `driver.conf` file. `driver.conf` files are optional for self-identifying devices (SID), where the entries can be used to add properties into SID nodes. See the `sbus(4)` and `pci(4)` man pages for details.

Preparing for Driver Installation

Before the driver is installed, it must be compiled into a binary, and a configuration file created, if necessary. The driver’s module name must either match the name of the device nodes, or the system must be informed through `add_drv(1M)` or `update_drv(1M)` that this driver should manage other names.
The system maintains a one-to-one association between the name of the driver module and the name of the dev_info node. For example, a dev_info node for a device named wombat is handled by a driver module called wombat in a subdirectory called drv (resulting in drv/wombat if a 32-bit kernel or drv/sparcv9/wombat if 64-bit) found in the module path.

If the driver is a STREAMS network driver, then the driver name needs to meet the following constraints:

- Alphanumeric characters (a-z, A-Z, 0-9), plus the underscore ('_'), are permitted only.
- Neither the first nor the last character of the name may be a digit.
- The name cannot exceed 16 characters in length. Names in the range of 3-8 characters in length are preferable.

If the driver should manage dev_info nodes with different names, the add_drv(1M) utility can create aliases. The -i flag specifies the names of other dev_info nodes that the driver handles. The updateDrv() function can also modify aliases for an installed device driver.

Compiling and Linking the Driver

Compile each driver source file and link the resulting object files into a driver module. The example below shows a driver called xx that has two C-language source files and generates a driver module xx. The driver created in this example is intended for the 32-bit kernel:

```
% cc -D_KERNEL -c xx1.c
% cc -D_KERNEL -c xx2.c
% ld -r -o xx xx1.o xx2.o
```

The _KERNEL symbol must be defined while compiling kernel (driver) code. No other symbols (such as sun4m) should be defined, aside from driver private symbols. DEBUG can also be defined to enable any calls to assert(9F). There is no need to use the -I flag for the standard headers.

Drivers intended for the 64-bit SPARC kernel should specify the -xarch=v9 option. Use the following compile line:

```
% cc -D_KERNEL -xarch=v9 -c xx1.c
```

After the driver is stable, optimization flags can be used to build a production quality driver. For the Sun WorkShop™ Compilers C, the normal -0 flag, or its equivalent -xO3, can be used. Note that -xO3 is the highest level of optimization device drivers should use (see cc(1)).

The following compile line was used to create 64-bit SPARC drivers provided with the Solaris 9 operating environment:
% cc -D_KERNEL -xcg92 -xarch=v9 -xcode=abs32 -xO3 -c xx1.c

Where -xcg92 refers to the code generator, and the use of -xcode=abs32 leads to more compact code.

---

**Note** – Running ld -r is necessary even if there is only one object module.

---

**Module Dependencies**

If the driver module depends on symbols exported by another kernel module, the dependency can be specified by the -dy and -N options of ld. If the driver depends on a symbol exported by misc/foo, the example below should be used to create the driver binary. See the ld(1) man page.

% ld -dy -r -o xx xx1.o xx2.o -N misc/foo

---

**Writing a Hardware Configuration File**

If the device is non-self-identifying, the kernel requires a hardware configuration file for it. If the driver is called xx, the hardware configuration file for it should be called xx.conf. See the driver.conf(4), pseudo(4), sbus(4), scsi(4), and update_drv(1M) man pages for more information on hardware configuration files. On the Intel platform, device information is now supplied by the booting system. Hardware configuration files should no longer be needed, even for non-self-identifying devices.

Arbitrary properties can be defined in hardware configuration files by adding entries of the form property=value, where property is the property name, and value is its initial value. This enables devices to be configured by changing the property values.

---

**Installing, Updating, and Removing Drivers**

Before a driver can be used, the system must be informed that it exists. The add_drv(1M) utility must be used to correctly install the device driver. After the driver is installed, it can be loaded and unloaded from memory without using add_drv(1M) again.
Copying the Driver to a Module Directory

A device driver’s module path (location) depends on the platform it runs on, the architecture it is compiled for, and whether it is needed at boot time. Platform-dependent device drivers reside in the following locations:

- `/platform/` contains drivers that run on a specific architecture (`/platform/uname -i` in 32-bit drivers)
- `/platform/` contains drivers that run on a family of platforms. This directory might not be present on some platforms (`/platform/uname -m` in 32-bit drivers).
- `/platform/sparcv9` contains 32-bit drivers for 64-bit systems.

Platform-independent drivers reside in either of these directories:

- `/usr/kernel/drv` contains drivers not required for system booting.
- `/kernel/drv` contains drivers required for booting.

To install a 32-bit driver, the driver and its configuration file must be copied to a `drv` directory in the module path. For example, to copy a driver to `/usr/kernel/drv`, type:

```
$ su
# cp xx /usr/kernel/drv
# cp xx.conf /usr/kernel/drv
```

To install a 64-bit SPARC driver, copy the driver to a `drv/sparcv9` directory in the module path. Copy the driver configuration file to the `drv` directory in the module path. For example, to copy a driver to `/usr/kernel/drv`, type:

```
$ su
# cp xx /usr/kernel/drv/sparcv9
# cp xx.conf /usr/kernel/drv
```

**Note** – All driver configuration files (`.conf` files) must go in the `drv` directory in the module path. Even on 64-bit systems, the `.conf` file goes in the `drv` directory, not the `drv/sparcv9` directory.

Installing Drivers with `add_drv()`

Run `add_drv(1M)` to install the driver in the system. If the driver installs successfully, `add_drv(1M)` will run `devfsadm(1M)` to create the logical names in `/dev`.

```
# add_drv xx
```
This is a simple case in which the device identifies itself as xx and the device special files will have default ownership and permissions (0600 root sys). add_drv(1M) also allows additional names for the device (aliases) to be specified. See add_drv(1M) to determine how to add aliases and set file permissions explicitly.

**Note** – add_drv(1M) should not be run when installing a STREAMS module. See the STREAMS Programming Guide for details.

If the driver creates minor nodes that do not represent disks, tapes, or ports (terminal devices), /etc/devlink.tab can be modified to cause devfsadm(1M) to create logical device names in /dev.

Alternatively, logical names can be created by a program run at driver installation time.

### Updating Driver Information

Use the update_drv(1M) command to notify the system of any changes to an installed device driver. By default, the system re-reads the driver.conf(4) file and reloads the driver binary module.

### Removing the Driver

To remove a driver from the system, use rem_drv(1M), then delete the driver module and configuration file from the module path. The driver cannot be used again until it is reinstalled with add_drv(1M). Removing a SCSI HBA driver will require a reboot to take effect.

### Loading and Unloading Drivers

Opening a special file associated with the device driver causes the driver to be loaded. modload(1M) can also be used to load the driver into memory, but it does not call any routines in the module. Opening the device is the preferred method.

Normally, the system automatically unloads device drivers when they are no longer in use. During development, it might be necessary to use modunload(1M) to unload the driver explicitly. In order for modunload(1M) to be successful, the device driver must be inactive; there must be no outstanding references to the device, such as through open(2) or mmap(2).
modunload takes a runtime-dependent module_id as an argument. The module_id can be found by using grep to search the output of modinfo for the driver name in question and looking at the first column.

# modunload -i module_id

To unload all currently unloadable modules, specify module ID zero:

# modunload -i 0

In addition to being inactive, the driver must have working detach(9E) and _fini(9E) routines for modunload(1M) to succeed.

Driver Packaging

The normal delivery vehicle for software is to create a package with all the components of the software packaged together. A package provides a controlled mechanism for installation and removal of all the components of a software product. In addition to the files for using the product, the package includes control files for installing (and de-installing) the application. The postinstall and preremove installation scripts are two such control files.

Package Postinstall

After installing a package that includes a driver binary onto a system, the add_drv(1M) command must be run to complete the installation of the driver. Typically, add_drv is run a postinstall script as in the following example.

#!/bin/sh
#
# Driver info
#
DRV=<driver-name>
DRVALIAS="<company-name>,<driver-name>"
DRVPERM='* 0666 root sys'
ADD_DRV=/usr/sbin/add_drv

# Select the correct add_drv options to execute.
Package Preremove

When removing a package that includes a driver, the remDrv(1M) command must be run prior to removing the driver binary and other components. Here is an example preremove script that uses remDrv(1M) for driver removal.

#!/bin/sh
#
# @(#)preremove 1.1
PATH="/usr/bin:/usr/sbin:${PATH}"
export PATH

#
# Driver info
#
DRV=<driver-name>
REM_DRV="/usr/sbin/rem_drv"

# Select the correct rem_drv options to execute.
Testing Drivers

Once a device driver is functional, it should be thoroughly tested before it is distributed. In addition to testing traditional UNIX device driver features, Solaris 9 drivers require testing of power management features, such as dynamic loading and unloading of drivers.

Configuration Testing

A driver's ability to handle multiple device configurations is an important part of the test process. Once the driver is working on a simple, or default, configuration, additional configurations should be tested. Depending upon the device, this can be accomplished by changing jumpers or DIP switches. If the number of possible configurations is small, all of them should be tried. If the number is large, various classes of possible configurations should be defined, and a sampling of configurations from each class should be tested. The designation of such classes depends on how the different configuration parameters might interact, which in turn depends on the device and on how the driver was written.

For each device configuration, the basic functions must be tested, which include loading, opening, reading, writing, closing, and unloading the driver. Any function that depends upon the configuration deserves special attention. For example, changing the base memory address of device registers is not likely to affect the
behavior of most driver functions; if the driver works well with one address, it is likely to work as well with a different address, provided the configuration code enables it to work at all. On the other hand, a special I/O control call might have different effects depending upon the particular device configuration.

Loading the driver with varying configurations ensures that the probe(9E) and attach(9E) entry points can find the device at different addresses. For basic functional testing, using regular UNIX commands such as cat(1) or dd(1M) is usually sufficient for character devices. Mounting or booting might be required for block devices.

Functionality Testing

After a driver has been completely tested for configuration, all of its functionality should be thoroughly tested. This requires exercising the operation of all the driver’s entry points.

Many drivers will require custom applications to test functionality, but basic drivers for devices such as disks, tapes, or asynchronous boards can be tested using standard system utilities. All entry points should be tested in this process, including devmap(9E), chpoll(9E), and ioctl(9E), if applicable. The ioctl(9E) tests might be quite different for each driver, and for nonstandard devices, a custom testing application will be required.

Error Handling

A driver might perform correctly in an ideal environment, but fail to handle cases where a device encounters an error or an application specifies erroneous operations or sends bad data to the driver. Therefore, an important part of driver testing is the testing of its error handling.

All possible error conditions of a driver should be exercised, including error conditions for actual hardware malfunctions. Some hardware error conditions might be difficult to induce, but an effort should be made to cause them or to simulate them if possible. All of these conditions could be encountered in the field. Cables should be removed or loosened, boards should be removed, and erroneous user application code should be written to test those error paths.

Caution – Be sure to take proper electrical precautions when testing.
Testing Loading and Unloading

Because a driver that will not load or unload can force unscheduled downtime, loading and unloading must be thoroughly tested.

A script like the following should suffice:

```bash
#!/bin/sh
cd <location_of_driver>
while [ 1 ]
do
    modunload -i `modinfo | grep "<driver_name>" | cut -cl-3`
    modload <driver_name>
done
```

Stress, Performance, and Interoperability Testing

To help ensure that the driver performs well, it should be subjected to vigorous stress testing. Running single threads through a driver will not test any of the locking logic and might not test condition variable waits. Device operations should be performed by multiple processes at once to cause several threads to execute the same code simultaneously. The way to do this depends upon the driver; some drivers will require special testing applications, but starting several UNIX commands in the background will be suitable for others. Appropriate testing depends upon where the particular driver uses locks and condition variables. Testing a driver on a multiprocessor machine is more likely to expose problems than testing on a single-processor machine.

Interoperability between drivers must also be tested, particularly because different devices can share interrupt levels. If possible, configure another device at the same interrupt level as the one being tested. Then stress-test the driver to determine if it correctly claims its own interrupts and otherwise operates according to expectations. Stress tests should be run on both devices at once. Even if the devices do not share an interrupt level, this test can still be valuable; for example, if serial communication devices start to experience errors while a network driver is being tested, this could indicate that the network driver is causing the rest of the system to encounter interrupt latency problems.

Driver performance under these stress tests should be measured using UNIX performance-measuring tools. This can be as simple as using the `time` command along with commands used for stress tests.

DDI/DKI Compliance Testing

To ensure compatibility with later releases and reliable support for the current release, every driver should be Solaris 9 DDI/DKI compliant. One way to determine if the driver is compliant is by inspection. The driver can be visually inspected to ensure
that only kernel routines and data structures specified in *man pages section 9F: DDI and DKI Kernel Functions* and *man pages section 9S: DDI and DKI Data Structures* of the *Solaris 8 Reference Manual Collection* are used.

The Solaris 9 Driver Developer Kit (DDK) includes a DDI compliance tool (DDICT) that checks device driver C source code for non-DDI/DKI compliance and issues either error or warning messages when it finds non-compliant code. For best results, all drivers should be written to pass DDICT. For more information, check out the Solaris Developer Connection, which is currently at www.sun.com/solaris/ddk.

**Installation and Packaging Testing**

Drivers are delivered to customers in packages. A package can be added and removed from the system using a standard mechanism (see the *Application Packaging Guide*).

Testing should be performed to ensure that the end user can add it to and remove it from a system. In testing, the package should be installed and removed from every type of media on which it will be released and on several system configurations. Packages must not make unwarranted assumptions about the directory environment of the target system. Certain valid assumptions, however, can be made about where standard kernel files are kept. Also test adding and removing of packages on newly installed machines that have not been modified for a development environment. A common packaging error is for a package to use a tool or file that exists only in a development environment, or only on the driver writer’s own development system. For example, no tools from Source Compatibility package, SUNWscpu, should be used in driver installation programs.

The driver installation must be tested on a minimal Solaris system without any of the optional packages installed.

**Testing Specific Types of Drivers**

Because each type of device is different, it is difficult to describe how to test them all specifically. This section provides some information about how to test certain types of standard devices.

**Tape Drivers**

Tape drivers should be tested by performing several archive and restore operations. The *cpio(1)* and *tar(1)* commands can be used for this purpose. The *dd(1M)* command can be used to write an entire disk partition to tape, which can then be read back and written to another partition of the same size, and the two copies compared. The *mt(1)* command will exercise most of the I/O controls that are specific to tape drivers (see *mtio(7I)*); all the options should be attempted. The error handling of tape
drivers can be tested by attempting various operations with the tape removed, attempting writes with the write protect on, and removing power during operations. Tape drivers typically implement exclusive-access open(9E) calls, which should be tested by having a second process try to open the device while a first process already has it open.

**Disk Drivers**

Disk drivers should be tested in both the raw and block device modes. For block device tests, a new file system should be created on the device and mounted. Multiple file operations can be performed on the device at this time.

---

**Note** – The file system uses a page cache, so reading the same file over and over again will not really exercise the driver. The page cache can be forced to retrieve data from the device by memory-mapping the file (with mmap(2)), and using msync(3C) to invalidate the in-memory copies.

---

Another (unmounted) partition of the same size can be copied to the raw device and then commands such as fsck(1M) can be used to verify the correctness of the copy. The new partition can also be mounted and compared to the old one on a file-by-file basis.

