Disables cache consistency checking. By default, periodic consistency checking is enabled. Specify *noconst* only when you know that the back file system will not be modified. Trying to perform cache consistency check using *cfsadmin -s* will result in error. *demandconst* and *noconst* are mutually exclusive.

ro | rw

Read-only or read-write (default).

suid | nosuid

Allow (default) or disallow *setuid* execution.

write-around | non-shared

Write modes for CacheFS. The *write-around* mode (the default) handles writes the same as NFS does; that is, writes are made to the back file system, and the affected file is purged from the cache. You can use the *non-shared* mode when you are sure that no one else will be writing to the cached file system. In this mode, all writes are made to both the front and the back file system, and the file remains in the cache.

-O

Overlay mount. Allows the filesystem to be mounted over an existing mount point, making the underlying filesystem inaccessible. If a mount is attempted on a pre-existing mount point without setting this flag, mount will fail with the error: *mount -F cachefs: mount failed Device busy*.

mount_cachefs(1M)

EXAMPLES

EXAMPLE 1 CacheFS-mounting a File System

The following example CacheFS-mounts the file system `server1:/user2`, which is already NFS-mounted on `/usr/abc` as `/xyz`.

```
example# mount -F cachefs -o backfstype=nfs,backpath=/usr/abc,  
             cachedir=/cache1 server1:/user2 /xyz
```

The lines similar to the following appear in the `/etc/mnttab` file after the mount command is executed:

```
server1:/user2  /usr/abc      nfs  
/usr/abc       /cache1/xyz    cachefs      backfstype=nfs
```

ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

SEE ALSO

BUGS

The output for the *generic_option* `-p` output is incorrect for `cachefs`.

NAME	mountd – server for NFS mount requests and NFS access checks				
SYNOPSIS	<code>/usr/lib/nfs/mountd [-v] [-r]</code>				
DESCRIPTION	mountd is an RPC server that answers requests for NFS access information and file system mount requests. It reads the file <code>/etc/dfs/sharetab</code> to determine which file systems are available for mounting by which remote machines. See <code>sharetab(4)</code>. <code>nfsd</code> running on the local server will contact mountd the first time an NFS client tries to access the file system to determine whether the client should get read-write, read-only, or no access. This access can be dependent on the security mode used in the <code>remoted</code> procedure call from the client. See <code>share_nfs(1M)</code>. The command also provides information as to what file systems are mounted by which clients. This information can be printed using the <code>showmount(1M)</code> command. The mountd daemon is automatically invoked in run level 3. Only super user can run the mountd daemon.				
OPTIONS	The following options are supported: <code>-r</code> Reject mount requests from clients. Clients that have file systems mounted will not be affected. <code>-v</code> Run the command in verbose mode. Each time mountd determines what access a client should get, it will log the result to the console, as well as how it got that result.				
FILES	<code>/etc/dfs/sharetab</code> shared file system table				
ATTRIBUTES	See <code>attributes(5)</code> for descriptions of the following attributes:				
	<table border="1"> <thead> <tr> <th>ATTRIBUTE TYPE</th><th>ATTRIBUTE VALUE</th></tr> </thead> <tbody> <tr> <td>Availability</td><td>SUNWnfssu</td></tr> </tbody> </table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	Availability	SUNWnfssu
ATTRIBUTE TYPE	ATTRIBUTE VALUE				
Availability	SUNWnfssu				
SEE ALSO	<code>nfsd(1M)</code> , <code>share_nfs(1M)</code> , <code>showmount(1M)</code> , <code>sharetab(4)</code> , <code>attributes(5)</code>				
NOTES	If <code>nfsd</code> is running, mountd must also be running in order to be assured that the NFS server can respond to requests, otherwise, the NFS service can hang. Some routines that compare hostnames use case-sensitive string comparisons; some do not. If an incoming request fails, verify that the case of the hostname in the file to be parsed matches the case of the hostname called for, and attempt the request again.				

mount_hsf(1M)

NAME	mount_hsf – mount hsf file systems
SYNOPSIS	mount -F hsf [<i>generic_options</i>] [-o <i>FSType-specific_options</i>] [-O] <i>special</i> <i>mount_point</i> mount -F hsf [<i>generic_options</i>] [-o <i>FSType-specific_options</i>] [-O] <i>special</i> <i>mount_point</i>
DESCRIPTION	mount attaches a High Sierra file system (hsf) to the file system hierarchy at the <i>mount_point</i>, which is the pathname of a directory. If <i>mount_point</i> has any contents prior to the mount operation, these are hidden until the file system is unmounted. If mount is invoked with <i>special</i> or <i>mount_point</i> as the only arguments, mount will search /etc/vfstab to fill in the missing arguments, including the <i>FSType-specific_options</i>; see mount(1M) for more details. If the file system being mounted contains Rock Ridge extensions, by default they will be used, enabling support of features not normally available under High Sierra file systems such as symbolic links, and special files.
OPTIONS	<i>generic_options</i> See mount(1M) for the list of supported options. -o Specify hsf file system specific options. If invalid options are specified, a warning message is printed and the invalid options are ignored. The following options are available: global noglobal If global is specified and supported on the file system, and the system in question is part of a cluster, the file system will be globally visible on all nodes of the cluster. If noglobal is specified, the mount will not be globally visible. The default behavior is noglobal. ro Mount the file system read-only. This option is required. nrr no Rock Ridge: if Rock Ridge extensions are present in the file system, ignore them; interpret it as a regular High Sierra file system. notraildot File names on High Sierra file systems consist of a proper name and an extension separated by a '.' (dot) character. By default, the separating dot is always considered part of the file's name for all file access operations, even if there is no extension present. Specifying notraildot makes it optional to specify the trailing dot to access a file whose name lacks an extension. <i>Exceptions:</i> This option is effective only on file systems for which Rock Ridge extensions are not active, either because they are not present on the CD-ROM, or they are explicitly ignored via the nrr option. If Rock Ridge extensions are active, hsf quietly ignores this option.

mount_hsf(1M)

nomaplcas

File names on High Sierra cdroms with no Rock Ridge extensions present should be uppercase characters only. By default, hsf maps file names read from a non-Rock Ridge disk to all lowercase characters. nomaplcas turns off this mapping. The exceptions for notraildot discussed above apply to nomaplcas.

nosuid

By default the file system is mounted with setuid execution allowed. Specifying nosuid causes the file system to be mounted with setuid execution disallowed.

-O

Overlay mount. Allow the file system to be mounted over an existing mount point, making the underlying file system inaccessible. If a mount is attempted on a pre-existing mount point without setting this flag, the mount will fail, producing the error device busy.

FILES /etc/mnttab table of mounted file systems

/etc/vfstab list of default parameters for each file system

ATTRIBUTES See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

SEE ALSO mount(1M), mountall(1M), mount(2), mnttab(4), vfstab(4), attributes (5)

NOTES If the directory on which a file system is to be mounted is a symbolic link, the file system is mounted on the directory to which the symbolic link refers, rather than on top of the symbolic link itself.

mount_nfs(1M)

NAME	mount_nfs – mount remote NFS resources
SYNOPSIS	mount [-F <i>nfs</i>] [<i>generic_options</i>] [-o <i>specific_options</i>] [-O] <i>resource</i> mount [-F <i>nfs</i>] [<i>generic_options</i>] [-o <i>specific_options</i>] [-O] <i>mount_point</i> mount [-F <i>nfs</i>] [<i>generic_options</i>] [-o <i>specific_options</i>] [-O] <i>resource mount_point</i>
DESCRIPTION	The mount utility attaches a named <i>resource</i> to the file system hierarchy at the pathname location <i>mount_point</i>, which must already exist. If <i>mount_point</i> has any contents prior to the mount operation, the contents remain hidden until the <i>resource</i> is once again unmounted. If the resource is listed in the <i>/etc/vfstab</i> file, the command line can specify either <i>resource</i> or <i>mount_point</i>, and mount consults <i>/etc/vfstab</i> for more information. If the -F option is omitted, mount takes the file system type from <i>/etc/vfstab</i>. If the resource is not listed in the <i>/etc/vfstab</i> file, then the command line must specify both the <i>resource</i> and the <i>mount_point</i>. <i>host</i> can be an IPv4 or IPv6 address string. As IPv6 addresses already contain colons, enclose <i>host</i> in a pair of square brackets when specifying an IPv6 address string. Otherwise the first occurrence of a colon can be interpreted as the separator between the host name and path, for example, [1080::8:800:200C:417A]:tmp/file. See <i>inet(7P)</i> and <i>inet6(7P)</i>. <i>host:pathname</i> Where <i>host</i> is the name of the NFS server host, and <i>pathname</i> is the path name of the directory on the server being mounted. The path name is interpreted according to the server's path name parsing rules and is not necessarily slash-separated, though on most servers, this is the case. <i>nfs://host[:port]/pathname</i> This is an NFS URL and follows the standard convention for NFS URLs as described in <i>NFS URL Scheme</i>, RFC 2224. See the discussion of URL's and the public option under NFS FILE SYSTEMS for a more detailed discussion. A comma-separated list of <i>host:pathname</i> and/or <i>nfs://host[:port]/pathname</i> resources See the discussion of replicated file systems and failover under NFS FILE SYSTEMS for a more detailed discussion. A comma-separated list of hosts followed by a <i>:pathname</i> suffix See the discussion of replicated file systems and failover under NFS FILE SYSTEMS for a more detailed discussion. The mount command maintains a table of mounted file systems in <i>/etc/mnttab</i>, described in <i>mnttab(4)</i>.
OPTIONS	See <i>mount(1M)</i> for the list of supported <i>generic_options</i>. -o <i>specific_options</i> Set file system specific options according to a comma-separated list with no intervening spaces.

`acdirmax=n`

Hold cached attributes for no more than *n* seconds after directory update. The default value is 60.

`acdirmin=n`

Hold cached attributes for at least *n* seconds after directory update. The default value is 30.

`acregmax=n`

Hold cached attributes for no more than *n* seconds after file modification. The default value is 60.

`acregmin=n`

Hold cached attributes for at least *n* seconds after file modification. The default value is 3.

`actimeo=n`

Set *min* and *max* times for regular files and directories to *n* seconds.

`bg | fg`

If the first attempt fails, retry in the background, or, in the foreground. The default is `fg`.

`forcedirectio | noforcedirectio`

If `forcedirectio` is specified, then for the duration of the mount, forced direct I/O is used. If the filesystem is mounted using `forcedirectio`, data is transferred directly between client and server, with no buffering on the client. If the filesystem is mounted using `noforcedirectio`, data is buffered on the client. `forcedirectio` is a performance option that is of benefit only in large sequential data transfers. The default behavior is `noforcedirectio`.

`grpuid`

By default, the GID associated with a newly created file obeys the System V semantics; that is, the GID is set to the effective GID of the calling process. This behavior may be overridden on a per-directory basis by setting the set-GID bit of the parent directory; in this case, the GID of a newly created file is set to the GID of the parent directory (see `open(2)` and `mkdir(2)`). Files created on file systems that are mounted with the `grpuid` option obeys BSD semantics independent of whether the set-GID bit of the parent directory is set; that is, the GID is unconditionally inherited from that of the parent directory.

`hard | soft`

Continue to retry requests until the server responds (`hard`) or give up and return an error (`soft`). The default value is `hard`.

`intr | nointr`

Allow (do not allow) keyboard interrupts to kill a process that is hung while waiting for a response on a hard-mounted file system. The default is `intr`, which makes it possible for clients to interrupt applications that may be waiting for a remote mount.

mount_nfs(1M)

noac

Suppress data and attribute caching. The data caching that is suppressed is the write-behind. The local page cache is still maintained, but data copied into it is immediately written to the server.

nocto

Do not perform the normal close-to-open consistency. When a file is closed, all modified data associated with the file is flushed to the server and not held on the client. When a file is opened the client sends a request to the server to validate the client's local caches. This behavior ensures a file's consistency across multiple NFS clients. When `-nocto` is in effect, the client does not perform the flush on close and the request for validation, allowing the possibility of differences among copies of the same file as stored on multiple clients.

This option can be used where it can be guaranteed that accesses to a specified file system are made from only one client and only that client. Under such a condition, the effect of `-nocto` can be a slight performance gain.

port=*n*

The server IP port number. The default is `NFS_PORT`. If the `port` option is specified, and if the resource includes one or more NFS URLs, and if any of the URLs include a port number, then the port number in the option and in the URL must be the same.

posix

Request POSIX.1 semantics for the file system. Requires a mount Version 2 `mountd(1M)` on the server. See `standards(5)` for information regarding POSIX.

proto=<*netid*>

<*netid*> is a value of `network_id` field from entry in the `/etc/netconfig` file. By default, the transport protocol used for the NFS mount is the first available connection oriented transport supported on both the client and the server. If no connection oriented transport is found, then the first available connectionless transport is used. This default behavior can be overridden with the `proto=<netid>` option.

public

The `public` option forces the use of the public file handle when connecting to the NFS server. The resource specified may or may not have an NFS URL. See the discussion of URL's and the `public` option under `NFS FILE SYSTEMS` for a more detailed discussion.

quota | noquota

Enable or prevent `quota(1M)` to check whether the user is over quota on this file system; if the file system has quotas enabled on the server, quotas are still checked for operations on this file system.

remount

Remounts a read-only file system as read-write (using the `rw` option). This option cannot be used with other `-o` options, and this option works only on currently mounted read-only file systems.

`retrans=n`

Set the number of NFS retransmissions to *n*. The default value is 5. For connection-oriented transports, this option has no effect because it is assumed that the transport performs retransmissions on behalf of NFS.

`retry=n`

The number of times to retry the mount operation. The default for the mount command is 10000.

The default for the automounter is 0, in other words, do not retry. You might find it useful to increase this value on heavily loaded servers, where automounter traffic is dropped, causing unnecessary “server not responding” errors.

`ro | rw`

resource is mounted read-only or read-write. The default is rw.

`rsize=n`

Set the read buffer size to *n* bytes. The default value is 32768 when using Version 3 of the NFS protocol. The default can be negotiated down if the server prefers a smaller transfer size. When using Version 2, the default value is 8192.

`sec=mode`

Set the security *mode* for NFS transactions. If *sec=* is not specified, then the default action is to use AUTH_SYS over NFS Version 2 mounts, or to negotiate a *mode* over NFS Version 3 mounts. NFS Version 3 mounts negotiate a security mode when the server returns an array of security modes. The client picks the first mode in the array that is supported on the client. Only one mode can be specified with the *sec=* option. See `nfssec(5)` for the available *mode* options.

`secure`

This option has been deprecated in favor of the *sec=dh* option.

`suid | nosuid`

Allow or disallow `setuid` execution. The default is `suid`.

`timeo=n`

Set the NFS timeout to *n* tenths of a second. The default value is 11 tenths of a second for connectionless transports, and 600 tenths of a second for connection-oriented transports.

`vers=<NFS version number>`

By default, the version of NFS protocol used between the client and the server is the highest one available on both systems. If the NFS server does not support NFS Version 3 protocol, then the NFS mount uses NFS Version 2 protocol.

`wsiz=n`

Set the write buffer size to *n* bytes. The default value is 32768 when using Version 3 of the NFS protocol. The default can be negotiated down if the server prefers a smaller transfer size. When using Version 2, the default value is 8192.

mount_nfs(1M)

NFS FILE SYSTEMS

xattr | noxattr

Allow or disallow the creation and manipulation of extended attributes. The default is xattr. See fsattr(5) for a description of extended attributes.

-O

Overlay mount. Allow the file system to be mounted over an existing mount point, making the underlying file system inaccessible. If a mount is attempted on a pre-existing mount point without setting this flag, the mount fails, producing the error "device busy."

Background versus Foreground

File systems mounted with the `bg` option indicate that `mount` is to retry in the background if the server's mount daemon (`mountd(1M)`) does not respond. `mount` retries the request up to the count specified in the `retry=n` option. (Note that the default value for `retry` differs between `mount` and `automount`. See the description of `retry`, above.) Once the file system is mounted, each NFS request made in the kernel waits `timeo=n` tenths of a second for a response. If no response arrives, the time-out is multiplied by 2 and the request is retransmitted. When the number of retransmissions has reached the number specified in the `retrans=n` option, a file system mounted with the `soft` option returns an error on the request; one mounted with the `hard` option prints a warning message and continues to retry the request.

Hard versus Soft

File systems that are mounted read-write or that contain executable files should always be mounted with the `hard` option. Applications using `soft` mounted file systems may incur unexpected I/O errors, file corruption, and unexpected program core dumps. The `soft` option is not recommended.

Authenticated requests

The server may require authenticated NFS requests from the client. `sec=dh` authentication might be required. See `nfssec(5)`.

URLs and the public option

If the `public` option is specified, or if the `resource` includes an NFS URL, `mount` attempts to connect to the server using the public file handle lookup protocol. See *WebNFS Client Specification*, RFC 2054. If the server supports the public file handle, the attempt is successful; `mount` does not need to contact the server's `rpcbind(1M)`, and the `mountd(1M)` daemons to get the port number of the `mount` server and the initial file handle of `pathname`, respectively. If the NFS client and server are separated by a firewall that allows all outbound connections through specific ports, such as `NFS_PORT`, then this enables NFS operations through the firewall. The `public` option and the NFS URL can be specified independently or together. They interact as specified in the following matrix:

	resource style	
	<i>host:pathname</i>	NFS URL
public option	Force public file handle and fail mount if not supported. Use Native paths.	Force public file handle and fail mount if not supported. Use Canonical paths.
default	Use MOUNT protocol.	Try public file handle with Canonical paths. Fall back to MOUNT protocol if not supported.

