Preface 19

1 Managing Printing Services Topics 23

2 Managing Printing Services (Overview) 25
   What's New in Printing? 25
      Changes to LP Scheduler (lpsched) 25
      USB Printer Support 26
      Managing Printer Information With LDAP 26
   Where to Find Printer Tasks 27
   Printing in the Solaris Operating Environment 27
      Solaris Print Manager 28
      Printing Support in the Name Service Switch 28
      Choosing a Method to Manage Printers 29
   The LP Print Service 30
      Managing Network Printers 30
      Administering Printers 31
      Setting Definitions for Printers 31
      Administering Character Sets, Filters, Forms, and Fonts 31
      Customizing the LP Print Service 32
   The Solaris Print Client-Server Process 32
      The Print Client Process 32
      Using Print Clients 33
      Printer Configuration Resources 34
      Using Print Servers 35
3 Planning Printers on Your Network (Overview) 37
Where to Find Printer Tasks 37
Distributing Printers on the Network 38
Assigning Print Servers and Print Clients 38
Print Server Requirements and Recommendations 39
  Spooling Space 39
  Disk Space 40
  Memory 40
  Swap Space 40
  Hard Disk 41
Planning for Printer Setup 41
  Setting Definitions for Printers 41
  Selecting a Printer Type 45
  Selecting a File Content Type 45

4 Setting Up Printers (Tasks) 49
Setting Up Printing (Task Map) 49
  Setting Up Printing With Solaris Print Manager 50
  Setting Up a Printer With Solaris Print Manager 51
  Solaris Print Manager and Special Characters 52
Starting Solaris Print Manager 52
  ▼ How to Start Solaris Print Manager 52
Setting Up a Print Server 54
  ▼ How to Add a New Attached Printer With Solaris Print Manager 55
Setting Up a Print Client 57
  ▼ How to Add Printer Access With Solaris Print Manager 57
Setting Up a .printers File 58
  ▼ How to Set Up a .printers File 58
Adding a Network Printer 59
  Printer Vendor Supplied Software for Network Printers 60
  Sun Support for Network Printers 60
  Invoking the Network Printer Support 61
  Selecting the Protocol 61
  Selecting the Printer Node Name 61
  Selecting the Destination (or Network Printer Access) Name 62
  Setting the Timeout Value 63
  Managing Network Printer Access 63
5 Administering Printers (Tasks) 71
Managing Printers and the Print Scheduler 72
Deleting Printers and Printer Access 72
  ▼ How to Delete a Printer and Remote Printer Access 72
Checking Printer Status 75
  ▼ How to Check the Status of Printers 75
Restarting the Print Scheduler 76
  ▼ How to Stop the Print Scheduler 76
  ▼ How to Restart the Print Scheduler 77
Setting or Resetting Miscellaneous Printer Definitions 77
  ▼ How to Add a Printer Description 77
Setting Up a Default Printer Destination 78
  ▼ How to Set a System’s Default Printer 78
Printing Banner Pages 79
  ▼ How to Make Banner Pages Optional 80
  ▼ How to Turn Off Banner Pages 81
Setting Up Printer Classes 81
  ▼ How to Define a Class of Printers 82
Setting Up Printer Fault Alerts 83
  ▼ How to Set Fault Alerts for a Printer 84
Setting Up Printer Fault Recovery 85
  ▼ How to Set Printer Fault Recovery 86
Limiting User Access to a Printer 87
  ▼ How to Limit User Access to a Printer 88
Managing Print Requests 89
  ▼ How to Check the Status of Print Requests 90
Enabling or Disabling a Printer From Printing 91
  ▼ How to Enable or Disable a Printer 92
Accepting or Rejecting Print Requests 93
▼ How to Accept or Reject Print Requests for a Printer 94
Canceling a Print Request 95
▼ How to Cancel a Print Request 95
▼ How to Cancel a Print Request From a Specific User 96
Moving a Print Request 97
▼ How to Move Print Requests to Another Printer 97
Changing the Priority of Print Requests 99
▼ How to Change the Priority of a Print Request 99

6 Managing Character Sets, Filters, Forms, and Fonts (Tasks) 101
Managing Character Sets 101
Selectable Character Sets 102
Hardware-Mounted Character Sets 103
Tracking Print Wheels 104
Alerts for Mounting Print Wheels or Cartridges 104
▼ How to Define a Print Wheel or Font Cartridge 104
▼ How to Unmount and Mount a Print Wheel or Font Cartridge 105
▼ How to Set an Alert to Mount a Print Wheel or Font Cartridge 106
▼ How to Set Up an Alias for a Selectable Character Set 108
Managing Print Filters 109
Creating Print Filters 110
Adding, Changing, Removing, and Restoring Print Filters 110
▼ How to Add a Print Filter 111
▼ How to Delete a Print Filter 112
▼ How to View Information About a Print Filter 112
Managing Forms 114
Adding, Changing, or Deleting Forms 114
Mounting Forms 114
Tracking Forms 115
Defining Alerts for Mounting Forms 115
Checking Forms 115
Limiting Access to Forms 116
▼ How to Add a Form 116
▼ How to Delete a Form 117
▼ How to Unmount and Mount a Form 117
▼ How to Set an Alert to Mount a Form 119
Managing Fonts 123
  Managing Printer-Resident Fonts 124
  Downloading Host-Resident Fonts 124
  Installing and Maintaining Host-Resident Fonts 125
  ▼ How to Install Downloaded PostScript Fonts 125
  ▼ How to Install Host-Resident PostScript Fonts 125

7 Customizing the LP Print Service (Tasks) 127
  Adjusting Printer Port Characteristics 127
  ▼ How to Adjust the Printer Port Characteristics 128
  Adding a terminfo Entry for an Unsupported Printer 129
  ▼ How to Add a terminfo Entry for an Unsupported Printer 132
  Customizing the Printer Interface Program 133
    The Standard Printer Interface Program 133
    Customizing stty Modes 134
    Exit Codes 134
    Fault Messages 135
    Using a Customized Printer Interface Program 136
    ▼ How to Set Up a Custom Printer Interface Program 136
  Creating a New Print Filter 137
    Writing a Print Filter Program 138
    Creating a Print Filter Definition 140
    ▼ How to Create a New Print Filter 146
  Creating a New Printer Form 148
    ▼ How to Create a New Form Definition 150

8 LP Print Service (Reference) 151
  Where to Find Printer Tasks 151
  The LP Print Service 152
    The Structure of the LP Print Service 152
    LP Print Service Commands 160
    Functions of the LP Print Service 161
    How LP Administers Files and Schedules Local Print Requests 161
15 Displaying and Changing System Information (Tasks) 213

Displaying System Information 213
- How to Determine If a System Can Run the 64-bit Solaris Operating Environment 214
- How to Determine If a System Has 64-bit Solaris Capabilities Enabled 214
- How to Display Solaris Release Information 215
- How to Display General System Information 216
- How to Display General System Information 216
- How to Display a System’s Host ID Number 217
- How to Display a System’s Installed Memory 217
- How to Display the Date and Time 217

Changing System Information 218
- How to Set a System’s Date and Time Manually 218
- How to Set Up a Message-of-the-Day 218
- How to Change a System’s Host Name 219

16 Managing Disk Use (Tasks) 221

Displaying Information About Files and Disk Space 221
- How to Display Information About Files and Disk Space 222

Checking the Size of Files 224
- How to Display the Size of Files 224
- How to Find Large Files 225
- How to Find Files That Exceed a Specified Size Limit 225

Checking the Size of Directories 226
- How to Display the Size of Directories, Subdirectories, and Files 226
- How to Display the User Ownership of Local UFS File Systems 228

Finding and Removing Old or Inactive Files 229
- How to List the Newest Files 229
- How to Find and Remove Old or Inactive Files 230
- How to Clear Out Temporary Directories 231
- How to Find and Delete core files 232
- How to Delete Crash Dump Files 232
17 Managing Quotas (Tasks) 235
What Are Quotas? 235
Using Quotas 236
  Setting Soft Limits and Hard Limits for Quotas 236
  The Difference Between Disk Block and File Limits 236
Setting Up Quotas 237
  Guidelines for Setting Up Quotas 238
Setting Up Quotas (Task Map) 238
  ▼ How to Configure File Systems for Quotas 239
  ▼ How to Set Up Quotas for a User 240
  ▼ How to Set Up Quotas for Multiple Users 241
  ▼ How to Check Quota Consistency 241
  ▼ How to Turn On Quotas 242
Checking Quotas 243
  ▼ How to Check for Exceeded Quotas 243
  ▼ How to Check Quotas on a File System 244
Changing and Removing Quotas 245
  ▼ How to Change the Soft Time Limit Default 246
  ▼ How to Change Quotas for a User 247
  ▼ How to Disable Quotas for a User 248
  ▼ How to Turn Off Quotas 249

18 Scheduling System Tasks (Tasks) 251
Ways to Automatically Execute System Tasks 251
  For Scheduling Repetitive Jobs: crontab 252
  For Scheduling a Single Job: at 253
Scheduling a Repetitive System Task (cron) 253
  Inside a crontab File 253
  How the cron Daemon Handles Scheduling 254
  Syntax of crontab File Entries 255
Creating and Editing crontab Files 256
  ▼ How to Create or Edit a crontab File 256
  ▼ How to Verify a crontab File 257
Displaying crontab Files 257
  ▼ How to Display a crontab File 257
Removing crontab Files 258
  ▼ How to Remove a crontab File 259
Controlling Access to the `crontab` Command
- How to Deny `crontab` Access 260
- How to Limit `crontab` Access to Specified Users 261
- How to Verify Limited `crontab` Access 262

Scheduling a Single System Task (`at`) 262
- Description of the `at` Command 262
- How to Create an `at` Job 263
- How to Display the `at` Queue 264
- How to Verify an `at` Job 264
- How to Display `at` Jobs 265
- How to Remove `at` Jobs 265
- How to Deny Access to the `at` Command 266
- How to Verify that `at` Access Is Denied 267

19 Managing System Accounting (Tasks) 269
- What is System Accounting? 269
  - How System Accounting Works 270
  - System Accounting Components 270
- Setting Up System Accounting 274
  - How to Set Up System Accounting 275
- Billing Users 276
  - How to Bill Users 277
- Maintaining Accounting Information 277
  - Fixing Corrupted Files and `wtmpx` Errors 277
  - How to Fix a Corrupted `wtmpx` File 278
  - Fixing `taacct` Errors 278
  - How to Fix `taacct` Errors 278
  - Restarting the `runacct` Script 279
  - How to Restart the `runacct` Script 279
- Stopping and Disabling System Accounting 280
  - How to Temporarily Stop System Accounting 280
  - How to Permanently Disable System Accounting 280

20 System Accounting (Reference) 283
- The `runacct` Script 283
- Daily Accounting Reports 285
  - Daily Report 286
21 Managing System Performance Topics 297

22 Managing System Performance (Overview) 299
What’s New in Managing System Performance? 299
DNLC Improvements 299
The pargs and preap Commands 300
Performance Tool 301
New Fair Share (FSS) and Fixed (FX) Schedulers 301
Where to Find System Performance Tasks 302
System Performance and System Resources 302
Processes and System Performance 303
About Monitoring Performance 304
Monitoring Tools 305

23 Managing System Processes (Tasks) 307
Commands for Managing System Processes (Overview) 307
The ps Command 308
▼ How to List Processes 309
The /proc File System and Commands 310
Managing Processes With /proc Process Commands 311
▼ How to Display Information About Processes 312
▼ How to Control Processes 313
Killing a Process (pkill) 314
▼ How to Kill a Process 314
Managing Process Class Information 315
Changing the Scheduling Priority of Processes (priocntl) 315
▼ How to Display Basic Information About Process Classes (priocntl) 315
▼ How to Display the Global Priority of a Process (priocntl) 316
▼ How to Designate a Process Priority (priocntl) 317
24 Monitoring System Performance (Tasks)  323
What’s New in Monitoring System Performance?  324
Displaying Virtual Memory Statistics (vmstat)  324
  ▼ How to Display Virtual Memory Statistics (vmstat)  325
  ▼ How to Display System Event Information (vmstat -s)  326
  ▼ How to Display Swapping Statistics (vmstat -S)  327
  ▼ How to Display Cache Flushing Statistics (vmstat -c)  327
  ▼ How to Display Interrupts Per Device (vmstat -i)  328
Displaying Disk Utilization Information (iostat)  328
  ▼ How to Display Disk Utilization Information (iostat)  329
  ▼ How to Display Extended Disk Statistics (iostat -xtc)  330
Displaying Disk Space Statistics (df)  331
  ▼ How to Display Disk Space Information (df)  331
Monitoring System Activities (sar)  332
  ▼ How to Check File Access (sar -a)  332
  ▼ How to Check Buffer Activity (sar -b)  333
  ▼ How to Check System Call Statistics (sar -c)  334
  ▼ How to Check Disk Activity (sar -d)  335
  ▼ How to Check Page-Out and Memory (sar -g)  337
  ▼ How to Check Kernel Memory Allocation (sar -k)  338
  ▼ How to Check Interprocess Communication (sar -m)  339
  ▼ How to Check Page-In Activity (sar -p)  340
  ▼ How to Check Queue Activity (sar -q)  342
  ▼ How to Check Unused Memory (sar -r)  343
  ▼ How to Check CPU Utilization (sar -u)  343
  ▼ How to Check System Table Status (sar -v)  344
  ▼ How to Check Swapping Activity (sar -w)  345
  ▼ How to Check Terminal Activity (sar -y)  347
  ▼ How to Check Overall System Performance (sar -A)  348
Collecting System Activity Data Automatically (sar)  348
  Running the sadc Command When Booting  349
Running the sadc Command Periodically With the sa1 Script 349
Producing Reports With the sa2 Shell Script 349
Setting Up Automatic Data Collection (sar) 349
How to Set Up Automatic Data Collection 351

25 Troubleshooting Solaris Software Topics 353

26 Troubleshooting Software Problems (Overview) 355
  What’s New in Troubleshooting Software Problems? 355
  New System Log Rotation 355
  New Fall Back Shell for root Account 357
Where to Find Software Troubleshooting Tasks 357
Troubleshooting a System Crash 357
  What to Do if the System Crashes 358
  Gathering Troubleshooting Data 358
Troubleshooting a System Crash Checklist 359
Viewing System Messages 360
  ▼ How to View System Messages 361
Customizing System Message Logging 362
  ▼ How to Customize System Message Logging 363
Enabling Remote Console Messaging 364
  Using Auxiliary Console Messaging During Run Level Transitions 364
  Using the consadm Command During an Interactive Login Session 365
  ▼ How to Enable an Auxiliary (Remote) Console 366
  ▼ How to Display a List of Auxiliary Consoles 367
  ▼ How to Enable an Auxiliary (Remote) Console Across System Reboots 367
  ▼ How to Disable an Auxiliary (Remote) Console 367

27 Managing Core Files (Tasks) 369
Managing Core Files (Task Map) 369
Managing Core Files Overview 370
  Configurable Core File Paths 370
  Expanded Core File Names 371
Setting the Core File Name Pattern 371
Enabling setuid Programs to Produce Core Files 372
How to Display the Current Core Dump Configuration 372
How to Set a Core File Name Pattern 372
How to Enable a Per-Process Core File Path 373
How to Enable a Global Core File Path 373
Troubleshooting Core File Problems 374
Examining Core Files 374
  Example—Examining Core Files With proc Tools 374

28 Managing System Crash Information (Tasks) 375
Managing System Crash Information (Task Map) 375
System Crashes (Overview) 376
  System Crash Dump Files 376
  Saving Crash Dumps 377
  The dumpadm Command 377
  Dump Devices and Volume Managers 378
Managing System Crash Dump Information 379
  ▼ How to Display the Current Crash Dump Configuration 379
  ▼ How to Modify a Crash Dump Configuration 379
  ▼ How to Examine a Crash Dump 381
  ▼ How to Recover From a Full Crash Dump Directory (Optional) 382
  ▼ How to Disable or Enable Saving Crash Dumps 382

29 Troubleshooting Miscellaneous Software Problems (Tasks) 383
What to Do If Rebooting Fails 383
  SPARC: Troubleshooting 64–bit Solaris Boot Problems 384
What to Do if You Forgot Root Password 385
  SPARC: Example—What to Do if You Forgot Root Password 385
  x86: Example—What to Do if You Forgot Root Password 386
What to Do if a System Hangs 387
What to Do if a File System Fills Up 388
  File System Fills Up Because a Large File or Directory Was Created 388
  A TMPFS File System is Full Because the System Ran Out of Memory 389
What to Do if File ACLs Are Lost After Copy or Restore 389
Troubleshooting Backup Problems 389
  The root (/) File System Fills Up After You Back Up a File System 389
  Make Sure the Backup and Restore Commands Match 390
  Check to Make Sure You Have the Right Current Directory 390
30 Troubleshooting File Access Problems (Tasks) 393
   Solving Problems With Search Paths (Command not found) 393
      ▼ How to Diagnose and Correct Search Path Problems 394
   Solving File Access Problems 396
      Changing File and GroupOwnerships 396
   Recognizing Problems With Network Access 396

31 Troubleshooting Printing Problems (Tasks) 397
   Tips on Troubleshooting Printing Problems 397
      Troubleshooting No Output (Nothing Prints) 398
      Troubleshooting Incorrect Output 399
      Troubleshooting Hung LP Commands 401
      Troubleshooting Idle (Hung) Printers 401
      Troubleshooting Conflicting Status Messages 402
   Troubleshooting Printing Problems 403
      ▼ How to Troubleshoot No Printer Output 403
      ▼ How to Check the Printer Hardware 403
      ▼ How To Check the Printer Network Connections 404
      ▼ How to Check the Basic Functions of the LP Print Service 405
      ▼ How to Check Printing From a Solaris Print Client to a Solaris Print Server 408
      ▼ How to Troubleshoot Incorrect Output 409
      ▼ How to Unhang the LP Print Service 413
      ▼ How to Troubleshoot an Idle (Hung) Printer 413
      ▼ How to Check That the Printer is Ready to Print 413
      ▼ How to Check for Print Filtering 414
      ▼ How to Resume Printing After a Printer Fault 414
      ▼ How to Send Print Requests to a Remote Printer When They Back Up in the Local Queue 414
      ▼ How to Free Print Requests From a Print Client That Back Up in the Print Server Queue 415
      ▼ How to Resolve Conflicting Printer Status Messages 415

32 Resolving UFS File System Inconsistencies (Tasks) 417
   fsck Error Messages 417
      General fsck Error Messages 419
      Initialization Phase fsck Messages 420
      Phase 1: Check Blocks and Sizes Messages 423
Phase 1B: Rescan for More DUPS Messages 426
Phase 2: Check Path Names Messages 426
Phase 3: Check Connectivity Messages 432
Phase 4: Check Reference Counts Messages 434
Phase 5: Check Cylinder Groups Messages 437
Cleanup Phase Messages 438

33 Troubleshooting Software Package Problems (Tasks) 439
Troubleshooting Software Package Symbolic Link Problems 439
Specific Software Package Installation Errors 440
General Software Package Installation Problems 441

Index 443
Preface

System Administration Guide: Advanced Administration is part of a set that covers a significant part of the Solaris™ system administration information. It includes information for both SPARC™ based and IA based systems.

This book assumes that you have already installed the SunOS™ 5.9 operating system, and you have set up any networking software that you plan to use. The SunOS 5.9 operating system is part of the Solaris 9 product family, which also includes many features, including the Solaris Common Desktop Environment (CDE). The SunOS 5.9 operating system is compliant with AT&T’s System V, Release 4 operating system.

For the Solaris 9 release, new features interesting to system administrators are covered in sections called What’s New in ... ? in the appropriate chapters.

Note – The Solaris operating environment runs on two types of hardware, or platforms—SPARC and IA. The Solaris operating environment runs on both 64–bit and 32–bit address spaces. The information in this document pertains to both platforms and address spaces unless called out in a special chapter, section, note, bullet, figure, table, example, or code example.

Who Should Use This Book

This book is intended for anyone responsible for administering one or more systems running the Solaris 9 release. To use this book, you should have 1-2 years of UNIX® system administration experience. Attending UNIX system administration training courses might be helpful.
How the System Administration Volumes Are Organized

Here is a list of the topics that are covered by the volumes of the System Administration Guides.

<table>
<thead>
<tr>
<th>Book Title</th>
<th>Topics</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Administration Guide: Basic Administration</td>
<td>User accounts and groups, server and client support, shutting down and booting a system, removable media, managing software (packages and patches), disks and devices, file systems, and backing up and restoring data</td>
</tr>
<tr>
<td>System Administration Guide: Advanced Administration</td>
<td>Printing services, terminals and modems, system resources (disk quotas, accounting, and crontabs), system processes, and troubleshooting Solaris software problems</td>
</tr>
<tr>
<td>System Administration Guide: Naming and Directory Services (DNS, NIS, and LDAP)</td>
<td>DNS, NIS, and LDAP naming and directory services</td>
</tr>
<tr>
<td>System Administration Guide: Naming and Directory Services (FNS and NIS+)</td>
<td>FNS and NIS+ naming and directory services</td>
</tr>
<tr>
<td>System Administration Guide: Resource Management and Network Services</td>
<td>Resource management, remote file systems, mail, SLP, and PPP</td>
</tr>
<tr>
<td>System Administration Guide: Security Services</td>
<td>Auditing, PAM, RBAC, and SEAM</td>
</tr>
</tbody>
</table>

To view license terms, attribution, and copyright statements for open source software included in this release of the Solaris operating environment, the default path is /usr/share/src/freeware-name or /usr/sfw/share/src/freeware-name. If the Solaris operating environment has been installed anywhere other than the default location, modify the given path to access the file at the installed location.

Accessing Sun Documentation Online

The docs.sun.comSM Web site enables you to access Sun technical documentation online. You can browse the docs.sun.com archive or search for a specific book title or subject. The URL is http://docs.sun.com
What Typographic Conventions Mean

The following table describes the typographic conventions used in this book.

**TABLE P–1 Typographic Conventions**

<table>
<thead>
<tr>
<th>Typeface or Symbol</th>
<th>Meaning</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>AaBbCc123</td>
<td>The names of commands, files, and directories; on-screen computer output</td>
<td>Edit your .login file. Use <code>ls -a</code> to list all files. machine_name% you have mail.</td>
</tr>
<tr>
<td>AaBbCc123</td>
<td>What you type, contrasted with on-screen computer output</td>
<td>machine_name% su Password:</td>
</tr>
<tr>
<td>AaBbCc123</td>
<td>Command-line placeholder: replace with a real name or value</td>
<td>To delete a file, type <code>rm filename</code>.</td>
</tr>
<tr>
<td>AaBbCc123</td>
<td>Book titles, new words or terms, or words to be emphasized.</td>
<td>Read Chapter 6 in <em>User’s Guide</em>. These are called <em>class</em> options. Do <em>not</em> save changes yet.</td>
</tr>
</tbody>
</table>

Shell Prompts in Command Examples

The following table shows the default system prompt and superuser prompt for the C shell, Bourne shell, and Korn shell.

**TABLE P–2 Shell Prompts**

<table>
<thead>
<tr>
<th>Shell</th>
<th>Prompt</th>
</tr>
</thead>
<tbody>
<tr>
<td>C shell prompt</td>
<td>machine_name%</td>
</tr>
<tr>
<td>C shell superuser prompt</td>
<td>machine_name#</td>
</tr>
<tr>
<td>Bourne shell and Korn shell prompt</td>
<td>$</td>
</tr>
<tr>
<td>Bourne shell and Korn shell superuser prompt</td>
<td>#</td>
</tr>
</tbody>
</table>
General Conventions

Be aware of the following conventions used in this book.

- When following steps or using examples, be sure to type double-quotes ("), left single-quotes (‘), and right single-quotes (’) exactly as shown.
- The key referred to as Return is labeled Enter on some keyboards.
- It is assumed that the root path includes the /sbin, /usr/sbin, /usr/bin, and /etc directories, so the steps in this book show the commands in these directories without absolute path names. Steps that use commands in other, less common, directories show the absolute path in the example.
- The examples in this book are for a basic SunOS 5.9 software installation without the Binary Compatibility Package installed and without /usr/ucb in the path.

Caution – If /usr/ucb is included in a search path, it should always be at the end of the search path. Commands like ps or df are duplicated in /usr/ucb with different formats and options from the SunOS 5.9 commands.
## Managing Printing Services Topics

This topic map lists the chapters that provide information for managing printing services.

<table>
<thead>
<tr>
<th>Chapter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Chapter 2</td>
<td>Provides overview information for managing printing services on a network, which includes information on print servers, print clients, and the LP print service.</td>
</tr>
<tr>
<td>Chapter 3</td>
<td>Provides overview information for planning printing services on a network, which includes information on allocating system resources and defining printers on a network.</td>
</tr>
<tr>
<td>Chapter 4</td>
<td>Provides step-by-step instructions for setting up a printer on a system and making it available to other systems on the network.</td>
</tr>
<tr>
<td>Chapter 5</td>
<td>Provides step-by-step instructions for administering printers, such as deleting printers, setting print policies, and managing print requests.</td>
</tr>
<tr>
<td>Chapter 6</td>
<td>Provides step-by-step instructions for setting up and maintaining character sets, print filters, forms, and fonts.</td>
</tr>
<tr>
<td>Chapter 7</td>
<td>Provides step-by-step instructions for customizing the LP print service, such as adjusting printer port characteristics or adding a terminfo entry for an unsupported printer.</td>
</tr>
<tr>
<td>Chapter 8</td>
<td>Provides background information on the LP print service.</td>
</tr>
</tbody>
</table>
Managing Printing Services
(Overview)

This chapter provides information about managing printers in the Solaris environment.

This is a list of the overview information in this chapter.

- “What’s New in Printing?” on page 25
- “Printing in the Solaris Operating Environment” on page 27
- “The LP Print Service” on page 30
- “The Solaris Print Client-Server Process” on page 32

What’s New in Printing?

This section describes new printing features in the Solaris 9 release.

Changes to LP Scheduler (lpsched)

In previous Solaris releases, the lpsched process was automatically started at system boot time whether or not there were local printers configured on the system.

In this Solaris release, the lpadmin command automatically starts the lpsched process when local printers are added to the system and stops it when the last local printer is removed.

This change does not alter either the use of or the administration of the print subsystem from the perspective of print clients. The lpsched process is not running on systems that do not have local printers configured. This situation does not effect the ability to print nor the ability to configure new printers.
USB Printer Support

You can use Solaris Print Manager to set up a USB printer that is attached to a SPARC or IA system with USB ports.

The new logical device names for USB printers are as follows:

/dev/printers/[0...N]*

When you add a USB printer to a printer server, select one of these devices for a USB printer under Printer Port on the Add New Attached Printer screen. For more information on using Solaris Print Manager to set up printers, see Chapter 4.

Although the new Solaris USB printer driver supports all USB printer-class compliant printers, a list of recommended PostScript™ printers is in the usbprn(7D) man page.

For information and cautions about hot-plugging USB printers, see the Notes and Diagnostics sections of the usbprn(7D) man page.

Managing Printer Information With LDAP

You can manage printer information in the following name services in this Solaris release:

- LDAP
- NIS
- NIS+
- NIS+ with Federated Naming Service (xfn)
- files

Keep the following in mind when managing printer information in the LDAP name service:

- If the LDAP server is the Netscape™ Directory Server (NSDS), the default distinguished name is cn=Directory Manager. If the LDAP server is Sun™ Directory Server, the distinguished name might be something like cn=admin, dc=xyz, dc=com. Solaris Print Manager uses the ldapclient command to determine the default LDAP server name. If more than one server is specified, the first one server is automatically selected. For more information, see ldapclient(1M).
- Solaris Print Manager always displays printer entries from the current LDAP server. If this is not the domain’s LDAP master server, the list of printers displayed might not be the current list of printers. This is because the LDAP replica server might not have been updated by the master server, and so, is out of sync with the
master. Replica servers can have various update replication agreements. For example, a change is made on the master, the replica servers can be updated immediately or updated once a day.

- If the selected LDAP server is a LDAP replica server, any updates are referred to the master server and are done there. This situation again means that the printer list could be out of sync with the master. For example, a deleted printer might still appear in the displayed printer list until the replica is updated from the master.

- Users can use the LDAP command line utilities, `ldapadd` and `ldapmodify`, to update printer entries in the directory, but this method is not recommended. If these utilities are used, the user must ensure that the `printer-name` attribute value is unique within the `ou=printers` container. If the `printer-name` attribute value is not unique, the result of modifications done by Solaris Print Manager, or the `lpset` command, might not be predictable.

**Printing in the Solaris Operating Environment**

The Solaris printing software provides an environment for setting up and managing client access to printers on a network.

The Solaris printing software contains these components:

- Solaris Print Manager, a graphic user interface, provides the ability to manage printing configuration on a local system or in a name service.
The LP print service commands, a command line interface used to set up and manage printers on a local system or in a name service. They also provide functionality that extend beyond the other print management tools.

Even if you do use Solaris Print Manager to set up printing, you will have to use some of the LP commands to completely manage printing in the Solaris environment. For more information, see Chapter 5.

The limitations of Solaris print software include the following:

- No support for print servers defined as a5 (the System V print protocol) in previous Solaris releases.
- No print filtering on print clients.

**Solaris Print Manager**

Solaris Print Manager is a Java-based graphical user interface that enables you to manage local and remote printer configuration. This tool can be used in the following name service environments: NIS, NIS+, NIS+ with Federated Naming Service (xfn), and files. You must be logged in as superuser to use this tool.

Using Solaris Printer Manager is the preferred method for managing printer configuration information. Solaris Printer Manager is preferred over Admintool: Printers because it centralizes printer information when used in conjunction with a name service. Using a name service for storing printer configuration information is desirable because a name service makes printer information available to all systems on the network. This method provides easier printing administration.

Solaris Print Manager recognizes existing printer information on the printer servers, print clients, and in the name service databases. No conversion tasks are required to use Solaris Print Manager as long as the print clients are running either the Solaris 2.6, 7, 8, or 9 releases.

The Solaris Print Manager package is SUNWppm.

For step-by-step instructions on setting up new printers with Solaris Print Manager, see Chapter 4.

**Printing Support in the Name Service Switch**

The printers database in /etc/nsswitch.conf, the name service switch file, provides centralized printer configuration information to print clients on the network.

By including the printers database and corresponding sources of information in the name service switch file, print clients automatically have access to printer configuration information without having to add it to their own systems.
The default printers entry in the `/etc/nsswitch.conf` file for files, LDAP, NIS, and NIS+ environments are described in the following table. The `nisplus` keyword represents the `printers.org_dir` table. The `xfn` keyword represents the FNS printer contexts.

<table>
<thead>
<tr>
<th>Name Service Type</th>
<th>Default printers Entry</th>
</tr>
</thead>
<tbody>
<tr>
<td>files</td>
<td>printers: user files</td>
</tr>
<tr>
<td>ldap</td>
<td>printers: user files ldap</td>
</tr>
<tr>
<td>nis</td>
<td>printers: user files nis</td>
</tr>
<tr>
<td>nis+</td>
<td>printers: user nisplus files xfn</td>
</tr>
</tbody>
</table>

For example, if your name service is NIS, printer configuration information on print clients is looked in the following sources in this order:

- `user` - Represents the user’s `$HOME/.printers` file
- `files` - Represents the `/etc/printers.conf` file
- `nis` - Represents the `printers.conf.byname` table

For more information, see `nsswitch.conf(4)` and *System Administration Guide: Naming and Directory Services (DNS, NIS, and LDAP)*.

### Choosing a Method to Manage Printers

Adding printer information to a name service makes access to printers available to all systems on the network and generally makes printer administration easier because all the information about printers is centralized.

<table>
<thead>
<tr>
<th>Name Service Configuration</th>
<th>Actions to Centralize Printer Information</th>
</tr>
</thead>
<tbody>
<tr>
<td>Use a name service</td>
<td>Adding the printer to the LDAP, NIS, NIS+, or NIS+ (xfn) database makes the printer available to all systems on the network.</td>
</tr>
<tr>
<td>Don’t use a name service</td>
<td>Adding the printer adds the printer information to the printer server’s configuration files only. Print clients will not know about the printer automatically. You will have to add the printer information to every print client that needs to use the printer.</td>
</tr>
</tbody>
</table>

The following table describes the major printer-related tasks and the tools available to perform the printing tasks.
TABLE 2-1 Solaris Printing Component Features

<table>
<thead>

</tbody>
</table>

After using the preceding table to determine which printing tool is best for your network environment, see Chapter 4 for printer setup information.

Most printing configuration tasks can be accomplished with Solaris Print Manager. However, if you need to write interface scripts or add your own filters, you need to use the LP print service commands. These commands underlie Solaris Print Manager. Performing printing administration tasks with LP commands are described in Chapter 5.

The LP Print Service

The *LP print service* is a set of software utilities that allows users to print files while the users continue to work.

For background information about the LP print service, see Chapter 8.

Other LP print service topics covered and their chapter references are described in the following sections.

Managing Network Printers

A *network printer* is a hardware device that is connected directly to the network. A network printer transfers data directly over the network to the output device. The printer or network connection hardware has its own system name and IP address.
Network printers often have software support provided by the printer vendor. If your printer has printer vendor supplied software, then use the printer vendor software. If the network printer vendor does not provide software support, Sun supplied software is available. This software provides generic support for network attached printers, but is not capable of providing full access to all possible printer capabilities.

For step-by-step instructions on setting up a network printer, see Chapter 4.

**Administering Printers**

After you set up print servers and print clients, you might need to perform a number of administration tasks frequently:

- Delete a printer and remote printer access
- Check the status of printers
- Restart the print scheduler

For step-by-step instructions on how to perform the printer administration tasks, see Chapter 5.

**Setting Definitions for Printers**

Establishing definitions for the printers on your network is an ongoing task that lets you provide a more effective print environment for users. For example, you can assign printer descriptions for all your site’s printers to help users find where a printer is located. Or, you can define a class of printers to provide the fastest turnaround for print requests.

For information on setting up printer definitions, see Chapter 3.

**Administering Character Sets, Filters, Forms, and Fonts**

Depending on your site’s requirements and the types of printers you have on the network, you might have to set up and administer printer-specific features of the LP print service. For example, you can assign different print wheels, filters, and forms to different printers. For background information and step-by-step instructions on how to set up character sets, print filters, forms, and fonts, see Chapter 6.
Customizing the LP Print Service

Although the LP print service is designed to be flexible enough to handle most printers and printing needs, the LP print service does not handle every possible situation. You might have a print request that is not accommodated by the standard features of the LP print service. Or, you can have a printer that does not quite fit into the way the LP print service handles printers.

You can customize the LP print service in the following ways:

- Adjust the printer port characteristics
- Adjust the terminfo database
- Customize the printer interface program
- Create a print filter
- Define a form

For detailed descriptions and step-by-step instructions to customize the LP print service, see Chapter 7.

The Solaris Print Client-Server Process

This section provides an overview of how Solaris printing works.

The Print Client Process

The following figure illustrates the path of a print request from the time the user initiates the request until the print request is printed.

**FIGURE 2-1** Overview of the Print Client Process

1. A user submits a print request from a print client.
2. The print command checks a hierarchy of print configuration resources to determine where to send the print request.
3. The print command sends the print request directly to the appropriate print server. A print server can be any server that accepts BSD printing protocol, including SVR4 (LP) print servers and BSD lpd-based print servers.

4. The print server sends the print request to the appropriate printer.

5. The print request is printed.

Using Print Clients

This section of the overview focuses on the print client, a system that can send print requests to a print server, and print commands, which enable the print client to initiate print requests.

The following figure highlights the part of the print process in which the user submits a print request from a print client.

![Print Client Diagram](image)

**FIGURE 2-2** The User Submits a Print Request from a Print Client

What Is a Print Client?

A system becomes a print client when you install the Solaris print software and enable access to remote printers on the system.

The Solaris print software checks the following resources to locate printers and printer configuration information:

- The command-line interface by using the `lp -d` command (atomic or POSIX format)
- A user’s `LPDEST` or `PRINTER` variables
- The `_default` variable in the sources configured for the `printers` database in the `/etc/nsswitch.conf` file
- The user’s `$HOME/.printers` file
- The local `/etc/printers.conf` file for the NIS name service
- The LDAP or NIS name service database
The print client sends its requests to the print server’s queue. The client does not have a local queue. The client writes the print request to a temporary spooling area only if the print server is not available or if an error occurs. This streamlined path to the server decreases the print client’s use of resources, reduces the chances for printing problems, and improves performance.

Printer Configuration Resources

This section describes the resources that the print software uses to locate printer names and printer configuration information.

The print software can use a name service, which is a network (shared) resource for storing printer configuration information for all printers on the network. The name service, LDAP, NIS, NIS+, or NIS+ (xfn), simplifies printer configuration maintenance. When you add a printer in the name service, all print clients on the network can access the printer.

How the Print Software Locates Printers

The following figure highlights the part of the print process in which the print software checks a hierarchy of printer configuration resources to determine where to send the print request.

![Diagram of printer configuration resources](image.png)

**FIGURE 2-3** How the Print Client Software Locates Printers

1. A user submits a print request from a print client by using the `lp` or `lpr` command. The user can specify a destination printer name or class in any of three styles:

   A. Atomic, POSIX, or Context-Based Printer Name or Class
   B. User’s PRINTER or LPDEST Environment Variable for Default Printer
   C. `_default` Variable in Printers Database in `/etc/nsswitch.conf`
   D. User’s `$HOME/.printers` File
   E. Local `/etc/printers.conf` File
   F. LDAP directory information tree for printers in the domain’s `ou=printers` container
   G. NIS `printers.conf.byname` Map
   H. NIS+ `printers.org_dir` Table
   I. NIS+ (xfn) FNS Printing Contexts
- Atomic style, which is the \texttt{lp} command and option followed by the printer name or class, as shown in this example.
  \begin{verbatim}
  \% lp -d neptune filename
  \end{verbatim}
- POSIX style, which is the print command and option followed by \texttt{server:printer}, as shown in the following example.
  \begin{verbatim}
  \% lpr -P galaxy:neptune filename
  \end{verbatim}
- Context-based style, as shown in the following example:
  \begin{verbatim}
  \% lpr -d thisdept/service/printer/printer-name filename
  \end{verbatim}

2. The print command locates a printer and printer configuration information as follows:

- The print command checks to see if the user specified a destination printer name or printer class in one of the three valid styles.
- If the user didn’t specify a printer name or class in a valid style, the command checks the user’s \texttt{PRINTER} or \texttt{LPDEST} environment variable for a default printer name.
- If neither environment variable for the default printer is defined, the command checks the sources configured for the printers database in the \texttt{/etc/nsswitch.conf} file. The name service sources might be one of the following:
  - LDAP directory information tree in the domain’s ou=printers container
  - NIS printers.conf.byname map
  - NIS+ printers.conf_dir map
  - NIS+ xfn (FNS) printing contexts

### Using Print Servers

The print server is a system that has a local printer connected to it and makes the printer available to other systems on the network. The following figure highlights the part of the print process in which the print server sends the print request to the printer.
FIGURE 2–4 The Print Server Sends a Print Request to the Printer

1. Print client submits a print request.
2. The print request is processed on the print client.
3. The print request goes to the print server.
4. The print request goes to the printer.
5. The print output is produced on the printer.

The BSD Printing Protocol

The print commands use the BSD printing protocol. One of the big advantages of this protocol is that it can communicate with a variety of print servers:

- lpd-based print servers
- SunOS 5.9 and compatible SVR4 (LP) print servers
- Any other print server or printer that accepts the BSD printing protocol

The BSD printing protocol is an industry standard that is widely used because it provides compatibility between different types of systems from various manufacturers. Sun has chosen to support the BSD printing protocol to provide interoperability in the future.

Where to Go From Here

Go to Chapter 4 for step-by-step instructions on setting up new printers with Solaris Print Manager. If you need printer planning information, see Chapter 3.
Planning Printers on Your Network (Overview)

This chapter provides information about distributing printers across your network to gain the best efficiency and about planning for printer setup.

This is a list of overview information in this chapter.

- “Distributing Printers on the Network” on page 38
- “Assigning Print Servers and Print Clients” on page 38
- “Print Server Requirements and Recommendations” on page 39

Where to Find Printer Tasks

</tbody>
</table>
Distributing Printers on the Network

The goal of setting up printers on a network is to give users access to one or more printers. As an administrator, you must determine whether each printer would be best used if it is dedicated to one system or available to many systems. In a network environment, distribute your printers on several print servers. The advantage of setting up several print servers is that when one print server has a problem, you can route print requests to other print servers.

If you use a centralized print configuration, you can still connect printers to users’ systems for convenience or for improved response. A printer that is connected to a user’s system is still available to other systems on the network.

The following figure shows an example of how you can have a centralized print configuration and still connect printers to users’ systems.

![Figure 3-1: How to Distribute Printers on a Network](image)

Assigning Print Servers and Print Clients

You must decide which systems will have local printers physically attached to them, and which will systems use printers on other systems. A system that has a local printer attached to it and makes the printer available to other systems on the network is called a print server. A system that sends its print requests to a print server is called a print client.

The LP print service software provides printing services in the Solaris environment. Besides physically connecting a printer to a system, you must define the printer server characteristics to the LP print service. Once you have print servers set up, you can set up other systems as print clients.
Print servers and print clients can run different versions of the Solaris release and different version of the UNIX operating system. Print clients running the Solaris 9 release and compatible versions can print to print servers running an lpd-based print service, such as the SunOS 4.1, BSD UNIX, and Linux releases. In addition, print clients running an lpd-based print service can print to print servers running the Solaris 9 release and compatible versions.

The following figure shows a print configuration on a network with systems running the Solaris release and an lpd-based print service. For details on how Solaris printing works in heterogeneous environments, see “How Remote Printing Works” on page 167.

![Diagram of Solaris and lpd-Based Systems Print Configuration](image)

**FIGURE 3-2** Solaris and lpd-Based Systems Print Configuration

---

Print Server Requirements and Recommendations

You can attach a printer to a standalone system or to any system on the network. Any networked system with a printer can be a print server, as long as the system has adequate resources to manage the printing load.

Spooling Space

_Spooling space_ is the amount of disk space that is used to store and process requests in the print queue. Spooling space is the single most important factor to consider when deciding which systems to designate as print servers. When users submit files for printing, the files are stored in the `/var/spool/lp` directory until the files are...
printed. The size of the \texttt{/var} directory depends on the size of the disk and how the disk is partitioned. Spooling space can be allocated in the \texttt{/var} directory on the print server, or mounted from a file server and accessed over the network.

\textbf{Note} – If \texttt{/var} is not created as a separate file system, the \texttt{/var} directory uses space in the root (/) file system, which is likely to be insufficient on a print server.

\section*{Disk Space}

When evaluating systems as possible print servers, consider their available disk space. A large spool directory can consume 600 Mbytes of disk space. Look at the size and division of disk space on systems that can be designated as print servers.

Also, carefully evaluate the printing needs and use patterns of print client systems. If users in a small group typically print only short email messages, simple ASCII files without sophisticated formatting requirements, a print server with 20 to 25 Mbytes of disk space allocated to the \texttt{/var} directory is probably sufficient. If, however, many print client users are printing large documents or bit-mapped or raster images, the users will likely fill up the spooling space quite frequently. When users cannot queue their jobs for printing, work flow is interrupted. Requests for more spooling space can force you to either add disk space for spooling or designate a different system as the print server.

If the print server has a \texttt{/var} directory that is too small, and a larger file system is available, you can mount the larger file system on the \texttt{/var} directory for additional spooling space. For information about mounting file systems and editing the \texttt{vfstab} file, see “Mounting and Unmounting File Systems (Tasks)” in \textit{System Administration Guide: Basic Administration}.

\section*{Memory}

The Solaris environment requires a minimum of 64 Mbytes of memory to run. A print server does not require additional memory. However, you might find that more memory improves performance in filtering print requests.

\section*{Swap Space}

The swap space allocation on the print server should be sufficient to handle LP print service requirements. For information about how to increase swap space, see “Configuring Additional Swap Space (Tasks)” in \textit{System Administration Guide: Basic Administration}.
Hard Disk

For optimal performance, the print server should have a hard disk and a local /var directory. You should mount spooling space for a print server on a local hard disk. If a print server has its own hard disk and a local /var directory, printing is much faster. And, you can more accurately predict the time needed to process print requests.

Planning for Printer Setup

This section provides an overview of planning for printing in the Solaris environment that includes:

- Setting definitions for printers such as printer name, printer description, printer port
- Selecting a printer type and file content type
- Setting up fault notification and a default printer destination
- Determining whether you want to print banner pages or limit user access to a printer
- Setting up printer classes and fault recovery

Setting Definitions for Printers

Establishing definitions for the printers on your network is an ongoing task that lets you provide a more effective print environment for users. For example, you can assign parameters for all your site’s printers to help users find where a printer is located. Or, you can define a class of printers to provide the fastest turnaround for print requests.

The ladmin command lets you set all of the print definitions, while Solaris Print Manager lets you set only some of them when you install or modify a printer. The following table lists the print definitions and shows whether you can assign the definition with Solaris Print Manager.

<table>
<thead>
<tr>
<th>Print Definition</th>
<th>Can You Set Print Definitions With Solaris Print Manager?</th>
</tr>
</thead>
<tbody>
<tr>
<td>Printer name</td>
<td>Yes</td>
</tr>
<tr>
<td>Printer description</td>
<td>Yes</td>
</tr>
</tbody>
</table>
TABLE 3–1 Print Definitions Set With Solaris Print Manager (Continued)

<table>

<tr>
<td>Printer class</td>
<td>No</td>
</tr>
<tr>
<td>Fault recovery</td>
<td>No</td>
</tr>
</tbody>
</table>

**Printer Name**

When adding a printer to a system, you specify a *printer name* for the printer. A printer name must be:

- Unique among all printers within the bounds of an administrative domain
- A maximum of 14 alphanumeric characters, which can include dashes and underscores
- Easy to remember and can identify the type of printer, its location, or the print server name

Establish a naming convention that works for your site. For example, if you have different types of printers on the network, including the printer type as part of the printer name can help users choose an appropriate printer. For instance, you could identify PostScript™ printers with the letters PS. If, however, all of the printers at your site are PostScript printers, you would not need to include the initials PS as part of the printer name.

**Printer Description**

You can assign a description to a printer by using the `lpadmin -D` command or Solaris Print Manager. The printer’s description should contain information to help users identify the printer. You might include the room number where the printer is located, the type of printer, the manufacturer, or the name of the person to call if printing problems occur.
Users can look at a printer description by using the following command:

```
$ lpstat -D -p printer-name
```

**Printer Port**

When you install a printer or later change its setup, you can specify the device, or the _printer port_, to which the printer is connected, by using Solaris Print Manager or the `lpadmin -p printer-name -v device-name` command.

Most systems have two serial ports and a parallel port or USB ports. Unless you add ports, you cannot directly connect more than two serial printers and a parallel printer or two USB printers to one system.

You can select the following printer port types with Solaris Print Manager. These options give you as much flexibility as the lpadmin command.

<table>
<thead>
<tr>
<th>Printer Port Type</th>
<th>Corresponding Device Name Options</th>
</tr>
</thead>
<tbody>
<tr>
<td>Serial</td>
<td>/dev/term/a</td>
</tr>
<tr>
<td>Serial</td>
<td>/dev/term/b</td>
</tr>
<tr>
<td>Parallel</td>
<td>/dev/printers/0 -&gt; /dev/ecpp0</td>
</tr>
<tr>
<td>USB</td>
<td>/dev/printers/[1-9]</td>
</tr>
<tr>
<td>Specify any port name that the print server recognizes</td>
<td>Other</td>
</tr>
</tbody>
</table>

The LP print service initializes the printer port by using the settings from the standard printer interface program. For more information about printer interface programs, see “Managing Print Filters” on page 109. If you have a parallel printer or a serial printer for which the default settings do not work, see “Adjusting Printer Port Characteristics” on page 127 for information about customizing the port settings.

**x86 only** – If you use multiple ports on an IA based system, only the first port is enabled by default. The second and any subsequent ports are disabled by default. To use more than one port, you must manually edit the device driver port configuration file for each additional _asy_ (serial) port or _lp_ (parallel) port. The pathnames for the IA port configuration files are:

```
/platform/i86pc/kernel/drv/asy.conf
/platform/i86pc/kernel/drv/lp.conf
```
Printer Type

The printer type is a generic name for a type of printer. Printer type identifies the terminfo database entry that contains various control sequences for the printer. By convention, printer type is usually derived from the manufacturer’s model name. For example, the printer type name for the DECwriter™ printer is decwriter. However, the common printer type PS does not follow this convention. PS is used as the printer type for many models of PostScript™ printers, such as Apple LaserWriter®I and Apple LaserWriterII printers.

You can specify the printer type by using the \texttt{lpadmin -T} command or Solaris Print Manager.

Solaris Print Manager lets you select a printer type from a menu or choose \texttt{Other} and specify any printer type in the terminfo database. This feature provides as much capability as the \texttt{lpadmin} command.

\textbf{Printer Names in the terminfo Database}

Information about each printer type is stored in the terminfo database (/usr/share/lib/terminfo). This information includes the printer capabilities and initialization control data. The printer you install must correspond to an entry in the terminfo database.

\$ \texttt{pwd}
/usr/share/lib/terminfo
\$ \texttt{ls}
1 3 5 7 9 B H P a c e g i k m o q s u w y
2 4 6 8 A G M S b d f h j l n p r t v x z
\$

Each subdirectory contains compiled database entries for terminals or printers. The entries are organized by the first letter of the printer or terminal type. For example, if you have an Epson® printer, look in the /usr/share/lib/terminfo/e directory to find your particular model of Epson printer.

\$ \texttt{cd /usr/share/lib/terminfo/e}
\$ \texttt{ls}
emots ep2500+high ep48 ergo4000 exidy2500
env230 ep2500+low epson2500 esprit
envision230 ep40 epson2500-80 ethernet
dos ep2500+basic ep4000 epson2500-hi ex3000
dos ep2500+color ep4080 epson2500-hi80 exidy
\$

The entries for Epson printers are included in the preceding example.

If you have a NEC® printer, look in the /usr/share/lib/terminfo/n directory for your NEC printer model.

\$ \texttt{cd /usr/share/lib/terminfo/n}
\$ \texttt{ls}
Selecting a Printer Type

For a local PostScript printer, use a printer type of either PostScript (PS) or Reverse PostScript (PSR). If your printer supports PostScript, choose PS or PSR even if the specific printer type is listed in the terminfo database.

If your PostScript printer prints pages face up, documents appear to be printed backwards, where the first page is at the bottom of the stack and the last page is on the top. If you specify the printer's type as PSR, the LP print service reverses the order of the pages before sending the pages to the printer. The last page is printed first, and the pages are stacked in forward order. However, the LP print service can reliably change the page order only for PostScript files that conform to the Adobe® Document Structuring Conventions in Appendix C of the PostScript Language Reference Manual written by Adobe Systems Incorporated, and published by Addison-Wesley, 1990.

If a printer can emulate more than one kind of printer, you can assign several printer types by using the lpadmin -T command. If you specify more than one printer type, the LP print service uses the type that is appropriate for each print request.

You might not find the printer type in the appropriate terminfo directory. The type of printer is not necessarily linked to the manufacturer's name on the printer. For example, for any type of PostScript printer, you can use the PS or PSR entry, found in the /usr/share/lib/terminfo/P directory, instead of an entry specific to manufacturer or product names.

If you have an unusual type of printer, you might need to try different entries before you can determine whether a particular terminfo entry works for your model of printer. If possible, find an entry in the terminfo database that works for your printer. Trying to use an existing entry will be much easier than trying to create an entry. If you have to create your own entry, “Adding a terminfo Entry for an Unsupported Printer” on page 129 contains some useful tips.

Selecting a File Content Type

Print filters convert the content type of a file to a content type that is acceptable to the destination printer. The file content type tells the LP print service the type of file contents that can be printed directly, without filtering. To print without filtering, the necessary fonts must also be available in the printer. You must set up and use filtering for other types of files.
You can specify the file content type for a printer by using the `lpadmin -I` command or Solaris Print Manager. With Solaris Print Manager, you can select a file content type from a menu. Not all available file content types are listed on the menu. You must use the `lpadmin` command to specify file content types that are not included on the Solaris Print Manager menu.

Most printers can print the following types of files directly:

- The same type as the printer type. For example, `PS` for a PostScript printer.
- The `simple` type. For example, an ASCII text file.

When submitting a file for printing, the user can indicate the content type of the file by using the `lp -T content-type` command. If no file content type is supplied when the request is submitted, the LP server looks at the first file in the request to determine the content type. If the file begins with `^D%` or `%`, the request is considered to contain PostScript™ data. Otherwise, the request is assumed to contain `simple` (ASCII) text. The LP print service uses the file content type to determine which filters to use to convert the file contents into a type the printer can handle.

Solaris Print Manager provides a list of file content types from which you can choose when you install or modify a local printer. The choices are translated to the names that the LP print service uses. The following table describes the file content types that you can choose with Solaris Print Manager.

<table>
<thead>
<tr>
<th>File Contents Choice</th>
<th>LP Print Service Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>PostScript</td>
<td>postscript</td>
<td>PostScript files do not require filtering.</td>
</tr>
<tr>
<td>ASCII</td>
<td>simple</td>
<td>ASCII files do not require filtering.</td>
</tr>
<tr>
<td>Both PostScript and ASCII</td>
<td>simple,postscript</td>
<td>PostScript files and ASCII files do not require filtering.</td>
</tr>
<tr>
<td>None</td>
<td>&quot;&quot;</td>
<td>All files require filtering, except those files matching the printer’s type.</td>
</tr>
<tr>
<td>Any</td>
<td>any</td>
<td>No filtering required. If the printer cannot handle a file content type directly, the file will not be printed.</td>
</tr>
</tbody>
</table>

Choose the file content type that best matches the printer’s capabilities. PostScript, which means filtering is not needed for PostScript files, is the default choice in Solaris Print Manager and is probably correct most of the time.

**Frequently Used Printers**

This section provides the printer type and file content type for the printers most commonly used with Solaris software. Although not shown, many of these printers can also directly print files with `simple` content type.
If you have a PostScript printer, use a printer type of PS or PSR and a content type of postscript. PSR reverses the pagination and prints the banner page last.

The following table lists additional non-PostScript printers and shows the printer type to use for configuring each printer. For all these printers, the file content type is simple.

<table>
<thead>
<tr>
<th>Printer</th>
<th>Printer Type</th>
</tr>

</tr>
<tr>
<td></td>
<td>epson2500-hi80</td>
</tr>
<tr>
<td>Hewlett-Packard HPCL printer</td>
<td>hplaser</td>
</tr>
<tr>
<td>IBM Proprinter</td>
<td>ibmproprinter</td>
</tr>
</tbody>
</table>

Note – Sun Microsystems does not supply filtering software for the printers listed in the following table, among others. However, you can use unsupported printers if you supply filtering or if the printer can directly print the file content type. If you have questions about any printer for which Sun Microsystems does not supply filters, contact the printer manufacturer.

If you want to set up a printer that is not in the terminfo database, see “How to Add a terminfo Entry for an Unsupported Printer” on page 132.
CHAPTER 4

Setting Up Printers (Tasks)

This chapter describes how to set up a printer and make it accessible to systems on the network with Solaris Print Manager.

For information on the procedures associated with setting up printers with Solaris Print Manager, see “Setting Up Printing (Task Map)” on page 49.

For overview information about printers, see Chapter 2.

Setting Up Printing (Task Map)

<table>
<thead>
<tr>
<th>Task</th>

</table>

**Setting Up Printing With Solaris Print Manager**

Solaris Print Manager is a Java-based graphical user interface that enables you to manage local and remote printer configuration. This tool can be used in the following name service environments: LDAP, NIS, NIS+, NIS+ with Federated Naming Service (xfn), and files. You must be logged in as superuser to use this tool.

You can use Solaris Print Manager to set up print servers (New Attached Printer) and print clients (Add Access to Printer). A local or attached printer is one which is physically cabled to the print server. A network printer is physically attached to the network. Adding access to a printer, or adding remote access, is the process of giving print clients (all those machines which are not the server) access to the printer.
Setting Up a Printer With Solaris Print Manager

The following table describes each printer attribute to help you determine the information needed to set up a printer with Solaris Print Manager.

<table>
<thead>
<tr>
<th>Printer Attribute</th>
<th>Description</th>

</table>
Solaris Print Manager and Special Characters

Solaris Print Manager checks user input for the various text fields in the input screens. There are two types of checking: general illegal input and input that is illegal for specific fields.

Solaris Print Manager does not accept the following characters as input, except for the help screens:

- Shell meta characters, such as "\$^&*{}()\|;?:<>", except for the destination field on the network printer screen, which accepts colons (:
- Multibyte characters
- Pound signs (#), spaces, or tabs, except the description field, which accepts tabs

Starting Solaris Print Manager

To use Solaris Print Manager to set up your printers, start Solaris Print Manager either by selecting Printer Administrator from the CDE Workspace menu or by starting it from the command line. See the following section for details.

▼ How to Start Solaris Print Manager

1. Verify that the following prerequisites are met. To use Solaris Print Manager, you must:
   - Have a bit-mapped display monitor. Solaris Print Manager can be used only on a system with a console that is a bit-mapped screen, such as a standard display monitor that comes with a Sun workstation.
   - Be running an X Window System, such as the CDE environment, or be using the remote display feature on a system running an xhost environment.
   - Be logged in as superuser on the printer server to install an attached or network printer, or on the print client to add access to a printer.
   - Have the required access privileges for managing the LDAP, NIS, NIS+, or NIS+ (xfn) database:
     - If your name service is LDAP, you must have the following:
       - The distinguished name (DN) of a printer administrator and password in the directory.
       - The name or IP address of an LDAP server hosting the administered domain. This is usually displayed and selected automatically.
For more information about using LDAP to manage printer information, see “Managing Printer Information With LDAP” on page 26.

- If your name service is NIS, you must have the root password for the NIS master.
- If your name service is NIS+, you might need to do the following:
  a. Log in to the NIS+ master as superuser.
  b. Identify the group that owns the printers table:

    ```
    # niscat -o printers.org_dir.domain_name.com
    
    Group : "admin.domain_name.com"
    ```
  c. If necessary, add the system that runs Solaris Print Manager to the NIS+ admin group authorized to update the printers.org_dir.<domain> file.

    ```
    # nisgrpadm -a admin.domain_name.com host_name
    ```
  d. Log in to the system that runs Solaris Print Manager as superuser. Depending on your NIS+ configuration, you might also need to run the /usr/bin/keylogin command. For more information, see keylogin(1).

- If your name service is NIS+ (xfn), you might need to do the following:
  a. Log in to the NIS+ master as superuser.
  b. Identify the group that owns the federated naming table:

    ```
    # niscat -o fns.ctx_dir.domain_name.com
    
    Group : "admin.domain_name.com"
    ```
  c. If necessary, add the system that runs Solaris Print Manager to the NIS+ admin group authorized to update the fns.ctx_dir.<domain> file.

    ```
    # nisgrpadm -a admin.domain_name.com host_name
    ```
  d. Log in to the system that runs Solaris Print Manager as superuser. Depending on your NIS+ configuration, you might also need to run the /usr/bin/keylogin command. See keylogin(1) for more information.

- Have the SUNWppm package installed.

  ```
  # pkginfo | grep SUNWppm
  system  SUNWppm  Solaris Print Manager
  ```

2. **Start Solaris Print Manager by one of the following methods:**

- Select Printer Administrator from the Tools option of the CDE Workspace menu.
- Select the Applications menu from the CDE front panel, and click the Printer Administrator icon in the Application Manager’s System_Admin window.
- From the command line:
The Select Naming Service window overlays the Solaris Print Manager main window. If you want to use Solaris Print Manager from a remote system, do the following:

Use the `xhost` command on the local system to give the remote system display access, like this:

```
# xhost +remote-system
```

Then log in to the remote system, set the DISPLAY environment variable, and start Solaris Print Manager:

```
# DISPLAY=local-system:display_number
# export DISPLAY
# /usr/sadm/admin/bin/printmgr &
```

**Note** – If Solaris Print Manager fails to start from the CDE menu or from the command line, check the following:

a. Superuser (root) might not have permission to connect to the X-server process on the local or remote system. If this happens, type the following:

```
$ xhost +hostname
$ su
(Enter root’s password)
# /usr/sadm/admin/bin/printmgr &
```

Replace `hostname` with either the local or remote system name before restarting Solaris Print Manager.

b. Verify that the SUNWppm package is installed on the local or remote system.

```
$ pkginfo | grep SUNWppm
```

3. Select the name service used in your network from the Select Naming Service window. Choices are: NIS+ (xfn), NIS+, NIS, or files.

4. Check that the domain name is correct.

The Solaris Print Manager main menu is displayed after the name service is loaded successfully.

---

**Setting Up a Print Server**

When you install an attached printer and/or a network printer to a system, the printer is made accessible to the local system. The system on which you install the printer becomes the print server.
The following sections describe how to use Solaris Print Manager to add an attached
printer or a network printer on a printer server. The example that follows each Solaris
Print Manager procedure describes how to add a printer with LP commands.

▼ How to Add a New Attached Printer With Solaris
Print Manager

1. Select the system to be the print server.

2. Connect the printer to the print server and turn on the power to the printer.
   Consult the printer vendor’s installation documentation for information about the
   hardware switches and cabling requirements.

3. Start Solaris Print Manager on the print server where you connected the printer.
   For instructions, see “How to Start Solaris Print Manager” on page 52.

4. Select New Attached Printer from the Printer menu.
   The New Attached Printer window is displayed.

5. Fill in the window.
   If you need information to complete a field, click the Help button.

6. Click OK.

7. Verify that the printer has been installed by checking for the new printer entry in
   the Solaris Print Manager main window.

8. Verify that the printer can print requests.
   $ lp -d printer-name filename

9. Exit Solaris Print Manager.
   Choose Exit from the Print Manager Menu.

Example—Adding a New Attached Printer With LP
Commands

This example shows how to make a local PostScript printer available for printing on a
print server. The commands in this example must be executed on the print server
where the printer is connected. The following information is used as an example. The
information you provide will vary:

- Printer name: luna
- Port device: /dev/term/b
- Printer type: PS
1. Gives lp ownership and sole access to a port device.
2. Defines the printer name and the port device the printer will use.
3. Sets the printer type of the printer.
4. Specifies the file content types to which the printer can print directly.
5. Adds print filters to the print server.
6. Accepts print requests for the printer and enables the printer.
7. Adds a description for the printer.
8. Verifies that the printer is ready.

Where to Go From Here

Use the following table to determine which tasks to complete next.

<table>
<thead>
<tr>
<th>Task</th>
<th>For More Information</th>
</tr>
</thead>
<tbody>
<tr>
<td>Add access to the newly installed printer on the print clients because you did not add the printer information to the name service database.</td>
<td>“How to Add Printer Access With Solaris Print Manager” on page 57</td>
</tr>
<tr>
<td>Set up a .printers file.</td>
<td>“How to Set Up a .printers File” on page 58</td>
</tr>
</tbody>
</table>
Setting Up a Print Client

A print client is a system that is not the server for the printer, yet has access to the printer. A print client uses the services of the print server to spool, schedule, and filter the print jobs. Note that one system can be a print server for one printer and be a print client for another printer.

Access to a printer can be configured on a domain-wide basis or on a per-machine basis depending on whether you add the printer information to the name service database.

The following sections describe how to use the new Solaris Print Manager to add access to a printer on a print client. The example that follows this procedure describes how to add printer access with LP commands.

▼ How to Add Printer Access With Solaris Print Manager

1. Start Solaris Print Manager on the system where you want to add access to a remote printer.
   For instructions, see “How to Start Solaris Print Manager” on page 52.

2. Select Add Access to Printer from the Printer menu.
   The Add Access to Printer window is displayed.

3. Fill in the window.
   If you need information to complete a field, click the Help button.

4. Click OK.

5. Verify that access to the printer is added by checking for the new printer entry in the Solaris Print Manager main window.

6. Verify that the printer can print requests.
   $ lp -d printer-name filename

7. Exit Solaris Print Manager.
   Choose Exit from the Print Manager Menu.
Example—Adding Printer Access With LP Commands

If you want to print to a remote printer, you must add access to the remote printer. This example shows how to configure access to a printer named luna, whose print server is saturn. The system saturn becomes a print client of the printer luna.

```
# lpadmin -p luna -s saturn  
# lpadmin -p luna -D "Room 1954 ps"  
# lpadmin -d luna  
# lpstat -p luna
```

1. Identifies the printer and the print server.
2. Adds a description for the printer.
3. Sets the printer as the system’s default printer destination.
4. Verifies that the printer is ready.

Setting Up a .printers File

There is no need to set up a .printers file in your users’ home directories if they don’t need customized printer information. However, the .printers file enables users to establish their own printer aliases. You can use the _default alias to make a printer the default. You can also set up a special _all alias to define a list of printers affected when you cancel a print request or check the status of printers.

Keep in mind that the use of the .printers file by the LP print service is controlled by the name service switch (/etc/nsswitch.conf). The default configuration is that the print service checks a user’s home directory to locate printer configuration information before its checks the other name services. This means you can tailor a user’s printer configuration file to use custom printer information rather than the shared information in the name service.

For more information about the .printers file, see printers(4). For more information about the name service switch, see nsswitch.conf(4).

▼ How to Set Up a .printers File

1. Log in to the user’s system as superuser.

2. Start the file editor you want to use to create a .printers file in the user’s home directory.

3. (Optional) Set up the _default alias to make a specific printer your default printer, using an entry similar to the one shown in the following example.

```
_default printer_name
```
4. (Optional) Set up the `all` alias to define the printers affected when you cancel a print request or check the status of printers, using an entry similar to the one shown in the next example.

```
_all printer1,printer2,printer3
```

5. Save the file as `.printers`.

---

**Adding a Network Printer**

A network printer is a hardware device that is directly connected to the network. This means it can be accessed from a print server without actually connecting it to the print server with a cable. It has its own system name and IP address. Even though a network printer is not connected to a print server, it is necessary to set up a print server for it. The print server provides queuing capabilities, filtering, and printing administration for the network printer.

Network printers might use one or more special protocols that require a vendor-supplied printing program. The procedures to set up the vendor-supplied printing program can vary. If the printer does not come with vendor supplied support, the Solaris network printer support can be used with most devices. Use the print vendor supplied software when possible.

The vendor might supply an SVR4 printer interface script to replace the standard printer interface script. If so, their SVR4 interface script will call the vendor-supplied printing program to send the job to the printer. If not, you will need to modify the standard interface script to call the vendor-supplied printing program. You can do this by editing the per-printer copy of the standard interface script to call the vendor-supplied printing program.

The terms used in network printer configuration are:

- **Print server** – The machine that spools and schedules the jobs for a printer. This is the machine on which the printer is configured.

- **Printer-host device** – The printer-host device is the software and hardware supplied by a vendor that provides network printer support for a non-network capable printer. The combination of the printer-host device with one or more printers attached to it creates a network printer.

- **Printer node** – This is either the physical printer or the printer-host device. It is the physical printer when the network support resides in the physical printer. It is the printer-host device when an external box is used to provide the network interface. The printer node name is the machine name given with the IP address. This name is selected by the system administrator and has no default or vendor requirement. The printer node name, as with all nodes, must be unique.
- **Printer name** – The name entered on the command line when using any of the printer commands. It is selected by the system administrator at the time of printer configuration. Any one physical printer can have several printer or queue names; each provides access to the printer.

- **Destination or network printer access name** – The internal name of the printer node port that is used by the printer subsystem to access the printer. It is the name of the printer node, or the name of the printer node with a printer vendor port designation. Any printer vendor port designation is explicitly defined in the printer vendor documentation. It is printer specific. In the case where the printer is a printer-host device and a printer, the port designation is documented in the printer-host device documentation. The format is:
  
  `printer_node_name`
  
  or
  
  `printer_node_name:port_designation`

- **Protocol** – The over-the-wire protocol used to communicate with the printer. The printer vendor documentation supplies the information regarding the protocol to select. The network printer support supplies both BSD Printer Protocol and raw TCP. Due to implementation variations, you might want to try both.

- **Timeout, or retry interval** – Is a seed number representing the number of seconds to wait between attempting connections to the printer. This seed number is the smallest amount of time to wait between attempted connections, and increases with an increase in failed connections. After repeated failures to connect to the printer, a message is returned to the user requesting possible human intervention. Attempts to reconnect continue until successful or the job is cancelled by the job owner.

### Printer Vendor Supplied Software for Network Printers

Network printers often have software support provided by the printer vendor. If your printer has printer vendor supplied software, use the printer vendor software when possible. The software is designed to support the attributes of the printer and can take full advantage of the printer capabilities. Read the printer vendor documentation to install and configure the printer under an LP print system.

### Sun Support for Network Printers

If the network printer vendor does not provide software support, the Sun supplied software is available. The software provides generic support for network printers and is not capable of providing full access to all possible printer attributes.