**Asynchronous Communication Drivers**

Asynchronous drivers can be tested at the basic level by setting up a login line to the serial ports. A good test is if a user can log in on this line. To sufficiently test an asynchronous driver, however, all the I/O control functions must be tested, with many interrupts at high speed. A test involving a loopback serial cable and high data transfer rates will help determine the reliability of the driver. Running uucp(1C) over the line also provides some exercise; however, since uucp(1C) performs its own error handling, verify that the driver is not reporting excessive numbers of errors to the uucp(1C) process.

These types of devices are usually STREAMS based (see STREAMS Programming Guide).

**Network Drivers**

Network drivers can be tested using standard network utilities. ftp(1) and rcp(1) are useful because the files can be compared on each end of the network. The driver should be tested under heavy network loading, so that various commands can be run by multiple processes. Heavy network loading means:
- Traffic to the test machine is heavy.
- Traffic among all machines on the network is heavy.

Network cables should be unplugged while the tests are executing to ensure that the driver recovers gracefully from the resulting error conditions. Another important test is for the driver to receive multiple packets in rapid succession (back-to-back packets). In this case, a relatively fast host on a lightly loaded network should send multiple packets in quick succession to the test machine. Verify that the receiving driver does not drop the second and subsequent packets.

These types of devices are usually STREAMS-based (see STREAMS Programming Guide).
Debugging

Debugging is the process of finding and eliminating faults from software. Almost every device driver writer will be faced with a difficult bug at some point in the development process. This chapter presents an overview of the tools available to make this process easier. This chapter provides information on the following subjects:

- “Machine Configuration” on page 337
- “Runtime Debugging Tools” on page 342
- “The kadb Kernel Debugger” on page 345
- “Post-Mortem Debugging” on page 360

Machine Configuration

Before you begin developing a Solaris driver, set up your test platform for this purpose. Testing on a separate system is safest. This section explains how to set up a pair of machines for development, and how to prepare a test system for disaster recovery.

Setting Up a tip Connection

A serial connection can be made between a test system (the machine executing the code to be debugged) and a host system using tip(1). This connection enables a window on the host system, called a tip window, to be used as the console of the test machine. See the tip(1) man page for additional information.

Using a tip window confers the following advantages:

- Interactions with the test system or kadb can be monitored. For example, the window can keep a log of the session for use if the driver crashes the test system.
The test machine can be accessed remotely by logging into a host machine (often called a **tip host**) and using `tip(1)` to connect to the test machine.

---

**Note** – A tip connection (and a second machine) is not required to debug a Solaris 9 device driver, but is recommended.

---

**To Set Up the Host System**

To set up the host system, do the following:

1. **Connect the host system to the test machine using serial port A on both machines.**
   This connection must be made with a *null modem* cable.

2. **On the host system, make an entry in /etc/remote for the connection if it is not already there (see the remote(4) man page for details).**
   The terminal entry must match the serial port being used. The Solaris 9 operating environment comes with the correct entry for serial port B, but a terminal entry must be added for serial port A:
   ```
   debug: \\
   :dv=/dev/term/a:br#9600:el=^C^S^Q^U^D:ie=%$:oe=^D:
   ```
   **Note** – The baud rate must be set to 9600.

3. **In a shell window on the host, run `tip(1)` and specify the name of the entry:**
   ```
   % tip debug
   connected
   ```
   The shell window is now a **tip window** connected to the console of the test machine.

   **Caution** – Do not use `STOP-A` for SPARC machines or `F1-A` for IA (Intel architecture) machines on the host machine to send a break to stop the test machine. This action actually stops the host machine. To send a break to the test machine, type `~#` in the tip window. Commands such as this are recognized only if they are the first characters on a line, so press the **Return** key or **Control-U** first if there is no effect.

---

**Setting Up the Test System for SPARC Platforms**

A quick way to set up the test machine is to unplug the keyboard before turning on the machine. The machine then automatically uses serial port A as the console.
Another way to set up the test machine is to use boot PROM commands to make serial port A the console. On the test machine, at the boot PROM ok prompt, direct console I/O to the serial line. To make the test machine always come up with serial port A as the console, set the environment variables \textit{input-device} and \textit{output-device}.

\begin{verbatim}
ok setenv input-device ttya
ok setenv output-device ttya
\end{verbatim}

The \texttt{eeprom} command can also be used to make serial port A the console. As superuser, execute the following commands to make the \textit{input-device} and \textit{output-device} parameters point to serial port A.

\begin{verbatim}
# eeprom input-device=ttya
# eeprom output-device=ttya
\end{verbatim}

Executing the \texttt{eeprom} commands causes the console to be redirected to serial port A at each subsequent system boot.

**Setting Up the Test System for IA Platforms**

On IA platforms, use the \texttt{eeprom} command to make serial port A the console. The procedure for this is the same as for SPARC platform and is discussed above. Executing the \texttt{eeprom} commands causes the console to switch to serial port A (COM1) during reboot.

\textbf{Note} – Unlike SPARC machines, where the \textit{tip} connection maintains console control throughout the boot process, IA machines don’t transfer console control to the \textit{tip} connection until an early stage in the boot process.

**Preparing for Disasters**

Under certain circumstances, a driver can render the system incapable of booting. To avoid system reinstallation in this event, some advance work must be done.

**Back Up Critical System Files**

A number of driver-related system files are difficult, if not impossible, to reconstruct. Files such as /\texttt{etc/name_to_major}, /\texttt{etc/driver_aliases}, /\texttt{etc/driver_classes}, and /\texttt{etc/minor_perm} can be corrupted if the driver crashes the system during installation (see the \texttt{add_drv(1M)} man page).

To be safe, after the test machine is in the proper configuration, make a backup copy of the root file system. If you plan on modifying the /\texttt{etc/system} file, make a backup copy of the file before modifying it.
Prepare and Boot an Alternate Kernel

A good strategy to avoid rendering a system inoperable is to make a copy of the kernel and associated binaries, and to boot that instead of the default kernel. To do so, make a copy of the drivers in /platform/* as follows:

```
# cp -r /platform/`uname -i`/kernel /platform/`uname -i`/kernel.test
```

When developing your driver, place it in /platform/`uname -i`/kernel.test/drv and boot that kernel instead of the default kernel:

```
# reboot -- kernel.test/unix
```

or from the PROM:

```
ok boot kernel.test/unix
```

This results in the test kernel and drivers being booted:

Rebooting with command: boot kernel.test/unix
Boot device: /sbus@1f,0/espdma@e,8400000/esp@e,8800000/sd@0,0:a File and args: kernel.test/unix
SunOS Release 5.9 Version Generic 32-bit
Copyright 1983-2002 Sun Microsystems, Inc. All rights reserved.
...

Alternately, the module path can be changed by booting with the ask (-a) option:

```
ok boot -a
```

This results in a series of prompts which you can use to configure the way the kernel boots:

Rebooting with command: boot -a
Boot device: /sbus@1f,0/espdma@e,8400000/esp@e,8800000/sd@0,0:a File and args: -a
Enter filename [kernel/sparcv9/unix]: kernel.test/sparcv9/unix
Enter default directory for modules
[/platform/sun4u/kernel.test /kernel /usr/kernel]: <CR>
Name of system file [etc/system]: <CR>
SunOS Release 5.9 Version Generic 64-bit
Copyright 1983-2002 Sun Microsystems, Inc. All rights reserved.
root filesystem type [ufs]: <CR>
Enter physical name of root device
[/sbus@1f,0/espdma@e,8400000/esp@e,8800000/sd@0,0:a]: <CR>

Prepare Other Backup Plans

If the system is attached to a network, the test machine can be added as a client of a server. If a problem occurs, the system can be booted off the network. The local disks can then be mounted and fixed. Alternatively, the system can be booted directly from the Solaris 9 CD-ROM.
Another way to recover from disaster is to have another bootable root file system. Use `format(1M)` to make a partition the exact size of the original, then use `dd(1M)` to copy it. After making a copy, run `fsck(1M)` on the new file system to ensure its integrity.

Later, if the system cannot boot from the original root partition, boot the backup partition and use `dd(1M)` to copy the backup partition onto the original one. If the system will not boot but the root file system is undamaged (just the boot block or boot program was destroyed), boot off the backup partition with the ask (-a) option, then specify the original file system as the root file system.

**Saving System Crash Dumps**

When the system panics, it writes an image of kernel memory to the dump device. The dump device by default is the most suitable swap device. The dump is a system crash dump, similar to core dumps generated by applications. On rebooting after a panic, `savecore(1M)` checks the dump device for a crash dump. If one is found, it makes a copy of the kernel's symbol table (called `unix.n`) and dumps a core file (called `vmcore.n`) in the core image directory which by default is `/var/crash/machine_name`. There must be enough space in `/var/crash` to contain the core dump or it will be truncated. `mdb(1)` can then be used on the core dump and the saved kernel.

In the Solaris 9 operating system, crash dump is enabled by default. The `dumpadm(1M)` command is used to configure system crash dumps. Use the `dumpadm(1M)` command to verify that crash dumps are enabled and to determine the location of the directory where core files are saved. See the `dumpadm(1M)` man page for more information.

---

**Note** – `savecore(1M)` can be prevented from filling the file system if there is a file called `minfree` in the directory in which the dump will be saved. This file contains a number of kilobytes to remain free after `savecore(1M)` has run. However, if not enough space is available, the core file is not saved.

---

**Disaster Recovery**

If the `/devices` or `/dev` directories are damaged—most likely to occur if the driver crashes during `attach(9E)”—they can be re-created by booting the system and running `fsck(1M)` to repair the damaged root file system. The root file system can then be mounted. Re-create `/dev` and `/devices` by running `devfsadm(1M)` and specifying the `/devices` directory on the mounted disk.

On SPARC, for example, if the damaged disk is `/dev/dsk/c0t3d0s0`, and an alternate boot disk is `/dev/dsk/c0t1d0s0`, do the following:

```
ok boot disk1
...
```
Rebooting with command: boot kernel.test/unix
Boot device: /sbus@1f,0/espdma@e,8400000/esp@e,8800000/sd@31,0:a File and args:
kernel/unix
SunOS Release 5.9 Version Generic 32-bit
Copyright 1983-2002 Sun Microsystems, Inc. All rights reserved.
...
# fsck /dev/dsk/c0t3d0s0** /dev/dsk/c0t3d0s0
** Last Mounted on /
** Phase 1 - Check Blocks and Sizes
** Phase 2 - Check Pathnames
** Phase 3 - Check Connectivity
** Phase 4 - Check Reference Counts
** Phase 5 - Check Cyl groups
1478 files, 9922 used, 29261 free
  (141 frags, 3640 blocks, 0.4% fragmentation)
# mount /dev/dsk/c0t3d0s0 /mnt
# devfsadm -r /mnt

Caution – Fixing /devices and /dev may allow the system to boot, but other parts of the system can still be corrupted. This is only a temporary fix to allow saving information (such as system crash dumps) before reinstalling the system.

Runtime Debugging Tools

This section describes some of the mechanisms that can be used to debug drivers at runtime. Runtime debugging is typically performed during driver development; this process is substantially simplified if you have followed the coding practices described in the previous section. Although the kadb debugger is a runtime debugging tool, it is treated at length in a separate section, “The kadb Kernel Debugger” on page 345.

/etc/system File

The /etc/system file serves several purposes, but for driver development, the most important is that it allows you to set the value of kernel variables at boot time. This can be used to toggle different behaviors in a driver, or to enable certain debugging features made available by the kernel.

/etc/system is read only once, while the kernel is booting. After this file is modified, the system must be rebooted for the changes to take effect. If a change in the file causes the system not to work, boot with the ask (-a) option and specify /dev/null as the system file.

The set command is used to change the value of module or kernel variables:
To set module variables, specify the module name and the variable:

\[ \text{set } \text{module\_name}:\text{variable}=\text{value} \]

For example, to set the variable `test\_debug` in the driver `test`, use the following set command:

\[ \text{set } \text{test}:\text{test\_debug}=1 \]

To set a variable exported by the kernel itself, omit the module name. Other assignments are also supported, such as bitwise OR'ing a value into an existing value:

\[ \text{set } \text{moddebug }|\ 0x80000000 \]

See the `system(4)` man page for more information.

**Note** – Most kernel variables are not guaranteed to be present in subsequent releases.

### Controlling Module Loading with `moddebug`

`moddebug` is a kernel variable that controls the module loading process. The possible values are:

- `0x80000000` Prints messages to the console when loading or unloading modules.
- `0x40000000` Gives more detailed error messages.
- `0x20000000` Prints more detail when loading or unloading (such as including the address and size).
- `0x00001000` No auto-unloading drivers: the system will not attempt to unload the device driver when the system resources become low.
- `0x00000080` No auto-unloading streams: the system will not attempt to unload the streams module when the system resources become low.
- `0x00000010` No auto-unloading of kernel modules of any type.
- `0x00000001` If running with `kadb`, `moddebug` causes a breakpoint to be executed and a return to `kadb` immediately before each module's `init(9E)` routine is called. Also generates additional debug messages when the module's `_info` and `_fini` routines are executed.

### `kmem\_flags`

`kmem\_flags` is a kernel variable used to enable debugging features in the kernel's memory allocator. Setting `kmem\_flags` to `0xf` enables the allocator's debugging features. These include runtime checks to find:
Code that writes to a buffer after it is freed
Code using memory before it is initialized
Code that writes past the end of a buffer

The “Debugging With the Kernel Memory Allocator” section of the Solaris Modular Debugger Guide describes how the kernel memory allocator can be used to determine the root cause of these problems.

---

**Note** – Testing and developing with kmem_flags set to 0xf is extremely valuable because it can detect latent memory corruption bugs. Because setting kmem_flags to 0xf changes the internal behavior of the kernel memory allocator, you should thoroughly test without kmem_flags as well.

---

**modload, modunload, and modinfo Commands**

The kernel automatically loads needed modules and unloads unused ones, so modload(1M), modunload(1M), and modinfo(1M) are not very useful for system administration. However, they can be useful when debugging and stress testing driver load/unload scenarios.

**modload** can be used to force a module into memory. The kernel might subsequently unload the module, but modload can be used to verify that the driver has no unresolved references when loaded. Keep in mind that loading a driver does *not* mean that the driver will attach. A driver that loads successfully will have its _info(9E) entrypoint called, but will not necessarily attach.

You can use modinfo to confirm that your driver is loaded. Here is an example:

```
$ modinfo
  Id Loadaddr Size Info Rev Module Name
  6 101b6000 732 - 1 obpsym (OBP symbol callbacks)
  7 101b65bd 1acd0 226 1 rpcmod (RPC syscall)
  7 101b65bd 1acd0 226 1 rpcmod (32-bit RPC syscall)
  7 101b65bd 1acd0 1 1 rpcmod (rpc interface str mod)
  8 101ce8dd 74600 0 1 ip (IP Streams module)
  8 101ce8dd 74600 3 1 ip (IP Streams device)
...
```

```
$ modinfo | grep mydriver
  169 781a@78 111f 0 1 mydriver (Test Driver 1.5)
```

The number in the info field is the major number chosen for the driver. modunload can be used to unload a module, given a module ID (which can be found in the leftmost column of modinfo output). A common bug is that a driver refuses to unload, even after a modunload is issued. Note that a driver will not unload if the system thinks the driver is busy. This occurs when the driver fails detach(9E), either because the driver really is busy, or because the detach entry point is implemented incorrectly.
To remove all currently unused modules from memory, run `modunload` with a module ID of 0:

```
# modunload -i 0
```

---

The `kadb` Kernel Debugger

`kadb` is a kernel debugger with facilities for disassembly, breakpoints, watch points, data display, and stack tracing. This section provides a tutorial on some of the features of `kadb`. For further information, consult the `kadb(1M)` man page.