A Native path is a path name that is interpreted according to conventions used on the native operating system of the NFS server. A Canonical path is a path name that is interpreted according to the URL rules. See *Uniform Resource Locators (URL)*, RFC 1738. See EXAMPLES for uses of Native and Canonical paths.

Replicated file systems and failover

resource can list multiple read-only file systems to be used to provide data. These file systems should contain equivalent directory structures and identical files. It is also recommended that they be created by a utility such as *rdist*(1). The file systems may be specified either with a comma-separated list of *host:pathname* entries and/or NFS URL entries, or with a comma-separated list of hosts, if all file system names are the same. If multiple file systems are named and the first server in the list is down, failover uses the next alternate server to access files. If the read-only option is not chosen, replication is disabled. File access is blocked on the original if NFS locks are active for that file.

File Attributes

To improve NFS read performance, files and file attributes are cached. File modification times get updated whenever a write occurs. However, file access times may be temporarily out-of-date until the cache gets refreshed.

The attribute cache retains file attributes on the client. Attributes for a file are assigned a time to be flushed. If the file is modified before the flush time, then the flush time is extended by the time since the last modification (under the assumption that files that changed recently are likely to change soon). There is a minimum and maximum flush time extension for regular files and for directories. Setting *actimeo=n* sets flush time to *n* seconds for both regular files and directories.

Setting *actimeo=0* disables attribute caching on the client. This means that every reference to attributes is satisfied directly from the server though file data is still cached. While this guarantees that the client always has the latest file attributes from the server, it has an adverse effect on performance through additional latency, network load, and server load.

mount_nfs(1M)

Setting the noac option also disables attribute caching, but has the further effect of disabling client write caching. While this guarantees that data written by an application is written directly to a server, where it can be viewed immediately by other clients, it has a significant adverse effect on client write performance. Data written into memory-mapped file pages (mmap(2)) are not written directly to this server.

EXAMPLES

EXAMPLE 1 Mounting an NFS File System

To mount an NFS file system:

```
example# mount serv:/usr/src /usr/src
```

EXAMPLE 2 Mounting An NFS File System Read-Only With No suid Privileges

To mount an NFS file system read-only with no suid privileges:

```
example# mount -r -o nosuid serv:/usr/src /usr/src
```

EXAMPLE 3 Mounting An NFS File System Over Version 2, with the UDP Transport

To mount an NFS file system over Version 2, with the UDP transport:

```
example# mount -o vers=2,proto=udp serv:/usr/src /usr/src
```

EXAMPLE 4 Mounting an NFS File System Using An NFS URL

To mount an NFS file system using an NFS URL (a canonical path):

```
example# mount nfs://serv/usr/man /usr/man
```

EXAMPLE 5 Mounting An NFS File System Forcing Use Of The Public File Handle

To mount an NFS file system and force the use of the public file handle and an NFS URL (a canonical path) that has a non 7-bit ASCII escape sequence:

```
example# mount -o public nfs://serv/usr/%A0abc /mnt/test
```

EXAMPLE 6 Mounting an NFS File System Using a Native Path

To mount an NFS file system using a native path (where the server uses colons (":") as the component separator) and the public file handle:

```
example# mount -o public serv:C:doc:new /usr/doc
```

EXAMPLE 7 Mounting a Replicated Set of NFS File Systems with the Same Pathnames

To mount a replicated set of NFS file systems with the same pathnames:

```
example# mount serv-a,serv-b,serv-c:/usr/man /usr/man
```

EXAMPLE 8 Mounting a Replicated Set of NFS File Systems with Different Pathnames

To mount a replicated set of NFS file systems with different pathnames:

```
example# mount serv-x:/usr/man,serv-y:/var/man,nfs://serv-z/man /usr/man
```

mount_nfs(1M)

Callaghan, Brent, *WebNFS Client Specification*, RFC 2054, October 1996.

Callaghan, Brent, *NFS URL Scheme*, RFC 2224, October 1997.

Berners-Lee, Masinter & McCahill, *Uniform Resource Locators (URL)*, RFC 1738, December 1994.

NOTES An NFS server should not attempt to mount its own file systems. See lofs(7FS).

If the directory on which a file system is to be mounted is a symbolic link, the file system is mounted on *the directory to which the symbolic link refers*, rather than being mounted on top of the symbolic link itself.

SunOS 4.x used the biod maintenance procedure to perform parallel read-ahead and write-behind on NFS clients. SunOS 5.x made biod obsolete with multi-threaded processing, which transparently performs parallel read-ahead and write-behind.

Since the root (/) file system is mounted read-only by the kernel during the boot process, only the remount option (and options that can be used in conjunction with remount) affect the root (/) entry in the /etc/vfstab file.

mount_pcfs(1M)

NAME	mount_pcfs – mount pcfs file systems				
SYNOPSIS	mount -F pcfs [<i>generic_options</i>] [-o <i>FSType-specific_options</i>] <i>special</i> <i>mount_point</i> mount -F pcfs [<i>generic_options</i>] [-o <i>FSType-specific_options</i>] <i>special mount_point</i>				
DESCRIPTION	mount attaches an MS-DOS file system (pcfs) to the file system hierarchy at the <i>mount_point</i>, which is the pathname of a directory. If <i>mount_point</i> has any contents prior to the mount operation, these are hidden until the file system is unmounted. If mount is invoked with <i>special</i> or <i>mount_point</i> as the only arguments, mount will search /etc/vfstab to fill in the missing arguments, including the <i>FSType-specific_options</i>; see mount(1M) for more details. The <i>special</i> argument can be one of two special device file types: ■ A floppy disk, such as /dev/diskette0 or /dev/diskette1. ■ A DOS logical drive on a hard disk expressed as <i>device-name:logical-drive</i>, where <i>device-name</i> specifies the special block device-file for the whole disk and <i>logical-drive</i> is either a drive letter (c through z) or a drive number (1 through 24). Examples are /dev/dsk/c0t0d0p0:c and /dev/dsk/c0t0d0p0:1. The <i>special</i> device file type must have a formatted MS-DOS file system with either a 12-bit, 16-bit, or 32-bit File Allocation Table.				
OPTIONS	<i>generic_options</i> See mount(1M) for the list of supported options. -o Specify pcfs file system specific options. The following options are available: rw ro Mount the file system read/write or read-only. The default is rw. foldcase nofoldcase Force uppercase characters in filenames to lowercase when reading them from the filesystem. This is for compatibility with the previous behavior of pcfs. The default is nofoldcase.				
FILES	/etc/mnttab table of mounted file systems /etc/vfstab list of default parameters for each file system				
ATTRIBUTES	See attributes(5) for descriptions of the following attributes:

mount_pcfs(1M)

NOTES | If the directory on which a file system is to be mounted is a symbolic link, the file system is mounted on the directory to which the symbolic link refers, rather than on top of the symbolic link itself.

mount_tmpfs(1M)

NAME	mount_tmpfs – mount tmpfs file systems								
SYNOPSIS	mount [-F tmpfs] [-o <i>specific_options</i>] [-O] <i>special mount_point</i>								
DESCRIPTION	tmpfs is a memory based file system which uses kernel resources relating to the VM system and page cache as a file system. mount attaches a tmpfs file system to the file system hierarchy at the pathname location <i>mount_point</i>, which must already exist. If <i>mount_point</i> has any contents prior to the mount operation, these remain hidden until the file system is once again unmounted. The attributes (mode, owner, and group) of the root of the tmpfs filesystem are inherited from the underlying <i>mount_point</i>, provided that those attributes are determinable. If not, the root's attributes are set to their default values. The <i>special</i> argument is usually specified as <i>swap</i> but is in fact disregarded and assumed to be the virtual memory resources within the system.								
OPTIONS	-o <i>specific_options</i> Specify tmpfs file system specific options in a comma-separated list with no intervening spaces. If invalid options are specified, a warning message is printed and the invalid options are ignored. The following options are available: <table> <tr> <td>size=sz</td><td>The sz argument controls the size of this particular tmpfs file system. If the argument is has a 'k' suffix, the number will be interpreted as a number of kilobytes. An 'm' suffix will be interpreted as a number of megabytes. No suffix is interpreted as bytes. In all cases, the actual size of the file system is the number of bytes specified, rounded up to the physical pagesize of the system.</td></tr> <tr> <td>suid nosuid</td><td>Allow or disallow <i>setuid</i> execution. The default is <i>suid</i>.</td></tr> <tr> <td>xattr noxattr</td><td>Allow or disallow the creation and manipulation of extended attributes. The default is <i>xattr</i>. See <i>fsattr</i>(5) for a description of extended attributes.</td></tr> <tr> <td>-O</td><td>Overlay mount. Allow the file system to be mounted over an existing mount point, making the underlying file system inaccessible. If a mount is attempted on a pre-existing mount point without setting this flag, the mount will fail, producing the <i>errordevice busy</i>.</td></tr> </table>	size=sz	The sz argument controls the size of this particular tmpfs file system. If the argument is has a 'k' suffix, the number will be interpreted as a number of kilobytes. An 'm' suffix will be interpreted as a number of megabytes. No suffix is interpreted as bytes. NOTES If the directory on which a file system is to be mounted is a symbolic link, the file system is mounted on the directory to which the symbolic link refers, rather than on top of the symbolic link itself.

mount_udfs(1M)

NAME	mount_udfs – mount a udfs file system
SYNOPSIS	mount -F udfs [<i>generic_options</i>] [-o <i>specific_options</i>] [-O] <i>special mount_point</i> mount -F udfs [<i>generic_options</i>] [-o <i>specific_options</i>] [-O] <i>special</i> <i>mount_point</i>
DESCRIPTION	The mount utility attaches a udfs file system to the file system hierarchy at the <i>mount_point</i>, which is the pathname of a directory. If <i>mount_point</i> has any contents prior to the mount operation, these are hidden until the file system is unmounted. If mount is invoked with either <i>special</i> or <i>mount_point</i> as the only arguments, mount searches <i>/etc/vfstab</i> to fill in the missing arguments, including the <i>specific_options</i>. See mount(1M). If <i>special</i> and <i>mount_point</i> are specified without any <i>specific_options</i>, the default is <i>rw</i>. If the directory on which a file system is to be mounted is a symbolic link, the file system is mounted on the directory to which the symbolic link refers, rather than on top of the symbolic link itself.
OPTIONS	See mount(1M) for the list of supported <i>generic_options</i>. The following options are supported: -o <i>specific_options</i> Specify udfs file system specific options in a comma-separated list with no intervening spaces. The following <i>specific_options</i> are available: - m Mount the file system without making an entry in <i>/etc/mnttab</i>. - nosuid Mount the file system with <i>setuid</i> execution disallowed. You can also use <i>nosuid</i> to disallow <i>setuid</i> when mounting devices. - By default, the file system is mounted with <i>setuid</i> execution allowed. - remount Remount the file system as read-write. The option is used in conjunction with the <i>rw</i> option. - A file system mounted read-only can be remounted as read-write. This option fails if the file system is not currently mounted. - rw ro Read-write (<i>rw</i>) or read-only (<i>ro</i>). <i>rw</i> is the default. -O Overlay mount. Allow the file system to be mounted over an existing mount point, making the underlying

mount_udfs(1M)

file system inaccessible. If a mount is attempted on a pre-existing mount point without setting this flag, the mount fails, producing the error device busy.

DIAGNOSTICS not super user
The command is run by a non-root user. Run as root.

no such device
The device name specified does not exist.

not a directory
The specified mount point is not a directory.

is not an udfs file system
The device specified does not contain a udf 1.50 file system or the udfs file system module is not available.

is already mounted
The specified device is already in use.

not a block device
The device specified is not a block device. Use block device to mount.

write-protected
The device is read-only.

is corrupted. needs checking
The file system is in an inconsistent state. Run `fsck`.

NOTES Copy-protected files can be stored on DVD-ROM media using Universal Disk Format (UDF). Reading these copy-protected files is not possible as this involves an authentication process. Unless an authentication process between the host and the drive is completed, reading these copy-protected files after mounting and before the authentication process, returns an error.

mount_ufs(1M)

NAME	mount_ufs – mount ufs file systems
SYNOPSIS	mount -F ufs [<i>generic_options</i>] [-o <i>specific_options</i>] [-O] <i>special</i> <i>mount_point</i> mount -F ufs [<i>generic_options</i>] [-o <i>specific_options</i>] [-O] <i>special mount_point</i>
DESCRIPTION	The mount utility attaches a ufs file system to the file system hierarchy at the <i>mount_point</i>, which is the pathname of a directory. If <i>mount_point</i> has any contents prior to the mount operation, these are hidden until the file system is unmounted. If mount is invoked with <i>special</i> or <i>mount_point</i> as the only arguments, mount will search /etc/vfstab to fill in the missing arguments, including the <i>specific_options</i>. See mount(1M). If <i>special</i> and <i>mount_point</i> are specified without any <i>specific_options</i>, the default is rw. If the directory on which a file system is to be mounted is a symbolic link, the file system is mounted on the directory to which the symbolic link refers, rather than on top of the symbolic link itself.
OPTIONS	See mount(1M) for the list of supported <i>generic_options</i>. The following options are supported: -o <i>specific_options</i> Specify ufs file system specific options in a comma-separated list with no intervening spaces. If invalid options are specified, a warning message is printed and the invalid options are ignored. The following options are available: noatime By default, the file system is mounted with normal access time (atime) recording. If noatime is specified, the file system will ignore access time updates on files, except when they coincide with updates to the ctime or mtime. See stat(2). This option reduces disk activity on file systems where access times are unimportant (for example, a Usenet news spool). noatime turns off access time recording regardless of dfratime or nodfratime. dfratime nodfratime By default, writing access time updates to the disk may be deferred (dfratime) for the file system until the disk is accessed for a reason other than updating access times. nodfratime disables this behavior. forcedirectio noforcedirectio If forcedirectio is specified and supported by the file system, then for the duration of the mount, forced direct I/O will be used. If the filesystem is mounted using forcedirectio, data is transferred directly between user address space and the disk. If the filesystem is mounted using noforcedirectio, data is buffered in kernel address space when data is

transferred between user address space and the disk. `forcedirectio` is a performance option that is of benefit only in large sequential data transfers. The default behavior is `noforcedirectio`.

`global | noglobal`

If `global` is specified and supported on the file system, and the system in question is part of a cluster, the file system will be globally visible on all nodes of the cluster. If `noglobal` is specified, the mount will not be globally visible. The default behavior is `noglobal`. The `global` option is mutually exclusive of the `nbmand` option, described below.

`intr | nointr`

Allow (do not allow) keyboard interrupts to kill a process that is waiting for an operation on a locked file system. The default is `intr`.

`largefiles | nolargefiles`

If `nolargefiles` is specified and supported by the file system, then for the duration of the mount it is guaranteed that all regular files in the file system have a size that will fit in the smallest object of type `off_t` supported by the system performing the mount. The mount will fail if there are any files in the file system not meeting this criterion. If `largefiles` is specified, there is no such guarantee. The default behavior is `largefiles`.

If `nolargefiles` is specified, mount will fail for `ufs` if the file system to be mounted has contained a large file (a file whose size is greater than or equal to 2 Gbyte) since the last invocation of `fsck` on the file system. The large file need not be present in the file system at the time of the mount for the mount to fail; it could have been created previously and destroyed. Invoking `fsck` (see `fsck_ufs(1M)`) on the file system will reset the file system state if no large files are present. After invoking `fsck`, a successful mount of the file system with `nolargefiles` specified indicates the absence of large files in the file system; an unsuccessful mount attempt indicates the presence of at least one large file.

`logging | nologging`

If `logging` is specified, then logging is enabled for the duration of the mounted file system. Logging is the process of storing transactions (changes that make up a complete UFS operation) in a log before the transactions are applied to the file system. Once a transaction is stored, the transaction can be applied to the file system later. This prevents file systems from becoming inconsistent, therefore eliminating the need to run `fsck`. And, because `fsck` can be bypassed, logging reduces the time required to reboot a system if it crashes, or after an unclean halt. The default behavior is `nologging`.

The log is allocated from free blocks on the file system, and is sized approximately 1 Mbyte per 1 Gbyte of file system, up to a maximum of 64 Mbytes. Logging can be enabled on any UFS, including root (/). The log created by UFS logging is continually flushed as it fills up. The log is totally flushed when the file system is unmounted or as a result of the `lockfs -f` command.

`m`

Mount the file system without making an entry in `/etc/mnttab`.

mount_ufs(1M)

`nbmand` | `nonbmand`

This option specifies that non-blocking mandatory locking semantics should be allowed on this file system. Non-blocking mandatory locking is disallowed by default. If the file system is mounted with the `nbmand` option, then applications can use the `fcntl(2)` interface to place non-blocking mandatory locks on files and the system will enforce those semantics. Enabling this option can cause standards conformant applications to see unexpected errors.

Do not use the `nbmand` option with `/`, `/var` and `/usr`.