A general discussion of how to add a network printer is provided in Chapter 4. The following is a discussion of printer management using the Sun supplied software.
Invoking the Network Printer Support

The software support for network printers is called through the interface script. Configuring a network printer with the network interface script, `netstandard`, causes the network printer support module to be called. The command to configure the printer with the network support is as follows:

```
lpadmin -p printer_name -m netstandard
```

Selecting the Protocol

The print subsystem uses BSD print protocol and raw TCP to communicate with the printer. The printer vendor documentation provides the information about which protocol to use. In general, we have found that the TCP protocol is more generic across printers.

The command to select the protocol is:

```
lpadmin -p printer_name -o protocol=bsd
do
```

or

```
lpadmin -p printer_name -o protocol=tcp
```

If the protocol selected is the BSD print protocol, you can further select the order of sending the control file to the printer. Some printers expect the control file, then the data file; others the reverse. For this information, see the printer vendor documentation. The default is to send the control file first.

The command to select the ordering is:

```
lpadmin -p printer_name -o bsdctrl=first
do
```

or

```
lpmadmin -p printer_name -o bsdctrl=last
```

Selecting the Printer Node Name

The system administrator selects the printer node name. This name must be unique, as with any node on the network. The printer node name is associated with the IP address of the printer.
Selecting the Destination (or Network Printer Access) Name

The print subsystem requires access information for the printer. This is the name that the subsystem uses when making the network connection to the printer. This name is supplied by the system administrator to the print subsystem by using the `lpadmin` command. It becomes part of the printer configuration database. The printer access name is the name of the printer node, sometimes qualified by a port name. Port designation varies across printer vendors. You will find information about port designation in the documentation that is provided with the printer by the printer vendor. The format of printer access name is:

`printer_node-name [:port_designation]`

Example 1—Destination (or Network Printer Access Name) With Port Designation (Number)

A common port designation with TCP is 9100. If the printer node name is `pn1`, and the printer vendor defines the port as 9100, then the printer access name is: `pn1:9100`. To configure a printer in this case use:

`lpadmin -p printer_name -o dest=pn1:9100`

Example 2—Destination (or Network Printer Access Name) With Port Designation (Name)

When using the BSD protocol, the port designation might not be a number, but some name defined by the printer vendor, for example: `xxx_parallel_1`. If the printer node name is `cardboard`, then the printer access name is: `cardboard:xxx_parallel_1`. To configure a printer in this case use:

`lpadmin -p printer_name -o dest=cardboard:xxx_parallel_1`

Example 3—Destination (or Network Printer Access Name) With No Port Designation

If there is no port designation, and the printer node name is `newspaper`, the printer access name is the printer node name: `newspaper`. To configure a printer in this case use:

`lpadmin -p printer_name -o dest=newspaper`
Setting the Timeout Value

The timeout option is provided to allow for individual selection of the amount of time (in seconds) to wait between successive attempts to connect to the printer. Some printers have a long warm up time and a longer timeout value is advised. The default is 10 seconds.

The timeout value does not impact the success or failure of the print process. It is a seed value which the software uses as the initial timeout count. On repeated failures, this count is increased. A message is sent to the spooler when repeated attempts to connect to the printer fail. This alerts the user that intervention might be required. This could be anything from the printer being turned off, to out of paper. Should these messages be produced too often, for example when the printer is warming up, increasing the timeout value will eliminate spurious messages.

The system administrator can experiment to find the optimal timeout value. The command to set the timeout is:

```
lpadmin -p printer_name -o timeout=n
```

Managing Network Printer Access

Each network printer should have one and only one server that provides access to it. This enables the server to manage the access to the printer and keep jobs coherent.

The default device for the network printer is /dev/null. This is sufficient when there is only one queue for the printer. Should more queues be required, set the device to a file. This enables the print system to restrict access to the printer across queues. The following commands create a device file and configure it as the network printer device.

```
touch /path/filename
chmod 600 /path/filename
lpadmin -p printer_name -v /path/filename
```

The following is an example of how to create a device file called devtreedown.

```
# touch /var/tmp/devtreedown
# chmod 600 /var/tmp/devtreedown
# lpadmin -p treedown -v /var/tmp/devtreedown
```

▼ How to Add a Network Printer With Printer Vendor Supplied Tools

1. Connect the printer to the network and turn on the power to the printer.

Consult the printer vendor’s installation documentation for information about the hardware switches and cabling requirements. Get an IP address and select a name for the printer node. This is equivalent to adding any node to the network.
2. Follow the printer vendor instructions to add the network printer.
   Use the printer vendor instructions to configure the network printer. These will be
   specific to the vendor and printer.

3. Add client access to the new printer.
   Now that the printer has been added, create access to the printer for the clients. For
   more information, see “Setting Up a Print Client” on page 57.

4. Optional tasks to complete.
   There are several optional tasks you might want to complete when setting up a
   network printer. For pointers to the remaining tasks, see “Setting Up Printing (Task
   Map)” on page 49.

How to Add A Network Printer With LP Commands

This procedure describes the steps necessary to setup a network printer using the
network printer support software. The use of this software is intended for those
printers that do not come with vendor supplied software.

1. Connect the printer to the network and turn on the power to the printer.
   Consult the printer vendor’s installation documentation for information about the
   hardware switches and cabling requirements. Get an IP address and select a name for
   the printer node. This is equivalent to adding any node to the network.

2. Collect the information required to configure a network printer.
   - Printer name
   - Printer server
   - Network printer access name
   - Protocol
   - Timeout
   For more information, see the terms described in “Adding a Network Printer”
on page 59.

3. Define the printer name, the device, the printer type and content type.
   a. Define the printer name and the port device the printer will use.
      
      # lpadmin -p printer-name -v /dev/null
      
      The device to use is /dev/null.

   b. Identify the interface script the printer will use.
      
      # lpadmin -p printer-name -m netstandard
      
      The interface script that is supplied with the network printer support software is
      /usr/lib/lp/model/netstandard.
c. Set the printer destination, protocol, and timeout values.

```
# lpadmin -p printer-name -o dest=access-name:port -o protocol=protocol
-o timeout=value
```

- `-p printer-name` Specifies the network printer name.
- `-o dest=access-name:port` Sets the printer destination to the network printer access name and a designated printer vendor port, if it is defined in the printer vendor documentation.
- `-o protocol=protocol` Sets the over-the-wire protocol used to communicate with the printer. Both BSD and raw TCP are supported.
- `-o timeout=value` Sets a retry timeout value that represents a number of seconds to wait between attempting connections to the printer.

d. Specify the file content types of the printer and the printer type.

```
# lpadmin -p printer-name -I content-type -T printer-type
```

For more information, see `lpadmin(1M)`.

4. Add filters to the print server.

```
# cd /etc/lp/fd
# for filter in *.fd; do
  > name=`basename $filter.fd`
  > lpfilter -f $name -F $filter
> done
```

5. Enable the printer to accept printer requests and to print the requests.

```
# accept printer-name
# enable printer-name
```

6. Verify that the printer is correctly configured.

```
# lpstat -p printer-name
```

7. Add client access to the new printer.

Now that the printer has been added, create access to the printer for the clients. For more information, see “Setting Up a Print Client” on page 57.

8. Optional tasks to complete.

There are several optional tasks you might want to complete when setting up a printer. For pointers to the remaining tasks, see “Setting Up Printing (Task Map)” on page 49.
Example—Adding A Network Printer With LP Commands

The commands in this example must be executed on the print server. The following information is used as an example. The information you provide will vary.

- Printer name: luna1
- Server: saturn
- Network printer access name: nimquat:9100
- Protocol: tcp
- Timeout: 5
- Interface: /usr/lib/lp/model/netstandard
- Printer type: PS
- Content types: postscript
- Device: /dev/null

1. Defines printer name and sets the device to /dev/null.
2. Defines the interface script for network printers.
3. Sets the destination, protocol, and timeout.
4. Specifies the file content types to which the printer can print directly, and the printer type.
5. Adds print filters to the print server.
6. Accepts print requests for the printer and enables the printer.
7. Adds a description for the printer.
8. Verifies that the printer is ready.
Converting Printer Configuration Information

This section explains how to convert the printer configuration information from systems running the SunOS 5.5.1 release and copy this information to print clients so they can access existing printers.

**Note** – If you have only a few existing printers, it might be easier to add access to the printers by using Solaris Print Manager rather than convert the printer configuration information and distribute it to print clients. For information on adding access to printers, see “Setting Up Printing (Task Map)” on page 49.

---

Converting Printer Configuration Information (Task Map)

The following task map identifies the tasks associated with converting printer configuration information.

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>For Instructions</th>
</tr>
</thead>
<tbody>
<tr>
<td>Convert Existing Printer Configuration Information</td>
<td>Convert Printer Configuration Information for Systems Running the SunOS 5.5.1 Release – If your site uses the SunOS 5.5.1 release, you can convert the printer configuration information in the /etc/lp/printers directory to the /etc/printers.conf configuration file. This is usually a one-time task.</td>
<td>“How to Convert Printer Information For a System Running the Solaris 2.5.1 Release” on page 69</td>
</tr>
</tbody>
</table>
Converting Existing Printer Configuration Information

Existing printer configuration information is automatically converted when installing or upgrading to the Solaris 9 release. This section explains how to convert the printer configuration information for a system running SunOS 5.5.1 release or a system running a lpd-based printer server to the /etc/printers.conf printer configuration file. You’ll use one of two print administration commands to automate the conversion task:

- The conv_lp command enables you to convert information in the /etc/lp/printers directory on a SunOS 5.9 system to entries in the system’s /etc/printers.conf file. For instructions, see “How to Convert Printer Information For a System Running the Solaris 2.5.1 Release” on page 69.

- The conv_lpd command enables you to convert information in a /etc/printcap configuration file from a system running a lpd-based printer server to entries in a /etc/printers.conf file. For instructions, see “How to Convert Printer Information For a System Running an lpd-based Print Server” on page 69.

If you are not using a name service, you should create a master /etc/printers.conf file that includes the existing printers at your site. You can then copy the master file to all the print clients or by loading it into the NIS or NIS+ name service. This is a good way to initially enable all the new print clients access to the existing printers at your site.

---

**Caution** – If you are using the NIS or NIS+ name service to configure printer information, do not use a /etc/printers.conf file on your print clients. A print client uses the /etc/printers.conf file first to locate a printer; however, the /etc/printers.conf file might conflict with the printer information in the NIS or NIS+ maps and cause unexpected results. To avoid this problem, remove the /etc/printers.conf file on print clients when you want them to use NIS or NIS+ for printer information.
How to Convert Printer Information For a System Running the Solaris 2.5.1 Release

1. Log in as superuser on the system running the Solaris 9 release.

2. Convert the printer configuration information in the system’s `/etc/lp/printers` directory to the `/etc/printers.conf` file.

   # /usr/lib/print/conv_lp

How to Convert Printer Information For a System Running an `lpd`-based Print Server

1. Copy the `/etc/printcap` file from a system running an `lpd`-based print server to a system running the Solaris 9 release.

2. Log in as superuser on the system running the Solaris 9 release where you copied the `/etc/printcap` file.

3. Convert the printer configuration information in the `/etc/printcap` file to the `/etc/printers.conf` file.

   # /usr/lib/print/conv_lpd
CHAPTER 5

Administering Printers (Tasks)

This chapter describes the procedures for administer printers with the LP commands.

This is a list of the step-by-step instructions in this chapter.

- "How to Delete a Printer and Remote Printer Access" on page 72
- "How to Check the Status of Printers" on page 75
- "How to Stop the Print Scheduler" on page 76
- "How to Restart the Print Scheduler" on page 77
- "How to Add a Printer Description" on page 77
- "How to Set a System’s Default Printer" on page 78
- "How to Make Banner Pages Optional" on page 80
- "How to Turn Off Banner Pages" on page 81
- "How to Define a Class of Printers" on page 82
- "How to Set Fault Alerts for a Printer" on page 84
- "How to Set Printer Fault Recovery" on page 86
- "How to Limit User Access to a Printer" on page 88
- "How to Check the Status of Print Requests" on page 90
- "How to Accept or Reject Print Requests for a Printer" on page 94
- "How to Enable or Disable a Printer" on page 92
- "How to Cancel a Print Request" on page 95
- "How to Cancel a Print Request From a Specific User" on page 96
- "How to Move Print Requests to Another Printer" on page 97
- "How to Change the Priority of a Print Request" on page 99

For overview information about printing and the LP print service, see Chapter 2
Managing Printers and the Print Scheduler

This section provides instructions for day-to-day tasks you perform to manage printers and the print scheduler.

Deleting Printers and Printer Access

If a printer needs to be replaced or you want to move the printer to a different location, you must delete the printer information from the LP print service before you physically remove it from the print server. You should also make sure that all the current print requests on the printer are printed or moved to another printer to be printed.

Not only does the printer information need to be deleted from the print server, but it also needs to be deleted from the print clients or network name service. If you delete a local printer from a print server, you should delete the remote printer entry from the print clients or network name service. If you move a printer to another print server, you need to delete the old remote print entry from the print clients or network name service. Then, add access to the remote printer in its new location.

For detailed information on how to delete a local and remote printer, see “How to Delete a Printer and Remote Printer Access” on page 72. You can use Solaris Print Manager to delete a local or remote printer. However, Solaris Print Manager does not enable you to move queued print requests to another printer.

▼ How to Delete a Printer and Remote Printer Access

Use this procedure when you remove a printer from service and you want to remove the printer access from the print clients. Then, remove the printer information from the print server.

1. Log in as superuser, lp, or assume an equivalent role on a print client that has access to the printer you want to delete.

2. Delete information about the printer from the print client.

```
print-client# lpadmin -x printer-name
```

- `-x` Deletes the specified printer.
printer-name Name of the printer you want to delete.

Information for the specified printer is deleted from the print client’s /etc/lp/printers directory.

3. If the print client does not use another printer on the same print server, delete information about the print server from the print client.

   \texttt{print-client} \# \texttt{lpsystem -r \ print-server}

\texttt{-r} Removes the specified print server.

\texttt{print-server} Name of the print server you want to delete.

The print server is deleted from the print client’s /etc/lp/Systems file.

4. Repeat Step 2 through Step 3 on each print client that has access to the printer.

5. Log in as superuser or lp or assume an equivalent role on the print server.

6. Stop accepting print requests on the printer.

   \texttt{print-server} \# \texttt{reject \ printer-name}

\texttt{reject \ printer-name} Rejects print requests for the specified printer.

This step prevents any new requests from entering the printer’s queue while you are in the process of removing the printer. For a detailed description, see “How to Accept or Reject Print Requests for a Printer” on page 94.

7. Stop the printer.

   \texttt{print-server} \# \texttt{disable \ printer-name}

This step stops print requests from printing. For a detailed description on how to stop printing, see “How to Enable or Disable a Printer” on page 92.

8. Move any print requests that are still in the queue to another printer.

   For a detailed description on how to move print requests to another printer, see “How to Move Print Requests to Another Printer” on page 97.

9. Delete the printer from the print server.

   \texttt{print-server} \# \texttt{ladmin -x \ printer-name}

Configuration information for the printer is deleted from the print server’s /etc/lp/printers directory.
10. Delete information about the print clients that were using the printer you just deleted, unless they are still using another printer on the print server.

```
print-server# lpsystem -r print-client1 [, print-client2 ...]
```

- `r` Removes the specified print client.
- `print-client` Name of the print client you want to delete from the print server. You can specify multiple print clients in this command. Use a space or a comma to separate print client names. If you use spaces, enclose the list of print clients in quotes.

The specified print clients are deleted from the print server's `/etc/lp/Systems` file.

11. Verify that the printer information has been deleted:

   a. Confirm that the printer information has been deleted on the print client.

      ```
      print-client$ lpstat -p printer-name -l
      ```

      You should receive an error indicating that the printer does not exist in the output of the preceding command.

   b. Confirm that the printer information has been deleted on the print server.

      ```
      print-server$ lpstat -p printer-name -l
      ```

      You should receive an error indicating that the printer does not exist in the output of the preceding command.

Example—Deleting a Printer and Remote Printer Access

The following example shows how to delete the printer `luna` from the print client `terra` and from the print server `jupiter`. This example also shows how to delete the print client `terra` from the print server.

```bash
terra# lpadmin -x luna
Removed “luna”.
terra# lpstat -p luna -l
jupiter# lpadmin -x luna
jupiter# lpsystem -r terra
Removed “terra”.
jupiter# lpstat -p luna -l
```
Checking Printer Status

Many routine printer administration tasks require information about the status of the LP print service or a specific printer. For example, you can determine which printers are available for use and can examine the characteristics of those printers. You can use the `lpstat` command to find out status information about the LP print service or a specific printer.

**How to Check the Status of Printers**

1. Log in to any system on the network.

2. Check the status of printers.

   Only the most commonly used options are shown here. For other options, see `lpstat(1)`.

   ```
   
   -d  Shows the system’s default printer.
   
   -p printer-name  Shows if a printer is active or idle, when the printer was enabled or disabled, and whether the printer is accepting print requests.
   
   You can specify multiple printer names with this command. Use a space or a comma to separate printer names. If you use spaces, enclose the list of printer names in quotes. If you don’t specify `printer-name`, the status of all printers is displayed.
   
   -D  Shows the description of the specified `printer-name`.
   
   -l  Shows the characteristics of the specified `printer-name`.
   
   -t  Shows status information about the LP print service, including the status of all printers, such as whether they are active and whether they are accepting print requests.
   
   Examples—Checking the Status of Printers

   The following example shows how to displays the system’s default printer.
   
   ```
   $ lpstat -d
   system default destination: luna
   ```
   
   The following example shows how to display the status of the printer luna.
   
   ```
   $ lpstat -p luna
   printer luna is idle. enabled since Jul 12 11:17 2001. available.
   ```
   
   The following example shows how to display the description of the printers asteroid and luna.
The following example shows how to display the characteristics of the printer luna.

```bash
$ lpstat -p luna -l
printer luna is idle. enabled since Thu Jul 12 15:02:32 ...

Form mounted:
  Content types: postscript
  Printer types: PS
  Description:
  Connection: direct
  Interface: /usr/lib/lp/model/standard
  After fault: continue
  Users allowed:
    (all)
  Forms allowed:
    (none)
  Banner not required
  Character sets:

  Default pitch:
  Default page size: 80 wide 66 long
  Default port settings:
```

### Restarting the Print Scheduler

The print scheduler, `lpsched`, handles print requests on print servers. However, there might be times when the print scheduler stops running on a system, so print requests stop being accepted or printed.

The following section describes how to restart the print scheduler. If a print request was printing when the print scheduler stopped running, the print request will be printed in its entirety when you restart the print scheduler.

#### How to Stop the Print Scheduler

1. Log in as superuser, `lp`, or assume an equivalent role on the print server.

2. Check to see if the print scheduler is running.

   ```bash
   # lpstat -r
   ```

   If the print scheduler is not running, the message `scheduler is not running` is displayed.
3. If the print scheduler is running, stop it.

# /etc/init.d/lp stop

▼ How to Restart the Print Scheduler

1. Log in as superuser, lp, or assume an equivalent role on the print server.

2. Check to see if the print scheduler is running.

   # lpstat -r

   If the print scheduler is not running, the message scheduler is not running is displayed.

3. If the print scheduler is not running, start it.

   # /etc/init.d/lp start

Setting or Resetting Miscellaneous Printer Definitions

This section provides step-by-step instructions on setting or resetting printer definitions. Some of the following printer definitions can be set by using Solaris Print Manager. The following procedures show how to use the LP commands to quickly set or reset printer definitions.

▼ How to Add a Printer Description

1. Log in as superuser, lp, or assume an equivalent role on the print server.

2. Add a printer description.

   # lpadmin -p printer-name -D "comment"

   `-p printer-name` Name of the printer for which you are adding a description.

   `-D "comment"` Specifies the characteristics of the printer, such as location or administrative contact. Enclose characters that the shell might interpret, such as *, ?, \, !, ^, in single quotation marks.

For more information, see `lpadmin(1M)`. 
The printer description is added in the print server's /etc/lp/printers/printer-name/comment file.

3. **Verify that the Description information is correct.**

```bash
$ lpstat -p printer-name -l
```

**Example—Adding a Printer Description**

The following example shows how to add a printer description for the printer luna.

```bash
# lpadmin -p luna -D "Nathans office"
```

**Setting Up a Default Printer Destination**

You can specify a default printer destination for a user so the user does not need to type the printer name when using the print commands. Before you can designate a printer as the default, the printer must be known to the print service on the system. You can set a user's default printer destination by setting any of the following:

- LPDEST environment variable
- PRINTER environment variable
- The _default variable in the user's .PRINTERS file
- The system's default printer by using the lpadmin -d command or Solaris Print Manager

When an application provides a printer destination, that destination is used by the print service, regardless of whether you have set a system's default printer destination. If an application doesn't provide a printer destination or if you don't provide a printer name when using a print command, the print command searches for the default printer in a specific order. The following table shows the search order for a system's default printer destination.

<table>
<thead>
<tr>
<th>Search Order</th>
<th>Using /usr/bin/lp Command</th>
<th>Using lpd-Based Compatibility Commands (lpr, lpq, and lprm)</th>
</tr>
</thead>
<tbody>
<tr>
<td>First</td>
<td>LPDEST variable</td>
<td>PRINTER variable</td>
</tr>
<tr>
<td>Second</td>
<td>PRINTER variable</td>
<td>LPDEST variable</td>
</tr>
<tr>
<td>Third</td>
<td>System's default printer</td>
<td>System's default printer</td>
</tr>
</tbody>
</table>

**▼ How to Set a System's Default Printer**

1. **Log in as superuser, lp, or assume an equivalent role on the system where you want to set a default printer.**
2. Set the system’s default printer.

   # lpadmin -d [printer-name]

   -d printer-name  Name of the printer you are assigning as the system’s default printer. If you don’t specify printer-name, the system is set up with no default printer.

   The default printer name is entered in the system’s /etc/lp/default file.

3. Check the system’s default printer.

   $ lpstat -d

Example—Setting a System’s Default Printer

The following example shows how to set the printer luna as the system’s default printer. This means that luna is used as the system’s default printer if the LPDEST or PRINTER environment variables are not set.

   # lpadmin -d luna
   # lpstat -d
   system default destination: luna

Printing Banner Pages

A banner page identifies who submitted the print request, the print request ID, and when the request was printed. A banner page will also have a modifiable title to help users identify their printouts.

Banner pages make identifying the owner of a print job easy, which is especially helpful when many users submit jobs to the same printer. Printing banner pages uses more paper, however, and might not be necessary if a printer has only a few users. In some cases, printing banner pages is undesirable. For example, if a printer has special paper or forms mounted, like paycheck forms, printing banner pages might cause problems.

By default, the print service forces banner pages to be printed. However, you can give users a choice to turn off printing of a banner page when they submit a print request. You can set this choice through the lpadmin command or through Solaris Print Manager. If you give the users a choice, they have to use the -o banner option to turn off banner page printing.

Also, if you don’t need or want banner pages, you can turn off banner pages so they are never printed. You can turn off banner page printing by using the lpadmin command.
TABLE 5-2 Banner Page Printing

<table>
<thead>
<tr>
<th>Command Used</th>
<th>Banner Page Printing</th>
<th>Override?</th>
</tr>
</thead>
<tbody>
<tr>
<td>lpadmin -p printer -o banner or</td>
<td>Required and printed</td>
<td>If you are a regular user and use \texttt{lp -o nobanner}, the request is printed, but the nobanner argument is ignored.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>If you are root or another privileged user, the nobanner argument is honored.</td>
</tr>
<tr>
<td>lpadmin -p printer -o banner=always</td>
<td>On by default, can be</td>
<td>Non-applicable</td>
</tr>
<tr>
<td></td>
<td>disabled on a per request</td>
<td></td>
</tr>
<tr>
<td></td>
<td>basis with the \texttt{lp -o nobanner} command.</td>
<td></td>
</tr>
<tr>
<td>lpadmin -p printer -o nobanner</td>
<td>Disabled</td>
<td>No</td>
</tr>
<tr>
<td>lpadmin -p printer -o banner=optional</td>
<td></td>
<td></td>
</tr>
<tr>
<td>lpadmin -p printer -o banner=never</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

For step-by-step command-line instructions, see “How to Turn Off Banner Pages” on page 81

\textbf{\textindex{How to Make Banner Pages Optional}}

1. Log in as superuser, \texttt{lp}, or assume an equivalent role on the print server.

   \begin{verbatim}
   # lpadmin -p printer-name -o banner=optional
   \end{verbatim}

   \begin{itemize}
   \item \texttt{-p printer-name} Name of the printer for which you are making banner pages optional.
   \item \texttt{-o banner=optional} Enables users to specify no banner page when they submit a print request.
   \end{itemize}

   If you want to force a banner page to print with every print request, specify the \texttt{-o banner=always} option.

   The banner page setting is entered in the print server’s \texttt{/etc/lp/printers/printer-name/configuration} file.

3. Verify that the output from the following command contains the line \texttt{Bannernot required}.

   \begin{verbatim}
   $ lpstat -p printer-name -l
   \end{verbatim}
Example—Making Banner Pages Optional
The following example shows how to make the banner page optional on the printer luna.

```
# lpadmin -p luna -o banner=optional
```

▼ How to Turn Off Banner Pages
1. Log in as superuser, lp, or assume an equivalent role on the print server.
2. Turn off banner printing.

```
lpadmin -p printer-name -o banner=never
```

- **-p printer-name**
  - Name of the printer for which you are making banner pages optional.

- **-o banner=never**
  - Disables banner page printing under all circumstances.

The banner page setting is entered in the print server’s `/etc/lp/printers/printer-name/configuration` file.

3. Verify that the output from the following command contains the line Banner not printed.

```
$ lpstat -p printer-name -l
```

4. Submit a print request to the printer to make sure a banner page does not print.

Example—Turning Off Printing Banner Pages
The following example shows how to disable printing banner pages on the printer luna.

```
# lpadmin -p luna -o banner=never
```

Setting Up Printer Classes
The print service enables you to group several locally attached printers into one class. You can perform this task only by using the `lpadmin -c` command.

After you set up a printer class, users can then specify the class, rather than individual printers, as the destination for a print request. The first printer in the class that is free to print is used. The result is faster turnaround because printers are kept as busy as possible.
No default printer classes are known to the print service. Printer classes exist only if you define them. Here are some ways you could define printer classes:

- By printer type. For example, a PostScript printer.
- By location. For example, a printer located on the 5th floor.
- By work group or department. For example, the accounting department.

Alternatively, a class might contain several printers that are used in a particular order. The LP print service always checks for an available printer in the order in which printers were added to a class. Therefore, if you want a high-speed printer to be accessed first, you would add the high-speed printer to the class before you add a low-speed printer. As a result, the high-speed printer would handle as many print requests as possible. The low-speed printer would be reserved as a backup printer when the high-speed printer is in use.

**Note** – Print requests are balanced between printers in a class only for local printers.

Class names, like printer names, must be unique and can contain a maximum of 14 alphanumeric characters and underscores.

You are not obligated to define printer classes. You should add them only if you determine that using printer classes would benefit users on the network.

▼ **How to Define a Class of Printers**

1. Log in as superuser, lp, or assume an equivalent role on the print server.

2. Define a class of printers.

   ```bash
   # lpadmin -p printer-name -c printer-class
   ```

   - `-p printer-name` Name of the printer you are adding to a class of printers.
   - `-c printer-class` Name of a class of printers.

   The specified printer is added to the end of the list in the print server’s `/etc/lp/classes/printer-class` file. If the printer class does not exist, it is created.

3. Verify that the printers are in a printer class.

   ```bash
   $ lpstat -c printer-class
   ```
Example—Defining a Class of Printers

The following example shows how to add the printer luna in the printer class roughdrafts.

# lpadmin -p luna -c roughdrafts

Setting Up Printer Fault Alerts

If you choose, the print service can notify you when it detects a printer fault. You can select any of the following methods to receive printer fault notification with the \texttt{lpadmin -A} command or with Solaris Print Manager:

- Write a message to the terminal on which root is logged in
- Electronic mail to root
- No notification

However, the \texttt{lpadmin -A} command offers you an additional option of receiving a message specified by the program of your choice. The \texttt{lpadmin -A} command also enables you to selectively turn off notification for an error that you already know about.

Unless you specify a program to deliver fault notification, the content of the fault alert is a predefined message that says the printer has stopped printing and needs to be fixed.

The following table lists the alert values that you can set for a printer with the \texttt{lpadmin -A} command. These alert values can also be set for print wheels, font cartridges, and forms.

<table>
<thead>
<tr>
<th>Value for -A alert</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'mail [user-name]'</td>
<td>Send the alert message by email to root or \texttt{lpr} on the print server, or the specified \texttt{user-name}, which is a name of a user.</td>
</tr>
<tr>
<td>'write [user-name]'</td>
<td>Send the alert message to the root or \texttt{lpr} console window on the print server, or to the console window of the specified \texttt{user-name}, which is a name of a user. The specified user must be logged in to the print server to get the alert message.</td>
</tr>
<tr>
<td>'command'</td>
<td>Run the \texttt{command} file for each alert. The environment variables and current directory are saved and restored when the file is executed.</td>
</tr>
<tr>
<td>quiet</td>
<td>Stop alerts until the fault is fixed. Use this when you, root or a specified user, receive repeated alerts.</td>
</tr>
</tbody>
</table>
TABLE 5-3 Values for Printing Problem Alerts (Continued)

<table>
<thead>
<tr>
<th>Value for -A alert</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>none</td>
<td>Do not send any alerts. This value setting is the default if you don’t specify fault alerts for a printer.</td>
</tr>
</tbody>
</table>

▼ How to Set Fault Alerts for a Printer

1. Log in as superuser, lp, or assume an equivalent role on the print server.

2. Set fault alerts for a printer.

   # lpadmin -p printer-name -A alert [-W minutes]

   -p printer-name  Name of the printer for which you are specifying an alert for printer faults.
   -A alert         Specifies what kind of alert will occur when the printer faults. For detailed information about the valid values for alert, see Table 5-3. Some valid values are mail, write, and quiet.
   -W minutes       Specifies how often, in minutes, the fault alert will occur. If you don’t specify this option, the alert is sent once.

   The fault alert setting is entered in the print server’s /etc/lp/printers/printer-name/alert.sh file.

3. Check the information following the On fault heading from the output of the following command.

   $ lpstat -p printer-name -l

Examples—Setting Fault Alerts for a Printer

The following example shows how to set up the printer mars to send fault alerts by email to a user named joe, with reminders every 5 minutes.

   # lpadmin -p mars -A ‘mail joe’ -W 5

The following example shows how to set up the printer venus to send fault alerts to the console window, with reminders every 10 minutes.

   # lpadmin -p venus -A write -W 10

The following example shows how to stop fault alerts for the printer mercury.

   # lpadmin -p mercury -A none

The following example shows how to stop fault alerts until the printer venus has been fixed.
Setting Up Printer Fault Recovery

If you choose not to send any fault notification, you can find out about printing faults so you can correct the problem. The LP print service will not continue to use a printer that has a fault. In addition to alerts for printer faults, you can also provide alerts that tell the system administrator to mount print wheels, font cartridges, and forms when print requests require them.

You can define the fault recovery options for a printer only by using the \texttt{lpadmin -F} command. This task is not available in Solaris Print Manager.

Printer faults can be as simple as running out of paper or needing to replace a toner cartridge. Other more serious problems can include complete printer failure or power failure. After you fix a printer fault, the print request that was active when the fault occurred begins printing in one of three ways:

- Starts printing from the beginning
- Continues printing from the top of the page where printing stopped
- After you enable the printer, continues printing from the top of the page where the printing stopped

A print filter is required to continue printing from the top of a page where the printing stopped. A print filter records the control sequences used by the printer to track page boundaries, which the default filters used, but the print service cannot do. You will be notified by the print service if recovery cannot proceed with the specified print filter. For information about writing filters, see “How to Create a New Print Filter” on page 146.

If you want printing to resume immediately after a printer fault is fixed, enable the printer by using the \texttt{enable} command.

The following table lists the fault recovery values you can set for a printer with the \texttt{lpadmin -F} command.

\begin{table}[h]
\centering
\begin{tabular}{|l|l|}
\hline
\textbf{Value for} \texttt{-F recover-options} & \textbf{Description} \\
\hline
beginning & After a fault recovery, printing restarts from the beginning of the file. \\
continue & After a fault recovery, printing starts at the top of the page where the printing stopped. This recovery option requires a print filter. \\
\hline
\end{tabular}
\end{table}
### TABLE 5-4 Values for Printer Fault Recovery (Continued)

<table>
<thead>
<tr>
<th>Value for -F recover-options</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>wait</td>
<td>After a fault recovery, printing stops until you enable the printer. After you enable the printer with the enable command, printing starts at the top of the page where printing stopped. This recovery option requires a print filter.</td>
</tr>
</tbody>
</table>

### How to Set Printer Fault Recovery

1. Log in as superuser, lp, or assume an equivalent role on the print server.
2. Set up fault recovery for the printer.
   ```
   # lpadmin -p printer-name -F recovery-options
   
   -p printer-name  
   Name of the printer for which you are specifying fault recovery.
   
   -F recovery-options  
   One of the three valid recovery options: beginning, continue, or wait.
   
   For detailed information about the valid values for recovery-options, see Table 5-4.
   ```

For more information, see `lpadmin(1M)`.

The fault recovery setting is entered in the print server's `/etc/lp/printers/printer-name/configuration` file.

3. Check the information following the After fault heading in the output of the following command.

   ```
   $ lpstat -p printer-name -l
   ```

### Example—Setting Printer Fault Recovery

The following example shows how to set up the printer luna to continue printing at the top of the page where printing stopped.

```
# lpadmin -p luna -F continue
```
Limiting User Access to a Printer

You can control which users can access some printers or all of the available printers. For example, you can prevent some users from printing on a high-quality printer to minimize expense. To restrict user access to printers, you can create allow and deny lists by using the `lpadmin -u` command on the print server. Solaris Print Manager enables you to create only allow lists. If you create neither, a printer is available to all users who can access the printer.

An allow list contains the names of users allowed access to the specified printer. A deny list contains the names of users denied access to the specified printer.

The rules for allow and deny lists are as follows:

<table>
<thead>
<tr>
<th>Allow and Deny List Rule</th>
<th>User Consequence</th>
</tr>
</thead>
<tbody>
<tr>
<td>Do not create allow and deny lists, or if you leave both lists empty</td>
<td>All users can access the printer.</td>
</tr>
<tr>
<td>Specify <code>all</code> in the allow list</td>
<td>All users can access the printer.</td>
</tr>
<tr>
<td>Specify <code>all</code> in the deny list</td>
<td>All users, except root and lp on the server, are denied access to the printer.</td>
</tr>
<tr>
<td>Make any entry in the allow list</td>
<td>The deny list is ignored. Only those users who are listed can access the printer.</td>
</tr>
<tr>
<td>Create a deny list, but you do not create an allow list or you leave the allow list empty</td>
<td>Users who are listed in the deny list are denied access to the printer.</td>
</tr>
</tbody>
</table>

Because the print server is actually controlling access to the printer, allow and deny lists can only be created on the print server itself. If you create allow and deny lists, the print server will exclusively control user access to printers.

The following table lists the values you can add to an allow or deny list to limit user access to a printer.

**TABLE 5-5 Values for Allow and Deny Lists**

<table>
<thead>
<tr>
<th>Value for <code>user-list</code></th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>user</code></td>
<td><code>User</code> on any system</td>
</tr>
<tr>
<td><code>all</code></td>
<td>All users on all systems</td>
</tr>
<tr>
<td><code>none</code></td>
<td>No user on any system</td>
</tr>
<tr>
<td><code>system!user</code></td>
<td><code>User</code> on system only</td>
</tr>
<tr>
<td><code>!user</code></td>
<td><code>User</code> on local system only</td>
</tr>
</tbody>
</table>
### TABLE 5–5 Values for Allow and Deny Lists (Continued)

<table>
<thead>
<tr>
<th>Value for user-list</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>all!user</td>
<td>User on any system</td>
</tr>
<tr>
<td>all!all</td>
<td>All users on all systems</td>
</tr>
<tr>
<td>system!all</td>
<td>All users on system</td>
</tr>
<tr>
<td>!all</td>
<td>All users on local system</td>
</tr>
</tbody>
</table>

#### How to Limit User Access to a Printer

1. Log in as superuser, lp, or assume an equivalent role on the print server.

2. Allow or deny users access to a printer.

   ```
   # lpadmin -p printer-name -u allow:user-list [-u deny:user-list]
   ```

   - `-p printer-name` Name of the printer to which the allow or deny user access list applies.
   - `-u allow:user-list` User names to be added to the allow user access list. You can specify multiple user names with this command. Use a space or a comma to separate names. If you use spaces, enclose the list of names in quotes.
     
     Table 5-5 provides the valid values for `user-list`.
   
   - `-u deny:user-list` User names to be added to the deny user access list. You can specify multiple user names with this command. Use a space or a comma to separate names. If you use spaces, enclose the list of names in quotes.
     
     Table 5-5 provides the valid values for `user-list`.

   The specified users are added to the allow or deny list for the printer in one of the following files on the print server:

   `/etc/lp/printers/printer-name/users.allow`
   `/etc/lp/printers/printer-name/users.deny`
Note – If you specify none as the value for user-list in the allow list, the following files are not created for the print server:

/etc/lp/printers/printer-name/alert.sh
/etc/lp/printers/printer-name/alert.var
/etc/lp/printers/printer-name/users.allow
/etc/lp/printers/printer-name/users.deny

3. Check the information following the Users allowed or Users denied heading in the output of the following command.

$ lpstat -p printer-name -l

Examples—Limiting User Access to a Printer

The following example shows how to allow only nathan and george access to the printer luna.

# lpadmin -p luna -u allow:nathan,george

The following example shows how to deny nathan and george access to the printer asteroid.

# lpadmin -p asteroid -u deny:"nathan george"

Managing Print Requests

When a user submits a print request from a print client, the print request is added to a queue on the print server before it is sent to the printer. While a print request is in the queue, you can cancel or gain status information on the request from a client system. You must login to the print server to move, hold, resume, or change the priorities of print requests with LP commands. These actions can help you keep printing services operating smoothly.

The following table lists the values for changing the priority of a print request with the lp -H command.
### TABLE 5-6 Values for Changing the Priority of a Print Request

<table>
<thead>
<tr>
<th>Value for <code>-h change-priority</code></th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>hold</td>
<td>Places the print request on hold until you cancel the request or instruct the LP print service to resume printing the request.</td>
</tr>
<tr>
<td>resume</td>
<td>Places a print request that has been on hold back in the queue. The request will be printed according to its priority and placement in the queue. If you put a hold on a print job that is already printing, <code>resume</code> puts the print request at the head of the queue so it becomes the next request printed.</td>
</tr>
<tr>
<td>immediate</td>
<td>Places a print request at the head of the queue. If a request is already printing, you can put the request on hold to allow the next request to print immediately.</td>
</tr>
</tbody>
</table>

### How to Check the Status of Print Requests

1. Log in on any system on the network.

2. **Check the status of printers and print requests.**
   - Only the most commonly used options are shown here. For other valid options, see `lpstat(1).
   ```
   $ lpstat -o [list] | -u [user-list]
   ```
   - `-o list`  
     Shows the status of print requests on a specific printer. `list` can be one or more printer names, printer class names, or print request IDs.
     - You can specify multiple printer names, class names, and IDs for `list`. Use a space or a comma to separate values. If you use spaces, enclose the list of values in quotes.
     - If you don’t specify `list`, the status of print requests to all printers is displayed.
   - `-u user-list`  
     Shows the status of print requests for a specific user. `user-list` can be one or more user names.
     - You can specify multiple users with this command. Use a space or a comma to separate user names. If you use spaces, enclose the list of names in quotes.
     - If you don’t specify `user-list`, the status of print requests for all users is displayed.
When used to check the status of print requests, the `lpstat` command displays one line for each print request. From left to right, the line shows the request ID, the user, the output size in bytes, the date and time of the request, and information about the request, such as “being filtered.”

Examples—Checking the Status of Print Requests

The following example shows that user `fred` has one print request queued to the printer `luna`.

```
$ lpstat
luna-1 fred 1261 Jul 12 17:34
```

The following example shows that the user `paul` currently has no print requests in queue.

```
$ lpstat -u paul
```

The following example shows that two print requests are queued on the printer `moon`.

```
$ lpstat -o moon
moon-78 root 1024 Jul 14 09:07
moon-79 root 1024 Jul 14 09:08
```

Enabling or Disabling a Printer From Printing

The `enable` and `disable` commands control whether a printer prints or stops printing requests that are in the print queue. When you disable a printer, the printer stops printing requests in queue. However, requests are still added to the queue. You must set the printer to reject print requests so requests are not added to the queue. For information about rejecting print requests, see “Accepting or Rejecting Print Requests” on page 93.

A printer is enabled to print and accepts print requests when the printer is added by using Solaris Print Manager. Solaris Print Manager doesn’t provide any additional printer processing management.

You must enable the printer whenever it has been disabled, which can happen when a printer fault occurs. When you enable a printer, it prints requests from the print queue until the queue is empty, even if the print service rejects additional requests for the print queue.

The following figure shows the point at which processing of print requests is interrupted when a printer is disabled.
How to Enable or Disable a Printer

1. Log in as superuser, lp, or assume an equivalent role on the print server.

2. Stop printing print requests.

   ```
   # disable [-c | -W] [-r "reason"] printer-name
   ```

   - `disable` Cancels the current job, then disables the printer. The current job is saved to reprint when the printer is enabled.
   - `-c` Cancels the current job, then disables the printer. The current job is not printed later.
   - `-W` Waits until the current job is finished before disabling the printer.
   - `-r "reason"` Provides users with a reason why the printer is disabled. The reason is stored and displayed whenever a user checks on the status of the printer with the `lpstat -p` command.
   - `printer-name` Name of the printer that will stop printing print requests.

   **Note** — You cannot enable or disable classes of printers. Only individual printers can be enabled or disabled.

3. Start printing print requests.

   ```
   # enable printer-name
   ```

4. Verify that the printer is enabled.

   ```
   $ lpstat -p printer-name
   ```
Examples—Enabling or Disabling a Printer

The following example shows how to stop the current job on the printer luna, save it to print later, and provide a reason why the printer has stopped printing print requests.

# disable -r "changing the form" luna

The following example shows how to start printing print requests on the printer luna.

# enable luna
printer "luna" enabled

Accepting or Rejecting Print Requests

The accept and reject commands enable you to turn on or turn off a print queue that stores requests to be printed.

When you use the reject command, the print queue for a specified printer is turned off. No new print requests can enter the queue on the print server. All print requests that are in the queue are still printed. You must disable the printer if you want it to stop printing requests that are already in the queue. The following table compares the functions of the accept, reject, enable, and disable commands.

<table>
<thead>
<tr>
<th>Command</th>
<th>Function</th>
</tr>
</thead>
<tbody>
<tr>
<td>accept</td>
<td>Accept print requests that are sent to the print queue.</td>
</tr>
<tr>
<td>enable</td>
<td>Print the requests that are in the print queue.</td>
</tr>
<tr>
<td>reject</td>
<td>Reject print requests that are sent to the print queue.</td>
</tr>
<tr>
<td>disable</td>
<td>Stop printing requests that are currently in the print queue.</td>
</tr>
</tbody>
</table>

If a print request is rejected, the print service writes or mails a message to the user who submitted the request, saying that print requests are not being accepted for the specified printer.

You can also specify a reason for not accepting requests through the command line. The reason is displayed on users’ systems when one tries to check the printer’s queue. The following figure shows the point at which processing of print requests is interrupted when a print queue rejects print requests.
How to Accept or Reject Print Requests for a Printer

1. Log in as superuser, lp, or assume an equivalent role on the print server.

2. Stop accepting print requests for the printer.

```bash
# reject [-r "reason"] printer-name
```

- `-r "reason"` Provides users a reason why the printer is rejecting print requests. The reason is stored and displayed whenever a user checks on the status of the printer with the `lpstat -p` command.

- `printer-name` Name of the printer that will stop accepting print requests.

The queued requests will continue printing as long as the printer is enabled. For instructions on disabling a printer so it stops printing, see “How to Enable or Disable a Printer” on page 92.

3. Start accepting print requests for the printer.

```bash
# accept printer-name
```

4. Check that the status of the printer to see whether it is accepting or rejecting print requests.

```bash
$ lpstat -p printer-name
```

Examples—Accepting or Rejecting Print Requests for a Printer

The following example shows how to stop the printer *luna* from accepting print requests.
The following example shows how to set the printer luna to accept print requests.

```bash
# accept luna
destination "luna" now accepting requests
```

### Canceling a Print Request

You can use the `cancel` command to cancel print requests from printer queues or to cancel jobs that are printing. Three ways to use the `cancel` command are as follows:

- Cancel requests by request identification number (request ID)
- Cancel requests from a specific user on all printers or specific printers
- Cancel the job currently printing

When you use the `cancel` command, a message tells you the request(s) are canceled, and the next request in queue is printed. You can cancel a print request only if you are:

- The user who submitted the request and you are logged in on the system from which you submitted the request
- The user who submitted the request on any client system and the print server has the “user-equivalence” option configured for the printer in its `/etc/printers.conf` file.
- Logged in as superuser or `lp` or have assumed an equivalent role on the print server.

To cancel a specific request, you need to know its request ID. The request ID contains the name of the printer, a dash, and the number of the print request. For example, `luna-185`.

When you submit the print request, the request ID is displayed. If you do not remember the print request ID, you can find it by using the `lpstat` command with the `-o printer` option.

#### How to Cancel a Print Request

1. If you are going to cancel print requests of other users, become superuser, `lp`, or assume an equivalent role.

2. Determine the request IDs of the print requests to cancel.

   ```bash
   # lpstat
   For more details, see “How to Check the Status of Print Requests” on page 90.
   ```

3. Cancel a print request.
$ cancel request-id | printer-name

request-id  Request ID of a print request to be canceled. You can specify multiple request IDs with this command. Use a space or a comma to separate request IDs. If you use spaces, enclose the list of request IDs in quotes.

printer-name Specifies the printer for which you want to cancel the currently printing print request.

You can specify multiple printer names with this command. Use a space or a comma to separate printer names. If you use spaces, enclose the list of printer names in quotes.

4. Verify that the print requests are canceled.

$ lpstat -o printer-name

Examples—Canceling a Print Request

The following example shows how to cancel the luna-3 and luna-4 print requests.

$ cancel luna-3 luna-4
request "luna-3" cancelled
request "luna-4" cancelled

The following example shows how to cancel the print request that is currently printing on the printer luna.

# cancel luna
request "luna-9" cancelled

How to Cancel a Print Request From a Specific User

1. (Optional) Become superuser, lp, or assume an equivalent role if you are going to cancel print requests of other users.

2. Cancel a print request from a specific user.

$ cancel -u user-list [printer-name]
-u user-list Cancels the print request for a specified user. 

user-list can be one or more user names. Use a space or a comma to separate user names. If you use spaces, enclose the list of names in quotes.

printer-name Specifies the printer for which you want to cancel the specified user’s print requests. 

printer-name can be one or more printer names. Use a space or a comma to separate printer names. If you use spaces, enclose the list of printer names in quotes. 

If you don’t specify the printer-name, the user’s print requests will be canceled on all printers.

Examples—Canceling a Print Request From a Specific User

The following example shows how to cancel all the print requests submitted by the user george on the printer luna.

# cancel -u george luna

request "luna-23" cancelled

The following example shows how to cancel all the print requests submitted by the user george on all printers.

# cancel -u george

request "asteroid-3" cancelled
request "luna-8" cancelled

Moving a Print Request

If you plan to change the way a printer is used or decide to take a printer out of service, you should set up the LP print service to reject additional print requests. Then, move or cancel any requests that are currently queued to the printer. You can use the lpmove command to move individual or all print requests to another local printer.

Request IDs are not changed when you move print requests, so users can still find their requests. Print requests that have requirements, such as file content type or forms, that cannot be met by the newly specified printer cannot be moved. These print requests must be canceled.

How to Move Print Requests to Another Printer

To move all print requests from one printer to another printer, you do not need to know the request IDs. However, it is a good idea to see how many print requests are affected before you move them.
1. Log in as superuser, lp, or assume an equivalent role on the print server.

2. (Optional) Check the request IDs of the print requests on the original printer.
   
   # lpstat -o printer-name1

3. (Optional) Check to see if the destination printer is accepting print requests.
   
   # lpstat -p printer-name2

   -p printer-name2 Name of the printer to which you are moving the print requests.

4. Move all the print requests from the original printer to the destination printer.
   
   # lpmove printer-name1 printer-name2

   printer-name1 Name of the printer from which all print requests will be moved.
   
   printer-name2 Name of the printer to which all print requests will be moved.

   For more information, see lpmove(1M).

   If some requests cannot be printed on the destination printer, the requests are left in
   the original printer’s queue. By using request IDs, you can also move specific print
   requests to another printer with the lpmove command.

5. Start accepting print requests on the original printer.
   
   If you move all the print requests to another printer, the lpmove command
   automatically stops accepting print requests for the printer. This step is necessary if
   you want to begin accepting new print requests for the printer.
   
   # accept printer-name1

6. Check for any remaining print requests in the original printer’s queue.
   
   $ lpstat -o printer-name1
   Make sure all specified print requests were moved to the destination printer’s queue
   by using the following command.
   
   $ lpstat -o printer-name2

Example—Moving Print Requests to Another Printer

The following example shows how to move print requests from the printer luna to
the printer terra, and then tells the original printer luna to resume accepting print
requests.

# lpmove luna terra
# accept luna
Changing the Priority of Print Requests

After a user has submitted a print request, you can change its priority in the print server’s queue by:

- Putting any print request on hold if it has not finished printing. Putting a request on hold stops it, if it is currently printing, and keeps it from printing until you resume printing it. Other print requests go ahead of the on-hold request.

- Moving any print request to the head of the queue, where it will be the next job eligible for printing. If you want a job to start printing immediately, you can interrupt the job that is currently printing by putting it on hold.

- Changing the priority of a job still waiting to be printed, moving it in the queue so it is ahead of lower priority requests and behind requests at the same level or at a higher priority.

▼ How to Change the Priority of a Print Request

1. Log in as superuser, lp, or assume an equivalent role on the print server that is holding the print request.

2. Determine the request IDs of the print requests whose priority you want to change.
   
   # lpstat
   For more information, see “How to Check the Status of Print Requests” on page 90.

3. Change the priority of a print request.
   
   # lp -i request-id -H change-priority

   -i request-id
   Request ID of a print request you want to change.
   You can specify multiple request IDs with this command. Use a space or a comma to separate request IDs. If you use spaces, enclose the list of request IDs in quotes.

   -H change-priority
   One of the three ways to change the priority of a print request: hold, resume, immediate.
   For detailed information about valid values for change-priority, see Table 5-6.

You can also use the lp -q command to change the priority level of a specified print request. You can change the priority level from 0, the highest priority, to 39, the lowest priority.
Example—Changing the Priority of a Print Request

The following example shows how to change a print request with the request ID asteroid-79, to priority level 1.

```
# lp -i asteroid-79 -q 1
```
CHAPTER 6

Managing Character Sets, Filters, Forms, and Fonts (Tasks)

This chapter provides background information and step-by-step instructions for setting up and administering character sets, print filters, forms, and fonts.

This is a list of the step-by-step instructions in this chapter.
- “How to Define a Print Wheel or Font Cartridge” on page 104
- “How to Unmount and Mount a Print Wheel or Font Cartridge” on page 105
- “How to Set an Alert to Mount a Print Wheel or Font Cartridge” on page 106
- “How to Set Up an Alias for a Selectable Character Set” on page 108
- “How to Add a Print Filter” on page 111
- “How to Delete a Print Filter” on page 112
- “How to View Information About a Print Filter” on page 112
- “How to Add a Form” on page 116
- “How to Delete a Form” on page 117
- “How to Unmount and Mount a Form” on page 117
- “How to Set an Alert to Mount a Form” on page 119
- “How to View Information About a Form” on page 120
- “How to View the Current Status of a Form” on page 120
- “How to Limit User Access to a Form” on page 121
- “How to Limit Printer Access to a Form” on page 122
- “How to Install Downloaded PostScript Fonts” on page 125
- “How to Install Host-Resident PostScript Fonts” on page 125

For overview information about printing, see Chapter 2.

Managing Character Sets
Printers differ in the method they use to print text in various font styles. For example, PostScript printers treat text as graphics. These printers can generate text in different fonts, and place the text in any position, size, or orientation on the page. Other types
of printers support a more limited number of font styles and sizes, using either print wheels, font cartridges, or preprogrammed selectable character sets. Usually, only one of these printing methods applies to a given printer type.

Print wheels and font cartridges, from the perspective of the LP print service, are similar, because someone must intervene and mount the hardware on the printer, when needed. Character sets that require you to physically mount a wheel or cartridge are referred to as hardware character sets. Character sets that do not require hardware mounting, that come preprogrammed with the printer, and can be selected by a print request, are referred to as software character sets.

When you set up a non-PostScript printer, you need to tell the LP print service which print wheels or selectable character sets are available to users. When users submit print requests, the `lp -S` command enables them to specify a print wheel or selectable character set to use for the print job. Users do not have to know which type of character set applies. They just refer to the font style by the name you have defined. For example, you can define a print wheel as `gothic`. To request the `gothic` print wheel, the user would use the following command:

```
% lp -S gothic filename
```

## Selectable Character Sets

The selectable character sets supported by a printer are listed in the `terminfo` entry for that printer. For example, the entry for the `ln03` printer is `/usr/share/lib/terminfo/l/ln03`. You can find the names of selectable character sets for any printer type in the `terminfo` database by using the `tput` command. The syntax for the `tput` command is:

```
tput -T printer-type cs
```

The `csn` option is an abbreviation for character set number. The number starts with 0, which is always the default character set number after the printer is initialized. You can repeat the command, using `-1`, `-2`, `-3`, and so on in place of the `-0`, to display the names of the other character sets. For each selectable character set, a `terminfo` name (for example, `usascii`, `english`, `finnish`, and so forth) is returned.

In general, the `terminfo` character set names should closely match the character set names used in the manufacturer’s documentation for the printer. Because manufacturers do not all use the same character set names, the `terminfo` character set names can differ from one printer type to the next.

You do not have to register the selectable character set names with the LP print service. However, you can give them more meaningful names or aliases.
Note – If you do not specify the selectable character sets that can be used with a printer, the LP print service assumes that the printer can accept any character set name (such as cs0, cs1, or cs2) or the terminfo name known for the printer.

Users can use the `lpstat -p -l` command to display the names of the selectable character sets that you have defined for each printer on a print server.

Note – Character sets for PostScript printers are not listed when you use the `lpstat -p -l` command because the PostScript fonts are controlled by PostScript filters, not by entries in the terminfo database. For information about how to administer PostScript fonts, see “Managing Fonts” on page 123.

Hardware-Mounted Character Sets

Another method to obtain alternative character sets is to use removable print wheels or font cartridges that you physically attach, or mount, in a printer.

To administer hardware-mounted character sets, you inform the LP print service of the names you want to use for the available print wheels, and how you want to be alerted when a printer needs a different print wheel. Then, when a user requests a particular character set with the `lp -s` command, the scheduler sends an alert to mount the print wheel, and the print request is placed in the print queue. When you mount the correct print wheel and tell the LP print service that the print wheel is mounted, the job is printed. For more information, see “How to Unmount and Mount a Print Wheel or Font Cartridge” on page 105.

If you do not specify multiple print wheels or cartridges for a printer, the LP print service assumes that the printer has a single, fixed print wheel or cartridge, and users cannot specify a special print wheel or cartridge when using the printer.

Unlike selectable character sets, the names you use for print wheels or cartridges are not tied to entries in the terminfo database. Print wheel or cartridge names are used only for the purpose of communicating with the LP print service and its users.

The names you choose for print wheels or cartridges, however, should have meaning to the users. The names should refer to font styles. In addition, the names should be the same across printers that have similar print wheels or cartridges, or selectable character sets. That way, users can ask for a font style (character set) without regard to which printer—or even whether a print wheel or cartridges—or selectable character set will be used.

Of course, you and the printer users should agree on the meanings of print wheel or cartridge names. Otherwise, what a user asks for and what you mount, might not be the same character set.
Tracking Print Wheels

The procedure for tracking print wheels is similar to the procedure for tracking forms. Some printers (usually letter-quality printers) have removable print heads, such as print wheels or print cartridges, that provide a particular font or character set. A user can request a named character set. If that character set is not available, the LP print service notifies root of the request. The job is stored in the print queue until the print wheel is changed.

Alerts for Mounting Print Wheels or Cartridges

You request alerts for mounting print wheels or cartridges in the same way you request other alerts from the LP print service. For general information about alerts, see “Setting Up Printer Fault Alerts” on page 83.

▼ How to Define a Print Wheel or Font Cartridge

1. Log in as superuser, lp, or assume an equivalent role on the print server.

2. Define a print wheel or font cartridge that can be used with the printer.

   \texttt{print-server# lpadmin -p printer-name -S hard-charset1 [,hard-charset2 ...]}

   \begin{itemize}
   \item \texttt{-p printer-name} Name of the printer for which you are defining a print wheel or font cartridge.
   \item \texttt{-S hard-charset} Hardware character set name of the print wheel or font cartridge.
   \end{itemize}

   You can specify multiple hardware character sets with this command. Use commas or spaces to separate character set names. If you use spaces, enclose the list of character set names in quotes.

   Define names that are meaningful to users, and inform the users of the names.

   The print wheel or font cartridge definition is added in the print server’s 
   /etc/lp/printers/printer-name/configuration file.

3. Log in as superuser, lp, or assume an equivalent role on a print client of the print server.

4. Define the same print wheel or font cartridge for the print client.

   \texttt{print-client# lpadmin -p printer-name -S hard-charset1 [,hard-charset2 ...]}

   In this command, the variables are the same as those in Step 2.
The print wheel or font cartridge definition is added in the print client’s
/etc/lp/printers/printer-name/configuration file.

5. Repeat Step 3 and Step 4 for each print client that might need to use the print wheel
or font cartridge.

6. Verify that the information following the Character sets heading in the
following output is correct on both the print server and the print client.

```bash
$ lpstat -p printer-name -l
```

Example—Defining a Print Wheel

The following example shows how to define the pica print wheel on the printer luna
for a print client named asteroid.

```bash
asteroid# lpadmin -p luna -S pica
```

▼ How to Unmount and Mount a Print Wheel or
Font Cartridge

1. Log in as superuser, lp, or assume an equivalent role on the print server.

2. Unmount the print wheel or font cartridge that is in the printer.

```bash
# lpadmin -p printer-name -M -S none
```

- `-p printer-name` Printer on which you are unmounting a print wheel or font
cartridge.

- `-M -S none` Specifies unmounting the current print wheel or font cartridge.

For more information, see `lpadmin(1M)`.

The current print wheel or font cartridge is deleted from the print server’s
/etc/lp/printers/printer-name/configuration file.

3. Remove the print wheel or font cartridge from the printer.

4. Put the new print wheel or font cartridge in the printer.

5. Mount the new print wheel or font cartridge.

```bash
# lpadmin -p printer-name -M -S hard-charset
```
Printer on which you are mounting a print wheel or font cartridge.

Hardware character set name of the print wheel or font cartridge you want to mount.

The print wheel or font cartridge is added in the print server’s /etc/lp/printers/printer-name/configuration file. The mounted print wheel or font cartridge remains active until it is unmounted or until a new print wheel or font cartridge is mounted.

6. Check that the information under the Print wheels or Character set heading in the output of the following command. You should see the name of the print wheel or character set and the notation (mounted)

```
$ lpstat -p printer-name -l
```

Example—Unmounting and Mounting a Print Wheel

The following example shows how to unmount the current print wheel on the printer luna and mount the pica print wheel.

```
# lpadmin -p luna -M -S none
# lpadmin -p luna -M -S pica
```

▼ How to Set an Alert to Mount a Print Wheel or Font Cartridge

1. Log in as superuser, lp, or assume an equivalent role on the print server.

2. Set an alert to mount a print wheel or font cartridge.

```
# lpadmin -S hard-charset -A alert [-Q requests] [-W minutes]
```

Hardware character set name of the print wheel or font cartridge for which you want to set an alert.
-A alert  Specifies what kind of alert will occur when a print wheel or font cartridge is requested. For detailed information about the valid values for alert, see Table 5-3. Some valid values are mail, write, and quiet.

If you specify mail or write, a predefined alert message says to mount the specified print wheel or font cartridge and includes the names of one or more printers that have been set up to use such a print wheel or cartridge.

-Q requests  Specifies the number of print requests that require the print wheel or font cartridge that must be in the queue before an alert occurs. If you don’t specify this option, only one print request in the queue triggers an alert.

-W minutes  Specifies how often (in minutes) the alert will occur. If you don’t specify this option, the alert is sent only once.

For more information, see lpadmin(1M).

The alert is added in the print server’s /etc/lp/pwheels/charset-name/alert.sh file.

3. Verify that the alert has been added for the print wheel or font cartridge by checking the output of the following command.

# lpadmin -S hard-charset -A list

Otherwise, if you have set a low number of print requests to trigger the alert, submit enough print requests to meet the minimum requirement and make sure you receive an alert to mount the print wheel or font cartridge.

Examples—Setting an Alert to Mount a Print Wheel or Font Cartridge

The following example shows how to set email alerts to occur every five minutes for the elite print wheel when there are ten print requests for elite in the print queue.

# lpadmin -S elite -A mail -Q 10 -W 5

The following example shows how to set email alerts to occur every minute for the finnish font cartridge when there are five print requests for finnish in the print queue.

# lpadmin -S finnish -A mail -Q 5 -W 1

The following example shows how to set console-window alerts to occur every 10 minutes for the elite print wheel when there are five print requests for elite in the print queue.

# lpadmin -S elite -A write -Q 5 -W 10
The following example shows how to set no alerts to occur for the `elite` print wheel.

```
# lpadmin -S elite -A none
```

▼ How to Set Up an Alias for a Selectable Character Set

You do not need to perform this procedure if the `terminfo` names for the selectable character sets are adequate. For more information on using the `terminfo` database, see “Adding a `terminfo` Entry for an Unsupported Printer” on page 129.

1. Log in as superuser, `lp`, or assume an equivalent role on the print server.

2. Display the names of the selectable character sets for the specified printer type.

```
# tput -T printer-type cs
```

- `-T printer-type` Printer type found in the `terminfo` database. For information on entries in the `terminfo` database, see “Printer Type” on page 44

- `n` Number (0, 1, 2, 3, 4, 5, and so on) that represents a selectable character set for the specified printer type. The system displays the selectable character set name followed by the prompt symbol. For example, `cs1` could cause the system to display `enenglish#`.

For more information, see `tput(1)`.

3. Set up an alias for a selectable character set.

```
# lpadmin -p printer-name -S select-charset1=alias1[,select-charset2=alias2...]
```

- `-p printer-name` Printer on which you are setting up aliases for selectable character sets.

- `-S select-charset` Selectable character set name for which to set an alias. The name can be found in Step 2

- `alias` Alias for the specified selectable character set. This alias can be used in addition to the selectable character set name.

You can set up more than one alias with this command. Use commas or spaces to separate the aliases. If you use spaces, enclose the list of aliases in quotes.

The alias is added in the print server’s `/etc/lp/printers/printer-name/configuration` file.
4. Log in as superuser, lp, or assume an equivalent role on a system that is a print client of the print server.

5. Set up an alias for the selectable character set.

   
   \# \texttt{lpadmin -p printer-name -S select-charset1=alias1[.select-charset2=alias2][...]
   
   In this command, the variables are the same as those in Step 3.
   
   The alias is added in the print client's `/etc/lp/printers/printer-name/configuration` file.

6. Repeat Step 4 and Step 5 for each print client that might need to use the alias.

7. Verify that the selectable character set alias is listed in the output of the following command on the print server and print clients.

   $ \texttt{lpstat -p printer-name -l}
   
   Otherwise, submit a print request that uses the alias for the selectable character set and check for output.

Example—Setting Up an Alias for a Selectable Character Set

The following example shows how to display the names of selectable character sets and specify `text` as an alias for the `usascii` selectable character set on the printer `luna`, which is an `ln03` printer type.

   
   \# \texttt{tput -T ln03 cs0 usascii}\# \texttt{tput -T ln03 cs1 english}\# \texttt{tput -T ln03 csn2 finnish}\# \texttt{tput -T ln03 csn3 japanese}\# \texttt{tput -T ln03 cs4 norwegian}\#
   
   \# \texttt{lpadmin -p luna -S usascii=text}

Managing Print Filters

Print filters are programs that convert the content type of a file to a content type that is acceptable to the destination printer. The LP print service uses filters to:

- Convert a file from one data format to another format so that it can be printed properly on a specific type of printer
- Handle the special modes of printing, like two-sided printing, landscape printing, or draft- and letter-quality printing
- Detect printer faults and notify the LP print service of them so the print service can alert users and system administrators
Not every print filter can perform all these tasks. Because each task is printer-specific, the tasks can be implemented separately.

The LP print service provides the PostScript filters listed in Table 6–1. The filter programs are located in the /usr/lib/lp/postscript directory. For PostScript printing, you usually do not need to do anything beyond installing the filter programs when setting up a print server. Solaris Print Manager automatically enables the supplied filters. However, if you administer other printers, you might need to administer print filters for them.

Creating Print Filters

To create a new print filter, you must write a print filter program and create a print filter definition. Filters contain input types, output types, and complex options that provide a language to process command-line arguments within the filter. For background information and step-by-step instructions, see “Creating a New Print Filter” on page 137.

Adding, Changing, Removing, and Restoring Print Filters

Print filters are added, changed, or removed on the print server only.

You can use the lpfilter command to manage the list of available filters. System information about filters is stored in the /etc/lp/filter.table file. The lpfilter command gets the information about filters to write to the table from filter descriptor files. The filter descriptor files supplied (PostScript only) are located in the /etc/lp/fd directory. The actual filter programs are located in the /usr/lib/lp directory.

The LP print service imposes no fixed limit on the number of print filters you can define. You can remove filters that are no longer used to avoid extra processing by the LP print service. (LP examines all filters to find one that works for a specific print request.) If in doubt, do not remove a filter.

As you add, change, or delete filters, you can overwrite or remove some of the original filters provided by the LP print service. You can restore the original set of filters, if necessary, and remove any filters you have added.

SunOS software provides a default set of PostScript filters, which Solaris Print Manager automatically adds to a print server. Some of the TranScript filters used with lpd-based print services have SunOS equivalents, but others do not. The following table lists the default PostScript filters and identifies the TranScript filters, where applicable.
TABLE 6-1 Default PostScript Filters

<table>
<thead>
<tr>
<th>Filter</th>
<th>Action</th>
<th>TranScript Equivalent</th>
</tr>
</thead>
<tbody>
<tr>
<td>download</td>
<td>Download fonts</td>
<td></td>
</tr>
<tr>
<td>dpost</td>
<td>ditroff to PostScript</td>
<td>psdit</td>
</tr>
<tr>
<td>postdaisy</td>
<td>daisy to PostScript</td>
<td></td>
</tr>
<tr>
<td>postdmd</td>
<td>dmd to PostScript</td>
<td></td>
</tr>
<tr>
<td>postio</td>
<td>Serial interface for PostScript printer</td>
<td>pscomm</td>
</tr>
<tr>
<td>postior</td>
<td>Communicate with printer</td>
<td></td>
</tr>
<tr>
<td>postmd</td>
<td>Matrix gray scales to PostScript</td>
<td></td>
</tr>
<tr>
<td>postplot</td>
<td>plot to PostScript</td>
<td>psplot</td>
</tr>
<tr>
<td>postprint</td>
<td>simple to PostScript</td>
<td>enscript</td>
</tr>
<tr>
<td>postreverse</td>
<td>Reverse or select pages</td>
<td>psrev</td>
</tr>
<tr>
<td>posttek</td>
<td>TEK4014 to PostScript</td>
<td>ps4014</td>
</tr>
</tbody>
</table>

The SunOS software does not provide the following filters:

- TEX
- oscat (NeWSprint opost)
- Enscript

The postreverse, postprint, postio, and dpost filters are provided in place of Enscript.

Solaris Print Manager adds the default PostScript filters to a print server. If you have printing needs that are not met by these filters, see “How to Create a New Print Filter” on page 146 for information about writing a custom print filter.

▼ How to Add a Print Filter

1. Log in as superuser, lp, or assume an equivalent role on the print server.

2. Add a print filter that is based on a print filter definition.

   # lpfilter -f filter-name -F filter-def

   -f filter-name          Name you choose for the print filter.
   -F filter-def           Name of the print filter definition.
For more information, see `lpfilter`(1M).
The print filter is added in the print server’s `/etc/lp/filter.table` file.

3. Verify that the print filter was added by checking for information about the print filter in the output of the following command.
   
   ```
   # lpfilter -f filter-name -l
   ```

   **Example—Adding a Print Filter**
   
   The following example shows how to add the `daisytroff` print filter that has the `daisytroff.fd` print filter definition.
   
   ```
   # lpfilter -f daisytroff -F /etc/lp/fd/daisytroff.fd
   ```

   ▼ **How to Delete a Print Filter**

   1. Log in as superuser, `lp`, or assume an equivalent role on the print server.

   2. Delete the print filter.
      
      ```
      # lpfilter -f filter-name -x
      ```

      `-f filter-name` Name of the print filter to be deleted.

      `-x` Deletes the specified filter.

      The print filter is deleted from the print server’s `/etc/lp/filter.table` file.

   3. **Verify that filter was deleted.**
      
      ```
      # lpfilter -f filter-name -l
      ```

      You should receive an error indicating that no filter by the specified name exists.

   **Example—Deleting a Print Filter**

   The following example shows how to delete the `daisytroff` print filter.

   ```
   # lpfilter -f daisytroff -x
   ```

   ▼ **How to View Information About a Print Filter**

   1. Log in as superuser, `lp`, or assume an equivalent role on the print server.

   2. Request information about a print filter.
      
      ```
      # lpfilter -f filter-name -l
      ```
-f filter-name  Print filter for which you want to view information. Specify all for filter-name to view information about all the available print filters.

-1  Displays information about the specified filter.

Information about the specified print filter(s) is displayed.

Examples—Viewing Information About a Print Filter

The following example shows how to request information for the postdaisy print filter, and the information that is displayed in response.