Starting `kadb`

In order to start up `kadb`, the system must be booted with `kadb(1M)` enabled:

```
ok boot kadb
...
```

By default, `kadb(1M)` boots (and debugs) `kernel/unix`, or `kernel/sparcv9/unix` on a system capable of running a 64-bit kernel. To boot `kadb` with an alternate kernel, pass the `-D` flag to boot, as follows:

```
ok boot kadb -D kernel.test/unix
```

In this example, the 32-bit version of the alternate kernel `kernel.test` was booted.

Another option is to pass `kadb` the `-d` flag, which causes `kadb` to prompt for the kernel name. The `-d` flag also causes `kadb(1M)` to provide a prompt after it has loaded the kernel, so breakpoints can be set.
ok boot kadb -d
...
Rebooting with command: boot kadb -d
Boot device: /sbus@1f,0/espdma@e,8400000/esp@e,8800000/sd@0,0:a File
and args: kadb -d
kadb: kernel.test/unix
Size: 482384+67201+88883 Bytes
/platform/sun4u/kernel.test/unix loaded - 0xfc000 bytes used
stopped at _start: sethi %hi(0x10006c00), %g1
kadb[0]:

At this point you can set breakpoints or continue execution with the :c command.

---

**Note** – Kernel modules are dynamically loaded. Consequently, driver symbols are not available until the driver is loaded. To set breakpoints in modules that have not been loaded, use deferred breakpoints. For information on deferred breakpoints, refer to “Breakpoints” on page 351.

---

kadb(1M) passes any kernel flags to the booted kernel. For example, to boot an alternate kernel and pass the -r flag:

ok boot kadb -r -D kernel.test/unix

Rebooting with command: boot kadb -r -D kernel.test/unix
Boot device: /sbus@1f,0/espdma@e,8400000/esp@e,8800000/sd@0,0:a
File and args: kadb -r -D kernel.test/unix
kadb: kernel.test/unix
Size: 482384+67201+88883 Bytes
/platform/sun4u/kernel.test/unix loaded - 0xfe000 bytes used
SunOS Release 5.9 Version Generic 32-bit
Copyright 1983-2002 Sun Microsystems, Inc. All rights reserved.
obpsym: symbolic debugging is available.
Read 208377 bytes from misc/forthdebug
configuring IPv4 interfaces: le0.
Hostname: test
Configuring /dev and /devices

After the system is booted, sending a break passes control to kadb(1M). A break is generated with STOP-A (on the console of SPARC machines), or with F1-A (on the console of IA machines), or by using ~# (if the console is connected through a tip window).

...

The system is ready.

test console login: ~#
stopped at edd000d8: ta %icc,%g0 + 125
kadb[0]:

346  Writing Device Drivers • May 2002
The number in brackets is the CPU that `kadb(1M)` is currently executing on; the remaining CPUs are halted. The CPU number is zero on a uniprocessor system.

---

**Caution** – Before rebooting or turning off the power, always halt the system cleanly (with `init 0` or `shutdown`). Buffers might not be flushed otherwise. If the shutdown must occur from the boot PROM prompt, make sure to flush buffers using the `sync` command at the `ok` prompt.

---

To return control to the operating system, use `:c`.

```
kadb[0]: :c
login: test console
```

**Exiting kadb**

To exit `kadb(1M)`, use `$q`. On SPARC machines, this will exit to the `ok` prompt. On IA machines, you will be prompted to reboot the system.

```
kadb[0]: $q
```

Type 'go' to resume

```
ok
```

`kadb(1M)` can be resumed by typing `go` at the `ok` prompt.

---

**Caution** – No other commands should be performed from the PROM if the system is to be resumed. PROM commands other than `go` can change system state that the Solaris 9 operating environment depends upon.

---

Staying at the `kadb(1M)` prompt for too long can cause the system to lose track of the time of day, and can cause network connections to time out.

**kadb Command Usage**

The general form of a `kadb` command is:

```
[ address ] [ ,count ] command [ ; ]
```

If `address` is omitted, the current location is used (‘.’ could also be used to represent the current location). The address can be a kernel symbol. If `count` is omitted, it defaults to 1.

Commands to `kadb` consist of a `verb` followed by a `modifier` or list of modifiers. Verbs can be:

/    Prints locations starting at address in the kernel address space
=    Prints the value of address itself
>    Assigns a value to a debugger variable or machine register
<    Reads a value from a debugger variable or machine register
RETURN Repeats the previous command with a count of 1. Increments ’.’ (the current location)

With / and =, output format specifiers can be used. Lowercase letters normally print 2 bytes, uppercase letters print 4 bytes. The values of these specifiers are:

 o, O 2-, 4-byte octal
 g    8-byte octal
 G    8-byte unsigned octal
 d, D 2-, 4-byte decimal
 e    8-byte decimal
 E    8-byte unsigned decimal
 x, X 2-, 4-byte hexadecimal
 J    8-byte hexadecimal
 K    4-byte hexadecimal for 32-bit programs, 8-byte hexadecimal for 64-bit programs. Use this format specifier to examine pointers.
 u, U 2-, 4-byte unsigned decimal
 c    Prints the addressed character
 C    Prints the addressed character using ^ escape notation
 s    Prints the addressed string
 S    Prints the addressed string using ^ escape notation
 i    Prints as machine instructions (disassemble)
 a    Prints the value of ’.’ in symbolic form
 w, W 2-, 4-byte write
 Z    8-byte write
Caution – When using w, W or Z to modify a kernel variable, make sure that the size of the variable matches the size of the write you are performing. If you specify an incorrect size you could corrupt neighboring data.

For example, to set a bit in the `moddebug` variable when debugging a driver, first examine the value of `moddebug`, then set it to the desired bit.

```
karb[0]: moddebug/X
moddebug: 1000
karb[0]: moddebug/W 0x80001000
moddebug: 0x1000 = 0x80001000
```

Routines can be disassembled with the ‘i’ command. This is useful when tracing crashes, since the only information might be the program counter at the time of the crash. For example, to print the first four instructions of the `kmem_alloc` function:

```
karb[0]: kmem_alloc,4/i
kmem_alloc:
kmem_alloc: save %sp, -0x60, %sp
sub %i0, 0x1, %l6
sra %l6, 0x3, %i5
tst %i5
```

Specify symbolic notation with the ‘a’ command, to show the addresses:

```
karb[0]: kmem_alloc,4/ai
kmem_alloc:
kmem_alloc: save %sp, -0x60, %sp
kmem_alloc+4: sub %i0, 0x1, %l6
kmem_alloc+8: sra %l6, 0x3, %i5
kmem_alloc+0xc: tst %i5
```

Register Identifiers

You can discover what machine registers are available on your processor architecture using the `$r` command. This example shows the output of `$r` on a SPARC system with the sun4 architecture:

```
karb[0]: $r

<table>
<thead>
<tr>
<th>Register</th>

kadb exports each of these registers as a debugger variable with the same name.
Reading from the variable fetches the current value of the register. Writing to the
variable changes the value of the associated machine register. For example, you can
change the value of the ‘%00’ register:

kadb[0] = 0
kadb[0] = 0x1
kadb[0] = 1

Display and Control Commands
The following commands display and control the status of kadb(1M):

$b       Display all breakpoints
$g       Display stack trace
$D       Change default radix to value of dot
$q       Quit
$r       Display registers
$M       Display built-in macros

‘$c’ is useful when a breakpoint is reached, but is usually not useful if kadb(1M) is
entered at a random time. The number of arguments to print can be passed following
the ‘$c’ (‘$c 2’ for two arguments).
Breakpoints

In kadb(1M), breakpoints can be set. When reached, the kernel will automatically drop back into kadb. The standard form of a breakpoint command is:

```
[module_name#] addr [, count]:b [command]
```

`addr` is the address at which the program will be stopped and the debugger will receive control, `count` is the number of times that the breakpoint address occurs before stopping, and `command` is almost any adb(1) command.

The optional `module_name` specifies deferred breakpoints that are set when the module is loaded. `module_name` identifies a particular module that contains `addr`. If the module has been loaded, kadb will try to set a regular breakpoint; if the module is not loaded, kadb will set a deferred breakpoint. When the module is loaded, kadb will try to resolve the location of the breakpoint and convert the breakpoint to a regular breakpoint.

Other breakpoint commands are:

- `:c` Continue execution
- `:d` Delete breakpoint
- `:s` Single step
- `:e` Single step, but step over function calls
- `:u` Stop after return to caller of current function
- `:z` Delete all breakpoints

The following example sets a breakpoint in scsi_transport(9F), a commonly used routine. Upon reaching the breakpoint, `:*c` is used to print a stack trace. The top of the stack is displayed first. Note that kadb does not know how many arguments were passed to each function.

```
stopped at edd000d8: ta %icc,%g0 + 125
kadb[0]: scsi_transport:b
kadb[0]: :c
```

```
test console login: root
breakpoint at:
scsi_transport: save %sp, -0x60, %sp
kadb[0]: :c
```

```
scsi_transport(702bb578,1000,1,10000,0,702bb7fe)
sd_strategy(10198c0,702bb61c,0,0,702bb578,70cad7b8) + 704
bdev_strategy(1042a808,70cad7b8,705f3efc,40,10597900,2000) + 98
ufs_getpage_miss(70cad7b8,0,10597900,0,0,4023ba8c) + 2b0
ufs_getpage(0,0,0,0,2000,4023ba8c) + 7c0
segvn_fault(4023ba8c,2000,ff3b0000,0,0,0) + 7c8
as_fault(1,ff3b0000,70d98030,2000,0,ff3b0000) + 49c
pagefault(0,0,70df8048,705c7450,0,ff3b0000) + 4c
```
Conditional Breakpoints

Breakpoints can also be set to occur only if a certain condition is met. By providing a command, the breakpoint will be taken only if the count is reached or the command returns zero. For example, a breakpoint that occurs only on certain I/O controls could be set in the driver’s ioctl(9E) routine. This is the general syntax of conditional breakpoints:

```
address,count:b command
```

In this example, `address` is the address at which to set the breakpoint. `count` is the number of times the breakpoint should be ignored (note that 0 means break only when the command returns zero). `command` is the kadb(1M) command to execute.

Here is an example of breaking only in the sdioctl() routine if the DKIOGVTOC (get volume table of contents) I/O control occurs.

```
kadb[0]: sdioctl+4,0:b <i1-0x40B
kadb[0]: $b
breakpoints
count bkpt type len command
0 sdioctl+4 :b instr 4 <i1-0x40B
kadb[0]: :c
```

Adding four to `sdioctl` skips to the second instruction in the routine, bypassing the save instruction that establishes the stack. The ‘<i1’ refers to the first input register, which is the second parameter to the routine (the cmd argument of ioctl(9E)). The count of zero is impossible to reach, so it stops only when the command returns zero, which is when ‘i1 = 0x40B’ is true. This means i1 contains 0x40B (the value of the ioctl(9E) command, determined by examining the ioctl definition).

To force the breakpoint to be reached, the prtvtoc(1M) command, which is known to issue the following I/O control, is used:

```
# prtvtoc /dev/rdsk/c0t0d0s0
breakpoint at:
   sdioctl+4: mov %15, %10
kadb[0]: $c
sdioctl(800000,40b,ffbefb54,100005,704a3ce8,4026bc7c) + 4
ioctl(3,40b,70ca27b8,40b,ffbefb54,0) + 1e0
```
**kadb Macros**

kadb(1M) supports macros that are used for displaying kernel data structures. kadb macros can be displayed with $M. Macros are used in the form:

```
[ address ] $<macroname
```

**Note** – Neither the information displayed by these macros, nor the format in which the information is displayed constitute an interface. Therefore, the information and format can change at any time.

**Device Macros**

This section describes the kadb(1M) macros that can be used to retrieve information from the kernel about a device during a debugging session.

- **devinfo_brief** Prints a brief summary of a dev_info_t structure; the name and addr fields are shown in string form and are used in the /devices path to the node
- **devinfo** Prints devinfo_brief information for a dev_info_t structure followed by an in-order dump of all fields
- **devinfo.parent** Prints devinfo_brief information for the specified node and its parents all the way back to the root of the devinfo tree
- **devinfo.sibling** Prints devinfo_brief information for all siblings of the specified node; you see all sibling nodes if you start at the parent's child
- **devinfo.minor** Prints the ddi_minor_data structure for all minor name nodes associated with the specified device node
- **devinfo.prop** Prints all the property lists associated with the specified device node
- **devinfo_major** Prints devinfo_brief information for all device nodes associated with the specified driver major number
- **devt** Breaks a dev_t into its major and minor parts and prints the values in hexadecimal and decimal
- **devnames** Prints the contents of the specified devnames structure
- **devnames_major** Prints the contents of the devnames structure for the specified major number
- **bus_op** Prints the contents of a bus_ops structure

The devinfo commands, such as devinfo and devinfo_brief, return a node_state value, which may be one of the following:
DS_LINKED
This device node has been linked into the kernel’s device tree, but the system has not yet found a driver for it.

DS_BOUND
The node is bound to a driver, but the driver’s probe(9E) routine has not yet been called.

DS_INITIALIZED
The parent nexus has assigned a bus address for the driver and completed implementation-specific initializations, but the driver’s probe(9E) routine has not yet been called.

DS_PROBED
The driver’s probe(9E) routine returned successfully.

DS_Attached
The node is bound to a driver, but the driver’s probe(9E) routine has not yet been called.

DS_READY
The device is fully configured.

Examples: Use of Device Macros
The examples in this section show how some of the device-related macros can be used to debug a driver.

The following ls -l command shows how the /devices path fits into the devinfo structure:

```
# ls -l /dev/ttya
lrwxrwxrwx 1 root root 6 Aug 17 17:50 /dev/ttya -> term/a
# ls -l /dev/term/a
lrwxrwxrwx 1 root root 32 Aug 17 17:42 /dev/term/a -> ../../devices/obio/zs@0,100000:a
```

Example 18–1 shows how to obtain information about the /dev/ttya device from the devinfo structure and other kernel structures, beginning with devinfo_major.

**EXAMPLE 18–1 The devinfo_major Macro**

```
# ls -lL /dev/ttya
crw-rw-rw- 1 root sys 29, 0 Aug 17 17:42 /dev/ttya
# -stopped at:
edd000d8: ta %icc, %g0 + 125
kadb [0]: 0t29$<devinfo_major

------------ devinfo f5f0dc0
    binding_name
    addr
    node_name
    node_state
    major (hex) 6
    instance
```
EXAMPLE 18–1 The devinfo_major Macro  (Continued)

    1

0xf5f0dba8: parent    child    sibling
            f5f0f380  0      f5f0da80

Example 18–2 shows the use of the devinfo_brief macro. It also shows the use of
top_devinfo. top_devinfo is a pointer to the root of the devinfo tree
(rootnexus)—all other devinfo nodes are descendants of this node. If you want to look
at the device tree top-down in the debugger, this is where you start.

EXAMPLE 18–2 The devinfo_brief Macro

Thread Macros

threadlist is a useful macro that displays the stacks of all the threads in the system.

**EXAMPLE 18-3** The threadlist Macro