The `remount` option should not be used to change the `nbmand` disposition of the file system. The `nbmand` option is mutually exclusive of the `global` option, described above.

`onerror = action`

This option specifies the action that UFS should take to recover from an internal inconsistency on a file system. Specify *action* as `panic`, `lock`, or `umount`. These values cause a forced system shutdown, a file system lock to be applied to the file system, or the file system to be forcibly unmounted, respectively. The default is `panic`.

`quota`

Quotas are turned on for the file system.

`remount`

Remounts a file system with a new set of options. All options not explicitly set with `remount` revert to their default values.

`rq`

Read-write with quotas turned on. Equivalent to `rw`, `quota`.

`ro` | `rw`

Read-only or read-write. Default is `rw`.

`suid` | `nosuid`

Allow or disallow `setuid`/`setgid` execution. The default is `suid`. This option also allows/disallows opening any device-special entries that appear within the filesystem.

This option is highly recommended whenever the file system is shared via NFS with the `root=` option, because, without it, NFS clients could add `setuid` programs to the server, or create devices that could open security holes.

`-O`

Overlay mount. Allow the file system to be mounted over an existing mount point, making the underlying file system inaccessible. If a mount is attempted on a pre-existing mount point without setting this flag, the mount will fail, producing the error "device busy".

The `mount_ufs` command supports the `xattr` flag, to allow the creation and manipulation of extended attributes. See `fsattr(5)` for a description of extended attributes. The `xattr` flag is always on.

mount_ufs(1M)

FILES /etc/mnttab table of mounted file systems
 /etc/vfstab list of default parameters for each file system

ATTRIBUTES See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

SEE ALSO fsck(1M), fsck_ufs(1M), mount(1M), mountall(1M), fcntl(2), mount(2),
 stat(2), mnttab(4), vfstab(4), attributes(5), fsattr(5), largefile(5)

NOTES Since the root (/) file system is mounted read-only by the kernel during the boot
 process, only the remount option (and options that can be used in conjunction with
 remount) affect the root (/) entry in the /etc/vfstab file.

mount_xmemfs(1M)

NAME	mount_xmemfs – mount xmemfs file systems								
SYNOPSIS	mount -F xmemfs [<i>generic_options</i>] -o[largebsize,]size=sz [-O] <i>special</i> <i>mount_point</i>								
DESCRIPTION	xmemfs is an extended memory file system which provides file system semantics to manage and access large amounts of physical memory which can exceed 4 GB in size. mount attaches a xmemfs file system to the file system hierarchy at the pathname location <i>mount_point</i>, which must already exist. If <i>mount_point</i> has any contents prior to the mount operation, these remain hidden until the file system is once again unmounted. The attributes (mode, owner, and group) of the root of the xmemfs filesystem are inherited from the underlying <i>mount_point</i>, provided that those attributes are determinable. If not, the root's attributes are set to their default values. The special argument is not currently used by xmemfs but a placeholder, (such as <i>xmem</i>), needs to be specified nevertheless.								
OPTIONS	See mount(1M) for the list of supported <i>generic_options</i>. -o<i>specific_options</i> Specify xmemfs file system specific options in a comma-separated list with <i>no intervening spaces</i>. If invalid options are specified, a warning message is printed and the invalid options are ignored. The <i>size=sz specific option</i> is required. The following options are available: <table> <tr> <td>size=sz</td><td>The <i>sz</i> argument specifies the desired size of this particular xmemfs file system. If the <i>sz</i> argument has a <i>k</i> suffix, the number is interpreted as kilobytes. An <i>m</i> suffix is interpreted as megabytes and <i>g</i> is interpreted as gigabytes. A <i>sz</i> specified with no suffix is interpreted as bytes.</td></tr> <tr> <td></td><td>In all cases, the actual size of the file system is the number of bytes specified, rounded up to the physical <i>pagesize</i> of the system or to the large page size if <i>largebsize</i> is specified.</td></tr> <tr> <td></td><td>This <i>specific_option</i> is required.</td></tr> <tr> <td>largebsize</td><td>If <i>largebsize</i> is specified, xmemfs uses the large memory page size as the file system block</td></tr> </table>	size=sz	The <i>sz</i> argument specifies the desired size of this particular xmemfs file system. If the <i>sz</i> argument has a <i>k</i> suffix, the number is interpreted as kilobytes. An <i>m</i> suffix is interpreted as megabytes and <i>g</i> is interpreted as gigabytes. A <i>sz</i> specified with no suffix is interpreted as bytes.		In all cases, the actual size of the file system is the number of bytes specified, rounded up to the physical <i>pagesize</i> of the system or to the large page size if <i>largebsize</i> is specified.		This <i>specific_option</i> is required.	largebsize	If <i>largebsize</i> is specified, xmemfs uses the large memory page size as the file system block
size=sz	The <i>sz</i> argument specifies the desired size of this particular xmemfs file system. If the <i>sz</i> argument has a <i>k</i> suffix, the number is interpreted as kilobytes. An <i>m</i> suffix is interpreted as megabytes and <i>g</i> is interpreted as gigabytes. A <i>sz</i> specified with no suffix is interpreted as bytes.								
	In all cases, the actual size of the file system is the number of bytes specified, rounded up to the physical <i>pagesize</i> of the system or to the large page size if <i>largebsize</i> is specified.								
	This <i>specific_option</i> is required.								
largebsize	If <i>largebsize</i> is specified, xmemfs uses the large memory page size as the file system block								

mount_xmemfs(1M)

size. On IA32, the large memory page size with mmu36 which supports PAE (Physical Address Extension) is 2 MB. The large memory page size without mmu36/PAE is 4 MB. If there is no large page support, the file system block size is PAGE_SIZE.

-O Overlay mount. Allow the file system to be mounted over an existing mount point, making the underlying file system inaccessible. If a mount is attempted on a pre-existing mount point without setting this flag, the mount fails, producing the error device busy.

FILES /etc/mnttab table of mounted file systems

ATTRIBUTES See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu
Architecture	i386
Interface Stability	Evolving

SEE ALSO mount(1M), mount(2), mkdir(2), open(2), umount(2), mnttab(4), attributes(5), xmemfs(7FS)

NOTES If the directory on which a file system is to be mounted is a symbolic link, the file system is mounted on the directory to which the symbolic link refers, rather than on top of the symbolic link itself.

The only file types allowed on xmemfs are directories and regular files. The execution of object files resident in xmemfs is not supported. Execution is prevented by not allowing users to set execute permissions on regular files.

mpstat(1M)

NAME	mpstat – report per-processor or per-processor-set statistics																																				
SYNOPSIS	/usr/bin/mpstat [-a] [-p -P <i>set</i>] [<i>interval</i> [<i>count</i>]]																																				
DESCRIPTION	mpstat reports processor statistics in tabular form. Each row of the table represents the activity of one processor. The first table summarizes all activity since boot; each subsequent table summarizes activity for the preceding interval. All values are rates (events per second) unless otherwise noted. During execution of this kernel status command, the "state" of the kernel can change. An example would be CPUs going online or offline. mpstat reports this as State change. mpstat reports the following information: <table><tr><td>CPU or SET</td><td>Without the -a option, mpstat reports CPU, the processor ID. With the -a option, mpstat reports SET, the processor set ID.</td></tr><tr><td>minf</td><td>minor faults</td></tr><tr><td>mjf</td><td>major faults</td></tr><tr><td>xcal</td><td>inter-processor cross-calls</td></tr><tr><td>intr</td><td>interrupts</td></tr><tr><td>ithr</td><td>interrupts as threads (not counting clock interrupt)</td></tr><tr><td>csw</td><td>context switches</td></tr><tr><td>icsw</td><td>involuntary context switches</td></tr><tr><td>migr</td><td>thread migrations (to another processor)</td></tr><tr><td>smtx</td><td>spins on mutexes (lock not acquired on first try)</td></tr><tr><td>srw</td><td>spins on readers/writer locks (lock not acquired on first try)</td></tr><tr><td>syscl</td><td>system calls</td></tr><tr><td>usr</td><td>percent user time</td></tr><tr><td>sys</td><td>percent system time</td></tr><tr><td>wt</td><td>percent wait time</td></tr><tr><td>idl</td><td>percent idle time</td></tr></table> With the -a option, mpstat also reports: <table><tr><td>size</td><td>number of processors in the set</td></tr></table> With the -p option, mpstat also reports: <table><tr><td>set</td><td>processor set membership of the CPU</td></tr></table>	CPU or SET	Without the -a option, mpstat reports CPU, the processor ID. With the -a option, mpstat reports SET, the processor set ID.	minf	minor faults	mjf	major faults	xcal	inter-processor cross-calls	intr	interrupts	ithr	interrupts as threads (not counting clock interrupt)	csw	context switches	icsw	involuntary context switches	migr	thread migrations (to another processor)	smtx	spins on mutexes (lock not acquired on first try)	srw	spins on readers/writer locks (lock not acquired on first try)	syscl	system calls	usr	percent user time	sys	percent system time	wt	percent wait time	idl	percent idle time	size	number of processors in the set	set	processor set membership of the CPU
CPU or SET	Without the -a option, mpstat reports CPU, the processor ID. With the -a option, mpstat reports SET, the processor set ID.																																				
minf	minor faults																																				
mjf	major faults																																				
xcal	inter-processor cross-calls																																				
intr	interrupts																																				
ithr	interrupts as threads (not counting clock interrupt)																																				
csw	context switches																																				
icsw	involuntary context switches																																				
migr	thread migrations (to another processor)																																				
smtx	spins on mutexes (lock not acquired on first try)

NOTES The sum of CPU utilization might vary slightly from 100 because of rounding errors in the production of a percentage figure.

msgid(1M)

NAME	msgid – generate message IDs				
SYNOPSIS	/usr/sbin/msgid				
DESCRIPTION	The <code>msgid</code> utility generates message IDs. A message ID is a numeric identifier that, with a high probability, uniquely identifies a message. The probability of two distinct messages having the same ID is about one in a million. Specifically, the message ID is a hash signature on the message's unexpanded format string, generated by <code>STRLOG_MAKE_MSGID()</code> as defined in <code><sys/strlog.h></code>. <code>syslogd(1M)</code> is a simple filter that takes strings as input and produces those same strings, preceded by their message IDs, as output. Every message logged by <code>syslogd(1M)</code> includes the message ID. The message ID is intended to serve as a small, language-independent identifier.				
EXAMPLES	EXAMPLE 1 Using the <code>msgid</code> command to generate a message ID The following example uses the <code>msgid</code> command to generate a message ID for the <code>echo</code> command. <pre>example# echo hello msgid205790 hello</pre> EXAMPLE 2 Using the <code>msgid</code> command to generate a message catalog The following example uses the <code>msgid</code> command to enumerate all of the messages in the binary <code>ufs</code>, to generate a message catalog. <pre>example# strings /kernel/fs/ufs msgid137713 free: freeing free frag, dev:0x%lx, blk:%ld, cg:%d, ino:%lu, fs:%s 567420 iallocg: block not in mapfs = %s 845546 alloc: %s: file system full ...</pre>

NAME	mvdir – move a directory						
SYNOPSIS	/usr/sbin/mvdir <i>dirname name</i>						
DESCRIPTION	mvdir moves directories within a file system. <i>dirname</i> must be a directory. If <i>name</i> does not exist, it will be created as a directory. If <i>name</i> does exist, and is a directory, <i>dirname</i> will be created as <i>name/dirname</i>. <i>dirname</i> and <i>name</i> may not be on the same path; that is, one may not be subordinate to the other. For example: <pre>example% mvdir x/y x/z</pre> is legal, but <pre>example% mvdir x/y x/y/z</pre> is not.						
OPERANDS	dirname	The name of the directory that is to be moved to another directory in the filesystem.					
	name	The name of the directory into which <i>dirname</i> is to be moved. If <i>name</i> does not exist, it will be created. It may not be on the same path as <i>dirname</i> .					
USAGE	See largefile(5) for the description of the behavior of mvdir when encountering files greater than or equal to 2 Gbyte (2 ³¹ bytes).						
EXIT STATUS	0	Successful operation.					
	>0	Operation failed.					
ATTRIBUTES	See attributes(5) for descriptions of the following attributes:

NAME	named-xfer – ancillary agent for inbound zone transfers				
SYNOPSIS	named-xfer -z <i>zone_to_transfer</i> -f <i>db_file</i> -s <i>serial_no</i> [-d <i>debuglevel</i>] [-l <i>debug_log_file</i>] [-t <i>trace_file</i>] [-p <i>port#</i>] [-S] <i>nameserver...</i>				
DESCRIPTION	The named-xfer program is an ancillary program executed by <code>in.named</code> to perform an inbound zone transfer. It is rarely executed directly, and only by system administrators who are trying to debug a zone transfer problem. See RFC's 1033, 1034, and 1035 for more information on the Internet name-domain system.				
OPTIONS	-z Specifies the name of the zone to be transferred. -f Specifies the name of the file into which the zone should be dumped when it is received from the primary server. -s Specifies the serial number of the current copy of this zone. If the SOA RR from the primary server does not have a serial number higher than this, the transfer will be aborted. -d Print debugging information. A number after the "d" determines the level of messages printed. -l Specifies a log file for debugging messages. The default is system-dependent but is usually in <i>/var/tmp</i> or <i>/usr/tmp</i>. Note that this only applies if -d is also specified. -t Specifies a trace file which will contain a protocol trace of the zone transfer. This is probably only of interest to those debugging the name server itself. -p Use a different port number. The default is the standard port number as returned by <code>getservbyname(3SOCKET)</code> for service "domain". -S Perform a restricted transfer of only the SOA, NS records and glue A records for the zone. The SOA record will not be loaded by named but will be used to determine when to verify the NS records. See the "stubs" directive in <code>in.named(1M)</code> for more information. Additional arguments are taken as name server addresses in so-called "dotted-quad" syntax only; no host names are allowed. At least one address must be specified. If the first one fails to transfer successfully, the additional addresses will be tried in the order given.				
ATTRIBUTES	See <code>attributes(5)</code> for descriptions of the following attributes: <table border="1"> <thead> <tr> <th>ATTRIBUTE TYPE</th><th>ATTRIBUTE VALUE</th></tr> </thead> <tbody> <tr> <td>Availability</td><td>SUNWinamd</td></tr> </tbody> </table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	Availability	SUNWinamd

Name Server Operations Guide for BIND

NAME	ncaconfd – Solaris Network Cache and Accelerator (NCA) configuration daemon				
SYNOPSIS	<code>/usr/lib/inet/ncaconfd</code>				
DESCRIPTION	Use the <code>ncaconfd</code> utility to set up NCA on a system. At boot time, the <code>ncakmod</code> initialization script reads in <code>nca.if(4)</code> to determine on which interface(s) NCA should run. <code>ncaconfd</code> then sets up the interface. <code>ncaconfd</code> also operates as a daemon if the <code>nca_active</code> key is set to enabled in <code>ncakmod.conf(4)</code> file. In this case, <code>ncaconfd</code> will continue as a daemon after all the NCA interfaces have been set up, listening for routing changes. The changes are then passed to NCA to control which interface NCA should use to make active outgoing TCP connections.

ncheck(1M)

NAME	ncheck – generate a list of path names versus i-numbers	
SYNOPSIS	ncheck [-F <i>FSType</i>] [-V] [<i>generic_options</i>] [-o <i>FSType-specific_options</i>] [<i>special...</i>]	
DESCRIPTION	ncheck with no options generates a path-name versus i-number list of all files on <i>special</i> . If <i>special</i> is not specified on the command line the list is generated for all <i>specials</i> in /etc/vfstab which have a numeric fsckpass. <i>special</i> is the raw device on which the file system exists.	
OPTIONS	-F	Specify the <i>FSType</i> on which to operate. The <i>FSType</i> should either be specified here or be determinable from /etc/vfstab by finding an entry in the table that has a numeric fsckpass field and an fsckdev that matches <i>special</i> .
	-V	Echo the complete command line, but do not execute the command. The command line is generated by using the options and arguments provided by the user and adding to them information derived from /etc/vfstab. This option may be used to verify and validate the command line.
	<i>generic_options</i>	Options that are commonly supported by most <i>FSType</i> -specific command modules. The following options are available:
	-i <i>i-list</i>	Limit the report to the files on the <i>i-list</i> that follows. The <i>i-list</i> must be separated by commas with no intervening spaces.
	-a	Print the names “.” and “. .” which are ordinarily suppressed.
	-s	Report only special files and files with set-user-ID mode. This option may be used to detect violations of security policy.
	-o	Specify <i>FSType-specific_options</i> in a comma separated (without spaces) list of suboptions and keyword-attribute pairs for interpretation by the <i>FSType</i> -specific module of the command.
USAGE	See largefile(5) for the description of the behavior of ncheck when encountering files greater than or equal to 2 Gbyte (2 ³¹ bytes).	
FILES	/etc/vfstab list of default parameters for each file system	
ATTRIBUTES	See attributes(5) for descriptions of the following attributes:	

ncheck(1M)

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

SEE ALSO `vfstab(4)`, `attributes(5)`, `largefile(5)` Manual pages for the FSType-specific modules of `ncheck`

NOTES This command may not be supported for all *FSTypes*.

ncheck_ufs(1M)

NAME	ncheck_ufs – generate pathnames versus i-numbers for ufs file systems				
SYNOPSIS	ncheck -F ufs [<i>generic_options</i>] [-o m] [<i>special...</i>]				
DESCRIPTION	ncheck -F ufs generates a pathname versus i-number list of files for the ufs file system residing on <i>special</i> . Names of directory files are followed by '/.'.				
OPTIONS	See ncheck(1M) for the list of <i>generic_options</i> supported. -o Specify ufs file system specific options. The available option is: m Print mode information.				
ATTRIBUTES	See attributes(5) for descriptions of the following attributes: <table><thead><tr><th>ATTRIBUTE TYPE</th><th>ATTRIBUTE VALUE</th></tr></thead><tbody><tr><td>Availability</td><td>SUNWcsu</td></tr></tbody></table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	Availability	SUNWcsu
ATTRIBUTE TYPE	ATTRIBUTE VALUE				
Availability	SUNWcsu				
SEE ALSO	ff(1M), ncheck(1M), attributes(5)				
DIAGNOSTICS	When the file system structure is improper, '??' denotes the "parent" of a parentless file and a pathname beginning with './..' denotes a loop.				