```bash
# lpfilter -f postdaisy -l
Input types: daisy
Output types: postscript
Printer types: any
Printers: any
Filter type: slow
Command: /usr/lib/lp/postscript/postdaisy
Options: PAGES*=-o*
Options: COPIES*=-c*
Options: MODES group\=[\(2-9]\) = -n\1
Options: MODES portrait = -pp
Options: MODES landscape = -pl
Options: MODES x\=[\(-.*[.0-9]*\)] = -x\1
Options: MODES y\=[\(-.*[.0-9]*\)] = -y\1
Options: MODES magnify\=[\(.*[.0-9]*\)] = -m\1
```

The following example shows how to redirect information about the daisytroff filter to a file (create the filter definition for that filter). This is useful if a filter definition is removed unintentionally.

```bash
# lpfilter -f daisytroff -l > daisytroff.fd
```

The following example shows how to display all the print filters that have been added to the system, and the information that is displayed in response.

```bash
# lpfilter -f all -l | grep Filter
(Filter "download")
Filter type: fast
(Filter "postio")
Filter type: fast
(Filter "postior")
Filter type: fast
(Filter "postreverse")
Filter type: fast
(Filter "slow")
Filter type: slow
Managing Forms

A form is a sheet of paper on which information is printed in a predetermined format. Unlike plain paper stock, forms usually have text or graphics preprinted on them. Common examples of forms are company letterhead, invoices, blank checks, receipts, and labels.

The term form has two meanings: the physical medium (the paper) and the software that defines a form to the LP print service.

The LP print service allows you to control the use of forms. This section provides information about adding, changing, removing, mounting, and controlling access to forms.

Adding, Changing, or Deleting Forms

When you add a form, you tell the LP print service to include the form in its list of available forms. You also have to supply the information required to describe or define the form. Although you can enter such definitions when you add the form, it helps to create the definitions first and save them in files. You can then change the form definition by editing the file.

Note – No form definitions are supplied with the LP print service.

To change a form, you must re-add the form with a different definition.

The LP print service imposes no limit on the number of forms you can define. However, you should delete forms that are no longer appropriate. Obsolete forms can result in unnecessary processing by the print service.

Mounting Forms

To print a form, you must load the paper in the printer and use a command to mount the form, which notifies the LP print service that print requests submitted to the printer are to be printed using the form definition. If you use one printer for different types of printing, including forms, you should:

- Disable the printer before you load the paper and mount the form.
- Re-enable the printer when the form is ready. Otherwise, the LP print service will continue to print files that do not need the form on the printer.
When you mount a form, make sure it is aligned properly. If an alignment pattern has been defined for the form, you can request that the pattern print repeatedly after you have mounted the form until you have adjusted the printer so the alignment is correct.

When you want to change or discontinue using a form on a printer, you must notify the LP print service by unmounting the form.

Tracking Forms

The LP print service helps you track which forms are mounted on each printer and notifies you when it cannot find a description it needs to print a form. You are responsible for creating form descriptions and mounting and unmounting form paper in each printer, either as part of setting up a printer or in response to alerts from the LP print service.

Users can specify the form on which they want a job to print. As root, you can mount a specific form, then tell the LP print service that the form is available and on which printer it is mounted. Users can submit print requests specifying a particular form. When the LP print service receives the request, it sends an alert message to root requesting that you mount the form.

Defining Alerts for Mounting Forms

You request alerts for mounting forms in the same way you request other alerts from the LP print service. For general information about alerts, see “Setting Up Printer Fault Alerts” on page 83.

Checking Forms

When you have defined a form for the LP print service, you can check it with either of two commands, depending on the type of information you want to check.

- Show the attributes of the form by using the `lpforms` command. You can also redirect the output of the command into a file to save it for future reference.
- Display the current status of the form by using the `lpstat` command. To protect potentially sensitive content, the alignment pattern is not shown.

If you are not sure about the name of an existing form, you can list the contents of the `/etc/lp/forms` directory to see the names of the forms there.
Limiting Access to Forms

You can control which printers and users have access to some or all of the forms available on the network. For example, you might want only the people in the payroll or accounts payable department to be able to print check forms. In addition, you might want the check forms to be available only on certain printers.

To limit user access to forms, see “How to Limit User Access to a Form” on page 121.
To limit printer access to a form, see “How to Limit Printer Access to a Form” on page 122.

▼ How to Add a Form

1. Log in as superuser, lp, or assume an equivalent role on the print server.

2. Add a form that is based on a form definition.

   # lpforms -f form-name -F /etc/lp/forms/form

   `-f form-name` Name you choose for the form.
   `-F /etc/lp/forms/form` Name of the form definition.

   For more information, see lpforms(1M).
   The form is added in the print server’s `/etc/lp/forms/form-name/describe` file.

3. Verify that the form was added by checking for a listing of information about the form in the output of the following command.

   # lpforms -f form-name -l

Example—Adding a Form

The following example shows how to add the medical form that uses the medical.fmd form definition.

   # lpforms -f medical -F /etc/lp/forms/medical.fmd

Note – Before the form can be used, one or more printers must be given access to the form. For more information, see “How to Limit Printer Access to a Form” on page 122
How to Delete a Form

1. Log in as superuser, lp, or assume an equivalent role on the print server.

2. Delete the form.
   
   ```
   # lpforms -f form-name -x
   ```

   - `f form-name` Form to be deleted.
   - `-x` Deletes the specified form.

   For more information, see `lpforms(1M)`. The form is deleted from `/etc/lp/forms/form-name` file.

3. Verify that form was deleted.

   ```
   # lpforms -f form-name -l
   ```

   You should receive an error indicating that a form by the specified name does not exist.

Example—Deleting a Form

The following example shows how to delete the `medical` form.

```
# lpforms -f medical -x
```

How to Unmount and Mount a Form

1. Log in as superuser, lp, or assume an equivalent role on the print server.

2. Stop accepting print requests on the printer on which you are unmounting the current form.

   ```
   # reject printer-name
   ```

   `printer-name` Name of the printer on which you are unmounting a form.

   New print requests (which might not require the form) are not allowed to enter the printer’s queue.

3. Unmount the current form.

   ```
   # ladmin -p printer-name -M -f none
   ```

   In this command, the variable `printer-name` is the same as in Step 2.
The current form is deleted from the print server’s /etc/lp/printers/printer-name/configuration file.

4. Remove the form paper from the printer.

5. Load the form paper for the next print request.

6. Mount the form.

```
# lpadmin -p printer-name -M -f form-name [-a -o filebreak]
```

- `-p printer-name` Printer on which you are mounting a form.
- `-M -f form-name` Name of the form to be mounted.
- `-a -o filebreak` Optionally enables you to print a copy of the alignment pattern defined for the form, if it has one.

The specified form is added in the print server’s /etc/lp/printers/printer-name/configuration file.

7. Start accepting print requests on the printer.

```
# accept printer-name
```

The printer is ready to print the form you just mounted.

8. Verify that the form has been mounted by checking for the form name under the Form mounted heading in the output of the following command.

```
$ lpstat -p printer-name -l
```

Otherwise, submit a print request that requires the new form and check the printer for output.

Examples—Unmounting and Mounting a Form

The following example shows the process of unmounting the currently mounted form on the printer luna.

```
# reject luna
destination "luna" will no longer accept requests
# lpadmin -p luna -M f none
# accept luna
destination "luna" now accepting requests
```

The following example shows the process of mounting the medical form on the printer luna.

```
# reject luna
destination "luna" will no longer accept requests
# lpadmin -p luna -M f medical -a -o filebreak
```
# accept luna
destination "luna" now accepting requests

▼ How to Set an Alert to Mount a Form

1. Log in as superuser, lp, or assume an equivalent role on the print server.

2. Set a request alert for mounting a form.

   # lpforms -f form-name -A alert [-Q requests] [-W minutes]

   -f form-name            Form for which you want to set a request alert.
   -A alert                Specifies what kind of alert will occur when a form is requested. See Table 5–3 for detailed information about the valid values for alert. Some valid values are mail, write, and quiet. If you choose mail or write, a predefined alert message says to mount the specified form and includes the names of one or more printers that have been set up to use the form.
   -Q requests             Specifies how many print requests that require the form must be in the queue to trigger an alert. If you don’t specify this option, an alert occurs with just one print request in the queue.
   -W minutes              Specifies how often (in minutes) the alert will occur. If you don’t specify this option, the alert is sent once.

   The request alert is added in the print server’s /etc/lp/forms/form-name>alert.sh file.

3. Verify that the alert has been added for the form by checking the output of the following command.

   # lpforms -f form-name -A list

   Otherwise, if you have set a low number of print requests to trigger the alert, submit print requests to meet the minimum requirement and make sure you receive an alert to mount the form.

Examples—Setting an Alert to Mount a Form

The following example shows how to set email alerts to occur every five minutes for the letterhead form when there are 10 print requests for letterhead in the print queue.

   # lpforms -f letterhead -A mail -Q 10 -W 5

   The following example shows how to set console window alerts to occur every 10 minutes for the letterhead form when there are five requests for letterhead in the print queue.
# lpforms -f letterhead -A write -Q 5 -W 10

The following example shows how to set no request alerts for the invoice form.

# lpforms -f invoice -A none

▼ How to View Information About a Form

1. Log in as superuser, lp, or assume an equivalent role on the print server.

2. Request information about a form.

   # lpforms -f form-name -l

   -f form-name     Form for which you want to view information. Specify all for form-name to view information about all the available forms.

   -l               Lists the specified form.

Information about the specified form(s) is displayed.

Examples—Viewing Information About a Form

The following example shows how to display information about the medical form.

   # lpforms -f medical -l
   Page length: 62
   Page width: 72
   Number of pages: 2
   Line pitch: 6
   Character pitch: 12
   Character set choice: pica
   Ribbon color: black
   Comment:
   Medical claim form

The following example shows how to redirect the information about the medical form to a file. (This command creates the form definition for the form.) This is useful if a form definition gets removed unintentionally.

   # lpforms -f medical -l > medical.fmd

▼ How to View the Current Status of a Form

1. Log in on the print server.

2. Request information about the current status of a form.
$ lpstat -f form-name

- f form-name
Form for which you want to view the current status. Specify all for form-name to view the current status of all the forms.

Information about the current status of the specified form(s) is displayed.

Example—Viewing the Current Status of a Form

the following example shows how to display the status of the medical form.

$ lpstat -f medical
form medical is available to you

▼ How to Limit User Access to a Form

1. Log in as superuser, lp, or assume an equivalent role on the print server.

2. Allow or deny users access to a form.

   # lpforms -f form-name -u allow:user-list | deny:user-list

   - f form-name
Name of the form for which the allow or deny user access list is being created.

   - u allow:user-list
Represents users to be added to the allow access list. Use a comma or a space to separate users’ login IDs. If you use spaces, enclose the list of IDs in quotes.
   
   Table 5–5 provides the valid values for user-list.

   deny:user-list
Represents users to be added to the deny user access list. Use a comma or a space to separate users’ login IDs. If you use spaces, enclose the list of IDs in quotes. Table 5–5 provides the valid values for user-list.

The specified user(s) are added to the allow or deny user access list for the specified form in one of the following files on the print server:

/etc/lp/forms/form-name/allow or
/etc/lp/forms/form-name/deny

3. Verify the allow and deny user access lists.

   # lpforms -f form-name -l
Examples—Limiting User Access to a Form

The following example shows how to allow only the users nathan and marcia access to the check form.

```
# lpforms -f check -u allow:nathan,marcia
```

The following example shows how to deny users jones and smith access to the dental form.

```
# lpforms -f dental -u deny:"jones,smith"
```

▼ How to Limit Printer Access to a Form

1. Log in as superuser, lp, or assume an equivalent role on the print server.

2. Allow or deny use of forms on a printer.

```
# lpadmin -p printer-name -f allow:form-list | deny:form-list
```

```
-p printer-name
Name of the printer for which the allow or deny forms list is being created.

-f allow:form-list | deny:form-list
Form names to be added to the allow or deny list. Use a space or a comma to separate multiple form names. If you use spaces to separate form names, enclose the list of form names in quotes.
```

The specified form(s) are added to the allow or deny forms list in one of the following files on the print server:

```
/etc/lp/printers/printer-name/form.allow
/etc/lp/printers/printer-name/form.deny
```

3. Verify the allow and deny forms lists.

```
# lpstat -p printer-name -l
```

Examples—Limiting Printer Access to a Form

The following example shows how to allow the printer luna to access only the medical, dental, and check forms.

```
# lpadmin -p luna -f allow:medical,dental,check
```

The following example shows how to deny the printer luna from accessing the medical, dental, and check forms.

```
# lpadmin -p luna -f deny:"medical dental check"
```
Managing Fonts

If you have a laser printer, you might need to install and maintain PostScript fonts. You might also have to decide where to install PostScript fonts and how to manage them. For many printers, the fonts are set up as part of the printer installation process.

PostScript fonts are stored in outline form, either on the printer or on a system that communicates with the printer. When a document is printed, the PostScript interpreter generates each character as needed (in the appropriate size) from the outline description of it. If a font required for a document is not stored on the printer being used, it must be transmitted to that printer before the document can be printed. This transmission process is called downloading fonts.

Fonts are stored and accessed in several ways:

- **Printer-resident fonts** are stored permanently on a printer. These fonts are installed in read-only memory (ROM) on the printer by the manufacturer. If the printer has a disk, you can install fonts on that disk. Most PostScript printers are shipped with 35 standard fonts.

- A **permanently downloaded font** is transmitted to a printer with a PostScript exitserver program. A permanently downloaded font remains in printer memory until the printer is turned off. Memory allocated to a downloaded font reduces the memory available on the server for PostScript print requests. Use of an exitserver program requires the printer system password and can be reserved for the printer administrator. You should permanently download a font if most print requests serviced by the printer use that font.

- Fonts that are used infrequently or for special purposes can be stored on a user’s system. The user can specify these fonts when submitting the print request. The fonts are appended to the print request and transmitted to the printer. When the print request is processed, the space allocated for the font is freed for other print requests.

- **Host-resident fonts** are stored on a system shared by many users. The system that stores the fonts can be a print server or a print client. Each user can request fonts in the document to be printed. This method is useful when there are numerous available fonts, or when these fonts are not used by all print requests. If the fonts will be used only on printers attached to a print server, they should be stored on the print server. If the fonts are to be used by the users on one system and the users can submit requests to multiple printers on a network, the fonts should be stored on the users’ system.

The LP print service provides a special download filter to manage host-resident fonts. It also supplies **troff** width tables for the 35 standard PostScript fonts which reside on many PostScript printers, for use by the **troff**(1) program.
Managing Printer-Resident Fonts

Most PostScript printers come equipped with fonts resident in the printer ROM. Some printers have a disk on which additional fonts are stored. When a printer is installed, you should add the list of printer-resident fonts to the font list for that printer. By identifying printer-resident fonts, you prevent fonts from being transmitted unnecessarily across a network. Each printer has its own list of resident fonts, which is contained in the file:

```
/etc/lp/printers/printer-name/residentfonts
```

When the printer is attached to a print server, make sure the list in the residentfonts file includes fonts that are on the print server and which are available for downloading to the printer.

You must edit the files containing the list of printer-resident fonts by using a text editor such as vi.

Downloading Host-Resident Fonts

When a PostScript document contains a request for fonts not loaded on the printer, the download filter manages this request. The download filter uses PostScript document structuring conventions to determine which fonts to download.

LP print filters are either fast or slow. A fast filter quickly prepares a file for printing, and it must have access to the printer while the filter is processing. A slow filter takes longer to convert a file, and it does not need to access the printer while the filter is processing. An example of a slow filter is ASCII to PostScript.

The download filter is a fast filter; it downloads fonts automatically if the fonts are on the print server. The download filter can also be used to send fonts to a print server. To do this, you can create a new filter table entry that calls the download filter as a slow filter by using the `lp -y` command. Alternatively, you can force selection of this filter by changing the input type.

The download filter performs five tasks:

1. It searches the PostScript document to determine which fonts are requested. These requests are documented with the following PostScript structuring comments: `%%DocumentFonts: font1 font2 ...` in the header comments.
2. It searches the list of printer-resident fonts to determine if the requested font must be downloaded.
3. If the font is not resident on the printer, the download filter searches the host-resident font directory (by getting the appropriate file name from the map table) to determine if the requested font is available.
4. If the font is available, the filter takes the file for that font and appends it to the file to be printed.
5. It sends the font definition file and the source file (the file to be printed) to the PostScript printer.

Installing and Maintaining Host-Resident Fonts

Some fonts reside on the host system and are transmitted to the printer as needed for particular print requests. As the administrator, you make PostScript fonts available to all users on a system. To do so, you must know how and where to install these fonts. Because fonts are requested by name and stored in files, the LP print service keeps a map file that shows the correspondence between the names of fonts and the names of the files containing those fonts. Both the map and the font list must be updated when you install host-resident fonts.

The fonts available for use with PostScript printers are stored in directories you create called `/usr/share/lib/hostfontdir/typeface/font`, where `typeface` is replaced by a name like `palatino` or `helvetica`, and `font` is replaced by a name like `bold` or `italic`.

How to Install Downloaded PostScript Fonts

1. Log in as superuser, lp, or assume an equivalent role on the print server or print client.

2. Change directory to the `/etc/lp/printers/printer-name` directory.
   
   ```
   # cd /etc/lp/printers/printer-name
   ```

   `printer-name` Name of the printer on which you want to install downloaded PostScript fonts.

3. Create the `residentfonts` file, if it does not already exist.
   
   ```
   # touch residentfonts
   ```

   This file might not exist if this is the first time you are adding permanently downloaded fonts.

4. Edit the `residentfonts` file and add all the printer-resident fonts and fonts to be permanently downloaded.

How to Install Host-Resident PostScript Fonts

1. Log in as superuser, lp, or assume an equivalent role on the print server or print client.

2. Create the `hostfontdir` directory, if it does not already exist.
3. Create a directory for a new typeface, if the directory does not already exist.
   
   ```bash
   # mkdir typeface
   ```

4. Copy the font file to the appropriate directory.
   
   ```bash
   # cp filename /usr/share/lib/hostfontdir/typeface/font
   ```

5. Add the name of the font and the name of the file in which it resides to the map table.
   
   a. Change to the `/usr/share/lib/hostfontdir` directory.

   b. Edit the map file using a text editor such as vi.
      Add a one-line entry for each font you want to add to the table, with the font name first, followed by a space, followed by the name of the file where the font resides.
      For example:
      ```text
      Palatino-Bold /usr/share/lib/hostfontdir/palatino/bold
      ```

   c. Save the file.
      When an example entry exists in the map table on the appropriate system, users will be able to apply the font (for example, Palatino Bold) in their print jobs. When they submit a print request containing this font, the LP print service appends a copy of the file `/usr/share/lib/hostfontdir/palatino/bold` to that file before sending it to the printer.

6. If you are using troff, you must create new width tables for this font in the standard troff font directory.
Customizing the LP Print Service
(Tasks)

This chapter provides background information and procedures for customizing the LP print service.

This is a list of the step-by-step instructions in this chapter.

- “How to Adjust the Printer Port Characteristics” on page 128
- “How to Add a terminfo Entry for an Unsupported Printer” on page 132
- “How to Set Up a Custom Printer Interface Program” on page 136
- “How to Create a New Print Filter” on page 146
- “How to Create a New Form Definition” on page 150

For overview information about printers, see Chapter 2

Adjusting Printer Port Characteristics

The printer port characteristics set by the LP print service must be compatible with the printer communication settings. If the default printer port settings provided by the LP print service do not work with a printer, refer to the printer manual from the manufacturer to find out what settings the printer requires from the LP print service.

Use the `stty` command to set and display printer communication settings.

The following table shows the default `stty` settings used by the LP print service.

<table>
<thead>
<tr>
<th>Option</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>-9600</td>
<td>Set baud to 9600</td>
</tr>
</tbody>
</table>
How to Adjust the Printer Port Characteristics

1. Log in as superuser, lp, or assume an equivalent role on the print server.

2. Adjust the printer port characteristics.

   # lpadmin -p printer-name -o "stty=\"options\""

   -p printer-name
   Name of the printer for which you are adjusting the port characteristics.

   -o "stty=options"
   Sets the port characteristic (stty option) specified by options. You can change more than one stty option setting with this command. Enclose each option in single quotation marks and use a space to separate the options. For a complete list of options, see stty(1). Table 7-1 shows the default stty settings used by the LP print service.

3. Verify that the printer port characteristics have been changed.
Examples—Adjusting the Printer Port Characteristics

The following example shows how to set the port characteristics for the printer luna. The `parenb` option enables parity checking/generation, `parodd` sets odd parity generation, and `cs7` sets the character size to 7 bits.

```
# lpadmin -p luna -o "stty=parenb parodd cs7"
```

The following example shows how to set the terminal baud rate to 19200 for the printer venus.

```
# lpadmin -p venus -o "stty=19200"
```

Adding a `terminfo` Entry for an Unsupported Printer

The LP print service uses an interface program and the `terminfo` database to initialize each printer and establish a selected page size, character pitch, line pitch, and character set.

Each printer is identified in the `terminfo` database with a short name. The name required by the `terminfo` database is identical to the name used to set the `TERM` shell variable. This name is also the printer type you specify when setting up a printer. For example, the entries for different types of PostScript printers are in the `/usr/share/lib/terminfo/P` directory. The default entries provided with the SunOS release are `PS` (for PostScript) and `PSR` (for PostScript Reverse).

If you cannot find a `terminfo` entry for your printer, you still might be able to use the printer with the LP print service without the automatic selection of page size, pitch, and character sets. However, you might have trouble keeping the printer set in the correct modes for each print request.

If there is no `terminfo` entry for your type of printer and you want to keep the printer set in the correct modes, you can either customize the interface program used with the printer or add an entry to the `terminfo` database. A terminal or printer entry in the `terminfo` database contains and defines hundreds of items. The LP print service, however, uses fewer than 50 of these items. The following table lists the required `terminfo` items for a printer.
### TABLE 7-2 Required `terminfo` Items for a Printer

<table>
<thead>
<tr>
<th>Item</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Booleans:</strong></td>

<td>vpa</td>
<td>Vertical position absolute</td>
</tr>
</tbody>
</table>
How to Add a `terminfo` Entry for an Unsupported Printer

**Note** – Before you create a `terminfo` entry for a printer, you should first make sure none of the existing `terminfo` entries will support the printer. To do so, try to set up the printer with an entry for a similar printer, if there is one.

1. Log in as superuser, `lp`, or assume an equivalent role on the print server.
2. Determine a `terminfo` entry name for the printer.
   The directories in the `/usr/share/lib/terminfo` directory contain all the valid `terminfo` entries. Use them as a guide for choosing a name for the printer.
3. Create a `terminfo` entry file for the printer.
   Table 7-2 shows the items you must define in the `terminfo` entry to add a new printer to the LP print service. For more details about the structure of the `terminfo` database, see `terminfo(4)`.
   To help you start writing a new `terminfo` entry, use the `infocmp` command to save an existing `terminfo` entry to a file. This is helpful if there is a `terminfo` entry that is similar to one you want to create. For example, the following command saves the `ps` entry to the `ps_cust` file, which will become the new `terminfo` entry.
   ```
   infocmp ps > ps_cust
   ```
4. Compile the `terminfo` entry file into the `terminfo` database.
   ```
   # tic terminfo_entry
   ```
   `terminfo_entry` The `terminfo` entry file you created.
5. Check for the new `terminfo` entry file in the `/usr/share/lib/terminfo` directory.
Customizing the Printer Interface Program

If you have a printer that is not supported by the standard printer interface program, you can furnish your own printer interface program. You can copy the standard program and then tell the LP print service to use it for a specified printer. But first you need to understand what is in the standard program. The following section describes the standard program.

A printer interface program should:

- Initialize the printer port, if necessary. The standard printer interface program uses the `stty` command to initialize the printer port.
- Initialize the printer hardware. The standard printer interface program gets the control sequences from the `terminfo` database and the `TERM` shell variable.
- Print a banner page, if necessary.
- Print the number of copies specified by the print request.

**Caution** — If you have a printer interface program from a release of UNIX System V prior to Release 3.2, it will probably work with the SunOS 5.9 or compatible LP print service. However, several `-o` options have been standardized in the SunOS 5.9 or compatible LP print service and will be passed to every printer interface program. These options might interfere with similarly named options used by the old interface.

The LP print service, not a printer interface program, is responsible for opening the printer port. The printer port is given to the printer interface program as standard output, and the printer is identified as the “controlling terminal” for the printer interface program so that a “hang-up” of the port will cause a SIGHUP signal to be sent to the printer interface program.

The Standard Printer Interface Program

The standard (model) printer interface program, `/usr/lib/lp/model/standard`, is used by the LP print service to set the printing defaults shown in Table 7-3.
TABLE 7-3 Default Printer Port Characteristics

<table>
<thead>
<tr>
<th>Characteristic</th>
<th>Default Setting</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default filter</td>
<td>None</td>
</tr>
<tr>
<td>Character pitch</td>
<td>None</td>
</tr>
<tr>
<td>Line pitch</td>
<td>None</td>
</tr>
<tr>
<td>Page width</td>
<td>None</td>
</tr>
<tr>
<td>Page length</td>
<td>None</td>
</tr>
<tr>
<td>Character set</td>
<td>None</td>
</tr>
<tr>
<td>stty options</td>
<td>9600 cs8 -cstopb -parenb -parodd ixon -ixany opost -olcuc onlcr -ocrnl -onocr -onlret -ofill nl0 cr0 tab0 bs0 vt0 ff0</td>
</tr>
<tr>
<td>Exit code</td>
<td>0</td>
</tr>
</tbody>
</table>

Customizing stty Modes

If you need to change the terminal characteristics, like baud rate or output options, look for the section of the standard printer interface program that begins with the following comment:

```shell
## Initialize the printer port
```

Exit Codes

When printing is complete, your interface program should exit with a code that shows the status of the print job. The exit code is the last entry in the printer interface program.

The following table shows the exit codes and how they are interpreted by the LP print service.

TABLE 7-4 Printer Interface Program Exit Codes

<table>
<thead>
<tr>
<th>Code</th>
<th>Meaning to the LP Print Service</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>The print request has been successfully completed. If a printer fault occurred, it has been cleared.</td>
</tr>
</tbody>
</table>
### TABLE 7-4 Printer Interface Program Exit Codes

<table>
<thead>
<tr>
<th>Code</th>
<th>Meaning to the LP Print Service</th>
</tr>
</thead>
<tbody>
<tr>
<td>1 to 127</td>
<td>A problem was encountered when printing a request (for example, too many nonprintable characters or the request exceeds the printer capabilities). The LP print service notifies the person who submitted the request that there was an error when printing it. This error will not affect future print requests. If a printer fault has occurred, it has been cleared.</td>
</tr>
<tr>
<td>128</td>
<td>This code is reserved for internal use by the LP print service. Interface programs must not exit with this code.</td>
</tr>
<tr>
<td>129</td>
<td>A printer fault was encountered when printing the request. This fault will affect future print requests. If the fault recovery for the printer directs the LP print service to wait for the administrator to correct the problem, the LP print service disables the printer. If the fault recovery is to continue printing, the LP print service will not disable the printer, but it will try printing again in a few minutes.</td>
</tr>
<tr>
<td>&gt;129</td>
<td>These codes are reserved for internal use by the LP print service. Interface programs must not exit with codes in this range.</td>
</tr>
</tbody>
</table>

If the program exits with a code of 129, root is alerted of a printer fault. The LP print service must also reprint the request from the beginning, after the fault has been cleared. If you do not want the entire request to be reprinted, you can have the interface program send a fault message to the LP print service, but wait for the fault to be cleared. When the fault is cleared, the interface program can resume printing the file. When printing is finished, the printer interface program can give a zero exit code, just as if the fault had never occurred. An added advantage of this approach is that the interface program can detect when the fault is cleared automatically, so that the administrator does not need to re-enable the printer.

### Fault Messages

You can use the `lp.tell` program to send fault messages to the LP print service. This program is referenced by the `LPTELL` shell variable in the standard printer interface code. The program takes standard input and sends it to the LP print service, where it is put into the message that alerts the administrator to the printer fault. If its standard input is empty, `lp.tell` does not initiate an alert. For an example of how the `lp.tell` program is used, examine the standard printer interface code immediately after the following comment:

```# Set up the $LPTELL program to capture fault messages here```

If you use the special exit code 129 or the `lp.tell` program, the printer interface program does not need to disable the printer itself. The interface program can disable the printer directly, but doing so will override the fault-alerting mechanism. Alerts are sent only if the LP print service detects that the printer has a fault, and the special exit code and the `lp.tell` program are its main detection tools.
If the LP print service has to interrupt printing of a file at any time, it kills the interface program with a signal TERM (trap number 15). (For more information, see kill(1) and signal(3C).) If the printer interface program dies from receipt of any other signal, the LP print service assumes that future print requests will not be affected, and continues to use the printer. The LP print service notifies the user who submitted the request that the request has not been finished successfully.

When the interface is first invoked, the signals HUP, INT, QUIT, and PIPE (trap numbers 1, 2, 3, and 13) are ignored. The standard interface changes this so the signals are trapped at appropriate times. The standard interface interprets receipt of these signals as warnings that the printer has a problem; when it receives a signal, it issues a fault alert.

### Using a Customized Printer Interface Program

You can create a customized printer interface program and use it in place of the standard printer interface program on the print server. To do so, you use the `lpadmin` command to register the program with the LP print service for a specific printer.

#### ▼ How to Set Up a Custom Printer Interface Program

1. Log in as superuser, lp, or assume an equivalent role on the print server.

2. Determine your next step based on whether you have a custom printer interface program.

<table>
<thead>
<tr>
<th>Custom Printer Interface Status</th>
<th>Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>Need to create a custom printer interface program</td>
<td>Go to Step 3.</td>
</tr>
<tr>
<td>Already have a custom printer interface program</td>
<td>Go to Step 5.</td>
</tr>
</tbody>
</table>

3. Copy the standard printer interface program.

   ```
   # cp /var/spool/lp/model/standard custom-interface
   ```

4. Change the copy of the standard printer interface program to meet your needs.

   Refer to the description of the program in “The Standard Printer Interface Program” on page 133 to determine what you need to change.

5. Set up the custom printer interface program for a specific printer.

   ```
   # lpadmin -p printer-name -i custom-interface
   ```
- `p printer-name` The printer that will use the custom printer interface program.
- `i custom-interface` Name of the custom printer interface program.

The custom printer interface program is registered with the LP print service, and will be used by that printer when users submit print requests.

6. **Verify that the custom printer interface program has been added in the `/etc/lp/printers/printer-name/configuration` file.**

**Examples—Setting Up a Custom Printer Interface Program**

The following example shows how to set up a custom printer interface program named custom for the printer luna.

```
# lpadmin -p luna -i custom
```

The following example shows how to set up a custom printer interface program that the system venus is using on the printer asteroid.

```
# lpadmin -p asteroid -e venus
```

---

**Creating a New Print Filter**

A filter is used by the LP print service each time it has to print a type of file that the printer cannot interpret. Creating a new print filter is not easy; it usually requires extensive experimentation. The process of defining a new print filter consists of two steps:

- Writing a print filter program
- Creating a print filter definition

A print filter can be as simple or as complex as needed. Filters contain input types, output types, and complex options that provide a language to process command-line arguments within the filter.

If you have non-PostScript printers, you have to create and add print filters as required. First, you need to understand what print filters are and the requirements that must be met by a filter program.
Writing a Print Filter Program

The LP print service provides filter programs in the /usr/lib/lp/postscript directory. These filters cover most PostScript printing situations—where the destination printer requires the data to be in PostScript format. A print filter program must be a binary executable.

Types of Filters

There are two types of print filters: fast filters and slow filters.

Fast filters do not require much processing time to prepare a file for printing. They must have access to the printer when they run. To be capable of detecting printer faults, a print filter must be a fast filter. Any filter that uses the PRINTER keyword as a filter option must be installed as a fast filter.

Slow filters require a great deal of processing time to prepare a file for printing. They do not require access to the printer when they run. Slow filters are run in the background so they do not tie up the printer, allowing other files that do not need slow filtering to be printed.

Converting Files

The LP print service uses print filters to convert files from one content type to another. You can specify the accepted file content types for each printer. The user specifies the file content type when submitting a print request, and the LP print service finds a printer that can print files of that content type. Because many applications can generate files for various printers, this is often sufficient. However, some applications can generate files that cannot be printed on any available printers.

Each time the LP print service receives a request to print a type of file that is in a format that cannot be accepted directly by a printer, the LP print service tries to match the content type of the print request with the content type of the available (or specified) printer. If there is a match, the file can be sent directly to the printer without filtering. If no match is found, or if the content type specifies that a filter be used, the LP print service tries to match the content type of the file with the input content type of available filters, and match the output type of the filter with the content type of the printer. When an appropriate filter is found, the print request is passed through the filter.

Handling Special Printing Modes

A print filter handles special modes and requests to print specific pages. A special printing mode is needed to print any characteristics of print requests that require a customized filter. Filters handle the following characteristics:
The LP print service provides default settings for these characteristics; however, a print filter can handle some characteristics more efficiently. For example, some printers can handle multiple copies more efficiently than the LP print service, and, in this case, you can provide a filter for multiple-copy page control.

Detecting Printer Faults

Each printer has its own way of detecting printer faults and transmitting fault signals to the LP print service. The LP print service only checks for hang-ups (loss of carrier) and excessive delays in printing.

Some printers provide good fault coverage and can send a message describing the reason for a fault. Other printers indicate a fault by using signals other than the signals indicating loss of carrier signal or shut off of data flow. A filter is required to interpret this additional printer fault information.

A filter can also put a print request on hold, wait for a printer fault to clear, and then resume printing. With this capability, the print request that was interrupted does not need to be reprinted in its entirety. Only a filter that knows the control sequences used by a printer can determine where to break a file into pages. Consequently, only such a filter can find the place in the file where printing should start after a fault is cleared.

When a print filter generates messages, those messages are handled by the LP print service, and alerts are sent to the system administrator if alerts are enabled. For further information, see “Setting Up Printer Fault Alerts” on page 83.

Requirements for a Print Filter Program

A print filter can be simple or complex, but it has to meet the following requirements:

- The filter should get the contents of a file from its standard input and send the converted file to the standard output.
- A program cannot be used as a filter if it references external files. You might be tempted to use a program like **troff**, **nroff**, or a similar word processing program as a filter. The LP print service does not recognize references to other files, known as include files, from a filter program. Because **troff** and **nroff** allow...
include files, they can fail when used as filters. If the program needs other files to complete its processing, it should not be used as a filter.

- The filter should not depend on files that normally would not be accessible to a user. If a filter fails when run directly by a user, it will fail when run by the LP print service.

- A slow filter can send messages about errors in the file to standard error; a fast filter should not. Error messages from a slow filter are collected and sent to the user who submitted the print request.

- If a slow filter dies because it received a signal, the print request is stopped and the user who submitted the request is notified. Likewise, if a slow filter exits with a non-zero exit code, the print request is stopped and the user is notified. The exit codes from fast filters are treated differently.

If you want the filter to detect printer faults, it should also meet the following requirements:

- If possible, the filter should wait for a fault to be cleared before exiting. It should also continue to print at the top of the page where printing stopped after the fault is cleared. If you do not want use the continuation feature, the LP print service will stop the filter before alerting the administrator.

- The filter should send printer fault messages to its standard error as soon as the fault is recognized. It does not have to exit; it can wait for the fault to be cleared.

- The filter should not send messages about errors in the file to standard error. These messages should be included in the standard output, where they can be read by the user.

- The filter should exit with a zero exit code if the file is finished printing (even if errors in the file have prevented it from being printed correctly).

- The filter should exit with a non-zero exit code only if a printer fault has prevented it from finishing a print request.

- When added to the filter table, the filter must be added as a fast filter.

Creating a Print Filter Definition

A print filter definition tells the LP print service about the filter, what print filter program to run, what kind of conversion it does, and so on. A set of filter descriptor files are provided in the `/etc/lp/fd` directory. These files describe the characteristics of the filters (for example, fast or slow filter), and point to the filter programs (for example, `/usr/lib/lp/postscript/postdaisy`).

When defining a new print filter, in addition to writing a filter program, you must create a print filter definition. A print filter definition contains the following information used by the LP print service:

- Name of the filter program to run
- Input types it accepts
- Output types it produces
- Printer types to which it can send jobs
- Names of specific printers to which it can send jobs
- Filter types (either fast or slow)
- Options

You can type the characteristics as direct input to the `lpfilter` command. You also can create a file that specifies the filter’s characteristics, and use the file name as input to the `lpfilter` command. Such a file is called a filter descriptor file and should be located in the `/etc/lp/fd` directory. These files are not the filters themselves, but rather point to the filters.

Whether you store the information in a file, or enter it directly on the command line, use the following format:

```
Command: command-pathname [options]
Input types: input-type-list
Output types: output-type-list
Printer types: printer-type-list
Printers: printer-list
Filter type: fast or slow
Options: template-list
```

**Note** – If you provide more than one definition (that is, more than one line) for any filter characteristic other than Options, only the second definition will be used by the print service.

The information can be arranged in any order, and not all the information is required. When you do not specify values, those shown in the following table are assigned by default. They are not very useful, which is why you should specify explicit values.

<table>
<thead>
<tr>
<th>Table 7-5 Default Values for <code>lpfilter</code> Arguments</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Item</strong></td>
</tr>
<tr>
<td>Input types</td>
</tr>
<tr>
<td>Output type</td>
</tr>
<tr>
<td>Printer types</td>
</tr>
<tr>
<td>Printers</td>
</tr>
<tr>
<td>Filter type</td>
</tr>
</tbody>
</table>

**Command**

Use the full path of the filter program. If there are any fixed options that the program always needs, include them here.
Input Types

Input types is a list of file content types that the print filter can process. The LP print service does limit the number of input types, but most filters can accept only one type. Several file types can be similar enough that the filter can deal with them. You can use whatever names you like, with a maximum of 14 alphanumeric characters and dashes. Do not use underscores as part of the input type name.

The LP print service uses these names to match a filter to a file type, so follow a consistent naming convention. For example, if more than one filter can accept the same input type, use the same name for that input type when you specify it for each filter. Inform your users of these names so they know how to identify the file type when submitting a file for printing.

Output Types

Output types is list of file types that the filter can produce as output. For each input type, the filter produces a single output type. The output type can vary, however, from job to job. The name of the output type is restricted to 14 alphanumeric characters and dashes.

The output type names should either match the types of available (local or remote) printers, or match the input types handled by other filters. The LP print service groups filters in a shell pipeline if it finds that several passes by different filters are needed to convert a file. It is unlikely that you will need this level of sophistication, but the LP print service allows it. Try to find a set of filters that takes as input types all the different files the users might want printed, and that converts those files directly into file types the printer can handle.

Printer Types

Printer types is a list of the types of printers into which the print filter can convert files. For most printers and filters, you can leave this part of the filter definition blank, because it is identical to the list of output types. But it can be different. For example, you could have a printer with a single printer type for purposes of initialization, but which can recognize several different file content types. Essentially, this printer has an internal filter that converts the various file types into one that it can handle. Thus, a filter might produce one of several output types that match the file types that the printer can handle. The print filter should be marked as working with that printer type.

As another example, you might have two different models of printers that are listed as accepting the same file types. Due to slight differences in manufacture, however, one printer deviates in the results it produces. You label the printers as being of different
printer types, say A and B, where B is the one that deviates. You create a filter that adjusts files to account for the deviation produced by printers of type B. Because this filter is needed only for those printer types, you would list it as working only on type B printers.

Printers

A print filter is normally able to work with all printers that accept its output, so you can usually skip this part of the filter definition.

You might, however, have some printers that are or inappropriate for the output that the filter produces. For example, you might want to dedicate one printer for fast turnaround, only sending files that require no filtering to that printer. Other printers of identical type can be used for files that need extensive filtering before they can be printed.

Filter Type

The LP print service recognizes fast and slow filters, as described in “Types of Filters” on page 138.

Slow filters that are invoked by printing modes (using the \texttt{lp -y} command) must be run on the system from which the print request originated. The LP print service cannot pass values for modes to print servers. It can, however, match a file content type (specified after the \texttt{-T} option of the \texttt{lp} command) to a content type on a print server. Therefore, if you want to activate special modes on a print server, you must specify content types that permit the LP print service to match input types and output types.

Options

Options specify how different types of information are converted into command-line arguments to the filter command. This information can include specifications from a user (with the print request), the printer definition, and the specifications implemented by any filters used to process the request.

\textit{Defining Print Filter Options With Templates}

There are 13 sources of information for defining print filter options, each of which is represented by a \textit{keyword}. Each option is defined in a \textit{template}. A template is a statement in a filter definition that defines an option to be passed to the filter command, based on the value of one of the characteristics of the filter.
The options specified in a filter definition can include none, all, or any subset of the 13 keywords. In addition, a single keyword can be defined more than once, if multiple definitions are required for a complete filter definition. The following table contains descriptions of the 13 keywords available for defining options in a print filter definition.

**TABLE 7-6 Print Filter Options Keywords**

<td>mode</td>
<td>landscape</td>
</tr>
</tbody>
</table>

A print filter definition can include more than one template. Multiple templates are entered on a single line and separated with commas, or they are entered on separate lines, preceded by the Options: prefix.

The format of a template is as follows:

**keyword**pattern = replacement

The keyword identifies the type of option being registered for a particular characteristic of the filter.

The **pattern** is a specific option for the keyword.

The **replacement** is what happens when the keyword has the noted value.

For an example of how an option is defined for a particular filter, suppose you want to have the print service scheduler assign print requests to filters following this criteria:
If the type of OUTPUT to be produced by the filter is impress, then pass the -I option to the filter.

If the type of OUTPUT to be produced by the filter is postscript, then pass the -P option to the filter.

To specify these criteria, provide the following templates as options to the lpfILTER command:

Options: OUTPUT impress=-I, OUTPUT postscript=-P

If the Options line becomes too long, put each template on a separate line, as follows:

Options: OUTPUT impress=-I
Options: OUTPUT postscript=-P

In both templates, the keyword is defined as OUTPUT. In the first template, the pattern is impress and the value of the replacement is -I. In the second template, the value of pattern is postscript and the value of replacement is -P.

To find out which values to supply for each type of template (that is, for the pattern and replacement arguments for each keyword), consider the following:

- The values for the INPUT templates come from the file content type that needs to be converted by the filter.
- The values for the OUTPUT templates come from the output type that has to be produced by the filter.
- The value for the TERM template is the printer type.
- The value for the PRINTER template is the name of the printer that will print the final output.
- The values for the CPI, LPI, LENGTH, and WIDTH templates come from the user’s print request, the form being used, or the default values for the printer.
- The value for the PAGES template is a list of pages that should be printed. Typically, it is a list of page ranges separated by commas. Each page range consists of a pair of numbers separated by a dash, or a single number. (For example, 1-5,6,8,10 indicates pages 1 through 5, plus pages 6, 8, and 10.) However, whatever value was given in the -P option to a print request is passed unchanged.
- The value for the CHARSET template is the name of the character set to be used.
- The value for the FORM template is the name of the form requested by the lp-f command (the command used to submit a print request).
- The value of the COPIES template is the number of copies of the file to print. If the filter uses this template, the LP print service will reduce to one the number of copies of the filtered file it prints, since this “single copy” includes the multiple copies produced by the filter.
- The value of the MODES template comes from the lp-y command. Because a user can specify several -y options, there might be several values for the MODES template. The values will be applied in the left-to-right order given by the user.
The replacement part of a template shows how the value of a template should be given to the filter program. It is typically a literal option, sometimes with the placeholder asterisk (*) included to show where the value goes. The pattern and replacement also can use the regular expression syntax of the ed command for more complex conversion of user input options into filter options. All regular expression syntax of ed is supported, including the \( ... \) and \n constructions, which can be used to extract portions of the pattern for copying into the replacement, and the \, which can be used to copy the entire pattern into the replacement. For more information, see ed(1).

Note – If a comma or an equal sign (=) is included in a pattern or a replacement, precede it with a backslash (\). A backslash in front of any of these characters is removed when the pattern or replacement is used.

▼ How to Create a New Print Filter

1. Log in as superuser, lp, or assume an equivalent role on the print server.

2. Create a print filter program.
   For information on print filter programs, see “Writing a Print Filter Program” on page 138. By convention, filter programs for PostScript printers are located in the /usr/lib/lp/postscript directory. You should put programs you create under the /usr/lib/lp directory in a directory of your choosing.

3. Create a print filter definition.
   For information on print filter definitions, see “Creating a Print Filter Definition” on page 140. You should save the printer filter definition in a text file. By convention, filter definitions are located in the /etc/lp/fd directory and are identified with the .fd suffix.

4. Add the print filter to a print server.
   For instructions, see “How to Add a Print Filter” on page 111.

Examples—Creating a New Print Filter

The following example shows a print filter definition to convert N37 or Nlp to simple.

Input types: N37, Nlp, simple
Output types: simple
Command: /usr/bin/col
Options: MODES expand = -x
Options: INPUT simple = -p -f

In this example, the print filter program is named col. Once you add the new print filter to a print server, a user’s print requests will be handled as follows:
When a user enters the following command:

```
$ lp -y expand report.doc
```

The print filter program is run with the following arguments to convert the file:

```
/usr/bin/col -x -p -f
```

When a user enters the following command:

```
$ lp -T N37 -y expand report.doc
```

The print filter program is run with the following arguments to convert the file:

```
/usr/bin/col -x
```

The following example shows a print filter definition to convert from `troff` to PostScript:

**Input types:** troff

**Output types:** postscript

**Printer types:** PS

**Filter type:** slow

**Command:** /usr/lib/lp/postscript/dpost

**Options:**

- `LENGTH * = -l*`
- `MODES port = -pp, MODES land = -pl`
- `MODES group \={1-9} = -n\l`

In this example, the filter program is named `dpost`. It takes one input type, `troff`, produces a `postscript` output, and works with any printer of type `PS` (PostScript). Users need to give just the abbreviation `port` or `land` when they ask for the paper orientation to be in portrait mode or landscape mode. Because these options are not intrinsic to the LP print service, users must specify them using the `lp -y` command.

After you add the new print filter to a print server, print requests will be handled as follows:

When a user enters the following command to submit a `troff` file type for printing on a PostScript printer (type `PS`), with requests for landscape orientation and a page length of 60 lines:

```
$ lp -T troff -o length=60 -y land -d luna ch1.doc
```

The print filter program `dpost` is run with the following arguments to convert the file:

```
/usr/lib/lp/postscript/dpost -l60 -pl luna ch1.doc
```

When a user enters the following command:
Creating a New Printer Form

When you want to provide a new form, you must define its characteristics by entering information about nine required characteristics (such as page length and page width) as input to the `lpforms` command. The LP print service uses this information to:

- Initialize the printer so that printing is done properly on the form
- Send reminders to the system administrator about how to handle the form

The form name can be anything you choose, as long as it does not contain more than 14 alphanumeric characters and underscores. The information must be in the following format:

- Page length: scaled number
- Page width: scaled number
- Number of pages: integer
- Line pitch: scaled number
- Character pitch: scaled number
- Character set choice: character-set-name [,mandatory]
- Ribbon color: ribbon-color
- Comment: informal notes about the form
- Alignment pattern: [content-type] alignment pattern

The optional phrase [,mandatory] means that the user cannot override the character set choice in the form. The content-type can be given, although this is optional, with an alignment pattern. If this attribute is given, the print service uses it to determine, as necessary, how to filter and print the file.

With two exceptions, the information can appear in any order. The exceptions are the Alignment pattern (which must always be last), and the comment (which must always follow the line with the Comment: prompt). If the comment contains a line beginning with a key phrase (like Page length, Page width, and so on), precede that line with a > character so the key phrase is not at the beginning of the line. The initial > character is stripped from the comment and is not displayed.

Not all of the information must be given. When you do not specify values for the items listed in the following table the default values are assigned. Before running the `lpforms` command, gather the following information about the new form:
<table>
<thead>
<tr>
<th>Item</th>
<th>Default</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Page length</td>
<td>66 lines</td>
<td>The length of the form, or the length of each page in a multipage form. This information can be the number of lines, or the size in inches or centimeters.</td>
</tr>
<tr>
<td>Page width</td>
<td>80 columns</td>
<td>The width of the form, in characters, inches, or centimeters.</td>
</tr>
<tr>
<td>Number of pages</td>
<td>1</td>
<td>The number of pages in a multipage form. The LP print service uses this number with a print filter (if available) to restrict the alignment pattern to a length of one form. See the description of alignment pattern below. If no filter is available, the LP print service does not truncate the output.</td>
</tr>
<tr>
<td>Line pitch</td>
<td>6 lines per inch</td>
<td>A measurement of how close lines appear on the form. This is also called leading. It is the distance between two lines, from baseline to baseline, measured by either lines per inch or lines per centimeter.</td>
</tr>
<tr>
<td>Character pitch</td>
<td>10 characters per inch</td>
<td>A measurement of how close together characters appear on the form. It is the distance between characters, measured by either characters per inch or characters per centimeter.</td>
</tr>
<tr>
<td>Character set choice</td>
<td>Any</td>
<td>The character set, print wheel, or font cartridge that should be used when this form is used. Users can choose a different character set for their own print requests when using this form, or you can require that only one character set be used.</td>
</tr>
<tr>
<td>Ribbon color</td>
<td>Any</td>
<td>If the form should always be printed using a certain color ribbon, the LP print service can give a mount alert message indicating which color to use.</td>
</tr>
<tr>
<td>Comment</td>
<td>(No default)</td>
<td>Any remarks that might help users understand the form. For example, the remarks could indicate the name of the form, its revision, its purpose, or restrictions on its use.</td>
</tr>
</tbody>
</table>
TABLE 7–7 Default Form Values  (Continued)

<table>
<thead>
<tr>
<th>Item</th>
<th>Default</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Alignment pattern</td>
<td>(No default)</td>
<td>A sample file that the LP print service uses to fill one blank form. When mounting the form, you can print this pattern on the form to align it properly. You can also define a content type for this pattern so that the print service knows how to print it.</td>
</tr>
</tbody>
</table>

**Note** – The LP print service does not try to mask sensitive information in the alignment pattern. If you do not want sensitive information printed on sample forms—for example when you align checks—then you should mask the appropriate data. The LP print service keeps the alignment pattern stored in a safe place, where only those logged in as root or lp can read it.

When you have gathered the information for the form, you enter it as input to the `lpforms` command. You should record this information first in a separate file so you can edit it before entering it with the `lpforms` command. You can then use the file as input instead of typing each piece of information separately after a prompt.

▼ How to Create a New Form Definition

1. Log in as superuser, lp, or assume an equivalent role on the print server.

2. Create a form definition file.
   For a description on creating print forms, see “Creating a New Printer Form” on page 148. You should save the printer definition in a text file.

3. Add the form to the LP print service.
   
   ```
   # lpadmin -p printer-name -M -f form-name
   ```

4. Add the form to a print server.
   For instructions, see “How to Add a Form” on page 116

The LP Print Service

The LP print service is a set of software utilities that allows users to print files while users continue to work. Originally, the print service was called the LP spooler. (LP stood for line printer, but its meaning now includes many other types of printers, such as laser printers. Spool is an acronym for system peripheral operation off-line.)

The print service consists of the LP print service software, any print filters you might provide, and the hardware, such as the printer, system, and network connections.

The Structure of the LP Print Service

This section describes the directory structure, files, logs, and commands of the LP print service.

LP Print Service Directories

The files of the LP print service are distributed among seven directories, as shown in the following table.

<table>
<thead>
<tr>
<th>Directory</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>/usr/bin</td>
<td>The LP print service user commands</td>
</tr>
<tr>
<td>/etc/lp</td>
<td>A hierarchy of LP server configuration files</td>
</tr>
<tr>
<td>/usr/share/lib</td>
<td>The terminfo database directory</td>
</tr>
<tr>
<td>/usr/lib/print</td>
<td>The lp conversion scripts, in.lpd daemon and the printd daemon. The printd daemon transfers all pending jobs in the/var/spool/print directory once per minute. When no jobs are remaining to transfer, it exits.</td>
</tr>
<tr>
<td>/usr/sbin</td>
<td>The LP print service administrative commands</td>
</tr>
<tr>
<td>/usr/lib/lp</td>
<td>The lpsched program, binary files, PostScript filters, and the model directory, which contains the standard printer interface program.</td>
</tr>
<tr>
<td>/var/lp/logs</td>
<td>LP log files such as lpsched.n, which includes messages from lpsched and requests.n, which includes information about completed print requests.</td>
</tr>
</tbody>
</table>
TABLE 8–1 Directories for the LP Print Service (Continued)

<table>
<thead>
<tr>
<th>Directory</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>/var/spool/lp</td>
<td>The spooling directory where files are queued for printing</td>
</tr>
<tr>
<td>/var/spool/print</td>
<td>The LP print service client-side request staging area</td>
</tr>
</tbody>
</table>

LP Print Service Configuration Files

The lpsched daemon stores configuration information in the /etc/lp directory, as described in the following table.

**Caution** – The configuration files listed in this table are private interfaces, and are subject to change in future releases. You should not build software that relies on these files being in their current locations or that relies on the data being in the format currently used.

TABLE 8–2 Contents of the /etc/lp Directory

<table>
<thead>
<tr>
<th>File</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>classes</td>
<td>Directory</td>
<td>Files identifying classes provided by the ladmin -c command.</td>
</tr>
<tr>
<td>fd</td>
<td>Directory</td>
<td>Description of existing filters.</td>
</tr>
<tr>
<td>filter.table</td>
<td>File</td>
<td>Print filter lookup table.</td>
</tr>
<tr>
<td>forms</td>
<td>Directory</td>
<td>Location to put files for each form. Initially, this directory is empty.</td>
</tr>
<tr>
<td>interfaces</td>
<td>Directory</td>
<td>Printer interface program files.</td>
</tr>
<tr>
<td>logs</td>
<td>Link to /var/lp/logs</td>
<td>Log files of printing activities.</td>
</tr>
<tr>
<td>model</td>
<td>Link to /usr/lib/lp/model</td>
<td>The standard printer interface program.</td>
</tr>
<tr>
<td>printers</td>
<td>Directory</td>
<td>Directories for each local printer. Each directory contains configuration information and alert files for an individual printer.</td>
</tr>
<tr>
<td>pwhells</td>
<td>Directory</td>
<td>Print wheel or cartridge files.</td>
</tr>
</tbody>
</table>

These configuration files serve a similar function to the /etc/printcap file on lpd-based print servers.
Note – You can check the contents of the configuration files, but you should not edit these files directly. Instead, use the lpadmin command to make configuration changes. Your changes will be written to the configuration files in the /etc/lp directory. The lpsched daemon administers and updates the configuration files.

The /etc/lp/printers directory has a subdirectory for each local printer known to the system. The following example shows the /etc/lp/printers subdirectories of printers sparc1 and luna.

$ ls -l /etc/lp/printers
  drwxrwxr-x 2 lp lp 512 Jan 23 23:53 luna
  drwxrwxr-x 2 lp lp 512 Jan 11 17:50 sparc1

The following table describes the files within each of the printer-specific directories.

<table>
<thead>
<tr>
<th>File Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>alert.sh</td>
<td>Shell to execute in response to alerts</td>
</tr>
<tr>
<td>alert.vars</td>
<td>Alert variables</td>
</tr>
<tr>
<td>configuration</td>
<td>Configuration file</td>
</tr>
<tr>
<td>users.deny</td>
<td>List of users to whom printer access is denied</td>
</tr>
<tr>
<td>comment</td>
<td>Printer description</td>
</tr>
</tbody>
</table>

The configuration file for the printer luna, /etc/lp/printers/luna/configuration, would typically appear as follows:

Banner: on: Always
Content types: PS
Device: /dev/term/b
Interface: /usr/lib/lp/model/standard
Printer type: PS
Modules: default

The terminfo Database

The /usr/share/lib directory contains the terminfo database directory, which contains definitions for many types of terminals and printers. The LP print service uses information in the terminfo database to initialize a printer, to establish a selected page size, character pitch, line pitch, and character set, as well as to communicate the sequence of codes to a printer.
Each printer is identified in the terminfo database with a short name. For a description of the structure of the terminfo database, see “Printer Type” on page 44. If necessary, you can add entries to the terminfo database, but doing so is a tedious and time-consuming process. For more information, see “Adding a terminfo Entry for an Unsupported Printer” on page 129.

Daemons and LP Internal Files

The /usr/lib/lp directory contains daemons and files used by the LP print service, as described in the following table.

<table>
<thead>
<tr>
<th>File</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>bin</td>
<td>Directory</td>
<td>Contains files for generating printing alerts, slow filters, and queue management programs.</td>
</tr>
<tr>
<td>lpsched</td>
<td>Daemon</td>
<td>Manages scheduling of LP print requests.</td>
</tr>
<tr>
<td>model</td>
<td>Directory</td>
<td>Contains the standard printer interface program.</td>
</tr>
<tr>
<td>postscript</td>
<td>Directory</td>
<td>Contains all PostScript filter programs provided by the LP print service. These filters come with descriptor files in the /etc/lp/fd directory that tell the LP print service the characteristics of the filters and where to locate them.</td>
</tr>
</tbody>
</table>

LP Print Service Log Files

The LP print service maintains two sets of log files that are described in the following table.

<table>
<thead>
<tr>
<th>Log File Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>syslogd(1M)</td>
<td>Set lpr.debug in /etc/syslog.conf to enable LP print service logging</td>
</tr>
<tr>
<td>/var/spool/lp</td>
<td>A list of current requests that are in the print queue</td>
</tr>
<tr>
<td>/var/lp/logs/requests</td>
<td>An ongoing history of print requests</td>
</tr>
</tbody>
</table>
Print Queue Logs

The scheduler for each system keeps a log of print requests in the /var/spool/lp/tmp/system and /var/spool/lp/requests/system directories. Each print request has two files, one in each directory, that contain information about the request. The information in the /var/spool/lp/requests/system directory can be accessed only by root or lp. The information in the /var/spool/lp/tmp/system directory can be accessed only by the user who submitted the request, root, or lp.

The following example shows the contents of the /var/spool/lp/tmp/starbug directory:

```
$ ls /var/spool/lp/tmp/starbug
5 5-0
# cat 5-0
C 1
D print1
F /etc/profile
P 20
T /etc/profile
t simple
U root
s 0000
v 2
```

These files remain in their directories only as long as the print request is in the queue. Once the request is finished, the information in the files is combined and appended to the /var/lp/logs/requests file. This file is described in the next section.

Use the information in the /var/spool/lp/logs directory if you need to track the status of a print request that is currently in the queue.

History Logs

The LP print service records a history of printing services in two log files, lpsched and requests. These log files are located in the /var/lp/logs directory. You can use the information in these logs to diagnose and troubleshoot printing problems. An example of the contents of the /var/lp/logs directory is as follows:

```
# cd /var/lp/logs
# ls
lpsched.1  requests  requests.2
lpsched    lpsched.2  requests.1
#
```

The two most important log files for troubleshooting is the lpsched log, which contains information about local printing requests and the requests log, which contains information about print requests that are completed and no longer in the print queue.
The requests log has a simple structure, so that you can extract data using common UNIX shell commands. Requests are listed in the order they are printed, and are separated by lines showing their request IDs. Each line below the separator line, the line that starts with =, is marked with a single letter that identifies the kind of information contained in that line. Each letter is separated from the data by a single space.

The following example shows the contents of a requests log:

```
# pwd
/var/lp/logs
# tail requests.2
= print1-3, uid 0, gid 1, size 206662, Wed Nov 14 08:56:30 MST 2001
z print1
C 1
D print1
F /usr/dict/words
P 20
T /usr/dict/words
t simple
U root
s 0x0014
v 2
#
```

The following table shows the letter codes and the content of their corresponding lines in the LP requests log.

<table>
<thead>
<tr>
<th>Letter</th>
<th>Content of Line</th>
</tr>
</thead>
<tbody>
<tr>
<td>=</td>
<td>The separator line, which contains the following items: request ID, user ID (UID), and group IDs (GIDs) of the user, the total number of bytes in the original (unfiltered) file size, and the time when the request was queued.</td>
</tr>
<tr>
<td>z</td>
<td>The name of the printer.</td>
</tr>
<tr>
<td>C</td>
<td>The number of copies printed.</td>
</tr>
<tr>
<td>D</td>
<td>The printer or class destination or the word any.</td>
</tr>
<tr>
<td>F</td>
<td>The name of the file printed. The line is repeated for each file printed. Files were printed in the order shown.</td>
</tr>
<tr>
<td>f</td>
<td>(Optional) The name of the form used.</td>
</tr>
<tr>
<td>H</td>
<td>(Optional) One of three types of special handling: resume, hold, and immediate.</td>
</tr>
<tr>
<td>N</td>
<td>(Optional) The type of alert used when the print request was successfully completed. The type is the letter M if the user was notified by email or W if the user was notified by a message to the terminal.</td>
</tr>
</tbody>
</table>
### TABLE 8-4 Letter Codes in the LP requests Log (Continued)

<table>
<thead>
<tr>
<th>Letter</th>
<th>Content of Line</th>
</tr>
</thead>
<tbody>
<tr>
<td>O</td>
<td>(Optional) The printer-dependent -o options. For example, nobanner.</td>
</tr>
<tr>
<td>P</td>
<td>The priority of the print request.</td>
</tr>
<tr>
<td>p</td>
<td>The list of pages printed.</td>
</tr>
<tr>
<td>r</td>
<td>(Optional) A single-letter line that is included if the user asked for “raw” processing of the files with the <code>lp -r</code> command.</td>
</tr>
<tr>
<td>S</td>
<td>(Optional) The character set, print wheel, or cartridge used.</td>
</tr>
<tr>
<td>T</td>
<td>The title placed on the banner page.</td>
</tr>
<tr>
<td>t</td>
<td>The type of content found in the files.</td>
</tr>
<tr>
<td>U</td>
<td>The name of the user who submitted the print request.</td>
</tr>
<tr>
<td>s</td>
<td>The outcome of the request, shown as a combination of individual bits expressed in hexadecimal form. Several bits are used internally by the print service. The bits and what they mean are described in the table that follows this table.</td>
</tr>
<tr>
<td>x</td>
<td>(Optional) The slow filter used for the print request.</td>
</tr>
<tr>
<td>Y</td>
<td>(Optional) The list of special modes for the print filters used to print the request.</td>
</tr>
<tr>
<td>z</td>
<td>(Optional) The printer used for the request. This printer differs from the destination (the D line) if the request was queued for any printer or a class of printers, or if the request was moved to another destination.</td>
</tr>
</tbody>
</table>

The following table shows the outcome codes in the LP requests log and their descriptions.

### TABLE 8-5 Outcome Codes in the LP requests Log

<table>
<thead>
<tr>
<th>Outcome Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0x0001</td>
<td>The request was held pending resume.</td>
</tr>
<tr>
<td>0x0002</td>
<td>Slow filtering is running.</td>
</tr>
<tr>
<td>0x0004</td>
<td>Slow filtering finished successfully.</td>
</tr>
<tr>
<td>0x0008</td>
<td>The request is on the printer.</td>
</tr>
<tr>
<td>0x0010</td>
<td>Printing finished successfully.</td>
</tr>
<tr>
<td>0x0020</td>
<td>The request was held pending user change.</td>
</tr>
<tr>
<td>0x0040</td>
<td>The request was canceled.</td>
</tr>
</tbody>
</table>
TABLE 8–5 Outcome Codes in the LP requests Log  (Continued)

<table>
<thead>
<tr>
<th>Outcome Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0x0080</td>
<td>The request will print next.</td>
</tr>
<tr>
<td>0x0100</td>
<td>The request failed filtering or printing.</td>
</tr>
<tr>
<td>0x0200</td>
<td>The request is in transit to a remote printer. (obsolete)</td>
</tr>
<tr>
<td>0x0400</td>
<td>The user will be notified.</td>
</tr>
<tr>
<td>0x0800</td>
<td>A notification is running.</td>
</tr>
<tr>
<td>0x1000</td>
<td>A remote system has accepted the request. (obsolete)</td>
</tr>
<tr>
<td>0x2000</td>
<td>The administrator placed a hold on the request.</td>
</tr>
<tr>
<td>0x4000</td>
<td>The printer had to change filters.</td>
</tr>
<tr>
<td>0x8000</td>
<td>The request is temporarily stopped.</td>
</tr>
</tbody>
</table>

Spooling Directories

Files queued for printing are stored in the /var/spool/lp directory until they are printed, which might be only seconds. The following table shows the contents of the /var/spool/lp directory.

TABLE 8–6 Contents of the /var/spool/lp Directory

<table>
<thead>
<tr>
<th>File</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SCHEDLOCK</td>
<td>File</td>
<td>Lock file for the scheduler. Check for this file if the scheduler terminates and will not restart.</td>
</tr>
<tr>
<td>admins</td>
<td>Directory</td>
<td>Link to /etc/lp.</td>
</tr>
<tr>
<td>bin</td>
<td>Directory</td>
<td>Link to /usr/lib/lp/bin.</td>
</tr>
<tr>
<td>logs</td>
<td>Link</td>
<td>Link to ../lp/logs where completed print requests are logged.</td>
</tr>
<tr>
<td>model</td>
<td>Link</td>
<td>Link to /usr/lib/lp/model.</td>
</tr>
<tr>
<td>requests</td>
<td>Directory</td>
<td>Directory that contains subdirectories for each configured printer where print requests are logged until printed. Users cannot access this log.</td>
</tr>
<tr>
<td>system</td>
<td>Directory</td>
<td>A print status file for the system.</td>
</tr>
<tr>
<td>temp</td>
<td>Link</td>
<td>Link to /var/spool/lp/tmp/hostname, which contains the spooled requests.</td>
</tr>
</tbody>
</table>
TABLE 8-6 Contents of the /var/spool/lp Directory  (Continued)

<table>
<thead>
<tr>
<th>File</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>tmp</td>
<td>Directory</td>
<td>Directory for each configured printer where print requests are logged until printed. Changes to existing print requests are also recorded in this log.</td>
</tr>
</tbody>
</table>

LP Print Service Commands

The following table lists frequently used LP print service commands. You must be root, lp, or assume an equivalent role to use the 1M commands.

TABLE 8-7 Quick Reference to LP Print Service Commands

<table>
<thead>
<tr>
<th>Command</th>
<th>Man Page</th>
<th>Task</th>
</tr>
</thead>
<tbody>
<tr>
<td>enable</td>
<td>enable(1)</td>
<td>Activate a printer</td>
</tr>
<tr>
<td>cancel</td>
<td>cancel(1)</td>
<td>Cancel a print request</td>
</tr>
<tr>
<td>lp</td>
<td>lp(1)</td>
<td>Send one or more file(s) to a printer</td>
</tr>
<tr>
<td>lpstat</td>
<td>lpstat(1)</td>
<td>Report the status of the LP print service</td>
</tr>
<tr>
<td>disable</td>
<td>enable(1)</td>
<td>Deactivate one or more printers</td>
</tr>
<tr>
<td>accept</td>
<td>accept(1M)</td>
<td>Permit print requests to be queued for a specific destination</td>
</tr>
<tr>
<td>reject</td>
<td>accept(1M)</td>
<td>Prevent print requests from being queued for a specific destination</td>
</tr>
<tr>
<td>ladmin</td>
<td>ladmin(1M)</td>
<td>Set up or change printer configuration</td>
</tr>
<tr>
<td>lpfilter</td>
<td>lpfilter(1M)</td>
<td>Set up or change filter definitions</td>
</tr>
<tr>
<td>lpforms</td>
<td>lpforms(1M)</td>
<td>Set up or change preprinted forms</td>
</tr>
<tr>
<td>ladmin</td>
<td>ladmin(1M)</td>
<td>Mount a form</td>
</tr>
<tr>
<td>lmove</td>
<td>lmove(1M)</td>
<td>Move output requests from one destination to another destination</td>
</tr>
<tr>
<td>lpsched</td>
<td>lpsched(1M)</td>
<td>Start the LP print service scheduler</td>
</tr>
<tr>
<td>lpshut</td>
<td>lpshut(1M)</td>
<td>Stop the LP print service scheduler</td>
</tr>
<tr>
<td>lusers</td>
<td>lusers(1M)</td>
<td>Set or change the default priority and priority limits that can be requested by users of the LP print service</td>
</tr>
</tbody>
</table>
Functions of the LP Print Service

The LP print service performs the following functions:

- Administers files and schedules local print requests
- Receives and schedules network requests
- Filters files, if necessary, so they print properly
- Starts programs that interface with the printers
- Tracks the status of jobs
- Tracks forms mounted on the printer
- Tracks print wheels currently mounted
- Delivers alerts to mount new forms or different print wheels
- Delivers alerts about printing problems

How LP Administers Files and Schedules Local Print Requests

The LP print service has a scheduler daemon called lpsched. The scheduler daemon updates the LP system files with information about printer setup and configuration.

The lpsched daemon schedules all local print requests on a print server, as shown in the following figure, whether users issue the requests from an application or from the command line. Also, the scheduler tracks the status of printers and filters on the print server. When a printer finishes a request, the scheduler schedules the next request, if one exists, in the queue on the print server.
Each print server must have only one LP scheduler running. The scheduler is started when a system is booted, or enters run level 2, by the /etc/rc2.d/S80lp control script. Without rebooting the systems, you can stop the scheduler with the /etc/init.d/lp stop command and restart the scheduler with the /etc/init.d/lp start command. The scheduler for each system manages requests issued to the system by the lp commands.

Scheduling Network Print Requests

Each print client communicates directly with a print server over the network. The communication is done between the requesting command, such as lp, lpstat, cancel, lpr, lpq, or lprm, and the print service on the print server. Doing so, reduces the print system overhead on client only systems, improving scalability, performance and accuracy of data.

Print servers listen for print request with the Internet services daemon (inetd). Upon hearing a request for print service from the network, the inetd daemon starts a program called the “protocol adaptor” (in.lpd). The protocol adaptor translates the print request and communicates it to the print spooler, and returns the results to the requester. This protocol starts on demand and exits when it has serviced the network request. This process eliminates idle system overhead for printing. This process also eliminates any additional system configuration for network printing support as was the case in previous versions of Solaris printing.
Filtering Print Files

Print filters are programs on the print server that convert the content of a queued file from one format to another format.

A print filter can be as simple or as complex as needed. The SunOS release provides print filters in the /usr/lib/lp/postscript directory that cover most situations where the destination printer requires the data to be in PostScript format. If you need filters for non-PostScript printers, you have to create the filters and add them to the systems that need filters.

A set of print filter descriptor files are provided in the /etc/lp/fd directory. These descriptor files describe the characteristics of the filter (for example, fast or slow filter), and point to the filter program (for example, /usr/lib/lp/postscript/postdaisy).

What the Printer Interface Program Does

The LP print service interacts with other parts of the operating system. The print service uses a standard printer interface program to do the following:

- Initialize the printer port, if necessary. The standard printer interface program uses the stty command to initialize the printer port.
- Initialize the printer. The standard printer interface program uses the terminfo database and the TERM shell variable to find the appropriate control sequences.
- Print a banner page, if necessary.
- Print the correct number of copies specified by the print request.

The LP print service uses the standard interface program, found in the /usr/lib/lp/model directory, unless you specify a different program. You can create custom interface programs, but you must make sure that the custom program does not terminate the connection to the printer or interfere with proper printer initialization.

How the lpsched Daemon Tracks the Status of Print Requests

The lpsched daemon keeps a log of each print request that it processes and notes any errors that occur during the printing process. This log is kept in the /var/lp/logs/lpsched file. Every night, the lp cron job renames the /var/lp/logs/lpsched file to a new lpsched.n file and starts a new log file. If errors occur or jobs disappear from the print queue, you can use the log files to determine what the lpsched daemon has done with a printing job.
Cleaning Out Log Files

The lpsched and requests log files in the /var/1p/logs directory grow as information is appended. The LP print service uses a default cron job to clean out the log files. The lp cron job is located in the /var/spool/cron/crontabs/lp file. The cron job periodically moves the contents of the log files. The contents of log are moved to log.1, and the contents of log.1 are moved to log.2. The contents of log.2 are lost (that is, replaced by the former contents of log.1) when log.2 gets overwritten.

▼ How to Change Frequency of Printer Request Log Rotation

Starting with the Solaris 2.6 release, the requests log file on the printer server is rotated weekly rather than daily. You can change the rotation interval back to daily if the printer server is busy.

1. Become superuser or lp on the printer server.

2. Set the EDITOR environment variable.

   # EDITOR=vi
   # export EDITOR

3. Edit the lp crontab file.

   # crontab -e lp

4. Change the first line of the file which rotates the requests log files every Sunday (0) to an asterisk (*) for daily rotation:

   1 3 * * * cd /var/lp/logs; if [ -f requests ]; then if
   [ -f requests.1 ]; then /bin/mv requests.1 requests.2; fi; /usr/bin/cp
   requests requests.1; >requests; fi

5. Save the file and exit.

How Local Printing Works

The print request follows the same path it would if the client and server were separate systems. Requests always flow from client to server following the same path.

The following figure shows what happens when a user submits a request to print a PostScript file on a local printer, which is a printer connected to the user’s system. The lpsched daemon on the local system does all processing, which might include matching the printer and content type, identifying the default printer, filtering the request, and starting the specified printer interface program.

The printer interface program does the following:
- Prints the banner page.
- Catches printer faults.
- Determines the printer fault policy to either reset, continue, or begin the print job over again.
- Finally, the interface program uses the lpcat program to download the print request to the local printer's serial port.
A user submits a print request. \(\rightarrow\) lpsched

Local system /var/spool/lp

lpsched spools the print request.

lpsched matches the printer type and the file content type, and identifies the default printer for the system.

lpsched filters the job. (It also can put the filtered output back into the spooling area.)

When the printer is free, lpsched starts the printer’s specified interface program on the serial port.

The interface program:
- Prints the banner page
- Catches faults
- Depending on the fault policy, it waits to be reset, continues, or begins job over.

The interface program uses the lpcat program to download the file into the serial port.

Document

FIGURE 8-2 The Local Printing Process
How Remote Printing Works

The following figure shows what happens when a user on a Solaris print client submits a print request to an lpd-based print server. The command opens a connection and handles it’s own communications with the print server directly.

![Diagram showing the process flow for remote printing between a Solaris print client and an lpd-based print server.]

1p sends a print request to the lpd-based print server.

lpd accepts the request, spools it, filters it, and schedules the local printing.

FIGURE 8–3 Printing Between a Solaris Print Client and a lpd-based Print Server

The following figure shows a lpd-based print client submitting a print request to a Solaris print server. The lpd daemon handles the local part of the print request and the connection to the print server. On the print server, the inetd process waits for network printing requests and starts a protocol adaptor to service the request. The protocol adaptor communicates with the lpsched daemon, which processes the request on the print server.
The following figure shows what happens when a user on a Solaris print client submits a print request to a Solaris print server. The print command on the print client handles the local part of each print request by communicating directly with the print server.

The inetd process on the print server monitors network printing requests and starts a protocol adaptor to communicate with the lpsched daemon on the print server, which processes the print request.
inetd listens for a request and starts in.lpd. in.lpd looks at the request and loads bsd_lpsched.so. in.lpd passes the request through bsd_lpsched.so to lpsched for local printing.

</tr>
</tbody>
</table>
Managing Terminals and Modems
(Overview)

This chapter provides the overview information for managing terminals and modems. This is a list of the overview information in this chapter.

- “Terminals, Modems, Ports, and Services” on page 174
- “Tools for Managing Terminals and Modems” on page 176
- “Serial Ports Tool” on page 176
- “Service Access Facility” on page 177

For step-by-step instructions about how to set up terminals and modems with Serial Ports Tool, see Chapter 11.

For step-by-step instructions about how to set up terminals and modems with the Service Access Facility (SAF), see Chapter 12.

What’s New in Managing Terminals and Modems?

The Solaris Management Console provides a Serial Ports Tool for setting up terminals and modems. For information on starting the Solaris Management Console, see “Starting the Solaris Management Console” in System Administration Guide: Basic Administration. For information on step-by-step instructions for setting up a terminal or modem, see the console online help.
Terminals, Modems, Ports, and Services

Terminals and modems provide both local and remote access to system and network resources. Setting up terminals and modem access is an important responsibility of a system administrator. This section explains some of the concepts behind modem and terminal management in the Solaris environment.

Terminals

Your system’s bit-mapped graphics display is not the same as an alphanumeric terminal, which connects to a serial port and displays only text. You don’t have to perform any special steps to administer the graphics display.

Modems

Modems can be set up in three basic configurations:

- Dial-out
- Dial-in
- Bidirectional

A modem connected to your home computer might be set up to provide dial-out service, meaning you can access other computers from your own home, but nobody outside can gain access to your machine.

Dial-in service is just the opposite. It allows people to access a system from remote sites, but it does not permit calls to the outside world.

Bidirectional access, as the name implies, provides both dial-in and dial-out capabilities.

Ports

A port is a channel through which a device communicates with the operating system. From a hardware perspective, a port is a “receptacle” into which a terminal or modem cable might be physically connected.

However, a port is not strictly a physical receptacle, but an entity with hardware (pins and connectors) and software (a device driver) components. A single physical receptacle often provides multiple ports, allowing connection of two or more devices.

Common types of ports include serial, parallel, small computer systems interface (SCSI), and Ethernet.
A serial port, using a standard communications protocol, transmits a byte of information bit-by-bit over a single line.

Devices that have been designed according to RS-232-C or RS-423 standards, this includes most modems, alphanumeric terminals, plotters, and some printers, can be connected interchangeably, using standard cables, into serial ports of computers that have been similarly designed.

When many serial port devices must be connected to a single computer, you might need to add an adapter board to the system. The adapter board, with its driver software, provides additional serial ports for connecting more devices than could otherwise be accommodated.

Services

Modems and terminals gain access to computing resources by using serial port software. Serial port software must be set up to provide a particular “service” for the device attached to the port. For example, you can set up a serial port to provide bidirectional service for a modem.

Port Monitors

The main mechanism for gaining access to a service is through a port monitor. A port monitor is a program that continuously monitors for requests to log in or access printers or files.

When a port monitor detects a request, it sets whatever parameters are required to establish communication between the operating system and the device requesting service. Then the port monitor transfers control to other processes that provide the services needed.

The following table describes the two types of port monitors included in the Solaris environment.

<table>
<thead>
<tr>
<th>TABLE 10-1 Port Monitor Types</th>
</tr>
</thead>
<tbody>
<tr>
<td>Port Monitor</td>
</tr>
<tr>
<td>listen</td>
</tr>
</tbody>
</table>
You might be familiar with an older port monitor called `getty(1M)`. The new `ttymon` is more powerful. A single `ttymon` can replace multiple occurrences of `getty`. Otherwise, these two programs serve the same function.

### Tools for Managing Terminals and Modems

The following table lists the tools for managing terminals and modems.

<table>
<thead>
<tr>
<th>Tool Description</th>

### Serial Ports Tool

Serial Ports Tool sets up the serial port software to work with terminals and modems by calling the `pmadm` command with the appropriate information. Serial Ports Tool also provides:

- Templates for common terminal and modem configurations
- Multiple port setup, modification, or deletion
- Quick visual status of each port
Service Access Facility

The SAF is the tool used for administering terminals, modems, and other network devices. In particular, SAF enables you to set up:

- **ttymon and listen** port monitors by using the `sacadm` command
- **ttymon** port monitor services by using the `pmadm` and `ttyadm` commands
- **listen** port monitor services by using the `pmadm` and `nlsadmin` commands
- And troubleshoot **tty** devices
- And troubleshoot incoming network requests for printing service
- And troubleshoot the Service Access Controller by using the `sacadm` command

The SAF is an open-systems solution that controls access to system and network resources through **tty** devices and local-area networks (LANs). SAF is not a program, but a hierarchy of background processes and administrative commands.
Setting Up Terminals and Modems (Tasks)

This chapter provides step-by-step instructions for setting up terminals and modems using Solaris Management Console’s Serial Ports Tool.

This is a list of the step-by-step instructions in this chapter.

- “How to Set Up a Terminal” on page 182
- “How to Set Up a Modem” on page 183
- “How to Initialize a Port” on page 183

For overview information about terminals and modems, see Chapter 10.

Setting Up Terminals and Modems with Serial Ports Tool

You can set up serial ports with the Solaris Management Console’s Serial Ports Tool. Select a serial port from the Serial Ports window and then choose a Configure option from the Action menu to configure the following.

- Terminal
- Modem – Dial In
- Modem – Dial Out
- Modem – Dial In/Dial Out
- Initialize Only – No Connection

The Configure options provide access to the templates for configuring the preceding services. You can view two levels of detail for each serial port: Basic and Advanced. You can access the Advanced level of detail for each serial port after it is configured by selecting the serial port and selecting the Properties option from the Action menu. After a serial port is configured, you can disable or enable the port with the SAF commands. For information on using the SAF commands, see Chapter 12.
For information on using the Serial Ports command line interface, see man serialport(1M).

### Setting Up Terminals

The following table describes the menu items (and their default values) when setting up a terminal using Serial Ports.

**TABLE 11–1 Terminal Default Values**

<table>
<thead>
<tr>
<th>Detail</th>

▼ How to Set Up a Terminal

1. Start the Solaris Management Console, if it’s not already running.
   
   ```
   $ /usr/sadm/bin/smc &
   ```

   For information on starting the Solaris Management Console, see “Starting the Solaris Management Console” in *System Administration Guide: Basic Administration*.

2. Click This Computer icon in the Navigation pane.

3. Click Devices and Hardware—>Serial Ports.
   
   The Serial Ports menu is displayed.

4. Select the port that will be used with a terminal.

5. Choose Configure—>Terminal from the Action menu.
   
   The Configure Serial Port window appears in the Basic Detail mode.

6. Change values of template entries if desired.

7. To configure the advanced items, select the port configured as a terminal. Then, select Properties from the Action menu.

8. Click OK to configure the port.

9. Verify that the terminal service has been added.
   
   ```
   $ pmadm -l -s ttyw
   ```
How to Set Up a Modem

1. Start the Solaris Management Console, if it’s not already running.
   ```
   % /usr/sadm/bin/smc &
   ```
   For information on starting the Solaris Management Console, see “Starting the Solaris Management Console” in *System Administration Guide: Basic Administration*.

2. Click This Computer icon in the Navigation pane.

3. Click Devices and Hardware—>Serial Ports.
   The Serial Ports menu is displayed.

4. Select the port that will be used with a modem.

5. Choose one of the following Configure options from the Action menu.
   a. Configure—>Modem (Dial In)
   b. Configure—>Modem (Dial Out)
   c. Configure—>Modem (Dial In/Out)
      The Configure Serial Port window appears in the Basic Detail mode.
      For a description of the Modem menu items, see Table 11–3

6. Click OK.

7. To configure the advanced items, select the port configured as a modem. Then, select Properties from the Action menu.

8. Change the values of template entries if desired.

9. Click OK to configure the port.

10. Verify that the modem service has been configured.
    ```
    $ pmadm -l -s ttyN
    ```

How to Initialize a Port

1. Start the Solaris Management Console, if it’s not already running.
   ```
   % /usr/sadm/bin/smc &
   ```
   For information on starting the Solaris Management Console, see “Starting the Solaris Management Console” in *System Administration Guide: Basic Administration*.

2. Click This Computer icon in the Navigation pane.

3. Click Devices and Hardware—>Serial Ports.
The Serial Ports menu is displayed.

4. Select the port to be initialized.

5. Choose Configure--->Initialize Only – No Connection
   The Serial Port window appears in the Basic Detail mode.
   For a description of the Initialize Only menu items, see Table 11–4

6. Click OK.

7. To configure the advanced items, select the port configured as a initialize only.
   Then, select Properties from the Action menu.

8. Change the values of template entries if desired.

9. Click OK to configure the port.

10. Verify that the modem service has been initialized.

    $ pmadm -l -s ttyN

---

Troubleshooting Terminal and Modem Problems

If users are unable to log in over serial port lines after you have added a terminal or modem and set up the proper services, consider the following possible causes of failure.

- Check with the user.
  Malfunctions in terminals and modem use are typically reported by a user who has failed to log in or dial in. For this reason, it is best to begin troubleshooting by checking for a problem on the desktop.
  Some common reasons for login failure include:
  - Login ID or password is incorrect.
  - Terminal is waiting for X-ON flow control key (Control-q).
  - Serial cable is loose or unplugged.
  - Terminal configuration is incorrect.
  - Terminal is shut off or otherwise has no power.

- Check the terminal.
  Continue to troubleshoot by checking the configuration of the terminal or modem. Determine the proper ttylabel for communicating with the terminal or modem. Verify that the terminal or modem settings match those of the ttylabel.
  - Check the terminal server.
If the terminal checks out, continue to search for the source of the problem on the terminal or modem server. Use the `pmadm` command to verify that a port monitor has been configured to service the terminal or modem and that it has the correct `ttylabel` associated with it.

```bash
$ pmadm -l -t ttymon
```

Examine `/etc/ttydefs` and double check the label definition against the terminal configuration. Use `sacadm` to check the port monitor's status. Use `pmadm` to check the service associated with the port the terminal uses.

- Check the serial connection.

If the Service Access Controller is starting the TTY port monitor and `pmadm` reports that the service for the terminal's port is enabled, and if the terminal's configuration matches the port monitor's, then continue to search for the problem by checking the serial connection. A serial connection comprises serial ports, cables, and terminals. Test each of these parts by using it with two other parts that are known to be reliable.

Test all of the following:

- Serial ports
- Modems
- Cables
- Connectors

- Do not use Serial Ports Tool to modify serial port settings if the serial port is being used as a console. The correct procedure for changing console settings is by modifying the following line in the `/etc/inittab` file:

```bash
co:234:respawn:/usr/lib/saf/ttymon -g -h -p "'uname -n' console login: " -T terminal_type -d /dev/console -l console -m ldterm,ttcompat
```
Managing Serial Ports With the Service Access Facility (Tasks)

This chapter describes how to manage serial port services with the Service Access Facility (SAF).

This is a list of the step-by-step instructions in this chapter.

- “How to Add a ttymon Port Monitor” on page 195
- “How to View ttymon Port Monitor Status” on page 195
- “How to Stop a ttymon Port Monitor” on page 196
- “How to Start a ttymon Port Monitor” on page 197
- “How to Disable a ttymon Port Monitor” on page 197
- “How to Enable a ttymon Port Monitor” on page 197
- “How to Remove a ttymon Port Monitor” on page 198
- “How to Add a Service” on page 198
- “How to View the Status of a TTY Port Service” on page 199
- “How to Enable a Port Monitor Service” on page 202
- “How to Disable a Port Monitor Service” on page 202

This is a list of the overview information in this chapter.

- “Using the Service Access Facility” on page 188
- “Overall SAF Administration (sacadm)” on page 189
- “Port Monitor Service Administration (pmadm)” on page 190
- “TTY Monitor and Network Listener Port Monitors” on page 192

For reference information about the SAF, see “Service Access Facility Administration (Reference)” on page 202
Using the Service Access Facility

You can set up terminals and modems with the Solaris Management Console’s Serial Ports Tool, admintool, or the SAF commands.

The SAF is the tool that is used to administer terminals, modems, and other network devices. The top-level SAF program is the Service Access Controller (SAC). The SAC controls port monitors that you administer through the sacadm command. Each port monitor can manage one or more ports.

You administer the services associated with ports through the pmadm command. While services provided through SAC can differ from network to network, the SAC and its administrative commands, sacadm and pmadm, are network independent.

The following table describes the SAF control hierarchy. The sacadm command is used to administer the SAC, which controls the ttymon and listen port monitors.

The services of ttymon and listen are in turn controlled by the pmadm command. One instance of ttymon can service multiple ports. One instance of listen can provide multiple services on a network interface.

**TABLE 12-1 SAF Control Hierarchy**

</tr>
</tbody>
</table>
Overall SAF Administration (**sacadm**)

The **sacadm** command is the top level of the SAF. The **sacadm** command primarily is used to add and remove port monitors such as `ttymon` and `listen`. Other **sacadm** functions include listing the current status of port monitors and administering port monitor configuration scripts.

Service Access Controller (SAC Program)

The Service Access Controller program (SAC) oversees all port monitors. A system automatically starts SAC upon entering multiuser mode.

When the SAC is invoked, it first looks for, and interprets, each system’s configuration script. You can use configuration script to customizes the SAC environment. This script is empty by default. The modifications made to the SAC environment are inherited by all the “children” of the SAC. This inherited environment might be modified by the children.

After the SAC has interpreted the per-system configuration script, the SAC program reads its administrative file and starts the specified port monitors. For each port monitor, SAC runs a copy of itself, forking a child process. Each child then interprets its per-port monitor configuration script, if such a script exists.

Any modifications to the environment specified in the per-port monitor configuration script affect the port monitor and will be inherited by all its children. Finally, the child process runs the port monitor program by using the command found in the SAC administrative file.

SAC Initialization Process

The following steps summarize what happens when SAC is first started:

1. The SAC program is spawned by `init` at run level two.
2. The SAC program reads `/etc/saf/_sysconfig`, the per-system configuration script.
3. The SAC program reads `/etc/saf/_sactab`, the SAC administrative file.
4. The SAC program forks a child process for each port monitor it starts.
5. Each port monitor reads `/etc/saf/pmtag/_config`, the per-port monitor configuration script.
Port Monitor Service Administration (pmadm)

The pmadm command enables you to administer port monitors’ services. In particular, you use the pmadm command to add or remove a service and to enable or disable a service. You can also install or replace per-service configuration scripts, or print information about a service.

Each instance of a service must be uniquely identified by a port monitor and a port. When you use the pmadm command to administer a service, you specify a particular port monitor with the pmtag argument, and a particular port with the svctag argument.

For each port monitor type, the SAF requires a specialized command to format port monitor-specific configuration data. This data is used by the pmadm command. For ttymon and listen type port monitors, these specialized commands are ttyadm and nlsadmin, respectively.

ttymon Port Monitor

Whenever you attempt to log in by using a directly connected modem or alphanumeric terminal, ttymon goes to work.

As shown in the following figure, the init process is the first process to be started at boot time. Consulting its administrative file (/etc/inittab), the init process starts other processes as they are needed. Listed among those processes is the SAC.

SAC, in turn, automatically starts the port monitors designated in its administrative file, /etc/saf/_sactab. The following figure shows only a single ttymon port monitor.

After the ttymon port monitor has been started, it monitors the serial port lines for service requests.
When someone attempts to log in by using an alphanumeric terminal or a modem, the serial port driver passes the activity to the operating system. The `ttymon` port monitor notes the serial port activity, and attempts to establish a communications link. The `ttymon` port monitor determines what data transfer rate, line discipline, and handshaking protocol are required to communicate with the device.

After the proper parameters for communication with the modem or terminal are established, the `ttymon` port monitor passes these parameters to the login program and transfers control to it.

### Port Initialization Process

When an instance of the `ttymon` port monitor is invoked by SAC, `ttymon` starts to monitor its ports. For each port, the `ttymon` port monitor first initializes the line disciplines, if they are specified, and the speed and terminal settings. The values used for initialization are taken from the appropriate entry in the `/etc/ttydefs` file.
The `ttymon` port monitor then writes the prompt and waits for user input. If the user indicates that the speed is inappropriate by pressing the Break key, the `ttymon` port monitor tries the next speed and writes the prompt again.

If `autobaud` is enabled for a port, the `ttymon` port monitor tries to determine the baud rate on the port automatically. Users must press Return before the `ttymon` port monitor can recognize the baud rate and print the prompt.

When valid input is received, the `ttymon` port monitor does the following tasks:
- Interprets the per-service configuration file for the port
- Creates an `/etc/utmpx` entry if required
- Establishes the service environment
- Invokes the service associated with the port

After the service terminates, the `ttymon` port monitor cleans up the `/etc/utmpx` entry, if one exists, and returns the port to its initial state.

**Bidirectional Service**

If a port is configured for bidirectional service, the `ttymon` port monitor will:
- Allow users to connect to a service
- Allow the `uucico`, `cu`, or `ct` commands to use the port for dialing out, if the port is free.
- Wait to read a character before printing a prompt
- Invoke the port’s associated service, without sending the prompt message, when a connection is requested, if the connect-on-carrier flag is set

**TTY Monitor and Network Listener Port Monitors**

Though SAF provides a generic means for administering any future or third-party port monitors, only two are implemented in the Solaris environment: `ttymon` and `listen`.

**TTY Port Monitor (`ttymon`)**

The `ttymon` port monitor is STREAMS-based and does the following:
- Monitors ports
- Sets terminal modes, baud rates, and line disciplines
Invokes the login process

The `ttymon` port monitor provides Solaris users the same services that `getty` did under previous versions of SunOS 4.1 software.

The `ttymon` port monitor runs under the SAC program and is configured with the `sacadm` command. Each instance of `ttymon` can monitor multiple ports. These ports are specified in the port monitor’s administrative file. The administrative file is configured by using the `pmadm` and `ttyadm` commands.

**ttymon and the Console Port**

Console services are not managed by the Service Access Controller nor any explicit `ttymon` administration file. An entry in the `/etc/inittab` file is used to manage the console port by using `ttymon` in *express* mode. Express mode is a special `ttymon` mode that is invoked directly by a command that requires login service.

The default console entry in the `/etc/inittab` file is as follows:

```
co:234:respawn:/usr/lib/saf/ttymon -g -h -p "'uname -n' console login:"
   -T terminal_type -d /dev/console -l console -m ldterm,ttcompat
```

- `co` identifies the entry as the console.
- `234` identifies the run levels for the action.
- `respawn` means the console entry should be restarted if it fails or doesn’t exist at run levels 2, 3, and 4.

- `/usr/lib/saf/ttymon -g -h` The `-g` option is used so the correct baud rate and terminal setting can be set on a port and connect to a login service without being preconfigured by the SAC. The `-h` option forces a line hangup by setting the line speed to zero before setting the default or specified speed.

- `-p "'uname -n' console login:"` Identifies the prompt string for the console port.

- `-t terminal_type` Identifies the terminal type of the console.

- `-d /dev/console -l console` The `-d` option identifies the console device. The `-l` option identifies the `ttylabel` in the `/etc/ttydefs` file.

- `-m ldterm,ttcompat` The `-m` option identifies the STREAMS modules to be pushed.
ttymon-Specific Administrative Command
(ttyadm)

The ttymon administrative file is updated by sacadm and pmadm, as well as by the
ttyadm command. The ttyadm command formats ttymon-specific information and
writes it to the standard output, providing a means for presenting formatted
ttymon-specific data to the sacadm and pmadm commands.

Thus, ttyadm does not administer ttymon directly. The ttyadm command
complements the generic administrative commands, sacadm and pmadm. For more
information, see ttyadm(1M).

Network Listener Service (listen)

The listen port monitor runs under SAC and does the following:

- Monitors the network for service requests
- Accepts requests when they arrive
- Invokes servers in response to those service requests

The listen port monitor is configured by using the sacadm command. Each instance
of listen can provide multiple services. These services are specified in the port
monitor's administrative file. This administrative file is configured by using the pmadm
and nlsadmin commands.

The network listener process can be used with any connection-oriented transport
provider that conforms to the Transport Layer Interface (TLI) specification. In the
Solaris environment, listen port monitors can provide additional network services
not provided by the inetd service.

Special listen-Specific Administrative Command
(nlsadmin)

The listen port monitor's administrative file is updated by sacadm and pmadm, as
well as by the nlsadmin command. The nlsadmin command formats
listen-specific information and writes it to standard output, providing a means of
presenting formatted listen-specific data to the sacadm and pmadm commands.

Thus, nlsadmin does not administer listen directly. It complements the generic
administrative commands, sacadm and pmadm.

Each network, configured separately, can have at least one instance of the network
listener process associated with it. The nlsadmin command controls the operational
states of listen port monitors.
The nlsadmin command can establish a listen port monitor for a given network, configure the specific attributes of that port monitor, and start and kill the monitor. The nlsadmin command can also report on the listen port monitors on a machine.

For more information, see nlsadmin(1M).

---

**Administering ttymon Port Monitors**

Use the sacadm command to add, list, remove, kill, start, enable, disable, enable, and remove a ttymon port monitor.

**Note** – You must be superuser to perform the following procedures.

#### ▼ How to Add a ttymon Port Monitor

To add a ttymon port monitor, type the following:

```
# sacadm -a -p mbmon -t ttymon -c /usr/lib/saf/ttymon -v 'ttyadm -V' -y "TTY Ports a & b"
```

- **-a** The **add** port monitor flag.
- **-p** Specifies the **pmtag** mbmon as the port monitor tag.
- **-t** Specifies the port monitor **type** as ttymon.
- **-c** Defines the **command** string used to start the port monitor.
- **-v** Specifies the **version** number of the port monitor.
- **-y** Defines a comment to describe this instance of the port monitor.

#### ▼ How to View ttymon Port Monitor Status

To see the status of a ttymon port monitor, type the following:

```
# sacadm -l -p mbmon
```

- **-l** The **list** port monitor status flag.
-p Specifies the pmtag mbmon as the port monitor tag.

Example—Viewing ttymon Port Monitor Status

```
# sacadm -l -p mbmon
PMTAG  PMTYPE  FLGS  RCNT  STATUS  COMMAND
mbmon  ttymon  -  0  STARTING  /usr/lib/saf/ttymon #TTY Ports a & b
```

- **PMTAG** Identifies the port monitor name, mbmon.
- **mbmon**
- **PMTYPE** Identifies the port monitor type, ttymon.
- **ttymon**
- **FLGS** Indicates whether the following two flags are set:
- **-** d, do not enable the new port monitor, or
- **x**, do not start the new port monitor. No flags are set in this example.
- **RCNT** Indicates the return count value. A return count of 0 indicates that the port monitor is not to be restarted if it fails.
- **0**
- **STATUS** Indicates the current status of the port monitor.
- **STARTING**
- **COMMAND** Identifies the command used to start the port monitor.
- **/usr/lib/saf ...**
- **#TTY Ports a & b** Identifies any comment used to describe the port monitor.

▼ How to Stop a ttymon Port Monitor

To kill a ttymon port monitor, type the following:
```
# sacadm -k -p mbmon
```

- **-k** The *kill* port monitor status flag.
- **-p** Specifies the *pmtag* mbmon as the port monitor tag.
How to Start a `ttymon` Port Monitor

To start a killed `ttymon` port monitor, type the following:

```
# sacadm -s -p mbmon
```

- `-s` The `start` port monitor status flag.
- `-p` Specifies the `pmtag` `mbmon` as the port monitor tag.

How to Disable a `ttymon` Port Monitor

Disabling a port monitor prevents new services from starting, without affecting existing services.

To disable a `ttymon` port monitor, type the following:

```
# sacadm -d -p mbmon
```

- `-d` The `disable` port monitor status flag.
- `-p` Specifies the `pmtag` `mbmon` as the port monitor tag.

How to Enable a `ttymon` Port Monitor

Enabling a `ttymon` port monitor allows it to service new requests.

To enable a `ttymon` port monitor, type the following:

```
# sacadm -e -p mbmon
```

- `-e` The `enable` port monitor status flag.
- `-p` Specifies the `pmtag` `mbmon` as the port monitor tag.
How to Remove a ttymon Port Monitor

To remove a ttymon port monitor, type the following:

```
# sacadm -r -p mbmon
```

- **-r** The *remove* port monitor status flag.
- **-p** Specifies the *pmtag* `mbmon` as the port monitor tag.

---

**Note** – Removing a port monitor deletes all the configuration files associated with it. Port monitor configuration files cannot be updated or changed by using the `sacadm` command. To reconfigure a port monitor, remove it and add a new one.

---

Administering ttymon Services

Use `pmadm` to add services, list the services of one or more ports associated with a port monitor, and enable or disable a service.

---

**Note** – You must be superuser to perform the following procedures.

---

How to Add a Service

To add a standard terminal service to the `mbmon` port monitor, type the following:

```
# pmadm -a -p mbmon -s a -i root -v ttymon -v -m ttyadm -i 'Terminal disabled' -l contty -m ldterm,ttcompat -S y -d /dev/term/a -s /usr/bin/login"
```

---

**Note** – In this example, the input wraps to the next line. Do not put a Return or line feed after `contty`.

---

- **-a** The *add* port monitor status flag
- **-p** Specifies the *pmtag* `mbmon` as the port monitor tag.
The preceding `pmadm` command contains an embedded `ttyadm` command. The options in this embedded command are as follows:

- `-b` The bidirectional port flag.
- `-i` Specifies the inactive (disabled) response message.
- `-l` Specifies which TTY label in the `/etc/ttydefs` file to use.
- `-m` Specifies the STREAMS modules to push before invoking this service.
- `-d` Specifies the full path name to the device to use for the TTY port.
- `-s` Specifies the full path name of the service to invoke when a connection request is received. If arguments are required, enclose the command and its arguments in quotation marks (".

How to View the Status of a TTY Port Service

Use the `pmadm` command as shown to list the status of a TTY port, or all the ports associated with a port monitor.

To list one service of a port monitor, type the following:

```
# pmadm -l -p mbmon -s a
```

- `-l` Lists service information.
- `-p` Specifies the `pmtag` `mbmon` as the port monitor tag.
- `-s` Specifies the `svctag` `a` as the port monitor `service` tag.

To list all services of all port monitors, type the following:

```
# pmadm -l
```

- `-l` Lists service information

To list all services of a port monitor, type the following:
# `pmadm -l -p mbmon`

- `l` Lists service information
- `p` Specifies the `pmtag` `mbmon` as the port monitor tag

## Example—Viewing the Status of a TTY Port Monitor Service

```
# pmadm -l -p mbmon

PMTAG  PMTYPE  SVCTAG  FLAGS  ID  <PMSPECIFIC>
mbmon  ttymon  a      -      root /dev/term/a - /usr/bin/login - contty
      ldterm,ttcompat login: Terminal disabled - y #
```

- `mbmon` Identifies the port monitor name, `mbmon`, set by using the `pmadm -p` command.
- `ttymon` Identifies the port monitor type, `ttymon`.
- `a` Indicates the service tag value set by using the `pmadm -s` command.
- `-` Identifies whether the following flags are set by using the `pmadm -f` command:
  - `x`, which means do not enable the service
  - `u`, which means create a `utmpx` entry for the service. No flags are set in this example.
- `root` Identifies the ID assigned to the service when its started. This value is set by using the `pmadm -i` command.

### <PMSPECIFIC> Information

- `/dev/term/a` Indicates the TTY port pathname set by using the `ttyadm -d` command.
Indicates whether the following flags are set by using the `ttyadm -c -b -h -I -r` command:

- `c`, sets the connect on carrier flag for the port
- `b`, sets the port as bidirectional, allowing both incoming and outgoing traffic
- `h`, suppresses an automatic hangup immediately after an incoming call is received
- `I`, initializes the port
- `r`, forces `ttymon` to wait until it receives a character from the port before it prints the `login:` message.

Indicates a value set by using the `ttyadm -r` option. This option determines when `ttymon` displays a prompt after receiving data from a port. If count is 0, `ttymon` will wait until it receives any character. If count is greater than 0, `ttymon` will wait until count new lines have been received. No value is set in this example.

`/usr/bin/login` Identifies the full pathname of the service to be invoked when a connected is received. This value is set by using `ttyadm -s` command.

Identifies the `ttyadm -t` command’s timeout value. This option specifies that `ttymon` should close a port if the open on the port succeeds, and no input data is received in `timeout` seconds. There is no timeout value in this example.

`contty` Identifies the TTY label in the `/etc/ttydefs` file. This value is set by using the `ttyadm -l` command.

`ldterm,ttcompat` Identifies the STREAMS modules to be pushed. These modules are set by using the `ttyadmin -m` command.

`login: Terminal disabled` Identifies an inactive message to be displayed when the port is disabled. This message is set by using the `ttyadm -i` command.

`tvi925` Identifies the terminal type, if set, by using the `ttyadm -T` command. The terminal type is `tvi925` in this example.

`y` Identifies the software carrier value set by using the `ttyadm -S` command: `n` will turn software carrier off, `y` will turn software carrier on. Software carrier is turned on in this example.

`#` Identifies any comment specified with the `pmadm -y` command. There is no comment in this example.
How to Enable a Port Monitor Service

To enable a disabled port monitor service, type the following:

```
# pmadm -e -p mbmon -s a
```

- `e` The *enable* flag.
- `p` Specifies the *pmtag* mbmon as the port monitor tag.
- `s` Specifies the *svctag* a as the port monitor *service* tag.

How to Disable a Port Monitor Service

To disable a port monitor service, type the following:

```
# pmadm -d -p mbmon -s a
```

- `d` The *disable* flag.
- `p` Specifies the *pmtag* mbmon as the port monitor tag.
- `s` Specifies the *svctag* a as the port monitor *service* tag.

Service Access Facility Administration
(Reference)

Files Associated With SAF

SAF uses configuration files which can be modified by using the sacadm and pmadm commands. You should not need to edit the configuration files manually.

<table>
<thead>
<tr>
<th>File Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>/etc/saf/_sysconfig</td>
<td>Per-system configuration script.</td>
</tr>
</tbody>
</table>
The `/etc/saf/_sactab` File

The `/etc/saf/_sactab` is as follows:

```
# VERSION=1
zsmon:ttymon::0:/usr/lib/saf/ttymon    #

# VERSION=1 Indicates the Service Access Facility version number.

zsmon Is the name of the port monitor.

ttymon Is the type of port monitor.

:: Indicates whether the following two flags are set:

d, do not enable the port monitor

x, do not start the port monitor. No flags are set in this example.

0 Indicates the return code value. A return count of 0 indicates that the port monitor is not be restarted if the port monitor fails.

/usr/lib/saf/ttymon Indicates the port monitor pathname.
```
# The `/etc/saf/pmtab/_pmtab` File

The `/etc/saf/pmtab/_pmtab` file, such as `/etc/saf/zsmon/_pmtab`, looks similar to the following:

```plaintext
# VERSION=1
ttya:u:root:reserved:reserved:reserved:/dev/term/a:I::/usr/bin/login::9600:
ldterm,ttscompat:ttya login:\: :tvi925:y:#
```

<table>
<thead>
<tr>
<th>Field</th>

<td></td>
</tr>
<tr>
<td>message</td>
<td>Identifies any inactive (disabled) response message.</td>
</tr>
</tbody>
</table>
Identifies the terminal type.

Indicates whether software carrier is set (y/n).

Service States

The `sacadm` command controls the states of services. The following table describes the possible states of services.

<table>
<thead>
<tr>
<th>State</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Enabled</td>
<td>Default state – When the port monitor is added, the service operates.</td>
</tr>
<tr>
<td>Disabled</td>
<td>Default state – When the port monitor is removed, the service stops.</td>
</tr>
</tbody>
</table>

To determine the state of any particular service, use the following:

```
# pmadm -l -p portmon_name -s svctag
```

Port Monitor States

The `sacadm` command controls the states of `ttymon` and `listen` port monitors. The following table describes the possible port monitor states.

<table>
<thead>
<tr>
<th>State</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Started</td>
<td>Default state – When the port monitor is added, it is automatically started.</td>
</tr>
<tr>
<td>Enabled</td>
<td>Default state – When the port monitor is added, it is automatically ready to accept requests for service.</td>
</tr>
<tr>
<td>Stopped</td>
<td>Default state – When the port monitor is removed, it is automatically stopped.</td>
</tr>
<tr>
<td>Disabled</td>
<td>Default state – When the port monitor is removed, it automatically continues existing services and refuses to add new services.</td>
</tr>
<tr>
<td>Starting</td>
<td>Intermediate state – The port monitor is in the process of starting.</td>
</tr>
<tr>
<td>Stopping</td>
<td>Intermediate state – The port monitor has been manually terminated, but it has not completed its shutdown procedure. The port monitor is on the way to becoming stopped.</td>
</tr>
</tbody>
</table>
State Description
Notrunning  

*Inactive state* – The port monitor has been killed. All ports previously monitored are inaccessible. An external user cannot tell whether a port is disabled or not running.

Failed  

*Inactive state* – The port monitor is unable to start and remain running.

To determine the state of any particular port monitor, use the following:

```bash
# sacadm -l -p portmon_name
```

**Port States**

Ports can be enabled or disabled depending on the state of the port monitor that controls the ports.

<table>
<thead>
<tr>
<th>State</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Serial (ttymon) Port States</strong></td>
<td></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>State</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Enabled</td>
<td>The ttymon port monitor sends a prompt message to the port and provides login service to it.</td>
</tr>
<tr>
<td>Disabled</td>
<td>Default state of all ports if ttymon is killed or disabled. If you specify this state, ttymon will send out the disabled message when it receives a connection request.</td>
</tr>
</tbody>
</table>
# Managing System Resources Topics

This topic map lists the chapters that provide information for managing system resources.

<table>
<thead>
<tr>
<th>Chapter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Chapter 14</td>
<td>Provides an overview of Solaris commands and utilities that help you manage system resources by using disk quotas, the \texttt{cron} and \texttt{at} commands, and accounting programs.</td>

</tbody>
</table>
Managing System Resources
(Overview)

This chapter provides a brief description of new Solaris 9 features and a map of features to help you manage system resources.

Using these features, you can display general system information, monitor disk space, set disk quotas, use accounting programs, and schedule the crontab and at commands to automatically run routine commands.

This section does not cover Solaris resource management that enables you to allocate, monitor, and control system resources in a flexible way.

For information on the procedures associated with managing system resources without Solaris resource management, see “High-Level View of Managing System Resources (Task Map)” on page 211.

For information on managing system resources with Solaris resource management, see “Introduction to Solaris 9 Resource Manager” in System Administration Guide: Resource Management and Network Services.

What’s New in Managing System Resources?

New df, du, and ls Options

The df, du, and ls commands have a new -h option to display disk usage and file or file system sizes in powers of 1024. This option makes it easier to interpret the output of the df, du, and ls -l commands by providing disk space in kilobytes, Mbytes, Gbytes, or terabytes if the file or directory size is larger than 1024 bytes.
For more information, see \texttt{df(1B)}, \texttt{du(1)}, and \texttt{ls(1)}.

For more information in this guide, see “How to Display Information About Files and Disk Space” on page 222.

Changing System Parameters

In previous versions of this book, there was a section on changing system parameters such as increasing the number of processes per user and shared memory segments. This section has been removed. For information on changing system tunable parameters, see \textit{Solaris Tunable Parameters Reference Manual}.

In addition, information on setting up a network time server has been moved to “Time-Related Services” in \textit{System Administration Guide: Resource Management and Network Services}.

Solaris Resource Management

Solaris resource management enables you to control how applications use available system resources.

You can also set up the extended accounting facility to monitor and record resource consumption on a task or process basis.

\textit{Extended} accounting introduces a new, variable length general-purpose accounting file format that represents general groups of accounting data. It provides the ability to configure resource utilization recorded by the kernel in the various accounting files.

Solaris resource management features include:

- \textit{Tasks} – New process collectives for tracking resource usage.
- \textit{Projects} – New administrative databases for charging resource usage. Resource usage can be charged to a project based on tasks performed.
- \texttt{acctadm} – A new tool for configuring various attributes of the extended accounting feature. For example, the resources tracked by the system accounting can be configured on a system-wide basis.

The new default accounting configuration requires no administration. However, do not remove the \texttt{/etc/project} file, even if you do not use the extended accounting features. Users cannot log in to the system unless this file exists.

Use the following table to find more information about the extended accounting features in this release.
<table>
<thead>
<tr>
<th>Solaris Resource Management Feature</th>
<th>For More Information</th>
</tr>
</thead>
<tbody>
<tr>
<td>Description of the projects database</td>
<td>“Projects and Tasks” in System Administration Guide: Resource Management and Network Services and project(4)</td>

CHAPTER 15

Displaying and Changing System Information (Tasks)

This chapter describes the tasks required to display and change the most common system information. This is a list of the step-by-step instructions in this chapter.

- “How to Determine If a System Can Run the 64–bit Solaris Operating Environment” on page 214
- “How to Display General System Information” on page 216
- “How to Display a System’s Host ID Number” on page 217
- “How to Display the Date and Time” on page 217
- “How to Set a System’s Date and Time Manually” on page 218
- “How to Set Up a Message-of-the-Day” on page 218
- “How to Change a System’s Host Name” on page 219

Displaying System Information

The following table describes commands that enable you to display general system information.

**TABLE 15–1 Commands for Displaying System Information**

<table>
<thead>
<tr>
<th>Command</th>
<th>Man Page</th>
<th>System Information Displayed</th>
</tr>
</thead>
<tbody>
<tr>
<td>psrinfo</td>
<td>psrinfo(1M)</td>
<td>Processor type</td>
</tr>
<tr>
<td>isainfo</td>
<td>isainfo(1)</td>
<td>Reports the number of bits supported by <em>native</em> applications on the running system, which can be passed as a token to scripts</td>
</tr>
</tbody>
</table>
### TABLE 15-1  Commands for Displaying System Information  (Continued)

<table>
<thead>
<tr>
<th>Command</th>

<tr>
<td>prtconf</td>
<td>prtconf(1M)</td>
<td>Installed memory</td>
</tr>
<tr>
<td>date</td>
<td>date(1)</td>
<td>Date and time</td>
</tr>
</tbody>
</table>

#### ▼ How to Determine If a System Can Run the 64–bit Solaris Operating Environment

Currently, the only platform capable of supporting the 64–bit Solaris operating environment is an UltraSPARC system. To verify if a system is an UltraSPARC system, use the following command:

```bash
$ uname -m
sun4u
```

If the output of the `uname -m` command is `sun4u`, then the machine is an UltraSPARC system.

If you are running the Solaris 9 release, you can verify that the machine is an UltraSPARC system by using the `psrinfo` command:

```bash
# psrinfo -v
Status of processor 0 as of: 05/30/01 13:48:46
  Processor has been on-line since 05/18/01 10:02:40.
  The sparcv9 processor operates at 333 MHz, 
  and has a sparcv9 floating point processor.
```

If the processor type is `sparcv9`, the platform is capable of running the 64-bit Solaris operating environment. This test does not work on previous versions of the `psrinfo` command, where all platforms report the less precise `sparc` as the processor type.

#### ▼ How to Determine If a System Has 64-bit Solaris Capabilities Enabled

Use the `isainfo` command to determine if a system has 64-bit capabilities enabled, which means that the system is booted with the 64–bit kernel.
Examples—Determining If a System Has 64–bit Solaris Capabilities Enabled

The output for an UltraSPARC system running a 32-bit kernel appears as follows:

$ isainfo -v
32-bit sparc applications

This output means that this system is capable of supporting only 32-bit applications.

The output for an UltraSPARC system running a 64-bit kernel appears as follows:

$ isainfo -v
64-bit sparcv9 applications
32-bit sparc applications

This output means that this system is capable of supporting both 32-bit and 64-bit applications.

Use the isainfo -b command to display the number of bits supported by native applications on the running system.

The output from a SPARC, IA, or UltraSPARC system running the 32–bit Solaris operating environment appears as follows:

$ isainfo -b
32

The output from a 64–bit UltraSPARC system running the 64–bit Solaris operating environment appears as follows:

$ isainfo -b
64

The command returns 64 only. Even though a 64–bit UltraSPARC system is capable of running both types of applications, 64–bit applications are the best kind of applications to run on a 64–bit system.

▼ How to Display Solaris Release Information

Display the contents of the /etc/release file to identify your Solaris release version.

$ more /etc/release
Solaris 8 2/02 s28s_u7wos_08a SPARC
Copyright 2002 Sun Microsystems, Inc. All Rights Reserved.
Assembled 18 December 2001
How to Display General System Information

To display general system information, use the `showrev` command.

```
$ showrev [-a]
```

The `-a` option displays all available system information.

Example—Displaying General System Information

The following example shows the `showrev` command output.

```
$ showrev -a
Hostname: starbug
Hostid: nnnnnnnn
Release: 5.9
Kernel architecture: sun4u
Application architecture: sparc
Hardware provider: Sun_Microsystems
Domain: solar.com
Kernel version: SunOS 5.9 May 2002

OpenWindows version:
X11 Version 6.4.2 11 April 2001

No patches are installed
$
```

How to Display General System Information

To display system information, use the `uname` command.

```
$ uname[-a]
```

The `-a` option displays the operating system name as well as the system node name, operating system release, operating system version, hardware name, and processor type.

Example—Displaying General System Information

The following example shows the `uname` command output.

```
$ uname
SunOS
$ uname -a
SunOS starbug 5.9 Generic sun4u sparc SUNW,Ultra-5_10
$
```
How to Display a System’s Host ID Number

To display the host ID number in hexadecimal format, use the `hostid` command.

```
$ hostid
```

Example—Displaying a System’s Host ID Number

The following example shows sample output from the `hostid` command.

```
$ hostid
80a5d34c
```

How to Display a System’s Installed Memory

To display the amount of memory installed on your system, use the `prtconf` command.

```
$ prtconf | grep Memory
```

The `grep Memory` command selects output from the `prtconf` command to display memory information only.

Example—Displaying a System’s Installed Memory

The following example shows sample output from the `prtconf` command.

```
# prtconf | grep Memory
Memory size: 128 Megabytes
```

How to Display the Date and Time

To display the current date and time according to your system clock, use the `date` command.

```
$ date
```

Example—Displaying the Date and Time

The following example shows sample output from the `date` command.

```
$ date
Thu May 31 17:44:58 MDT 2001
$
Changing System Information

This section describes commands that enable you to change general system information.

▼ How to Set a System’s Date and Time Manually

1. Become superuser.

2. Enter the new date and time.
   
   # date mmdHHMM[cc][yy]

   - **mm**: Month, using two digits.
   - **dd**: Day of the month, using two digits.
   - **HH**: Hour, using two digits and a 24-hour clock.
   - **MM**: Minutes, using two digits.
   - **cc**: Century, using two digits.
   - **yy**: Year, using two digits.

   See `date(1)` for more information.

3. Verify that you have reset your system’s date correctly by using the `date` command with no options.

Example—Setting a System’s Date and Time Manually

The following example shows how to use the `date` command to manually set a system’s date and time.

# date
Thu Jun 21 13:59:15 MDT 2001
# date 0621141001
Thu Jun 21 14:10:00 MDT 2001

▼ How to Set Up a Message-of-the-Day

Edit the message-of-the-day file, `/etc/motd`, to include announcements or inquiries to all users of a system when they log in. Use this feature sparingly, and edit this file regularly to remove obsolete messages.
1. Become superuser.

2. Edit the /etc/motd file and add a message of your choice.
   Edit the text to include the message that will be displayed during user login. Include spaces, Tabs, and Returns.

3. Verify the changes by displaying the contents of the /etc/motd file.
   $ cat /etc/motd
   Welcome to the UNIX Universe. Have a nice day.

Example—Setting Up a Message-of-the-Day

The default message-of-the-day, provided when you install Solaris software, contains SunOS version information.

$ cat /etc/motd
Sun Microsystems Inc. SunOS 5.9 Generic May 2002

The following example shows an edited /etc/motd file that provides information about system availability to each user who logs in.

$ cat /etc/motd
The system will be down from 7:00 a.m to 2:00 p.m. on Saturday, July 7, for upgrades and maintenance.
Do not try to access the system during those hours.
Thank you.

▼ How to Change a System’s Host Name

A system’s host name is specified in several different locations.

Remember to update your name service database to reflect the new host name.

1. Become superuser.

2. Change the system’s host name in the following files:
   - /etc/nodename
   - /etc/hostname
   - /etc/inet/hosts
   - /etc/net/ticlts/hosts
   - /etc/net/ticots/hosts
   - /etc/net/ticotsord/hosts

3. (Optional) If using a name service, change the system’s host name in the host file.

4. Reboot the system to activate the new host name.
   # init 6
Managing Disk Use (Tasks)

This chapter describes how to optimize disk space by locating unused files and large directories.

This is a list of the step-by-step instructions in this chapter.

- “How to Display Information About Files and Disk Space” on page 222
- “How to Display the Size of Files” on page 224
- “How to Find Large Files” on page 225
- “How to Find Files That Exceed a Specified Size Limit” on page 225
- “How to Display the Size of Directories, Subdirectories, and Files” on page 226
- “How to Display the User Ownership of Local UFS File Systems” on page 228
- “How to List the Newest Files” on page 229
- “How to Find and Remove Old or Inactive Files” on page 230
- “How to Clear Out Temporary Directories” on page 231
- “How to Find and Delete core Files” on page 232
- “How to Delete Crash Dump Files” on page 232

Displaying Information About Files and Disk Space

This table summarizes the commands available for displaying information about file size and disk space.

<table>
<thead>
<tr>
<th>Command</th>
<th>Man Page</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>df</td>
<td>df(1M)</td>
<td>Reports the number of free disk blocks and files.</td>
</tr>
</tbody>
</table>

221
How to Display Information About Files and Disk Space

Display information about how disk space is used by using the df command.

\$ df [directory] [-h] [-t] [-t]

df
With no options, lists all mounted file systems and their device names, the number of 512-byte blocks used, and the number of files.
directory
Specifies the directory whose file system you want to check.
-h
Displays disk space in the power of 1024.
-t
Displays the total blocks as well as the blocks used for all mounted file systems.

Examples—Displaying Information About File Size and Disk Space

In the following example, all the file systems listed are locally mounted except for /usr/dist, which is mounted remotely from the system venus.

\$ df

/ (/dev/dsk/c0t0d0s0 ): 287530 blocks 92028 files
/usr (/dev/dsk/c0t0d0s6 ): 1020214 blocks 268550 files
/proc (/proc ): 0 blocks 878 files
/dev/fd (fd ): 0 blocks 0 files
/etc/mnttab (mnttab ): 0 blocks 0 files
/var/run (swap ): 396016 blocks 9375 files
/tmp (swap ): 396016 blocks 9375 files
/opt (/dev/dsk/c0t0d0s5 ): 381552 blocks 96649 files
/export/home (/dev/dsk/c0t0d0s7 ): 434364 blocks 108220 files
/usr/dist (venus:/usr/dist ):14750510 blocks 2130134 files
In the following example, file system information is displayed in 1024 bytes.

```
$ df -h
Filesystem size used avail capacity Mounted on
/dev/dsk/c0t0d0s0 1.9G 58M 1.8G 4% /
/dev/dsk/c0t0d0s6 2.5G 765M 1.7G 1% /usr
/proc 0K 0K 0K 0% /proc
fd 0K 0K 0K 0% /dev/fd
mnttab 0K 0K 0K 0% /etc/mnttab
swap 2.1G 24K 2.1G 1% /var/run
swap 2.1G 0K 2.1G 0% /tmp
/dev/dsk/c0t0d0s5 1.9G 12M 1.8G 1% /opt
/dev/dsk/c0t0d0s7 1.9G 10K 1.8G 1% /export/home
```

**Note** — Although /proc and /tmp are local file systems, they are not UFS file systems. /proc is a PROCFS file system, /var/run and /tmp are TMPFS file systems, and /etc/mnttab is a MNTFS file system.

The following example shows a list of all mounted file systems, device names, total 512-byte blocks used, and number of files. The second line of each two-line entry displays the total number of blocks and files allocated for the file system.

```
$ df -t
/ (/dev/dsk/c0t0d0s0 ): 287530 blocks 92028 files
total: 385614 blocks 96832 files
/usr (/dev/dsk/c0t0d0s6 ): 1020214 blocks 268550 files
total: 2381102 blocks 300288 files
/proc (/proc ): 0 blocks 879 files
total: 0 blocks 924 files
/dev/fd (fd ): 0 blocks 0 files
total: 0 blocks 72 files
/etc/mnttab (mnttab ): 0 blocks 0 files
total: 0 blocks 1 files
/var/run (swap ): 396112 blocks 9375 files
total: 396112 blocks 9395 files
/tmp (swap ): 396112 blocks 9395 files
total: 396112 blocks 9395 files
/opt (/dev/dsk/c0t0d0s5 ): 381552 blocks 96649 files
total: 385614 blocks 96832 files
/export/home (/dev/dsk/c0t0d0s7 ): 434364 blocks 108220 files
total: 434382 blocks 108224 files
/usr/dist (venus:/usr/dist ): 14750510 blocks 2130134 files
total: 41225162 blocks 2482176 files
```
Checking the Size of Files

You can check the size of files and sort them by using the `ls` command. You can find files that exceed a size limit by using the `find` command. For more information, see `ls(1)` and `find(1)`.

▼ How to Display the Size of Files

1. Change to the directory where the files you want to check are located.

2. Display the size of the files.

   $ ls [-lh] [-s]

   - `l` Displays a list of files and directories in long format, showing the sizes in bytes. (See the example that follows.)

   - `h` Scales file and directory sizes into Kbytes, Mbytes, Gbytes, or Terabytes when the file or directory size is larger than 1024 bytes. This option also modifies the output displayed by the `-o`, `-n`, `-a`, and `-g` options to display file or directory sizes in the new format. For more information, see `ls(1)`.

   - `s` Displays a list of the files and directories, showing the sizes in blocks.

Examples—Displaying the Size of Files

The following example shows that the `lastlog` and `messages` files are larger than the other files in the `/var/adm` directory.

$ cd /var/adm
$ ls -lh

```
total 148
drwxrwxr-x 5 adm adm 512 Nov 26 09:39 acct/
-rw------- 1 uucp bin 0 Nov 26 09:25 aculog
drwxr-xr-x 2 adm adm 512 Nov 26 09:25 exacct/
-r--r--r-- 1 root other 342K Nov 26 13:56 lastlog
```

```
drwxr-xr-x 2 adm root 20K Nov 26 13:55 messages
```

```
drwxr-xr-x 2 root sys 512 Nov 26 09:49 sm.bin/
-rw-rw-rw- 1 root bin 0 Nov 26 09:25 spellhist
```

```
drwxr-xr-x 2 root sys 512 Nov 26 09:25 streams/
-rw-r--r-- 1 root bin 3.3K Nov 26 13:56 utmpx
```
The following example shows that the lpsched.1 file uses two blocks.

```bash
$ cd /var/lp/logs
$ ls -s
total 2 0  lpsched  2 lpsched.1
```

### ▲ How to Find Large Files

1. Change to the directory that you want to search.

2. Display the size of files in blocks from largest to smallest.

```bash
$ ls -s | sort -nr | more
```

`sort -nr` sorts the list of files by block size from largest to smallest.

### Example—Finding Large Files

In the following example, the lastlog and messages files are the largest files in the /var/adm directory.

```bash
$ cd /var/adm
$ ls -s | sort -nr | more
 48  lastlog
 30  messages
 24  wtmpx
 18  pacct
  8  utmpx
  2  vold.log
  2  sulog
  2  sm.bin/
  2  sa/
  2  passwd/
  2  pacct1
  2  log/
  2  acct/
  0  spellhist
  0  aculog
total 144
```

### ▼ How to Find Files That Exceed a Specified Size Limit

To locate and display the names of files that exceed a specified size, use the `find` command.
$ find directory -size +nnn

directory Identifies the directory you want to search.
-size +nnn Is a number of 512-byte blocks. Files that exceed this size are listed.

Example—Finding Files That Exceed a Specified Size Limit

The following example shows how to find files larger than 400 blocks in the current working directory.

$ find . -size +400 -print

./Howto/howto.doc
./Howto/howto.doc.backup
./Howto/howtotest.doc
./Routine/routineBackupconcepts.doc
./Routine/routineIntro.doc
./Routine/routineTroublefsck.doc
./.record
./Mail/pagination
./Config/configPrintadmin.doc
./Config/configPrintsetup.doc
./Config/configMailappx.doc
./Config/configMailconcepts.doc
./snapshot.rs

Checking the Size of Directories

You can display the size of directories by using the du command and options. Additionally, you can find the amount of disk space used by user accounts on local UFS file systems by using the quot command. For more information about these commands, see du(1) and quot(1M).

▼ How to Display the Size of Directories, Subdirectories, and Files

Display the size of one or more directories, subdirectories, and files by using the du command. Sizes are displayed in 512-byte blocks.

$ du [-as] [directory ...]
du Displays the size of each directory you specify, including each subdirectory beneath it.

-a Displays the size of each file and subdirectory, and the total number of blocks contained in the specified directory.

-s Displays the total number of blocks contained in the specified directory.

-h Displays the size of each directory in 1024 bytes.

-H Displays the size of each directory in 1000 bytes.

directory ... Identifies one or more directories you want to check.

Examples—Displaying the Size of Directories, Subdirectories, and Files

The following example shows the total sizes of two directories.

$ du -s /var/adm /var/spool/lp
130 /var/adm
40 /var/spool/lp

The following example shows the sizes of two directories, all of the subdirectories and files they contain, and the total number of blocks contained in each directory.

$ du /var/adm /var/spool/lp
2 /var/adm/log
2 /var/adm/passwd
2 /var/adm/acct/fiscal
2 /var/adm/acct/nite
2 /var/adm/acct/sum
8 /var/adm/acct
2 /var/adm/sa
2 /var/adm/sm.bin
130 /var/adm
4 /var/spool/lp/admins
2 /var/spool/lp/fifos/private
2 /var/spool/lp/fifos/public
6 /var/spool/lp/fifos
2 /var/spool/lp/requests/starbug
4 /var/spool/lp/requests
2 /var/spool/lp/system
2 /var/spool/lp/tmp/starbug
2 /var/spool/lp/tmp/.net/tmp/starbug
4 /var/spool/lp/tmp/.net/tmp
2 /var/spool/lp/tmp/.net/requests/starbug
4 /var/spool/lp/tmp/.net/requests
10 /var/spool/lp/tmp/.net
14 /var/spool/lp/tmp
40 /var/spool/lp

The following example shows directory sizes in 1024 bytes.
How to Display the User Ownership of Local UFS File Systems

1. Become superuser.

2. Display users, directories, or file systems, and the number of 1024-byte blocks used.

```
# quot [-a] [filesystem]
```

- **-a** Lists all users of each mounted UFS file system and the number of 1024-byte blocks used.
- **filesystem** Identifies a UFS file system. Users and the number of blocks used are displayed.

**Note**—The quot command works only on local UFS file systems.

Example—Displaying the User Ownership of Local UFS File Systems

In the following example, users of the root (/) file system are displayed. Then, users of all mounted UFS file systems are displayed.

```
# quot /
/dev/rdsk/c0t0d0s0:
 43340  root
  3142  rimmer
   47   uucp
   35    lp
   30   adm
    4    bin
    4   daemon
# quot -a
/dev/rdsk/c0t0d0s0 (/):
 43340  root
  3150  rimmer
   47   uucp
   35    lp
   30   adm
    4    bin
```
Finding and Removing Old or Inactive Files

Part of the job of cleaning up heavily loaded file systems involves locating and removing files that have not been used recently. You can locate unused files using the \texttt{ls} or \texttt{find} commands. For more information, see \texttt{ls(1)} and \texttt{find(1)}.

Other ways to conserve disk space include emptying temporary directories such as the ones located in \texttt{/var/tmp} or \texttt{/var/spool}, and deleting core and crash dump files. For more information about crash dump files, refer to Chapter 28.

\section*{How to List the Newest Files}

List files, displaying the most recently created or changed files first, by using the \texttt{ls -t} command.

\texttt{$ \texttt{ls} \ -t \ [directory]$}

\begin{itemize}
  \item \texttt{-t} \hspace{1cm} Sorts files by latest time stamp first.
  \item \texttt{directory} \hspace{1cm} Identifies the directory you want to search.
\end{itemize}

\textbf{Example—Listing the Newest Files}

The following example shows how to use the \texttt{ls -tl} command to locate the most recently created or changed files within the \texttt{/var/adm} directory. The \texttt{sulog} file was created or edited most recently.

\texttt{$ \texttt{ls} \ -tl \ /var/adm$}

\texttt{total 134}

\texttt{-rw------- 1 root root 315 Sep 24 14:00 sulog}$
How to Find and Remove Old or Inactive Files

1. Become superuser.

2. Find files that have not been accessed for a specified number of days and list them in a file.

   ```
   # find directory -type f -atime +nnn [-mtime +nnn] -print > filename
   ```

   - `directory` Identifies the directory you want to search. Directories below this directory are also searched.
   - `-atime +nnn` Finds files that have not been accessed within the number of days (nnn) you specify.
   - `-mtime +nnn` Finds files that have not been modified within the number of days (nnn) you specify.
   - `filename` Identifies the file that contains the list of inactive files.

3. Remove the inactive files that you listed in the previous step.

   ```
   # rm 'cat filename'
   ```

   `filename` identifies the file created in the previous step which contains the list of inactive files.

Example—Finding and Removing Old or Inactive Files

The following example shows files in the `/var/adm` directory and the subdirectories that have not been accessed in the last 60 days. The `/var/tmp/deadfiles` file contains the list of inactive files. The `rm` command removes these inactive files.

```
# find /var/adm -type f -atime +60 -print > /var/tmp/deadfiles
# more /var/tmp/deadfiles
/var/adm/aculog
```
How to Clear Out Temporary Directories

1. Become superuser.

2. Change to the directory to clean out.
   
   # cd directory

Caution — Be sure you are in the right directory before completing step 3. Step 3 deletes all files in the current directory.

3. Delete the files and subdirectories in the current directory.
   
   # rm -r *

4. Change to other directories containing unnecessary temporary or obsolete subdirectories and files, and delete them by repeating Step 3.

Example—Clearing Out Temporary Directories

The following example shows how to clear out the mywork directory, and how to verify that all files and subdirectories were removed.

# cd mywork
# ls
filea.000
fileb.000
filec.001
# rm -r *
# ls
How to Find and Delete **core** Files

1. Become superuser.

2. Change to the directory where you want to search for **core** files.

3. Find and remove any **core** files in this directory and its subdirectories.

   ```bash
   # find . -name core -exec rm {} 
   ```

**Example—Finding and Deleting **core** Files**

The following example shows how to find and remove **core** files from the **jones** user account by using the `find` command.

```bash
# cd /home/jones
# find . -name core -exec rm {} 
```

How to Delete Crash Dump Files

Crash dump files can be very large, so if you have enabled your system to store these files, do not retain them for longer than necessary.

1. Become superuser.

2. Change to the directory where crash dump files are stored.

   ```bash
   # cd /var/crash/system
   ```

   Where `system` identifies a system that created the crash dump files.

   **Caution**– Be sure you are in the right directory before completing step 3. Step 3 deletes all files in the current directory.

3. Remove the crash dump files.

   ```bash
   # rm *
   ```

4. Verify that the crash dump files are removed.

   ```bash
   # ls
   ```

**Example—Deleting Crash Dump Files**

The following example shows how to remove crash dump files from the system `venus`, and how to verify that the crash dump files were removed.
# cd /var/crash/venus
# rm *
# ls
Managing Quotas (Tasks)

This chapter describes how to set up and administer quotas for disk space and inodes. This is a list of the step-by-step instructions in this chapter.

- “How to Configure File Systems for Quotas” on page 239
- “How to Set Up Quotas for a User” on page 240
- “How to Set Up Quotas for Multiple Users” on page 241
- “How to Check Quota Consistency” on page 241
- “How to Turn On Quotas” on page 242
- “How to Check for Exceeded Quotas” on page 243
- “How to Check Quotas on a File System” on page 244
- “How to Change the Soft Time Limit Default” on page 246
- “How to Change Quotas for a User” on page 247
- “How to Disable Quotas for a User” on page 248
- “How to Turn Off Quotas” on page 249

What Are Quotas?

Quotas enable system administrators to control the size of UFS file systems by limiting the amount of disk space and the number of inodes, which roughly corresponds to the number of files, that individual users can acquire. For this reason, quotas are especially useful on the file systems where user home directories reside. As a rule, public and /tmp file systems usually do not benefit as much from the establishment of quotas.
Using Quotas

Once quotas are in place, quotas can be changed to adjust the amount of disk space or number of inodes that users can consume. Additionally, quotas can be added or removed as system needs change. See “Changing and Removing Quotas” on page 245 for instructions on changing quotas or the amount of time that quotas can be exceeded, disabling individual quotas, or removing quotas from file systems.

In addition, quota status can be monitored. Quota commands enable administrators to display information about quotas on a file system, or search for users who have exceeded their quotas. For procedures that describe how to use these commands, see “Checking Quotas” on page 243.

Setting Soft Limits and Hard Limits for Quotas

You can set both soft and hard limits. The system will not allow a user to exceed his or her hard limit. However, a system administrator might set a soft limit, which the user can temporarily exceed. The soft limit must be less than the hard limit.

Once the user exceeds the soft limit, a timer begins. While the timer is ticking, the user is allowed to operate above the soft limit but cannot exceed the hard limit. Once the user goes below the soft limit, the timer is reset. However, if the user’s usage remains above the soft limit when the timer expires, the soft limit is enforced as a hard limit. By default, the soft limit timer is set to seven days.

The timeleft field in the repquota and quota commands shows the value of the timer.