```
kadb[0]: $<threadlist

=============== thread_id 10404000
p0+0x300:  
           process args sched

0x20: lwp procp wchan

1041b810 10424688 0

0x24:

   pc  sp
   sched+0x4f4 10403be8

?\{10404000,1040c000,2,10424604,0,6e\}
_start(10006ef4,1041adb0,1041adb0,1041adb0,10462910,50) + 15c

...```

```
=============== thread_id 40043e60
p0+0x300:  
           process args sched

40043f08: lwp procp wchan

0 10424688 10473c56

40043e84:  

   pc  sp
   cv_wait+0x60 40043c08

?\{10473c56,10473c5c,0,40043cd0,40043e60,10093084\}
ufs_thread_idle(10471e80,0,10473c5c,10424688,81010100,0) + bc
thread_start(0,0,0,0,0) + 4

...
```

Another useful macro is thread. Given a thread ID, this macro prints the corresponding thread structure. This can be used to look at a certain thread found with the threadlist macro, to look at the owner of a mutex, or to look at the current thread, as shown here:

**EXAMPLE 18-4** The thread Macro

```
kadb[0]: <g7$<thread

70e87ac0: link stk startpc
0 4026bc80 0

70e87acc: bound_cpu affinitycnt bind_cpu
0 0 -1

70e87ad4: flag proc_flag schedflag
0 4 3

70e87ada: preempt preempt_lk state
0 0 4

70e87ae0: pri epri
```
EXAMPLE 18–4 The thread Macro (Continued)

```
70e87ae4: pc        sp
          10098350     4026b618
70e87aec: wchan         wchan         sobj_ops
           0           0
70e87af8:  cid       clfuncs       cldata
            1         10470ff8   702c0488
70e87b04:  ctx       lofault       onfault
           0           0
...```

Note – No type information is maintained by kadb, so using a macro on an inappropriate address results in garbage output.

Macros do not necessarily output all the fields of the structures, nor is the output necessarily in the order given in the structure definition. Occasionally, memory needs to be dumped for certain structures and then matched with the structure definition in the kernel header files.

Caution – Drivers should never reference system header files or structures not listed in man pages section 9S: DDI and DKI Data Structures. However, examining non-DDI-compliant structures (such as thread structures) can be useful in debugging drivers.

kadb Output Pager

Some kadb commands (like $<threadlist) output lots of data, which can scroll off of the screen very rapidly. kadb provides a simple output pager to remedy this problem. The pager command is lines::more, where lines represents the number of lines to print before pausing the console output. Keep in mind that this does not take into account lines that wrap because they are wider than the terminal width. Here is an example usage:

```
kadb[0]: 0t10::more
kadb[0]: $<threadlist

p0+0x4c0:
    process args sched
    ============== thread_id 10408000
```
Pressing the space bar at the "--More--" prompt pages the output by the number of lines specified to :more (in this case, 10). Pressing "Return" prints only the next line of output. You can abort the output and return to the kadb prompt by typing Ctrl-C. To disable the pager, issue '0:more' at the kadb prompt.

Example: kadb on a Deadlocked Thread

This example shows how kadb can be used to debug a driver bug. This example was taken from the development of the ramdisk sample driver. This driver exports physical memory as a virtual disk. In this case, the dd(1M) command hangs while trying to copy some data onto the device and cannot be aborted. Though a crash dump could be forced, for illustrative purposes, kadb(1M) will be used. After logging into the system remotely, ps was used to determine that the system was still running; and only the dd(1M) command is hung.

At this point, the system is rebooted with kadb, which can now be entered by typing STOP-A on the system console. After the rest of the kernel has loaded, moddebug is patched to see if loading is the problem:

```
stopped at:
edd000d8: ts %icc,%g0 + 125
kadb[0]: moddebug/X
moddebug: 0
kadb[0]: moddebug/W 0x80000000
moddebug: 0x0 = 0x80000000
kadb[0]: :c
```

modload(1M) is used to load the driver, to separate module loading from the real access:

```
# modload /home/driver/drv/ramdisk
```
It loads without errors, so loading is not the problem. The condition is recreated with `dd(1M):

```
# dd if=/dev/zero of=/devices/pseudo/ramdisk@0:c,raw
```

dd(1M) hangs. At this point, kadb(1M) is entered and the stack examined:

```
stopped at:
edd000d8:   ta %icc,%g0 + 125
kadb[0]: $c
intr_vector() + 7dcfd0d8
debug_enter(0,0,10431e50,10,1,b0) + 78
zsa_xsint(80,7044a06c,44,7044a000,ff0113,0) + 278
zs_high_intr(7044a000,1,1,1042f78c,10424680,100949d0) + 20c
sbus_intr_wrapper(704dfad4,0,702bd048,7029c0c0,630,10260250) + 30
current_thread(4001fe60,1041a550,10424698,10424698,10150f08,0) + 180
idle(1040b6c0,0,0,1041a550,704d6a98,0) + 54
thread_start(0,0,0,0,0,0) + 4
```

The presence of idle on the current thread stack indicates that this thread is not the cause of the deadlock. To determine the deadlocked thread, the entire thread list is checked:

```
kadb[0]: $<threadlist
...  
70c88bc0:
   ----------- thread_id 70cef120
   process args dd if=/dev/zero of=/devices/pseudo/ramdisk@0:c,raw

70cef1c8:
   lwp proc wchan
      70fa9080 70c8aec0 70691fc8

70cef144:
   pc sp
      sema_p+0x290 40331a78
   ?(70691fc8,10424680,1,1042b99c,10460f8c,70691fc8)
   biowait(70691fc8,1041a56c,70691fc8,70691fc8,70691fc8,70691fc8,70691fc8,70691fc8,70691fc8) + 8c
   default_physio(1042e8fc,200,129,100,70eb5b54,705c73a0) + 3bc
   write(2002,70aac1d0,70f9f9ac,200,4,200) + 23c
...
```

Of all the threads, only one has a stack trace which references the ramdisk driver. It seems that the process running `dd(1M)` is blocked in `biowait(9F)`. `biowait(9F)`'s first parameter is a `buf(9S)` structure. The next step is to examine this structure:

```
kadb[0]: 70691fc60$70691fd60$
70691fc60:  flags forw back
     204129 0 0
70691fc8:  av_forw av_back bcount
     0 0 512
70691fa0:  bufsize error edev
     0 0 1180000
70691fc7:  un_b_addr _b_blkno resid
     710e0000 0 0
70691fc9:  proc iodone vp
```
The resid field is 0, which indicates that the transfer is complete. `physio(9F)` is still blocked, however. The reference for `physio(9F)` in the Solaris 9 Reference Manual Collection points out that `biodone(9F)` should be called to unblock `biowait(9F)`. This is the problem; `rd_strategy()` did not call `biodone(9F)`. Adding a call to `biodone(9F)` before returning fixes this problem.

Post-Mortem Debugging

When `kadb` is running and the system panics, control is passed to the debugger so that you can investigate the source of the problem. However, `kadb` is not always the best tool for problem analysis; frequently it is easier to use `':c'` to continue execution and allow the system to save a crash dump. When the system reboots, you can perform post-mortem analysis on the saved crash dump. This process is analogous to debugging an application crash from a process core file.

Post-mortem analysis offers several advantages to driver developers: it allows more than one developer to examine a problem in parallel; it allows developers to retrieve information on a problem that occurred in production at a customer site, where it is not acceptable to debug interactively; it is necessary to perform certain types of advanced kernel analysis, such as checking for kernel memory leaks.

Getting Started With the Modular Debugger

The modular debugger, `mdb`, provides sophisticated debugging support for analyzing kernel problems. This section provides an overview of `mdb` features. For a more complete discussion of `mdb`, refer to the Solaris Modular Debugger Guide.

`mdb` command syntax is compatible with the `kadb` syntax and `mdb` can execute all of the `kadb` (and legacy `adb`) macros. These are stored in `/usr/lib/adb` and in `/usr/platform/`uname -i`/lib/adb` for 32-bit kernels; and in `/usr/lib/adb/sparcv9` and `/usr/platform/`uname -i`/lib/adb/sparcv9` for 64-bit kernels.
In addition to macro files, mdb supports debugger commands (or dcmds). These dcmds can be dynamically loaded at runtime from a set of debugger modules. mdb provides a first-class programming API for implementing debugger modules so that driver developers can implement their own custom debugging support. mdb also provides a host of usability features, such as command line editing, command history, an output pager, and online help.

mdb provides a rich set of modules and dcmds for debugging the Solaris kernel and associated modules and device drivers. Some of the activities these facilities enable you to do include:

- formulate complex debugging queries
- locate all the memory allocated by a particular thread
- print a visual picture of a kernel STREAM
- determine what type of structure a particular address refers to
- locate leaked memory blocks in the kernel
- analyze memory to locate stack traces

**Note** – In earlier versions of the Solaris operating environment, adb(1) was the recommended tool for post-mortem analysis. In the Solaris 9 operating environment, mdb(1) is the recommended tool for post-mortem analysis. It provides an upward-compatible syntax and feature set that surpass the set of commands available from the legacy crash(1M) utility, which has been removed from Solaris 9.

To get started, type mdb and supply it with a system crash dump:

```
% cd /var/crash/testsystem
% ls
bounds  unix.0  vmcore.0
% mdb unix.0 vmcore.0
Loading modules: [ unix krtld genunix ufs_log ip usba s1394 cpc nfs ]
> ::status
debugging crash dump vmcore.0 (64-bit) from testsystem
operating system: 5.9 Generic (sun4u)
panic message: zero
dump content: kernel pages only
```

When mdb responds with the ‘>’ prompt, it is ready for commands. To examine the running kernel on a live system, type:

```
# mdb -k
Loading modules: [ unix krtld genunix ufs_log ip usba s1394 ptm cpc ipc nfs ]
> ::status
debugging live kernel (64-bit) on testsystem
operating system: 5.9 Generic (sun4u)
```
Important mdb Commands

This section provides a tutorial for some of the mdb debugger commands most applicable to driver authors. Note that the information presented here is dependent on the type of system used. A Sun Blade™ 100 workstation running the 64-bit kernel was used to produce these examples.

The Solaris Modular Debugger Guide provides details about each debugger command discussed here, as well as more information about all aspects of mdb. Online help is available from within mdb using the ::help built-in command.

Displaying Data Structures with mdb

mdb provides a powerful facility for displaying kernel data structures, so that earlier kadb(1) and mdb(1) debugger macros are no longer needed. Starting in Solaris 9, the operating system kernel maintains a highly compressed database of data structure type information in nonpageable system memory. This means that when a crash occurs, this type information is saved as part of the crash dump.

Here is an example of using the kernel type information to display all of the fields of a scsi_pkt structure:

EXAMPLE 18-5 Displaying Kernel Information with mdb

> 7079ceb0::print -t 'struct scsi_pkt'
{
  opaque_t pkt_ha_private = 0x7079ce20
  struct scsi_address pkt_address = {
    struct scsi_hba_tran *a_hba_tran = 0x70175e68
    ushort_t a_target = 0x6
    uchar_t a_lun = 0
    uchar_t a_sublun = 0
  }
  opaque_t pkt_private = 0x708db4d0
  int (*)(*) *pkt_comp = sd_intr
  uint_t pkt_flags = 0
  int pkt_time = 0x78
  uchar_t *pkt_scbp = 0x7079ce74
  uchar_t *pkt_cdbp = 0x7079ce64
  ssize_t pkt_resid = 0
  uint_t pkt_state = 0x37
  uint_t pkt_statistics = 0
  uchar_t pkt_reason = 0
}

Each data structure member is presented along with its type. Nested structures are expanded for easy viewing. ::print can also decode arrays and unions.
It is frequently helpful to discover the size of a particular kernel data structure; doing so is simple, using the `::sizeof` dcmd:

```
> ::sizeof 'struct scsi_pkt'
sizeof (struct scsi_pkt) = 0x58
```

You can also locate the offset of a field within a data structure:

```
> ::offsetof 'struct scsi_pkt' pkt_state
offsetof (pkt_state) = 0x48
```

The `-a` option may be used to view the offset of each member of a data structure; if no address is specified to `::print`, the output begins at address 0, providing the offset of each field:

**EXAMPLE 18-6** mdb: Viewing Data Members

```
> ::print -at 'struct scsi_pkt'
{
  0 opaque_t pkt_ha_private
  8 struct scsi_address pkt_address {
    8 struct scsi_hba_tran *a_hba_tran
    10 ushort_t a_target
    12 uchar_t a_lun
    13 uchar_t a_sublun
  }
  18 opaque_t pkt_private
  20 int (*)(*) *pkt_comp
  28 uint_t pkt_flags
  2c int pkt_time
  30 uchar_t *pkt_scbp
  38 uchar_t *pkt_cdbp
  40 ssize_t pkt_resid
  48 uint_t pkt_state
  4c uint_t pkt_statistics
  50 uchar_t pkt_reason
}
```

The `::print`, `::sizeof` and `::offsetof` facilities make it possible to more rapidly debug problems which arise when your driver interacts with the Solaris kernel.

---

**Caution** – This facility provides access to “raw” kernel data structures. You may examine any structure whether it appears as part of the DDI or not; therefore, refrain from relying on any data structure that is not explicitly part of the DDI.
Note – These dcmds may only be used with objects that contain compressed symbolic debugging information designed for use with `mdb`. This information is currently only available for certain Solaris kernel modules. The `SUNWzlib` (32-bit) or `SUNWzlibx` (64-bit) decompression software must be installed in order to process the symbolic debugging information.

Navigating the Device Tree with `mdb`

`mdb` provides the `::prtconf` dcmd to display the kernel device tree. The output of this dcmd is similar to the output of the `prtconf(1M)` command:

```
> ::prtconf
300015d3e08 SUNW,Sun-Blade-100
  300015d3c28 packages (driver not attached)
    300015d3868 SUNW,builtin-drivers (driver not attached)
    300015d3688 deblocker (driver not attached)
    300015d34a8 disk-label (driver not attached)
    300015d32c8 terminal-emulator (driver not attached)
    300015d30e8 obp-tftp (driver not attached)
    300015d2f08 dropins (driver not attached)
    300015d2d28 kbd-translator (driver not attached)
    300015d2b48 ufs-file-system (driver not attached)
  300015d3a48 chosen (driver not attached)
  300015d2968 openprom (driver not attached)
...```

The node can then be displayed using a macro (such as the `$<devinfo_brief` macro) or the `::devinfo` dcmd:

```
> 300015d3e08::devinfo
300015d3e08 SUNW,Sun-Blade-100
  System properties at 0x300015abdc0:
    name='relative-addressing' type=int items=1
      value=00000001
    name='MMU_PAGEOFFSET' type=int items=1
      value=00001fff
    name='MMU_PAGESIZE' type=int items=1
      value=00002000
    name='PAGESIZE' type=int items=1
      value=00002000
  Driver properties at 0x300015abe00:
    name='pm-hardware-state' type=string items=1
      value='no-suspend-resume'

> 300015d3e08$<devinfo_brief

============== devinfo 300015d3e08
  binding_name
```

364 Writing Device Drivers • May 2002
Use `::prtconf` to see where your driver has attached in the device tree, and to display device properties. You can also specify the verbose (-v) flag to `::prtconf` to display the properties for each device node:

```
> ::prtconf -v
DEVINFO       NAME
300015d3e08   SUNW,Sun-Blade-100

System properties at 0x300015abdc0:
  name='relative-addressing' type=int items=1
    value=00000001
  name='MMU_PAGEOFFSET' type=int items=1
    value=00001fff
  name='MMU_PAGESIZE' type=int items=1
    value=00002000
  name='PAGESIZE' type=int items=1
    value=00002000

Driver properties at 0x300015abe00:
  name='pm-hardware-state' type=string items=1
    value='no-suspend-resume'

... 300015ce798 pci10b9,5229, instance #0

Driver properties at 0x300015ab980:
  name='target2-dcd-options' type=any items=4
    value=00.00.00.a4
  name='target1-dcd-options' type=any items=4
    value=00.00.00.a2
  name='target0-dcd-options' type=any items=4
    value=00.00.00.a4

...
```

Another way to locate instances of your driver is the `::devbindings` dcmd. Given a driver name, it displays a list of all instances of the named driver:

```
> ::devbindings dad
300015ce3d8 ide-disk (driver not attached)
300015c9a60 dad, instance #0

System properties at 0x300015ab400:
  name='lun' type=int items=1
    value=00000000
  name='target' type=int items=1
    value=00000000
  name='class_prop' type=string items=1
    value=
```

Chapter 18 • Debugging  365
Retrieving Driver Soft State Information

A common problem when debugging a driver is retrieving the soft state for a particular driver instance. The soft state is allocated with the ddi_soft_state_zalloc(9F) routine and obtained by drivers using ddi_get_soft_state(9F). If you know the name of the soft state pointer (the first argument to ddi_soft_state_init(9F)), mdb enables you to retrieve the soft state for a particular driver instance using the ::softstate dcmd:

```
> *bst_state::softstate 0x3
702b7578
```

In this case, ::softstate is used to fetch the soft state for instance 3 of the bst sample driver. This pointer points to a bst_soft structure used by the driver to track state for this instance.