NAME	ndc – name daemon control program
SYNOPSIS	ndc [-c <i>channel</i>] [-l <i>localsock</i>] [-p <i>pidfile</i>] [-d] [-q] [-s] [-t] [<i>command</i>]
DESCRIPTION	System administrators use the <i>ndc</i> utility to control the operation of a name server. If the system administrator fails to list a command, <i>ndc</i> will prompt for one until it reads EOF.
OPTIONS	The <i>ndc</i> command supports the following options: -c <i>channel</i> Specify the rendezvous point for the control channel. The default value for <i>channel</i> is <i>/var/run/ndc</i>, a UNIX domain socket that is also the server's default control channel. If the desired control channel is a TCP/IP socket, then the format for the <i>channel</i> argument is <i>ipaddr/port</i>. For example, a value of <i>127.0.0.1/54</i> would be TCP port 54 on the local host. -d Turn on debugging mode. This option is mainly of interest to developers. -l <i>localsock</i> Bind the client side of the control channel to a specific address. Servers can be configured to reject connections that do not come from specific addresses. If the desired control channel is a TCP/IP socket, then the format for the <i>localsock</i> argument is <i>ipaddr/port</i>. -p <i>pidfile</i> Use for backwards compatibility with older name servers. It enables <i>ndc</i> to use UNIX signals for control communications. Optional with modern name servers, this capability may not be supported in future releases. The command set that is available is narrower when the signal interface is used. A likely value for the <i>pidfile</i> argument is <i>/var/run/named.pid</i>. -q Suppress prompt and result text. -s Suppress non-fatal error announcements. -t Turn on protocol and system tracing. Use this option in installation debugging.
COMMANDS	The following commands are built into the <i>ndc</i> utility. The full set of commands that the name server supports is dynamic. Use the <i>help</i> command for information on the available commands . /help Show help information for built in commands. /exit Exit from <i>ndc</i> command interpreter. /trace Toggle protocol and system tracing on and off. See -t. /debug Toggle debugging mode on and off. See -d. /quiet Toggle prompt and result information on and off. See -q.

ndc(1M)

/silent Toggle announcement of non-fatal errors on and off.
See -s.

ATTRIBUTES See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu
Interface Stability	Standard, BIND 8.2.4

SEE ALSO in.named(1M), execvp(2), attributes(5)

NOTES When the ndc utility is running in *pidfile* mode, pass any arguments to start and restart commands to the new name server on the command line. If the ndc utility is running in *channel* mode, there is no start command, and the restart command just tells the name server to execvp(2) itself.

NAME	ndd – get and set driver configuration parameters				
SYNOPSIS	ndd [-set] <i>driver parameter</i> [<i>value</i>]				
DESCRIPTION	ndd gets and sets selected configuration parameters in some kernel drivers. Currently, ndd only supports the drivers that implement the TCP/IP Internet protocol family. Each driver chooses which parameters to make visible using ndd. Since these parameters are usually tightly coupled to the implementation, they are likely to change from release to release. Some parameters may be read-only. If the -set option is omitted, ndd queries the named <i>driver</i>, retrieves the value associated with the specified <i>parameter</i>, and prints it. If the -set option is given, ndd passes <i>value</i>, which must be specified, down to the named <i>driver</i> which assigns it to the named <i>parameter</i>. By convention, drivers that support ndd also support a special read-only <i>parameter</i> named “?” which can be used to list the parameters supported by the driver.				
EXAMPLES	EXAMPLE 1 Getting Parameters Supported By The TCP Driver To see which parameters are supported by the TCP driver, use the following command: <pre>example% ndd /dev/tcp \?</pre> The parameter name “?” may need to be escaped with a backslash to prevent its being interpreted as a shell meta character. The following command sets the value of the parameter <i>ip_forwarding</i> in the dual stack IP driver to zero. This disables IPv4 packet forwarding. <pre>example% ndd -set /dev/ip ip_forwarding 0</pre> Similarly, in order to disable IPv6 packet forwarding, the value of parameter <i>ip6_forwarding</i> <pre>example% ndd -set /dev/ip ip6_forwarding 0</pre> To view the current IPv4 forwarding table, use the following command: <pre>example% ndd /dev/ip ipv4_ire_status</pre> To view the current IPv6 forwarding table, use the following command: <pre>example% ndd /dev/ip ipv6_ire_status</pre>				
ATTRIBUTES	See attributes(5) for descriptions of the following attributes: <table border="1"> <thead> <tr> <th>ATTRIBUTE TYPE</th><th>ATTRIBUTE VALUE</th></tr> </thead> <tbody> <tr> <td>Availability</td><td>SUNWcsu</td></tr> </tbody> </table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	Availability	SUNWcsu
ATTRIBUTE TYPE	ATTRIBUTE VALUE				
Availability	SUNWcsu				

ndd(1M)

SEE ALSO nca(1), ioctl(2), attributes(5), arp(7P), ip(7P), ip6(7P), tcp(7P), udp(7P)

NOTES The parameters supported by each driver may change from release to release. Like programs that read `/dev/kmem`, user programs or shell scripts that execute `ndd` should be prepared for parameter names to change.

The `ioctl()` command that `ndd` uses to communicate with drivers is likely to change in a future release. User programs should avoid making dependencies on it.

The meanings of many `ndd` parameters make sense only if you understand how the driver is implemented.

NAME	netstat – show network status				
SYNOPSIS	<pre> netstat [-anv] [-f <i>address_family</i>] [-P <i>protocol</i>] netstat -g [-n] [-f <i>address_family</i>] netstat -p [-n] [-f <i>address_family</i>] netstat -s [-f <i>address_family</i>] [-P <i>protocol</i>] netstat -m [-v] netstat -i [-I <i>interface</i>] [-an] [-f <i>address_family</i>] [<i>interval</i> [<i>count</i>]] netstat -r [-anv] [-f <i>address_family</i> <i>filter</i>] netstat -M [-ns] [-f <i>address_family</i>] netstat -D [-I <i>interface</i>] [-f <i>address_family</i>] </pre>				
DESCRIPTION	The netstat command displays the contents of certain network-related data structures in various formats, depending on the options you select. The netstat command has the several forms shown in the SYNOPSIS section, above, listed as follows: ■ The first form of the command (with no required arguments) displays a list of active sockets for each protocol. ■ The second, third, and fourth forms (-g, -p, and -s options) display information from various network data structures. ■ The fifth form (-m option) displays STREAMS memory statistics. ■ The sixth form (-i option) shows the state of the interfaces. ■ The seventh form (-r option) displays the routing table. ■ The eighth form (-M option) displays the multicast routing table. ■ The ninth form (-D option) displays the state of DHCP on one or all interfaces. These forms are described in greater detail below. With no arguments (the first form), netstat displays connected sockets for PF_INET, PF_INET6, and PF_UNIX, unless modified otherwise by the -f option.				
OPTIONS	<table> <tr> <td>-a</td><td>Show the state of all sockets, all routing table entries, or all interfaces, both physical and logical. Normally, listener sockets used by server processes are not shown. Under most conditions, only interface, host, network, and default routes are shown and only the status of physical interfaces is shown.</td></tr> <tr> <td>-f <i>address_family</i></td><td>Limit all displays to those of the specified <i>address_family</i>. The value of <i>address_family</i> can be one of the following:</td></tr> </table>	-a	Show the state of all sockets, all routing table entries, or all interfaces, both physical and logical. Normally, listener sockets used by server processes are not shown. Under most conditions, only interface, host, network, and default routes are shown and only the status of physical interfaces is shown.	-f <i>address_family</i>	Limit all displays to those of the specified <i>address_family</i> . The value of <i>address_family</i> can be one of the following:
-a	Show the state of all sockets, all routing table entries, or all interfaces, both physical and logical. Normally, listener sockets used by server processes are not shown. Under most conditions, only interface, host, network, and default routes are shown and only the status of physical interfaces is shown.				
-f <i>address_family</i>	Limit all displays to those of the specified <i>address_family</i> . The value of <i>address_family</i> can be one of the following:				

netstat(1M)

-f *filter*

inet For the AF_INET address family showing IPv4 information.

inet6 For the AF_INET6 address family showing IPv6 information.

unix For the AF_UNIX address family.

With -r only, limit the display of routes to those matching the specified filter. A filter rule consists of a "keyword:value" pair. The known keywords and the value syntax are:

af:{inet|inet6|unix|*number*}

Selects an address family. This is identical to -f *address_family* and both syntaxes are supported.

{inif|outif}:{*name*|*ifIndex*|any|none}

Selects an input or output interface. You can specify the interface by name (such as hme0) or by *ifIndex* number (for example, 2). If any is used, the filter matches all routes having a specified interface (anything other than null). If none is used, the filter matches all routes having a null interface. Note that you can view the index number (*ifIndex*) for an interface with the -a option of ifconfig(1M).

{src|dst}:{*ip-address*[/*mask*]|any|none}

Selects a source or destination IP address. If specified with a mask length, then any routes with matching or longer (more specific) masks are selected. If any is used, then all but addresses but 0 are selected. If none is used, then address 0 is selected.

flags:[+ -]?[ABDGHLSU]+

Selects routes tagged with the specified flags. By default, the flags as specified must be set in order to match. With a leading +, the flags specified must be set but others are ignored. With a leading -, the flags specified must not be set and others are permitted.

You can specify multiple instances of -f to specify multiple filters. For example:

```
% netstat -nr -f outif:hme0 -f outif:hme1 -f dst:10.0.0.0/8
```

The preceding command displays routes within network 10.0.0.0/8, with mask length 8 or greater, and an output interface of either hme0 or hme1, and excludes all other routes.

	-g	Show the multicast group memberships for all interfaces. See DISPLAYS, below.
	-i	Show the state of the interfaces that are used for IP traffic. Normally this shows statistics for the physical interfaces. When combined with the -a option, this will also report information for the logical interfaces. See ifconfig(1M).
	-m	Show the STREAMS memory statistics.
	-n	Show network addresses as numbers. <code>netstat</code> normally displays addresses as symbols. This option may be used with any of the display formats.
	-p	Show the net to media tables. See DISPLAYS, below.
	-r	Show the routing tables. Normally, only interface, host, network, and default routes are shown, but when this option is combined with the -a option, all routes will be displayed, including cache.
	-s	Show per-protocol statistics. When used with the -M option, show multicast routing statistics instead. When used with the -a option, per-interface statistics will be displayed, when available, in addition to statistics global to the system. See DISPLAYS, below.
	-v	Verbose. Show additional information for the sockets, STREAMS memory statistics, and the routing table.
	-I <i>interface</i>	Show the state of a particular interface. <i>interface</i> can be any valid interface such as hme0 or le0. Normally, the status and statistics for physical interfaces are displayed. When this option is combined with the -a option, information for the logical interfaces is also reported.
	-M	Show the multicast routing tables. When used with the -s option, show multicast routing statistics instead.
	-P <i>protocol</i>	Limit display of statistics or state of all sockets to those applicable to <i>protocol</i> . The protocol can be one of ip, ipv6, icmp, icmpv6, igmp, udp, tcp, rawip. rawip can also be specified as raw. The command accepts protocol options only as all lowercase.
	-D	Show the status of DHCP configured interfaces.
OPERANDS	<i>interval</i>	Display interface statistics accumulated since last display every <i>interval</i> seconds, repeating forever, unless <i>count</i> is specified. When invoked with <i>interval</i> , the first row of <code>netstat</code> output shows statistics accumulated since last reboot.

netstat(1M)

	<i>count</i>	Display interface statistics the number of times specified by <i>count</i> , at the interval specified by <i>interval</i> .
Active Sockets (First Form)	The display for each active socket shows the local and remote address, the send and receive queue sizes (in bytes), the send and receive windows (in bytes), and the internal state of the protocol.	
	The symbolic format normally used to display socket addresses is either <i>hostname.port</i> when the name of the host is specified, or <i>network.port</i> if a socket address specifies a network but no specific host.	
	The numeric host address or network number associated with the socket is used to look up the corresponding symbolic hostname or network name in the <i>hosts</i> or <i>networks</i> database.	
	If the network or hostname for an address is not known, or if the <i>-n</i> option is specified, the numerical network address is shown. Unspecified, or "wildcard", addresses and ports appear as "*". For more information regarding the Internet naming conventions, refer to <i>inet(7P)</i> and <i>inet6(7P)</i> .	
TCP Sockets	The possible state values for TCP sockets are as follows:	
	BOUND	Bound, ready to connect or listen.
	CLOSED	Closed. The socket is not being used.
	CLOSING	Closed, then remote shutdown; awaiting acknowledgment.
	CLOSE_WAIT	Remote shutdown; waiting for the socket to close.
	ESTABLISHED	Connection has been established.
	FIN_WAIT_1	Socket closed; shutting down connection.
	FIN_WAIT_2	Socket closed; waiting for shutdown from remote.
	IDLE	Idle, opened but not bound.
	LAST_ACK	Remote shutdown, then closed; awaiting acknowledgment.
	LISTEN	Listening for incoming connections.
	SYN_RECEIVED	Initial synchronization of the connection under way.
	SYN_SENT	Actively trying to establish connection.
	TIME_WAIT	Wait after close for remote shutdown retransmission.
Network Data Structures (Second Through Fifth Forms)	The form of the display depends upon which of the <i>-g</i> , <i>-m</i> , <i>-p</i> , or <i>-s</i> options you select.	
	<i>-g</i>	Displays the list of multicast group membership.
	<i>-m</i>	Displays the memory usage, for example, STREAMS mblks.

- p Displays the net to media mapping table. For IPv4, the address resolution table is displayed. See arp(1M). For IPv6, the neighbor cache is displayed.
- s Displays the statistics for the various protocol layers.

The statistics use the MIB specified variables. The defined values for ipForwarding are:

- forwarding (1) Acting as a gateway.
- not-forwarding (2) Not acting as a gateway.

The IPv6 and ICMPv6 protocol layers maintain per-interface statistics. If the -a option is specified with the -s option, then the per-interface statistics as well as the total sums are displayed. Otherwise, just the sum of the statistics are shown.

For the second, third, and fourth forms of the command, you must specify at least -g, -p, or -s. You can specify any combination of these options. You can also specify -m (the fifth form) with any set of the -g, -p, and -s options. If you specify more than one of these options, netstat displays the information for each one of them.

Interface Status (Sixth Form)

The interface status display lists information for all current interfaces, one interface per line. If an interface is specified using the -I option, it displays information for only the specified interface.

The list consists of the interface name, mtu (maximum transmission unit, or maximum packet size)(see ifconfig(1M)), the network to which the interface is attached, addresses for each interface, and counter associated with the interface. The counters show the number of input packets, input errors, output packets, output errors, and collisions, respectively. For Point-to-Point interfaces, the Net/Dest field is the name or address on the other side of the link.

If the -a option is specified with either the -i option or the -I option, then the output includes names of the physical interface(s), counts for input packets and output packets for each logical interface, plus additional information.

If the -n option is specified, the list displays the IP address instead of the interface name.

If an optional *interval* is specified, the output will be continually displayed in *interval* seconds until interrupted by the user or until *count* is reached. See OPERANDS.

The physical interface is specified using the -I option. When used with the *interval* operand, output for the -I option has the following format:

input	le0	output	input	(Total)	output
packets	errs	packets errs colls	packets	errs packets	errs colls
227681	0	659471 1 502	261331	0 99597	1 502
10	0	0 0 0	10	0 0	0 0
8	0	0 0 0	8	0 0	0 0
10	0	2 0 0	10	0 2	0 0

netstat(1M)

**Routing Table
(Seventh Form)**

If the input interface is not specified, the first interface of address family `inet` or `inet6` will be displayed.

The routing table display lists the available routes and the status of each. Each route consists of a destination host or network, and a gateway to use in forwarding packets. The *flags* column shows the status of the route (U if "up"), whether the route is to a gateway (G), whether it is a redundant route established with the `-multirt` option (M), whether the route was established using the `-setsrc` option (S), and whether the route was created dynamically by a redirect (D). If the `-a` option is specified, there will be routing entries with flags for combined routing and address resolution entries (A), broadcast addresses (B), and the local addresses for the host (L).