For example, let’s say a user has a soft limit of 10,000 blocks and a hard limit of 12,000 blocks. If the user’s block usage exceeds 10,000 blocks and the seven-day timer is also exceeded, the user will not be able to allocate more disk blocks on that file system until his or her usage drops below the soft limit.

The Difference Between Disk Block and File Limits

A file system provides two resources to the user, blocks for data and inodes for files. Each file consumes one inode. File data is stored in data blocks, which are usually made up of 1 Kbyte blocks.

Assuming there are no directories, a user can exceed his or her inode quota by creating all empty files without using any blocks. A user can also use one inode yet exceed his or her block quota by creating one file large enough to consume all the data blocks in the user’s quota.
Setting Up Quotas

Setting up quotas involves these general steps:

1. Ensure that quotas are enforced each time the system is rebooted by adding an quota option to the `/etc/vfstab` file entries, and creating a `quotas` file in the top-level directory of the file system.

2. After you create a quota for one user, you can copy the quota as a prototype to set up other user quotas.

3. Before you turn quotas on, check the consistency of the proposed quotas with the current disk usage to make sure that there are no conflicts.

4. Finally, turn the quotas on for one or more file systems.

For specific information about these procedures, see “Setting Up Quotas (Task Map)” on page 238.

The following table describes the commands you use to set up disk quotas.

**TABLE 17-1 Commands for Setting Up Quotas**

<table>
<thead>
<tr>
<th>Command</th>
<th>Task</th>
<th>Man Page</th>
</tr>
</thead>
<tbody>
<tr>
<td>edquota</td>
<td>Sets the hard limits and soft limits on the number of inodes and the amount of disk space for each user</td>
<td>edquota(1M)</td>
</tr>
<tr>
<td>quotacheck</td>
<td>Examines each mounted UFS file system, comparing the file system’s current disk usage against information stored in the file system’s disk quota file, and resolves inconsistencies</td>
<td>quotacheck(1M)</td>
</tr>
<tr>
<td>quotaon</td>
<td>Activates the quotas for the specified file systems</td>
<td>quotaon(1M)</td>
</tr>
<tr>
<td>quota</td>
<td>Displays users’ disk quotas on mounted file systems to verify that the quotas have been correctly set up</td>
<td>quota(1M)</td>
</tr>
</tbody>
</table>
Guidelines for Setting Up Quotas

Before you set up quotas, you need to determine how much space and how many inodes to allocate to each user. If you want to be sure that the total file system space is never exceeded, you can divide the total size of the file system between the number of users. For example, if three users share a 100-Mbyte slice and have equal disk space needs, you could allocate 33 Mbytes to each user.

In environments where not all users are likely to push their limits, you might want to set individual quotas so that they add up to more than the total size of the file system. For example, if three users share a 100-Mbyte slice, you could allocate 40 Mbytes to each user.

When you have established a quota for one user by using the edquota command, you can use this quota as a prototype to set the same quota for other users on the same file system.

Before you turn on the quotas, you must first configure the UFS file systems for the quotas, establish quotas for each user, and run the quotacheck command to check for consistency between current disk usage and quota files. Also, you should run the quotacheck command periodically if systems are rebooted infrequently.

The quotas you set up with the edquota command are not enforced until you turn them on by using the quotaon command. If you have properly configured the quota files, the quotas are turned on automatically each time a system is rebooted and the file system is mounted.

Setting Up Quotas (Task Map)

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>For Instructions</th>
</tr>
</thead>
<tbody>
<tr>
<td>1. Configure a file system for quotas</td>
<td>Edit the /etc/vfstab file so that quotas are activated each time the file system is mounted, and create a quotas file.</td>
<td>“How to Configure File Systems for Quotas” on page 239</td>
</tr>
<tr>
<td>2. Set up quotas for a user</td>
<td>Use the edquota command to create disk quotas and inode quotas for a single user account.</td>
<td>“How to Set Up Quotas for a User” on page 240</td>
</tr>
</tbody>
</table>
How to Configure File Systems for Quotas

1. Become superuser.

2. Edit the /etc/vfstab file and add rq to the mount options field for each UFS file system that will have quotas.

3. Change directory to the root of the file system that will have quotas.

4. Create a file named quotas.

   # touch quotas

5. Change permissions to read/write for root access only.

   # chmod 600 quotas

Where to Go From Here

Use the following table to determine which tasks to complete next.

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>For More Information</th>
</tr>
</thead>
<tbody>
<tr>
<td>3. (Optional) Set up quotas for multiple users</td>
<td>Use the edquota command to apply prototype quotas to other user accounts.</td>
<td>“How to Set Up Quotas for Multiple Users” on page 241</td>
</tr>
<tr>
<td>4. Check for consistency</td>
<td>Use the quotacheck command to compare quotas to current disk usage for consistency across one or more file systems.</td>
<td>“How to Check Quota Consistency” on page 241</td>
</tr>
<tr>
<td>5. Turn on quotas</td>
<td>Use the quotaon command to initiate quotas on one or more file systems.</td>
<td>“How to Turn On Quotas” on page 242</td>
</tr>
</tbody>
</table>
Examples—Configuring File Systems for Quotas

The following /etc/vfstab example shows that the /export/home directory from the system pluto is mounted as an NFS file system on the local system. You can tell quotas are enabled by the rq entry under the mount options column.

```
#device  device mount  FS  fsck mount mount
#to mount to fsck point  type pass  at boot options
#
pluto:/export/home - /export/home nfs - yes  rq
```

The following example line from /etc/vfstab shows that the local /work directory is mounted with quotas enabled, signified by the rq entry under the mount options column.

```
#device  device mount  FS  fsck mount mount
#to mount to fsck point  type pass  at boot options
#
/dev/dsk/c0t4d0s0 /dev/rdsk/c0t4d0s0 /work ufs  3 yes  rq
```

▼ How to Set Up Quotas for a User

1. Become superuser.

2. Use the quota editor to create a temporary file that contains one line of quota information for each mounted UFS file system that has a quotas file in the file system’s root directory.

   ```
   # edquota  username
   Where username is the user for whom you want to set up quotas.
   ```

3. Change the number of 1-Kbyte disk blocks, both soft and hard, and the number of inodes, both soft and hard, from 0, the default, to the quotas you specify for each file system.

4. Verify the user’s quota.

   ```
   # quota  -v  username
   ```

   -v Displays the user’s quota information on all mounted file systems where quotas exist.
username  Specifies the user name to view quota limits.

Examples—Setting Up Quotas for a User

The following example shows the contents of the temporary file opened by edquota on a system where /files is the only mounted file system containing a quotas file in the root directory.

```
fs /files blocks (soft = 0, hard = 0) inodes (soft = 0, hard = 0)
```

The following example shows the same line in the temporary file after quotas have been set up.

```
fs /files blocks (soft = 50, hard = 60) inodes (soft = 90, hard = 100)
```

▼ How to Set Up Quotas for Multiple Users

1. Become superuser.

2. Use the quota editor to apply the quotas you already established for a prototype user to the additional users you specify.

```bash
# edquota -p prototype-user username ...
```

- **prototype-user**  User name of the account for which you have set up quotas.
- **username ...**  Specifies one or more user names of additional accounts.

Example—Setting Up Prototype Quotas for Multiple Users

The following example shows how to apply the quotas established for user bob to users mary and john.

```bash
# edquota -p bob mary john
```

▼ How to Check Quota Consistency

The quotacheck command is run automatically when a system is rebooted. You generally do not have to run the quotacheck command on an empty file system with quotas. However, if you are setting up quotas on an file system with existing files, you need to run the quotacheck command to synchronize the quota database with the files or inodes that already exist in the file system.
Also keep in mind that running the `quotacheck` command on large file systems can be time-consuming.

**Note** – To ensure accurate disk data, the file systems being checked should be quiescent when you run the `quotacheck` command manually.

1. Become superuser.
2. Run a consistency check on UFS file systems.
   ```
   # quotacheck [-va] filesystem
   ```
   - `-v` (Optional) Identifies the disk quotas for each user on a particular file system.
   - `-a` Checks all file systems with an `rq` entry in the `/etc/vfstab` file.
   - `filesystem` Specifies the file system to check.

   See `quotacheck(1M)` for more information.

**Example—Checking Quota Consistency**

The following example shows how to check quotas for the `/export/home` file system on the `/dev/rdsk/c0t0d0s7` slice. The `/export/home` file system is the only file system with an `rq` entry in the `/etc/vfstab` file.

```bash
# quotacheck -va
*** Checking quotas for /dev/rdsk/c0t0d0s7 (/export/home)
```

▼ **How to Turn On Quotas**

1. Become superuser.
2. Turn on file system quotas.

   ```
   # quotaon [-v] -a filesystem ...
   ```
   `-v` Displays a message for each file system after quotas are turned on.
-a  
  Turns on quotas for all file systems with an rq entry in the /etc/vfstab file.

`filesystem ...`  
  Turns on quotas for one or more file systems that you specify. More than one file system is specified by separating each file system name with a space.

Example—Turning On Quotas

The following example shows how to turn quotas on for the file systems on the /dev/dsk/c0t4d0s7 and /dev/dsk/c0t3d0s7 slices.

```
# quotaon -v /dev/dsk/c0t4d0s7 /dev/dsk/c0t3d0s7
/dev/dsk/c0t4d0s7: quotas turned on
/dev/dsk/c0t3d0s7: quotas turned on
```

Checking Quotas

After you have set up and turned on disk quotas and inode quotas, you can check for users who exceed their quotas. In addition, you can check quota information for entire file systems.

The following table describes the commands you use to check quotas.

**TABLE 17-2 Commands for Checking Quotas**

<table>
<thead>
<tr>
<th>Command</th>
<th>Task</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>quota</code></td>
<td>Displays user quotas and current disk use, and information about users who are exceeding their quotas</td>
</tr>
<tr>
<td><code>repquota</code></td>
<td>Displays quotas, files, and the amount of space owned for specified file systems</td>
</tr>
</tbody>
</table>

▼ How to Check for Exceeded Quotas

You can display the quotas and disk use for individual users on file systems on which quotas have been activated by using the `quota` command.

1. **Become superuser.**

2. **Display user quotas for mounted file systems where quotas are enabled.**

   ```
   # quota [-v] username
   ```
-v Displays one or more users’ quotas on all mounted file systems that have quotas.

username Is the login name or UID of a user’s account.

Example—Checking for Exceeded Quotas

The following example shows that the user account identified by UID 301 has one 1-Kbyte quota but has not used any disk space.

```
# quota -v 301
Disk quotas for bob (uid 301):
Filesystem usage quota limit timeleft files quota limit timeleft
/export/home 0 1 2 0 2 3
```

Filesystem Is the mount point for the file system.
usage Is the current block usage.
quota Is the soft block limit.
limit Is the hard block limit.
timeleft Is the amount of time, in days, left on the quota timer.
files Is the current inode usage.
quota Is the soft inode limit.
limit Is the hard inode limit.
timeleft Is the amount of time, in days, left on the quota timer.

▼ How to Check Quotas on a File System

Display the quotas and disk use for all users on one or more file systems by using the repquota command.

1. Become superuser.

2. Display all quotas for one or more file systems, even if there is no usage.

```
# repquota [-v] -a filesystem
```

- v Reports on quotas for all users, even those users who do not consume resources.
- a Reports on all file systems.
Example—Checking Quotas on a File System

The following example shows output from the `repquota` command on a system that has quotas enabled on only one file system (`/export/home`).

```
# repquota -va
/dev/dsk/c0t3d0s7 (/export/home):
```

<table>
<thead>
<tr>
<th>User</th>
<th>Block limits</th>
<th>File limits</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Block limits</td>
<td>File limits</td>
</tr>
<tr>
<td></td>
<td>used soft hard timeleft used soft hard timeleft</td>
<td></td>
</tr>
<tr>
<td>#301</td>
<td>0 1 2.0 days</td>
<td>0 2 3</td>
</tr>
<tr>
<td>#341</td>
<td>57 50 60 7.0 days</td>
<td>2 90 100</td>
</tr>
</tbody>
</table>

**Block limits**
- **used**: Is the current block usage.
- **soft**: Is the soft block limit.
- **hard**: Is the hard block limit.
- **timeleft**: Is the amount of time, in days, left on the quota timer.

**File limits**
- **used**: Is the current inode usage.
- **soft**: Is the soft inode limit.
- **hard**: Is the hard inode limit.
- **timeleft**: Is the amount of time, in days, left on the quota timer.

Changing and Removing Quotas

You can change quotas to adjust the amount of disk space or the number of inodes users can consume. You can also remove quotas, for individual users or from entire file systems, as needed.

The following table describes the commands you use to change quotas or remove quotas.
### TABLE 17–3 Commands for Changing Quotas and Removing Quotas

<table>
<thead>
<tr>
<th>Command</th>
<th>Man Page</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>edquota</td>
<td>edquota</td>
<td>Changes the hard limits and soft limits on the number of inodes or amount of disk space for each user. Also, changes the soft quota time limit for each file system with a quota.</td>
</tr>
<tr>
<td>quotaoff</td>
<td>quotaoff(IM)</td>
<td>Turns off quotas for specified file systems.</td>
</tr>
</tbody>
</table>

#### ▼ How to Change the Soft Time Limit Default

By default, users can exceed the soft time limits for their quotas for one week. So, after a week of repeated violations of the soft time limits of either disk space quotas or inode quotas, the system prevents users from using any more inodes or disk blocks.

You can change the length of time that users might exceed their disk space quotas or inode quotas by using the `edquota` command.

1. **Become superuser.**

2. **Use the quota editor to create a temporary file that contains soft time limits.**

   ```
   # edquota -t
   ```

   Where the `-t` option specifies the editing of the soft time limits for each file system.

3. **Change the time limits from 0 (the default) to the time limits you specify by numbers and the keywords month, week, day, hour, min, or sec.**

   ```
   Note – This procedure does not affect current quota violators.
   ```

#### Examples—Changing the Soft Time Limit Default

The following example shows the contents of the temporary file opened by the `edquota` command on a system where `/export/home` is the only mounted file system with quotas. The default value, 0, means that the default time limit of one week is used.

```
fs /export/home blocks time limit = 0 (default), files time limit = 0 (default)
```

The following example shows the same temporary file after the time limit for exceeding the blocks quota has been changed to two weeks, and the time limit for exceeding the number of files has been changed to 16 days.

```
fs /export/home blocks time limit = 2 weeks, files time limit = 16 days
```
How to Change Quotas for a User

1. Become superuser.

2. Use the quota editor to open a temporary file containing one line for each mounted file system that has a quotas file in the file system’s root directory.

   # edquota username

   Where username specifies the user name whose quota you want to change.

   **Caution** – Although you can specify multiple users as arguments to the edquota command, the information displayed does not show which user this information belongs to, which could create some confusion.

3. Enter the number of 1-Kbyte disk blocks, both soft and hard, and the number of inodes, both soft and hard.

4. Verify that a user’s quota has been correctly changed.

   # quota -v username

   -v Displays user quota information on all mounted file systems with quotas enabled.

   username Specifies the user name whose quota you want to check.

Examples—Changing Quotas for a User

The following example shows the contents of the temporary file opened by the edquota command on a system where /files is the only mounted file system containing a quotas file in the file system’s root directory.

fs /files blocks (soft = 0, hard = 0) inodes (soft = 0, hard = 0)

The following example shows the same temporary file after quotas have been changed.

fs /files blocks (soft = 0, hard = 500) inodes (soft = 0, hard = 100)

The following example shows how to verify that the hard quotas for user smith have been changed to 500 1-Kbyte blocks, and 100 inodes.

# quota -v smith

Disk quotas for smith (uid 12):
Filesystem usage quota limit timeleft files quota limit timeleft
/files 1 0 500 1 0 100
How to Disable Quotas for a User

1. Become superuser.

2. Use the quota editor to create a temporary file containing one line for each mounted file system that has a quotas file in its top-level directory.

   # edquota username

   Where username specifies the user name whose quota you want to disable.

   **Caution** – Although you can specify multiple users as arguments to the edquota command, the information displayed does not show which user this information belongs with, which could create some confusion.

3. Change the number of 1-Kbyte disk blocks, both soft and hard, and the number of inodes, both soft and hard, to 0.

   **Note** – Be sure you change the values to zero. Do not delete the line from the text file.

4. Verify that you have disabled a user’s quota.

   # quota -v username

   -v Displays user quota information on all mounted file systems with quotas enabled.
   username Specifies the user name (UID) whose quota you want to check.

### Examples—Disabling Quotas for a User

The following example shows the contents of the temporary file opened by the edquota command on a system where /files is the only mounted file system that contains a quotas file in the file system’s root directory.

```
fs /files blocks (soft = 50, hard = 60) inodes (soft = 90, hard = 100)
```

The following example shows the same temporary file after quotas have been disabled.

```
fs /files blocks (soft = 0, hard = 0) inodes (soft = 0, hard = 0)
```
How to Turn Off Quotas

1. Become superuser.

2. Turn off file system quotas.

   # quotaoff [-v] -a filesystem ...

   -v Displays a message from each file system when quotas are turned off.

   -a Turns off quotas for all file systems.

   filesystem Turns off quotas for one or more file systems you specify. More than one file system is specified by separating each file system name with a space.

Example—Turning Off Quotas

The following example shows how to turn off the quotas for the /export/home file system.

   # quotaoff -v /export/home
   /export/home: quotas turned off
CHAPTER 18

Scheduling System Tasks (Tasks)

This chapter describes how to schedule routine or single (one-time) systems tasks by using the crontab and at commands. This chapter also explains how to control access to these commands by using cron.deny, cron.allow, and at.deny files.

This is a list of the step-by-step instructions in this chapter.

- “How to Create or Edit a crontab File” on page 256
- “How to Display a crontab File” on page 257
- “How to Remove a crontab File” on page 259
- “How to Deny crontab Access” on page 260
- “How to Limit crontab Access to Specified Users” on page 261
- “How to Create an at Job” on page 263
- “How to Display the at Queue” on page 264
- “How to Display at Jobs” on page 265
- “How to Remove at Jobs” on page 265
- “How to Deny Access to the at Command” on page 266

Ways to Automatically Execute System Tasks

You can set up many system tasks to execute automatically. Some of these tasks should occur at regular intervals. Other tasks need to run only once, perhaps during off hours such as evenings or weekends.

This section contains overview information about two commands, crontab and at, which enable you to schedule routine tasks to execute automatically. The crontab schedules repetitive commands. The at command schedules tasks that execute once.
The following table summarizes `crontab` and `at` commands, as well as the files that enable you to control access to these commands.

### TABLE 18-1 Command Summary: Scheduling System Tasks

<table>
<thead>
<tr>
<th>Command</th>
<th>What It Schedules</th>
<th>Location of Files</th>
<th>Files That Control Access</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>crontab</code></td>
<td>Multiple system tasks at regular intervals</td>
<td><code>/var/spool/cron/crontabs</code></td>
<td>/etc/cron.d/cron.allow and /etc/cron.d/cron.deny</td>
</tr>
<tr>
<td><code>at</code></td>
<td>A single system task</td>
<td><code>/var/spool/cron/atjobs</code></td>
<td>/etc/cron.d/at.deny</td>
</tr>
</tbody>
</table>

You can also use the Solaris Management Console’s Scheduled Jobs tool to schedule routine tasks. For information on using and starting the Solaris Management Console, see “Working With the Management Console (Tasks)” in System Administration Guide: Basic Administration.

### For Scheduling Repetitive Jobs: `crontab`

You can schedule routine system administration tasks to execute daily, weekly, or monthly by using the `crontab` command.

**Daily `crontab` system administration tasks might include:**
- Removing files more than a few days old from temporary directories
- Executing accounting summary commands
- Taking snapshots of the system by using the `df` and `ps` commands
- Performing daily security monitoring
- Running system backups

**Weekly `crontab` system administration tasks might include:**
- Rebuilding the `catman` database for use by the `man -k` command
- Running the `fsck -n` command to list any disk problems

**Monthly `crontab` system administration tasks might include:**
- Listing files not used during a specific month
- Producing monthly accounting reports

Additionally, users can schedule `crontab` commands to execute other routine system tasks, such as sending reminders and removing backup files.

For step-by-step instructions on scheduling `crontab` jobs, see “How to Create or Edit a `crontab` File” on page 256.
For Scheduling a Single Job: at

The at command allows you to schedule a job for execution at a later time. The job can consist of a single command or a script.

Similar to crontab, the at command allows you to schedule the automatic execution of routine tasks. However, unlike crontab files, at files execute their tasks once, and then are removed from their directory. Therefore, at is most useful for running simple commands or scripts that direct output into separate files for later examination.

Submitting an at job involves entering a command and following the at command syntax to specify options to schedule the time your job will be executed. For more information about submitting at jobs, see “Description of the at Command” on page 262.

The at command stores the command or script you entered, along with a copy of your current environment variable in the /var/spool/cron/atjobs directory. Your at job file name is given a long number that specifies its location in the at queue, followed by the .a extension, such as 793962000.a.

The cron daemon periodically executes the atrun program, usually at 15-minute intervals. Then the atrun program executes at jobs at their scheduled times. After the cron daemon executes your at job, the at job’s file is removed from the atjobs directory.

For step-by-step instructions on scheduling at jobs, see “How to Create an at Job” on page 263.

Scheduling a Repetitive System Task (cron)

The following sections describe how to create, edit, display, and remove crontab files, as well as how to control access to them.

Inside a crontab File

The cron daemon schedules system tasks according to commands found within each crontab file. A crontab file consists of commands, one per line, that will be executed at regular intervals. The beginning of each line contains date and time information that tells the cron daemon when to execute the command.

For example, a crontab file named root is supplied during SunOS software installation. The file’s contents include these command lines:
The first line runs the `logadm` command at 3:10 a.m. every day. The second line executes the `nfsfind` script every Sunday at 3:15 a.m. The third line runs a script that checks for daylight savings time (and make corrections if necessary) at 2:10 a.m. daily. If there is no RTC time zone nor an `/etc/rtc_config` file, this entry does nothing. The fourth line checks for (and removes) duplicate entries in the Generic Security Service table, `/etc/gss/gsscred_db`, at 3:30 a.m. daily.

For more information about the syntax of lines within a `crontab` file, see “Syntax of `crontab` File Entries” on page 255.

The `crontab` files are stored in the `/var/spool/cron/crontabs` directory. Several `crontab` files besides `root` are provided during SunOS software installation (see the following table).

<table>
<thead>
<tr>
<th><code>crontab</code> File</th>
<th>Function</th>
</tr>
</thead>
<tbody>
<tr>
<td>adm</td>
<td>Accounting</td>
</tr>
<tr>
<td>lp</td>
<td>Printing</td>
</tr>
<tr>
<td>root</td>
<td>General system functions and file system cleanup</td>
</tr>
<tr>
<td>sys</td>
<td>Performance collection</td>
</tr>
<tr>
<td>uucp</td>
<td>General uucp cleanup</td>
</tr>
</tbody>
</table>

Besides the default `crontab` files, users can create `crontab` files to schedule their own system tasks. Other `crontab` files are named after the user accounts in which they are created, such as `bob`, `mary`, `smith`, or `jones`.

To access `crontab` files that belong to root or other users, superuser privileges are required.

Procedures explaining how to create, edit, display, and remove `crontab` files are described in subsequent sections.

### How the cront Daemon Handles Scheduling

The `cron` daemon manages the automatic scheduling of `crontab` commands. The role of the `cron` daemon is to check the `/var/spool/cron/crontab` directory for the presence of `crontab` files, normally every 15 minutes. The `cron` daemon checks for new `crontab` files or changes to existing ones, reads the execution times listed within the files, and submits the commands for execution at the proper times.
In much the same way, the cron daemon controls the scheduling of at files, which are stored in the `/var/spool/cron/atjobs` directory.

**Syntax of `crontab` File Entries**

A `crontab` file consists of commands, one per line, that execute automatically at the time specified by the first five fields at the beginning of each command line. These first five fields, described in the following table, are separated by spaces.

<table>
<thead>
<tr>
<th><strong>TABLE 18-3 Acceptable Values for <code>crontab</code> Time Fields</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Time Field</strong></td>
</tr>
<tr>
<td>Minute</td>
</tr>
<tr>
<td>Hour</td>
</tr>
<tr>
<td>Day of month</td>
</tr>
<tr>
<td>Month</td>
</tr>
<tr>
<td>Day of week</td>
</tr>
</tbody>
</table>

Follow these guidelines for using special characters in `crontab` time fields:
- Use a space to separate each field.
- Use a comma to separate multiple values.
- Use a hyphen to designate a range of values.
- Use an asterisk as a wildcard to include all possible values.
- Use a comment mark (#) at the beginning of a line to indicate a comment or a blank line.

For example, the following `crontab` command entry displays a reminder in the user’s console window at 4 p.m. on the first and fifteenth of every month.

```
0 16 1,15 * * echo Timesheets Due > /dev/console
```

Each command within a `crontab` file must consist of one line, even if that line is very long, because `crontab` does not recognize extra carriage returns. For more detailed information about `crontab` entries and command options, refer to `crontab(1)`.
Creating and Editing crontab Files

The simplest way to create a crontab file is to use the crontab -e command. This command invoke the text editor set up for your system environment, which is defined by the EDITOR environment variable. If this variable has not been set, crontab uses the default editor, ed. Preferably, you should choose an editor that you know well.

The following example shows how to determine if an editor has been defined, and how to set up vi as the default.

```
$ which $EDITOR
$ EDITOR=vi
$ export EDITOR
```

When you create a crontab file, it is automatically placed in the /var/spool/cron/crontabs directory and is given your user name. You can create or edit a crontab file for another user, or root, if you have superuser privileges.

▼ How to Create or Edit a crontab File

1. (Optional) Become superuser to create or edit a crontab file that belongs to root or another user.

2. Create a new crontab file, or edit an existing one.

```
$ crontab -e [username]
```

Where username specifies the name of the user’s account for which you want to create or edit a crontab file. To create or edit crontab files requires superuser privileges.

![Caution](image)

**Caution** – If you accidentally type the crontab command with no option, press the interrupt character for your editor. This character allows you to quit without saving changes. If you instead saved changes and exited the file, the existing crontab file is overwritten with an empty file.

3. Add command lines to the file.

Follow the syntax described in “Syntax of crontab File Entries” on page 255. The crontab file will be placed in /var/spool/cron/crontabs.

4. Verify your crontab file changes.

```
# crontab -l [username]
```
Example—Creating or Editing a crontab File

The following example shows how to create a crontab file for another user.

```bash
# crontab -e jones
```

The following command entry added to a new crontab file automatically removes any log files from the user’s home directory at 1:00 a.m. every Sunday morning. Because the command entry does not redirect output, redirect characters are added to the command line after `*.log` to make sure that the command executes properly.

```bash
# This command helps clean up user accounts.
1 0 * * 0 rm /home/jones/*.log > /dev/null 2>&1
```

▼ How to Verify a crontab File

To verify that a crontab file exists for a user, use the `ls -l` command in the `/var/spool/cron/crontabs` directory. For example, the following display shows that crontab files exist for users smith and jones.

```
$ ls -l /var/spool/cron/crontabs
-rw-r--r-- 1 root sys 190 Feb 26 16:23 adm
-rw------- 1 root staff 225 Mar 1 9:19 jones
-rw-r--r-- 1 root root 1063 Feb 26 16:23 lp
-rw-r--r-- 1 root sys 441 Feb 26 16:25 root
-rw------- 1 root staff 60 Mar 1 9:15 smith
-rw-r--r-- 1 root sys 308 Feb 26 16:23 sys
```

Verify the contents of user’s crontab file by using the `crontab -l` command as described in “How to Display a crontab File” on page 257.

Displaying crontab Files

The `crontab -l` command displays the contents of your crontab file much the way the `cat` command displays the contents of other types of files. You do not have to change directories to `/var/spool/cron/crontabs` (where crontab files are located) to use this command.

By default, the `crontab -l` command displays your own crontab file. To display crontab files that belong to other users, you must be superuser.

▼ How to Display a crontab File

1. (Optional) Become superuser to display a crontab file that belongs to root or another user.
2. Display the crontab file.

$ crontab -l [username]

Where username specifies the name of the user’s account for which you want to create or edit a crontab file. To create or edit crontab files requires superuser privileges.

Caution – If you accidentally type the crontab command with no option, press the interrupt character for your editor. This character allows you to quit without saving changes. If you instead saved changes and exited the file, the existing crontab file is overwritten with an empty file.

Example—Displaying a crontab File

The following example shows how to use the crontab -l command to display the contents of the user’s default crontab file, the default root crontab file, and the crontab file belonging to another user.

$ crontab -l
13 13 * * * chmod g+w /home1/documents/*.book > /dev/null 2>&1

$ su
Password:
# crontab -l
#ident "#@(#)root 1.19 98/07/06 SMI" /* SVr4.0 1.1.3.1 */
#
# The root crontab should be used to perform accounting data collection.
#
# The rtc command is run to adjust the real time clock if and when
# daylight savings time changes.
#
10 3 * * * /usr/sbin/logadm
15 3 * * 0 /usr/lib/fs/nfs/nfsfind
1 2 * * [ -x /usr/sbin/rtc ] && /usr/sbin/rtc -c > /dev/null 2>&1
30 3 * * [ -x /usr/lib/gss/gsscred_clean ] && /usr/lib/gss/gsscred_clean
# crontab -l jones
13 13 * * * cp /home/jones/work_files /usr/backup/. > /dev/null 2>&1

Removing crontab Files

By default, crontab file protections are set up so that you cannot inadvertently delete a crontab file by using the rm command. Instead, use the crontab -r command to remove crontab files.

By default, crontab -r removes your own crontab file. You must be superuser to remove crontab files that belong to superuser or other users.
You do not have to change directories to /var/spool/cron/crontabs (where crontab files are located) to use this command.

▼ How to Remove a crontab File

1. (Optional) Become superuser to remove a crontab file that belongs to root or another user.

2. Remove the crontab file.

   $ crontab -r [username]

   Where username specifies the name of the user’s account for which you want to create or edit a crontab file. To create or edit crontab files requires superuser privileges.

   Caution – If you accidentally type the crontab command with no option, press the interrupt character for your editor. This character allows you to quit without saving changes. If you instead saved changes and exited the file, the existing crontab file is overwritten with an empty file.

3. Verify that the crontab file is removed.

   # ls /var/spool/cron/crontabs

Example—Removing a crontab File

The following example shows how user smith uses the crontab -r command to remove his crontab file.

   $ ls /var/spool/cron/crontabs
   adm  jones  lp  root  smith  sys  uucp
   $ crontab -r
   $ ls /var/spool/cron/crontabs
   adm  jones  lp  root  sys  uucp

Controlling Access to the crontab Command

You can control access to the crontab command by using two files in the /etc/cron.d directory: cron.deny and cron.allow. These files permit only specified users to perform the crontab command tasks such as creating, editing, displaying, or removing their own crontab files.
The `cron.deny` and `cron.allow` files consist of a list of user names, one per line. These access control files work together as follows:

- If `cron.allow` exists, only the users listed in this file can create, edit, display, or remove `crontab` files.
- If `cron.allow` does not exist, all users can submit `crontab` files, except for users listed in `cron.deny`.
- If neither `cron.allow` nor `cron.deny` exists, superuser privileges are required to run the `crontab` command.

Superuser privileges are required to edit or create the `cron.deny` and `cron.allow` files.

The `cron.deny` file, created during SunOS software installation, contains the following user names:

```bash
$ cat /etc/cron.d/cron.deny
daemon
bin
smtp
nuucp
listen
nobody
noaccess

username1
username2
```

None of the user names in the default `cron.deny` file can access the `crontab` command. You can edit this file to add other user names that will be denied access to the `crontab` command.

No default `cron.allow` file is supplied. So, after Solaris software installation, all users (except the ones listed in the default `cron.deny` file) can access the `crontab` command. If you create a `cron.allow` file, only these users can access the `crontab` command.

---

**How to Deny `crontab` Access**

1. Become superuser.

2. Edit the `/etc/cron.d/cron.deny` file and add user names, one per line, who will be prevented from using `crontab` commands.
3. Verify the `/etc/cron.d/cron.deny` file.
   
   ```
   # cat /etc/cron.d/cron.deny
   ```

▼ How to Limit `crontab` Access to Specified Users

1. Become superuser.

2. Create the `/etc/cron.d/cron.allow` file.

3. Enter the `root` user name into the `cron.allow` file.
   - If you do not add `root` to the file, superuser access to `crontab` commands will be denied.

4. Enter the user names, one per line, that will be allowed to use the `crontab` command.
   ```
   root
   username1
   username2
   username3
   ```

Examples—Limiting `crontab` Access to Specified Users

The following example shows a `cron.deny` file that prevents user names `visitor`, `jones`, and `temp` from accessing the `crontab` command.

```
$ cat /etc/cron.d/cron.deny
daemon
bin
smtp
nuucp
listen
nobody
noaccess
jones
temp
visitor
```

The following example shows a `cron.allow` file. The users `smith`, `jones`, `lp`, and `root` are the only ones who can access the `crontab` command.

```
$ cat /etc/cron.d/cron.allow
root
jones
```
How to Verify Limited crontab Access

To verify if a specific user can access crontab, use the crontab -l command while you are logged into the user account.

$ crontab -l

If the user can access crontab, and already has created a crontab file, the file is displayed. Otherwise, if the user can access crontab but no crontab file exists, a message such as the following is displayed:
crontab: can't open your crontab file

This user either is listed in cron.allow (if the file exists), or the user is not listed in cron.deny.

If the user cannot access the crontab command, the following message is displayed whether or not a previous crontab file exists:
crontab: you are not authorized to use cron. Sorry.

This message means that either the user is not listed in cron.allow (if the file exists), or the user is listed in cron.deny.

Scheduling a Single System Task (at)

The following sections describe how to use the at command to schedule jobs (commands and scripts) for execution at a later time, how to display and remove these jobs, and how to control access to the at command.

By default, users can create, display, and remove their own at job files. To access at files that belong to root or other users, you must have superuser privileges.

When you submit an at job, it is assigned a job identification number along with the .a extension, which becomes the job's file name.

Description of the at Command

Submitting an at job file involves:

1. Invoking the at utility and specifying a command execution time.
2. Entering a command or script to execute later.
**Note** – If output from this command or script is important, be sure to direct the output to a file for later examination.

For example, the following `at` job removes `core` files from the user account `smith` near midnight on the last day of July.

```
$ at 11:45pm July 31
at> rm /home/smith/*core*
at> Press Control-d
commands will be executed using /bin/csh
job 933486300.a at Tue Jul 31 23:45:00 2001
```

### Controlling access to the `at` Command

You can set up a file to control access to the `at` command, permitting only specified users to create, remove, or display queue information about their `at` jobs. The file that controls access to the `at` command, `/etc/cron.d/at.deny`, consists of a list of user names, one per line. The users listed in this file cannot access `at` commands.

The `at.deny` file, created during SunOS software installation, contains the following user names:

- daemon
- bin
- smtp
- nuucp
- listen
- nobody
- noaccess

With superuser privileges, you can edit the `at.deny` file to add other user names whose `at` access you want to restrict.

### How to Create an `at` Job

1. **Start the `at` utility, specifying the time you want your job executed.**

   ```
   $ at [-m] time [date]
   ```

   `-m` Sends you email after the job is completed.
**time**

Hour that you want to schedule the job. Add am or pm if you do not specify the hours according to a 24-hour clock. Acceptable keywords are midnight, noon, and now. Minutes are optional.

**date**

First three or more letters of a month, a day of the week, or the keywords today or tomorrow.

2. **At the at prompt, type the commands or scripts you want to execute, one per line.**
   You may enter more than one command by pressing Return at the end of each line.

3. **Exit the at utility and save the at job by pressing Control-D.**
   Your at job is assigned a queue number, which is also the job’s file name. This number is displayed when you exit the at utility.

**Examples—Creating an at Job**

The following example shows the at job that user jones created to remove her backup files at 7:30 p.m. She used the -m option so that she would receive an email message after her job completed.

```
$ at -m 1930
at> rm /home/jones/*.backup
at> Press Control-D
job 897355800.a at Thu Jul 12 19:30:00 2001
```

She received a mail message which confirmed the execution of her at job.

Your "at" job "rm /home/jones/*.backup"
completed.

The following example shows how jones scheduled a large at job for 4:00 a.m. Saturday morning. The job output was directed to big.file.

```
$ at 4 am Saturday
at> sort -r /usr/dict/words > /export/home/jones/big.file
```

**How to Display the at Queue**

To check your jobs that are waiting in the at queue, use the atq command. This command displays status information about the at jobs that you created.

```
$ atq
```

**How to Verify an at Job**

To verify that you have created an at job, use the atq command. The atq command confirms that at jobs that belong to jones have been submitted to the queue.
How to Display `at` Jobs

To display information about the execution times of your `at` jobs, use the `at -l` command.

```
$ at -l [job-id]
```

Where the `-l job-id` option identifies the identification number of the job whose status you want to display.

Example—Displaying `at` Jobs

The following example shows output from the `at -l` command, which provides status information on all jobs submitted by a user.

```
$ at -l
897543900.a Sat Jul 14 23:45:00 2001
897355800.a Thu Jul 12 19:30:00 2001
897732000.a Tue Jul 17 04:00:00 2001
```

The following example shows the output displayed when a single job is specified with the `at -l` command.

```
$ at -l 897732000.a
897732000.a Tue Jul 17 04:00:00 2001
```

How to Remove `at` Jobs

1. (Optional) Become superuser to remove an `at` job that belongs to root or another user.

2. Remove the `at` job from the queue before the job is executed.

   ```
   $ at -r [job-id]
   ```

   Where the `-r job-id` option specifies the identification number of the job you want to remove.

3. Verify that the `at` job is removed by using the `at -l` (or the `atq`) command.

   The `at -l` command displays the jobs remaining in the `at` queue. The job whose identification number you specified should not appear.
Example—Removing at Jobs

In the following example, a user wants to remove an at job that was scheduled to execute at 4 a.m. on July 17th. First, the user displays the at queue to locate the job identification number. Next, the user removes this job from the at queue. Finally, the user verifies that this job has been removed from the queue.

$ at -l
897543900.a Sat Jul 14 23:45:00 2001
897355800.a Thu Jul 12 19:30:00 2001
897732000.a Tue Jul 17 04:00:00 2001
$ at -r 897732000.a
$ at -l 897732000.a
at: 858142000.a: No such file or directory

▼ How to Deny Access to the at Command

1. Become superuser.

2. Edit the /etc/cron.d/at.deny file and add the names of users, one per line, that will be prevented from using at commands.

daemon
bin
smtp
nuucp
listen
nobody
noaccess
username1
username2
username3
...
...

Example—Denying at Access

The following example shows an at.deny file that has been edited so that the users smith and jones cannot access the at command.

$ cat at.deny
daemon
bin
smtp
nuucp
How to Verify that at Access Is Denied

To verify that a username was added correctly to /etc/cron.d/at.deny, use the at -l command while logged in as the user. If the user cannot access the at command, the following message is displayed.

```
# su smith
Password:
$ at -l
at: you are not authorized to use at. Sorry.
```

Likewise, if the user tries to submit an at job, the following message is displayed:

```
$ at 2:30pm
at: you are not authorized to use at. Sorry.
```

This message confirms that the user is listed in the at.deny file.

If at access is allowed, the at -l command returns nothing.
Managing System Accounting (Tasks)

This section describes how to set up and maintain system accounting.

This is a list of the step-by-step instructions in this chapter.

- “How to Set Up System Accounting” on page 275
- “How to Bill Users” on page 277
- “How to Fix a Corrupted wtmpx File” on page 278
- “How to Fix tacct Errors” on page 278
- “How to Restart the runacct Script” on page 279
- “How to Set Up System Accounting” on page 275
- “How to Permanently Disable System Accounting” on page 280

This is a list of the overview information in this chapter.

- “What is System Accounting?” on page 269
- “Setting Up System Accounting” on page 274

For reference information on the various system accounting reports, see Chapter 20.

What is System Accounting?

The SunOS 5.9 system accounting software is a set of programs that enables you to collect and record data about user connect time, CPU time charged to processes, and disk usage. Once you collect this data, you can generate reports and charge fees for system usage.

You can use the accounting programs to:

- Monitor system usage
- Locate and correct performance problems
- Maintain system security

After you set up the system accounting programs, they run mostly on their own.

**How System Accounting Works**

Automatic accounting is set up by first putting the accounting startup script into root's `crontab` file. The accounting startup script can then be started automatically by the `cron` command.

The following overview illustrates the system accounting process.

1. Between system startup and shutdown, raw data about system use (such as user logins, running processes, and data storage) are collected in accounting files.
2. Periodically (usually once a day), the `/usr/lib/acct/runacct` script processes the various accounting files and produces both cumulative summary files and daily accounting reports. Then the `/usr/lib/acct/prdaily` script prints the daily reports.
   
   For more information about the `runacct` script, see “The `runacct` Script” on page 283.
3. Monthly, you can process and print the cumulative `runacct` summary files by executing the `monacct` script. The summary reports produced by the `monacct` script provide an efficient means for billing users on a monthly or other fiscal basis.

**System Accounting Components**

The accounting software provides C language programs and shell scripts that organize data into summary files and reports. These programs reside in the `/usr/lib/acct` directories. The accounting reports reside in the `/var/adm/acct` directory.

Daily accounting can help you perform four types of auditing:

- Connect
- Process
- Disk
- Fee calculations

**Connect Accounting**

Connect accounting enables you to determine:

- The length of time a user was logged in
- How the `tty` lines are being used
- The number of reboots on your system
- How many times the accounting software was turned off and on

To provide this information, the system stores:

- Records of time adjustments
- Boot times
- Times the accounting software was turned off and on
- Changes in run levels
- The creation of user processes (login processes and init processes), and the terminations of processes.

These records (produced from the output of system programs such as date, init, login, ttymon, and acctwtmp) are stored in the /var/adm/wtmpx file. Entries in the wtmpx file can contain the following information:

- Login name
- Device name
- Process ID
- Entry type
- Time stamp that denotes when the entry was made.

**Process Accounting**

Process accounting enables you to keep track of the following data about each process that runs on your system:

- User IDs and group IDs of users using the process
- Beginning times and elapsed times of the process
- CPU time for the process (user time and system time)
- Amount of memory used
- Commands run
- The tty controlling the process

Every time a process terminates, the exit program collects this information and writes it to the /var/adm/pacct file.

**Disk Accounting**

Disk accounting enables you to gather and format the following data about the files each user has on disks:

- User name and user ID of the user
- Number of blocks used by the user’s files
This data is collected by the /usr/lib/acct/dodisk shell script at intervals determined by the entry you add to the /var/spool/cron/crontabs/root file. In turn, the dodisk script invokes the acctdisk and acctdusg commands, which gather disk usage by login.

**Caution** – Information gathered by running the dodisk script is stored in the /var/adm/acct/nite/disktacct file. This information is overwritten the next time the dodisk script is run. Therefore, avoid running the dodisk script twice in the same day.

The acctdusg command might overcharge for files that are written randomly, which can create holes in the files. This problem occurs because the acctdusg command does not read the indirect blocks of a file when determining the file size. Rather, the acctdusg command determines the file size by checking the di_size value of the inode.

**Calculating User Fees**

The chargefee utility stores charges for special services provided to a user, such as file restoration, in the /var/adm/fee file. Each entry in the file consists of a user login name, user ID, and the fee. This file is checked by the runacct script every day and new entries are merged into the accounting records. For instructions on running the chargefee script to bill users, see “How to Bill Users” on page 277.

**How Daily Accounting Works**

Here is a step-by-step summary of how daily accounting works:

1. When the system is switched into multiuser mode, the /usr/lib/acct/startup program is executed. The startup program executes several other programs that invoke daily accounting.

2. The acctwtmp program adds a “boot” record to the /var/adm/wtmpx file. In this record, the system name is shown as the user name in the wtmpx record. The following table summarizes how the raw accounting data is gathered and where it is stored.

<table>
<thead>
<tr>
<th>File in /var/adm</th>
<th>Information Stored</th>
<th>Written By</th>
<th>Format</th>
</tr>
</thead>
<tbody>
<tr>
<td>wtmpx</td>
<td>Connect sessions</td>
<td>login, init</td>
<td>binary</td>
</tr>
<tr>
<td></td>
<td>Changes</td>
<td>date</td>
<td></td>
</tr>
</tbody>
</table>

TABLE 19–1 Raw Accounting Data
TABLE 19–1 Raw Accounting Data  
(Continued)

<table>
<thead>
<tr>
<th>File in /var/adm</th>
<th>Information Stored</th>
<th>Written By</th>
<th>Format</th>
</tr>
</thead>
<tbody>
<tr>
<td>Reboots</td>
<td>acctwtmp</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Shutdowns</td>
<td>shutacct</td>
<td></td>
<td></td>
</tr>
<tr>
<td>pacctn</td>
<td>Processes</td>
<td>Kernel (when the process ends)</td>
<td>binary</td>
</tr>
<tr>
<td></td>
<td></td>
<td>turnacct switch (which creates a new file when the old one reaches 500 blocks)</td>
<td></td>
</tr>
<tr>
<td>fee</td>
<td>Special charges</td>
<td>chargefee</td>
<td>ASCII</td>
</tr>
<tr>
<td>acct/nite/disktacct</td>
<td>Disk space used</td>
<td>dodisk</td>
<td>binary</td>
</tr>
</tbody>
</table>

3. The *turnacct* script, invoked with the `-on` option, begins process accounting. Specifically, the *turnacct* script executes the *accton* program with the /var/adm/pacct argument.

4. The *remove* shell script “cleans up” the saved pacct and wtmpx files left in the *sum* directory by the *runacct* script.

5. The *login* and *init* programs record connect sessions by writing records into the /var/adm/wtmpx file. Date changes (using date with an argument) are also written to the /var/adm/wtmpx file. Reboots and shutdowns using the acctwtmp command are also recorded in the /var/adm/wtmpx the.

6. When a process ends, the kernel writes one record per process, using the acct.h format, in the /var/adm/pacct file.

   Every hour, the *cron* command executes the ckpacct script to check the size of the /var/adm/pacct file. If the file grows past 500 blocks (default), the *turnacct switch* command is executed. (The program moves the pacct file to the pacctn file and creates a new one.) The advantage of having several smaller pacct files becomes apparent when you try to restart the *runacct* script if a failure occurs when processing these records.

7. The *runacct* script is executed by the *cron* command each night. The *runacct* script processes the accounting files: /var/adm/pacctn, /var/adm/wtmpx, /var/adm/fee, and /var/adm/acct/nite/disktacct, to produce command summaries and usage summaries by user name.

8. The /usr/lib/acct/prdaily script is executed on a daily basis by the *runacct* script to write the daily accounting information in the /var/adm/acct/sum/rprtMMDD files.

9. The *monacct* script should be executed on a monthly basis (or at intervals you determine, such as the end of every fiscal period). The *monacct* script creates a report based on data stored in the sum directory that has been updated daily by the
runacct script. After creating the report, the monacct script “cleans up” the sum directory to prepare the directory’s files for the new runacct data.

What Happens if the System Shuts Down

If the system is shut down using the shutdown command, the shutacct script is executed automatically. The shutacct script writes a reason record into the /var/adm/wtmpx file and turns off process accounting.

Setting Up System Accounting

You can set up system accounting to run while the system is in multiuser mode (system state 2). Generally, this task involves:

1. Creating the /etc/rc0.d/K22acct and /etc/rc2.d/S22acct startup scripts
2. Modifying the /var/spool/cron/crontabs/adm and /var/spool/cron/crontabs/root crontab files

The following table describes the default accounting scripts.

<table>
<thead>
<tr>
<th>Accounting Script</th>
<th>Man Page</th>
<th>Purpose</th>
<th>Run Frequency</th>
</tr>
</thead>
<tbody>
<tr>
<td>ckpacct</td>
<td>ckpacct(1M)</td>
<td>Checks the size of the /usr/adm/pacct log file and makes sure it does not get too large.</td>
<td>Periodically</td>
</tr>
<tr>
<td>runacct</td>
<td>runacct(1M)</td>
<td>Processes connect, disk, and fee accounting information. You can remove the commands from this script for the accounting features you do not want processed.</td>
<td>Daily</td>
</tr>
<tr>
<td>monacct</td>
<td>monacct(1M)</td>
<td>Generates fiscal accounting summary reports on a monthly basis. You can determine how often this script is run. You can remove the commands from this script for the accounting features you do not want generated.</td>
<td>On a fiscal basis</td>
</tr>
</tbody>
</table>
You can choose which accounting scripts run by default. After these entries have been added to the crontab files, accounting should run automatically.

▼ How to Set Up System Accounting

1. Become superuser.

2. If necessary, install the SUNWaccr and SUNWaccu packages on your system by using the pkgadd command.

3. Install /etc/init.d/acct as the startup script for Run Level 2.
   
   ```
   # ln /etc/init.d/acct /etc/rc2.d/S22acct
   ```

4. Install /etc/init.d/acct as the stop script for Run Level 0.
   
   ```
   # ln /etc/init.d/acct /etc/rc0.d/K22acct
   ```

5. Add the following lines to the admcrontab file to start the ckpacct, runacct, and monacct scripts automatically.
   
   ```
   #EDITOR=vi; export EDITOR
   # crontab -e adm
   0 * * * * /usr/lib/acct/ckpacct
   30 2 * * * /usr/lib/acct/runacct 2> /var/adm/acct/nite/fd2log
   30 7 1 * * /usr/lib/acct/monacct
   ```

6. Add the following line to the root crontab file to start the dodisk script automatically.
   
   ```
   # crontab -e
   30 22 * * 4 /usr/lib/acct/dodisk
   ```

7. Edit /etc/acct/holidays to include national and local holidays.
   For more information, see holidays(4) and the example that follows.

8. Reboot the system, or start accounting manually by typing:
   
   ```
   # /etc/init.d/acct start
   ```

Examples—Setting Up Accounting

This modified adm crontab contains entries for the ckpacct, runacct, and monacct scripts.

```bash
#ident "(@)adm 1.5 92/07/14 SMI" /* SVr4.0 1.2 */
#
# The adm crontab file should contain startup of performance
# collection if the profiling and performance feature has been
# installed.
```
This modified root crontab contains entries for the dodisk program.

```bash
#ident "@(#)root 1.19 98/07/06 SMI" /* SVr4.0 1.1.3.1 */
#
# The root crontab should be used to perform accounting data collection.
#
# The rtc command is run to adjust the real time clock if and when
daylight savings time changes.
#
10 3 * * * /usr/sbin/logadm
15 3 * * 0 /usr/lib/fs/nfs/nfsfind
1 2 * * * [-x /usr/sbin/rtc ] && /usr/sbin/rtc -c > /dev/null 2>&1
30 3 * * * [-x /usr/lib/gss/gsscred_clean ] && /usr/lib/gss/gsscred_clean
30 22 * * 4 /usr/lib/acct/dodisk
```

The following example shows a sample /etc/acct/holidays file.

```
* @(#)holidays January 1, 2001
*
* Prime/Nonprime Table for UNIX Accounting System
*
* Curr Prime Non-Prime
* Year Start Start
*
* 1999 0800 1800
*
* only the first column (month/day) is significant.
*
* month/day Company
* Holiday
*
* 1/1 New Years Day
* 7/4 Indep. Day
* 12/25 Christmas
```

**Billing Users**

If you provide special user services by request, such as restoring files or remote printing, you might want to bill users by running the chargefee utility. The chargefee utility records charges in the /var/adm/fee file. Each time the runacct utility is executed, new entries are merged into the total accounting records.

See acctsh(1M) for more information.
How to Bill Users

1. Become superuser.
2. Charge a user for special services.

```
# /usr/lib/acct/chargefee username amount
```

<table>
<thead>
<tr>
<th>username</th>
<th>User account you want to bill.</th>
</tr>
</thead>
<tbody>
<tr>
<td>amount</td>
<td>Number of units to bill the user. This is an arbitrary unit that you set to charge users based on some task like printing or restoring a file. You would have to write a script that invokes chargefee and charges a user for a specific task.</td>
</tr>
</tbody>
</table>

Example—Billing Users

The following example charges the user `print_customer` 10 units.

```
# /usr/lib/acct/chargefee print_customer 10
```

Maintaining Accounting Information

This section describes how to fix corrupted accounting files and how to restart the `runacct` script.

Fixing Corrupted Files and `wtmpx` Errors

Unfortunately, system accounting is not foolproof. Occasionally, a file becomes corrupted or lost. Some of the files can simply be ignored or restored from backup. However, certain files must be fixed to maintain the integrity of system accounting.

The `wtmpx` files seem to cause the most problems in the daily operation of the system accounting. When the date is changed manually and the system is in multiuser mode, a set of date change records is written into the `/var/adm/wtmpx` file. The `wtmpfix` utility is designed to adjust the time stamps in the `wtmp` records when a date change is encountered. However, some combinations of date changes and reboots slip through the `wtmpfix` utility and cause the `acctcon` program to fail.
How to Fix a Corrupted `wtmpx` File

1. Become superuser.
2. Change to the `/var/adm` directory.
3. Convert the `wtmpx` file from binary to ASCII format.
   ```bash
   # /usr/lib/acct/fwtmp < wtmpx > wtmpx.ascii
   ```
4. Edit `wtmpx.ascii` to delete the corrupted records.
5. Convert the `wtmpx.ascii` file back to a binary file.
   ```bash
   # /usr/lib/acct/fwtmp -ic < wtmpx.ascii > wtmpx
   ```
See `fwtmp(1M)` for more information.

Fixing `tacct` Errors

The integrity of the `/var/adm/acct/sum/tacct` file is important if you are charging users for system resources. Occasionally, unusual `tacct` records appear with negative numbers, duplicate user IDs, or a user ID of 65535. First, check the `/var/adm/acct/sum/tacctprev` file by using the `prtacct` script to print it. If the contents look all right, patch the latest `/var/adm/acct/sum/tacctMMDD` file, then recreate the `/var/adm/acct/sum/tacct` file. The following steps outline a simple patch procedure.

How to Fix `tacct` Errors

1. Become superuser.
2. Change to the `/var/adm/acct/sum` directory.
3. Convert the `tacctMMDD` file from binary to ASCII format.
   ```bash
   # /usr/lib/acct/acctmerg -v < tacctMMDD > xtacct
   ```
   `MMDD` is pair of two-digit numbers that represent the month and day.
4. Edit the `xtacct` file, removing corrupted records and writing duplicate records to another file.
5. Convert the `xtacct` file from ASCII format to binary.
   ```bash
   # /usr/lib/acct/acctmerg -i < xtacct > tacctMMDD
   ```
   `MMDD` is pair of two-digit numbers that represent the month and day.
6. Merge the files `tacctprev` and `tacct.MMDD` into the `tacct` file.
Restarting the runacct Script

The runacct script can fail for a variety of reasons. The most common reasons are a system crash, the /var directory running out of space, or a corrupted wtmpx file. If the active.MMDD file exists, check it first for error messages. If the active and lock files exist, check fd2log for any relevant messages.

Run without arguments, the runacct script assumes that this invocation is the first invocation of the day. The argument MMDD is necessary if the runacct script is being restarted and specifies the month and day for which the runacct script reruns the accounting. The entry point for processing is based on the contents of the statefile file. To override the statefile file, include the desired state on the command line. For a description of the available states, see runacct(1M).

Caution – When you run the runacct program manually, be sure to run it as user adm.

▼ How to Restart the runacct Script

1. Remove the lastdate file and any lock* files, if any.

   $ cd /var/adm/acct/nite
   $ rm lastdate lock*

   The lastdate file contains the date that the runacct program was last run. Restarting runacct in the next step recreates this file.

2. Restart the runacct script.

   $ /usr/lib/acct/runacct MMDD [state] 2> /var/adm/acct/nite/fd2log &

   MMDD
   Month and day specified by two-digit numbers.

   state
   Specifies a state, or starting point, where the runacct processing should begin.
Stopping and Disabling System Accounting
You can temporarily stop system accounting or disable it permanently.

▼ How to Temporarily Stop System Accounting
1. Become superuser.

2. Edit the `adm crontab` file to stop the `ckpacct`, `runacct`, and `monacct` programs from running by commenting out the appropriate lines.

   ```
   # EDITOR=vi; export EDITOR
   # crontab -e adm
   #0 * * * * /usr/lib/acct/ckpacct
   #30 2 * * * /usr/lib/acct/runacct 2> /var/adm/acct/nite/fd2log
   #30 7 1 * * /usr/lib/acct/monacct
   ```

3. Edit the `crontab` file for user root to stop the `dodisk` program from running by commenting out the appropriate line.

   ```
   # crontab -e
   #30 22 * * 4 /usr/lib/acct/dodisk
   ```

4. Stop the accounting program.

   ```
   # /etc/init.d/acct stop
   ```

5. (Optional) Remove the newly added comment symbols from the `crontab` files and restart the accounting program to re-enable system accounting.

   ```
   # /etc/init.d/acct start
   ```

▼ How to Permanently Disable System Accounting
1. Become superuser.

2. Edit the `adm crontab` file and delete the entries for the `ckpacct`, `runacct`, and `monacct` programs.

   ```
   # EDITOR=vi; export EDITOR
   # crontab -e adm
   ```

3. Edit the root `crontab` file and delete the entries for the `dodisk` program.

   ```
   # crontab -e
   ```
4. Remove the startup script for Run Level 2.

   # unlink /etc/rc2.d/S22acct

5. Remove the stop script for Run Level 0.

   # unlink /etc/rc0.d/K22acct

6. Stop the accounting program.

   # /etc/init.d/acct stop
System Accounting (Reference)

This chapter provides reference information about system accounting.

This is a list of reference information in this chapter.
- “Daily Accounting Reports” on page 285
- “The runacct Script” on page 283
- “System Accounting Files” on page 293

The runacct Script

The main daily accounting script, runacct, is normally invoked by the cron command outside of prime business hours. The runacct script processes connect, fee, disk, and process accounting files. This script also prepares daily and cumulative summary files for use by the prdaily and monacct scripts for billing purposes.

The runacct script takes care not to damage files if errors occur. A series of protection mechanisms are used to recognize an error, provide intelligent diagnostics, and complete processing in such a way that the runacct script can be restarted with minimal intervention. It records its progress by writing descriptive messages into the active file. Files used by the runacct script are assumed to be in the /var/adm/acct/nite directory, unless otherwise noted. All diagnostic output during the execution of the runacct script is written into the fd2log file.

When the runacct script is invoked, it creates the lock and lock1 files. These files are used to prevent simultaneous execution of runacct. The runacct program prints an error message if these files exist when it is invoked. The lastdate file contains the month and day the runacct script was last invoked, and is used to prevent more than one execution per day. If the runacct script detects an error, a
message is written to the console, mail is sent to root and adm, locks might be removed, diagnostic files are saved, and execution is ended. For instructions on how to start the runacct script again, see “How to Restart the runacct Script” on page 279.

To allow the runacct script to be restarted, processing is broken down into separate re-entrant states. The statefile file is used to keep track of the last state completed. When each state is completed, the statefile file is updated to reflect the next state. After processing for the state is complete, the statefile file is read and the next state is processed. When the runacct script reaches the CLEANUP state, it removes the locks and ends. States are executed as shown in the following table.

**TABLE 20–1 runacct States**

<table>
<thead>
<tr>
<th>State</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>SETUP</strong></td>
<td>The turnacct switch command is executed to create a new pacct file. The /var/adm/pacctn process accounting files (except for the pacct file) are moved to the /var/adm/Spacctn.MMDD files. The /var/adm/wtmpx file is moved to the /var/adm/acct/nite/wtmp.MMDD file (with the current time record added on the end) and a new /var/adm/wtmp file is created. The closewtmp and utmp2wtmp programs add records to the wtmp.MMDD file and the new wtmpx file to account for users currently logged in.</td>
</tr>
<tr>
<td><strong>WTMPFIX</strong></td>
<td>The wtmpfix program checks the wtmp.MMDD file in the nite directory for accuracy. Because some date changes cause the acctcon program to fail, the wtmpfix program attempts to adjust the time stamps in the wtmpx file if a record of a date change appears. This program also deletes any corrupted entries from the wtmpx file. The fixed version of the wtmp.MMDD file is written to the tmpwtmp file.</td>
</tr>
<tr>
<td><strong>CONNECT</strong></td>
<td>The acctcon program is used to record connect accounting records in the file ctacct.MMDD. These records are in tacct.h format. In addition, acctcon creates the lineuse and reboots files. The reboots file records all the boot records found in the wtmpx file.</td>
</tr>
<tr>
<td><strong>PROCESS</strong></td>
<td>The acctprc program is used to convert the /var/adm/Spacctn.MMDD process accounting files into total accounting records in the ptacctn.MMDD files. The Spacct and ptacct files are correlated by number so that if the runacct script fails, the Spacct files are not processed.</td>
</tr>
<tr>
<td><strong>MERGE</strong></td>
<td>The acctmerg program merges the process accounting records with the connect accounting records to form the daytacct file.</td>
</tr>
<tr>
<td><strong>FEES</strong></td>
<td>The acctmerg program merges ASCII tacct records from the fee file into the daytacct file.</td>
</tr>
</tbody>
</table>
TABLE 20–1 runacct States  (Continued)

<table>
<thead>
<tr>
<th>State</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>DISK</td>
<td>If the dodisk script procedure has been run, which produces the disktacct file, the DISK program merges the file into the daytacct file and moves the disktacct file to the /tmp/disktacct.MMDD file.</td>
</tr>
<tr>
<td>MERGETACCT</td>
<td>The acctmerg program merges the daytacct file with the sum/tacct file, the cumulative total accounting file. Each day, the daytacct file is saved in the sum/tacct.MMDD file so that the sum/tacct file can be re-created if it is corrupted or lost.</td>
</tr>
<tr>
<td>CMS</td>
<td>The acctcms program is run several times. This program is first run to generate the command summary by using the Spacctn files and write the data to the sum/daycms file. The acctcms program is then run to merge the sum/daycms file with the sum/cms cumulative command summary file. Finally, the acctcms program is run to produce nite/daycms and nite/cms, the ASCII command summary files from the sum/daycms and sum/cms files, respectively. The lastlogin program is used to create the /var/adm/acct/sum/loginlog log file, the report of when each user last logged in. If the runacct script is run after midnight, the dates showing the time last logged in by some users will be incorrect by one day.</td>
</tr>
<tr>
<td>USEREXIT</td>
<td>Any installation-dependent (local) accounting program can be included at this point. The runacct script expects it to be called the /usr/lib/acct/runacct.local program.</td>
</tr>
<tr>
<td>CLEANUP</td>
<td>Cleans up temporary files, runs the prdaily script and saves its output in the sum/rpt.MMDD file, removes the locks, and then exits.</td>
</tr>
</tbody>
</table>

Caution – When restarting the runacct script in the CLEANUP state, remove the last ptacct file because it will not be complete.

Daily Accounting Reports

The runacct shell script generates five basic reports upon each invocation. The following table describes the five basic reports generated.
### TABLE 20–2 Daily Accounting Reports

<table>
<thead>
<tr>
<th>Report Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>“Daily Report” on page 286</td>
<td>Shows terminal line utilization by tty number.</td>
</tr>
<tr>
<td>“Daily Usage Report” on page 287</td>
<td>Indicates usage of system resources by users (listed in order of user ID).</td>
</tr>
<tr>
<td>“Daily Command Summary” on page 288</td>
<td>Indicates usage of system resources by commands, listed in descending order of memory use. In other words, the command that used the most memory is listed first. This same information is reported for the month with the monthly command summary.</td>
</tr>
<tr>
<td>“Monthly Command Summary” on page 290</td>
<td>A cumulative summary that reflects the data accumulated since the last invocation of the monacct program.</td>
</tr>
<tr>
<td>“Last Login Report” on page 290</td>
<td>Shows the last time each user logged in (arranged in chronological order).</td>
</tr>
</tbody>
</table>

### Daily Report

This report gives information about each terminal line used. The following is a sample Daily Report.

Oct 16 02:30 2001  DAILY REPORT FOR venus Page 1

from Mon Oct 15 02:30:02 2001
to Tue Oct 16 02:30:01 2001
1 runacct
1 acctcon

TOTAL DURATION IS 1440 MINUTES

<table>
<thead>
<tr>
<th>LINE</th>
<th>MINUTES</th>
<th>PERCENT</th>
<th># SESS</th>
<th># ON</th>
<th># OFF</th>
</tr>
</thead>
<tbody>
<tr>
<td>console</td>
<td>868</td>
<td>60</td>
<td>1</td>
<td>1</td>
<td>2</td>
</tr>
<tr>
<td>TOTALS</td>
<td>868</td>
<td>--</td>
<td>1</td>
<td>1</td>
<td>2</td>
</tr>
</tbody>
</table>

The from and to lines specify the time period reflected in the report. This time period covers the time the last Daily Report was generated to the time the current Daily Report was generated. Then, comes a log of system reboots, shutdowns, power failure recoveries, and any other record dumped into the /var/adm/wtmpx file by the acctwtmp program. For more information, see acct(1M).

The second part of the report is a breakdown of terminal line utilization. The TOTAL DURATION tells how long the system was in multiuser mode (accessible through the terminal lines). The following table describes the data provided in the Daily Report.
TABLE 20–3 Daily Report Data

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>LINE</td>
<td>The terminal line or access port.</td>
</tr>
<tr>
<td>MINUTES</td>
<td>The total number of minutes that the line was in use during the accounting period.</td>
</tr>
<tr>
<td>PERCENT</td>
<td>The TOTAL DURATION divided by the total number of MINUTES.</td>
</tr>
<tr>
<td># SESS</td>
<td>The number of times this line or port was accessed for a login session.</td>
</tr>
<tr>
<td># ON</td>
<td>Same as # SESS. (This column no longer has meaning. Previously, it listed the number of times that a line or port was used to log in a user.)</td>
</tr>
<tr>
<td># OFF</td>
<td>This column reflects the number of times a user logs out and any interrupts that occur on that line. Generally, interrupts occur on a port when ttymon is first invoked after the system is brought to multiuser mode. If the # OFF exceeds the # SESS by a large factor, the multiplexer, modem, or cable is probably going bad, or there is a bad connection somewhere. The most common cause is an unconnected cable dangling from the multiplexer.</td>
</tr>
</tbody>
</table>

During real time, you should monitor the /var/adm/wtmpx file because it is the file from which the connect accounting is derived. If the wtmpx file grows rapidly, execute the following command to see which tty line is the noisiest.

```
#/usr/lib/acct/acctcon -l file < /var/adm/wtmpx
```

If interruption is occurring frequently, general system performance will be affected. Additionally, the wtmp file might become corrupted. To correct this problem, see “How to Fix a Corrupted wtmp File” on page 278.

Daily Usage Report

The Daily Usage Report gives a breakdown of system resource utilization by user. A sample of this report follows.

```
Oct 16 02:30 2001 DAILY USAGE REPORT FOR skisun Page 1

<table>
<thead>
<tr>
<th>UID</th>
<th>NAME</th>

<td>1603</td>
<td>1</td>
</tr>
</tbody>
</table>
```

The following table describes the data provided in the Daily Usage Report.
### TABLE 20-4 Daily Usage Report Data

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>UID</td>
<td>User ID number.</td>
</tr>
<tr>
<td>LOGIN NAME</td>
<td>Login (or user) name of the user. Identifies a user who has multiple login names.</td>
</tr>
<tr>
<td>CPU (MINS)</td>
<td>Amount of time, in minutes, that the user’s process used the central processing unit. Divided into PRIME and NPRIME (non-prime) utilization. The accounting system’s version of this data is located in the <code>/etc/acct/holidays</code> file.</td>
</tr>
<tr>
<td>KCORE-MINS</td>
<td>A cumulative measure of the amount of memory in Kbyte segments per minute that a process uses while running. Divided into PRIME and NPRIME utilization.</td>
</tr>
<tr>
<td>CONNECT (MINS)</td>
<td>Amount of time in minutes, that the a user was logged into the system, or “real time.” Divided into PRIME and NPRIME use. If these numbers are high while the # OF PROCS is low, you can conclude that the user logs in first thing in the morning and hardly touches the terminal the rest of the day.</td>
</tr>
<tr>
<td>DISK BLOCKS</td>
<td>Output from the <code>acctdusg</code> program, which runs the disk accounting programs and merges the accounting records (<code>daytaacct</code>). For accounting purposes, a block is 512 bytes.</td>
</tr>
<tr>
<td># OF PROCS</td>
<td>Number of processes invoked by the user. If large numbers appear, a user might have a shell procedure that has run out of control.</td>
</tr>
<tr>
<td># OF SESS</td>
<td>Number of times a user logged on to the system.</td>
</tr>
<tr>
<td># DISK SAMPLES</td>
<td>Number of times disk accounting was run to obtain the average number of DISK BLOCKS.</td>
</tr>
<tr>
<td>FEE</td>
<td>Often unused field that represents the total accumulation of units charged against the user by the <code>chargefee</code> script.</td>
</tr>
</tbody>
</table>

### Daily Command Summary

The Daily Command Summary report shows the system resource use by command. With this report, you can identify the most heavily used commands and, based on how those commands use system resources, gain insight on how best to tune the system.