Detecting Kernel Memory Leaks

The ::findleaks dcmd provides powerful and efficient detection of memory leaks in kernel crash dumps. The full set of kernel-memory debugging features should be enabled for ::findleaks to be effective. For more information see “kmem_flags” on page 343. Running ::findleaks during driver development and testing can detect code which is leaking memory and wasting kernel resources. See “Debugging With the Kernel Memory Allocator” in the Solaris Modular Debugger Guide for a complete discussion of ::findleaks.
Note – Use \\findleaks to detect and eliminate kernel memory leaks caused by your code. Code that leaks kernel memory can render the system vulnerable to denial-of-service attacks.

Writing Debugger Commands with mdb

mdb provides a powerful API for implementing new debugger facilities that you can use to debug your driver. The Solaris Modular Debugger Guide explains the programming API in more detail, and the SUNWmdbdm package installs sample mdb source code in the directory /usr/demo/mdb. You can use mdb to automate lengthy debugging chores or help to validate that your driver is behaving properly. You can also package your mdb debugging modules with your driver product so that these facilities will be available to service personnel at a customer site.
Recommended Coding Practices

This chapter describes how to write drivers that are robust. Drivers that are written in accordance with the guidelines discussed in this chapter:

- Are easier to debug
- Protect the system from hardware and software faults

This chapter provides information on the following subjects:

- “Debugging” on page 369
- “Defensive Programming” on page 372
- “Declaring a Variable Volatile” on page 377
- “Serviceability” on page 379

Debugging

Driver code is more difficult to debug than user programs because:

- The driver interacts directly with the hardware
- The driver operates without the protection of the operating system available to user processes

Be sure to build debugging support into your driver. Debugging support facilitates future development and maintenance work.
Use \texttt{cmn\_err()} to Log Driver Activity

Use the \texttt{cmn\_err()} function to print messages to the console from within the device driver. \texttt{cmn\_err()} is similar to \texttt{printf(3C)}, but provides additional format characters (such as \texttt{%b}) to print device register bits. See the \texttt{cmn\_err(9F)} man page for more information.

\textbf{Note} – To ensure that the driver is DDI-compliant, use \texttt{cmn\_err()} instead of \texttt{printf()} and \texttt{uprintf()}. 

Use \texttt{ASSERT()} to Catch Invalid Assumptions

The syntax for \texttt{ASSERT(9F)} is as follows:

\begin{verbatim}
void ASSERT(EXPR)
\end{verbatim}

\texttt{ASSERT()} is a macro that is used to halt the execution of the kernel if a condition expected to be true is actually false. \texttt{ASSERT} provides a way for the programmer to validate the assumptions made by a piece of code.

The \texttt{ASSERT()} macro is defined only when the \texttt{DEBUG} compilation symbol is defined. However, when \texttt{DEBUG} is not defined, the \texttt{ASSERT()} macro has no effect.

For example, if a driver pointer should be non-\texttt{NULL} and is not, the following assertion can be used to check the code:

\begin{verbatim}
ASSERT(ptr != NULL);
\end{verbatim}

If the driver is compiled with \texttt{DEBUG} defined and the assertion fails, a message is printed to the console and the system panics:

\begin{verbatim}
panic: assertion failed: ptr != NULL, file: driver.c, line: 56
\end{verbatim}

\textbf{Note} – Because \texttt{ASSERT(9F)} uses the \texttt{DEBUG} compilation symbol, any conditional debugging code should also use \texttt{DEBUG}.

Assertions are an extremely valuable form of active documentation.

Use \texttt{mutex\_owned()} to Validate and Document Locking Requirements

The syntax for \texttt{mutex\_owned(9F)} is as follows:

\begin{verbatim}
int mutex_owned(kmutex_t *mp);
\end{verbatim}
A significant portion of driver development involves properly handling multiple threads. Comments should always be used when a mutex is acquired; they are even more useful when an apparently necessary mutex is not acquired. To determine if a mutex is held by a thread, use mutex_owned() within assert(9F):

```c
void helper(void)
{
    /* this routine should always be called with xsp's mutex held */
    ASSERT(mutex_owned(&xsp->mu));
    ...
}
```

**Caution** – mutex_owned() is only valid within assert() macros. Under no circumstances should you use it to control the behavior of a driver.

---

### Use Conditional Compilation to Toggle Costly Debugging Features

Debugging code can be placed in a driver by conditionally compiling code based on a preprocessor symbol such as DEBUG or by using a global variable. Conditional compilation has the advantage that unnecessary code can be removed in the production driver. Using a variable allows the amount of debugging output to be chosen at runtime. This can be accomplished by setting a debugging level at runtime with an ioctl or through a debugger. Commonly, these two methods are combined.

The following example relies on the compiler to remove unreachable code (the code following the always-false test of zero), and also provides a local variable that can be set in `/etc/system` or patched by a debugger.

```c
#ifdef DEBUG
    comments on values of xxdebug and what they do
    static int xxdebug;
    #define dcmn_err if (xxdebug) cmn_err
#else
    #define dcmn_err if (0) cmn_err
#endif
...
    dcmn_err(CE_NOTE, "Error!\n");
```

This method handles the fact that cmn_err(9F) has a variable number of arguments. Another method relies on the macro having one argument, a parenthesized argument list for cmn_err(9F), which the macro removes. It also removes the reliance on the optimizer by expanding the macro to nothing if DEBUG is not defined.

```c
#ifdef DEBUG
    comments on values of xxdebug and what they do
    static int xxdebug;
```
#define dcmn_err(X) if (xxdebug) cmn_err X
#else
#define dcmn_err() /* nothing */
#endif

... 
/* Note: double parentheses are required when using dcmn_err. */
 dcmn_err((CE_NOTE, "Error!"));

You can extend this in many ways, such as by having different messages from cmn_err(9F), depending on the value of xxdebug, but be careful not to obscure the code with too much debugging information.

Another common scheme is to write an xxlog() function, which uses vsprintf(9F) or vcmn_err(9F) to handle variable argument lists.

---

Defensive Programming

Use the following defensive programming techniques to prevent your code from causing system panics or hangs, draining system resources, or allowing the spread of corrupted data.

All Solaris drivers should abide by these coding practices:

- Each piece of hardware should be controlled by a separate instance of the device driver. (See “Device Configuration Concepts” on page 72.)
- Programmed I/O (PIO) must be performed only through the DDI access functions, using the appropriate data access handle. (See Chapter 6.)
- The device driver must assume that data it receives from the device could be corrupted. The driver must check the integrity of the data before using it.
- The driver must avoid releasing bad data to the rest of the system.
- Use only documented DDI functions and interfaces in your driver.
- The driver must ensure that all writes by the device into DMA buffers (DDI_DMA_READ) are contained within pages of memory controlled entirely by the driver. This prevents a DMA fault from corrupting an arbitrary part of the system’s main memory.
- The device driver must not be an unlimited drain on system resources if the device locks up. It should time-out if a device claims to be continuously busy. The driver should also detect a pathological (stuck) interrupt request and take appropriate action.
- The device driver must support Solaris Hot-Plug.
- The device driver must use callbacks instead of waiting on resources.
The driver must free up resources after a fault. For example, the system must be able to close all minor devices and detach driver instances even after the hardware fails.

Using Separate Device Driver Instances

The Solaris kernel allows multiple instances of a driver. Each instance has its own data space but shares the text and some global data with other instances. The device is managed on a per-instance basis. Drivers should use a separate instance for each piece of hardware unless the driver is designed to handle fail-over internally. There can be multiple instances of a driver per slot, for example, multi-function cards, which is standard behavior for Solaris device drivers.

Exclusive Use of DDI Access Handles

All PIO access by a driver must use Solaris DDI access functions from the ddi_getX, ddi_putX, ddi_rep_getX, and ddi_rep_putX families of routines. The driver should not directly access the mapped registers by the address returned from ddi_regs_map_setup(9F). (Avoid the ddi.peek(9F) and ddi poke(9F) routines because they do not use access handles.)

The DDI access mechanism is important because it provides an opportunity to control how data is read into the kernel.

Detecting Corrupted Data

The following sections consider where data corruption can occur and the steps you can take to detect it.

Corruption of Device Management and Control Data

The driver should assume that any data obtained from the device, whether by PIO or DMA, could have been corrupted. In particular, extreme care should be taken with pointers, memory offsets, or array indexes read or calculated from data supplied by the device. Such values can be malignant, meaning they can cause a kernel panic if dereferenced. All such values should be checked for range and alignment (if required) before use.

Even if a pointer is not malignant, it can still be misleading. For example, it can point at a valid instance of an object, but not the correct one. Where possible, the driver should cross-check the pointer with the pointed-to object, or otherwise validate the data obtained through it.
Other types of data can also be misleading, such as packet lengths, status words, or channel IDs. Each should be checked to the extent possible: a packet length can be range-checked to ensure that it is not negative or larger than the containing buffer; a status word can be checked for "impossible" bits; and a channel ID can be matched against a list of valid IDs.

Where a value is used to identify a Stream, the driver must ensure that the Stream still exists. The asynchronous nature of STREAMS processing means that a Stream can be dismantled while device interrupts are still outstanding.

The driver should not reread data from the device; the data should be read once, validated, and stored in the driver’s local state. This avoids the hazard presented by data that, although correct when initially read and validated, is incorrect when reread later.

The driver should also ensure that all loops are bounded, so that a device returning a continuous BUSY status, or claiming that another buffer needs to be processed, does not lock up the entire system.

Corruption of Received Data

Device errors can result in corrupted data being placed in receive buffers. Such corruption is indistinguishable from corruption that occurs beyond the domain of the device—for example, within a network. Typically, existing software is already in place to handle such corruption; for example, through integrity checks at the transport layer of a protocol stack or within the application using the device.

If the received data will not be checked for integrity at a higher layer—as in the case of a disk driver, for example—it can be integrity-checked within the driver itself. Methods of detecting corruption in received data are typically device-specific (checksums, CRC, and so forth).

DMA Isolation

A defective device might initiate an improper DMA transfer over the bus. This data transfer could corrupt good data that was previously delivered. A device that fails might generate a corrupt address that can contaminate memory that does not even belong to its own driver.

In systems with an IOMMU, a device can write only to pages mapped as writable for DMA. Therefore, pages that are to be the target of DMA writes should be owned solely by one driver instance and not shared with any other kernel structure. While the page in question is mapped as writable for DMA, the driver should be suspicious of data in that page. The page must be unmapped from the IOMMU before it is passed beyond the driver, or before any validation of the data.
You can use `ddi_umem_alloc(9F)` to guarantee that a whole aligned page is allocated, or allocate multiple pages and ignore the memory below the first page boundary. You can find the size of an IOMMU page by using `ddi_ptob(9F)`.

Alternatively, the driver can choose to copy the data into a safe part of memory before processing it. If this is done, the data must first be synchronized using `ddi_dma_sync(9F)`.

Calls to `ddi_dma_sync(9F)` should specify `SYNC_FOR_DEV` before using DMA to transfer data to a device, and `SYNC_FOR_CPU` after using DMA to transfer data from the device to memory.

On some PCI-based systems with an IOMMU, devices may be able to use PCI dual address cycles (64-bit addresses) to bypass the IOMMU. This gives the device the potential to corrupt any region of main memory. Device drivers must not attempt to use such a mode and should disable it.

**Handling Stuck Interrupts**

The driver must identify stuck interrupts because a persistently asserted interrupt severely affects system performance, almost certainly stalling a single-processor machine.

Sometimes the driver might have difficulty in identifying a particular interrupt as bogus. For network drivers, if a receive interrupt is indicated but no new buffers have been made available, no work was needed. When this is an isolated occurrence, it is not a problem, as the actual work might already have been completed by another routine (read service, for example).

On the other hand, continuous interrupts with no work for the driver to process can indicate a stuck interrupt line. For this reason, all platforms allow a number of apparently bogus interrupts to occur before taking defensive action.

While appearing to have work to do, a hung device might be failing to update its buffer descriptors. The driver should defend against such repetitive requests.

In some cases, platform–specific bus drivers might be capable of identifying a persistently unclaimed interrupt and can disable the offending device. However, this relies on the driver's ability to identify the valid interrupts and return the appropriate value. The driver should therefore return a `DDI_INTR_UNCLAIMED` result unless it detects that the device legitimately asserted an interrupt (that is, the device actually requires the driver to do some useful work).

The legitimacy of other, more incidental, interrupts is much harder to certify. To this end, an interrupt-expected flag is a useful tool for evaluating whether an interrupt is valid. Consider an interrupt such as `descriptor free`, which can be generated if all the
device’s descriptors had been previously allocated. If the driver detects that it has
taken the last descriptor from the card, it can set an interrupt-expected flag. If this flag
is not set when the associated interrupt is delivered, it is suspicious.

Some informative interrupts might not be predictable, such as one indicating that a
medium has become disconnected or frame sync has been lost. The easiest method of
detecting whether such an interrupt is stuck is to mask this particular source on first
occurrence until the next polling cycle.

If the interrupt occurs again while disabled, this should be considered a false
interrupt. Some devices have interrupt status bits that can be read even if the mask
register has disabled the associated source and might not be causing the interrupt.
Driver designers can devise more appropriate algorithms specific to their devices.

Avoid looping on interrupt status bits indefinitely. Break such loops if none of the
status bits set at the start of a pass requires any real work.