Interface routes are created for each interface attached to the local host; the gateway field for such entries shows the address of the outgoing interface.

The *use* column displays the number of packets sent using a combined routing and address resolution (A) or a broadcast (B) route. For a local (L) route, this count is the number of packets received, and for all other routes it is the number of times the routing entry has been used to create a new combined route and address resolution entry.

The *interface* entry indicates the network interface utilized for the route.

**Multicast Routing
Tables (Eighth
Form)**

The multicast routing table consists of the virtual interface table and the actual routing table.

**DHCP Interface
Information
(Ninth Form)**

The DHCP interface information consists of the interface name, its current state, lease information, packet counts, and a list of flags.

The states correlate with the specifications set forth in *RFC 2131*.

Lease information includes:

- when the lease began;
- when lease renewal will begin; and
- when the lease will expire.

The flags currently defined include:

BOOTP The interface has a lease obtained through BOOTP.

BUSY The interface is busy with a DHCP transaction.

PRIMARY The interface is the primary interface. See `dhcinfo(1)`.

FAILED The interface is in failure state and must be manually restarted.

Packet counts are maintained for the number of packets sent, the number of packets received, and the number of lease offers declined by the DHCP client. All three counters are initialized to zero and then incremented while obtaining a lease. The

netstat(1M)

counters are reset when the period of lease renewal begins for the interface. Thus, the counters represent either the number of packets sent, received, and declined while obtaining the current lease, or the number of packets sent, received, and declined while attempting to obtain a future lease.

FILES /etc/default/inet_type DEFAULT_IP setting

ATTRIBUTES See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

SEE ALSO arp(1M), dhcinfo(1), dhcagent(1M), ifconfig(1M), iostat(1M), mibiisa(1M), savecore(1M), vmstat(1M), hosts(4), inet_type(4), networks(4), protocols(4), services(4), attributes(5), inet(7P), inet6(7P)

Droms, R., *RFC 2131, Dynamic Host Configuration Protocol*, Network Working Group, March 1997.

NOTES When displaying interface information, netstat honors the DEFAULT_IP setting in /etc/default/inet_type. If it is set to IP_VERSION4, then netstat will omit information relating to IPv6 interfaces, statistics, connections, routes and the like.

However, you can override the DEFAULT_IP setting in /etc/default/inet_type on the command-line. For example, if you have used the command-line to explicitly request IPv6 information by using the inet6 address family or one of the IPv6 protocols, it will override the DEFAULT_IP setting.

If you need to examine network status information following a kernel crash, use the mdb(1) utility on the savecore(1M) output.

The netstat utility obtains TCP statistics from the system by opening /dev/tcp and issuing queries. Because of this, netstat might display an extra, unused connection in IDLE state when reporting connection status.

newaliases(1M)

NAME	newaliases – rebuild the data base for the mail aliases file																	
SYNOPSIS	newaliases																	
DESCRIPTION	newaliases rebuilds the random access data base for the mail aliases file /etc/mail/aliases. newaliases accepts all the flags that sendmail(1M) accepts. However, most of these flags have no effect, except for the -C option and three of the Processing Options that can be set from a configuration file with the -o option: <table><tr><td>-C /path/to/alt/config/file</td><td>Use alternate configuration file.</td></tr><tr><td>-oAfile</td><td>Specify possible alias files.</td></tr><tr><td>-oLn</td><td>Set the default log level to n. Defaults to 9.</td></tr><tr><td>-on</td><td>Validate the RHS of aliases when rebuilding the aliases(4) database.</td></tr></table> newaliases runs in verbose mode (-v option) automatically.		-C /path/to/alt/config/file	Use alternate configuration file.	-oAfile	Specify possible alias files.	-oLn	Set the default log level to n. Defaults to 9.	-on	Validate the RHS of aliases when rebuilding the aliases(4) database.								
-C /path/to/alt/config/file	Use alternate configuration file.																	
-oAfile	Specify possible alias files.																	
-oLn	Set the default log level to n. Defaults to 9.																	
-on	Validate the RHS of aliases when rebuilding the aliases(4) database.																	
EXAMPLES	EXAMPLE 1 Running the newaliases Command The following command runs newaliases on an alias file different from the /etc/mail/aliases default in sendmail(1M): <pre>example% newaliases -oA/path/to/alternate/alias/file</pre>																	
EXIT STATUS	newaliases returns an exit status describing what it did. The codes are defined in /usr/include/sysexits.h. <table><tr><td>EX_OK</td><td>Successful completion on all addresses.</td></tr><tr><td>EX_NOUSER</td><td>User name not recognized.</td></tr><tr><td>EX_UNAVAILABLE</td><td>Catchall. Necessary resources were not available.</td></tr><tr><td>EX_SYNTAX</td><td>Syntax error in address.</td></tr><tr><td>EX_SOFTWARE</td><td>Internal software error, including bad arguments.</td></tr><tr><td>EX_OSERR</td><td>Temporary operating system error, such as “cannot fork”.</td></tr><tr><td>EX_NOHOST</td><td>Host name not recognized.</td></tr><tr><td>EX_TEMPFAIL</td><td>Message could not be sent immediately, but was queued.</td></tr></table>		EX_OK	Successful completion on all addresses.	EX_NOUSER	User name not recognized.	EX_UNAVAILABLE	Catchall. Necessary resources were not available.	EX_SYNTAX	Syntax error in address.	EX_SOFTWARE	Internal software error, including bad arguments.	EX_OSERR	Temporary operating system error, such as “cannot fork”.	EX_NOHOST	Host name not recognized.	EX_TEMPFAIL	Message could not be sent immediately, but was queued.
EX_OK	Successful completion on all addresses.																	
EX_NOUSER	User name not recognized.																	
EX_UNAVAILABLE	Catchall. Necessary resources were not available.																	
EX_SYNTAX	Syntax error in address.																	
EX_SOFTWARE	Internal software error, including bad arguments.																	
EX_OSERR	Temporary operating system error, such as “cannot fork”.																	
EX_NOHOST	Host name not recognized.																	
EX_TEMPFAIL	Message could not be sent immediately, but was queued.																	
FILES	<table><tr><td>/etc/aliases</td><td>Symbolic link to /etc/mail/aliases</td></tr><tr><td>/etc/mail/aliases.pag</td><td></td></tr><tr><td>/etc/mail/aliases.dir</td><td>ndbm files maintained by newaliases</td></tr></table>		/etc/aliases	Symbolic link to /etc/mail/aliases	/etc/mail/aliases.pag		/etc/mail/aliases.dir	ndbm files maintained by newaliases

newfs(1M)

NAME	newfs – construct a new UFS file system
SYNOPSIS	newfs [-Nv] [<i>mkfs-options</i>] <i>raw-device</i>
DESCRIPTION	<i>newfs</i> is a "friendly" front-end to the <i>mkfs</i>(1M) program for making UFS file systems on disk partitions. <i>newfs</i> calculates the appropriate parameters to use and calls <i>mkfs</i>. If run interactively (that is, standard input is a tty), <i>newfs</i> will prompt for confirmation before making the file system. If the -N option is not specified and the inodes of the device are not randomized, <i>newfs</i> will call <i>fsirand</i>(1M). You must be super-user to use this command, except when creating a UFS file system on a <i>diskette</i> (see EXAMPLES).
OPTIONS	The following options are supported: -N Print out the file system parameters that would be used in creating the file system without actually creating the file system. <i>fsirand</i>(1M) is not called here. -v Verbose. <i>newfs</i> prints out its actions, including the parameters passed to <i>mkfs</i>. <i>mkfs-options</i> Options that override the default parameters are: -a <i>apc</i> The number of alternate sectors per cylinder (SCSI devices only) to reserve for bad block replacement. The default is 0. -b <i>bsize</i> The logical block size of the file system in bytes (either 4096 or 8192). The default is 8192. The sun4u architecture does not support the 4096 block size. -c <i>cgsz</i> The number of cylinders per cylinder group (ranging from 16 to 256). The default is calculated by dividing the number of sectors in the file system by the number of sectors in a gigabyte, and then multiplying the result by 32. The default value will always be between 16 and 256. <i>mkfs</i> may override this value. See <i>mkfs_ufs</i>(1M) for details. -C <i>maxcontig</i> The maximum number of logical blocks, belonging to one file, that will be allocated contiguously before inserting a rotational delay. The default is determined from the disk drive's maximum transfer rate.

UFS supports no more than 1048576 byte (1MB) runs. With a logical block size of 4096, this gives a *maxcontig* limit of 256. With 8192, the limit is 128.

This parameter can be subsequently changed using the `tunefs(1M)` command.

This parameter also controls clustering. Regardless of the value of *gap*, clustering is enabled only when *maxcontig* is greater than 1. Clustering allows higher I/O rates for sequential I/O and is described in `tunefs(1M)`.

-d *gap* Rotational delay. The expected time (in milliseconds) to service a transfer completion interrupt and initiate a new transfer on the same disk. It is used to decide how much rotational spacing to place between successive blocks in a file. This parameter can be subsequently changed using the `tunefs(1M)` command. The default is 0.

-f *fragsize* The smallest amount of disk space in bytes to allocate to a file. The smallest amount of disk space in bytes to allocate to a file. If the logical block size is 4096, legal values are 512, 1024, 2048, and 4096. When the logical block size is 8192, legal values are 1024, 2048, 4096, and 8192. The default value is 1024.

-i *nbpi* The number of bytes per inode. This specifies the density of inodes in the file system. The number is divided into the total size of the file system to determine the fixed number of inodes to create. It should reflect the expected average size of files in the file system. If fewer inodes are desired, a larger number should be used; to create more inodes a smaller number should be given. The default for *nbpi* is as follows:.

<i>Disk size</i>	<i>Density</i>
–1GB	2048
–2GB	4096
–3GB	6144
3GB–	8192

newfs(1M)

	<i>-m free</i>	The minimum percentage of free space to maintain in the file system (between 1% and 99%, inclusively). This space is off-limits to normal users. Once the file system is filled to this threshold, only the super-user can continue writing to the file system. This parameter can be subsequently changed using the <code>tunefs(1M)</code> command.
	<i>-n nrpos</i>	The default is ((64 Mbytes/partition size) * 100), rounded down to the nearest integer and limited between 1% and 10%, inclusively.
	<i>-o opt</i>	The number of different rotational positions in which to divide a cylinder group. The default is 8.
	<i>-r rpm</i>	(space or time). The file system can either be instructed to try to minimize the time spent allocating blocks, or to try to minimize the space fragmentation on the disk. The default is time.
	<i>-s size</i>	The speed of the disk in revolutions per minute. The default is driver- or device-specific.
	<i>-t ntrack</i>	The size of the file system in sectors. The default is to use the entire partition.
		The number of tracks per cylinder on the disk. The default is taken from the disk label.
OPERANDS	The following operands are supported:	
	<i>raw-device</i>	The name of a raw special device residing in <code>/dev/rdisk</code> (for example, <code>/dev/rdisk/c0t0d0s6</code>) on which to create the file system.
USAGE	See <code>largefile(5)</code> for the description of the behavior of <code>newfs</code> when encountering files greater than or equal to 2 Gbyte (2^{31} bytes).	
EXAMPLES	EXAMPLE 1 Verbosely displaying the parameters for the raw special device. The following example verbosely displays the parameters for the raw special device, <code>c0t0d0s6</code>, but does not actually create a new file system: <pre>example# newfs -Nv /dev/rdisk/c0t0d0s6 mkfs -F ufs -o N /dev/rdisk/c0t0d0s6 1112940 54 15 8192 1024 16 10 60 2048 t 0 -1 8 /dev/rdisk/c0t0d0s6: 1112940 sectors in 1374 cylinders of 15 tracks, 54 sectors 569.8MB in 86 cyl groups (16 c/g, 6.64MB/g, 3072 i/g) super-block backups</pre>	

EXAMPLE 1 Verbosely displaying the parameters for the raw special device. (Continued)

```
(for fsck -b #) at:
32, 13056, 26080, 39104, 52128, 65152, 78176, 91200, 104224, . . .
```

EXAMPLE 2 Creating a UFS file system.

The following example uses the command to create a UFS file system on a diskette that is managed by Volume Manager.

```
example% newfs /vol/dev/aliases/floppy0
newfs: construct a new file system /vol/dev/aliases/floppy0: (y/n)? y
/vol/dev/aliases/floppy0: 2880 sectors in 80 cylinders of 2 tracks,
18 sectors 1.4MB in 5 cyl groups (16 c/g, 0.28MB/g, 128 i/g)
super-block backups (for fsck -F ufs -o b=#) at:
32, 640, 1184, 1792, 2336, . . .
```

EXIT STATUS The following exit values are returned:

```
0          The operation was successful.
1, 10      Usage error or internal error. A message is output to STDERR explaining the
           error.
```

Other exit values may be returned by `mkfs(1M)`, which is called by `newfs`.

newkey(1M)

NAME	newkey – create a new Diffie-Hellman key pair in the publickey database				
SYNOPSIS	newkey -h <i>hostname</i> [-s nisplus nis files ldap] newkey -u <i>username</i> [-s nisplus nis files ldap]				
DESCRIPTION	newkey establishes new public keys for users and machines on the network. These keys are needed when using secure RPC or secure NFS service. newkey prompts for a password for the given <i>username</i> or <i>hostname</i> and then creates a new public/secret Diffie-Hellman 192 bit key pair for the user or host. The secret key is encrypted with the given password. The key pair can be stored in the <code>/etc/publickey</code> file, the NIS publickey map, or the NIS+ <code>cred.org_dir</code> table. newkey consults the publickey entry in the name service switch configuration file (see <code>nsswitch.conf(4)</code>) to determine which naming service is used to store the secure RPC keys. If the publickey entry specifies a unique name service, newkey will add the key in the specified name service. However, if there are multiple name services listed, newkey cannot decide which source to update and will display an error message. The user is required to specify the source explicitly with the <code>-s</code> option. In the case of NIS, newkey should be run by the superuser on the master NIS server for that domain. In the case of NIS+, newkey should be run by the superuser on a machine which has permission to update the <code>cred.org_dir</code> table of the new user/host domain. In the case of NIS+, <code>nisaddcred(1M)</code> should be used to add new keys. newkey cannot be used to create keys other than 192-bit Diffie-Hellman.				
OPTIONS	-h <i>hostname</i> Create a new public/secret key pair for the privileged user at the given <i>hostname</i>. Prompts for a password for the given <i>hostname</i>. -u <i>username</i> Create a new public/secret key pair for the given <i>username</i>. Prompts for a password for the given <i>username</i>. -s nisplus -s nis -s files -s ldap Update the database in the specified source: nisplus (for NIS+), nis (for NIS), files, or ldap (LDAP). Other sources may be available in the future.				
ATTRIBUTES	See <code>attributes(5)</code> for descriptions of the following attributes: <table border="1"> <thead> <tr> <th>ATTRIBUTE TYPE</th><th>ATTRIBUTE VALUE</th></tr> </thead> <tbody> <tr> <td>Availability</td><td>SUNWcsu</td></tr> </tbody> </table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	Availability	SUNWcsu

NOTES NIS+ might not be supported in future releases of the Solaris™ Operating
Environment. Tools to aid the migration from NIS+ to LDAP are available in the
Solaris 9 operating environment. For more information, visit
<http://www.sun.com/directory/nisplus/transition.html>.

nfsd(1M)

NAME	nfsd – NFS daemon
SYNOPSIS	/usr/lib/nfs/nfsd [-a] [-c #_conn] [-l <i>listen_backlog</i>] [-p <i>protocol</i>] [-t <i>device</i>] [<i>nservers</i>]
DESCRIPTION	nfsd is the daemon that handles client file system requests. Only the super-user can run this daemon. The nfsd daemon is automatically invoked in run level 3 with the -a option, described below. By default, nfsd starts over the TCP and UDP transports. You can change this with the -p option, described below. A previously invoked nfsd daemon started with or without options must be stopped before invoking another nfsd command. Administrators wanting to change startup parameters for nfsd should, as root, make changes in the /etc/default/nfs file rather than editing the /etc/init.d/nfs.server file. See nfs(4).
OPTIONS	The following options are supported: -a Start a NFS daemon over all available connectionless and connection-oriented transports, including UDP and TCP. Equivalent of setting the NFSD_PROTOCOL parameter to ALL in the nfs file. -c #_conn This sets the maximum number of connections allowed to the NFS server over connection-oriented transports. By default, the number of connections is unlimited. Equivalent of the NFSD_MAX_CONNECTIONS parameter in the nfs file. -l Set connection queue length for the NFS TCP over a connection-oriented transport. The default value is 32 entries. Equivalent of the NFSD_LISTEN_BACKLOG parameter in the nfs file. -p <i>protocol</i> Start a NFS daemon over the specified protocol. Equivalent of the NFSD_PROTOCOL parameter in the nfs file. -t <i>device</i> Start a NFS daemon for the transport specified by the given device. Equivalent of the NFSD_DEVICE parameter in the nfs file.
OPERANDS	The following operands are supported: <i>nservers</i> This sets the maximum number of concurrent NFS requests that the server can handle. This concurrency is achieved by up to <i>nservers</i> threads created as needed in the kernel. <i>nservers</i> should be based on the load expected on this server. 16 is the usual number of <i>nservers</i>. If <i>nservers</i> is not specified, the maximum number of concurrent NFS requests will default to 1. Equivalent of the

NFSD_MAX_CONNECTIONS parameter in the `nfs` file.