These reports are sorted by TOTAL KCOREMIN, which is an arbitrary gauge but often a good one for calculating drain on a system.

A sample daily command summary follows.

<table>
<thead>
<tr>
<th>COMMAND NUMBER TOTAL COMMAND SUMMARY</th>
</tr>
</thead>
<tbody>
<tr>
<td>COMMAND NUMBER</td>
</tr>
</tbody>
</table>

288 System Administration Guide: Advanced Administration • December 2002
### TABLE 20-5 Daily Command Summary

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>COMMAND NAME</td>
<td>Name of the command. Unfortunately, all shell procedures are lumped together under the name sh because only object modules are reported by the process accounting system. You should monitor the frequency of programs called a.out or core or any other unexpected name. You can use the acctcom program to determine who executed an oddly named command and if superuser privileges were used.</td>
</tr>
<tr>
<td>NUMBER CMDS</td>
<td>Total number of times this command was run during prime time.</td>
</tr>
<tr>
<td>TOTAL KCOREMIN</td>
<td>Total cumulative measurement of the Kbyte segments of memory used by a process per minute of run time.</td>
</tr>
<tr>
<td>TOTAL CPU-MIN</td>
<td>Total processing time this program accumulated during prime time.</td>
</tr>
<tr>
<td>TOTAL REAL-MIN</td>
<td>Total real-time (wall-clock) minutes this program accumulated.</td>
</tr>
<tr>
<td>MEAN SIZE-K</td>
<td>Mean of the TOTAL KCOREMIN over the number of invocations reflected by NUMBER CMDS.</td>
</tr>
<tr>
<td>MEAN CPU-MIN</td>
<td>Mean derived between the NUMBER CMDS and TOTAL CPU-MIN.</td>
</tr>
<tr>
<td>HOG FACTOR</td>
<td>Total CPU time divided by elapsed time. Shows the ratio of system availability to system use, providing a relative measure of total available CPU time consumed by the process during its execution.</td>
</tr>
<tr>
<td>CHARS TRNSFD</td>
<td>Total number of characters pushed around by the read and write system calls. Might be negative due to overflow.</td>
</tr>
</tbody>
</table>
## TABLE 20–5 Daily Command Summary (Continued)

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>BLOCKS READ</td>
<td>Total number of the physical block reads and writes that a process performed.</td>
</tr>
</tbody>
</table>

### Monthly Command Summary

The format of the Daily Command Summary and the Monthly Command Summary reports are virtually the same. However, the daily summary reports only on the current accounting period while the monthly summary reports on the start of the fiscal period to the current date. In other words, the monthly report is a cumulative summary that reflects the data accumulated since the last invocation of the `monacct` program.

A sample report follows.

<table>
<thead>
<tr>
<th>COMMAND NAME</th>

<td>01-09-08</td>
<td>protoB</td>
<td>01-10-15</td>
<td>scutter1</td>
</tr>
</tbody>
</table>
Looking at the pacct File With acctcom

At any time, you can examine the contents of the "/var/adm/pacctn" files, or any file with records in the acct.h format, by using the acctcom program. If you do not specify any files and do not provide any standard input when you run this command, the acctcom command reads the pacct file. Each record read by the acctcom command represents information about a terminated process. Active processes can be examined by running the ps command. The default output of the acctcom command provides the following information:

Sample acctcom output follows:

<table>
<thead>
<tr>
<th>COMMAND</th>
<th>USER</th>
<th>TTYNAME</th>
<th>START TIME</th>
<th>END TIME</th>
<th>REAL TIME</th>
<th>CPU TIME</th>
<th>MEAN SIZE</th>
</tr>
</thead>
<tbody>

</tbody>
</table>

- Command name (pound (#) sign if the command was executed with superuser privileges)
- User name
- tty name (listed as ? if unknown)
- Command starting time
- Command ending time
- Real time (in seconds)
- CPU time (in seconds)
- Mean size (in Kbytes)

You can obtain the following information by using acctcom options:
- State of the fork/exec flag (1 for fork without exec)
- System exit status
- Hog factor
- Total kcore minutes
- CPU factor
- Characters transferred
- Blocks read

The following table describes the `acctcom` options.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>-a</code></td>
<td>Shows average statistics about the processes selected. The statistics are printed after the output is recorded.</td>
</tr>
<tr>
<td><code>-b</code></td>
<td>Reads the files backward, showing latest commands first. This option has no effect if reading standard input.</td>
</tr>
<tr>
<td><code>-f</code></td>
<td>Prints the fork/exec flag and system exit status columns. The output is an octal number.</td>
</tr>
<tr>
<td><code>-h</code></td>
<td>Instead of mean memory size, shows the hog factor, which is the fraction of total available CPU time consumed by the process during its execution. Hog factor = total_CPU_time/elapsed_time.</td>
</tr>
<tr>
<td><code>-i</code></td>
<td>Prints columns containing the I/O counts in the output.</td>
</tr>
<tr>
<td><code>-k</code></td>
<td>Shows total kcore minutes instead of memory size.</td>
</tr>
<tr>
<td><code>-m</code></td>
<td>Shows mean core size. This is the default.</td>
</tr>
<tr>
<td><code>-q</code></td>
<td>Prints average statistics, not output records.</td>
</tr>
<tr>
<td><code>-r</code></td>
<td>Shows CPU factor: user_time/(system_time + user_time).</td>
</tr>
<tr>
<td><code>-t</code></td>
<td>Shows separate system and user CPU times.</td>
</tr>
<tr>
<td><code>-v</code></td>
<td>Excludes column headings from the output.</td>
</tr>
<tr>
<td><code>-C sec</code></td>
<td>Shows only processes with total CPU time (system plus user) exceeding sec seconds.</td>
</tr>
<tr>
<td><code>-e time</code></td>
<td>Shows processes existing at or before time, given in the format hr:min[sec].</td>
</tr>
<tr>
<td><code>-E time</code></td>
<td>Shows processes starting at or before time, given in the format hr:min[sec]. Using the same time for both <code>-S</code> and <code>-E</code>, shows processes that existed at the time.</td>
</tr>
<tr>
<td><code>-g group</code></td>
<td>Shows only processes that belong to group.</td>
</tr>
<tr>
<td><code>-H factor</code></td>
<td>Shows only processes that exceed factor, where factor is the “hog factor” (see the <code>-h</code> option).</td>
</tr>
<tr>
<td><code>-I chars</code></td>
<td>Shows only processes that transferred more characters than the cutoff number specified by chars.</td>
</tr>
<tr>
<td><code>-l line</code></td>
<td>Show only processes belonging to the terminal /dev/line.</td>
</tr>
</tbody>
</table>
TABLE 20-6 acctcom Options  (Continued)

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-n pattern</td>
<td>Shows only commands matching pattern (a regular expression except that “+” means one or more occurrences).</td>
</tr>
<tr>
<td>-o ofile</td>
<td>Instead of printing the records, copies them in acct.h format to ofile.</td>
</tr>
<tr>
<td>-o sec</td>
<td>Shows only processes with CPU system time exceeding sec seconds.</td>
</tr>
<tr>
<td>-s time</td>
<td>Show processes existing at or after time, given in the format hr[min[sec]].</td>
</tr>
<tr>
<td>-S time</td>
<td>Show processes starting at or after time, given in the format hr[min[sec]].</td>
</tr>
<tr>
<td>-u user</td>
<td>Shows only processes that belong to user.</td>
</tr>
</tbody>
</table>

## System Accounting Files

The /var/adm directory contains the active data collection files. The following table describes the accounting files in this directory.

TABLE 20-7 Files in the /var/adm Directory

<table>
<thead>
<tr>
<th>File</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dtmp</td>
<td>Output from the acctdusg program</td>
</tr>
<tr>
<td>fee</td>
<td>Output from the chargefee program, which are the ASCII tacct records</td>
</tr>
<tr>
<td>pacct</td>
<td>Active process accounting file</td>
</tr>
<tr>
<td>pacctn</td>
<td>Process accounting files switched by running the turnacct script</td>
</tr>
<tr>
<td>Spacctn.MMDD</td>
<td>Process accounting files for MMDD during execution of the runacct script</td>
</tr>
</tbody>
</table>

The /var/adm/acct directory contains the nite, sum, and fiscal directories, which contain the actual data collection files. For example, the nite directory contains files that are reused daily by the runacct script. A brief summary of the files in the /var/adm/acct/nite directory follows.
**TABLE 20–8 Files in the /var/adm/acct/nite Directory**

<table>
<thead>
<tr>
<th>File</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>active</td>
<td>Used by the runacct script to record progress and print warning and error messages</td>
</tr>
<tr>
<td>active.MMDD</td>
<td>Same as the active file after the runacct script detects an error</td>
</tr>
<tr>
<td>cms</td>
<td>ASCII total command summary used by prdaily</td>
</tr>
<tr>
<td>ctacct.MMDD</td>
<td>Connect accounting records in tacct.h format</td>
</tr>
<tr>
<td>ctmp</td>
<td>Output of acctcon1 program, connect session records in ctmp.h format (acctcon1 and acctcon2 are provided for compatibility purposes)</td>
</tr>
<tr>
<td>daycms</td>
<td>ASCII daily command summary used by the prdaily script</td>
</tr>
<tr>
<td>daytacct</td>
<td>Total accounting records for one day in tacct.h format</td>
</tr>
<tr>
<td>disktacct</td>
<td>Disk accounting records in tacct.h format, created by the dodisk script</td>
</tr>
<tr>
<td>fd2log</td>
<td>Diagnostic output during execution of the runacct script</td>
</tr>
<tr>
<td>lastdate</td>
<td>Last day the runacct script executed (in date +%m%d format)</td>
</tr>
<tr>
<td>lock</td>
<td>Used to control serial use of the runacct script</td>
</tr>
<tr>
<td>lineuse</td>
<td>tty line usage report used by the prdaily script</td>
</tr>
<tr>
<td>log</td>
<td>Diagnostic output from the acctcon program</td>
</tr>
<tr>
<td>log.MMDD</td>
<td>Same as the log file after the runacct script detects an error</td>
</tr>
<tr>
<td>owttmpx</td>
<td>Previous day’s wtmpx file</td>
</tr>
<tr>
<td>reboots</td>
<td>Beginning and ending dates from the wtmpx file and a listing of reboots</td>
</tr>
<tr>
<td>statefile</td>
<td>Used to record current state during execution of the runacct script</td>
</tr>
<tr>
<td>tmpwttmp</td>
<td>wtmpx file corrected by the wtmpfix program</td>
</tr>
<tr>
<td>wtmperror</td>
<td>Contains wtmpfix error messages</td>
</tr>
<tr>
<td>wtmperror.MMDD</td>
<td>Same as the wtmperror file after the runacct script detects an error</td>
</tr>
<tr>
<td>wtmp.MMDD</td>
<td>The runacct script’s copy of the wtmpx file</td>
</tr>
</tbody>
</table>

The sum directory contains the cumulative summary files updated by the runacct script and used by the monacct script. The following table summarizes the files in the /var/adm/acct/sum directory.
TABLE 20–9 Files in the /var/adm/acct/sum Directory

<table>
<thead>
<tr>
<th>File</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>cms</td>
<td>Total command summary file for current fiscal period in binary format</td>
</tr>
<tr>
<td>cmsprev</td>
<td>Command summary file without latest update</td>
</tr>
<tr>
<td>daycms</td>
<td>Command summary file for the day’s usage in internal summary format</td>
</tr>
<tr>
<td>loginlog</td>
<td>Record of last date each user logged on; created by the lastlogin script and used in the prdaily script</td>
</tr>
<tr>
<td>rprt.MMDD</td>
<td>Saved output of prdaily script</td>
</tr>
<tr>
<td>tacct</td>
<td>Cumulative total accounting file for current fiscal period</td>
</tr>
<tr>
<td>tacctprev</td>
<td>Same as tacct without latest update</td>
</tr>
<tr>
<td>tacct.MMDD</td>
<td>Total accounting file for MMDD</td>
</tr>
</tbody>
</table>

The fiscal directory contains periodic summary files created by the monacct script. The following table summarizes the files in the /var/adm/acct/fiscal directory.

TABLE 20–10 Files in the /var/adm/acct/fiscal Directory

<table>
<thead>
<tr>
<th>File</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>cmsn</td>
<td>Total command summary file for fiscal period n in internal summary format</td>
</tr>
<tr>
<td>fiscrptn</td>
<td>Report similar to rprtn for fiscal period n</td>
</tr>
<tr>
<td>tacctn</td>
<td>Total accounting file for fiscal period n</td>
</tr>
</tbody>
</table>

Files Produced by the runacct Script

The following table summarizes most useful files produced by the runacct script found in the /var/adm/acct directory.
<table>
<thead>
<tr>
<th>File</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>nite/lineuse</td>
<td>The <code>runacct</code> script calls the <code>acctcon</code> program to gather data on terminal line usage from the <code>/var/adm/acct/nite/tmpwtmp</code> file and writes the data to the <code>/var/adm/acct/nite/lineuse</code> file. The <code>prdaily</code> script uses this data to report line usage. This report is especially useful for detecting bad lines. If the ratio between the number of logouts to logins is greater than about three to one, the line is very likely failing.</td>
</tr>
<tr>
<td>nite/daytacct</td>
<td>The total accounting file for the day in <code>tacct.h</code> format.</td>
</tr>
<tr>
<td>sum/tacct</td>
<td>Contains the accumulation of each day's <code>nite/daytacct</code> data and is used for billing purposes. The <code>monacct</code> script restarts accumulating this data each month or fiscal period.</td>
</tr>
<tr>
<td>sum/daycms</td>
<td>The <code>runacct</code> script calls the <code>acctcms</code> program to process the commands used during the day to create the Daily Command Summary report and stores the data in the <code>/var/adm/acct/sum/daycms</code> file. The ASCII version is the <code>/var/adm/acct/nite/daycms</code> file.</td>
</tr>
<tr>
<td>sum/cms</td>
<td>This file is the accumulation of each day's command summaries. It is restarted by the execution of the <code>monacct</code> script. The ASCII version is the <code>nite/cms</code> file.</td>
</tr>
<tr>
<td>sum/loginlog</td>
<td>The <code>runacct</code> script calls <code>lastlogin</code> script to update the last date logged in for the logins in the <code>/var/adm/acct/sum/loginlog</code> file. The <code>lastlogin</code> command also removes from this file any logins that are no longer valid.</td>
</tr>
<tr>
<td>sum/rprt.MMDD</td>
<td>Each execution of the <code>runacct</code> script saves a copy of the daily report that was printed by the <code>prdaily</code> script.</td>
</tr>
</tbody>
</table>
Managing System Performance Topics

This topic map lists the chapters that provide information for managing system performance.

<table>
<thead>
<tr>
<th>Chapter 22</th>
<th>Provides overview information about system performance topics.</th>

<td>Provides step-by-step instructions for using process commands to enhance system performance.</td>
</tr>
<tr>
<td>Chapter 24</td>
<td>Provides step-by-step instructions for using vmstat, sar, and disk utilization commands to monitor system performance.</td>
</tr>
</tbody>
</table>
Managing System Performance
(Overview)

Achieving good performance from a computer or network is an important part of system administration. This chapter is an overview of some factors that contribute to maintaining and managing the performance of the computer systems in your care.

This is a list of the overview information in this chapter.

- “Where to Find System Performance Tasks” on page 302
- “System Performance and System Resources” on page 302
- “Processes and System Performance” on page 303
- “About Monitoring Performance” on page 304

What’s New in Managing System Performance?

This section describes new features for managing system performance.

DNLC Improvements

The directory name look-up cache (DNLC) is enhanced to provide improved performance when you access files in large directories with 1000 or more files.

The DNLC is a general file system service that caches the most recently referenced directory names and their associated vnodes. UFS directory entries are stored linearly on disk, which means that locating an entry requires searching each entry for the name. The addition of a new entry requires searching the entire directory to ensure that the name does not exist. To solve this performance problem, the DNLC caches entire directories in memory.
Another feature in this release is the DNLC caching of file objects that have been looked up, but do not exist. This feature is known as negative caching, and is useful because some applications repeatedly test to check if a file exists.

For more information, see Solaris Tunable Parameters Reference Manual.

The `pargs` and `preap` Commands

Two new commands, `pargs` and `preap`, improve process debugging. The `pargs` command can be used to print the arguments and environment variables associated with a live process or core file. The `preap` command can be used to remove defunct (zombie) processes.

The `pargs` command solves a long-standing problem of being unable to display all the arguments that are passed to a process with the `ps` command. Use the `pargs` command in combination with the `pgrep` command to display the arguments that are passed to a process, as follows:

```
# pargs 'pgrep ttymon'
579: /usr/lib/saf/ttymon -g -h -p system-name console login:
    -T sun -d /dev/console -l
argv[0]: /usr/lib/saf/ttymon
argv[1]: -g
argv[2]: -h
argv[3]: -p
argv[4]: system-name console login:
argv[5]: -T
argv[6]: sun
argv[7]: -d
argv[8]: /dev/console
argv[9]: -l
argv[10]: console
argv[11]: -m
argv[12]: ldterm,tterm,ttcompat
548: /usr/lib/saf/ttymon
argv[0]: /usr/lib/saf/ttymon
```

Use the `pargs -e` command to display the environment variables that are associated with a process, as in the following example:

```
$ pargs -e 6763
6763: tcsh
envp[0]: DISPLAY=:0.0
```

You can use the `pargs` and `preap` commands to examine any process that you have the privileges to examine. As superuser, you can examine any process.

You can use the `preap` command to clean up a defunct process. A defunct process is also called a zombie process. A zombie process has not yet had its exit status reaped, or claimed, by its parent. These processes are generally harmless, but can consume system resources if they are numerous.
For information on using the preap command, see *preap*(1). For information on the using the pargs command, see *proc*(1).

**Performance Tool**

You can monitor system performance and system resource utilization with the Solaris Management Console’s Performance Tool.

For information on allocating, monitoring, and controlling system resources with the Solaris resource management, see “Introduction to Solaris 9 Resource Manager” in *System Administration Guide: Resource Management and Network Services*.

For information on using and starting the Solaris Management Console, see “Working With the Management Console (Tasks)” in *System Administration Guide: Basic Administration*.

**New Fair Share (FSS) and Fixed (FX) Schedulers**

The FSS and FX schedulers are new user process schedulers. Both schedulers use the same range of priorities (0 to 59) as the time sharing (TS) and interactive (IA) scheduling classes.

FX is a fixed-priority scheduler that gives processes that run in it an assured priority. FX is not meant to be a default scheduler. TS balances loads. FX does not. You can run FX and TS on the same system, but if you set the priority too high for FX, you could starve the processes that run in TS.

The FSS guarantees application performance by explicitly allocating shares of CPU resources to projects. Additional advantages of the FSS are as follows:

- Allows the fine-grained sharing of CPU resources on a system.
- Controls the allocation of available CPU resources among workloads based on their importance. Their importance is expressed by the number of shares of CPU resources that you assign to each workload.

FSS should not be used with TS or FX on the same system unless processor sets are used. If you use processor sets, you can mix TS, IA, and FX with FSS in one system as long as all the processes that run on each processor set are in one scheduling class to prevent them from competing for the same CPUs. The FX scheduler, in particular, should not be used in conjunction with the new FSS scheduling class unless processor sets are used, to prevent applications in the FX class from using priorities that are high enough to starve applications in the FSS class.

The following table identifies where to get more information about using these schedulers and other Solaris resource management features, such as projects and tasks, to better manage system resources.
Where to Find System Performance Tasks

</tbody>
</table>

System Performance and System Resources

The performance of a computer system depends upon how the system uses and allocates its resources. Monitor your system’s performance regularly so that you know how it behaves under normal conditions. You should have a good idea of what to expect, and be able to recognize a problem when it occurs.

System resources that affect performance are described in the following table.
Central processing unit (CPU)  
The CPU processes instructions by fetching instructions from memory and executing them.

Input/output (I/O) devices  
I/O devices transfer information into and out of the computer. Such a device could be a terminal and keyboard, a disk drive, or a printer.

Memory  
Physical (or main) memory is the amount of memory (RAM) on the system.

Chapter 24 describes the tools that display statistics about the activity and the performance of a system.

---

**Processes and System Performance**

The following table describes terms related to processes.

**TABLE 22-1 Process Terminology**

<table>
<thead>
<tr>
<th>Term</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Process</td>
<td>Any system activity or job. Each time you boot a system, execute a command, or start an application, the system activates one or more processes.</td>
</tr>
<tr>
<td>Lightweight process (LWP)</td>
<td>A virtual CPU or execution resource. LWPs are scheduled by the kernel to use available CPU resources based on their scheduling class and priority. LWPs include a kernel thread and an LWP. A kernel thread contains information that has to be in memory all the time. An LWP contains information that is swappable.</td>
</tr>
<tr>
<td>Application thread</td>
<td>A series of instructions with a separate stack that can execute independently in a user’s address space. Application threads can be multiplexed on top of LWPs.</td>
</tr>
</tbody>
</table>

A process can consist of multiple LWPs and multiple application threads. The kernel schedules a kernel-thread structure, which is the scheduling entity in the SunOS environment. Various process structures are described in the following table.
**TABLE 22-2 Process Structures**

<table>
<thead>
<tr>
<th>Structure</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>proc</td>
<td>Contains information that pertains to the whole process and must be in main memory all the time.</td>
</tr>
<tr>
<td>kthread</td>
<td>Contains information that pertains to one LWP and must be in main memory all the time.</td>
</tr>
<tr>
<td>user</td>
<td>Contains the “per process” information that is swappable.</td>
</tr>
<tr>
<td>klwp</td>
<td>Contains the “per LWP process” information that is swappable.</td>
</tr>
</tbody>
</table>

The following figure illustrates the relationship of these process structures.

![FIGURE 22-1 Process Structures](image)

Most process resources are accessible to all the threads in the process. Almost all process virtual memory is shared. A change in shared data by one thread is available to the other threads in the process.

---

**About Monitoring Performance**

While your computer is running, counters in the operating system are incremented to track various system activities. System activities that are tracked are as follows:

- Central processing unit (CPU) utilization
- Buffer usage
- Disk and tape input/output (I/O) activity
- Terminal device activity
Monitoring Tools

The Solaris software provides several tools to help you track how your system is performing. The following table describes these tools.

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
<th>For More Information</th>
</tr>
</thead>
<tbody>
<tr>
<td>sar and sadc commands</td>
<td>Collects and reports on system activity data</td>
<td>Chapter 24</td>
</tr>

</tr>
</tbody>
</table>
Managing System Processes (Tasks)

This chapter describes the procedures for managing system processes. This is a list of the step-by-step instructions in this chapter.

- “How to List Processes” on page 309
- “How to Display Information About Processes” on page 312
- “How to Control Processes” on page 313
- “How to Kill a Process” on page 314
- “How to Display Basic Information About Process Classes (priocntl)” on page 315
- “How to Display the Global Priority of a Process (priocntl)” on page 316
- “How to Designate a Process Priority (priocntl)” on page 317
- “How to Change Scheduling Parameters of a Timesharing Process (priocntl)” on page 317
- “How to Change the Class of a Process (priocntl)” on page 318
- “How to Change the Priority of a Process (nice)” on page 320

Commands for Managing System Processes (Overview)

The following table describes the commands for managing system processes.
### TABLE 23-1 Commands for Managing Processes

<table>
<thead>
<tr>
<th>Command</th>
<th>Man Page</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>ps</code>, <code>pgrep</code>, <code>prstat</code></td>
<td><code>ps(1)</code>, <code>pgrep(1)</code>, and <code>prstat(1M)</code></td>
<td>Checks the status of active processes on a system, as well as displays detailed information about the processes</td>
</tr>
<tr>
<td><code>dispadmin</code></td>
<td><code>dispadmin(1M)</code></td>
<td>Lists default scheduling policies</td>
</tr>
<tr>
<td><code>priocntl</code></td>
<td><code>priocntl(1)</code></td>
<td>Assigns processes to a priority class and manages process priorities</td>
</tr>
<tr>
<td><code>nice</code></td>
<td><code>nice(1)</code></td>
<td>Changes the priority of a timesharing process</td>
</tr>
<tr>
<td><code>psrset</code></td>
<td><code>psrset(1M)</code></td>
<td>Binds specific process groups to a group of processors rather than to just a single processor</td>
</tr>
</tbody>
</table>

The Solaris Management Console’s Processes Tool enables you to manage processes with a user-friendly interface. For information on using and starting the Solaris Management Console, see “Working With the Management Console (Tasks)” in *System Administration Guide: Basic Administration*.

### The `ps` Command

The `ps` command enables you to check the status of active processes on a system, as well as display technical information about the processes. This data is useful for such administrative tasks as determining how to set process priorities.

Depending on which options you use, the `ps` command reports the following information:

- Current status of the process
- Process ID
- Parent process ID
- User ID
- Scheduling class
- Priority
- Address of the process
- Memory used
- CPU time used

The following table describes some fields that are reported by the `ps` command. Which fields are displayed depend on which option you choose. For a description of all available options, see `ps(1)`.
### TABLE 23-2 Summary of Fields in `ps` Reports

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>UID</td>
<td>The effective user ID of the process’s owner.</td>
</tr>
<tr>
<td>PID</td>
<td>The process ID.</td>
</tr>
<tr>
<td>PPID</td>
<td>The parent process ID.</td>
</tr>
<tr>
<td>C</td>
<td>The processor utilization for scheduling. This field is not displayed when the <code>-c</code> option is used.</td>
</tr>
<tr>
<td>CLS</td>
<td>The scheduling class to which the process belongs such as real-time, system, or timesharing. This field is included only with the <code>-c</code> option.</td>
</tr>
<tr>
<td>PRI</td>
<td>The kernel thread’s scheduling priority. Higher numbers indicate a higher priority.</td>
</tr>
<tr>
<td>NI</td>
<td>The process’s nice number, which contributes to its scheduling priority. Making a process “nicer” means lowering its priority.</td>
</tr>
<tr>
<td>ADDR</td>
<td>The address of the proc structure.</td>
</tr>
<tr>
<td>SZ</td>
<td>The virtual address size of the process.</td>
</tr>
<tr>
<td>WCHAN</td>
<td>The address of an event or lock for which the process is sleeping.</td>
</tr>
<tr>
<td>STIME</td>
<td>The starting time of the process in hours, minutes, and seconds.</td>
</tr>
<tr>
<td>TTY</td>
<td>The terminal from which the process, or its parent, was started. A question mark indicates that there is no controlling terminal.</td>
</tr>
<tr>
<td>TIME</td>
<td>The total amount of CPU time used by the process since it began.</td>
</tr>
<tr>
<td>CMD</td>
<td>The command that generated the process.</td>
</tr>
</tbody>
</table>

#### How to List Processes

You can use the `ps` command to list all the processes on a system.

```bash
$ ps [-efc]
```

- `ps` : Displays only the processes that are associated with your login session.
- `-ef` : Displays full information about all the processes that are being executed on the system.
- `-c` : Displays process scheduler information.
Example—Listing Processes

The following example shows output from the `ps` command when no options are used.

```
$ ps
   PID TTY TIME COMD
 1664 pts/4   0:06 csh
 2081 pts/4   0:00 ps
```

The following example shows output from `ps -ef`. This output shows that the first process that is executed when the system boots is `sched` (the swapper) followed by the `init` process, `pageout`, and so on.

```
$ ps -ef
   UID   PID PPID  C STIME TTY TIME CMD
 root    0    0    0 Dec 20 ?   0:17   sched
 root    1    0    0 Dec 20 ?   0:00  /etc/init -
 root    2    0    0 Dec 20 ?   0:00    pageout
 root    3    0    0 Dec 20 ?   4:20   fsflush
 root   374   367    0 Dec 20 ?   0:00  /usr/lib/saf/ttymon
 root   367    1    0 Dec 20 ?   0:00  /usr/lib/saf/sac -t 300
 root   126    1    0 Dec 20 ?   0:00   /usr/sbin/rpcbind
 root    54    1    0 Dec 20 ?   0:00   /usr/lib/procfs/syseventd
 root    59    1    0 Dec 20 ?   0:00   /usr/lib/picl/picld
 root   178    1    0 Dec 20 ?   0:03   /usr/lib/autofs/automountd
 root   129    1    0 Dec 20 ?   0:00   /usr/sbin/keyserv
 root   213    1    0 Dec 20 ?   0:00   /usr/lib/lpfs/lpsched
 root   154    1    0 Dec 20 ?   0:00   /usr/sbin/inetd -s
 root   139    1    0 Dec 20 ?   0:00   /usr/lib/netsvc/yp/ypbind ...
 root   191    1    0 Dec 20 ?   0:00   /usr/sbin/syslogd
 root   208    1    0 Dec 20 ?   0:02   /usr/sbin/nscd
 root   193    1    0 Dec 20 ?   0:00   /usr/sbin/cron
 root   174    1    0 Dec 20 ?   0:00   /usr/lib/nfs/lockd
 daemon  175    1    0 Dec 20 ?   0:00   /usr/lib/nfs/statd
 root   376    1    0 Dec 20 ?   0:00   /usr/lib/ssh/sshd
 root   226    1    0 Dec 20 ?   0:00   /usr/lib/power/powerd
 root   315    1    0 Dec 20 ?   0:00   /usr/lib/nfs/mountd
 root   237    1    0 Dec 20 ?   0:00   /usr/lib/utmpd
```

The `/proc` File System and Commands

You can display detailed information about the processes listed in the `/proc` directory by using process commands. The `/proc` directory is also known as the process file system (PROCFS). Images of active processes are stored here by their process ID number.
The process tools are similar to some options of the `ps` command, except that the output that is provided by these commands is more detailed. In general, the process commands do the following:

- Display more information about processes, such as `fstat` and `fcntl`, working directories, and trees of parent and child processes
- Provide control over processes by allowing users to stop or resume them

### Managing Processes With `/proc` Process Commands

You can display detailed, technical information about or control active processes by using some of the process commands. Table 23-3 lists some of the `/proc` commands.

If a process becomes trapped in an endless loop, or if it takes too long to execute, you might want to stop (kill) the process. For more information about stopping processes using the `pkill` command, see Chapter 23.

The `/proc` file system is a directory hierarchy that contains additional subdirectories for state information and control functions.

The `/proc` file system also provides a watchpoint facility that is used to remap read and write permissions on the individual pages of a process’s address space. This facility has no restrictions and is MT-safe.

Debugging tools have been modified to use `/proc`’s watchpoint facility, which means that the entire watchpoint process is faster.

The following restrictions have been removed when setting watchpoints by using the `dbx` debugging tool:

- Setting watchpoints on local variables on the stack due to SPARC register windows
- Setting watchpoints on multithreaded processes

For more information, see `proc(4)`, `core(4)`, and `mdb(1).

### TABLE 23-3 /proc Process Commands

<table>

<tr>
<td>ptree</td>
<td>Displays the process trees that contain the process</td>
</tr>
<tr>
<td>pwait</td>
<td>Displays status information after a process terminates</td>
</tr>
<tr>
<td>pwdx</td>
<td>Displays the current working directory for a process</td>
</tr>
</tbody>
</table>

For more information, see proc(1).

**▼ How to Display Information About Processes**

1. Obtain the process ID of the process you want to display more information about.
   ```bash
   # pgrep process
   process
   ```
   
   process is the name of the process you want to display more information about. The process ID is displayed in the first column of the output.

2. Display the process information you need.
   ```bash
   # /usr/bin/proc pcommand pid
   ```
   
   **pcommand**
   Process tool command that you want to run. Table 23–3 lists these commands.
   
   **pid**
   Indicates the process ID.

**Example—Displaying Information About Processes**

The following example shows how to use process tool commands to display more information about an lpsched process.

```bash
# pgrep lpsched
lpsched 213
# pwdx 213
```

312 System Administration Guide: Advanced Administration • December 2002
213: /  
# ptree 213 3  
213: /usr/lib/lpsched  
# pfiles 213 4  
213: /usr/lib/lpsched  
Current rlimit: 4096 file descriptors  
0: S_IFIFO mode:0000 dev:270,0 ino:67 uid:0 gid:0 size:0  
O_RDWR  
1: S_IFIFO mode:0000 dev:270,0 ino:67 uid:0 gid:0 size:0  
O_RDWR  
3: S_IFCHR mode:0666 dev:136,0 ino:35882 uid:0 gid:3 rdev:21,0  
O_WRONLY FD_CLOEXEC  
4: S_IFDOOR mode:0444 dev:275,0 ino:18526 uid:0 gid:0 size:0  
O_RDONLY|O_LARGEFILE FD_CLOEXEC  
5: S_IFREG mode:0664 dev:136,0 ino:64648 uid:71 gid:8 size:0  
O_WRONLY  

1. Obtains the process identification number for lpsched  
2. Displays the current working directory for lpsched  
3. Displays the process tree that contains lpsched  
4. Displays fstat and fcntl information  

▼ How to Control Processes  

1. Obtain the process ID of the process you want to control.  
   
   # pgrep process  
   
   process is the name of the process you want to control.  
   The process identification number is in the first column of the output.  

2. Use the appropriate process command to control the process.  
   
   # /usr/bin/pcommand pid  
   
   pcommand Process command you want to run. Table 23–3 lists these  
   commands.  
   pid Identifies the process ID.  

3. Verify the process status.  
   
   # ps -ef | grep PID  

Example—Controlling Processes  

The following example shows how to use process tools to stop and restart dtpad.  

# pgrep dtpad 1  
2921  
# pstop 2921 2
# prun 2921

1. Obtains the process identification number for dtpad
2. Stops the dtpad process
3. Restarts the dtpad process

## Killing a Process (pkill)

Sometimes, you might need to stop (kill) a process. The process might be in an endless loop, or you might have started a large job that you want to stop before it is completed. You can kill any process that you own, and superuser can kill any process in the system except for those processes with process IDs of 0, 1, 2, 3, and 4. Killing these processes might crash the system.

For more information, see pgrep(1).

### How to Kill a Process

1. (Optional) To kill a process that belongs to another user, become superuser.

2. Obtain the of the process ID of the process you want to stop.

   ```
   $ pgrep process
   ``
   
   process is the name of the process you want to display more information about.
   The process identification number is displayed in the first column of the output.

3. Stop the process.

   ```
   $ pkill [-9] pid
   ``
   
   -9 Ensures that the process terminates promptly.
   
   pid Process ID to stop.

4. Verify that the process has been stopped.

   ```
   $ pgrep process
   ```
Managing Process Class Information

The following list identifies the process scheduling classes that can be configured on your system, and the user priority range for the timesharing class. The possible process scheduling classes are as follows:

- Fair share (FSS)
- Fixed (FX)
- System (SYS)
- Interactive (IA)
- Real-time (RT)
- Timesharing (TS)

- The user-supplied priority ranges from -60 to +60.
- The priority of a process is inherited from the parent process. This priority is referred to as the user-mode priority.
- The system looks up the user-mode priority in the timesharing dispatch parameter table and adds in any nice or priocntl (user-supplied) priority and ensures a 0–59 range to create a global priority.

Changing the Scheduling Priority of Processes (priocntl)

The scheduling priority of a process is the priority assigned by the process scheduler, according to scheduling policies. The dispadmin command lists the default scheduling policies.

You can use the priocntl command to assign processes to a priority class and to manage process priorities. For instructions on using the priocntl command to manage processes, see “How to Designate a Process Priority (priocntl)” on page 317.

▼ How to Display Basic Information About Process Classes (priocntl)

You can display process scheduling classes and priority ranges with the priocntl -l command.

$ priocntl -l
Example—Getting Basic Information About Process Classes (priocntl)

The following example shows output from the priocntl -l command.

```
# priocntl -l
CONFIGURED CLASSES
===================
SYS (System Class)
TS (Time Sharing)
  Configured TS User Priority Range: -60 through 60
FX (Fixed priority)
  Configured FX User Priority Range: 0 through 60
IA (Interactive)
  Configured IA User Priority Range: -60 through 60
```

▼ How to Display the Global Priority of a Process (priocntl)

You can display the global priority of a process by using the ps command.

```
$ ps -ecl
```

The global priority is listed under the PRI column.

Example—Displaying the Global Priority of a Process (priocntl)

The following example shows ps -ecl command output. The values in the PRI column show that the pageout process has the highest priority, while sh has the lowest.

```
$ ps -ecl
  F S UID PID PPID CLS PRI ADDR SZ  WCHAN  TTY TIME CMD
19 T 0 0 0 SYS 96  f00d05a8 0   ?  0:03 sched
  8 S 0 1 0 TS 50  fff0f4678 185  fff0f4848 ?  36:51 init
19 S 0 2 0 SYS 98  fff0f4018 0  f00c645c ?  0:01 pageout
  19 S 0 3 0 SYS 60  fff0f5998 0  f00d0c68 ?  241:01 fsflush
  8 S 0 269 1 TS 58  fff0f5338 303  fff49837e ?  0:07 sac
  8 S 0 204 1 TS 43  fff2f6008 50  fff2f606e console 0:02 sh
```
▼ How to Designate a Process Priority (**priocntl**)

1. Become superuser.

2. Start a process with a designated priority.

   ```bash
   # priocntl -e -c -m userlimit -p pri command-name
   ```

   - **-e**
     
     Executes the command.

   - **-c class**
     
     Specifies the class within which to run the process. The valid classes are TS (timesharing), RT (real time), IA (interactive), FSS (fair share), or FX (fixed priority).

   - **-m userlimit**
     
     Specifies the maximum amount you can raise or lower your priority, when using the **-p** option.

   - **-p pri command-name**
     
     Lets you specify the relative priority in the RT class, for a real-time thread. For a timesharing process, the **-p** option lets you specify the user-supplied priority, which ranges from -60 to +60.

3. Verify the process status.

   ```bash
   # ps -ecl | grep command-name
   ```

Example—Designating a Process Priority (**priocntl**)

The following example shows how to start the `find` command with the highest possible user-supplied priority.

```bash
# priocntl -e -c TS -m 60 -p 60 find . -name core -print
# ps -ecl | grep find
```

▼ How to Change Scheduling Parameters of a Timesharing Process (**priocntl**)

1. Become superuser.

2. Change the scheduling parameters of a running timesharing process.

   ```bash
   # priocntl -s -m userlimit [-p userpriority] -i idtype idlist
   ```

   - **-s**
     
     Lets you set the upper limit on the user priority range and change the current priority.
-m userlimit Specifies the maximum amount you can raise or lower your priority, when you use the -p option.

-p userpriority Allows you to designate a priority.

-i idtype idlist Uses a combination of idtype and idlist to identify the process or processes. The idtype specifies the type of ID, such as pid or UID. Use idlist to identify a list of pids or UIDs.

3. Verify the process status.

   # ps -ecl | grep idlist

Example—Changing Scheduling Parameters of a Timesharing Process (priocntl)

The following example shows how to execute a command with a 500-millisecond time slice, a priority of 20 in the RT class, and a global priority of 120.

   # priocntl -e -c RT -t 500 -p 20 myprog
   # ps -ecl | grep myprog

▼ How to Change the Class of a Process (priocntl)

1. (Optional) Become superuser.

   Note – You must be superuser or working in a real-time shell to change a process from, or to, a real-time process.

2. Change the class of a process.

   # priocntl -s -c class -i idtype idlist

   -s Lets you set the upper limit on the user priority range and change the current priority.

   -c class Specifies the class, TS or RT, to which you are changing the process.

   -i idtype idlist Uses a combination of idtype and idlist to identify the process or processes. The idtype specifies the type of ID, such as pid or UID. Use idlist to identify a list of pids or UIDs.

3. Verify the process status.
Example—Changing the Class of a Process (priocntl)

The following example shows how to change all the processes belonging to user 15249 to real-time processes.

```
# priocntl -s -c RT -i uid 15249
# ps -ecl | grep 15249
```

**Note** – If, as superuser, you change a user process to the real-time class, the user cannot subsequently change the real-time scheduling parameters by using the priocntl -s command.

Changing the Priority of a Timesharing Process (nice)

The `nice` command is only supported for backward compatibility to previous Solaris releases. The `priocntl` command provides more flexibility in managing processes.

The priority of a process is determined by the policies of its scheduling class, and by its *nice number*. Each timesharing process has a global priority. The global priority is calculated by adding the user-supplied priority, which can be influenced by the `nice` or `priocntl` commands, and the system-calculated priority.

The execution priority number of a process is assigned by the operating system, and is determined by several factors, including its scheduling class, how much CPU time it has used, and in the case of a timesharing process, its `nice` number.

Each timesharing process starts with a default `nice` number, which it inherits from its parent process. The `nice` number is shown in the `NI` column of the `ps` report.

A user can lower the priority of a process by increasing its user-supplied priority. But only superuser can lower a `nice` number to increase the priority of a process. This restriction prevents users from increasing the priorities of their own processes, thereby monopolizing a greater share of the CPU.

The `nice` numbers range between 0 and +39, with 0 representing the highest priority. The default `nice` value for each timesharing process is 20. Two versions of the command are available, the standard version, `/usr/bin/nice`, and the C shell built-in command.
How to Change the Priority of a Process (nice)

Note – This section describes the syntax of the /usr/bin/nice command and not the C-shell nice built-in command. For information about the C-shell nice command, see csh(1).

1. Determine whether you want to lower the priority of a command as a user or raise or lower the priority of a command as superuser and select one of the following:
   - Follow the examples in step 1 to lower the priority of a command as a user.
   - Follow the examples in step 2 to raise or lower priorities of a command as superuser.

2. As a user, lower the priority of a command by increasing the nice number.
   The following nice command executes command-name with a lower priority by raising the nice number by 5 units.
   $ /usr/bin/nice -5 command-name
   In the preceding command, the minus sign designates that what follows is an option. This command could also be specified as follows:
   % /usr/bin/nice -n 5 command-name
   The following nice command lowers the priority of command-name by raising the nice number by the default increment of 10 units, but not beyond the maximum value of 40.
   % /usr/bin/nice command-name

3. As superuser, raise or lower the priority of a command by changing the nice number.
   The following nice command raises the priority of command-name by lowering the nice number by 10 units, but not below the minimum value of 0.
   # /usr/bin/nice --10 command-name
   In the preceding command, the first minus sign designates that what follows is an option. The second minus sign indicates a negative number.
   The following nice command lowers the priority of command-name by raising the nice number by 5 units, but not beyond the maximum value of 40.
   # /usr/bin/nice -5 command-name
   For more information, see nice(1).

Troubleshooting Problems With System Processes

Here are some tips on obvious problems you might find:
- Look for several identical jobs that are owned by the same user. This problem might occur because of a running script that starts a lot of background jobs without waiting for any of the jobs to finish.

- Look for a process that has accumulated a large amount of CPU time. You can identify this problem by checking the `TIME` field in the `ps` output. Possibly, the process is in an endless loop.

- Look for a process that is running with a priority that is too high. Use the `ps -c` command to see the `CLS` field, which displays the scheduling class of each process. A process executing as a real-time (RT) process can monopolize the CPU. Or, look for a timesharing (TS) process with a high `nice` number. A user with superuser privileges might have increased the priority of a process. The system administrator can lower the priority by using the `nice` command.

- Look for a runaway process. A runaway process progressively uses more and more CPU time. You can identify this problem by looking at the time when the process started (`STIME`) and by watching the cumulation of CPU time (`TIME`) for a while.
CHAPTER 24

Monitoring System Performance (Tasks)

This chapter describes procedures for monitoring system performance by using the `vmstat`, `iostat`, `df`, and `sar` commands. This is a list of the step-by-step instructions in this chapter.

- “How to Display Virtual Memory Statistics (`vmstat`)” on page 325
- “How to Display System Event Information (`vmstat -s`)” on page 326
- “How to Display Swapping Statistics (`vmstat -S`)” on page 327
- “How to Display Cache Flushing Statistics (`vmstat -c`)” on page 327
- “How to Display Interrupts Per Device (`vmstat -i`)” on page 328
- “How to Display Disk Utilization Information (`iostat`)” on page 329
- “How to Display Extended Disk Statistics (`iostat -xtc`)” on page 330
- “How to Display Disk Space Information (`df`)” on page 331
- “How to Check File Access (`sar -a`)” on page 332
- “How to Check Buffer Activity (`sar -b`)” on page 333
- “How to Check System Call Statistics (`sar -c`)” on page 334
- “How to Check Disk Activity (`sar -d`)” on page 335
- “How to Check Page-Out and Memory (`sar -g`)” on page 337
- “How to Check Kernel Memory Allocation (`sar -k`)” on page 338
- “How to Check Interprocess Communication (`sar -m`)” on page 339
- “How to Check Page-In Activity (`sar -p`)” on page 340
- “How to Check Queue Activity (`sar -q`)” on page 342
- “How to Check Unused Memory (`sar -r`)” on page 343
- “How to Check CPU Utilization (`sar -u`)” on page 343
- “How to Check System Table Status (`sar -v`)” on page 344
- “How to Check Swapping Activity (`sar -w`)” on page 345
- “How to Check Terminal Activity (`sar -y`)” on page 347
- “How to Check Overall System Performance (`sar -A`)” on page 348
- “How to Set Up Automatic Data Collection” on page 351
What’s New in Monitoring System Performance?

The `vmstat` command now includes all system interrupts in the `faults-in` column. In previous Solaris releases, this column did not report clock device interrupts. For more information, see `vmstat(1M)`.

Displaying Virtual Memory Statistics (`vmstat`)

You can use the `vmstat` command to report virtual memory statistics and information about system events as CPU load, paging, number of context switches, device interrupts, and system calls. The `vmstat` command can also display statistics on swapping, cache flushing, and interrupts.

The following table describes the fields in the `vmstat` output.

**TABLE 24-1 Output From the `vmstat` Command**

<table>
<thead>
<tr>
<th>Category</th>
<th>Field Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>procs</td>
<td>r</td>
<td>The number of kernel threads in the dispatch queue</td>
</tr>
<tr>
<td></td>
<td>b</td>
<td>The number of blocked kernel threads that are waiting for resources</td>
</tr>
<tr>
<td></td>
<td>w</td>
<td>The number of swapped out LWP's that are waiting for processing resources to finish</td>
</tr>
<tr>
<td>memory</td>
<td>swap</td>
<td>Available swap space</td>
</tr>
<tr>
<td></td>
<td>free</td>
<td>Size of the free list</td>
</tr>
<tr>
<td>page</td>
<td>re</td>
<td>Pages reclaimed</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Reports on usage of real memory and virtual memory:</td>
</tr>
</tbody>
</table>

Available as PDF [here](#).
### TABLE 24–1 Output From the `vmstat` Command  
*(Continued)*

<table>
<thead>
<tr>
<th>Category</th>

<td>Idle time</td>
</tr>
</tbody>
</table>

For a more detailed description of this command, see `vmstat(1M)`.

✦ **How to Display Virtual Memory Statistics (vmstat)**

Collect virtual memory statistics by using the `vmstat` command with a time interval in seconds.

```bash
$ vmstat n
```

`n` is the interval in seconds between reports.
Example—Displaying Virtual Memory Statistics

The following example shows the `vmstat` display of statistics gathered at five-second intervals.

```
$ vmstat 5
procs memory page disk faults cpu
  r  b  w  swap  free  re  mf  pi  po  fr  de  sr  f0  s3  --  --  in  sy  cs  us  sy  id
0  0  8  28312  668  0  9  2  0  1  0  0  0  1  0  0  10  61  82  1  2  97
0  0  3  31940  248  0 10  20  0 26  0 27  0  4  0  0 53 189 191 6  6  88
0  0  3  32080  288  3 19  49  6 26  0 15  9  0  0 75 415 277 6 15 79
0  0  3  32080  256  0 26  20  6 21  0 12  1  6  0  0 163 110 138 1  3  96
0  1  3  32060  256 3 45  52  28 61  0 27  5 12  0  0 195 191 223 7 11 82
0  0  3  32056  260  0 1  0  0  0  0  0  0  0  0  0  4 52  84 0  1  99
```

▼ How to Display System Event Information

**(vmstat -s)**

Run the `vmstat -s` command to show the total of various system events that have taken place since the last time the system was booted.

```
$ vmstat -s
 0 swap ins
 0 swap outs
 0 pages swapped in
 0 pages swapped out
392182 total address trans. faults taken
 20419 page ins
 923 page outs
10072 pages paged in
 9194 pages paged out
65167 total reclaims
65157 reclaims from free list
 0 micro (hat) faults
392182 minor (as) faults
19383 major faults
85775 copy-on-write faults
66637 zero fill page faults
46309 pages examined by the clock daemon
 6 revolutions of the clock hand
15578 pages freed by the clock daemon
 4398 forks
 352 vforks
 4267 execs
12926285 cpu context switches
109029866 device interrupts
 499296 traps
 22461261 system calls
778068 total name lookups (cache hits 97%)
 18739 user  cpu
 34662 system  cpu
```
How to Display Swapping Statistics (vmstat -S)

Run `vmstat -S` to show swapping statistics.

```
$ vmstat -S
procs memory page disk faults cpu
r b w swap free si so pi po fr de sr f0 s0 s6 -- in sy cs us sy id
0 0 0 209968 17936 0 0 0 0 0 0 0 0 0 0 0 0 0 100 43 24 0 0 100
```

The swapping statistics fields are described in the following table. For a description of the other fields, see Table 24–1.

<table>
<thead>
<tr>
<th>Field Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>si</td>
<td>Average number of LWPs that are swapped in per second</td>
</tr>
<tr>
<td>so</td>
<td>Number of whole processes that are swapped out</td>
</tr>
</tbody>
</table>

**Note** – The `vmstat` command truncates the output of both fields. Use the `sar` command to display a more accurate accounting of swap statistics.

How to Display Cache Flushing Statistics (vmstat -c)

Run the `vmstat -c` command to show cache flushing statistics for a virtual cache.

```
$ vmstat -c
usr ctx rgn seg pag par
0 60714 5 134584 4486560 4718054
```

The output shows the total number of cache flushes since the last boot. The cache types are described in the following table.

<table>
<thead>
<tr>
<th>Cache Name</th>
<th>Cache Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>usr</td>
<td>User</td>
</tr>
</tbody>
</table>
TABLE 24–3 Output From the `vmstat -c` Command (Continued)

<table>
<thead>
<tr>
<th>Cache Name</th>
<th>Cache Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>ctx</td>
<td>Context</td>
</tr>
<tr>
<td>rgn</td>
<td>Region</td>
</tr>
<tr>
<td>seg</td>
<td>Segment</td>
</tr>
<tr>
<td>pag</td>
<td>Page</td>
</tr>
<tr>
<td>par</td>
<td>Partial-page</td>
</tr>
</tbody>
</table>

▼ How to Display Interrupts Per Device (`vmstat -i`)

Run the `vmstat -i` command to show the number of interrupts per device.

```
$ vmstat -i
```

Example—Displaying Interrupts Per Device

The following example shows output from the `vmstat -i` command.

```
$ vmstat -i
interrupt  total     rate
---------------------------------
clock      52163269  100
esp0       2600077  4
zsc0       25341  0
zsc1       48917  0
cgsixc0    459  0
leco       400882  0
fdco       14  0
bppc0      0  0
audiocs0   0  0
---------------------------------
Total   55238959  105
```

Displaying Disk Utilization Information (`iostat n`)

Use the `iostat` command to report statistics about disk input and output, and produces measures of throughput, utilization, queue lengths, transaction rates, and service time. For a detailed description of this command, refer to `iostat(1M)`. 328 System Administration Guide: Advanced Administration • December 2002
How to Display Disk Utilization Information (iostat)

You can display disk utilization information by using the `iostat` command with a time interval in seconds.

```bash
$ iostat 5
```

The first line of output shows the statistics since the last time the system was booted. Each subsequent line shows the interval statistics. The default is to show statistics for the terminal (`tty`), disks (`fd` and `sd`), and CPU (`cpu`).

The following table describes the fields in the `iostat` command output.

### TABLE 24–4 Output From the `iostat` n Command

<table>
<thead>
<tr>
<th>Device Type</th>
<th>Field Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Terminal</td>
<td><code>tin</code></td>
<td>Number of characters in the terminal input queue</td>
</tr>
<tr>
<td></td>
<td><code>tout</code></td>
<td>Number of characters in the terminal output queue</td>
</tr>
<tr>
<td>Disk</td>
<td><code>bps</code></td>
<td>Blocks per second</td>
</tr>
<tr>
<td></td>
<td><code>tps</code></td>
<td>Transactions per second</td>
</tr>
<tr>
<td></td>
<td><code>serv</code></td>
<td>Average service time, in milliseconds</td>

330  System Administration Guide: Advanced Administration  •  December 2002
Displaying Disk Space Statistics (df)

Use the `df` command to show the amount of free disk space on each mounted disk. The *usable* disk space that is reported by `df` reflects only 90 percent of full capacity, as the reporting statistics leave 10 percent above the total available space. This headroom normally stays empty for better performance.

The percentage of disk space actually reported by the `df` command is used space divided by usable space.

If the file system exceeds 90 percent capacity, you could transfer files to a disk that is not as full by using the `cp` command, or to a tape by using the `tar` or `cpio` commands. Or, you could remove the files.

For a detailed description of this command, see `df(1M)`.

How to Display Disk Space Information (df)

Use the `df -k` command to display disk space information in Kbytes.

```
$ df -k
Filesystem  kbytes used  avail capacity Mounted on
/dev/dsk/c0t3d0s0  192807  40231  133296   24%  /
```

The following table describes the `df -k` command output.

### TABLE 24-6 Output From the df -k Command

<table>
<thead>
<tr>

<td>/usr/dist</td>
</tr>
</tbody>
</table>

Monitoring System Activities (sar)

Use the sar command to do the following:

- Organize and view data about system activity
- Access system activity data on a special request basis
- Generate automatic reports to measure and monitor system performance, and special request reports to pinpoint specific performance problems. “Collecting System Activity Data Automatically (sar)” on page 348 describes these tools.

For a detailed description of this command, see sar(1).

▼ How to Check File Access (sar -a)

Display file access operation statistics with the sar -a command.

$ sar -a

SunOS venus 5.9 Generic sun4u 06/24/2001

00:00:00 iget/s namei/s dirbk/s
01:00:00 0 0 0
02:00:02 0 0 0
03:00:00 0 1 0
The following table describes the operating system routines that are reported by the `sar -a` command.

**TABLE 24–7 Output from the sar -a Command**

<table>
<thead>
<tr>
<th>Field Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>iget/s</code></td>
<td>The number of requests made for inodes that were not in the directory name look-up cache (DNLC).</td>
</tr>
<tr>
<td><code>namei/s</code></td>
<td>The number of file system path searches per second. If <code>namei</code> does not find a directory name in the DNLC, it calls <code>iget</code> to get the inode for either a file or directory. Hence, most <code>iget</code>s are the result of DNLC misses.</td>
</tr>
<tr>
<td><code>dirbk/s</code></td>
<td>The number of directory block reads issued per second.</td>
</tr>
</tbody>
</table>

The larger the reported values, the more time the kernel is spending to access user files. The amount of time reflects how heavily programs and applications are using the file systems. The `-a` option is helpful for viewing how disk-dependent an application is.

**How to Check Buffer Activity (sar -b)**

Display buffer activity statistics with the `sar -b` command.

The buffer is used to cache metadata, which includes inodes, cylinder group blocks, and indirect blocks.

```
$ sar -b
```

<table>
<thead>
<tr>
<th>Field Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>bread/s</code></td>
<td>Average number of reads per second that are submitted to the buffer cache from the disk</td>
</tr>
</tbody>
</table>

The following table describes the buffer activities that are displayed by the `-b` option.

**TABLE 24–8 Output From the sar -b Command**

<table>
<thead>
<tr>
<th>Field Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>bread/s</code></td>
<td>Average number of reads per second that are submitted to the buffer cache from the disk</td>
</tr>
</tbody>
</table>
### TABLE 24-8 Output From the `sar -b` Command (Continued)

<table>
<thead>
<tr>
<th>Field Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>lread/s</td>
<td>Average number of logical reads per second from the buffer cache</td>
</tr>
<tr>
<td>%rcache</td>
<td>Fraction of logical reads that are found in the buffer cache (100% minus the ratio of bread/s to lread/s)</td>
</tr>
<tr>
<td>bwrit/s</td>
<td>Average number of physical blocks (512 blocks) that are written from the buffer cache to disk, per second</td>
</tr>
<tr>
<td>lwrit/s</td>
<td>Average number of logical writes to the buffer cache, per second</td>
</tr>
<tr>
<td>%wcache</td>
<td>Fraction of logical writes that are found in the buffer cache (100% minus the ratio of bwrit/s to lwrit/s)</td>
</tr>
<tr>
<td>pread/s</td>
<td>Average number of physical reads, per second that use character device interfaces</td>
</tr>
<tr>
<td>pwrit/s</td>
<td>Average number of physical write requests, per second that use character device interfaces</td>
</tr>
</tbody>
</table>

The most important entries are the cache hit ratios %rcache and %wcache, which measure the effectiveness of system buffering. If %rcache falls below 90 percent, or if %wcache falls below 65 percent, it might be possible to improve performance by increasing the buffer space.

#### Example—Checking Buffer Activity

The following abbreviated example of `sar -b` output shows that the %rcache and %wcache buffers are not causing any slowdowns. All the data is within acceptable limits.

```bash
$ sar -b
SunOS venus 5.9 Generic sun4u 06/24/2001
00:00:00 bread/s lread/s %rcache bwrit/s lwrit/s %wcache pread/s pwrit/s
00:00:00 0 0 100 0 0 55 0 0
01:00:00 0 0 100 0 0 55 0 0
02:00:00 0 0 100 0 0 55 0 0
03:00:00 0 0 100 0 0 72 0 0
04:00:00 0 0 100 0 0 56 0 0
05:00:01 0 0 100 0 0 55 0 0
06:00:00 0 0 100 0 0 55 0 0
Average 0 0 94 0 0 64 0 0
```

▼ How to Check System Call Statistics (`sar -c`)

Display system call statistics by using the `sar -c` command.
The following table describes the system call categories that are reported by the -c option. Typically, reads and writes account for about half of the total system calls, although the percentage varies greatly with the activities that are being performed by the system.

### TABLE 24-9 Output From the `sar -c` Command

<table>
<thead>
<tr>
<th>Field Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>scall/s</td>
<td>All types of system calls per second, which is generally about 30 per second on a system with 4 to 6 users.</td>
</tr>
<tr>
<td>sread/s</td>
<td>read system calls per second.</td>
</tr>
<tr>
<td>swrit/s</td>
<td>write system calls per second.</td>
</tr>
<tr>
<td>fork/s</td>
<td>fork system calls per second, which is about 0.5 per second on a system with 4 to 6 users. This number will increase if shell scripts are running.</td>
</tr>
<tr>
<td>exec/s</td>
<td>exec system calls per second. If <code>exec/s</code> divided by <code>fork/s</code> is greater than three, look for inefficient <code>PATH</code> variables.</td>
</tr>
<tr>
<td>rchar/s</td>
<td>Characters (bytes) transferred by read system calls per second.</td>
</tr>
<tr>
<td>wchar/s</td>
<td>Characters (bytes) transferred by write system calls per second.</td>
</tr>
</tbody>
</table>

### Example—Checking System Call Statistics

The following abbreviated example shows output from the `sar -c` command.

```bash
$ sar -c
00:00:00 scall/s sread/s swrit/s fork/s exec/s rchar/s wchar/s
01:00:00 38 2 2 0.00 0.00 149 120
02:00:02 38 2 2 0.00 0.00 149 120
03:00:00 42 2 2 0.05 0.05 218 147
04:00:00 39 2 2 0.01 0.00 155 123
05:00:01 38 2 2 0.00 0.00 150 120
06:00:00 38 2 2 0.01 0.00 149 120
Average 50 4 3 0.02 0.02 512 238
```

### How to Check Disk Activity (sar -d)

Display disk activity statistics with the `sar -d` command.
The following table describes the disk device activities that are reported by the \texttt{-d} option.

**TABLE 24–10 Output From the \texttt{sar -d} Command**

<table>
<thead>
<tr>
<th>Field Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>device</td>
<td>Name of the disk device that is being monitored</td>
</tr>
<tr>
<td>%busy</td>
<td>Percentage of time the device spent servicing a transfer request</td>
</tr>
<tr>
<td>avque</td>
<td>The sum of the average wait time plus the average service time</td>
</tr>
<tr>
<td>r+w/s</td>
<td>Number of read and write transfers to the device, per second</td>
</tr>
<tr>
<td>blks/s</td>
<td>Number of 512-byte blocks that are transferred to the device, per second</td>
</tr>
<tr>
<td>avwait</td>
<td>Average time, in milliseconds, that transfer requests wait idly in the queue. This time is measured only when the queue is occupied.</td>
</tr>
<tr>
<td>avserv</td>
<td>Average time, in milliseconds, for a transfer request to be completed by the device. For disks, this value includes seek, rotational latency, and data transfer times.</td>
</tr>
</tbody>
</table>

Note that queue lengths and wait times are measured when something is in the queue. If %busy is small, large queues and service times probably represent the periodic efforts by the system to ensure that altered blocks are promptly written to the disk.

**Examples—Checking Disk Activity**

This abbreviated example illustrates the \texttt{sar -d} output.

\begin{verbatim}
$ sar -d
SunOS venus 5.9 Generic sun4u 06/24/2001
00:00:00 device %busy avque r+w/s blks/s avwait avserv
01:00:00 fd0 0 0.0 0 0 0.0 0.0
nfs1 0 0.0 0 0 0.0 0.0
sd0 0 0.0 0 0 0.0 39.6
sd0,a 0 0.0 0 0 0.0 39.6
sd0,b 0 0.0 0 0 0.0 0.0
sd0,c 0 0.0 0 0 0.0 0.0
sd0,f 0 0.0 0 0 0.0 0.0
sd0,g 0 0.0 0 0 0.0 0.0
sd0,h 0 0.0 0 0 0.0 0.0
\end{verbatim}

336 System Administration Guide: Advanced Administration • December 2002
How to Check Page-Out and Memory (sar -g)

Use the sar -g command to display page-out and memory freeing activities in averages.

```
$ sar -g
00:00:00  pgout/s  ppgout/s  pgfree/s  pgscan/s  %ufs_ipf
01:00:00  0.00     0.00     0.00     0.00     0.00
```

The output displayed by the sar -g command is a good indicator of whether more memory might be needed. Use the ps -elf command to show the number of cycles that are used by the page daemon. A high number of cycles, combined with high values for pgfree/s and pgscan/s, indicates a memory shortage.

The sar -g command also shows whether inodes are being recycled too quickly and causing a loss of reusable pages.

The following table describes the output from the -g option.

<table>
<thead>
<tr>
<th>Field Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pgout/s</td>
<td>The number of page-out requests per second.</td>
</tr>
<tr>
<td>ppgout/s</td>
<td>The actual number of pages that are paged-out, per second. A single page-out request might involve paging-out multiple pages.</td>
</tr>
<tr>
<td>pgfree/s</td>
<td>The number of pages, per second, that are placed on the free list.</td>
</tr>
<tr>
<td>pgscan/s</td>
<td>The number of pages, per second, that are scanned by the page daemon. If this value is high, the page daemon is spending a lot of time checking for free memory. This situation implies that more memory might be needed.</td>
</tr>
<tr>
<td>%ufs_ipf</td>
<td>The percentage of ufs inodes taken off the free list by iget that had reusable pages associated with them. These pages are flushed and cannot be reclaimed by processes. Thus, this field represents the percentage of igets with page flushes. A high value indicates that the free list of inodes is page-bound, and the number of ufs inodes might need to be increased.</td>
</tr>
</tbody>
</table>

Example—Checking Page-Out and Memory

The following abbreviated example shows output from the sar -g command.

```
$ sar -g
SunOS venus 5.9 Generic sun4u 06/24/2001
```
How to Check Kernel Memory Allocation (\texttt{sar -k})

Use the \texttt{sar -k} command to report on the following activities of the Kernel Memory Allocator (KMA).

The KMA allows a kernel subsystem to allocate and free memory as needed. Rather than statically allocating the maximum amount of memory it is expected to require under peak load, the KMA divides requests for memory into three categories: small (less than 256 bytes), large (512 bytes to 4 Kbytes), and oversized (greater than 4 Kbytes). The KMA keeps two pools of memory to satisfy small and large requests. The oversized requests are satisfied by allocating memory from the system page allocator.

If you are investigating a system that is being used to write drivers or STREAMS that use KMA resources, then the \texttt{sar -k} command will likely prove useful. Otherwise, you will probably not need the information it provides. Any driver or module that uses KMA resources, but does not specifically return the resources before it exits, can create a memory leak. A memory leak causes the amount of memory that is allocated by KMA to increase over time. Thus, if the alloc fields of the \texttt{sar -k} command increase steadily over time, there might be a memory leak. Another indication of a memory leak is failed requests. If this problem occurs, a memory leak has probably caused KMA to be unable to reserve and allocate memory.

If it appears that a memory leak has occurred, you should check any drivers or STREAMS that might have requested memory from KMA and not returned it.

\texttt{\$ sar -k}

\begin{verbatim}
 00:00:00  sml_mem  alloc  fail  lg_mem  alloc  fail  ovsz_alloc  fail
 01:00:00  2523136  1866512  0  18939904  14762364  0  360448  0
 02:00:02  2523136  1861724  0  18939904  14778748  0  360448  0
\end{verbatim}

The following table describes the output from the -k option.
TABLE 24–12 Output From the sar -k Command

<table>
<thead>
<tr>
<th>Field Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>sml_mem</td>
<td>The amount of memory, in bytes, that the KMA has available in the small memory request pool, where a small request is less than 256 bytes.</td>
</tr>
<tr>
<td>alloc</td>
<td>The amount of memory, in bytes, that the KMA has allocated from its small memory request pool to small memory requests.</td>
</tr>
<tr>
<td>fail</td>
<td>The number of requests for small amounts of memory that failed.</td>
</tr>
<tr>
<td>lg_mem</td>
<td>The amount of memory, in bytes, that the KMA has available in the large memory request pool, where a large request is from 512 bytes to 4 Kbytes.</td>
</tr>
<tr>
<td>alloc</td>
<td>The amount of memory, in bytes, that the KMA has allocated from its large memory request pool to large memory requests.</td>
</tr>
<tr>
<td>fail</td>
<td>The number of failed requests for large amounts of memory.</td>
</tr>
<tr>
<td>ovsz_alloc</td>
<td>The amount of memory that is allocated for oversized requests, which are requests that are greater than 4 Kbytes. These requests are satisfied by the page allocator. Thus, there is no pool.</td>
</tr>
<tr>
<td>fail</td>
<td>The number of failed requests for oversized amounts of memory.</td>
</tr>
</tbody>
</table>

Example—Checking Kernel Memory Allocation (sar)

The following is an abbreviated example of sar -k output.

```
$ sar -k
SunOS venus 5.9 Generic sun4u 06/24/2001
00:00:00 sml_mem alloc fail lg_mem alloc fail ovsz_alloc fail
01:00:00 2523136 1866512 0 18939904 14762364 0 360448 0
02:00:02 2523136 1861724 0 18939904 14778748 0 360448 0
03:00:00 2523136 1865664 0 18939904 14745884 0 360448 0

Average 2724096 1791806 0 20089344 15434591 0 360448 0
```

▼ How to Check Interprocess Communication (sar -m)

Use the sar -m command to report interprocess communication activities.

```
$ sar -m
00:00:00 msg/s sema/s
```
These figures will usually be zero (0.00), unless you are running applications that use messages or semaphores.

The following table describes the output from the \texttt{-m} option.

\begin{table}[h]
\centering
\begin{tabular}{|l|l|}
\hline
\textbf{Field Name} & \textbf{Description} \\
\hline
\texttt{msg/s} & The number of message operations (sends and receives) per second \\
\texttt{sema/s} & The number of semaphore operations per second \\
\hline
\end{tabular}
\end{table}

Example—Checking Interprocess Communication

The following abbreviated example shows output from the \texttt{sar -m} command.

\$ \texttt{sar -m}

\texttt{SunOS venus 5.9 Generic sun4u 06/24/2001}

\begin{verbatim}
00:00:00 msg/s  sema/s  01:00:00 0.00 0.00 02:00:02 0.00 0.00 03:00:00 0.00 0.00 04:00:00 0.00 0.00 05:00:01 0.00 0.00 06:00:00 0.00 0.00
Average 0.00 0.00
\end{verbatim}

\textbf{How to Check Page-In Activity (\texttt{sar -p})}

Use the \texttt{sar -p} command to report page-in activity, which includes protection and translation faults.