Additional Programming Considerations

In addition to the requirements discussed in the previous sections, the driver
developer must consider a few other issues. These are:

- Thread interaction
- Threats from top-down requests
- Adaptive strategies

Thread Interaction

Kernel panics in a device driver are often caused by unexpected interaction of kernel
threads after a device failure. When a device fails, threads can interact in ways that the
designer had not anticipated.

If processing routines terminate early, the condition variable waiters are blocked
because an expected signal is never given. Attempting to inform other modules of the
failure or handling unanticipated callbacks can result in undesirable thread
interactions. Consider the sequence of mutex acquisition and relinquishing that can
occur during device failures.

Threads that originate in an upstream STREAMS module can run into unfortunate
paradoxes if used to return to that module unexpectedly. You might use alternative
threads to handle exception messages. For instance, a \texttt{wput} procedure might use a
read-side service routine to communicate an \texttt{M\_ERROR}, rather than doing it directly
with a read-side \texttt{putnext}.

A failing STREAMS device that cannot be quiesced during close (because of the fault)
can generate an interrupt after the stream has been dismantled. The interrupt handler
must not attempt to use a stale stream pointer to try to process the message.
Threats From Top-Down Requests

While protecting the system from defective hardware, the driver designer also needs to protect against driver misuse. Although the driver can assume that the kernel infrastructure is always correct (a trusted core), user requests passed to it can be potentially destructive.

For example, a user can request an action to be performed upon a user-supplied data block (M_IOCTL) that is smaller than that indicated in the control part of the message. The driver should never trust a user application.

The design should consider the construction of each type of ioctl that it can receive with a view to the potential harm that it could cause. The driver should make checks to be sure that it does not process malformed ioctls.

Adaptive Strategies

A driver can continue to provide service with faulty hardware, attempting to work around the identified problem by using an alternative strategy for accessing the device. Given that broken hardware is unpredictable and given the risk associated with additional design complexity, adaptive strategies are not always wise. At most, they should be limited to periodic interrupt polling and retry attempts. Periodically retrying the device lets the driver know when a device has recovered. Periodic polling can control the interrupt mechanism after a driver has been forced to disable interrupts.

Ideally, a system always has an alternative device to provide a vital system service. Service multiplexors in kernel or user space offer the best method of maintaining system services when a device fails. Such practices are beyond the scope of this chapter.

Declaring a Variable Volatile

volatile is a keyword that must be used when declaring any variable that will reference a device register. If this is not done, the compile-time optimizer might optimize important accesses away. This is important; neglecting to use volatile can result in bugs that are difficult to track down.

The correct use of volatile is necessary to prevent elusive bugs. It instructs the compiler to use exact semantics for the declared objects—in particular, to not optimize away or reorder accesses to the object. There are two instances where device drivers must use the volatile qualifier:
1. When data refers to an external hardware device register (memory that has side effects other than just storage). Note, however, that if the DDI data access functions are used to access device registers, it is not necessary to use `volatile`.

2. When data refers to global memory that is accessible by more than one thread, that is not protected by locks, and that relies on the sequencing of memory accesses. Using `volatile` is less expensive than using lock.

The following example uses `volatile`. A busy flag is used to prevent a thread from continuing while the device is busy and the flag is not protected by a lock:

```c
while (busy) {
    /* do something else */
}
```

The testing thread will continue when another thread turns off the `busy` flag:

```c
busy = 0;
```

However, since `busy` is accessed frequently in the testing thread, the compiler may optimize the test by placing the value of `busy` in a register, then test the contents of the register without reading the value of `busy` in memory before every test. The testing thread would never see `busy` change and the other thread would only change the value of `busy` in memory, resulting in deadlock. Declaring the `busy` flag as `volatile` forces its value to be read before each test.

**Note** – It would probably be preferable to use a condition variable, discussed under “Condition Variables in Thread Synchronization” on page 48 rather than the `busy` flag in this example.

It is also recommended that the `volatile` qualifier be used in such a way as to avoid the risk of accidental omission. For example, this code

```c
struct device_reg {
    volatile uint8_t csr;
    volatile uint8_t data;
};
struct device_reg *regp;
```

is recommended over:

```c
struct device_reg {
    uint8_t csr;
    uint8_t data;
};
volatile struct device_reg *regp;
```
Although the two examples are functionally equivalent, the second one requires the writer to ensure that `volatile` is used in every declaration of type `struct device_reg`. The first example results in the data being treated as volatile in all declarations and is therefore preferred. Note as mentioned above, that the use of the DDI data access functions to access device registers makes it unnecessary to qualify variables as `volatile`.

Serviceability

To ensure serviceability, the driver must be enabled to do the following:

- Detect faulty devices and report the fault
- Remove a device (as supported by the Solaris hot-plug model)
- Add a new device (as supported by the Solaris hot-plug model)
- Perform periodic health checks to enable the detection of latent faults

Periodic Health Checks

A latent fault is one that does not show itself until some other action occurs. For example, a hardware failure occurring in a device that is a cold stand-by could remain undetected until a fault occurs on the master device. At this point, the system now contains two defective devices and might be unable to continue operation.

As a general rule, latent faults that are allowed to remain undetected will eventually cause system failure. Without latent fault checking, the overall availability of a redundant system is jeopardized. To avoid this, a device driver must detect latent faults and report them in the same way as other faults.

The driver should ensure that it has a mechanism for making periodic health checks on the device. In a fault-tolerant situation where the device can be the secondary or fail-over device, early detection of a failed secondary device is essential to ensure that it can be repaired or replaced before any failure in the primary device occurs.

Periodic health checks can:

- Check a register or memory location on the device whose value the driver expects to have been deterministically altered since the last poll.

  Features of a device that typically exhibit deterministic behavior include heartbeat semaphores, device timers (for example, local `lbolt` used by download), and event counters. Reading an updated predictable value from the device gives a degree of confidence that things are proceeding satisfactorily.
- Time-stamp outgoing requests (transmit blocks or commands) when issued by the driver.
  The periodic health check can look for any over-age requests that have not completed.
- Initiate an action on the device that should be completed before the next scheduled check.
  If this action is an interrupt, this is an ideal way of ensuring that the device’s circuitry is still capable of delivering an interrupt.
APPENDIX A

Hardware Overview

This appendix discusses general issues about hardware capable of supporting the Solaris 9 operating environment. This includes issues related to the processor, bus architectures, and memory models supported by the Solaris 9 operating environment, various device issues, and the PROM used in Sun platforms.

Note – The information presented here is for informational purposes only and might be of help during driver debugging. However, the DDI/DKI interfaces hide many of these implementation details from device drivers.

This appendix provides information on the following subjects:

- “SPARC Processor Issues” on page 381
- “IA Processor Issues” on page 383
- “Endianness” on page 384
- “Store Buffers” on page 385
- “System Memory Model” on page 386
- “Bus Architectures” on page 387
- “Bus Specifics” on page 387
- “Device Issues” on page 393
- “PROM on SPARC Machines” on page 394

SPARC Processor Issues

This section describes a number of SPARC processor-specific topics including data alignment, byte ordering, register windows, and availability of floating-point instructions. For information on IA processor-specific topics, see “IA Processor Issues” on page 383.
Caution – Drivers should never perform floating-point operations, as they are not supported in the kernel.

SPARC Data Alignment

All quantities must be aligned on their natural boundaries. Using standard C data types:

- short integers are aligned on 16-bit boundaries.
- int integers are aligned on 32-bit boundaries.
- long integers are aligned on either 32-bit boundaries or 64-bit boundaries, depending on whether the data model of the kernel is 64-bit or 32-bit. For information on data models, see Appendix C.
- long long integers are aligned on 64-bit boundaries.

Usually, the compiler handles alignment issues. However, driver writers are more likely to be concerned about alignment as they must use the proper data types to access their device. Because device registers are commonly accessed through a pointer reference, drivers must ensure that pointers are properly aligned when accessing the device.

SPARC Structure Member Alignment

Because of the data alignment restrictions imposed by the SPARC processor, C structures also have alignment requirements. Structure alignment requirements are imposed by the most strictly-aligned structure component. For example, a structure containing only characters has no alignment restrictions, while a structure containing a long long member must be constructed to guarantee that this member falls on a 64-bit boundary.

SPARC Byte Ordering

The SPARC processor uses big-endian byte ordering; in other words, the most significant byte (MSB) of an integer is stored at the lowest address of the integer.
SPARC Register Windows

SPARC processors use register windows. Each register window consists of 8 in registers, 8 local registers, and 8 out registers (which are the in registers of the next window). There are also 8 global registers. The number of register windows ranges from 2 to 32, depending on the processor implementation.

Because drivers are normally written in C, the compiler usually hides the fact that register windows are used. However, you might have to use them when debugging the driver.

SPARC Multiply and Divide Instructions

The Version 7 SPARC processors do not have multiply or divide instructions. These instructions are emulated in software and should be avoided. Because a driver cannot determine whether it is running on a Version 7, Version 8, or Version 9 processor, intensive integer multiplication and division should be avoided if possible. Instead, use bitwise left and right shifts to multiply and divide by powers of two.

IA Processor Issues

There are no alignment restrictions on data types. However, extra memory cycles might be required for the IA processor to properly handle misaligned data transfers.

Caution – Drivers should not perform floating-point operations, as they are not supported in the kernel.
IA Byte Ordering

The IA processor uses little-endian byte ordering. The least significant byte (LSB) of an integer is stored at the lowest address of the integer.

IA Architecture Manuals

Intel Corporation publishes a number of books on the IA family of processors. See http://www.intel.com.

Endianness

To achieve the goal of multiple-platform, multiple-instruction-set architecture portability, host bus dependencies were removed from the drivers. The first dependency issue to be addressed was the endianness (or byte ordering) of the processor. For example, the IA processor family is little-endian while the SPARC architecture is big-endian.

Bus architectures display the same endianness types as processors. The PCI local bus, for example, is little-endian, the SBus is big-endian, the ISA bus is little-endian, and so on.

To maintain portability between processors and buses, DDI-compliant drivers must be endian neutral. Although drivers could conceivably manage their endianness by runtime checks or by preprocessor directives like #ifdef _LITTLE_ENDIAN or _BIG_ENDIAN statements in the source code, long-term maintenance would be troublesome. In some cases, the DDI framework performs the byte swapping using a software approach. In other cases, where byte swapping can be done by hardware (as in memory management unit (MMU) page-level swapping or by special machine instructions), the DDI framework will take advantage of the hardware features to improve performance.
Along with being endian-neutral, portable drivers must also be independent from data ordering of the processor. Under most circumstances, data must be transferred in the sequence instructed by the driver. However, sometimes data can be merged, batched, or reordered to streamline the data transfer, as illustrated in Figure A–2. For example, data merging can be applied to accelerate graphics display on frame buffers. Drivers have the option to advise the DDI framework to use other optimal data transfer mechanisms during the transfer.

Store Buffers

To improve performance, the CPU uses internal store buffers to temporarily store data. This can affect the synchronization of device I/O operations. Therefore, the driver needs to take explicit steps to make sure that writes to registers are completed at the proper time.

For example, when access to device space (such as registers or a frame buffer) is synchronized by a lock, the driver needs to check that the store to the device space has actually completed before releasing the lock. Releasing the lock does not guarantee the flushing of I/O buffers.
To give another example, when acknowledging an interrupt, the driver usually sets or clears a bit in a device control register. The driver must ensure that the write to the control register has reached the device before the interrupt handler returns. Similarly, if the device requires a delay (the driver busy-waits) after writing a command to the control register, the driver must ensure that the write has reached the device before delaying.

If the device registers can be read without undesirable side effects, verification of a write can be as simple as reading the register immediately after writing to it. If that particular register cannot be read without undesirable side effects, another device register in the same register set can be used.

System Memory Model

The system memory model defines the semantics of memory operations such as load and store and specifies how the order in which these operations are issued by a processor is related to the order in which they reach memory. The memory model applies to both uniprocessors and shared-memory multiprocessors. Two memory models are supported: total store ordering (TSO) and partial store ordering (PSO).

Total Store Ordering (TSO)

TSO guarantees that the sequence in which store, FLUSH, and atomic load-store instructions appear in memory for a given processor is identical to the sequence in which they were issued by the processor.

Both IA and SPARC processors support TSO.

Partial Store Ordering (PSO)

PSO does not guarantee that the sequence in which store, FLUSH, and atomic load-store instructions appear in memory for a given processor is identical to the sequence in which they were issued by the processor. The processor can reorder the stores so that the sequence of stores to memory is not the same as the sequence of stores issued by the CPU.

SPARC processors support PSO; IA processors do not.

For SPARC processors, conformance between issuing order and memory order is provided by the system framework using the STBAR instruction: if two of the above instructions are separated by an STBAR in the issuing order of a processor, or if they
reference the same location, the memory order of the two instructions is the same as
the issuing order. Note that enforcement of strong data ordering in DDI-compliant
drivers is provided by the ddi_regs_map_setup(9F) interface. Compliant drivers
cannot use the STBAR instruction directly.

See the SPARC Architecture Manual, Version 9, for more details on the SPARC memory
model.

---

**Bus Architectures**

This section describes device identification, device addressing, and interrupts.

**Device Identification**

Device identification is the process of determining which devices are present in the
system. Some devices are self-identifying—the device itself provides information to
the system so that it can identify the device driver that needs to be used. SBus and PCI
local bus devices are examples of self-identifying devices. On SBus, the information is
usually derived from a small Forth program stored in the FCode PROM on the device.
Most PCI devices provide a configuration space containing device configuration
information. See the sbus(4) and pci(4) man pages for more information.

All modern bus architectures require devices to be self-identifying.

**Supported Interrupt Types**

Solaris supports both polling and vectored interrupts. The Solaris 9 DDI/DKI
interrupt model is the same for both. See Chapter 7 for more information about
interrupt handling.

---

**Bus Specifics**

This section covers addressing and device configuration issues specific to the buses
that Solaris supports.
PCI Local Bus

The PCI local bus is a high-performance bus designed for high-speed data transfer. The PCI bus resides on the system board and is normally used as an interconnect mechanism between highly integrated peripheral components, peripheral add-on boards, and host processor or memory systems. The host processor, main memory, and the PCI bus itself are connected through a PCI host bridge, as shown in Figure A–3.

A tree structure of interconnected I/O buses is supported through a series of PCI bus bridges. Subordinate PCI bus bridges can be extended underneath the PCI host bridge to enable a single bus system to be expanded into a complex system with multiple secondary buses. PCI devices can be connected to one or more of these secondary buses. In addition, other bus bridges, such as SCSI or USB, can be connected.

Every PCI device has a unique vendor ID and device ID. Multiple devices of the same kind are further identified by their unique device numbers on the bus where they reside.

![Machine Block Diagram](image)

**FIGURE A–3** Machine Block Diagram

The PCI host bridge provides an interconnect between the processor and peripheral components. Through the PCI host bridge, the processor can directly access main memory independent of other PCI bus masters. For example, while the CPU is fetching data from the cache controller in the host bridge, other PCI devices can also access the system memory through the host bridge. The advantage of this architecture lies in its separation of the I/O bus from the processor’s host bus.
The PCI host bridge also provides data access mappings between the CPU and peripheral I/O devices. It maps every peripheral device to the host address domain so that the processor can access the device through programmed I/O. On the local bus side, the PCI host bridge maps the system memory to the PCI address domain so that the PCI device can access the host memory as a bus master. Figure A–3 shows the two address domains.