USAGE If the `NFS_PORTMON` variable is set in `/etc/system`, then clients are required to use privileged ports (ports < `IPPORT_RESERVED`) to get NFS services. This variable is equal to zero by default. This variable has been moved from the "nfs" module to the "nfsrv" module. To set the variable, edit the `/etc/system` file and add this entry:

```
set nfssrv:nfs_portmon = 1
```

EXIT STATUS

0	Daemon started successfully.
1	Daemon failed to start.

FILES

<code>.nfsXXX</code>	client machine pointer to an open-but-unlinked file
<code>/etc/default/nfs</code>	contains startup parameters for <code>nfsd</code>
<code>/etc/init.d/nfs.server</code>	shell script for starting <code>nfsd</code>
<code>/etc/system</code>	system configuration information file

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWnfssu

System Administration Guide: Naming and Directory Services (DNS, NIS, and LDAP)

NOTES Manually starting and restarting `nfsd` is not recommended. If it is necessary to do so, use the NFS server start/stop script (`/etc/init.d/nfs.server`). See *System Administration Guide: Naming and Directory Services (DNS, NIS, and LDAP)* for more information.

nfslogd(1M)

NAME	nfslogd – nfs logging daemon
SYNOPSIS	<code>/usr/lib/nfs/nfslogd</code>
DESCRIPTION	The <code>nfslogd</code> daemon provides operational logging to the Solaris NFS server. It is the <code>nfslogd</code> daemon's job to generate the activity log by analyzing the RPC operations processed by the the NFS server. The log will only be generated for file systems exported with logging enabled. This is specified at file system export time by means of the <code>share_nfs(1M)</code> command. Each record in the log file includes a time stamp, the IP address (or hostname if it can be resolved) of the client system, the file or directory name the operation was performed on, and the type of operation. In the basic format, the operation can either be an input (i) or output (o) operation. The basic format of the NFS server log is compatible with the log format generated by the Washington University FTPd daemon. The log format can be extended to include directory modification operations, such as <code>mkdir</code>, <code>rmdir</code>, and <code>remove</code>. The extended format is not compatible with the Washington University FTPd daemon format. See <code>nfslog.conf(4)</code> for details. The NFS server logging mechanism is divided in two phases. The first phase is performed by the NFS kernel module, which records raw RPC requests and their results in work buffers backed by permanent storage. The location of the work buffers is specified in the <code>/etc/nfs/nfslog.conf</code> file. Refer to <code>nfslog.conf(4)</code> for more information. The second phase involves the <code>nfslogd</code> user-level daemon, which periodically reads the work buffers, interprets the raw RPC information, groups related RPC operations into single transaction records, and generates the output log. The <code>nfslogd</code> daemon then sleeps waiting for more information to be logged to the work buffers. The amount of time that the daemon sleeps can be configured by modifying the <code>IDLE_TIME</code> parameter in <code>/etc/default/nfslogd</code>. The work buffers are intended for internal consumption of the <code>nfslogd</code> daemon. NFS operations use file handles as arguments instead of path names. For this reason the <code>nfslogd</code> daemon needs to maintain a database of file handle to path mappings in order to log the path name associated with an operation instead of the corresponding file handle. A file handle entry is added to the database when a client performs a lookup or other NFS operation that returns a file handle to the client. Once an NFS client obtains a file handle from a server, it can hold on to it for an indefinite time, and later use it as an argument for an NFS operation on the file or directory. The NFS client can use the file handle even after the server reboots. Because the database needs to survive server reboots, it is backed by permanent storage. The location of the database is specified by the <code>htable</code> parameter in the <code>/etc/nfs/nfslog.conf</code> file. This database is intended for the internal use of the <code>nfslogd</code> daemon. In order to keep the size of the file handle mapping database manageable, <code>nfslogd</code> prunes the database periodically. It removes file handle entries that have not been accessed in more than a specified amount of time. The <code>PRUNE_TIMEOUT</code> configurable parameter in <code>/etc/default/nfslogd</code> specifies the interval length between

successive runs of the pruning process. A file handle record will be removed if it has not been used since the last time the pruning process was executed. Pruning of the database can effectively be disabled by setting the `PRUNE_TIMEOUT` as high as `INT_MAX`.

When pruning is enabled, there is always a risk that a client may have held on to a file handle longer than the `PRUNE_TIMEOUT` and perform an NFS operation on the file handle after the matching record in the mapping database had been removed. In such case, the pathname for the file handle will not be resolved, and the log will include the file handle instead of the pathname.

There are various configurable parameters that affect the behavior of the `nfslogd` daemon. These parameters are found in `/etc/default/nfslogd` and are described below:

<code>UMASK</code>	Sets the file mode for the log files, work buffer files and file handle mapping database.
<code>MIN_PROCESSING_SIZE</code>	Specifies the minimum size, in bytes, that the buffer file must reach before processing the work information and writing to the log file. The value of <code>MIN_PROCESSING_SIZE</code> must be between 1 and <code>ulimit</code> .
<code>IDLE_TIME</code>	Specifies the amount of time, in seconds, the daemon should sleep while waiting for more information to be placed in the buffer file. <code>IDLE_TIME</code> also determines how often the configuration file will be reread. The value of <code>IDLE_TIME</code> must be between 1 and <code>INT_MAX</code> .
<code>MAX_LOGS_PRESERVE</code>	The <code>nfslogd</code> periodically cycles its logs. <code>MAX_LOGS_PRESERVE</code> specifies the maximum number of log files to save. When <code>MAX_LOGS_PRESERVE</code> is reached, the oldest files will be overwritten as new log files are created. These files will be saved with a numbered extension, beginning with <code>filename.0</code> . The oldest file will have the highest numbered extension up to the value configured for <code>MAX_LOGS_PRESERVE</code> . The value of <code>MAX_LOGS_PRESERVE</code> must be between 1 and <code>INT_MAX</code> .
<code>CYCLE_FREQUENCY</code>	Specifies how often, in hours, the log files are cycled. <code>CYCLE_FREQUENCY</code> is used to insure that the log files do not get too large.

nfslogd(1M)

		The value of <code>CYCLE_FREQUENCY</code> must be between 1 and <code>INT_MAX</code> .				
	<code>MAPPING_UPDATE_INTERVAL</code>	Specifies the time interval, in seconds, between updates of the records in the file handle to path mapping tables. Instead of updating the <code>atime</code> of a record each time that record is accessed, it is only updated if it has aged based on this parameter. The record access time is used by the pruning routine to determine whether the record should be removed from the database. The value of this parameter must be between 1 and <code>INT_MAX</code> .				
	<code>PRUNE_TIMEOUT</code>	Specifies when a database record times out, in hours. If the time that elapsed since the record was last accessed is greater than <code>PRUNE_TIMEOUT</code> then the record can be pruned from the database. The default value for <code>PRUNE_TIMEOUT</code> is 168 hours (7 days). The value of <code>PRUNE_TIMEOUT</code> must be between 1 and <code>INT_MAX</code> .				
EXIT STATUS	The following exit values are returned: 0 Daemon started successfully. 1 Daemon failed to start.

NAME	nfsstat – NFS statistics						
SYNOPSIS	nfsstat [-cnrsmza]						
DESCRIPTION	nfsstat displays statistical information about the NFS and RPC (Remote Procedure Call), interfaces to the kernel. It can also be used to reinitialize this information. If no options are given the default is <pre>nfsstat -csnra</pre> That is, display everything, but reinitialize nothing.						
OPTIONS	-a Display NFS_ACL information. -c Display client information. Only the client side NFS, RPC, and NFS_ACL information is printed. Can be combined with the -n, -r, and -a options to print client side NFS, RPC, and NFS_ACL information only. -m Display statistics for each NFS mounted file system. This includes the server name and address, mount flags, current read and write sizes, the retransmission count, the attribute cache timeout values, failover information, and the timers used for dynamic retransmission. Note that the dynamic retransmission timers are displayed only where dynamic retransmission is in use. By default, NFS mounts over the TCP protocols and NFS Version 3 mounts over either TCP or UDP do not use dynamic retransmission. If you specify the -m option, this is the only option nfsstat uses. Any options specified in addition to -m are checked for validity, then ignored. -n Display NFS information. NFS information for both the client and server side will be printed. Can be combined with the -c and -s options to print client or server NFS information only. -r Display RPC information. -s Display server information. -z Zero (reinitialize) statistics. This option is for use by the super user only, and can be combined with any of the above options to zero particular sets of statistics after printing them.						
DISPLAYS	The server RPC display includes the following fields: <table> <tr> <td>calls</td><td>The total number of RPC calls received.</td></tr> <tr> <td>badcalls</td><td>The total number of calls rejected by the RPC layer (the sum of badlen and xdr call as defined below).</td></tr> <tr> <td>nullrecv</td><td>The number of times an RPC call was not available when it was thought to be received.</td></tr> </table>	calls	The total number of RPC calls received.	badcalls	The total number of calls rejected by the RPC layer (the sum of badlen and xdr call as defined below).	nullrecv	The number of times an RPC call was not available when it was thought to be received.
calls	The total number of RPC calls received.						
badcalls	The total number of calls rejected by the RPC layer (the sum of badlen and xdr call as defined below).						
nullrecv	The number of times an RPC call was not available when it was thought to be received.						

nfsstat(1M)

badlen	The number of RPC calls with a length shorter than a minimum-sized RPC call.
xdr call	The number of RPC calls whose header could not be XDR decoded.
dupchecks	The number of RPC calls that looked up in the duplicate request cache.
dupreqs	The number of RPC calls that were found to be duplicates.
The server NFS display shows the number of NFS calls received (<code>calls</code>) and rejected (<code>badcalls</code>), and the counts and percentages for the various calls that were made.	
The server NFS_ACL display shows the counts and percentages for the various calls that were made.	
The client RPC display includes the following fields:	
<code>calls</code>	The total number of RPC calls made.
<code>badcalls</code>	The total number of calls rejected by the RPC layer.
<code>badxids</code>	The number of times a reply from a server was received which did not correspond to any outstanding call.
<code>timeouts</code>	The number of times a call timed out while waiting for a reply from the server.
<code>newcreds</code>	The number of times authentication information had to be refreshed.
<code>badverfs</code>	The number of times the call failed due to a bad verifier in the response.
<code>timers</code>	The number of times the calculated time-out value was greater than or equal to the minimum specified time-out value for a call.
<code>cantconn</code>	The number of times the call failed due to a failure to make a connection to the server.
<code>nomem</code>	The number of times the call failed due to a failure to allocate memory.
<code>interrupts</code>	The number of times the call was interrupted by a signal before completing.
<code>retrans</code>	The number of times a call had to be retransmitted due to a timeout while waiting for a reply from the server. Applicable only to RPC over connection-less transports.
<code>cantsend</code>	The number of times a client was unable to send an RPC request over a connectionless transport when it tried to do so.

The client NFS display shows the number of calls sent and rejected, as well as the number of times a CLIENT handle was received (`clgets`), the number of times the CLIENT handle cache had no unused entries (`cltoomany`), as well as a count of the various calls and their respective percentages.

The client NFS_ACL display shows the counts and percentages for the various calls that were made.

The `-m` option includes information about mount flags set by mount options, mount flags internal to the system, and other mount information. See `mount_nfs(1M)`.

The following mount flags are set by mount options:

<code>sec</code>	sec has one of the following values:
<code>none</code>	No authentication.
<code>sys</code>	UNIX-style authentication (UID, GID).
<code>short</code>	Short hand UNIX-style authentication.
<code>dh</code>	des-style authentication (encrypted timestamps).
<code>krb5</code>	kerberos v5-style authentication.
<code>krb5i</code>	kerberos v5-style authentication with integrity.
<code>krb5p</code>	kerberos v5-style authentication with privacy.
<code>hard</code>	Hard mount.
<code>soft</code>	Soft mount.
<code>intr</code>	Interrupts allowed on hard mount.
<code>nointr</code>	No interrupts allowed on hard mount.
<code>noac</code>	Client is not caching attributes.
<code>rsize</code>	Read buffer size in bytes.
<code>wsiz</code>	Write buffer size in bytes.
<code>retrans</code>	NFS retransmissions.
<code>timeo</code>	Initial NFS timeout, in tenths of a second.
<code>nocto</code>	No close-to-open consistency.
<code>llock</code>	Local locking being used (no lock manager).
<code>grp</code>	System V group id inheritance.
<code>rpctimesync</code>	RPC time sync.

The following mount flags are internal to the system:

<code>printed</code>	"Not responding" message printed.

nfsstat(1M)

down	Server is down.
dynamic	Dynamic transfer size adjustment.
link	Server supports links.
symlink	Server supports symbolic links.
readdir	Use readdir instead of readdirplus.
acl	Server supports NFS_ACL.

The following flags relate to additional mount information:

vers	NFS version.
proto	Protocol.

The -m option also provides attribute cache timeout values. The following fields in -m output provide timeout values for attribute cache:

acregmin	Minimum seconds to hold cached file attributes.
acregmax	Maximum seconds to hold cached file attributes.
acdirmin	Minimum seconds to hold cached directory attributes.
acdirmax	Maximum seconds to hold cached directory attributes.

The following fields in -m output provide failover information:

noresponse	How many times servers have failed to respond.
failover	How many times a new server has been selected.
remap	How many times files have been re-evaluated to the new server.
currserver	Which server is currently providing NFS service. See the <i>System Administration Guide: IP Services</i> for additional details.

The fields in -m output shown below provide information on dynamic retransmissions. Note that these items are displayed only where dynamic retransmission is in use.

srtt	The value for the smoothed round-trip time, in milliseconds.
dev	Estimated deviation, in milliseconds.
cur	Current backed-off retransmission value, in milliseconds.

EXIT STATUS The following exit values are returned:

0	Successful completion.
>0	An error occurred.

ATTRIBUTES See attributes(5) for descriptions of the following attributes:

nisaddcred(1M)

NAME	nisaddcred – create NIS+ credentials																				
SYNOPSIS	nisaddcred [-p <i>principal</i>] [-P <i>nis_principal</i>] [-l <i>login_password</i>] <i>auth_type</i> [<i>domain_name</i>] nisaddcred -r [<i>nis_principal</i>] [<i>domain_name</i>]																				
DESCRIPTION	The nisaddcred command is used to create security credentials for NIS+ principals. NIS+ credentials serve two purposes. The first is to provide authentication information to various services; the second is to map the authentication service name into a NIS+ principal name. When the nisaddcred command is run, these credentials get created and stored in a table named cred.org_dir in the default NIS+ domain. If <i>domain_name</i> is specified, the entries are stored in the cred.org_dir of the specified domain. The specified domain must either be the one to which you belong, or one in which you are authenticated and authorized to create credentials, that is, a subdomain. Note that the credentials of normal users must be stored in the same domain as their passwords. It is simpler to add credentials using nisclient(1M), because it obtains the required information itself. nispopulate(1M) is used for “bulk” updates and can also be used to add credentials for entries in the hosts and the passwd NIS+ tables. NIS+ principal names are used in specifying clients that have access rights to NIS+ objects. For more details, refer to the “Principal Names” subsection of the nis+(1) manual page. See nischmod(1), nischown(1), nis_objects(3NSL), and nis_groups(3NSL). Various other services can also implement access control based on these principal names. The cred.org_dir table is organized as follows: <table><tr><th>cname</th><th>auth_type</th><th>auth_name</th><th>public_data</th><th>private_data</th></tr><tr><td>user1.foo.com.</td><td>LOCAL</td><td>2990</td><td>10,102,44</td><td></td></tr><tr><td>user1.foo.com.</td><td>DES</td><td>unix.2990@foo.com</td><td>098...819</td><td>3b8...ab2</td></tr><tr><td>user1.foo.com.</td><td>DHmmm-n</td><td>unix.2990@foo.com</td><td>248...428</td><td>a42...f32</td></tr></table> The cname column contains a canonical representation of the NIS+ principal name. By convention, this name is the login name of a user, or the host name of a machine, followed by a dot (‘.’) followed by the fully qualified “home” domain of that principal. For users, the home domain is defined to be the domain where their DES credentials are kept. For hosts, their home domain is defined to be the domain name returned by the domainname(1M) command executed on that host. There are two basic types of <i>auth_type</i> entries in the cred.org_dir table, those with authentication type LOCAL, and those with authentication type DES, <i>auth_type</i>, specified on the command line in upper or lower case, should be either <i>local</i> or <i>des</i>.	cname	auth_type	auth_name	public_data	private_data	user1.foo.com.	LOCAL	2990	10,102,44		user1.foo.com.	DES	unix.2990@foo.com	098...819	3b8...ab2	user1.foo.com.	DHmmm-n	unix.2990@foo.com	248...428	a42...f32
cname	auth_type	auth_name	public_data	private_data																	
user1.foo.com.	LOCAL	2990	10,102,44																		
user1.foo.com.	DES	unix.2990@foo.com	098...819	3b8...ab2																	
user1.foo.com.	DHmmm-n	unix.2990@foo.com	248...428	a42...f32																	

However, the `cred.org_dir` table may also be used to hold data for other values of *auth_type*. Currently, this is limited to the mechanisms listed on the `nisauthconf(1M)` man page, for which the `nisaddcred auth_type` argument is the same as the name of the mechanism. These mechanisms use a modified form of Secure RPC, and they are similar to the DES authentication type.