\$ \texttt{sar -p}

\begin{verbatim}
00:00:00 atch/s pgin/s ppgin/s pflt/s vflt/s slock/s 01:00:00 0.07 0.00 0.00 0.21 0.39 0.00
\end{verbatim}

The following table describes the reported statistics from the \texttt{-p} option.
TABLE 24–14 Output From the sar -p Command

<table>
<thead>
<tr>
<th>Field Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>atch/s</td>
<td>The number of page faults, per second, that are satisfied by reclaiming a page currently in memory (attaches per second). Instances include reclaiming an invalid page from the free list and sharing a page of text that is currently being used by another process. For example, two or more processes that are accessing the same program text.</td>
</tr>
<tr>
<td>pgin/s</td>
<td>The number of times, per second, that file systems receive page-in requests.</td>
</tr>
<tr>
<td>ppgin/s</td>
<td>The number of pages paged in, per second. A single page-in request, such as a soft-lock request (see slock/s), or a large block size, might involve paging-in multiple pages.</td>
</tr>
<tr>
<td>pflt/s</td>
<td>The number of page faults from protection errors. Instances of protection faults are illegal access to a page and &quot;copy-on-writes.&quot; Generally, this number consists primarily of &quot;copy-on-writes.&quot;</td>
</tr>
<tr>
<td>vflt/s</td>
<td>The number of address translation page faults, per second. These faults are known as validity faults, and occur when a valid process table entry does not exist for a given virtual address.</td>
</tr>
<tr>
<td>slock/s</td>
<td>The number of faults, per second, caused by software lock requests that require physical I/O. An example of the occurrence of a soft-lock request is the transfer of data from a disk to memory. The system locks the page that is to receive the data, so that the page cannot be claimed and used by another process.</td>
</tr>
</tbody>
</table>

Example—Checking Page-In Activity

The following abbreviated example shows output from the sar -p command.

$ sar -p

How to Check Queue Activity (\texttt{\textit{sar} -q})

Use the \texttt{\textit{sar} -q} command to report the average queue length while the queue is occupied, and the percentage of time that the queue is occupied.

\begin{verbatim}
$ sar -q
00:00:00 runq-sz %runocc swpq-sz %swpocc
\end{verbatim}

\textbf{Note} – The number of LWPs swapped out might be greater than zero even if the system has an abundance of free memory. This situation happens when a sleeping LWP is swapped out and has not been awakened. For example, a process or LWP is sleeping, waiting for keyboard or mouse input.

The following table describes the output from the \texttt{-q} option.

\begin{table}[h]
\centering
\caption{Output From the \texttt{\textit{sar} -q} Command}
\begin{tabular}{l l}
\hline
Field Name & Description \\
\hline
runq-sz & The number of kernel threads in memory that are waiting for a CPU to run. Typically, this value should be less than 2. Consistently higher values mean that the system might be CPU-bound. \\
\%runocc & The percentage of time that the dispatch queues are occupied. \\
wspq-sz & The average number of swapped out LWPs. \\
wswpocc & The percentage of time LWPs are swapped out. \\
\hline
\end{tabular}
\end{table}

Example—Checking Queue Activity

The following abbreviated example shows output from the \texttt{\textit{sar} -q} command. If \%runocc is high (greater than 90 percent) and runq-sz is greater than 2, the CPU is heavily loaded and response is degraded. In this case, additional CPU capacity might be required to obtain acceptable system response.

\begin{verbatim}
$ sar -q
SunOS venus 5.9 Generic sun4u 06/24/2001
08:45:18 runq-sz \%runocc swpq-sz \%swpocc
08:45:18 unix restarts
09:00:00 1.0 0 0.0 0
09:20:00 0.0 0 0.0 0
09:40:00 0.0 0 0.0 0
Average 1.0 0 0.0 0
\end{verbatim}
How to Check Unused Memory (\texttt{sar -r})

Use the \texttt{sar -r} command to report the number of memory pages and swap-file disk blocks that are currently unused.

\begin{verbatim}
$ sar -r
00:00:00 freemem freeswap
01:00:00 2135 401922
\end{verbatim}

The following table describes the output from the \texttt{-r} option.

\begin{table}[h]
\centering
\begin{tabular}{|l|l|}
\hline
\textbf{Field Name} & \textbf{Description} \\
\hline
freemem & The average number of memory pages that are available to user processes over the intervals sampled by the command. Page size is machine-dependent. \\
\hline
freeswap & The number of 512-byte disk blocks that are available for page swapping. \\
\hline
\end{tabular}
\caption{Output From the \texttt{sar -r} Command}
\end{table}

Example—Checking Unused Memory

The following example shows output from the \texttt{sar -r} command.

\begin{verbatim}
$ sar -r
SunOS venus 5.9 Generic sun4u 06/24/2001
00:00:00 freemem freeswap
01:00:00 2135 401922
02:00:02 2137 401949
03:00:00 2137 402006
04:00:00 2139 401923
05:00:01 2138 402033
06:00:00 2137 401919
\end{verbatim}

Average 2500 399914

How to Check CPU Utilization (\texttt{sar -u})

Use the \texttt{sar -u} command to display CPU utilization statistics.

\begin{verbatim}
$ sar -u
00:00:00 %usr %sys %wio %idle
01:00:00 0 0 0 100
\end{verbatim}

The \texttt{sar} command without any options is equivalent to \texttt{sar -u}. At any given moment, the processor is either busy or idle. When busy, the processor is in either user mode or system mode. When idle, the processor is either waiting for I/O completion or “sitting still” with no work to do.
The following table describes output from the -u option.

### TABLE 24-17 Output From the `sar -u` Command

<table>
<thead>
<tr>
<th>Field Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>%usr</td>
<td>Lists the percentage of time that the processor is in user mode</td>
</tr>
<tr>
<td>%sys</td>
<td>Lists the percentage of time that the processor is in system mode</td>
</tr>
<tr>
<td>%wio</td>
<td>Lists the percentage of time that the processor is idle and waiting for I/O completion</td>
</tr>
<tr>
<td>%idle</td>
<td>Lists the percentage of time that the processor is idle and not waiting for I/O</td>
</tr>
</tbody>
</table>

A high %wio generally means that a disk slowdown has occurred.

### Example—Checking CPU Utilization

The following example shows output from the `sar -u` command.

$ `sar -u`

SunOS venus 5.9 Generic sun4u 06/24/2001

<table>

▼ How to Check System Table Status (`sar -v`)

Use the `sar -v` command to report the status of the process table, inode table, file table, and shared memory record table.
Output from the -v option is described in the following table.

### TABLE 24–18 Output From the sar -v Command

<table>
<thead>
<tr>
<th>Field Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>proc-sz</td>
<td>The number of process entries (proc structures) that are currently being used, or allocated in the kernel.</td>
</tr>
<tr>
<td>inod-sz</td>
<td>The total number of inodes in memory verses the maximum number of inodes that are allocated in the kernel. This number is not a strict high water mark. The number can overflow.</td>
</tr>
<tr>
<td>file-sz</td>
<td>The size of the open system file table. The sz is given as 0, since space is allocated dynamically for the file table.</td>
</tr>
<tr>
<td>ov</td>
<td>The number of shared memory record table entries that are currently being used or allocated in the kernel. The sz is given as 0 because space is allocated dynamically for the shared memory record table.</td>
</tr>
<tr>
<td>lock-sz</td>
<td>The number of shared memory record table entries that are currently being used or allocated in the kernel. The sz is given as 0 because space is allocated dynamically for the shared memory record table.</td>
</tr>
</tbody>
</table>

Example—Checking System Table Status

The following abbreviated example shows output from the sar -v command. This example shows that all tables are large enough to have no overflows. These tables are all dynamically allocated based on the amount of physical memory.

```
$ sar -v
SunOS venus 5.9 Generic sun4u 06/24/2001
00:00:00 proc-sz ov inod-sz ov file-sz ov lock-sz
01:00:00 43/922 0 2984/4236 0 322/322 0 0/0
02:00:02 43/922 0 2984/4236 0 322/322 0 0/0
03:00:00 43/922 0 2986/4236 0 323/323 0 0/0
04:00:00 43/922 0 2987/4236 0 322/322 0 0/0
05:00:01 43/922 0 2987/4236 0 322/322 0 0/0
06:00:00 43/922 0 2987/4236 0 322/322 0 0/0
```

▼ How to Check Swapping Activity (sar -w)

Use the sar -w command to report swapping and switching activity.
The following table describes target values and observations.

### TABLE 24–19 Output From the *sar -w* Command

<table>
<thead>
<tr>
<th>Field Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>swpin/s</td>
<td>The number of LWP transfers into memory per second.</td>
</tr>
<tr>
<td>bswin/s</td>
<td>The average number of processes that are swapped out of memory per second. If the number is greater than 1, you might need to increase memory.</td>
</tr>
<tr>
<td>swpot/s</td>
<td>The average number of processes that are swapped out of memory per second. If the number is greater than 1, you might need to increase memory.</td>
</tr>
<tr>
<td>bswot/s</td>
<td>The number of blocks that are transferred for swap-outs per second.</td>
</tr>
<tr>
<td>pswch/s</td>
<td>The number of kernel thread switches, per second.</td>
</tr>
</tbody>
</table>

**Note**—All process swap-ins include process initialization.

### Example—Checking Swap Activity

The following example shows output from the *sar -w* command.

```bash
$ sar -w
SunOS venus 5.9 Generic sun4u 06/24/2001
00:00:00 swpin/s bswin/s swpot/s bswot/s pswch/s
01:00:00 0.00 0.0 0.00 0.0 22
02:00:02 0.00 0.0 0.00 0.0 22
03:00:00 0.00 0.0 0.00 0.0 22
04:00:00 0.00 0.0 0.00 0.0 22
05:00:01 0.00 0.0 0.00 0.0 22
06:00:00 0.00 0.0 0.00 0.0 22
07:00:00 0.00 0.0 0.00 0.0 22
08:00:01 0.00 0.0 0.00 0.0 22
09:00:00 0.00 0.0 0.00 0.0 22
09:40:00 0.00 0.0 0.00 0.0 22
10:00:00 0.00 0.0 0.00 0.0 22
10:20:00 0.00 0.0 0.00 0.0 22
```

346  System Administration Guide: Advanced Administration • December 2002
Use the `sar -y` command to monitor terminal device activities.

```
$ sar -y
00:00:00 rawch/s canch/s outch/s rcvin/s xmtin/s mdmin/s
01:00:00 0 0 0 0 0 0
```

If you have a lot of terminal I/O, you can use this report to determine if there are any bad lines. The activities recorded are defined in the following table.

### TABLE 24–20 Output From the `sar -y` Command

<table>
<thead>
<tr>
<th>Field Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>rawch/s</td>
<td>Input characters (raw queue), per second</td>
</tr>
<tr>
<td>canch/s</td>
<td>Input characters that are processed by canon (canonical queue), per second</td>
</tr>
<tr>
<td>outch/s</td>
<td>Output characters (output queue) per second</td>
</tr>
<tr>
<td>rcvin/s</td>
<td>Receiver hardware interrupts per second</td>
</tr>
<tr>
<td>xmtin/s</td>
<td>Transmitter hardware interrupts per second</td>
</tr>
<tr>
<td>mdmin/s</td>
<td>Modem interrupts per second</td>
</tr>
</tbody>
</table>

The number of modem interrupts per second (`mdmin/s`) should be close to zero. The receive and transmit interrupts per second (`rcvin/s` and `xmtin/s`) should be less than or equal to the number of incoming or outgoing characters, respectively. If not, check for bad lines.

### Example—Checking Terminal Activity

The following abbreviated example shows output from the `sar -y` command.

```
$ sar -y
SunOS venus 5.9 Generic sun4u 06/24/2001
00:00:00 rawch/s canch/s outch/s rcvin/s xmtin/s mdmin/s
01:00:00 0 0 0 0 0 0
02:00:02 0 0 0 0 0 0
03:00:00 0 0 0 0 0 0
04:00:00 0 0 0 0 0 0
```
How to Check Overall System Performance (\texttt{sar -A})

Use the \texttt{sar -A} command to display statistics from all options to provide a view of overall system performance.

This command provides a more global perspective. If data from more than a single time segment is shown, the report includes averages.

Collecting System Activity Data Automatically (\texttt{sar})

Three commands are involved in the automatic collection of system activity data: \texttt{sadc}, \texttt{sal}, and \texttt{sa2}.

The \texttt{sadc} data collection utility periodically collects data on system activity and saves the data in a file in binary format, one file for each 24-hour period. You can set up the \texttt{sadc} command to run periodically (usually once each hour), and whenever the system boots to multiuser mode. The data files are placed in the \texttt{/var/adm/sa} directory. Each file is named \texttt{sadd}, where \texttt{dd} is the current date. The format of the command is as follows:

\texttt{/usr/lib/sa/sadc [t n] [ofile]}

The command samples \texttt{n} times with an interval of \texttt{t} seconds, which should be greater than 5 seconds between samples. This command then writes to the binary \texttt{ofile} file, or to standard output.
Running the \texttt{sadc} Command When Booting

The \texttt{sadc} command should be run at system boot time in order to record the statistics from when the counters are reset to zero. To make sure that \texttt{sadc} is run at boot time, the \texttt{/etc/init.d/perf} file contains a command line that writes a record to the daily data file.

The command entry has the following format:

\texttt{/usr/bin/su sys -c "/usr/lib/sa/sadc /var/adm/sa/sa\`date +%d"} 

Running the \texttt{sadc} Command Periodically With the \texttt{sa1} Script

To generate periodic records, you need to run the \texttt{sadc} command regularly. The simplest way to do so is uncomment the following lines in the \texttt{/var/spool/cron/crontab/sys} file:

\begin{verbatim}
#0   * * 0-6 /usr/lib/sa/sa1
#20,40 8-17 * * 1-5 /usr/lib/sa/sa1
#5 18 * * 1-5 /usr/lib/sa/sa2 -s 8:00 -e 18:01 -i 1200 -A
\end{verbatim}

The \texttt{sys crontab} entries do the following:

- The first two \texttt{crontab} entries cause a record to be written to the \texttt{/var/adm/sa/sadd} file every 20 minutes from 8 a.m. to 5 p.m., Monday through Friday, and every hour on the hour otherwise.
- The third entry writes a record to the \texttt{/var/adm/sa/saradd} file hourly, Monday through Friday, and includes all \texttt{sar} options.

You can change these defaults to meet your needs.

Producing Reports With the \texttt{sa2} Shell Script

Another shell script, \texttt{sa2}, produces reports rather than binary data files. The \texttt{sa2} command invokes the \texttt{sar} command and writes the ASCII output to a report file.

Setting Up Automatic Data Collection (\texttt{sar})

The \texttt{sar} command can be used either to gather system activity data itself or to report what has been collected in the daily activity files that are created by the \texttt{sadc} command.

The \texttt{sar} command has the following formats:
The following `sar` command samples cumulative activity counters in the operating system every `t` seconds, `n` times. The `t` should be 5 seconds or greater. Otherwise, the command itself might affect the sample. You must specify a time interval between which to take the samples. Otherwise, the command operates according to the second format. The default value of `n` is 1. The following example takes two samples separated by 10 seconds. If the `-o` option is specified, samples are saved in binary format.

```
$ sar -u 10 2
```

Other important information about the `sar` command includes the following:

- With no sampling interval or number of samples specified, the `sar` command extracts data from a previously recorded file, either the file specified by the `-f` option or, by default, the standard daily activity file, `/var/adm/sa/sadd`, for the most recent day.
- The `-s` and `-e` options define the starting and ending times for the report. Starting and ending times are of the form `hh:mm:ss`, where `h`, `m`, and `s` represent hours, minutes, and seconds.
- The `-i` option specifies, in seconds, the intervals between record selection. If the `-i` option is not included, all intervals that are found in the daily activity file are reported.

The following table lists the `sar` options and their actions.

<table>
<thead>
<tr>
<th>Option</th>
<th>Actions</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>-a</code></td>
<td>Checks file access operations</td>
</tr>
<tr>
<td><code>-b</code></td>
<td>Checks buffer activity</td>
</tr>
<tr>
<td><code>-c</code></td>
<td>Checks system calls</td>
</tr>
<tr>
<td><code>-d</code></td>
<td>Checks activity for each block device</td>
</tr>
<tr>
<td><code>-g</code></td>
<td>Checks page-out and memory freeing</td>
</tr>
<tr>
<td><code>-k</code></td>
<td>Checks kernel memory allocation</td>
</tr>
<tr>
<td><code>-m</code></td>
<td>Checks interprocess communication</td>
</tr>
<tr>
<td><code>-p</code></td>
<td>Checks swap and dispatch activity</td>
</tr>
<tr>
<td><code>-q</code></td>
<td>Checks queue activity</td>
</tr>
<tr>
<td><code>-r</code></td>
<td>Checks unused memory</td>
</tr>
<tr>
<td>Option</td>
<td>Actions</td>
</tr>
<tr>
<td>--------</td>
<td>---------</td>
</tr>
<tr>
<td>-u</td>
<td>Checks CPU utilization</td>
</tr>
<tr>
<td>-nv</td>
<td>Checks system table status</td>
</tr>
<tr>
<td>-w</td>
<td>Checks swapping and switching volume</td>
</tr>
<tr>
<td>-y</td>
<td>Checks terminal activity</td>
</tr>
<tr>
<td>-A</td>
<td>Reports overall system performance, which is the same as entering all options.</td>
</tr>
</tbody>
</table>

If no option is used, it is equivalent to calling the command with the -u option.

### How to Set Up Automatic Data Collection

1. Become superuser.

2. Edit the `/etc/init.d/perf` file and uncomment the following lines:

   ```bash
   # if [-z "$_INIT_RUN_LEVEL"] ; then
   #   set -- '/usr/bin/who -r'
   #   _INIT_RUN_LEVEL="$7"
   #   _INIT_RUN_NPREV="#8"
   #   _INIT_PREV_LEVEL="#9"
   # fi
   
   # if [ $_INIT_RUN_LEVEL -ge 2 -a $_INIT_RUN_NPREV -eq 0 -a "$_INIT_PREV_LEVEL = 1 -o $_INIT_PREV_LEVEL = $S \""); then
   #   /usr/bin/su sys -c "/usr/lib/sa/sadc /var/adm/sa/sa\n   #     date +%d"
   # fi
   
   This version of the `sadc` command writes a special record that marks the time when the counters are reset to zero (boot time).

3. Edit the `/var/spool/cron/crontabs/sys crontab` file and uncomment the following lines:

   ```bash
   # 0 0-6 * * * /usr/lib/sa/sal
   # 20,40 8-17 * * * /usr/lib/sa/sal
   # 5 18 * * 1-5 /usr/lib/sa/sa2 -s 8:00 -e 18:01 -i 1200 -A
   ```
Troubleshooting Solaris Software Topics

This topic map lists the chapters that provide information for troubleshooting Solaris software problems.

Troubleshooting Software Problems
(Overview)

This chapter provides a general overview of troubleshooting software problems, including information on troubleshooting system crashes and viewing system messages.

This is a list of information in this chapter.
- “What’s New in Troubleshooting Software Problems?” on page 355
- “Where to Find Software Troubleshooting Tasks” on page 357
- “Troubleshooting a System Crash” on page 357
- “Troubleshooting a System Crash Checklist” on page 359
- “Viewing System Messages” on page 360
- “Customizing System Message Logging” on page 362

What’s New in Troubleshooting Software Problems?

This section describes features that are new in the Solaris 9 release.

New System Log Rotation

In Solaris 9 release, system log files are now rotated by the logadm command from an entry in the root crontab file. The /usr/lib/newsyslog script is no longer used.
The new system log rotation is defined in the /etc/logadm.conf file. This file includes log rotation entries for processes such as syslogd. For example, one entry in the /etc/logadm.conf file specifies that the /var/log/syslog file is rotated weekly unless the file is empty. The most recent syslog file becomes syslog.0, the next most recent becomes syslog.1, and so on. Eight previous syslog log files are kept.

The /etc/logadm.conf file also contains time stamps of when the last log rotation occurred.

You can use the logadm command to customize system logging and to add additional logging in the /etc/logadm.conf file as needed.

For example, to rotate the Apache access and error logs, use the following commands:

```
# logadm -w /var/apache/logs/access_log -s 100m
# logadm -w /var/apache/logs/error_log -s 10m
```

In this example, the Apache access_log file is rotated when it reaches 100 Mbytes in size, with a .0, .1, (and so on) suffix, keeping 10 copies of the old access_log file. The error_log is rotated when it reaches 10 Mbytes in size with the same suffixes and number of copies as the access_log file.

The /etc/logadm.conf entries for the preceding Apache log rotation examples look similar to the following:

```
# cat /etc/logadm.conf
.
.
/var/apache/logs/error_log -s 10m
/var/apache/logs/access_log -s 100m
```

For more information, see logadm(1M).

You can use the logadm command as superuser or by assuming an equivalent role (with Log Management rights). With role-based access control (RBAC), you can grant non-root users the privilege of maintaining log files by providing access to the logadm command.

For example, add the following entry to the /etc/user_attr file to grant user andy the ability to use the logadm command:

```
andy:::profiles=Log Management
```

Or, you can set up a role for log management by using the Solaris Management Console. For more information about setting up a role, see “Role-Based Access Control (Overview)” in System Administration Guide: Security Services.
New Fall Back Shell for root Account

If you changed root’s shell to a non-existent shell in previous Solaris releases, you were forced to boot the system from a local CD or from the network and correct the root shell entry in the /etc/passwd file.

If you mistakenly provide a non-existent shell for root in the Solaris 9 release, root’s shell will automatically fall back to /sbin/sh when one of the following occurs:

- You use the su command to change to the superuser (root) account.
- You are prompted for the root password at the single-user mode password prompt.

For more information, see su(1M).

Where to Find Software Troubleshooting Tasks

Troubleshooting a System Crash

If a system running the Solaris operating environment crashes, provide your service provider with as much information as possible, including crash dump files.
What to Do if the System Crashes

The most important things to remember are:

1. Write down the system console messages.
   If a system crashes, making it run again might seem like your most pressing concern. However, before you reboot the system, examine the console screen for messages. These messages can provide some insight about what caused the crash. Even if the system reboots automatically and the console messages have disappeared from the screen, you might be able to check these messages by viewing the system error log, the /var/adm/messages file. For more information about viewing system error log files, see “How to View System Messages” on page 361.
   If you have frequent crashes and can’t determine their cause, gather all the information you can from the system console or the /var/adm/messages files, and have it ready for a customer service representative to examine. For a complete list of troubleshooting information to gather for your service provider, see “Troubleshooting a System Crash” on page 357.
   If the system fails to reboot successfully after a system crash, see Chapter 29

2. Synchronize the disks and reboot.

   ok sync

   If the system fails to reboot successfully after a system crash, see Chapter 29

Check to see if a system crash dump was generated after the system crash. System crash dumps are saved by default. For information about crash dumps, see Chapter 28

Gathering Troubleshooting Data

Answer the following questions to help isolate the system problem. Use “Troubleshooting a System Crash Checklist” on page 359 for gathering troubleshooting data for a crashed system.

<table>
<thead>
<tr>
<th>Question</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Can you reproduce the problem?</td>
<td>This is important because a reproducible test case is often essential for debugging really hard problems. By reproducing the problem, the service provider can build kernels with special instrumentation to trigger, diagnose, and fix the bug.</td>
</tr>
</tbody>
</table>
TABLE 26–1 Identifying System Crash Data  (Continued)

<table>
<thead>
<tr>
<th>Question</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Are you using any third-party drivers?</td>
<td>Drivers run in the same address space as the kernel, with all the same privileges, so they can cause system crashes if they have bugs.</td>
</tr>
<tr>
<td>What was the system doing just before it crashed?</td>
<td>If the system was doing anything unusual like running a new stress test or experiencing higher-than-usual load, that might have led to the crash.</td>
</tr>
<tr>
<td>Were there any unusual console messages right before the crash?</td>
<td>Sometimes the system will show signs of distress before it actually crashes; this information is often useful.</td>
</tr>
<tr>
<td>Did you add any tuning parameters to the /etc/system file?</td>
<td>Sometimes tuning parameters, such as increasing shared memory segments so that the system tries to allocate more than it has, can cause the system to crash.</td>
</tr>
<tr>
<td>Did the problem start recently?</td>
<td>If so, did the onset of problems coincide with any changes to the system, for example, new drivers, new software, different workload, CPU upgrade, or a memory upgrade.</td>
</tr>
</tbody>
</table>

Troubleshooting a System Crash Checklist

Use this checklist when gathering system data for a crashed system.

<table>
<thead>
<tr>
<th>Item</th>
<th>Your Data</th>
</tr>
</thead>
<tbody>
<tr>
<td>Is a system crash dump available?</td>
<td></td>
</tr>
<tr>
<td>Identify the operating system release and appropriate software application release levels.</td>
<td></td>
</tr>
<tr>
<td>Identify system hardware.</td>
<td></td>
</tr>
<tr>
<td>Include prtdiag output for sun4u systems.</td>
<td></td>
</tr>
<tr>
<td>Include Explorer output for other systems.</td>
<td></td>
</tr>
<tr>
<td>Are patches installed? If so, include showrev -p output.</td>
<td></td>
</tr>
<tr>
<td>Is the problem reproducible?</td>
<td></td>
</tr>
<tr>
<td>Does the system have any third-party drivers?</td>
<td></td>

<tr>
<td>Did the problem start recently?</td>
<td></td>
</tr>
</tbody>
</table>

**Viewing System Messages**

System messages display on the console device. The text of most system messages look like this:

[ID msgid facility.priority]

For example:

[ID 672855 kern.notice] syncing file systems...

If the message originated in the kernel, the kernel module name is displayed. For example:

Oct 1 14:07:24 mars ufs: [ID 845546 kern.notice] alloc: /: file system full

When a system crashes, it might display a message on the system console like this:

panic: error message

Less frequently, this message might be displayed instead of the panic message:

Watchdog reset !

The error logging daemon, syslogd, automatically records various system warnings and errors in message files. By default, many of these system messages are displayed on the system console and are stored in the /var/adm directory. You can direct where these messages are stored by setting up system message logging. For more information, see “How to Customize System Message Logging” on page 363. These messages can alert you to system problems, such as a device that is about to fail.

The /var/adm directory contains several message files. The most recent messages are in /var/adm/messages file (and in messages.*), and the oldest are in the messages.3 file. After a period of time (usually every ten days), a new messages file is created. The messages.0 file is renamed messages.1, messages.1 is renamed messages.2, and messages.2 is renamed messages.3. The current /var/adm/messages.3 file is deleted.
Because the `/var/adm` directory stores large files containing messages, crash dumps, and other data, this directory can consume lots of disk space. To keep the `/var/adm` directory from growing too large, and to ensure that future crash dumps can be saved, you should remove unneeded files periodically. You can automate this task by using the `crontab` file. For more information on automating this task, see “How to Delete Crash Dump Files” on page 232 and Chapter 18.

▼ How to View System Messages

Display recent messages generated by a system crash or reboot by using the `dmesg` command.

```
$ dmesg
```

Or, use the `more` command to display one screen of messages at a time.

```
$ more /var/adm/messages
```

For more information, see `dmesg(1M)`.

Example—Viewing System Messages

The following example shows output from the `dmesg` command.

```
$ dmesg
Jan 3 08:44:41 starbug genunix: [ID 540533 kern.notice] SunOS Release 5.9 ...

```

Chapter 26 • Troubleshooting Software Problems (Overview) 361
Customizing System Message Logging

You can capture additional error messages that are generated by various system processes by modifying the `/etc/syslog.conf` file. By default, the `/etc/syslog.conf` file directs many system process messages to the `/var/adm/messages` file. Crash and boot messages are stored here as well. To view `/var/adm messages", see “How to View System Messages” on page 361.

The `/etc/syslog.conf` file has two columns separated by tabs:

```
facility.level ... action
```

- **facility.level**: A facility or system source of the message or condition. May be a comma-separated listed of facilities. Facility values are listed in Table 26-2. A level, indicates the severity or priority of the condition being logged. Priority levels are listed in Table 26-3.
- **action**: The action field indicates where the messages are forwarded.

The following example shows sample lines from a default `/etc/syslog.conf` file:

```
user.err /dev/sysmsg
user.err /var/adm/messages
user.alert 'root, operator'
user.emerg *
```

This means the following user messages are automatically logged:

- User errors are printed to the console and also are logged to the `/var/adm/messages` file.
- User messages requiring immediate action (alert) are sent to the root and operator users.
- User emergency messages are sent to individual users.

The most common error condition sources are shown in the following table. The most common priorities are shown in Table 26-3 in order of severity.

**TABLE 26-2** Source Facilities for `syslog.conf` Messages

<table>
<thead>
<tr>
<th>Source</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>kern</td>
<td>The kernel</td>
</tr>
<tr>
<td>auth</td>
<td>Authentication</td>

</tr>
</tbody>
</table>

▼ How to Customize System Message Logging

1. Become superuser.

2. Edit the /etc/syslog.conf file, adding or changing message sources, priorities, and message locations according to the syntax described in syslog.conf(4).

3. Exit the file, saving the changes.

Example—Customizing System Message Logging

This sample /etc/syslog.conf user.emerg facility sends user emergency messages to root and * individual users.

```
user.emerg 'root, *'
```
Enabling Remote Console Messaging

The following new console features improve your ability to troubleshoot remote systems:

- The `consadm` command enables you to select a serial device as an auxiliary (or remote) console. Using the `consadm` command, a system administrator can configure one or more serial ports to display redirected console messages and to host `sulogin` sessions when the system transitions between run levels. This feature enables you to dial in to a serial port with a modem to monitor console messages and participate in `init` state transitions. (For more information, see `sulogin(1M)` and the step-by-step procedures that follow.)

  While you can log in to a system using a port configured as an auxiliary console, it is primarily an output device displaying information that is also displayed on the default console. If boot scripts or other applications read and write to and from the default console, the write output displays on all the auxiliary consoles, but the input is only read from the default console. (For more information on using the `consadm` command during an interactive login session, see “Using the `consadm` Command During an Interactive Login Session” on page 365.)

- Console output now consists of kernel and `syslog` messages written to a new pseudo device, `/dev/sysmsg`. In addition, `rc` script startup messages are written to `/dev/msglog`. Previously, all of these messages were written to `/dev/console`. Scripts that direct console output to `/dev/console` need to be changed to `/dev/msglog` if you want to see script messages displayed on the auxiliary consoles. Programs referencing `/dev/console` should be explicitly modified to use `syslog()` or `strlog()` if you want messages to be redirected to an auxiliary device.

- The `consadm` command runs a daemon to monitor auxiliary console devices. Any display device designated as an auxiliary console that disconnects, hangs up or loses carrier, is removed from the auxiliary console device list and is no longer active. Enabling one or more auxiliary consoles does not disable message display on the default console; messages continue to display on `/dev/console`.

Using Auxiliary Console Messaging During Run Level Transitions

Keep the following in mind when using auxiliary console messaging during run level transitions:

- Input cannot come from an auxiliary console if user input is expected for an `rc` script that is run when a system is booting. The input must come from the default console.
The **sulogin** program, invoked by **init** to prompt for the superuser password when transitioning between run levels, has been modified to send the superuser password prompt to each auxiliary device in addition to the default console device.

When the system is in single-user mode and one or more auxiliary consoles are enabled using the **consadm** command, a console login session runs on the first device to supply the correct superuser password to the **sulogin** prompt. When the correct password is received from a console device, **sulogin** disables input from all other console devices.

A message is displayed on the default console and the other auxiliary consoles when one of the consoles assumes single-user privileges. This message indicates which device has become the console by accepting a correct superuser password. If there is a loss of carrier on the auxiliary console running the single-user shell, one of two actions might occur:

- If the auxiliary console represents a system at run level 1, the system proceeds to the default run level.
- If the auxiliary console represents a system at run level S, the system displays the **ENTER RUN LEVEL (0-6, s or S):** message on the device where the **init** or **shutdown** command had been entered from the shell. If there isn’t any carrier on that device either, you will have to reestablish carrier and enter the correct run level. The **init** or **shutdown** command will not redisplay the run-level prompt.

If you are logged in to a system using a serial port, and an **init** or **shutdown** command is issued to transition to another run level, the login session is lost whether this device is the auxiliary console or not. This situation is identical to Solaris releases without auxiliary console capabilities.

Once a device is selected as an auxiliary console using the **consadm** command, it remains the auxiliary console until the system is rebooted or the auxiliary console is unselected. However, the **consadm** command includes an option to set a device as the auxiliary console across system reboots. (See the following procedure for step-by-step instructions.)

### Using the **consadm** Command During an Interactive Login Session

If you want to run an interactive login session by logging in to a system using a terminal that is connected to a serial port, and then using the **consadm** command to see the console messages from the terminal, note the following behavior:

- If you use the terminal for an interactive login session while the auxiliary console is active, the console messages are sent to the `/dev/sysmsg` or `/dev/msglog` devices.
- While you issue commands on the terminal, input goes to your interactive session and not to the default console (`/dev(console)`).
If you run the `init` command to change run levels, the remote console software kills your interactive session and runs the `sulogin` program. At this point, input is accepted only from the terminal and is treated like it’s coming from a console device. This allows you to enter your password to the `sulogin` program as described in “Using Auxiliary Console Messaging During Run Level Transitions” on page 364.

Then, if you enter the correct password on the (auxiliary) terminal, the auxiliary console runs an interactive `sulogin` session, locks out the default console and any competing auxiliary console. This means the terminal essentially functions as the system console.

From here you can change to run level 3 or go to another run level. If you change run levels, `sulogin` runs again on all console devices. If you exit or specify that the system should come up to run level 3, then all auxiliary consoles lose their ability to provide input. They revert to being display devices for console messages.

As the system is coming up, you must provide information to `rc` scripts on the default console device. After the system comes back up, the `login` program runs on the serial ports and you can log back into another interactive session. If you’ve designated the device to be an auxiliary console, you will continue to get console messages on your terminal, but all input from the terminal goes to your interactive session.

▼ How to Enable an Auxiliary (Remote) Console

The `consadm` daemon does not start monitoring the port until after you add the auxiliary console with the `consadm` command. As a security feature, console messages are only redirected until carrier drops, or the auxiliary console device is unselected. This means carrier must be established on the port before you can successfully use the `consadm` command.

For more information on enabling an auxiliary console, see `consadm(1M).

1. Log in to the system as superuser.

2. Enable the auxiliary console.

   ```
   # consadm -a devicename
   ```

3. Verify that the current connection is the auxiliary console.

   ```
   # consadm
   ```

Example—Enabling an Auxiliary (Remote) Console

```
# consadm -a /dev/term/a
# consadm
/dev/term/a
```
How to Display a List of Auxiliary Consoles

1. Log in to the system as superuser.

2. Select one of the following steps:
   a. Display the list of auxiliary consoles.
      
      # consadm
      /dev/term/a
   b. Display the list of persistent auxiliary consoles.
      
      # consadm -p
      /dev/term/b

How to Enable an Auxiliary (Remote) Console Across System Reboots

1. Log in to the system as superuser.

2. Enable the auxiliary console across system reboots.
   
   # consadm -a -p devicename
   This adds the device to the list of persistent auxiliary consoles.

3. Verify that the device has been added to the list of persistent auxiliary consoles.
   
   # consadm

Example—Enabling an Auxiliary (Remote) Console Across System Reboots

# consadm -a -p /dev/term/a
# consadm
/dev/term/a

How to Disable an Auxiliary (Remote) Console

1. Log in to the system as superuser.

2. Select one of the following steps:
   a. Disable the auxiliary console.
      
      # consadm -d devicename
b. Disable the auxiliary console and remove it from the list of persistent auxiliary consoles.

```
# consadm -p -d devicename
```

3. Verify that the auxiliary console has been disabled.

```
# consadm
```

Example—Disabling an Auxiliary (Remote) Console

```
# consadm -d /dev/term/a
# consadm
```
Managing Core Files (Tasks)

This chapter describes how to manage core files with the `coreadm` command.

For information on the procedures associated with managing core files, see “Managing Core Files (Task Map)” on page 369.

<td>“Examining Core Files” on page 374</td>
</tr>
</tbody>
</table>
Managing Core Files Overview

Core files are generated when a process or application terminates abnormally. Core files are managed with the coreadm command.

For example, you can use the coreadm command to configure a system so that all process core files are placed in a single system directory. This means it is easier to track problems by examining the core files in a specific directory whenever a Solaris process or daemon terminates abnormally.

Configurable Core File Paths

Two new configurable core file paths that can be enabled or disabled independently of each other are:

- A per-process core file path, which defaults to core and is enabled by default. If enabled, the per-process core file path causes a core file to be produced when the process terminates abnormally. The per-process path is inherited by a new process from its parent process.
  - When generated, a per-process core file is owned by the owner of the process with read/write permissions for the owner. Only the owning user can view this file.

- A global core file path, which defaults to core and is disabled by default. If enabled, an additional core file with the same content as the per-process core file is produced by using the global core file path.
  - When generated, a global core file is owned by superuser with read/write permissions for superuser only. Non-privileged users cannot view this file.

When a process terminates abnormally, it produces a core file in the current directory as in previous Solaris releases. But if the global core file path is enabled and set to /corefiles/core, for example, then each process that expires produce two core files: one in the current working directory and one in the /corefiles directory.

By default, a setuid process does not produce core files using either the global or per-process path.
Expanded Core File Names

If a global core file directory is enabled, core files can be distinguished from one another by using the variables described in the following table.

<table>
<thead>
<tr>
<th>Variable Name</th>
<th>Variable Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>%p</td>
<td>Process ID</td>
</tr>
<tr>
<td>%u</td>
<td>Effective user ID</td>
</tr>
<tr>
<td>%g</td>
<td>Effective group ID</td>
</tr>
<tr>
<td>%f</td>
<td>Executable file name</td>
</tr>
<tr>
<td>%n</td>
<td>System node name, equivalent to the <code>uname -n</code> output</td>
</tr>
<tr>
<td>%m</td>
<td>Machine name, equivalent to the <code>uname -m</code> output</td>
</tr>
<tr>
<td>%t</td>
<td>Decimal value of time(2) system call</td>
</tr>
<tr>
<td>%%</td>
<td>Literal %</td>
</tr>
</tbody>
</table>

For example, if the global core file path is set to:

`/var/core/core.%f.%p`

and a `sendmail` process with PID 12345 terminates abnormally, it produces the following core file:

`/var/core/core.sendmail.12345`

Setting the Core File Name Pattern

You can set a core file name pattern on a global basis or a per-process basis, and you can specify whether you want these settings saved across a system reboot.

For example, the following `coreadm` command sets the global core file pattern for all processes started by the `init` process. This pattern will persist across system reboots.

```
$ coreadm -i /var/core/core.%f.%p
```

Global core values are stored in the `/etc/coreadm.conf` file, which means these settings are saved across a system reboot.

This `coreadm` command sets the per-process core file name pattern for all processes:

```
$ coreadm -p /var/core/core.%f.%p $$
```

The $$ symbols represent a placeholder for the process ID of the currently running shell. The per-process core file name pattern is inherited by all child processes.
Once a global or per-process core file name pattern is set, it must be enabled with the coreadm -e command. See the following procedures for more information.

You can set the core file name pattern for all processes run during a user’s login session by putting the command in a user’s $HOME/.profile or .login file.

Enabling setuid Programs to Produce Core Files

You can use the coreadm command to enable or disable setuid programs to produce core files for all system processes or on a per-process basis by setting the following paths:

- If the global setuid option is enabled, a global core file path allows all setuid programs on a system to produce core files.
- If the per-process setuid option is enable, a per-process core file path allows specific setuid processes to produce core files.

By default, both flags are disabled. For security reasons, the global core file path must be a full pathname, starting with a leading /.

If superuser disables per-process core files, individual users cannot obtain core files.

The setuid core files are owned by superuser with read/write permissions for superuser only. Regular users cannot access them even if the process that produced the setuid core file was owned by an ordinary user.

For more information, see coreadm(1M).

How to Display the Current Core Dump Configuration

Use the coreadm command without any options to display the current core dump configuration.

```
$ coreadm
  global core file pattern: /var/core/core.%f.%p
  init core file pattern: core
  global core dumps: enabled
  per-process core dumps: enabled
  global setid core dumps: enabled
  per-process setid core dumps: disabled
  global core dump logging: disabled
```

How to Set a Core File Name Pattern

1. Determine whether you want to set a per-process or global core file and select one of the following:
a. Set a per-process file name pattern.

```
$ coreadm -p $HOME/corefiles/%f.%p $$
```

b. Set a global file name pattern.

Become superuser first.

```
# coreadm -g /var/corefiles/%f.%p
```

▼ How to Enable a Per-Process Core File Path

1. Become superuser.

2. Enable a per-process core file path.

```
# coreadm -e process
```

3. Display the current process core file path to verify the configuration.

```
$ coreadm $$
1180: /home/kryten/corefiles/%f.%p
```

▼ How to Enable a Global Core File Path

1. Become superuser.

2. Enable a global core file path.

```
# coreadm -e global -g /var/core/core.%f.%p
```

3. Display the current process core file path to verify the configuration.

```
# coreadm
  global core file pattern: /var/core/core.%f.%p
  init core file pattern: core
  global core dumps: enabled
  per-process core dumps: enabled
  global setid core dumps: disabled
  per-process setid core dumps: disabled
  global core dump logging: disabled
```
Troubleshooting Core File Problems

Error Message

NOTICE: ‘set allow_setid_core = 1’ in /etc/system is obsolete
NOTICE: Use the coreadm command instead of ‘allow_setid_core’

Cause
You have an obsolete parameter that allows setuid core files in your /etc/system file.

Solution
Remove allow_setid_core=1 from the /etc/system file. Then use the coreadm command to enable global setuid core file paths.

Examining Core Files

Some of the proc tools have been enhanced to examine process core files as well as live processes. The proc tools are utilities that can manipulate features of the /proc file system.

The /usr/proc/bin/pstack, pmap, pldd, pflags, and pcred tools can now be applied to core files by specifying the name of the core file on the command line, similar to the way you specify a process ID to these commands.

For more information on using proc tools to examine core files, see proc(1).

Example—Examining Core Files With proc Tools

$ ./a.out
Segmentation Fault (coredump)
$ /usr/proc/bin/pstack ./core
core '/core' of 19305: ./a.out
  000108c4 main (1, ffbef5cc, ffbef5d4, 20800, 0, 0) + 1c
  00010880 _start (0, 0, 0, 0, 0, 0) + b8
Managing System Crash Information (Tasks)

This chapter describes how to manage system crash information in the Solaris environment.

For information on the procedures associated with managing system crash information, see “Managing System Crash Information (Task Map)” on page 375.

Managing System Crash Information (Task Map)

The following task map identifies the procedures needed to manage system crash information.

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>For Instructions</th>
</tr>
</thead>
<tbody>
<tr>
<td>1. Display the current crash dump configuration</td>
<td>Display the current crash dump configuration by using the <code>dumpadm</code> command.</td>
<td>“How to Display the Current Crash Dump Configuration” on page 379</td>
</tr>
<tr>
<td>2. Modify the crash dump configuration</td>
<td>Use the <code>dumpadm</code> command to specify the type of data to dump, whether or not the system will use a dedicated dump device, the directory for saving crash dump files, and the amount of space that must remain available after crash dump files are written.</td>
<td>“How to Modify a Crash Dump Configuration” on page 379</td>
</tr>
<tr>
<td>3. Examine a crash dump file</td>
<td>Use the <code>mdb</code> command to view crash dump files.</td>
<td>“How to Examine a Crash Dump” on page 381</td>
</tr>
</tbody>
</table>
System Crashes (Overview)

System crashes can occur due to hardware malfunctions, I/O problems, and software errors. If the system crashes, it will display an error message on the console, and then write a copy of its physical memory to the dump device. The system will then reboot automatically. When the system reboots, the `savecore` command is executed to retrieve the data from the dump device and write the saved crash dump to your `savecore` directory. The saved crash dump files provide invaluable information to your support provider to aid in diagnosing the problem.

System Crash Dump Files

The `savecore` command runs automatically after a system crash to retrieve the crash dump information from the dump device and writes a pair of files called `unix.X` and `vmcore.X`, where `X` identifies the dump sequence number. Together, these files represent the saved system crash dump information.

Crash dump files are sometimes confused with `core` files, which are images of user applications that are written when the application terminates abnormally.

Crash dump files are saved in a predetermined directory, which by default, is `/var/crash/hostname`. In previous Solaris releases, crash dump files were overwritten when a system rebooted, unless you manually enabled the system to save the images of physical memory in a crash dump file. Now, the saving of crash dump files is enabled by default.

System crash information is managed with the `dumpadm` command. For more information, see “The `dumpadm` Command” on page 377.
Saving Crash Dumps

You can examine the control structures, active tables, memory images of a live or crashed system kernel, and other information about the operation of the kernel by using the `mdb` utility. Using `mdb` to its full potential requires a detailed knowledge of the kernel, and is beyond the scope of this manual. For information on using this utility, see `mdb(1)`.

Additionally, crash dumps saved by `savecore` can be useful to send to a customer service representative for analysis of why the system is crashing.

The `dumpadm` Command

Use the `dumpadm` command to manage system crash dump information in the Solaris environment.

- The `dumpadm` command enables you to configure crash dumps of the operating system. The `dumpadm` configuration parameters include the dump content, dump device, and the directory in which crash dump files are saved.
- Dump data is stored in compressed format on the dump device. Kernel crash dump images can be as big as 4 Gbytes or more. Compressing the data means faster dumping and less disk space needed for the dump device.
- Saving crash dump files is run in the background when a dedicated dump device, not the swap area, is part of the dump configuration. This means a booting system does not wait for the `savecore` command to complete before going to the next step. On large memory systems, the system can be available before `savecore` completes.
- System crash dump files, generated by the `savecore` command, are saved by default.
- The `savecore -L` command is a new feature which enables you to get a crash dump of the live running Solaris operating environment. This command is intended for troubleshooting a running system by taking a snapshot of memory during some bad state, such as a transient performance problem or service outage. If the system is up and you can still run some commands, you can execute the `savecore -L` command to save a snapshot of the system to the dump device, and then immediately write out the crash dump files to your `savecore` directory. Because the system is still running, you can only use the `savecore -L` command if you have configured a dedicated dump device.

The following table describes `dumpadm`'s configuration parameters.
### Dump Parameter Description

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dump device</td>
<td>The device that stores dump data temporarily as the system crashes. When the dump device is not the swap area, savecore runs in the background, which speeds up the boot process.</td>
</tr>
<tr>
<td>savecore directory</td>
<td>The directory that stores system crash dump files.</td>
</tr>
<tr>
<td>dump content</td>
<td>Type of memory data to dump.</td>
</tr>
<tr>
<td>minimum free space</td>
<td>Minimum amount of free space required in the savecore directory after saving crash dump files. If no minimum free space has been configured, the default is one Mbyte.</td>
</tr>
</tbody>
</table>

For more information, see `dumpadm(1M)`.

The dump configuration parameters managed by the `dumpadm` command are stored in the `/etc/dumpadm.conf` file.

**Note** – Do not edit the `/etc/dumpadm.conf` file manually. Editing this file manually could result in an inconsistent system dump configuration.

### How the dumpadm Command Works

During system startup, the `dumpadm` command is invoked by the `/etc/init.d/savecore` script to configure crash dumps parameters based on information in the `/etc/dumpadm.conf` file.

Specifically, `dumpadm` initializes the dump device and the dump content through the `/dev/dump` interface.

After the dump configuration is complete, the `savecore` script looks for the location of the crash dump file directory by parsing the content of `/etc/dumpadm.conf` file. Then, `savecore` is invoked to check for crash dumps and check the content of the `minfree` file in the crash dump directory.

### Dump Devices and Volume Managers

Do not configure a dedicated dump device that is under the control of volume management product such as Solaris Volume Manager for accessibility and performance reasons. You can keep your swap areas under the control of Solaris Volume Manager and this is a recommend practice, but keep your dump device separate.
Managing System Crash Dump Information

Keep the following key points in mind when you are working with system crash information:

- You must be superuser to access and manage system crash information.
- Do not disable the option of saving system crash dumps. System crash dump files provide an invaluable way to determine what is causing the system to crash.
- Do not remove important system crash information until it has been sent to your customer service representative.

▼ How to Display the Current Crash Dump Configuration

1. Become superuser.
2. Display the current crash dump configuration.

```bash
# dumpadm
Dump content: kernel pages
Dump device: /dev/dsk/c0t3d0s1 (swap)
Savecore directory: /var/crash/venus
Savecore enabled: yes
```

The preceding example output means:

- The dump content is kernel memory pages.
- Kernel memory will be dumped on a swap device, /dev/dsk/c0t3d0s1. You can identify all your swap areas with the `swap -l` command.
- System crash dump files will be written in the `/var/crash/venus` directory.
- Saving crash dump files is enabled.

▼ How to Modify a Crash Dump Configuration

1. Become superuser.
2. Identify the current crash dump configuration.

```bash
# dumpadm
Dump content: kernel pages
Dump device: /dev/dsk/c0t3d0s1 (swap)
Savecore directory: /var/crash/pluto
```
Savecore enabled: yes

This output identifies the default dump configuration for a system running the Solaris 9 release.

3. Modify the crash dump configuration.

```
# dumpadm -c content -d dump-device -m nnnk | nnnm | nnn% -n -s savecore-dir
```

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-c content</td>
<td>Specifies the type of data to dump. Use kernel to dump all kernel memory, all to dump all of memory, or curproc, to dump kernel memory and the memory pages of the process whose thread was executing when the crash occurred. The default dump content is kernel memory.</td>
</tr>
<tr>
<td>-d dump-device</td>
<td>Specifies the device that stores dump data temporarily as the system crashes. The primary swap device is the default dump device.</td>
</tr>
<tr>
<td>-m nnnk</td>
<td>Specifies the minimum free disk space for saving crash dump files by creating a minfree file in the current savecore directory. This parameter can be specified in Kbytes (nnnk), Mbytes (nnnm) or file system size percentage (nnn%). The savecore command consults this file prior to writing the crash dump files. If writing the crash dump files, based on their size, would decrease the amount of free space below the minfree threshold, the dump files are not written and an error message is logged. For information on recovering from this scenario, see “How to Recover From a Full Crash Dump Directory (Optional)” on page 382.</td>
</tr>
<tr>
<td>-n</td>
<td>Specifies that savecore should not be run when the system reboots. This dump configuration is not recommended. If system crash information is written to the swap device, and savecore is not enabled, the crash dump information is overwritten when the system begins to swap.</td>
</tr>
<tr>
<td>-s</td>
<td>Specifies an alternate directory for storing crash dump files. The default directory is /var/crash/hostname where hostname is the output of the uname -n command.</td>
</tr>
</tbody>
</table>

Example—Modifying a Crash Dump Configuration

In this example, all of memory is dumped to the dedicated dump device, /dev/dsk/c0t1d0s1, and the minimum free space that must be available after the crash dump files are saved is 10% of the file system space.

```
# dumpadm
   Dump content: kernel pages
   Dump device: /dev/dsk/c0t1d0s1 (swap)
   Savecore directory: /var/crash/pluto
   Savecore enabled: yes
```
# dumpadm -c all -d /dev/dsk/c0t1d0s1 -m 10%
  Dump content: all pages
  Dump device: /dev/dsk/c0t1d0s1 (dedicated)
Savecore directory: /var/crash/pluto (minfree = 77071KB)
  Savecore enabled: yes

▼ How to Examine a Crash Dump

1. Become superuser.

2. Examine a crash dump by using the mdb utility.
   
   # /usr/bin/mdb [-k] crashdump-file

   -k
   Specifies kernel debugging mode by assuming the file
   is an operating system crash dump file.

   crashdump-file
   Specifies the operating system crash dump file.

3. Display crash status information.
   
   # /usr/bin/mdb file-name
   > ::status
      .
      .
      .
   > ::system
      .
      .
      .

Example—Examining a Crash Dump

The following example shows sample output from the mdb utility, which includes
system information and identifies the tunables that are set in this system’s
/etc/system file.

# /usr/bin/mdb -k unix.0
Loading modules: [ unix krtld genunix ip nfs ipc ptm ]
> ::status
debugging crash dump /dev/mem (64-bit) from ozlo
operating system: 5.9 Generic (sun4u)
> ::system
set ufs_ninode=0x9c40 [0t40000]
set ncsize=0x4e20 [0t20000]
set pt_cnt=0x400 [0t1024]
How to Recover From a Full Crash Dump Directory (Optional)

In this scenario, the system crashes but no room is left in the savecore directory, and you want to save some critical system crash dump information.

1. Log in as superuser after the system reboots.

2. Clear out the savecore directory, usually /var/crash/hostname, by removing existing crash dump files that have already been sent to your service provider. Or, run the savecore command and specify an alternate directory that has sufficient disk space. See the next step.

3. Manually run the savecore command and if necessary, specify an alternate savecore directory.

   ```
   # savecore [ directory ]
   ```

How to Disable or Enable Saving Crash Dumps

1. Become superuser.

2. Disable or enable the saving of crash dumps on your system.

   ```
   # dumpadm -n | -y
   ```

Example—Disabling the Saving of Crash Dumps

This example illustrates how to disable the saving of crash dumps on your system.

   ```
   # dumpadm -n
   Dump content: all pages
   Dump device: /dev/dsk/c0t1d0s1 (dedicated)
   Savecore directory: /var/crash/pluto (minfree = 77071KB)
   Savecore enabled: no
   ```

Example—Enabling the Saving of Crash Dumps

This example illustrates how to enable the saving of crash dump on your system.

   ```
   # dumpadm -y
   Dump content: all pages
   Dump device: /dev/dsk/c0t1d0s1 (dedicated)
   Savecore directory: /var/crash/pluto (minfree = 77071KB)
   Savecore enabled: yes
   ```
Troubleshooting Miscellaneous Software Problems (Tasks)

This chapter describes miscellaneous software problems that may occur occasionally and are relatively easy to fix. Troubleshooting miscellaneous software problems includes solving problems that aren't related to a specific software application or topic, such as unsuccessful reboots and full file systems. Resolving these problems are described in the following sections.

This is a list of the information in this chapter.

- “What to Do If Rebooting Fails” on page 383
- “What to Do if a System Hangs” on page 387
- “What to Do if a File System Fills Up” on page 388
- “What to Do if File ACLs Are Lost After Copy or Restore” on page 389
- “Troubleshooting Backup Problems” on page 389

What to Do If Rebooting Fails

If the system does not reboot completely, or if it reboots and then crashes again, there may be a software or hardware problem that is preventing the system from booting successfully.

<table>
<thead>
<tr>
<th>Cause of System Not Booting</th>
<th>How to Fix the Problem</th>
</tr>
</thead>
<tbody>
<tr>
<td>The system can't find /platform/<code>uname -m</code>/kernel/unix.</td>
<td>You may need to change the boot-device setting in the PROM on a SPARC system. For information on changing the default boot device, see “SPARC: Booting a System (Tasks)” in System Administration Guide: Basic Administration.</td>
</tr>
</tbody>
</table>
## Cause of System Not Booting | How to Fix the Problem
---|---
There is no default boot device on an IA system. The message displayed is: Not a UFS filesystem. | Boot the system using the Configuration Assistant/boot diskette and select the disk from which to boot.
There's an invalid entry in the /etc/passwd file. | For information on recovering from an invalid passwd file, see “SPARC: Booting a System (Tasks)” in System Administration Guide: Basic Administration or “IA: Booting a System (Tasks)” in System Administration Guide: Basic Administration.
There’s a hardware problem with a disk or another device. | Check the hardware connections:
- Make sure the equipment is plugged in.
- Make sure all the switches are set properly.
- Look at all the connectors and cables, including the Ethernet cables.
- If all this fails, turn off the power to the system, wait 10 to 20 seconds, and then turn on the power again.

If none of the above suggestions solve the problem, contact your local service provider.

### SPARC: Troubleshooting 64–bit Solaris Boot Problems

After the 64–bit Solaris release is installed on an UltraSPARC system, the 64–bit kernel will be booted automatically unless any of the following conditions are true:

- A FLASH PROM upgrade might be required on an UltraSPARC system before it can successfully boot the 64–bit kernel. Refer to your hardware manufacturer’s documentation to determine whether your UltraSPARC system requires a firmware upgrade.
- The Open Boot PROM boot-file parameter is set to kernel/unix. If booting the 64–bit kernel fails and this parameter is set, unset it, and reboot the system.
- On some UltraSPARC systems, the 64-bit Solaris kernel is not booted by default, even when the system is completely installed with all the 64-bit Solaris components and the correct firmware is installed. Without booting the 64-bit Solaris kernel, 64-bit applications are unable to run.

To find out more about this issue, and how to enable booting the 64-bit Solaris kernel by default, see `boot(1M)`.
You can always discover which Solaris kernel the system is currently running by using the `isainfo -kv` command.

```
isainfo -kv
64-bit sparcv9 kernel modules
```

This output means the system is running the 64-bit Solaris kernel.

You cannot boot the 64-bit Solaris operating environment on a 32-bit Solaris system.

---

**What to Do if You Forgot Root Password**

If you forget the root password and you cannot log into the system, you will have to:

- Stop the system by using the keyboard stop sequence.
- Boot from a boot or install server or from a local CD-ROM.
- Mount the root (/) file system.
- Remove the root password from the `/etc/shadow` file.
- Reboot the system.
- Log in and set root's password.

This procedure is fully described in “SPARC: Booting a System” in System Administration Guide: Basic Administration and “IA: Booting a System” in System Administration Guide: Basic Administration.

The following examples describe how to recover from a forgotten root password on both SPARC and IA systems.

**SPARC: Example—What to Do if You Forgot Root Password**

The following example shows how to recover when you forget the root password by booting from the network. This example assumes that the boot server is already available. Be sure to apply a new root password after the system has rebooted.

```
(Use keyboard abort sequence--Press Stop A keys to stop the system)
ok boot net -s
# mount /dev/dsk/c0t3d0s0 /a
# cd /a/etc
# TERM=vt100
# export TERM
# vi shadow
( Remove root's encrypted password string)
# cd /
# umount /a
```
x86: Example—What to Do if You Forgot Root Password

The following example shows how to recover when you forget root’s password by booting from the network. This example assumes that the boot server is already available. Be sure to apply a new root password after the system has rebooted.

(Use keyboard abort sequence to stop the system
Type any key to continue

SunOS Secondary Boot version 3.00

Solaris Intel Platform Edition Booting System

Running Configuration Assistant...
Autobooting from Boot path: /pci@0,0/pci-ide@7,1/ide@0/cmdk@0,0:a

If the system hardware has changed, or to boot from a different device, interrupt the autoboot process by pressing ESC.

Press ESCape to interrupt autoboot in 5 seconds.

Boot Solaris

Select one of the identified devices to boot the Solaris kernel and choose Continue.

To perform optional features, such as modifying the autoboot and property settings, choose Boot Tasks.

An asterisk (*) indicates the current default boot device.

What to Do if a System Hangs

A system can freeze or hang rather than crash completely if some software process is stuck. Follow these steps to recover from a hung system.

1. Determine whether the system is running a window environment and follow these suggestions. If these suggestions don’t solve the problem, go to step 2.
   - Make sure the pointer is in the window where you are typing the commands
   - Press Control-q in case the user accidentally pressed Control-s, which freezes the screen. Control-s freezes only the window, not the entire screen. If a window is frozen, try using another window.
   - If possible, log in remotely from another system on the network. Use the pgrep command to look for the hung process. If it looks like the window system is hung, identify the process and kill it.
2. Press Control-\ to force a “quit” in the running program and (probably) write out a core file.
3. Press Control-c to interrupt the program that might be running.
4. Log in remotely and attempt to identify and kill the process that is hanging the system.
5. Log in remotely, become superuser and reboot the system.
6. If the system still does not respond, force a crash dump and reboot. For information on forcing a crash dump and booting, see “SPARC: Forcing a Crash Dump and Rebooting the System” in System Administration Guide: Basic Administration or “IA: Forcing a Crash Dump and Rebooting the System” in System Administration Guide: Basic Administration.
7. If the system still does not respond, turn the power off, wait a minute or so, then turn the power back on.
8. If you cannot get the system to respond at all, contact your local service provider for help.

What to Do if a File System Fills Up

When the root (/) file system or any other file system fills up, you will see the following message in the console window:

.... file system full

There are several reasons why a file system fills up. The following sections describe several scenarios for recovering from a full file system. For information on routinely cleaning out old and unused files to prevent full file systems, see Chapter 16.

File System Fills Up Because a Large File or Directory Was Created

<table>
<thead>
<tr>
<th>Reason Error Occurred</th>
<th>How to Fix the Problem</th>
</tr>
</thead>
<tbody>
<tr>
<td>Someone accidentally copied a file or directory to the wrong location. This also happens when an application crashes and writes a large core file into the file system.</td>
<td>Log in as superuser and use the ls -tl command in the specific file system to identify which large file is newly created and remove it. For information on removing core files, see “How to Find and Delete core Files” on page 232.</td>
</tr>
</tbody>
</table>
A TMPFS File System is Full Because the System Ran Out of Memory

<table>
<thead>
<tr>
<th>Reason Error Occurred</th>
<th>How to Fix the Problem</th>
</tr>
</thead>
<tbody>
<tr>
<td>This can occur if TMPFS is trying to write more than it is allowed or some current processes are using a lot of memory.</td>
<td>For information on recovering from tmpfs-related error messages, see tmpfs(7FS).</td>
</tr>
</tbody>
</table>

What to Do if File ACLs Are Lost After Copy or Restore

<table>
<thead>
<tr>
<th>Reason Error Occurred</th>
<th>How to Fix the Problem</th>
</tr>
</thead>
<tbody>
<tr>
<td>If files or directories with ACLs are copied or restored into the /tmp directory, the ACL attributes are lost. The /tmp directory is usually mounted as a temporary file system, which doesn’t support UFS file system attributes such as ACLs.</td>
<td>Copy or restore files into the /var/tmp directory instead.</td>
</tr>
</tbody>
</table>

Troubleshooting Backup Problems

This section describes some basic troubleshooting techniques to use when backing up and restoring data.

The root (/) File System Fills Up After You Back Up a File System

You back up a file system, and the root (/) file system fills up. Nothing is written to the media, and the ufsdump command prompts you to insert the second volume of media.
<table>
<thead>
<tr>
<th>Reason Error Occurred</th>
<th>How to Fix the Problem</th>
</tr>
</thead>
<tbody>
<tr>
<td>If you used an invalid destination device name with the -f option, the ufsdump command wrote to a file in the /dev directory of the root (/) file system, filling it up. For example, if you typed /dev/rmt/st0 instead of /dev/rmt/0, the backup file /dev/rmt/st0 was created on the disk rather than being sent to the tape drive.</td>
<td>Use the ls -tl command in the /dev directory to identify which file is newly created and abnormally large, and remove it.</td>
</tr>
</tbody>
</table>

Make Sure the Backup and Restore Commands Match

You can only use the ufsrestore command to restore files backed up with the ufsdump command. If you back up with the tar command, restore with the tar command. If you use the ufsrestore command to restore a tape that was written with another command, an error message tells you that the tape is not in ufsdump format.

Check to Make Sure You Have the Right Current Directory

It is easy to restore files to the wrong location. Because the ufsdump command always copies files with full path names relative to the root of the file system, you should usually change to the root directory of the file system before running the ufsrestore command. If you change to a lower-level directory, after you restore the files you will see a complete file tree created under that directory.

Interactive Commands

When you use the interactive command, a ufsrestore> prompt is displayed, as shown in this example:

```
# ufsrestore ivf /dev/rmt/0
Verify volume and initialize maps
Media block size is 126
Dump date: Thu Aug 30 10:13:46 2001
Dumped from: the epoch
Level 0 dump of /export/home on starbug:/dev/dsk/c0t0d0s7
Label: none
Extract directories from tape
Initialize symbol table.
ufsrestore >
```
At the `ufsrestore>` prompt, you can use the commands listed on “UFS Backup and Restore Commands (Reference)” in System Administration Guide: Basic Administration to find files, create a list of files to be restored, and restore them.
Troubleshooting File Access Problems (Tasks)

This chapter provides information on resolving file access problems such as those related to incorrect permissions and search paths.

This is a list of troubleshooting topics in this chapter.

- “Solving Problems With Search Paths (Command not found)” on page 393
- “Solving File Access Problems” on page 396
- ”Recognizing Problems With Network Access” on page 396

Users frequently experience problems, and call on a system administrator for help, because they cannot access a program, a file, or a directory that they could previously use. Whenever you encounter such a problem, investigate one of three areas:

- The user’s search path may have been changed, or the directories in the search path may not be in the proper order.
- The file or directory may not have the proper permissions or ownership.
- The configuration of a system accessed over the network may have changed.

This chapter briefly describes how to recognize problems in each of these three areas and suggests possible solutions.

Solving Problems With Search Paths (Command not found)

A message of Command not found indicates one of the following:

- The command is not available on the system.
- The command directory is not in the search path.
To fix a search path problem, you need to know the pathname of the directory where the command is stored.

If the wrong version of the command is found, a directory that has a command of the same name is in the search path. In this case, the proper directory may be later in the search path or may not be present at all.

You can display your current search path by using the `echo $PATH` command. For example:

```
$ echo $PATH
/home/kryten/bin:/sbin:/usr/sbin:/usr/bin:/usr/dt:/usr/dist/exe
```

Use the `which` command to determine whether you are running the wrong version of the command. For example:

```
$ which acroread
/usr/doctools/bin/acroread
```

Note – The `which` command looks in the `.cshrc` file for path information. The `which` command might give misleading results if you execute it from the Bourne or Korn shell and you have a `.cshrc` file than contains aliases for the `which` command. To ensure accurate results, use the `which` command in a C shell, or, in the Korn shell, use the `whence` command.

How to Diagnose and Correct Search Path Problems

1. Display the current search path to verify that the directory for the command is not in your path or that it isn’t misspelled.