**PCI Address Domain**

The PCI address domain consists of three distinct address spaces: configuration, memory, and I/O space.

**PCI Configuration Address Space**

Configuration space is defined geographically; in other words, the location of a peripheral device is determined by its physical location within an interconnected tree of PCI bus bridges. A device is located by its bus number and device (slot) number. Each peripheral device contains a set of well-defined configuration registers in its PCI configuration space. The registers are used not only to identify devices but also to supply device configuration information to the configuration framework. For example, base address registers in the device configuration space must be mapped before a device can respond to data access.

The method for generating configuration cycles is host dependent. In IA machines, special I/O ports are used. On other platforms, the PCI configuration space can be memory-mapped to certain address locations corresponding to the PCI host bridge in the host address domain. When a device configuration register is accessed by the processor, the request is routed to the PCI host bridge. The bridge then translates the access into proper configuration cycles on the bus.

**PCI Configuration Base Address Registers**

The PCI configuration space consists of up to six 32-bit base address registers for each device. These registers provide both size and data type information. System firmware assigns base addresses in the PCI address domain to these registers.

Each addressable region can be either memory or I/O space. The value contained in bit 0 of the base address register identifies the type. A value of 0 in bit 0 indicates a memory space and a value of 1 indicates an I/O space. Figure A–4 shows two base address registers: one for memory; the other for I/O types.
PCI Memory Address Space

PCI supports both 32-bit and 64-bit addresses for memory space. System firmware assigns regions of memory space in the PCI address domain to PCI peripherals. The base address of a region is stored in the base address register of the device’s PCI configuration space. The size of each region must be a power of two, and the assigned base address must be aligned on a boundary equal to the size of the region. Device addresses in memory space are memory-mapped into the host address domain so that data access to any device can be performed by the processor’s native load or store instructions.

PCI I/O Address Space

PCI supports 32-bit I/O space. I/O space can be accessed differently on different platforms. Processors with special I/O instructions, like the Intel processor family, access the I/O space with in and out instructions. Machines without special I/O instructions will map to the address locations corresponding to the PCI host bridge in the host address domain. When the processor accesses the memory-mapped addresses, an I/O request will be sent to the PCI host bridge, which then translates the addresses into I/O cycles and puts them on the PCI bus. Memory-mapped I/O is performed by the native load/store instructions of the processor.

PCI Hardware Configuration Files

Hardware configuration files should be unnecessary for PCI local bus devices. However, on some occasions drivers for PCI devices need to use hardware configuration files to augment the driver private information. See the driver.conf(4) and pci(4) man pages for further details.
SBus

Typical SBus systems consist of a motherboard (containing the CPU and SBus interface logic), a number of SBus devices on the motherboard itself, and a number of SBus expansion slots. An SBus can also be connected to other types of buses through an appropriate bus bridge.

The SBus is geographically addressed; each SBus slot exists at a fixed physical address in the system. An SBus card has a different address, depending on which slot it is plugged into. Moving an SBus device to a new slot causes the system to treat it as a new device.

The SBus uses polling interrupts. When an SBus device interrupts, the system only knows which of several devices might have issued the interrupt. The system interrupt handler must ask the driver for each device whether it is responsible for the interrupt.

SBus Physical Address Space

Table A–1 shows the physical address space layout of the Sun Ultra 2 computer. A physical address on the Ultra 2 consists of 41 bits. The 41-bit physical address space is further broken down into multiple 33-bit address spaces identified by \( PA(40:33) \).

<table>

</table>

Physical SBus Addresses

The SBus has 32 address bits, as described in the SBus Specification. Table A–2 describes how the Ultra 2 uses the address bits.

TABLE A–2 Ultra 2 SBus Address Bits

<table>
<thead>
<tr>
<th>Bits</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0 - 27</td>
<td>These bits are the SBus address lines used by an SBus card to address</td>

<td>the contents of the card.</td>
</tr>
<tr>
<td>28 - 31</td>
<td>Used by the CPU to select one of the SBus slots. These bits generate the</td>
</tr>
<tr>
<td></td>
<td>SlaveSelect lines.</td>
</tr>
</tbody>
</table>

This addressing scheme yields the Ultra 2 addresses shown in Table A–1. Other implementations might use a different number of address bits.

The Ultra 2 has seven SBus slots, four of which are physical. Slots 0 through 3 are available for SBus cards. Slots 4-12 are reserved. The slots are used in the following way:

- Slots 0–3 are physical slots that have DMA-master capability.
- Slots D, E, and F are not actual physical slots, but refer to the onboard direct memory access (DMA), SCSI, Ethernet, and audio controllers. For convenience, these are viewed as being plugged into slots D, E, and F.

**Note** – Some SBus slots are slave-only slots. Drivers that require DMA capability should use ddi_slaveonly(9F) to determine if their device is in a DMA-capable slot. For an example of this function, see “The attach() Entry Point” on page 76.

SBus Hardware Configuration Files

Hardware configuration files are normally unnecessary for SBus devices. However, on some occasions, drivers for SBus devices need to use hardware configuration files to augment the information provided by the SBus card. See driver.conf(4) and sbus(4) for further details.
Device Issues
This section describes issues with special devices.

Timing-Critical Sections
While most driver operations can be performed without mechanisms for synchronization and protection beyond those provided by the locking primitives, some devices require that a sequence of events occur in order without interruption. In conjunction with the locking primitives, the function `ddi_enter_critical(9F)` asks the system to guarantee, to the best of its ability, that the current thread will neither be preempted nor interrupted. This stays in effect until a closing call to `ddi_exit_critical(9F)` is made. See the `ddi_enter_critical(9F)` man pages for details.

Delays
Many chips specify that they can be accessed only at specified intervals. For example, the Zilog Z8530 SCC has a “write recovery time” of 1.6 microseconds. This means that a delay must be enforced with `drv_usecwait(9F)` when writing characters with an 8530. In some instances, the specifications do not make explicit what delays are needed, so they must be determined empirically.

Be careful not to compound delays for parts of devices that might exist in large numbers, for example thousands of SCSI disk drives.

Internal Sequencing Logic
Devices with internal sequencing logic map multiple internal registers to the same external address. There are various kinds of internal sequencing logic:

- The Intel 8251A and the Signetics 2651 alternate the same external register between two internal mode registers. Writing to the first internal register is accomplished by writing to the external register. This write, however, has the side effect of setting up the sequencing logic in the chip so that the next read/write operation refers to the second internal register.

- The NEC PD7201 PCC has multiple internal data registers. To write a byte into a particular register, two steps must be performed. The first step is to write into register zero the number of the register into which the following byte of data will go. The data is then written to the specified data register. The sequencing logic
automatically sets up the chip so that the next byte sent will go into data register zero.

- The AMD 9513 timer has a data pointer register that points at the data register into which a data byte will go. When sending a byte to the data register, the pointer is incremented. The current value of the pointer register cannot be read.

**Interrupt Issues**

The following are some common interrupt-related issues:

- A controller interrupt does not necessarily indicate that both the controller and one of its slave devices are ready. For some controllers, an interrupt can indicate that either the controller is ready or one of its devices is ready, but not both.
- Not all devices power up with interrupts disabled and can begin interrupting at any time.
- Some devices do not provide a way to determine that the board has generated an interrupt.
- Not all interrupting boards shut off interrupts when told to do so or after a bus reset.

**PROM on SPARC Machines**

Some platforms have a PROM monitor that provides support for debugging a device without an operating system. This section describes how to use the PROM on SPARC machines to map device registers so that they can be accessed. Usually, the device can be exercised enough with PROM commands to determine if the device is working correctly.

See the `boot(1M)` man page for a description of the IA boot subsystem.

The PROM has several purposes, including:

- Bringing the machine up from power on, or from a hard reset PROM reset command
- Providing an interactive tool for examining and setting memory, device registers, and memory mappings
- Booting the Solaris system or the kernel debugger `kadb(1M)`

Simply powering up the computer and attempting to use its PROM to examine device registers can fail. While the device might be correctly installed, those mappings are specific to the Solaris operating environment and do not become active until the Solaris kernel is booted. Upon power up, the PROM maps only
essential system devices, such as the keyboard.

- Taking a system crash dump using the `sync` command

Open Boot PROM 3

For complete documentation on the Open Boot PROM, see the *Open Boot PROM Toolkit User’s Guide* and the `monitor(1M)` man page. The examples in this section refer to a Sun-4u architecture; other architectures might require different commands to perform actions.

**Note** – The Open Boot PROM is currently used on Sun machines with an SBus or UPA/PCI. The Open Boot PROM uses an “ok” prompt. On older machines, you might have to type ‘n’ to get the “ok” prompt.

If the PROM is in *secure mode* (the `security-mode` parameter is not set to `none`), the PROM password might be required (set in the `security-password` parameter).

The `printenv` command displays all parameters and their values.

Help is available with the `help` command.

EMACS-style command-line history is available. Use Control-N (next) and Control-P (previous) to traverse the history list.

Forth Commands

The Open Boot PROM uses the Forth programming language. This is a stack-based language; arguments must be pushed on the stack before running the correct command (called a *word*), and the result is left on the stack.

To place a number on the stack, type its value.

```
ok 57
ok 68
```

To add the two top values on the stack, use the `+` operator.

```
ok +
```

The result remains on the stack. The stack is shown with the `.s word`.

```
ok .s
bf
```

The default base is hexadecimal. The `hex` and `decimal` words can be used to switch bases.
Walking the PROMs Device Tree

The commands `pwd`, `cd`, and `ls` walk the PROM device tree to get to the device. The `cd` command must be used to establish a position in the tree before `pwd` will work.

This example is from an Ultra 1 workstation with a `cgsix` frame buffer on an SBus.

```forth
ok cd /
```

To see the devices attached to the current node in the tree, use `ls`.

```forth
ok ls
f006a064 SUNW,UltraSPARC@0,0
f00599b0 sbus@1f,0
f00592dc counter-timer@1f,3c00
f004eeec8 virtual-memory
f004e8e8 memory@0,0
f002ca28 aliases
f002c9b8 options
f002c880 openprom
f002c814 chosen
f002c7a4 packages
```

The full node name can be used:

```forth
ok cd sbus@1f,0
ok ls
```

```forth
f006a4e4 cgsix@2,0
f0068194 SUNW,bpp@e,c800000
f0065370 ledmaze@e,8400010
f006120c espdma@e,8400000
f005a448 SUNW,pll@f,1304000
f005a394 sc@f,1300000
f005a24c zs@f,1000000
f005a174 zs@f,1100000
f005a0c0 eeprom@f,1200000
f0059f8c SUNW,fdtwos@f,1400000
f0059e04 flashprom@f,0
f0059e34 auxios@f,1900000
f0059d28 SUNW,CS4231@d,c000000
```

Rather than using the full node name in the previous example, you could have used an abbreviation. The abbreviated command-line entry looks like this:

```forth
ok cd sbus
```

The name is actually `device@slot,offset` (for SBus devices). The `cgsix` device is in slot 2 and starts at offset 0. If an SBus device is displayed in this tree, the device has been recognized by the PROM.
The `.properties` command displays the PROM properties of a device. These can be examined to determine which properties the device exports. (This is useful later to ensure that the driver is looking for the correct hardware properties.) These are the same properties that can be retrieved with `ddi_getprop(9F).

```
ok cd cgsix
ok .properties
character-set ISO8859-1
intr 00000005 00000000
interrupts 00000005
reg 00000002 00000000 01000000
dblbuf 00 00 00 00
vmsize 00 00 00 01
...
```

The `reg` property defines an array of register description structures containing the following fields:

```
uint_t bustype; /* cookie for related bus type*/
uint_t addr; /* address of reg relative to bus */
uint_t size; /* size of this register set */
```

For the `cgsix` example, the address is 0.

### Mapping the Device

To test the device, it must be mapped into memory. The PROM can then be used to verify proper operation of the device by using data-transfer commands to transfer bytes, words, and long words. If the device can be operated from the PROM, even in a limited way, the driver should also be able to operate the device.

To set up the device for initial testing, perform the following steps:

1. Determine the SBus slot number the device is in.
   
   In this example, the `cgsix` device is located in slot 2.

2. Determine the offset within the physical address space used by the device.
   
   The offset used is specific to the device. In the `cgsix` example, the video memory happens to start at an offset of 0x800000.

3. Use the `select-dev word` to select the Sbus device and the `map-in word` to map the device in.
   
   The `select-dev word` takes a string of the device path as its argument. The `map-in word` takes an `offset`, a `slot number`, and a `size` as arguments to map. Like the offset, the size of the byte transfer is specific to the device. In the `cgsix` example, the size is set to 0x100000 bytes.

   In the following code example, the sbus path is displayed as an argument to the `select-dev word`, and the offset, slot number, and size values for the frame buffer are displayed as arguments to the `map-in word`. Notice that there should be a space between the opening quote and `/` in the `select-dev` argument. The
virtual address to use remains on top of the stack. The stack is shown using the .s word. It can be assigned a name with the constant operation.

```
ok */sbus@1f,0* select-dev
ok 800000 2 100000 map-in
ok .s
ffe98000
ok constant fb
```

## Reading and Writing

The PROM provides a variety of 8-bit, 16-bit, and 32-bit operations. In general, a c (character) prefix indicates an 8-bit (one byte) operation; a w (word) prefix indicates a 16-bit (two byte) operation; and an L (longword) prefix indicates a 32-bit (four byte) operation.

A suffix of ! indicates a write operation. The write operation takes the first two items off the stack; the first item is the address, and the second item is the value.

```
ok 55 ffe98000 c!
```

A suffix of @ indicates a read operation. The read operation takes one argument (the address) off the stack.

```
ok ffe98000 c@
ok .s
55
```

A suffix of ? is used to display the value, without affecting the stack.

```
ok ffe98000 c?
55
```

Be careful when trying to query the device. If the mappings are not set up correctly, trying to read or write could cause errors. Special words are provided to handle these cases. cprobe, wprobe, and lprobe, for example, read from the given address but return zero if the location does not respond, or nonzero if it does.

```
ok fffe4000 c@
Data Access Error
```

```
ok fffe4000 cprobe
ok .s0
```

```
ok ffe98000 cprobe
ok .s
0 ffffffffffffffff
```

A region of memory can be shown with the dump word. This takes an address and a length, and displays the contents of the memory region in bytes.
In the following example, the fill word is used to fill video memory with a pattern. fill takes the address, the number of bytes to fill, and the byte to use (there is also a wfill and an Lfill for words and longwords). This causes the cgsix to display simple patterns based on the byte passed.

```
ok " /sbus" select-dev
ok 800000 2 100000 map-in
ok constant fb
ok fb 10000 ff fill
ok fb 20000 0 fill
ok fb 18000 55 fill
ok fb 15000 3 fill
ok fb 10000 5 fill ok fb 5000 f9 fill
```
Summary of Solaris 9 DDI/DKI Services

Introduction

This appendix discusses the interfaces provided by the Solaris 9 DDI/DKI. These descriptions should not be considered complete or definitive, nor do they provide a thorough guide to usage. The descriptions are intended to describe what the functions do in general terms. See man pages section 9F: DDI and DKI Kernel Functions for more detailed information. The categories are:

- “Module Functions” on page 402
- “Device Information Tree Node (dev_info_t) Functions” on page 402
- “Device (dev_t) Functions” on page 403
- “Property Functions” on page 403
- “Device Software State Functions” on page 404
- “Memory Allocation and Deallocation Functions” on page 405
- “Kernel Thread Control and Synchronization Functions” on page 406
- “Interrupt Functions” on page 407
- “Programmed I/O Functions” on page 407
- “Direct Memory Access (DMA) Functions” on page 414
- “User Space Access Functions” on page 416
- “User Process Event Functions” on page 418
- “User Process Information Functions” on page 418
- “User Application Kernel and Device Access Functions” on page 418
- “Time-Related Functions” on page 420
- “Power Management Functions” on page 420
- “Kernel Statistics Functions” on page 421
- “Kernel Logging and Printing Functions” on page 422
- “Buffered I/O Functions” on page 422
- “Virtual Memory Functions” on page 423
- “Device ID Functions” on page 424
- “SCSI Functions” on page 424
- “Resource Map Management Functions” on page 426
This appendix does not discuss STREAMS interfaces; to learn more about network drivers, see the *STREAMS Programming Guide*.