If the *auth_type* is `des`, and other authentication mechanisms are configured with `nisauthconf(1M)`, then credential entries are added or updated for each mechanism configured. To only add or update 192-bit Diffie Hellman credentials, that is, those with the *auth_type* of DES, use `dh192-0` on the command line. If there are no authentication mechanisms configured, using `des` on the command line will only add or update 192-bit Diffie Hellman credentials.

Entries of type LOCAL are used by the NIS+ service to determine the correspondence between fully qualified NIS+ principal names and users identified by UIDs in the domain containing the `cred.org_dir` table. This correspondence is required when associating requests made using the AUTH_SYS RPC authentication flavor (see `rpc_clnt_auth(3NSL)`) to a NIS+ principal name. It is also required for mapping a UID in one domain to its fully qualified NIS+ principal name whose home domain may be elsewhere. The principal's credentials for any authentication flavor may then be sought for within the `cred.org_dir` table in the principal's home domain (extracted from the principal name). The same NIS+ principal may have LOCAL credential entries in more than one domain. Only users, and not machines, have LOCAL credentials. In their home domain, users of NIS+ should have both types of credentials.

The *auth_name* associated with the LOCAL type entry is a UID that is valid for the principal in the domain containing the `cred.org_dir` table. This may differ from that in the principal's home domain. The public information stored in *public_data* for this type contains a list of GIDs for groups in which the user is a member. The GIDs also apply to the domain in which the table resides. There is no private data associated with this type. Neither a UID nor a principal name should appear more than once among the LOCAL entries in any one `cred.org_dir` table.

The DES *auth_type* is used for Secure RPC authentication (see `secure_rpc(3NSL)`).

The authentication name associated with the DES *auth_type* is a Secure RPC *netname*. A Secure RPC netname has the form `unix.id@domain.com`, where *domain* must be the same as the domain of the principal. For principals that are users the *id* must be the UID of the principal in the principal's home domain. For principals that are hosts, the *id* is the host's name. In Secure RPC, processes running under effective UID 0 (root) are identified with the host principal. Unlike LOCAL, there cannot be more than one DES credential entry for one NIS+ principal in the NIS+ namespace.

The public information in an entry of authentication type DES is the public key for the principal. The private information in this entry is the private key of the principal encrypted by the principal's network password.

nisaddcred(1M)

User clients of NIS+ should have credentials of both types in their home domain. In addition, a principal must have a LOCAL entry in the `cred.org_dir` table of each domain from which the principal wishes to make authenticated requests. A client of NIS+ that makes a request from a domain in which it does not have a LOCAL entry will be unable to acquire DES credentials. A NIS+ service running at security level 2 or higher will consider such users unauthenticated and assign them the name *nobody* for determining access rights.

This command can only be run by those NIS+ principals who are authorized to add or delete the entries in the `cred` table.

If credentials are being added for the caller itself, `nisaddcred` automatically performs a keylogin for the caller.

You can list the `cred` entries for a particular principal with `nismatch(1)`.

The `cred.org_dir` NIS+ table replaces the maps *publickey.byname* and *netid.byname* used in NIS (YP).

OPTIONS

The following options are supported:

`-p principal`

The name *principal* specifies the name of the principal as defined by the naming rules for that specific mechanism. For example, LOCAL credential names are supplied with this option by including a string specifying a UID. For DES credentials, the name should be a Secure RPC netname of the form `unix.id@domain.com`, as described earlier. If the `-p` option is not specified, the *auth_name* field is constructed from the effective UID of the current process and the name of the local domain.

`-P nis_principal`

Use the NIS+ principal name *nis_principal*. This option should be used when creating LOCAL or DES credentials for users whose home domain is different than the local machine's default domain.

Whenever the `-P` option is not specified, `nisaddcred` constructs a principal name for the entry as follows. When it is not creating an entry of type LOCAL, `nisaddcred` calls `nis_local_principal`, which looks for an existing LOCAL entry for the effective UID of the current process in the `cred.org_dir` table and uses the associated principal name for the new entry. When creating an entry of authentication type LOCAL, `nisaddcred` constructs a default NIS+ principal name by taking the login name of the effective UID for its

	own process, and appending to it a dot ('.') followed by the local machine's default domain. If the caller is a superuser, the machine name is used instead of the login name.
<code>-l login_password</code>	Use the <i>login_password</i> specified as the password to encrypt the secret key for the credential entry. This overrides the prompting for a password from the shell. This option is intended for administration scripts only. Prompting guarantees not only that no one can see your password on the command line using <code>ps(1)</code> but it also checks to make sure you have not made any mistakes. <i>login_password</i> does not really have to be the user's password but if it is, it simplifies logging in.
<code>-r [nis_principal]</code>	Remove all credentials associated with the principal <i>nis_principal</i> from the <code>cred.org_dir</code> table. This option can be used when removing a client or user from the system. If <i>nis_principal</i> is not specified the default is to remove credentials for the current <i>user</i> . If <i>domain_name</i> is not specified, the operation is executed in the default NIS+ domain.

EXAMPLES**EXAMPLE 1** Adding the LOCAL and DES Credentials

The following examples illustrate how to add the LOCAL and DES credentials for some user, `user1`, with a UID of 2990, who is an NIS+ user principal in the `some.domain.com` NIS+ domain:

```
example% nisaddcred -p 2990 -P user1.some.domain.com. local
```

Note that credentials are always added in the `cred.org_dir` table in the domain where `nisaddcred` is run, unless *domain_name* is specified as the last parameter on the command line. If credentials are being added from the domain server for its clients, then *domain_name* should be specified. The caller should have adequate permissions to create entries in the `cred.org_dir` table.

The system administrator can add a DES credential for the same user, using the following example:

```
example% nisaddcred -p unix.2990@some.domain.com -P user1.some.domain.com. des
```

Please note that DES credentials can be added only after the LOCAL credentials have been added. Also, if the system is configured to use more than one authentication mechanism, credentials will be made for each mechanism configured. See `nisauthconf(1M)`.

Note that the secure RPC netname does not end with a dot ('.') while the NIS+ principal name, specified with the `-P` option, does. This command should be executed from a machine in the same domain as is the user.

nisaddcred(1M)

EXAMPLE 1 Adding the LOCAL and DES Credentials *(Continued)*

The following example shows how to add a machine's DES credentials in the same domain:

```
example% nisaddcred -p unix.foo@some.domain.com -P foo.some.domain.com. des
```

Please note that no LOCAL credentials are needed in this case.

The following example illustrates how to add a NIS+ workstation's principal DES credential:

```
example% nisaddcred -p unix.host1@sub.some.domain.com \  
-P newhost.sub.some.domain.com. des sub.some.domain.com.
```

This format is particularly useful if you are running this command from a server which is in a higher domain than sub.some.domain.com. Without the last option for domain name, `nisaddcred` would fail because it would attempt to use the default domain of some.domain.com.

The following example illustrates adding DES credentials without being prompted for the root login password:

```
example% nisaddcred -p unix.2990@some.domain.com \  
-P user1.some.domain.com. -l login_password des
```

The following example shows how to add a credential for a user using a specific authentication mechanism that was previously configured with `nisauthconf(1M)`. See `nisauthconf(1M)` for a list of the valid values of `auth_type`:

```
example% nisaddcred -p unix.2990@some.domain.com \  
-P user.1.some.domain.com dh640-0
```

The password should be the same for all the credentials that belong to the user. Otherwise, only the credentials encrypted with the user's password will be used at login, and the user will have to run `chkey(1)` using the `-p` option.

The following example shows how to add a DES credential when other authentication mechanisms are configured on the system:

```
example% nisaddcred -p unix.2990@some.domain.com \  
-P user1.some.domain.com dh192-0
```

EXIT STATUS

The following exit values are returned:

0	Successful operation.
1	Operation failed.

nisaddent(1M)

NAME	nisaddent – create NIS+ tables from corresponding /etc files or NIS maps
SYNOPSIS	<pre> /usr/lib/nis/nisaddent [-D defaults] [-Paorv] [-t table] type [nisdomain] /usr/lib/nis/nisaddent [-D defaults] [-Paprmov] -f file [-t table] type [nisdomain] /usr/lib/nis/nisaddent [-D defaults] [-Parmv] [-t table] -y ypdomain [-Y map] type [nisdomain] /usr/lib/nis/nisaddent -d [-AMoq] [-t table] type [nisdomain] </pre>
DESCRIPTION	nisaddent creates entries in NIS+ tables from their corresponding /etc files and NIS maps. This operation is customized for each of the standard tables that are used in the administration of Solaris systems. The <i>type</i> argument specifies the type of the data being processed. Legal values for this <i>type</i> are one of <i>aliases</i>, <i>bootparams</i>, <i>ethers</i>, <i>group</i>, <i>hosts</i>, <i>ipnodes</i>, <i>netid</i>, <i>netmasks</i>, <i>networks</i>, <i>passwd</i>, <i>protocols</i>, <i>publickey</i>, <i>rpc</i>, <i>services</i>, <i>shadow</i>, or <i>timezone</i> for the standard tables, or <i>key-value</i> for a generic two-column (key, value) table. For a site specific table, which is not of <i>key-value</i> type, one can use <i>nistbladm(1)</i> to administer it. The NIS+ tables should have already been created by <i>nistbladm(1)</i>, <i>nissetup(1M)</i>, or <i>nisserver(1M)</i>. It is easier to use <i>nispopulate(1M)</i> instead of <i>nisaddent</i> to populate the system tables. By default, <i>nisaddent</i> reads from the standard input and adds this data to the NIS+ table associated with the <i>type</i> specified on the command line. An alternate NIS+ table may be specified with the <i>-t</i> option. For type <i>key-value</i>, a table specification is required. Note that the <i>data</i> type can be different than the table name (<i>-t</i>). For example, the automounter tables have <i>key-value</i> as the table type. Although, there is a <i>shadow</i> data type, there is no corresponding <i>shadow</i> table. Both the <i>shadow</i> and the <i>passwd</i> data is stored in the <i>passwd</i> table itself. Files may be processed using the <i>-f</i> option, and NIS version 2 (YP) maps may be processed using the <i>-y</i> option. The merge option is not available when reading data from standard input. When a <i>ypdomain</i> is specified, the <i>nisaddent</i> command takes its input from the dbm files for the appropriate NIS map (<i>mail.aliases</i>, <i>bootparams</i>, <i>ethers.byaddr</i>, <i>group.byname</i>, <i>hosts.byaddr</i>, <i>hosts.byname</i>, <i>ipnodes.byaddr</i>, <i>ipnodes.byname</i>, <i>netid.byname</i>, <i>netmasks.byaddr</i>, <i>networks.byname</i>, <i>passwd.byname</i>, <i>protocols.byname</i>, <i>publickey.byname</i>, <i>rpc.bynumber</i>, <i>services.byname</i>, or <i>timezone.byname</i>). An alternate NIS map may be specified with the <i>-Y</i> option. For type <i>key-value</i>, a map specification is required. The map must be in the <i>/var/yp/ypdomain</i> directory on the local machine. Note that <i>ypdomain</i> is case sensitive. <i>ypxfr(1M)</i> can be used to get the NIS maps.

If a *nisdomain* is specified, *nisaddent* operates on the NIS+ table in that NIS+ domain, otherwise the default domain is used.

In terms of performance, loading up the tables is fastest when done through the dbm files (-y).

To accommodate other credential entries used by other authentication mechanisms stored in the *cred.org_dir* table, the *publickey* dump output has been modified to include a special *algorithm type* field. This format is incompatible with older versions of *nisaddent*. To produce dumps that can be read by older versions of *nisaddent*, or to load dumps created by such older versions, use the -o option.

OPTIONS

The following options are supported:

-a	Add the file or map to the NIS+ table without deleting any existing entries. This option is the default. Note that this mode only propagates additions and modifications, not deletions.						
-A	All data. This option specifies that the data within the table and all of the data in tables in the initial table's concatenation path be returned.						
-d	Dump the NIS+ table to the standard output in the appropriate format for the given <i>type</i> . For tables of type <i>key-value</i> , use <i>niscat(1)</i> instead. To dump the <i>cred</i> table, dump the <i>publickey</i> and the <i>netid</i> types.						
-D <i>defaults</i>	This option specifies a different set of defaults to be used during this operation. The <i>defaults</i> string is a series of tokens separated by colons. These tokens represent the default values to be used for the generic object properties. All of the legal tokens are described below.						
	<table> <tr> <td><i>tth=thme</i></td><td>This token sets the default time to live for objects that are created by this command. The value <i>thme</i> is specified in the format as defined by the <i>nischthtth(1)</i> command. The default is 12 hours.</td></tr> <tr> <td><i>owner=ownername</i></td><td>This token specifies that the NIS+ principal <i>ownername</i> should own the created object. The default for this value is the principal who is executing the command.</td></tr> <tr> <td><i>group=groupname</i></td><td>This token specifies that the group <i>groupname</i> should be the group owner for the object that is created. The default is NULL.</td></tr> </table>	<i>tth=thme</i>	This token sets the default time to live for objects that are created by this command. The value <i>thme</i> is specified in the format as defined by the <i>nischthtth(1)</i> command. The default is 12 hours.	<i>owner=ownername</i>	This token specifies that the NIS+ principal <i>ownername</i> should own the created object. The default for this value is the principal who is executing the command.	<i>group=groupname</i>	This token specifies that the group <i>groupname</i> should be the group owner for the object that is created. The default is NULL.
<i>tth=thme</i>	This token sets the default time to live for objects that are created by this command. The value <i>thme</i> is specified in the format as defined by the <i>nischthtth(1)</i> command. The default is 12 hours.						
<i>owner=ownername</i>	This token specifies that the NIS+ principal <i>ownername</i> should own the created object. The default for this value is the principal who is executing the command.						
<i>group=groupname</i>	This token specifies that the group <i>groupname</i> should be the group owner for the object that is created. The default is NULL.						

nisaddent(1M)

	<code>access=rights</code>	This token specifies the set of access rights that are to be granted for the given object. The value <i>rights</i> is specified in the format as defined by the <code>nischmod(1)</code> command. The default is - - - -rmcdr - - -r - - -
<code>-f file</code>	Specify that <code>file</code> should be used as the source of input (instead of the standard input).	
<code>-m</code>	Merge the file or map with the NIS+ table. This is the most efficient way to bring an NIS+ table up to date with a file or NIS map when there are only a small number of changes. This option adds entries that are not already in the database, modifies entries that already exist (if changed), and deletes any entries that are not in the source. Use the <code>-m</code> option whenever the database is large and replicated, and the map being loaded differs only in a few entries. This option reduces the number of update messages that have to be sent to the replicas. Also see the <code>-r</code> option.	
<code>-M</code>	Master server only. This option specifies that lookups should be sent to the master server. This guarantees that the most up-to-date information is seen at the possible expense that the master server may be busy, or that it may be made busy by this operation.	
<code>-o</code>	Use strictly conforming <code>publickey</code> files. Dumps will not add the <code>algorithm type</code> field used by additional authentication mechanisms that might be configured using <code>nisauthconf(1M)</code> . 192-bit keys that are dumped using this option can be read by previous versions of <code>nisaddent</code> . However, the <code>algorithm</code> field will be lost and assumed to be "0" when read. Use the <code>-o</code> option when reading <code>publickey</code> files from previous versions of <code>nisaddent</code> to avoid warnings about the missing <code>algorithm</code> field.	
<code>-p</code>	Process the password field when loading password information from a file. By default, the password field is ignored because it is usually not valid (the actual password appears in a shadow file).	
<code>-P</code>	Follow concatenation path. This option specifies that lookups should follow the concatenation path of a table if the initial search is unsuccessful.	
<code>-q</code>	Dump tables in "quick" mode. The default method for dumping tables processes each entry individually. For some tables, for example, hosts, multiple entries must be combined into a single line, so extra requests to the server must be made. In "quick" mode, all of the entries for a table are retrieved in one call to the server, so the table can be dumped more quickly. However, for	

	large tables, there is a chance that the process will run out of virtual memory and the table will not be dumped.
<code>-r</code>	Replace the file or map in the existing NIS+ table by first deleting any existing entries, and then add the entries from the source (<code>/etc</code> files, or NIS+ maps). This option has the same effect as the <code>-m</code> option. The use of this option is <i>strongly</i> discouraged due to its adverse impact on performance, unless there are a large number of changes.
<code>-t table</code>	Specify that <i>table</i> should be the NIS+ table for this operation. This should be a relative name as compared to your default domain or the domainname if it has been specified.
<code>-v</code>	Verbose.
<code>-y ypdomain</code>	Use the dbm files for the appropriate NIS map, from the NIS domain <i>ypdomain</i> , as the source of input. The files are expected to be on the local machine in the <code>/var/yp/ypdomain</code> directory. If the machine is not an NIS server, use <code>ypxfr(1M)</code> to get a copy of the dbm files for the appropriate map.
<code>-Y map</code>	Use the dbm files for <i>map</i> as the source of input.