```
$ echo $PATH
```

2. Check the following:
   - Is the search path correct?
   - Is the search path listed before other search paths where another version of the command is found?
   - Is the command in one of the search paths?

   If the path needs correction, go to step 3. Otherwise, go to step 4.

3. Add the path to the appropriate file, as shown in this table.
<table>
<thead>
<tr>
<th>Shell</th>
<th>File Where Path Is Located</th>
<th>Use this Command to Activate The Path</th>
</tr>
</thead>
<tbody>
<tr>
<td>Bourne and Korn</td>
<td>.profile</td>
<td>$ ./.profile</td>
</tr>
<tr>
<td>C</td>
<td>.cshrc</td>
<td>hostname% source .cshrc</td>
</tr>
<tr>
<td></td>
<td>.login</td>
<td>hostname% source .login</td>
</tr>
</tbody>
</table>

4. Activate the new path as follows:

<table>
<thead>
<tr>
<th>Shell</th>
<th>File Where Path Is Located</th>
<th>Use this Command to Activate The Path</th>
</tr>
</thead>
<tbody>
<tr>
<td>Bourne and Korn</td>
<td>.profile</td>
<td>$ ./.profile</td>
</tr>
<tr>
<td>C</td>
<td>.cshrc</td>
<td>hostname% source .cshrc</td>
</tr>
<tr>
<td></td>
<td>.login</td>
<td>hostname% source .login</td>
</tr>
</tbody>
</table>

5. Verify the new path.

$ which command

---

Example—Diagnosing and Correcting Search Path Problems

This example shows that the mytool executable is not in any of the directories in the search path using the which command.

venus% mytool
mytool: Command not found
venus% which mytool
no mytool in /sbin /usr/sbin /usr/bin /etc /home/ignatz/bin .
venus% echo $PATH
/sbin /usr/sbin /usr/bin /etc /home/ignatz/bin
venus% vi -.cshrc
(Add appropriate command directory to the search path)
venus% source .cshrc
venus% mytool

If you cannot find a command, look at the man page for its directory path. For example, if you cannot find the lpsched command (the lp printer daemon), lpsched(1M) tells you the path is /usr/lib/lp/lpsched.
Solving File Access Problems

When users cannot access files or directories that they previously could access, the permissions or ownership of the files or directories probably has changed.

Changing File and Group Ownerships

Frequently, file and directory ownerships change because someone edited the files as superuser. When you create home directories for new users, be sure to make the user the owner of the dot (.) file in the home directory. When users do not own “.” they cannot create files in their own home directory.

Access problems can also arise when the group ownership changes or when a group of which a user is a member is deleted from the /etc/group database.

For information about how to change the permissions or ownership of a file that you are having problems accessing, see “Securing Files (Tasks)” in System Administration Guide: Security Services.

Recognizing Problems With Network Access

If users have problems using the rcp remote copy command to copy files over the network, the directories and files on the remote system may have restricted access by setting permissions. Another possible source of trouble is that the remote system and the local system are not configured to allow access.

See “Strategies for NFS Troubleshooting” in System Administration Guide: Resource Management and Network Services for information about problems with network access and problems with accessing systems through AutoFS.
Troubleshooting Printing Problems (Tasks)

This chapter explains how to troubleshoot printing problems that might occur when you set up or maintain printing services.

This is a list of the step-by-step instructions in this chapter.

- “How to Troubleshoot No Printer Output” on page 403
- “How to Troubleshoot Incorrect Output” on page 409
- “How to Unhang the LP Print Service” on page 413
- “How to Troubleshoot an Idle (Hung) Printer” on page 413
- “How to Resolve Conflicting Printer Status Messages” on page 415

For information about printing and the LP print service, see Chapter 2.

Tips on Troubleshooting Printing Problems

Sometimes after setting up a printer, you find that nothing prints. Or, you might get a little farther in the process: something prints, but it is not what you expect, the output is incorrect or illegible. Then, when you get past these problems, other problems might occur, such as:

- LP commands hanging
- Printers becoming idle
- Users getting conflicting messages

Note – Although many of the suggestions in this chapter are relevant to parallel printers, they are geared toward the more common serial printers.
Troubleshooting No Output (Nothing Prints)

When nothing prints, there are three general areas to check:

- The printer hardware
- The network
- The LP print service

If you get a banner page, but nothing else, this is a special case of incorrect output. See “Troubleshooting Incorrect Output” on page 399.

Check the Hardware

The hardware is the first area to check. As obvious as it sounds, you should make sure that the printer is plugged in and turned on. In addition, you should refer to the manufacturer’s documentation for information about hardware settings. Some computers use hardware switches that change the characteristics of a printer port.

The printer hardware includes the printer, the cable that connects it to the computer, and the ports into which the cable plugs at each end. As a general approach, you should work your way from the printer to the computer. Check the printer. Check where the cable connects to the printer. Check the cable. Check where the cable connects to the computer.

Check the Network

Problems are more common with remote print requests that are going from a print client to a print server. You should make sure that network access between the print server and print clients is enabled.

If the network is running the Network Information Service Plus (NIS+), see *System Administration Guide: Naming and Directory Services (FNS and NIS+)* for instructions to enable access between systems. If the network is not running the Network Information Service (NIS) or NIS+, before you set up print servers and print clients, include the Internet address and system name for each client system in the /etc/hosts file on the print server. Also, the IP address and system name for the print server must be included in the /etc/hosts file of each print client system.

Check the LP Print Service

For printing to work, the LP scheduler must be running on both the print server and print client. If it is not running, you need to start it using the /usr/lib/lp/lpsched command. If you have trouble starting the scheduler, see “How to Restart the Print Scheduler” on page 77.
In addition to the scheduler running, a printer must be enabled and accepting requests before it will produce any output. If the LP print service is not accepting requests for a printer, the submitted print requests are rejected. Usually, in that instance, the user receives a warning message after submitting a print request. If the LP print service is not enabled for a printer, print requests remain queued on the system until the printer is enabled.

In general, you should analyze a printing problem as follows:

- Follow the path of the print request step-by-step.
- Examine the status of the LP print service at each step.
  - Is the configuration correct?
  - Is the printer accepting requests?
  - Is the printer enabled to process requests?
- If the request is hanging on transmission, set up `lpr.debug` in `syslog.conf` to display the flow.
- If the request is hanging locally, examine the `lpsched` log (`/var/lp/logs/lpsched`).
- If the request is hanging locally, have notification of the printer device errors (faults) mailed to you, and re-enable the printer.

The procedures found in “Troubleshooting Printing Problems” on page 403 use this strategy to help you troubleshoot various problems with the LP print service.

**Troubleshooting Incorrect Output**

If the printer and the print service software are not configured correctly, the printer might print, but it might provide output that is not what you expect.

**Check the Printer Type and File Content Type**

If you used the wrong printer type when you set up the printer with the LP print service, inappropriate printer control characters can be sent to the printer. The results are unpredictable: nothing might print, the output might be illegible, or the output might be printed in the wrong character set or font.

If you specified an incorrect file content type, the banner page might print, but that is all. The file content types specified for a printer indicate the types of files the printer can print directly, without filtering. When a user sends a file to the printer, the file is sent directly to the printer without any attempt to filter it. The problem occurs if the printer cannot handle the file content type.
When setting up print clients, you increase the chance for a mistake because the file content types must be correct on both the print server and the print client. If you set up the print client as recommended with any as the file content type, files are sent directly to the print server and the print server determines the need for filtering. Therefore, the file content types have to be specified correctly only on the server.

You can specify a file content on the print client to off-load filtering from the server to the client, but the content type must be supported on the print server.

Check the \texttt{stty} Settings

Many formatting problems can result when the default \texttt{stty} (standard terminal) settings do not match the settings required by the printer. The following sections describe what happens when some of the settings are incorrect.

Wrong Baud Settings

When the baud setting of the computer does not match the baud setting of the printer, usually you get some output, but it does not look like the file you submitted for printing. Random characters are displayed, with an unusual mixture of special characters and undesirable spacing. The default for the LP print service is 9600 baud.

\begin{quote}
\textbf{Note} – If a printer is connected by a parallel port, the baud setting is irrelevant.
\end{quote}

Wrong Parity Setting

Some printers use a parity bit to ensure that data received for printing has not been garbled during transmission. The parity bit setting for the computer and the printer must match. If they do not match, some characters either will not be printed at all, or will be replaced by other characters. In this case, the output looks approximately correct. The word spacing is all right and many letters are in their correct place. The LP print service does not set the parity bit by default.

Wrong Tab Settings

If the file contains tabs, but the printer expects no tabs, the printed output might contain the complete contents of the file, but the text might be jammed against the right margin. Also, if the tab settings for the printer are incorrect, the text might not have a left margin, it might run together, it might be concentrated to a portion of the page, or it might be incorrectly double-spaced. The default is for tabs to be set every eight spaces.
Wrong Return Setting

If the output is double-spaced, but it should be single-spaced, either the tab settings for the printer are incorrect or the printer is adding a line feed after each return. The LP print service adds a return before each line feed, so the combination causes two line feeds.

If the print zigzags down the page, the stty option onlcr that sends a return before every line feed is not set. The stty=onlcr option is set by default, but you might have cleared it while trying to solve other printing problems.

Troubleshooting Hung LP Commands

If you type any of the LP commands (such as lpsystem, lpadmin, or lpstat) and nothing happens (no error message, status information, or prompt is displayed), chances are something is wrong with the LP scheduler. Such a problem can usually be resolved by stopping and restarting the LP scheduler. See “How to Stop the Print Scheduler” on page 76 for instructions.

Troubleshooting Idle (Hung) Printers

You might find a printer that is idle, even though it has print requests queued to it. A printer might seem idle when it should not be for one of the following reasons:

- The current print request is being filtered.
- The printer has a fault.
- Networking problems might be interrupting the printing process.

Check the Print Filters

Slow print filters run in the background to avoid tying up the printer. A print request that requires filtering will not print until it has been filtered.

Check Printer Faults

When the LP print service detects a fault, printing resumes automatically, but not immediately. The LP print service waits about five minutes before trying again, and continues trying until a request is printed successfully. You can force a retry immediately by enabling the printer.

Check Network Problems

When printing files over a network, you might encounter the following types of problems:

- Requests sent to print servers might back up in the client system (local) queue.
Requests sent to print servers might back up in the print server (remote) queue.

Print Requests Backed Up in the Local Queue

Print requests submitted to a print server might back up in the client system queue for the following reasons:

- The print server is down.
- The printer is disabled on the print server.
- The network between the print client and print server is down.
- Underlying network software was not set up properly.

While you are tracking the source of the problem, you should stop new requests from being added to the queue. See “How to Accept or Reject Print Requests for a Printer” on page 94 for more information.

Print Requests Backed Up in the Remote Queue

If print requests back up in the print server queue, the printer has probably been disabled. When a printer is accepting requests, but not processing them, the requests are queued to print. Unless there is a further problem, once the printer is enabled, the print requests in the queue should print.

Troubleshooting Conflicting Status Messages

A user might enter a print request and be notified that the client system has accepted it, then receive mail from the print server that the print request has been rejected. These conflicting messages might occur for the following reasons:

- The print client might be accepting requests, while the print server is rejecting requests.
- The definition of the printer on the print client might not match the definition of that printer on the print server. More specifically, the definitions of the print job components, like filters, character sets, print wheels, or forms are not the same on the client and server systems.

You should check that identical definitions of these job components are registered on both the print clients and print servers so that local users can access printers on the print servers.
Troubleshooting Printing Problems

This section contains step-by-step instructions that explain:

- How to troubleshoot no output
- How to troubleshoot incorrect output
- How to unhang the LP commands
- How to troubleshoot an idle (hung) printer
- How to resolve conflicting status messages

▼ How to Troubleshoot No Printer Output

This task includes the following troubleshooting procedures to try when you submit a print request to a printer and nothing prints:

- Check the hardware (“How to Check the Printer Hardware” on page 403).
- Check the network (“How To Check the Printer Network Connections” on page 404).
- Check the LP print service basic functions (“How to Check the Basic Functions of the LP Print Service” on page 405).
- Check printing from a Solaris print client to a Solaris print server (“How to Check Printing From a Solaris Print Client to a Solaris Print Server” on page 408).

Try the first three procedures in the order in which they are listed, before going to the print client/server section. However, if the banner page prints, but nothing else does, turn to the instructions under “How to Troubleshoot Incorrect Output” on page 409.

▼ How to Check the Printer Hardware

1. Check that the printer is plugged in and turned on.

2. Check that the cable is connected to the port on the printer and to the port on the system or server.

3. Make sure that the cable is the correct cable and that it is not defective.

   Refer to the manufacturer’s documentation. If the printer is connected to a serial port, verify that the cable supports hardware flow control. A NULL modem adapter supports this. The following table shows the pin configuration for NULL modem cables.
4. Check that any hardware switches for the ports are set properly.
   See the printer documentation for the correct settings.

5. Check that the printer is operational.
   Use the printer’s self-test feature, if the printer has one. Check the printer documentation for information about printer self-testing.

6. Check that the baud settings for the computer and the printer are correct.
   If the baud settings are not the same for both the computer and the printer, sometimes nothing will print, but more often you get incorrect output. For instructions, see “How to Troubleshoot Incorrect Output” on page 409.

▼ How To Check the Printer Network Connections

1. Check that the network link between the print server and the print client is set up correctly.

   print_client# ping print_server
   print_server is alive
   print_server# ping print_client
   print_client not available

   If the message says the system is alive, you know you can reach the system, so the network is all right. The message also tells you that either a name service or the local /etc/hosts file has translated the host (system) name you entered into an IP address; otherwise, you would need to enter the IP address.

   If you get a not available message, try to answer the following questions: How is NIS or NIS+ set up at your site? Do you need to take additional steps so that print servers and print clients can communicate with one another? If your site is not
running NIS or NIS+, have you entered the IP address for the print server in each print client's /etc/hosts file, and entered all print client IP addresses in the /etc/hosts file of the print server?

2. (On a SunOS 5.0–5.1 print server only) Check that the listen port monitor is configured correctly.

3. (On a SunOS 5.0–5.1 print server only) Check that the network listen services are registered with the port monitor on the print server.

▼ How to Check the Basic Functions of the LP Print Service

This procedure uses the printer luna as an example of checking basic LP print service functions.

1. On the print server, make sure that the LP print service is running.
   a. Check whether the LP scheduler is running.
      
      # lpstat -r
      
      scheduler is running

   b. If the scheduler is not running, become superuser or lp, and start the scheduler.
      
      # /usr/lib/lp/lpsched
      
      If you have trouble starting the scheduler, see “How to Unhang the LP Print Service” on page 413.

2. On both the print server and print client, make sure that the printer is accepting requests.
   a. Check that the printer is accepting requests.
      
      # lpstat -a
      
      mars accepting requests since Jul 12 14:23 2001
      luna not accepting requests since Jul 12 14:23 2001
      unknown reason
      
      This command verifies that the LP system is accepting requests for each printer configured for the system.

   b. If the printer is not accepting requests, become superuser or lp, and allow the printer to accept print requests.
      
      # accept luna
      
      The specified printer now accepts requests.

3. On both the print server and print client, make sure that the printer is enabled to print submitted print requests.
a. Check that the printer is enabled.

```
# lpstat -p luna
unknown reason
```

This command displays information about printer status. You can omit the printer name to obtain information about all printers set up for the system. The following example shows a printer that is disabled.

b. If the printer is disabled, become superuser or `lp`, and enable the printer.

```
# enable luna
printer "luna" now enabled.
The specified printer is enabled to process print requests.
```

4. On the print server, make sure that the printer is connected to the correct serial port.

a. Check that the printer is connected to the correct serial port.

```
# lpstat -t
scheduler is running
system default destination: luna
device for luna: /dev/term/a
```

The message `device for printer-name` shows the port address. Is the cable connected to the port to which the LP print service says is connected? If the port is correct, skip to Step 5.

b. Become superuser or `lp`.

c. Change the file ownership of the device file that represents the port.

```
# chown lp device-filename
```

This command assigns the special user `lp` as the owner of the device file. In this command, `device-filename` is the name of the device file.

d. Change the permissions on the printer port device file.

```
# chmod 600 device-filename
```

This command allows only superuser or `lp` to access the printer port device file.

5. On both the print server and print client, make sure that the printer is configured properly.

a. Check that the printer is configured properly.

```
# lpstat -p luna -l
printer luna is idle. enabled since Jul 12 14:24 2001. available
Content types: postscript
Printer types: PS
```

The above example shows a PostScript printer that is configured properly, and that is available to process print requests. If the printer type and file content type are
correct, skip to Step 6.

b. If the printer type or file content type is incorrect, try setting the print type to unknown and the content type to any on the print client.

   # lpadmin -p printer-name -T printer-type -I file-content-type

6. On the print server, make sure that the printer is not faulted.

   a. Check that the printer is not waiting because of a printer fault.

      # lpadmin -p printer-name -F continue

      This command instructs the LP print service to continue if it is waiting because of a fault.

   b. Force an immediate retry by re-enabling the printer.

      # enable printer-name

   c. (Optional) Instruct the LP print service to enable quick notification of printer faults.

      # lpadmin -p printer-name -A 'write root'

      This command instructs the LP print service to set a default policy of writing root, sending the printer fault message to the terminal on which root is logged in, if the printer fails. This might help you get quick notification of faults as you try to fix the problem.

7. Make sure that the printer is not set up incorrectly as a login terminal.

   **Note** – It is easy to mistakenly set up a printer as a login terminal, so be sure to check this possibility even if you think it does not apply.

   a. Look for the printer port entry in the `ps -ef` command output.

      # ps -ef

      root  169  167  0 Apr 04 0:08 /usr/lib/saf/listen tcp
      root  939   1  0 19:30:47 0:02 /usr/lib/lpsched
      root  859  858  0 19:18:54 term/a 0:01 /bin/sh -c \
      /etc/lp/interfaces/luna
      luna-294 rocketsmith *passwd

      In the output from this command, look for the printer port entry. In the above example, port `/dev/term/a` is set up incorrectly as a login terminal. You can tell by the "passwd" information at the end of the line. If the port is set correctly, skip the last steps in this procedure.

   b. Cancel the print request(s).

      # cancel request-id
In this command, *request-id* is the request ID number for a print request to be canceled.

c. Set the printer port to be a nonlogin device.
   
   ```
   # lpadmin -p printer-name -h
   ```

d. Check the `ps -ef` command output to verify that the printer port is no longer a login device.
   If you do not find the source of the printing problem in the basic LP print service functions, continue to one of the following procedures for the specific client/server case that applies.

▼ How to Check Printing From a Solaris Print Client to a Solaris Print Server

1. Check the basic functions of the LP print service on the print server, if you have not done so already.
   For instructions on checking basic functions, see “How to Check the Basic Functions of the LP Print Service” on page 405. Make sure that the printer works locally before trying to figure out why nothing prints when a request is made from a print client.

2. Check the basic functions of the LP print service on the print client, if you have not done so already.
   On the print client, the printer has to be enabled and accepting requests before any request from the client will print.

   **Note** – For most of the following steps, you must be logged in as root or `lp`.

3. Make sure that the print server is accessible.
   
   a. On the print client, send an “are you there?” request to the print server.
      
      ```
      print_client# ping print_server
      ```
      If you receive the message `print_server` not available, you might have a network problem.

4. Verify that the print server is operating properly.
   
   ```
   # lpstat -t luna
   scheduler is running
   system default destination: luna
device for luna: /dev/term/a
luna accepting requests since Jul 12 14:26 2001
available.
   ```
The above example shows a print server up and running.

5. If the print server is not operating properly, go back to step 1.

▼ How to Troubleshoot Incorrect Output

1. Log in as superuser or `lp`.

2. Make sure that the printer type is correct.

An incorrect printer type might cause incorrect output. For example, if you specify printer type `PS` and the pages print in reverse order, try printer type `PSR`. (These type names must be in uppercase.) Also, an incorrect printer type might cause missing text, illegible text, or text with the wrong font. To determine the printer type, examine the entries in the `terminfo` database. For information on the structure of the `terminfo` database, see “Printer Type” on page 44.

a. On the print server, display the printer’s characteristics.

```bash
$ lpstat -p luna -l
printer luna is idle. enabled since Thu Jul 12 15:02:32 ...
Form mounted:
  Content types: postscript
Printer types: PS
Description:
  Connection: direct
  Interface: /usr/lib/lp/model/standard
  After fault: continue
Users allowed:
  (all)
Forms allowed:
  (none)
Banner not required
Character sets:

Default pitch:
Default page size: 80 wide 66 long
Default port settings:

$ 
```

b. Consult the printer manufacturer’s documentation to determine the printer model.

c. If the printer type is not correct, change it with Solaris Print Manager’s Modify Printer Properties window, or use the following `lpadmin` command.

```bash
# lpstat -p printer-name -T printer-type
```

On the print client, the printer type should be unknown. On the print server, the printer type must match a `terminfo` entry that is defined to support the model of printer you have. If there is no `terminfo` entry for the type of printer you have,
3. If the banner page prints, but there is no output for the body of the document, check the file content types.

File content types specified for a printer indicate the types of files the printer can print directly without filtering. An incorrect file content type causes filtering to be bypassed when it might be needed.

a. Note the information on file content type that was supplied in the previous step by the `lpstat` command.

On the print client, the file content type should be `any`, unless you have good reason to specify one or more explicit content types. If a content is specified on the client, filtering is done on the print client, rather than the print server. In addition, content types on the client must match the content types specified on the print server, which in turn must reflect the capabilities of the printer.

b. Consult your printer manufacturer’s documentation to determine which types of files the printer can print directly.

The names you use to refer to these types of files do not have to match the names used by the manufacturer. However, the names you use must agree with the names used by the filters known to the LP print service.

c. If the file content type is not correct, change it with Solaris Print Manager’s Modify Printer Properties window, or the following `lpadmin` command.

```
# lpadmin -p printer-name -I file-content-type(s)
```

Run this command on either the print client, or print server, or both, as needed. Try `-I any` on the print client, and `-I ""` on the print server. The latter specifies a null file content type list, which means an attempt should be made to filter all files, because the printer can directly print only files that exactly match its printer type. This combination is a good first choice when files are not printing. If it works, you might want to try specifying explicit content types on the print server to reduce unnecessary filtering. For a local PostScript printer, you should use `postscript`, or `postscript,simple`, if the printer supports these types. Be aware that PS and PSR are not file content types; they are printer types.

If you omit `-I`, the file content list defaults to `simple`. If you use the `-I` option and want to specify file content types in addition to `simple`, `simple` must be included in the list.

When specifying multiple file content types, separate the names with commas. Or you can separate names with spaces and enclose the list in quotation marks. If you specify `any` as the file content type, no filtering will be done and only file types that can be printed directly by the printer should be sent to it.

4. Check that the print request does not bypass filtering needed to download fonts.

If a user submits a print request to a PostScript printer with the `lp -T PS` command, no filtering is done. Try submitting the request with the `lp -T postscript` command to force filtering, which might result in the downloading of non-resident...
5. Make sure that the `stty` settings for the printer port are correct.

   a. Read the printer documentation to determine the correct `stty` settings for the printer port.

   **Note** – If a printer is connected to a parallel or USB port, the baud setting is irrelevant.

   b. Examine the current settings by using the `stty` command.

   ```
   # stty -a < /dev/term/a
   speed 9600 baud;
   rows = 0; columns = 0; ypixels = 0; xpixels = 0;
   eucw 1:0:0:0, scrw 1:0:0:0
   intr = ^c; quit = ^|; erase = ^?; kill = ^u;
   eof = ^d; eol = <undef>; eol2 = <undef>; swtch = <undef>;
   start = ^q; stop = ^s; susp = ^z; dsusp = ^y;
   rprnt = ^r; flush = ^o; weare = ^w; lnext = ^v;

   #
   ```

   This command shows the current `stty` settings for the printer port.

   The following table shows the default `stty` options used by the LP print service’s standard printer interface program.

   **TABLE 31-2 Default stty Settings Used by the Standard Interface Program**

<table>
<thead>
<tr>
<th>Option</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>-9600</td>
<td>Set baud rate to 9600</td>
</tr>
<tr>
<td>-cs8</td>
<td>Set 8-bit bytes</td>
</tr>
<tr>
<td>-cstopb</td>
<td>Send one stop bit per byte</td>
</tr>
<tr>
<td>-parity</td>
<td>Do not generate parity</td>
</tr>
<tr>
<td>-ixon</td>
<td>Enable XON/XOFF (also known as START/STOP or DC1/DC3)</td>
</tr>
<tr>
<td>-opost</td>
<td>Do “output post-processing” using all the settings that follow in this table</td>
</tr>
<tr>
<td>-olcuc</td>
<td>Do not map lowercase to uppercase</td>
</tr>
</tbody>
</table>
### TABLE 31-2 Default stty Settings Used by the Standard Interface Program (Continued)

<table>
<thead>
<tr>
<th>Option</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>-onlcr</td>
<td>Change line feed to carriage return/line feed</td>
</tr>
<tr>
<td>-ocrnl</td>
<td>Do not change carriage returns into line feeds</td>
</tr>
<tr>
<td>-onocr</td>
<td>Output carriage returns even at column 0</td>
</tr>
<tr>
<td>-n10</td>
<td>No delay after line feeds</td>
</tr>
<tr>
<td>-cr0</td>
<td>No delay after carriage returns</td>
</tr>
<tr>
<td>-tab0</td>
<td>No delay after tabs</td>
</tr>
<tr>
<td>-bs0</td>
<td>No delay after backspaces</td>
</tr>
<tr>
<td>-vt0</td>
<td>No delay after vertical tabs</td>
</tr>
<tr>
<td>-ff0</td>
<td>No delay after form feeds</td>
</tr>
</tbody>
</table>

C. Change the stty settings.

```bash
# lpadmin -p printer-name -o "stty= options"
```

Use the following table to choose stty options to correct various problems affecting print output.

### TABLE 31-3 stty Options to Correct Print Output Problems

<table>
<thead>
<tr>
<th>stty Values</th>
<th>Result</th>
<th>Possible Problem From Incorrect Setting</th>
</tr>
</thead>
<tbody>
<tr>
<td>110, 300, 600, 1200, 1800, 2400, 4800, 9600, 19200, 38400</td>
<td>Sets baud rate to the specified value (enter only one baud rate)</td>
<td>Random characters and special characters might be printed and spacing might be inconsistent</td>
</tr>
<tr>
<td>oddp</td>
<td>Sets odd parity</td>
<td>Missing or incorrect characters appear randomly</td>
</tr>
<tr>
<td>evenp</td>
<td>Sets even parity</td>
<td></td>
</tr>
<tr>
<td>-parity</td>
<td>Sets no parity</td>
<td></td>
</tr>
<tr>
<td>-tabs</td>
<td>Sets no tabs</td>
<td>Text is jammed against right margin</td>
</tr>
<tr>
<td>tabs</td>
<td>Sets tabs every eight spaces</td>
<td>Text has no left margin, is run together, or is jammed together</td>
</tr>
<tr>
<td>-onlcr</td>
<td>Sets no carriage return at the beginning of line(s)</td>
<td>Incorrect double spacing</td>
</tr>
<tr>
<td>onlcr</td>
<td>Sets carriage return at beginning of line(s)</td>
<td>The print zigzags down the page</td>
</tr>
</tbody>
</table>
You can change more than one option setting by enclosing the list of options in single quotation marks and separating each option with spaces. For example, suppose the printer requires you to enable odd parity and set a 7-bit character size. You would type a command similar to that shown in the following example:

```
# lpadmin -p neptune -o "stty='parenb parodd cs7'"
```

The `stty` option `parenb` enables parity checking/generation, `parodd` sets odd parity generation, and `cs7` sets the character size to 7 bits.

6. **Verify that the document prints correctly.**

```
# lp -d printer-name filename
```

**▼ How to Unhang the LP Print Service**

1. Log in as superuser or lp.
2. Stop the LP print service.
   ```
   # /etc/init.d/lp stop
   ```
3. Restart the LP print service.
   ```
   # /etc/init.d/lp start
   ```
   The LP print service should restart. If you are having trouble restarting the scheduler, see “How to Restart the Print Scheduler” on page 77.

**▼ How to Troubleshoot an Idle (Hung) Printer**

This task includes a number of procedures to use when a printer appears idle but it should not be. It makes sense to try the procedures in order, but the order is not mandatory.

**▼ How to Check That the Printer is Ready to Print**

1. **Display printer status information.**
   ```
   # lpstat -p printer-name
   ```
   The information displayed shows you whether the printer is idle or active, enabled or disabled, or available or not accepting print requests. If everything looks all right, continue with other procedures in this section. If you cannot run the `lpstat` command, see “How to Unhang the LP Print Service” on page 413.
2. **If the printer is not available (not accepting requests), allow the printer to accept requests.**
# accept printer-name
The printer begins to accept requests into its print queue.

3. **If the printer is disabled, re-enable it.**

   # enable printer-name
   This command re-enables the printer so that it will act on the requests in its queue.

▼ **How to Check for Print Filtering**

Check for print filtering by using the `lpstat -o` command.

```
$ lpstat -o luna
luna-10    fred   1261   Mar 12 17:34 being filtered
luna-11    iggy   1261   Mar 12 17:36 on terra
luna-12    jack   1261   Mar 12 17:39 on terra
$
```

See if the first waiting request is being filtered. If the output looks like the above example, the file is being filtered; the printer is not hung, it just is taking a while to process the request.

▼ **How to Resume Printing After a Printer Fault**

1. **Look for a message about a printer fault and try to correct the fault if there is one.**
   Depending on how printer fault alerts have been specified, messages might be sent to root by email or written to a terminal on which root is logged in.

2. **Re-enable the printer.**

   # enable printer-name
   If a request was blocked by a printer fault, this command will force a retry. If this command does not work, continue with other procedures in this section.

▼ **How to Send Print Requests to a Remote Printer When They Back Up in the Local Queue**

1. **On the print client, stop further queuing of print requests to the print server.**

   # reject printer-name

2. **On the print client, send an “are you there?” request to the print server.**

   ```
   print_client# ping print_server
   print_server is alive
   ```
If you receive the message `print_server not available`, you might have a network problem.

3. After you fix the above problem, allow new print requests to be queued.
   
   ```
   # accept printer-name
   ```

4. If necessary, re-enable the printer.
   
   ```
   # enable printer-name
   ```

▼ How to Free Print Requests From a Print Client That Back Up in the Print Server Queue

1. On the print server, stop further queuing of print requests from any print client to the print server.
   
   ```
   # reject printer-name
   ```

2. Display the `lpsched` log file.
   
   ```
   # more /var/lp/logs/lpsched
   ```

   The information displayed might help you pinpoint what is preventing the print requests from the print client to the print server from being printed.

3. After you fix the problem, allow new print requests to be queued.
   
   ```
   # accept printer-name
   ```

4. If necessary, re-enable the printer on the print server.
   
   ```
   # enable printer-name
   ```

▼ How to Resolve Conflicting Printer Status Messages

1. On the print server, verify the printer is enabled and is accepting requests.
   
   ```
   # lpstat -p printer-name
   ```

   Users will see conflicting status messages when the print client is accepting requests, but the print server is rejecting requests.

2. On the print server, check that the definition of the printer on the print client matches the definition of the printer on the print server.
   
   ```
   # lpstat -p -l printer-name
   ```

   Look at the definitions of the print job components, like print filters, character sets, print wheels, and forms, to be sure they are the same on both the client and server systems so that local users can access printers on print server systems.
Resolving UFS File System Inconsistencies (Tasks)

This chapter describes the `fsck` error messages and the possible responses you can make to resolve the error messages.

This is a list of the information in this chapter.
- “General `fsck` Error Messages” on page 419
- “Initialization Phase `fsck` Messages” on page 420
- “Phase 1: Check Blocks and Sizes Messages” on page 423
- “Phase 1B: Rescan for More DUPS Messages” on page 426
- “Phase 2: Check Path Names Messages” on page 426
- “Phase 3: Check Connectivity Messages” on page 432
- “Phase 4: Check Reference Counts Messages” on page 434
- “Phase 5: Check Cylinder Groups Messages” on page 437
- “Cleanup Phase Messages” on page 438

For information about the `fsck` command and how to use it to check file system integrity, see “Checking UFS File System Consistency (Tasks)” in System Administration Guide: Basic Administration.

`fsck` Error Messages

Normally, the `fsck` command is run non-interactively to preen the file systems after an abrupt system halt in which the latest file system changes were not written to disk. Preening automatically fixes any basic file system inconsistencies and does not try to repair more serious errors. While preening a file system, the `fsck` command fixes the inconsistencies it expects from such an abrupt halt. For more serious conditions, the command reports the error and terminates.
When you run the `fsck` command interactively, it reports each inconsistency found and fixes innocuous errors. However, for more serious errors, the command reports the inconsistency and prompts you to choose a response. When you run the `fsck` command with the `-y` or `-n` options, your response is predefined as yes or no to the default response suggested by the `fsck` command for each error condition.

Some corrective actions will result in some loss of data. The amount and severity of data loss might be determined from the `fsck` diagnostic output.

The `fsck` command is a multipass file system check program. Each pass invokes a different phase of the `fsck` command with different sets of messages. After initialization, the `fsck` command performs successive passes over each file system, checking blocks and sizes, path names, connectivity, reference counts, and the map of free blocks (possibly rebuilding it). It also performs some cleanup.

The phases (passes) performed by the UFS version of the `fsck` command are:

- Initialization
- Phase 1 – Check blocks and sizes
- Phase 2 – Check path names
- Phase 3 – Check connectivity
- Phase 4 – Check reference counts
- Phase 5 – Check cylinder groups

The next sections describe the error conditions that might be detected in each phase, the messages and prompts that result, and possible responses you can make.

Messages that might appear in more than one phase are described in “General `fsck` Error Messages” on page 419. Otherwise, messages are organized alphabetically by the phases in which they occur.

The following table lists many of the abbreviations included in the `fsck` error messages.

<table>
<thead>
<tr>
<th>Abbreviation</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>BLK</td>
<td>Block number</td>
</tr>
<tr>
<td>DUP</td>
<td>Duplicate block number</td>
</tr>
<tr>
<td>DIR</td>
<td>Directory name</td>
</tr>
<tr>
<td>CG</td>
<td>Cylinder group</td>
</tr>
<tr>
<td>MTIME</td>
<td>Time file was last modified</td>
</tr>
<tr>
<td>UNREF</td>
<td>Unreferenced</td>
</tr>
</tbody>
</table>
Many of the messages also include variable fields, such as inode numbers, which are represented in this book by an italicized term, such as  *inode-number*. For example, this screen message:

**INCORRECT BLOCK COUNT I=2529**

is shown as follows:

**INCORRECT BLOCK COUNT I=inode-number**

## General `fsck` Error Messages

The error messages in this section might be displayed in any phase after initialization. Although they offer the option to continue, it is generally best to regard them as fatal. They reflect a serious system failure and should be handled immediately. When confronted with such a message, terminate the program by entering `n(o)`. If you cannot determine what caused the problem, contact your local service provider or another qualified person.

### CANNOT SEEK: BLK block-number (CONTINUE)

**Cause**

A request to move to a specified block number, *block-number*, in the file system failed. This message indicates a serious problem, probably a hardware failure.

If you want to continue the file system check, `fsck` will retry the move and display a list of sector numbers that could not be moved. If the block was part of the virtual memory buffer cache, `fsck` will terminate with a fatal I/O error message.

**Action**

If the disk is experiencing hardware problems, the problem will persist. Run `fsck` again to recheck the file system.

If the recheck fails, contact your local service provider or another qualified person.

### CANNOT READ: BLK block-number (CONTINUE)

**Cause**

A request to read a specified block number, *block-number*, in the file system failed. The message indicates a serious problem, probably a hardware failure.

If you want to continue the file system check, `fsck` will retry the read and display a list of sector numbers that could not be read. If the block was part of the virtual memory buffer cache, `fsck` will terminate with a fatal I/O error message. If `fsck` tries to write back one of the blocks on which the read failed, it will display the following message:

**WRITING ZERO`ED BLOCK sector-numbers TO DISK**

**Action**

If the disk is experiencing hardware problems, the problem will persist. Run `fsck` again to recheck the file system. If the recheck fails, contact your local service provider or another qualified person.
CANNOT WRITE: BLK block-number (CONTINUE)

Cause
A request to write a specified block number, block-number, in the file system failed.

If you continue the file system check, fsck will retry the write and display a list of sector numbers that could not be written. If the block was part of the virtual memory buffer cache, fsck will terminate with a fatal I/O error message.

Action
The disk might be write-protected. Check the write-protect lock on the drive. If the disk has hardware problems, the problem will persist. Run fsck again to recheck the file system. If the write-protect is not the problem or the recheck fails, contact your local service provider or another qualified person.

Initialization Phase fsck Messages

In the initialization phase, command-line syntax is checked. Before the file system check can be performed, fsck sets up tables and opens files.

The messages in this section relate to error conditions resulting from command-line options, memory requests, the opening of files, the status of files, file system size checks, and the creation of the scratch file. All such initialization errors terminate fsck when it is preening the file system.

Can’t roll the log for device-name.

DISCARDING THE LOG MAY DISCARD PENDING TRANSACTIONS.
DISCARD THE LOG AND CONTINUE?

Cause
fsck was unable to flush the transaction log of a logging UFS file system prior to checking the file system for errors.

Action
Answering yes means the file system operations that were in the log, but had not been applied to the file system, are lost. In this case, fsck runs the same checks it always runs and asks the following question in phase 5:

FREE BLK COUNT(S) WRONG IN SUPERBLK (SALVAGE)

Answering yes at this point reclaims the blocks that were used for the log. The next time the file system is mounted with logging enabled, the log will be recreated.

Answering no preserves the log and exits, but the file system isn’t mountable.

bad inode number inode-number to ginode

Cause
An internal error occurred because of a nonexistent inode inode-number. fsck exits.
Action
Contact your local service provider or another qualified person.

cannot alloc size-of-block map bytes for blockmap
cannot alloc size-of-free map bytes for freemap
cannot alloc size-of-state map bytes for statemap
cannot alloc size-of-lncntp bytes for lncntp

Cause
Request for memory for its internal tables failed. fsck terminates. This message indicates a serious system failure that should be handled immediately. This condition might occur if other processes are using a very large amount of system resources.

Action
Killing other processes might solve the problem. If not, contact your local service provider or another qualified person.

Can’t open checklist file: filename

Cause
The file system checklist file filename (usually /etc/vfstab) cannot be opened for reading. fsck terminates.

Action
Check if the file exists and if its access modes permit read access.

Can’t open filename

Cause
 fsck cannot open file system filename. When running interactively, fsck ignores this file system and continues checking the next file system given.

Action
Check to see if read and write access to the raw device file for the file system is permitted.

Can’t stat root

Cause
 fsck request for statistics about the root directory failed. fsck terminates.

Action
This message indicates a serious system failure. Contact your local service provider or another qualified person.

Can’t stat filename
Can’t make sense out of name filename

Cause
 fsck request for statistics about the file system filename failed. When running interactively, fsck ignores this file system and continues checking the next file system given.
Action
Check if the file system exists and check its access modes.

filename: (NO WRITE)

Cause
Either the -n option was specified or fsck could not open the file system filename for writing. When fsck is running in no-write mode, all diagnostic messages are displayed, but fsck does not attempt to fix anything.

Action
If -n was not specified, check the type of the file specified. It might be the name of a regular file.

IMPOSSIBLE MINFREE=percent IN SUPERBLOCK (SET TO DEFAULT)

Cause
The superblock minimum space percentage is greater than 99 percent or less than 0 percent.

Action
To set the minfree parameter to the default 10 percent, type y at the default prompt. To ignore the error condition, type n at the default prompt.

filename: BAD SUPER BLOCK: message
USE AN ALTERNATE SUPER-BLOCK TO SUPPLY NEEDED INFORMATION;
e.g., fsck[-f ufs] -o b=# [special ...]
where # is the alternate superblock. See fsck_ufs(1M)

Cause
The superblock has been corrupted.

Action
One of the following messages might be displayed:

CPG OUT OF RANGE
FRAGS PER BLOCK OR FRAGSIZE WRONG
INODES PER GROUP OUT OF RANGE
INOPB NONSENSICAL RELATIVE TO BSIZE
MAGIC NUMBER WRONG
NCG OUT OF RANGE
NCYL IS INCONSISTENT WITH NCG*CPG
NUMBER OF DATA BLOCKS OUT OF RANGE
NUMBER OF DIRECTORIES OUT OF RANGE
ROTATIONAL POSITION TABLE SIZE OUT OF RANGE
SIZE OF CYLINDER GROUP SUMMARY AREA WRONG
SIZE TOO LARGE
BAD VALUES IN SUPERBLOCK

Try to rerun fsck with an alternative superblock. Specifying block 32 is a good first choice. You can locate an alternative copy of the superblock by running the newfs -N command on the slice. Be sure to specify the -N option; otherwise, newfs overwrites the existing file system.

UNDEFINED OPTIMIZATION IN SUPERBLOCK (SET TO DEFAULT)
Cause
The superblock optimization parameter is neither OPT_TIME nor OPT_SPACE.

Action
To minimize the time to perform operations on the file system, type y at the SET TO DEFAULT prompt. To ignore this error condition, type n.

Phase 1: Check Blocks and Sizes Messages
This phase checks the inode list. It reports error conditions encountered while:
- Checking inode types
- Setting up the zero-link-count table
- Examining inode block numbers for bad or duplicate blocks
- Checking inode size
- Checking inode format

All errors in this phase except INCORRECT BLOCK COUNT, PARTIALLY TRUNCATED INODE, PARTIALLY ALLOCATED INODE, and UNKNOWN FILE TYPE terminate fsck when it is preening a file system.

These messages (in alphabetical order) might occur in phase 1:

block-number BAD I=inode-number

Cause
Inode inode-number contains a block number block-number with a number lower than the number of the first data block in the file system or greater than the number of the last block in the file system. This error condition might generate the EXCESSIVE BAD BLKS error message in phase 1 if inode inode-number has too many block numbers outside the file system range. This error condition generates the BAD/DUP error message in phases 2 and 4.

Action
N/A

BAD MODE: MAKE IT A FILE?

Cause
The status of a given inode is set to all 1s, indicating file system damage. This message does not indicate physical disk damage, unless it is displayed repeatedly after fsck -y has been run.

Action
Type y to reinitialize the inode to a reasonable value.

BAD STATE state-number TO BLKERR

Cause
An internal error has scrambled the fsck state map so that it shows the impossible value state-number. fsck exits immediately.
Action
Contact your local service provider or another qualified person.

block-number DUP I=inode-number

Cause
Inode inode-number contains a block number block-number, which is already claimed by the same or another inode. This error condition might generate the EXCESSIVE DUP BLKS error message in phase 1 if inode inode-number has too many block numbers claimed by the same or another inode. This error condition invokes phase 1B and generates the BAD/DUP error messages in phases 2 and 4.

Action
N/A

DUP TABLE OVERFLOW (CONTINUE)

Cause
There is no more room in an internal table in fsck containing duplicate block numbers. If the -o p option is specified, the program terminates.

Action
To continue the program, type y at the CONTINUE prompt. When this error occurs, a complete check of the file system is not possible. If another duplicate block is found, this error condition repeats. Increase the amount of virtual memory available (by killing some processes, increasing swap space) and run fsck again to recheck the file system. To terminate the program, type n.

EXCESSIVE BAD BLOCKS I=inode-number (CONTINUE)

Cause
Too many (usually more than 10) blocks have a number lower than the number of the first data block in the file system or greater than the number of the last block in the file system associated with inode inode-number. If the -o p (preen) option is specified, the program terminates.

Action
To continue the program, type y at the CONTINUE prompt. When this error occurs, a complete check of the file system is not possible. You should run fsck again to recheck the file system. To terminate the program, type n.

EXCESSIVE DUP BLKS I=inode-number (CONTINUE)

Cause
Too many (usually more than 10) blocks are claimed by the same or another inode or by a free-list. If the -o p option is specified, the program terminates.

Action
To continue the program, type y at the CONTINUE prompt. When this error occurs, a complete check of the file system is not possible. You should run fsck again to recheck the file system. To terminate the program, type n.

INCORRECT BLOCK COUNT I=inode-number (number-of-BAD-DUP-or-missing-blocks should be number-of-blocks-in-filesystem) (CORRECT)
Cause
The block count for inode \textit{inode-number} is \textit{number-of-BAD-DUP-or-missing-blocks}, but should be \textit{number-of-blocks-in-filesystem}. When preening, \texttt{fsck} corrects the count.

Action
To replace the block count of inode \textit{inode-number} by \textit{number-of-blocks-in-filesystem}, type \texttt{y} at the \texttt{CORRECT} prompt. To terminate the program, type \texttt{n}.

\textbf{LINK COUNT TABLE OVERFLOW (CONTINUE)}

Cause
There is no more room in an internal table for \texttt{fsck} containing allocated inodes with a link count of zero. If the \texttt{-o p} (preen) option is specified, the program exits and \texttt{fsck} has to be completed manually.

Action
To continue the program, type \texttt{y} at the \texttt{CONTINUE} prompt. If another allocated inode with a zero-link count is found, this error condition repeats. When this error occurs, a complete check of the file system is not possible. You should run \texttt{fsck} again to recheck the file system. Increase the virtual memory available by killing some processes or increasing swap space, then run \texttt{fsck} again. To terminate the program, type \texttt{n}.

\textbf{PARTIALLY ALLOCATED INODE I=inode-number (CLEAR)}

Cause
Inode \textit{inode-number} is neither allocated nor unallocated. If the \texttt{-o p} (preen) option is specified, the inode is cleared.

Action
To deallocate the inode \textit{inode-number} by zeroing out its contents, type \texttt{y}. This might generate the \texttt{UNALLOCATED} error condition in phase 2 for each directory entry pointing to this inode. To ignore the error condition, type \texttt{n}. A no response is appropriate only if you intend to take other measures to fix the problem.

\textbf{PARTIALLY TRUNCATED INODE I=inode-number (SALVAGE)}

Cause
\texttt{fsck} has found inode \textit{inode-number} whose size is shorter than the number of blocks allocated to it. This condition occurs only if the system crashes while truncating a file. When preening the file system, \texttt{fsck} completes the truncation to the specified size.

Action
To complete the truncation to the size specified in the inode, type \texttt{y} at the \texttt{SALVAGE} prompt. To ignore this error condition, type \texttt{n}.

\textbf{UNKNOWN FILE TYPE I=inode-number (CLEAR)}

Cause
The mode word of the inode \textit{inode-number} shows that the inode is not a pipe, special character inode, special block inode, regular inode, symbolic link, FIFO file, or directory inode. If the \texttt{-o p} option is specified, the inode is cleared.
Action
To deallocate the inode \textit{inode-number} by zeroing its contents, which results in the \texttt{UNALLOCATED} error condition in phase 2 for each directory entry pointing to this inode, type \texttt{y} at the \texttt{CLEAR} prompt. To ignore this error condition, type \texttt{n}.

Phase 1B: Rescan for More DUPS Messages
When a duplicate block is found in the file system, this message is displayed:

\texttt{block-number DUP I=inode-number}

Cause
Inode \textit{inode-number} contains a block number \textit{block-number} that is already claimed by the same or another inode. This error condition generates the \texttt{BAD/DUP} error message in phase 2. Inodes that have overlapping blocks might be determined by examining this error condition and the \texttt{DUP} error condition in phase 1.

Action
When a duplicate block is found, the file system is rescanned to find the inode that previously claimed that block.

Phase 2: Check Path Names Messages
This phase removes directory entries pointing to bad inodes found in phases 1 and 1B. It reports error conditions resulting from:

- Incorrect root inode mode and status
- Directory inode pointers out of range
- Directory entries pointing to bad inodes
- Directory integrity checks

When the file system is being preened (-op option), all errors in this phase terminate \texttt{fsck}, except those related to directories not being a multiple of the block size, duplicate and bad blocks, inodes out of range, and extraneous hard links.

These messages (in alphabetical order) might occur in phase 2:

\texttt{BAD INODE state-number TO DESCEND}

Cause
An \texttt{fsck} internal error has passed an invalid state \textit{state-number} to the routine that descends the file system directory structure. \texttt{fsck} exits.

Action
If this error message is displayed, contact your local service provider or another qualified person.

\texttt{BAD INODE NUMBER FOR '.' I=inode-number OWNER=UID MODE=file-mode SIZE=file-size MTIME=modification-time DIR=filename (FIX)}
Cause
A directory *inode-number* has been found whose inode number for "." does not equal *inode-number*.

Action
To change the inode number for "." to be equal to *inode-number*, type *y* at the *FIX* prompt. To leave the inode numbers for "." unchanged, type *n.*

```
BAD INODE NUMBER FOR "." I=inode-number OWNER=UID MODE=file-mode
SIZE=file-size MTIME=modification-time DIR=filename (FIX)
```

Cause
A directory *inode-number* has been found whose inode number for ".." does not equal the parent of *inode-number*.

Action
To change the inode number for ".." to be equal to the parent of *inode-number*, type *y* at the *FIX* prompt. (Note that ".." in the root inode points to itself.) To leave the inode number for ".." unchanged, type *n.*

```
BAD RETURN STATE state-number FROM DESCEND
```

Cause
An *fsck* internal error has returned an impossible state *state-number* from the routine that descends the file system directory structure. *fsck* exits.

Action
If this message is displayed, contact your local service provider or another qualified person.

```
BAD STATE state-number FOR ROOT INODE
```

Cause
An internal error has assigned an impossible state *state-number* to the root inode. *fsck* exits.

Action
If this error message is displayed, contact your local service provider or another qualified person.

```
BAD STATE state-number FOR INODE=inode-number
```

Cause
An internal error has assigned an impossible state *state-number* to inode *inode-number*. *fsck* exits.

Action
If this error message is displayed, contact your local service provider or another qualified person.

```
DIRECTORY TOO SHORT I=inode-number OWNER=UID MODE=file-mode
SIZE=file-size MTIME=modification-time DIR=filename (FIX)
```
Cause
A directory filename has been found whose size file-size is less than the minimum directory size. The owner UID, mode file-mode, size file-size, modify time modification-time, and directory name filename are displayed.

Action
To increase the size of the directory to the minimum directory size, type y at the FIX prompt. To ignore this directory, type n.

DIRECTORY filename: LENGTH file-size NOT MULTIPLE OF block-number (ADJUST)

Cause
A directory filename has been found with size file-size that is not a multiple of the directory block size block-number.

Action
To round up the length to the appropriate block size, type y. When preening the file system (-o p option), fsck only displays a warning and adjusts the directory. To ignore this condition, type n.

DIRECTORY CORRUPTED I=inode-number OWNER=UID MODE=file-mode SIZE=file-size MTIME=modification-time DIR=filename (SALVAGE)

Cause
A directory with an inconsistent internal state has been found.

Action
To throw away all entries up to the next directory boundary (usually a 512-byte boundary), type y at the SALVAGE prompt. This drastic action can throw away up to 42 entries. Take this action only after other recovery efforts have failed. To skip to the next directory boundary and resume reading, but not modify the directory, type n.

DUP/BAD I=inode-number OWNER=O MODE=M SIZE=file-size MTIME=modification-time TYPE=filename (REMOVE)

Cause
Phase 1 or phase 1B found duplicate blocks or bad blocks associated with directory or file entry filename, inode inode-number. The owner UID, mode file-mode, size file-size, modification time modification-time, and directory or file name filename are displayed. If the -p (preen) option is specified, the duplicate/bad blocks are removed.

Action
To remove the directory or file entry filename, type y at the REMOVE prompt. To ignore this error condition, type n.

DUPS/BAD IN ROOT INODE (REALLOCATE)

Cause
Phase 1 or phase 1B has found duplicate blocks or bad blocks in the root inode (usually inode number 2) of the file system.
Action
To clear the existing contents of the root inode and reallocate it, type \texttt{y} at the \texttt{REALLOCATE} prompt. The files and directories usually found in the root inode will be recovered in phase 3 and put into the \texttt{lost+found} directory. If the attempt to allocate the root fails, \texttt{fsck} will exit with: \texttt{CANNOT ALLOCATE ROOT INODE}. Type \texttt{n} to get the \texttt{CONTINUE} prompt. Type: \texttt{y} to respond to the \texttt{CONTINUE} prompt, and ignore the DUPS/BAD error condition in the root inode and continue running the file system check. If the root inode is not correct, this might generate many other error messages. Type \texttt{n} to terminate the program.

\texttt{EXTRA '.' ENTRY I=inode-number OWNER=UID MODE=file-mode SIZE=file-size MTIME=modification-time DIR=filename (FIX)}

Cause
A directory \texttt{inode-number} has been found that has more than one entry for “.”.

Action
To remove the extra entry for “.” type \texttt{y} at the \texttt{FIX} prompt. To leave the directory unchanged, type \texttt{n}.

\texttt{EXTRA '..' ENTRY I=inode-number OWNER=UID MODE=file-mode SIZE=file-size MTIME=modification-time DIR=filename (FIX)}

Cause
A directory \texttt{inode-number} has been found that has more than one entry for “..” (the parent directory).

Action
To remove the extra entry for ‘..’ (the parent directory), type \texttt{y} at the \texttt{FIX} prompt. To leave the directory unchanged, type \texttt{n}.

\texttt{hard-link-number IS AN EXTRANEOUS HARD LINK TO A DIRECTORY filename (REMOVE)}

Cause
\texttt{fsck} has found an extraneous hard link \texttt{hard-link-number} to a directory \texttt{filename}. When preening (-o p option), \texttt{fsck} ignores the extraneous hard links.

Action
To delete the extraneous entry \texttt{hard-link-number} type \texttt{y} at the \texttt{REMOVE} prompt. To ignore the error condition, type \texttt{n}.

\texttt{inode-number OUT OF RANGE I=inode-number NAME=filename (REMOVE)}

Cause
A directory entry \texttt{filename} has an inode number \texttt{inode-number} that is greater than the end of the inode list. If the -p (preen) option is specified, the inode will be removed automatically.

Action
To delete the directory entry \texttt{filename} type \texttt{y} at the \texttt{REMOVE} prompt. To ignore the error condition, type \texttt{n}.

\texttt{MISSING '.' I=inode-number OWNER=UID MODE=file-mode SIZE=file-size MTIME=modification-time DIR=filename (FIX)}
Cause
A directory *inode-number* has been found whose first entry (the entry for ".") is unallocated.

Action
To build an entry for "," with inode number equal to *inode-number*, type *y* at the FIX prompt. To leave the directory unchanged, type *n*.

    MISSING '..' I=inode-number OWNER=UID MODE=file-mode SIZE=file-size
    MTIME=modification-time DIR=filename CANNOT FIX, FIRST ENTRY IN DIRECTORY CONTAINS filename

Cause
A directory *inode-number* has been found whose first entry is filename. *fsck* cannot resolve this problem.

Action
If this error message is displayed, contact your local service provider or another qualified person.

    MISSING '..' I=inode-number OWNER=UID MODE=file-mode SIZE=file-size
    MTIME=modification-time DIR=filename CANNOT FIX, INSUFFICIENT SPACE TO ADD '..'

Cause
A directory *inode-number* has been found whose first entry is not ",". *fsck* cannot resolve the problem.

Action
If this error message is displayed, contact your local service provider or another qualified person.

    MISSING '..' I=inode-number OWNER=UID MODE=file-mode SIZE=file-size
    MTIME=modification-time DIR=filename (FIX)

Cause
A directory *inode-number* has been found whose second entry is unallocated.

Action
To build an entry for ".." with inode number equal to the parent of *inode-number*, type *y* at the FIX prompt. (Note that ".." in the root inode points to itself.) To leave the directory unchanged, type *n*.

    MISSING '..' I=inode-number OWNER=UID MODE=file-mode SIZE=file-size
    MTIME=modification-time DIR=filename CANNOT FIX, SECOND ENTRY IN DIRECTORY CONTAINS filename

Cause
A directory *inode-number* has been found whose second entry is filename. *fsck* cannot resolve this problem.

Action
If this error message is displayed, contact your local service provider or another qualified person.
MISSING ‘..’ I=inode-number OWNER=UID MODE=file-mode SIZE=file-size
MTIME=modification-time DIR=filename CANNOT FIX, INSUFFICIENT SPACE
TO ADD ‘..’

Cause
A directory inode-number has been found whose second entry is not “..” (the parent
directory). fsck cannot resolve this problem.

Action
If this error message is displayed, contact your local service provider or another
qualified person.

NAME TOO LONG filename

Cause
An excessively long path name has been found, which usually indicates loops in the
file system name space. This error can occur if a privileged user has made circular
links to directories.

Action
Remove the circular links.

ROOT INODE UNALLOCATED (ALLOCATE)

Cause
The root inode (usually inode number 2) has no allocate-mode bits.

Action
To allocate inode 2 as the root inode, type y at the ALLOCATE prompt. The files and
directories usually found in the root inode will be recovered in phase 3 and put into
the lost+found directory. If the attempt to allocate the root inode fails, fsck
displays this message and exits: CANNOT ALLOCATE ROOT INODE. To terminate the
program, type n.

ROOT INODE NOT DIRECTORY (REALLOCATE)

Cause
The root inode (usually inode number 2) of the file system is not a directory inode.

Action
To clear the existing contents of the root inode and reallocate it, type y at the
REALLOCATE prompt. The files and directories usually found in the root inode will
be recovered in phase 3 and put into the lost+found directory. If the attempt to
allocate the root inode fails, fsck displays this message and exits: CANNOT
ALLOCATE ROOT INODE. To have fsck prompt with FIX, type n.

UNALLOCATED I=inode-number OWNER=UID MODE=file-mode SIZE=file-size
MTIME=modification-time type=filename (REMOVE)

Cause
A directory or file entry filename points to an unallocated inode inode-number. The
owner UID, mode file-mode, size file-size, modify time modification-time, and file name
filename are displayed.
Action
To delete the directory entry \textit{filename}, type \texttt{y} at the \texttt{REMOVE} prompt. To ignore the error condition, type \texttt{n}.

\texttt{ZERO LENGTH DIRECTORY I=inode-number OWNER=UID MODE=file-mode}
\texttt{SIZE=file-size MTIME=modification-time DIR=filename (REMOVE)}

Cause
A directory entry \textit{filename} has a size \textit{file-size} that is zero. The owner UID, mode \textit{file-mode}, size \textit{file-size}, modify time \textit{modification-time}, and directory name \textit{filename} are displayed.

Action
To remove the directory entry \textit{filename}, type \texttt{y} at the \texttt{REMOVE} prompt. This results in the \texttt{BAD/DUP} error message in phase 4. To ignore the error condition, type \texttt{n}.

Phase 3: Check Connectivity Messages

This phase checks the directories examined in phase 2 and reports error conditions resulting from:
- Unreferenced directories
- Missing or full lost+found directories

These messages (in alphabetical order) might occur in phase 3:

\texttt{BAD INODE state-number TO DESCEND}

Cause
An internal error has caused an impossible state \textit{state-number} to be passed to the routine that descends the file system directory structure. \texttt{fsck} exits.

Action
If this occurs, contact your local service provider or another qualified person.

\texttt{DIR I=inode-number1 CONNECTED. PARENT WAS I=inode-number2}

Cause
This is an advisory message indicating a directory inode \textit{inode-number1} was successfully connected to the lost+found directory. The parent inode \textit{inode-number2} of the directory inode \textit{inode-number1} is replaced by the inode number of the lost+found directory.

Action
N/A

\texttt{DIRECTORY filename LENGTH file-size NOT MULTIPLE OF block-number (ADJUST)}

Cause
A directory \textit{filename} has been found with size \textit{file-size} that is not a multiple of the directory block size \textit{B}. (This condition can recur in phase 3 if it is not adjusted in phase 2.)
Action
To round up the length to the appropriate block size, type y at the ADJUST prompt. When preening, fsck displays a warning and adjusts the directory. To ignore this error condition, type n.

lost+found IS NOT A DIRECTORY (REALLOCATE)

Cause
The entry for lost+found is not a directory.

Action
To allocate a directory inode and change the lost+found directory to reference it, type y at the REALLOCATE prompt. The previous inode reference by the lost+found directory is not cleared and it will either be reclaimed as an unreferenced inode or have its link count adjusted later in this phase. Inability to create a lost+found directory displays the message: SORRY. CANNOT CREATE lost+found DIRECTORY and aborts the attempt to link up the lost inode, which generates the UNREF error message in phase 4. To abort the attempt to link up the lost inode, which generates the UNREF error message in phase 4, type n.

NO lost+found DIRECTORY (CREATE)

Cause
There is no lost+found directory in the root directory of the file system. When preening, fsck tries to create a lost+found directory.

Action
To create a lost+found directory in the root of the file system, type y at the CREATE prompt. This might lead to the message NO SPACE LEFT IN / (EXPAND). If the lost+found directory cannot be created, fsck displays the message: SORRY. CANNOT CREATE lost+found DIRECTORY and aborts the attempt to link up the lost inode. This in turn generates the UNREF error message later in phase 4. To abort the attempt to link up the lost inode, type n.

NO SPACE LEFT IN /lost+found (EXPAND)

Cause
Another entry cannot be added to the lost+found directory in the root directory of the file system because no space is available. When preening, fsck expands the lost+found directory.

Action
To expand the lost+found directory to make room for the new entry, type y at the EXPAND prompt. If the attempted expansion fails, fsck displays: SORRY. NO SPACE IN lost+found DIRECTORY and aborts the request to link a file to the lost+found directory. This error generates the UNREF error message later in phase 4. Delete any unnecessary entries in the lost+found directory. This error terminates fsck when preening is in effect. To abort the attempt to link up the lost inode, type n.

UNREF DIR I=inode-number OWNER=UID MODE=file-mode SIZE=file-size
MTIME=modification-time (RECONNECT)
Cause
The directory inode *inode-number* was not connected to a directory entry when the file system was traversed. The owner *UID*, mode *file-mode*, size *file-size*, and modification time *modification-time* of directory inode *inode-number* are displayed. When preening, `fsck` reconnects the non-empty directory inode if the directory size is non-zero. Otherwise, `fsck` clears the directory inode.

Action
To reconnect the directory inode *inode-number* into the *lost+found* directory, type `y` at the RECONNECT prompt. If the directory is successfully reconnected, a CONNECTED message is displayed. Otherwise, one of the *lost+found* error messages is displayed. To ignore this error condition, type `n`. This error causes the UNREF error condition in phase 4.

Phase 4: Check Reference Counts Messages
This phase checks the link count information obtained in phases 2 and 3. It reports error conditions resulting from:
- Unreferenced files
- A missing or full *lost+found* directory
- Incorrect link counts for files, directories, symbolic links, or special files
- Unreferenced files, symbolic links, and directories
- Bad or duplicate blocks in files and directories
- Incorrect total free_inode counts

All errors in this phase (except running out of space in the *lost+found* directory) are correctable when the file system is being preened.

These messages (in alphabetical order) might occur in phase 4:

BAD/DUP type I=*inode-number* OWNER=*UID* MODE=*file-mode* SIZE=*file-size* MTIME=*modification-time* (CLEAR)

Cause
Phase 1 or phase 1B found duplicate blocks or bad blocks associated with file or directory inode *inode-number*. The owner *UID*, mode *file-mode*, size *file-size*, and modification time *modification-time* of inode *inode-number* are displayed.

Action
To deallocate inode *inode-number* by zeroing its contents, type `y` at the CLEAR prompt. To ignore this error condition, type `n`.

(CLEAR)

Cause
The inode mentioned in the UNREF error message immediately preceding cannot be reconnected. This message does not display if the file system is being preened because lack of space to reconnect files terminates `fsck`. 

434 System Administration Guide: Advanced Administration • December 2002
Action
To deallocate the inode by zeroing out its contents, type y at the CLEAR prompt. To ignore the preceding error condition, type n.

```
LINK COUNT type I=inode-number OWNER=UID MODE=file-mode
SIZE=file-size
MTIME=modification-time COUNT link-count SHOULD BE corrected-link-count (ADJUST)
```

Cause
The link count for directory or file inode inode-number is link-count but should be corrected-link-count. The owner UID, mode file-mode, size file-size, and modification time modification-time of inode inode-number are displayed. If the -o p option is specified, the link count is adjusted unless the number of references is increasing. This condition does not occur unless there is a hardware failure. When the number of references is increasing during preening, fsck displays this message and exits:

```
LINK COUNT INCREASING
```

Action
To replace the link count of directory or file inode inode-number with corrected-link-count, type y at the ADJUST prompt. To ignore this error condition, type n.

```
lost+found IS NOT A DIRECTORY (REALLOCATE)
```

Cause
The entry for lost+found is not a directory.

Action
To allocate a directory inode and change the lost+found directory to reference it, type y at the REALLOCATE prompt. The previous inode reference by the lost+found directory is not cleared. It will either be reclaimed as an unreferenced inode or have its link count adjusted later in this phase. Inability to create a lost+found directory displays this message: SORRY. CANNOT CREATE lost+found DIRECTORY and aborts the attempt to link up the lost inode. This error generates the UNREF error message later in phase 4. To abort the attempt to link up the lost inode, type n.

```
NO lost+found DIRECTORY (CREATE)
```

Cause
There is no lost+found directory in the root directory of the file system. When preening, fsck tries to create a lost+found directory.

Action
To create a lost+found directory in the root of the file system, type y at the CREATE prompt. If the lost+found directory cannot be created, fsck displays the message: SORRY. CANNOT CREATE lost+found DIRECTORY and aborts the attempt to link up the lost inode. This error in turn generates the UNREF error message later in phase 4. To abort the attempt to link up the lost inode, type n.

```
NO SPACE LEFT IN / lost+found (EXPAND)
```
Cause
There is no space to add another entry to the lost+found directory in the root directory of the file system. When preening, fsck expands the lost+found directory.

Action
To expand the lost+found directory to make room for the new entry, type y at the EXPAND prompt. If the attempted expansion fails, fsck displays the message: SORRY, NO SPACE IN lost+found DIRECTORY and aborts the request to link a file to the lost+found directory. This error generates the UNREF error message later in phase 4. Delete any unnecessary entries in the lost+found directory. This error terminates fsck when preening (-op option) is in effect. To abort the attempt to link up the lost inode, type n.

UNREF FILE I=inode-number OWNER=UID MODE=mode SIZE=file-size
MTIME=modification-time (RECONNECT)

Cause
File inode inode-number was not connected to a directory entry when the file system was traversed. The owner UID, mode file-mode, size file-size, and modification time modification-time of inode inode-number are displayed. When fsck is preening, the file is cleared if either its size or its link count is zero; otherwise, it is reconnected.

Action
To reconnect inode inode-number to the file system in the lost+found directory, type y. This error might generate the lost+found error message in phase 4 if there are problems connecting inode inode-number to the lost+found directory. To ignore this error condition, type n. This error always invokes the CLEAR error condition in phase 4.

UNREF type I=inode-number OWNER=UID MODE=mode SIZE=file-size
MTIME=modification-time (CLEAR)

Cause
Inode inode-number (whose type is directory or file) was not connected to a directory entry when the file system was traversed. The owner UID, mode file-mode, size file-size, and modification time modification-time of inode inode-number are displayed. When fsck is preening, the file is cleared if either its size or its link count is zero; otherwise, it is reconnected.

Action
To deallocate inode inode-number by zeroing its contents, type y at the CLEAR prompt. To ignore this error condition, type n.

ZERO LENGTH DIRECTORY I=inode-number OWNER=UID MODE=mode
SIZE=file-size MTIME=modification-time (CLEAR)

Cause
A directory entry filename has a size file-size that is zero. The owner UID, mode file-mode, size file-size, modification time modification-time, and directory name filename are displayed.
Action
To deallocate the directory inode *inode-number* by zeroing out its contents, type *y*. To ignore the error condition, type *n*.

**Phase 5: Check Cylinder Groups Messages**

This phase checks the free-block and used-inode maps. It reports error conditions resulting from:

- Allocated inodes missing from used-inode maps
- Free blocks missing from free-block maps
- Free inodes in the used-inode maps
- Incorrect total free-block count
- Incorrect total used inode count

These messages (in alphabetical order) might occur in phase 5:

**BLK(S) MISSING IN BIT MAPS (SALVAGE)**

Cause
A cylinder group block map is missing some free blocks. During preening, *fsck* reconstructs the maps.

Action
To reconstruct the free-block map, type *y* at the SALVAGE prompt. To ignore this error condition, type *n*.

**CG character-for-command-option: BAD MAGIC NUMBER**

Cause
The magic number of cylinder group *character-for-command-option* is wrong. This error usually indicates that the cylinder group maps have been destroyed. When running interactively, the cylinder group is marked as needing reconstruction. *fsck* terminates if the file system is being preened.

Action
If this occurs, contact your local service provider or another qualified person.

**FREE BLK COUNT(S) WRONG IN SUPERBLK (SALVAGE)**

Cause
The actual count of free blocks does not match the count of free blocks in the superblock of the file system. If the *-o p* option was specified, the free-block count in the superblock is fixed automatically.

Action
To reconstruct the superblock free-block information, type *y* at the SALVAGE prompt. To ignore this error condition, type *n*.

**SUMMARY INFORMATION BAD (SALVAGE)**
Cause
   The summary information is incorrect. When preening, fsck recomputes the summary information.

Action
   To reconstruct the summary information, type y at the SALVAGE prompt. To ignore this error condition, type n.

Cleanup Phase Messages
   Once a file system has been checked, a few cleanup functions are performed. The cleanup phase displays the following status messages.

   number-of files, number-of-files used, number-of-files free
   (number-of frags, number-of blocks, percent fragmentation)

   This message indicates that the file system checked contains number-of files using number-of fragment-sized blocks, and that there are number-of fragment-sized blocks free in the file system. The numbers in parentheses break the free count down into number-of free fragments, number-of free full-sized blocks, and the percent fragmentation.

   ***** FILE SYSTEM WAS MODIFIED *****

   This message indicates that the file system was modified by fsck. If this file system is mounted or is the current root (/) file system, reboot. If the file system is mounted, you might need to unmount it and run fsck again; otherwise, the work done by fsck might be undone by the in-core copies of tables.

   filename FILE SYSTEM STATE SET TO OKAY

   This message indicates that file system filename was marked as stable. Use the fsck -m command to determine if the file system needs checking.

   filename FILE SYSTEM STATE NOT SET TO OKAY

   This message indicates that file system filename was not marked as stable. Use the fsck -m command to determine if the file system needs checking.
Troubleshooting Software Package Problems (Tasks)

This chapter describes problems you may encounter when installing or removing software packages. There are two sections: Specific Software Package Installation Errors, which describes package installation and administration errors you might encounter, and General Software Package Installation Problems, which describes behavioral problems that might not result in a particular error message.

This is a list of information in this chapter.
- “Specific Software Package Installation Errors” on page 440
- “General Software Package Installation Problems” on page 441

For information about managing software packages, see “Managing Software (Overview)” in System Administration Guide: Basic Administration.

Troubleshooting Software Package Symbolic Link Problems

In previous Solaris releases, there was no way to specify a symbolic link target in the pkgmap file when creating a software package. This meant a package or patch-related symbolic link was always followed to the source of the symbolic link rather than to the target of the symbolic link when a package was added with the pkgadd command. This created problems when upgrading a package or a patch package that needed to change a symbolic link target destination to something else.

Now, the default behavior is that if a package needs to change the target of a symbolic link to something else, the target of the symbolic link and not the source of the symbolic link is inspected by the pkgadd command.

Unfortunately, this means that some packages may or may not conform to the new pkgadd behavior.
The `PKG_NONABI_SYMLINKS` environment variable might help you transition between the old and new `pkgadd` symbolic link behaviors. If this environment variable is set to true, `pkgadd` follows the source of the symbolic link.

Setting this variable enables a non-conforming package to revert to the old behavior if set by the administrator before adding a package with the `pkgadd` command.

The new `pkgadd` symbolic link behavior might cause an existing package to fail when added with the `pkgadd` command. You might see the following error message in this situation:

```plaintext
unable to create symbolic link to <path>
```

If a package doesn’t install due to this problem, do the following:

1. If this is a Sun-supplied package, call the Resolution Center and report the non-conforming package name.
2. Set the `PKG_NONABI_SYMLINKS` environment variable and try adding the package with the `pkgadd` command again.

```plaintext
# PKG_NONABI_SYMLINKS=true
# export PKG_NONABI_SYMLINKS
# pkgadd pkg-name
```

### Specific Software Package Installation Errors

**WARNING: filename <not present on Read Only file system>**

<table>
<thead>
<tr>
<th>Reason Error Occurred</th>
<th>How to Fix the Problem</th>
</tr>
</thead>
<tbody>
<tr>
<td>This error message indicates that not all of a package’s files could be installed. This usually occurs when you are using <code>pkgadd</code> to install a package on a client. In this case, <code>pkgadd</code> attempts to install a package on a file system that is mounted from a server, but <code>pkgadd</code> doesn’t have permission to do so.</td>
<td>If you see this warning message during a package installation, you must also install the package on the server. See “Managing Software (Overview)” in <em>System Administration Guide: Basic Administration</em> for details.</td>