Making a Device Driver 64-Bit Ready

This appendix provides information for device driver writers who are converting their device drivers to support the 64-bit kernel. It presents the differences between 32-bit and 64-bit device drivers and describes the steps to convert 32-bit device drivers to 64-bit. This information is specific to regular character and block device drivers only.

This appendix provides information on the following subjects:

- “Introduction to 64–Bit Driver Design” on page 429
- “General Conversion Steps” on page 430
- “Well-known ioctl Interfaces” on page 437

Introduction to 64–Bit Driver Design

For drivers that only need support for the 32-bit kernel, existing 32-bit device drivers will continue to work without recompilation. However, most device drivers require some changes to run correctly in the 64-bit kernel, and all device drivers require recompilation to create a 64-bit driver module. The information in this appendix will help you to enable drivers for 32-bit and 64-bit environments to be generated from common source code, thus increasing code portability and reducing the maintenance effort.

Before starting to clean up a device driver for the 64-bit environment, you should understand how the 32-bit environment differs from the 64-bit environment. In particular, you must be familiar with the C language data type models ILP32 and LP64, and to be aware of driver-specific issues. Driver-specific issues are the subject of this appendix, while more general issues are covered extensively in Solaris 64-bit Developer’s Guide.

In addition to general code cleanup to support the data model changes for LP64, driver writers have to provide support for both 32-bit and 64-bit applications.
The `ioctl(9E), devmap(9E), and mmap(9E)` entry points enable data structures to be shared directly between applications and device drivers. If those data structures change size between the 32-bit and 64-bit environments, then the entry points must be modified so that the driver can determine whether the data model of the application is the same as that of the kernel. When the data models differ, data structures can be adjusted. See “I/O Control Support for 64-Bit Capable Device Drivers” on page 171, “32-bit and 64-bit Data Structure Macros” on page 174, and “Associating Kernel Memory With User Mappings” on page 203.

Practically speaking, in many drivers, only a few `ioctl`S need this kind of handling; the others will work without change as long as they pass around data structures that do not change in size.

---

**General Conversion Steps**

The sections below provide information on converting drivers to run in a 64-bit environment. Driver writers might need to do one or more of the following:

1. Use fixed-width types for hardware registers.
2. Use fixed-width common access functions.
3. Check and extend use of derived types.
4. Check changed fields within DDI data structures.
5. Check changed arguments of DDI functions.
6. Modify the driver entry points that handle user data, where needed.

These steps are explained in detail below.

After each step is complete, fix all compiler warnings, and use `lint` to look for other problems. The SC5.0 (or newer) version of `lint` should be used with `-Xarch=v9` and `-errchk=longptr64` specified to find 64-bit problems. See the notes on using and interpreting the output of `lint` in the *Solaris 64-bit Developer’s Guide*.

---

**Caution** – Do not ignore compilation warnings during conversion for LP64. Even those that were safe to ignore previously in the ILP32 environment might now indicate a more serious problem.

---

After all the steps are complete, compile and test the driver as both a 32-bit and 64-bit modules.
Use Fixed-width Types for Hardware Registers

Many device drivers that manipulate hardware devices use C data structures to describe the layout of the hardware. In the LP64 data model, data structures that use long or unsigned long to define hardware registers are almost certainly incorrect, because long is now a 64-bit quantity. Start by including `<sys/inttypes.h>`, and update this class of data structure to use int32_t or uint32_t instead of long for 32-bit device data. This preserves the binary layout of 32-bit data structures. For example, change:

```c
struct device_regs {
    ulong_t addr;
    uint_t count;
}; /* Only works for ILP32 compilation */
```
to:

```c
struct device_regs {
    uint32_t addr;
    uint32_t count;
}; /* Works for any data model */
```

Use Fixed-width Common Access Functions

The Solaris DDI permits device registers to be accessed by access functions for portability to multiple platforms. Previously, the DDI common access functions specified the size of data in terms of bytes, words, and so on. For example, `ddi_getl(9F)` is used to access 32-bit quantities. This function is not available in the 64-bit DDI environment, and has been replaced by versions that are specified using the number of bits that they manipulate.

These routines were added to the 32-bit kernel in the Solaris 2.6 operating environment, to permit their early adoption by driver writers. For example, to be portable to both 32-bit and 64-bit kernels, the driver must use `ddi_get32(9F)` to access 32-bit data rather than `ddi_getl(9F).

The entire set of common access routines is replaced by their fixed-width equivalents. See the `ddi_get8(9F), ddi_put8(9F), ddi_rep_get8(9F), and ddi_rep_put8(9F)` man pages for details.

Check and Extend Use of Derived Types

System-derived types, such as size_t, should be used where possible so that the resulting variables make sense when passed between functions. The new derived types uintptr_t or intptr_t should be used as the integral type for pointers.
Fixed-width integer types are useful for representing explicit sizes of binary data structures or hardware registers, while fundamental C language data types, such as int, can still be used for loop counters or file descriptors.

Some system-derived types represent 32-bit quantities on a 32-bit system but represent 64-bit quantities on a 64-bit system. Derived types that change size in this way include: clock_t, daddr_t, dev_t, ino_t, intptr_t, off_t, size_t, ssize_t, time_t, uintptr_t, and timeout_id_t.

Drivers that use these derived types should pay particular attention to their use, particularly if they are assigning these values to variables of another derived type, such as a fixed-width type.

Check Changed Fields in DDI Data Structures

The data types of some of the fields within DDI data structures, such as buf(9S), have been changed. Drivers that use these data structures should make sure that these fields are being used appropriately. The data structures and the fields that were changed in a significant way are listed below.

**buf Structure Changes**

```c
size_t b_bcount; /* was type unsigned int */
size_t b_resid; /* was type unsigned int */
size_t b_bufsize; /* was type long */
```

The fields changed here pertain to transfer size, which can now exceed more than 4 Gbytes.

**ddi_dma_attr**

The ddi_dma_attr(9S) structure defines attributes of the DMA engine and the device. Because these attributes specify register sizes, fixed-width data types have been used instead of fundamental types.

**ddi_dma_cookie Structure Changes**

```c
uint32_t dmac_address; /* was type unsigned long */
size_t dmac_size; /* was type u_int */
```

The ddi_dma_cookie(9S) structure contains a 32-bit DMA address, so a fixed-width data type has been used to define it. The size has been redefined as size_t.

**csi_arq_status Structure Changes**

```c
uint_t sts_rqpkt_state; /* was type u_long */
uint_t sts_rqpkt_statistics; /* was type u_long */
```
These fields in the structure do not need to grow and have been redefined as 32-bit quantities.

**scsi_pkt Structure Changes**

```
uint_t pkt_flags; /* was type u_long */
int pkt_time; /* was type long */
ssize_t pkt_resid; /* was type long */
uint_t pkt_state; /* was type u_long */
uint_t pkt_statistics; /* was type u_long */
```

Because the `pkt_flags`, `pkt_state`, and `pkt_statistics` fields in the `scsi_pkt(9S)` structure do not need to grow, they have been redefined as 32-bit integers. The data transfer size `pkt_resid` field does grow and has been redefined as `ssize_t`.

**Check Changed Arguments of DDI Functions**

Some DDI function argument data types have been changed. These routines are listed below.

**getrbuf() Argument Changes**

```
struct buf *getrbuf(int sleepflag);
```

In previous releases, `sleepflag` was defined as a type long.

**drv_getparm() Argument Changes**

```
int drv_getparm(unsigned int parm, void *value_p);
```

In previous releases, `value_p` was defined as type unsigned long.

In the 64-bit kernel, `drv_getparm(9F)` can be used to fetch both 32-bit and 64-bit quantities, yet the interface does not define the data types of these quantities, which encourages simple programming errors.

The following new routines offer a safer alternative:

```
clock_t ddi_get_lbolt(void);
time_t ddi_get_time(void);
cred_t *ddi_get_cred(void);
pid_t ddi_get_pid(void);
```

Driver writers are strongly urged to use these routines instead of `drv_getparm(9F)`.
delay() and timeout() Argument Changes
void delay(clock_t ticks);
timeout_id_t timeout(void (*func)(void *), void *arg, clock_t ticks);

The ticks argument to the delay(9F) and timeout(9F) routines has been changed from long to clock_t.

rmallocmap() and rmallocmap_wait() Argument Changes
struct map *rmallocmap(size_t mapsize);
struct map *rmallocmap_wait(size_t mapsize);

The mapsize argument to rmallocmap(9F) and rmallocmap_wait(9F) routines has been changed from ulong_t to size_t.

scsi_alloc_consistent_buf() Argument Changes
struct buf *scsi_alloc_consistent_buf(struct scsi_address *ap,
struct buf *bp, size_t datalen, uint_t bflags,
int (*callback)(caddr_t), caddr_t arg);

In previous releases, datalen was defined as an int and bflags was defined as a ulong.

uiomove() Argument Changes
int uiomove(caddr_t address, size_t nbytes,
enum uio_rw rwflag, uio_t *uio_p);

The nbytes argument was defined as a type long, but because it represents a size in bytes, size_t is more appropriate.

cv_timedwait() and cv_timedwait_sig() Argument Changes
int cv_timedwait(kcondvar_t *cvp, kmutex_t *mp, clock_t timeout);
int cv_timedwait_sig(kcondvar_t *cvp, kmutex_t *mp, clock_t timeout);

In previous releases, the timeout argument to the cv_timedwait(9F) and cv_timedwait_sig(9F) routines was defined to be of type long. Because they represent time in ticks, clock_t is more appropriate.

ddi_device_copy() Argument Changes
int ddi_device_copy(ddi_acc_handle_t src_handle,
caddr_t src_addr, ssize_t src_advcnt,
ddi_acc_handle_t dest_handle, caddr_t dest_addr,
ssize_t dest_advcnt, size_t bytecount, uint_t dev_datasz);

The src_advcnt, dest_advcnt, dev_datasz arguments have changed type. These were previously defined as long, long, and ulong_t respectively.

**ddi_device_zero() Argument Changes**

```c
int ddi_device_zero(ddi_acc_handle_t handle,
caddr_t dev_addr, size_t bytecount, ssize_t dev_advcnt,
uint_t dev_datasz);
```

In previous releases, dev_advcnt was defined as a type long and dev_datasz as a ulong_t.

**ddi_dma_mem_alloc() Argument Changes**

```c
int ddi_dma_mem_alloc(ddi_dma_handle_t handle,
size_t length, ddi_device_acc_attr_t *accattrp,
uint_t flags, int (*waitfp)(caddr_t), caddr_t arg,
caddr_t *kaddrp, size_t *real_length,
_ddi_acc_handle_t *handlep);
```

In previous releases, length, flags, and real_length were defined with types uint_t, ulong_t, and uint_t*.

**Modify Routines That Handle Data Sharing**

If a device driver shares data structures that contain longs or pointers with a 32-bit application using ioctl(9E), devmap(9E), or mmap(9E), and the driver is recompiled for a 64-bit kernel, the binary layout of data structures will be incompatible. If a field is currently defined in terms of type long, and there is no actual need for 64-bit data items, change the data structure to use data types that remain as 32-bit quantities (int and unsigned int). Otherwise, the driver needs to be aware of the different structure shapes for ILP32 and LP64 and determine whether there is a model mismatch between the application and the kernel.

To handle potential data model differences, the ioctl(), devmap(), and mmap() driver entry points, which interact directly with user applications, need to be written to determine whether the argument came from an application using the same data model as the kernel.

**Data Sharing in ioctl()**

To determine whether there is a model mismatch between the application and the driver, the driver uses the FMODELS mask to determine the model type from the ioctl() mode argument. The following values are OR-ed into mode to identify the application data model:
FLP64 – Application uses the LP64 data model
FILP32 – Application uses the ILP32 data model.

The code examples in “I/O Control Support for 64-Bit Capable Device Drivers” on page 171 show how this can be handled using ddi_model_convert_from(9F).

Data Sharing in devmap()

To enable a 64-bit driver and a 32-bit application to share memory, the binary layout generated by the 64-bit driver must be the same as consumed by the 32-bit application. The mapped memory being exported to the application might need to contain data-model-dependent data structures.

Few memory mapped devices face this problem because the device registers do not change size when the kernel data model changes. However, some pseudo-devices that export mappings to the user address space might want to export different data structures to ILP32 or LP64 applications. To determine whether there is a data model mismatch, devmap(9E) uses the model parameter to describe the data model expected by the application. The model parameter is set to one of the following:

- DDI_MODEL_ILP32 – The application uses the ILP32 data model
- DDI_MODEL_LP64 – The application uses the LP64 data model

The model parameter can be passed untranslated to the ddi_model_convert_from(9F) routine or to STRUCT_INIT(). See “32-bit and 64-bit Data Structure Macros” on page 174.

Data Sharing in mmap()

Because mmap(9E) does not have a parameter that can be used to pass data model information, the driver’s mmap(9E) entry point can be written to use the new DDI function ddi_model_convert_from(9F). This function returns one of the following values to indicate the application’s data type model:

- DDI_MODEL_ILP32 – Application expects the ILP32 data model
- DDI_MODEL_LP64 – Application expects the LP64 data model
- DDI_FAILURE – Function was not called from mmap(9E)

As with ioctl() and devmap(), the model bits can be passed to ddi_model_convert_from(9F) to determine whether data conversion is necessary, or the model can be handed to STRUCT_INIT().

Alternatively, migrate the device driver to support the devmap(9E) entry point.
Well-known ioctl Interfaces

Many ioctl(9E) operations are common to a class of device drivers. For example, most disk drivers implement many of the dkio(7I) family of ioctl()s. Many of these interfaces copy in or copy out data structures from the kernel, and some of these data structures have changed size in the LP64 data model. The following section lists the ioctls that now require explicit conversion in 64-bit driver ioctl routines for the dkio, fdio(7I), fbio(7I), cdio(7I), and mtio(7I) families of ioctl()s.

Device Sizes

The \texttt{nblocks} property is exported by each slice of a block device driver. It contains the number of 512 byte blocks that each slice of the device can support. The \texttt{nblocks} property is defined as a signed 32-bit quantity, which limits the maximum size of a slice to 1 Tbyte.

Disk devices that provide more than 1 Tbyte of storage per disk must define the \texttt{Nblocks} property, which should still contain the number of 512 byte blocks that the device can support. However, \texttt{Nblocks} is a signed 64-bit quantity, which removes any practical limit on disk space.

The \texttt{nblocks} property is now deprecated; all disk devices should provide the \texttt{Nblocks} property.