EXAMPLES

EXAMPLE 1 Using `nisaddent`

This example adds the contents of `/etc/passwd` to the `passwd.org_dir` table:

```
example% cat /etc/passwd | nisaddent passwd
```

The next example adds the shadow information. Note that the table type here is “shadow”, not “passwd”, even though the actual information is stored in the `passwd` table:

```
example% cat /etc/shadow | nisaddent shadow
```

This example replaces the `hosts.org_dir` table with the contents of `/etc/hosts` (in verbose mode):

```
example% nisaddent -rv -f /etc/hosts hosts
```

This example merges the `passwd` map from `ypdomain` with the `passwd.org_dir.nisdomain` table (in verbose mode). The example assumes that the `/var/yp/myypdomain` directory contains the `yppasswd` map.

```
example% nisaddent -mv -y myypdomain passwd nisdomain
```

This example merges the `auto.master` map from `myypdomain` with the `auto_master.org_dir` table:

```
example% nisaddent -m -y myypdomain -Y auto.master \
    -t auto_master.org_dir key-value
```

nisaddent(1M)

EXAMPLE 1 Using nisaddent (Continued)

This example dumps the `hosts.org_dir` table:

```
example% nisaddent -d hosts
```

This example dumps the `ipnodes.org_dir` table:

```
example% nisaddent -d ipnodes
```

ENVIRONMENT VARIABLES

- NIS_DEFAULTS** This variable contains a default string that will override the NIS+ standard defaults. If the `-D` switch is used, those values will then override both the `NIS_DEFAULTS` variable and the standard defaults. To avoid security accidents, the access rights in the `NIS_DEFAULTS` variable are ignored for the `passwd` table (but access rights specified with `-D` are used).
- NIS_PATH** If this variable is set, and neither the *nisdomain* nor the *table* are fully qualified, each directory specified in `NIS_PATH` will be searched until the table is found (see `nisdefaults(1)`).

EXIT STATUS

The following exit values are returned:

- 0 Successful operation.
- 1 Failure caused by an error other than parsing.
- 2 A parsing error occurred on an entry. A parsing error does not cause termination; the invalid entries are simply skipped.

NOTES

NIS+ might not be supported in future releases of the Solaris™ Operating Environment. Tools to aid the migration from NIS+ to LDAP are available in the Solaris 9 operating environment. For more information, visit <http://www.sun.com/directory/nisplus/transition.html>.

NAME	nisauthconf – configure NIS+ security								
SYNOPSIS	nisauthconf [-v] [<i>mechanism</i> , ...]								
DESCRIPTION	nisauthconf controls which authentication flavors NIS+ should use when communicating with other NIS+ clients and servers. If the command is not executed, then NIS+ will default to the AUTH_DES authentication flavor when running security level 2. See <code>rpc.nisd(1M)</code>. nisauthconf takes a list of authentication <i>mechanism</i>'s in order of preference. An authentication <i>mechanism</i> may use one or more authentication flavors listed below. If <code>des</code> is the only specified mechanism, then NIS+ only use AUTH_DES with other NIS+ clients and servers. If <code>des</code> is the first mechanism, then other authentication <i>mechanism</i>'s after <code>des</code> will be ignored by NIS+, except for <code>nisaddcred(1M)</code>. After changing the mechanism configuration, the <code>keyserv(1M)</code> daemon must be restarted. Note that doing so will remove encryption keys stored by the running <code>keyserv</code> process. This means that a <code>reboot</code> usually is the safest option when the mechanism configuration has been changed. The following mechanisms are available: <table border="1"> <thead> <tr> <th>Authentication <i>mechanism</i></th><th>Authentication Flavor</th></tr> </thead> <tbody> <tr> <td><code>des</code></td><td>AUTH_DES</td></tr> <tr> <td><code>dh640-0</code></td><td>RPCSEC_GSS using 640-bit Diffie-Hellman keys</td></tr> <tr> <td><code>dh1024-0</code></td><td>RPCSEC_GSS using 1024-bit Diffie-Hellman keys</td></tr> </tbody> </table> If no mechanisms are specified, then a list of currently configured mechanisms is printed.	Authentication <i>mechanism</i>	Authentication Flavor	<code>des</code>	AUTH_DES	<code>dh640-0</code>	RPCSEC_GSS using 640-bit Diffie-Hellman keys	<code>dh1024-0</code>	RPCSEC_GSS using 1024-bit Diffie-Hellman keys
Authentication <i>mechanism</i>	Authentication Flavor								
<code>des</code>	AUTH_DES								
<code>dh640-0</code>	RPCSEC_GSS using 640-bit Diffie-Hellman keys								
<code>dh1024-0</code>	RPCSEC_GSS using 1024-bit Diffie-Hellman keys								
OPTIONS	-v Displays a verbose table listing the currently configured authentication mechanisms.								
EXAMPLES	EXAMPLE 1 Configuring a System with only RPCSEC_GSS Authentication Flavor To configure a system to use only the RPCSEC_GSS authentication flavor with 640-bit Diffie-Hellman keys, execute the following as root: <pre>example# /usr/lib/nis/nisauthconf dh640-0</pre> EXAMPLE 2 Configuring a System with both RPCSEC_GSS and AUTH_DES Authentication Flavors To configure a system to use both RPCSEC_GSS (with 640-bit Diffie-Hellman keys) and AUTH_DES authentication flavors:								

nisauthconf(1M)

EXAMPLE 2 Configuring a System with both RPCSEC_GSS and AUTH_DES Authentication Flavors *(Continued)*

```
example# /usr/lib/nis/nisauthconf dh640-0 des
```

EXAMPLE 3 Transitioning to Other Authentication Flavors

The following example can be used while adding credentials for a new mechanism before NIS+ is authenticating with the new mechanism:

```
example# /usr/lib/nis/nisauthconf des dh640-0
```

Note that except for `nisaddcred(1M)`, NIS+ will not use mechanisms that follow 'des.'

EXIT STATUS The following exit values are returned:

0	Successful completion.
1	An error occurred.

FILES `/etc/rpcsec/nisplussec.conf`
NIS+ authentication configuration file. This file may change or be removed in future versions of Solaris.

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWnisu

SEE ALSO `nis+(1)`, `keyserv(1M)`, `nisaddcred(1M)`, `rpc.nisd(1M)`, `attributes(5)`

NOTES A NIS+ client of a server that is configured for either `dh640-0` or `dh1024-0` must run Solaris 7 or later, even if the server is also configured with `des`.

NIS+ might not be supported in future releases of the Solaris™ Operating Environment. Tools to aid the migration from NIS+ to LDAP are available in the Solaris 9 operating environment. For more information, visit <http://www.sun.com/directory/nisplus/transition.html>.

NAME	<code>nisbackup</code> – backup NIS+ directories
SYNOPSIS	<code>nisbackup</code> [-v] <i>backup-dir</i> <i>directory...</i> <code>nisbackup</code> [-v] -a <i>backup-dir</i>
DESCRIPTION	<code>nisbackup</code> backs up a NIS+ directory object on a NIS+ master server. Updates to the NIS+ database will be temporarily disabled while <code>nisbackup</code> is running. The <i>backup-dir</i> is a UNIX directory that must exist prior to running <code>nisbackup</code>. The <code>nisbackup</code> command can be used to backup an individual NIS+ directory object or all (-a) of the NIS+ directory objects served by a master server. The NIS+ directory objects being backed up will be placed into subdirectories under the <i>backup-dir</i> directory. These subdirectories are named according to the NIS+ directory object they contain. <code>nisbackup</code> operates on individual NIS+ directory objects (for example, <code>org_dir.wiz.com</code>). This allows an administrator to selectively backup specific directories. The <code>rpc.nisd(1M)</code> process must be running on the master server with a stable NIS+ database for <code>nisbackup</code> to complete. <code>nisbackup</code> will not attempt to correct any corruption in the NIS+ database, so it is important that backups be done regularly as part of the NIS+ administration. The first synopsis is used to backup a single NIS+ directory object or a list of NIS+ directory objects. The objects can be partially qualified or fully qualified. The machine on which the command is executing must be the master for the NIS+ directory objects specified. The second synopsis will backup all of the NIS+ directory objects that are served by this master. The -a option is the recommended method of backing up a master server, since it will backup all NIS+ directory objects that are served by this master. If this server is a master server for more than one domain, the backup will include NIS+ directories that belong to all of the domains served. Individual NIS+ directory objects can be selected for restoring from a <i>backup-dir</i> created with the -a option. See <code>nisrestore(1M)</code>. The -a option only includes directory objects for which this server is the master. It is possible, but not recommended, to configure a master server as a replica for other domains. The objects belonging to those replicated domains will not be backed up with the -a option. The backup of replicated objects must be run on the master server for those objects. Do not use the same <i>backup-dir</i> to backup different master servers. Each master server must have its own <i>backup-dir</i>. <code>nisbackup</code> will set the <code>rpc.nisd(1M)</code> to read only mode, which will disable updates to the NIS+ database. This is necessary to ensure the consistency of the backup. For this reason, <code>nisbackup</code> should not be run while large numbers of updates are being applied to the NIS+ database. Update utilities such as <code>nisaddent(1M)</code> should not be run simultaneously with <code>nisbackup</code>.

nisbackup(1M)

OPTIONS	-a	Creates a backup of all NIS+ directory objects for which this server is a master.
	-v	Verbose option. Additional output will be produced and sent to syslog(3C) upon execution of the command (see syslog.conf(4)).
OPERANDS	<i>backup-dir</i>	The directory into which the subdirectories containing the backed up objects are placed. This must be created prior to running nisbackup.
	<i>directory</i>	The NIS+ directory object(s) being backed up.
EXAMPLES	EXAMPLE 1 Backup of the <i>org_dir</i> NIS+ directory object of the domain <i>foo.com</i> on a master server to a directory named <i>/backup</i> To backup the <i>org_dir</i> NIS+ directory object of the domain <i>foo.com</i> on a master server to a directory named <i>/backup</i>: <pre>master_server# nisbackup /backup org_dir.foo.com.</pre>	
	EXAMPLE 2 Backup of the entire NIS+ domain <i>foo.com</i> to a directory named <i>/backup</i> To backup the entire NIS+ domain <i>foo.com</i> to a directory named <i>/backup</i>: <pre>master_server# nisbackup /backup foo.com. \ org_dir.foo.com. groups_dir.foo.com. \ ctx_dir.foo.com.</pre>	
	EXAMPLE 3 Backup of an entire NIS+ database to a backup directory named <i>/backup</i> To backup an entire NIS+ database to a backup directory named <i>/backup</i>: <pre>master_server# nisbackup -a /backup</pre>	
EXIT STATUS	0	Successful completion.
	1	An error occurred.
FILES	<i>/backup-dir/backup_list</i>	This ascii file contains a list of all the objects contained in this <i>backup-dir</i> directory.
	<i>/backup-dir/directory-object</i>	A subdirectory that is created in the <i>backup-dir</i> that contains the NIS+ directory-object backup.
	<i>/backup-dir/directory-object/data</i>	A subdirectory that contains the data files that are part of the NIS+ directory-object backup.
	<i>/backup-dir/directory-object/last.upd</i>	This data file contains timestamp information about the directory-object.

nisbackup(1M)

/backup-dir/directory-object/data.dict

A NIS+ data dictionary for all of the objects contained in the NIS+ directory-object backup.

nis_cachemgr(1M)

NAME	nis_cachemgr – NIS+ utility to cache location information about NIS+ servers	
SYNOPSIS	/usr/sbin/nis_cachemgr [-i] [-v]	
DESCRIPTION	The <code>nis_cachemgr</code> daemon maintains a cache of NIS+ directory objects and active servers for domains. It is responsible for locating servers for a domain on behalf of client processes. This improves performance because only one process has to search for servers. The cache contains location information necessary to contact the NIS+ servers. This includes transport addresses, information needed to authenticate the server, and a time to live field which gives a hint on how long the directory object can be cached. The cache helps to improve the performance of the clients that are traversing the NIS+ name space. <code>nis_cachemgr</code> should be running on all the machines that are using NIS+. However, it is not required that the <code>nis_cachemgr</code> program be running in order for NIS+ requests to be serviced. The cache maintained by this program is shared by all the processes that access NIS+ on a machine. The cache is maintained in a file that is memory mapped by all the processes. See <code>mmap(2)</code>. On start up, <code>nis_cachemgr</code> initializes the cache from the cold start file and preserves unexpired entries that already exist in the cache file. See <code>nisinit(1M)</code>. Thus, the cache survives machine reboots. The <code>nis_cachemgr</code> program is normally started from a system startup script. <code>nisshowcache(1M)</code> can be used to look at the cached objects and active servers. The <code>nisprefadm(1M)</code> command can be used to control which NIS+ servers the <code>nis_cachemgr</code> program will try to select. The <code>nis_cachemgr</code> program makes NIS+ requests under the NIS+ principal name of the host on which it runs. Before running <code>nis_cachemgr</code>, security credentials for the host should be added to the <code>cred.org_dir</code> table in the host's domain using <code>nisaddcred(1M)</code>. Credentials of type DES will be needed if the NIS+ service is operating at security level 2 (see <code>rpc.nisd(1M)</code>). See the DIAGNOSTICS section, below. Additionally, a "keylogin -r" should be done on the machine.	
OPTIONS	-i	Force <code>nis_cachemgr</code> to ignore the previous cache file and reinitialize the cache from just the cold start file. By default, the cache manager initializes itself from both the cold start file and the old cache file, thereby maintaining the entries in the cache across machine reboots.
	-v	This flag sets verbose mode. In this mode, the <code>nis_cachemgr</code> program logs not only errors and warnings, but also additional status messages. The additional messages are logged using <code>syslog(3C)</code> with a priority of <code>LOG_INFO</code> .
FILES	/var/nis/NIS_SHARED_DIRCACHE	the shared cache file
	/var/nis/NIS_COLD_START	the coldstart file
	/etc/init.d/rpc	initialization scripts for NIS+
ATTRIBUTES	See <code>attributes(5)</code> for descriptions of the following attributes:

DIAGNOSTICS The nis_cachemgr daemon logs error messages and warnings using syslog(3C). Error messages are logged to the DAEMON facility with a priority of LOG_ERR . Warning messages are logged with a priority of LOG_WARNING. Additional status messages can be obtained using the -v option.

NOTES NIS+ might not be supported in future releases of the Solaris™ Operating Environment. Tools to aid the migration from NIS+ to LDAP are available in the Solaris 9 operating environment. For more information, visit <http://www.sun.com/directory/nisplus/transition.html>.

nisclient(1M)

NAME	<code>nisclient</code> – initialize NIS+ credentials for NIS+ principals
SYNOPSIS	<pre> /usr/lib/nis/nisclient -c [-x] [-o] [-v] [-l <network_password>] [-d <NIS+_domain>] client_name... /usr/lib/nis/nisclient -i [-x] [-v] -h <NIS+_server_host> [-a <NIS+_server_addr>] [-k <key_domain>] [-d <NIS+_domain>] [-s 0 2] /usr/lib/nis/nisclient -u [-x] [-v] /usr/lib/nis/nisclient -r [-x] </pre>
DESCRIPTION	The <code>nisclient</code> shell script can be used to: ■ create NIS+ credentials for hosts and users ■ initialize NIS+ hosts and users ■ restore the network service environment NIS+ credentials are used to provide authentication information of NIS+ clients to NIS+ service. Use the first synopsis (<code>-c</code> option) to create individual NIS+ credentials for hosts or users. You must be logged in as a NIS+ principal in the domain for which you are creating the new credentials. You must also have write permission to the local "cred" table. The <i>client_name</i> argument accepts any valid host or user name in the NIS+ domain (for example, the <i>client_name</i> must exist in the hosts or passwd table). <code>nisclient</code> verifies each <i>client_name</i> against both the host and passwd tables, then adds the proper NIS+ credentials for hosts or users. Note that if you are creating NIS+ credentials outside of your local domain, the host or user must exist in the host or passwd tables in both the local and remote domains. By default, <code>nisclient</code> will not overwrite existing entries in the credential table for the hosts and users specified. To overwrite, use the <code>-o</code> option. After the credentials have been created, <code>nisclient</code> will print the command that must be executed on the client machine to initialize the host or the user. The <code>-c</code> option requires a network password for the client which is used to encrypt the secret key for the client. You can either specify it on the command line with the <code>-l</code> option or the script will prompt you for it. You can change this network password later with <code>passwd(1)</code> or <code>chkey(1)</code>. <code>nisclient -c</code> is not intended to be used to create NIS+ credentials for all users and hosts which are defined in the passwd and hosts tables. To define credentials for all users and hosts, use <code>nispopulate(1M)</code>. Use the second synopsis (<code>-i</code> option) to initialize a NIS+ client machine. The <code>-i</code> option can be used to convert machines to use NIS+ or to change the machine's domainname. You must be logged in as super-user on the machine that is to become a NIS+ client. Your administrator must have already created the NIS+ credential for this host by using <code>nisclient -c</code> or <code>nispopulate -C</code>. You will need the network password your administrator created. <code>nisclient</code> will prompt you for the network password to decrypt your secret key and then for this machine's root login password to generate a

new set of secret/public keys. If the NIS+ credential was created by your administrator using `nisclient -c`, then you can simply use the initialization command that was printed by the `nisclient` script to initialize this host instead of typing it manually.

To initialize an unauthenticated NIS+ client machine, use the `-i` option with `-s 0`. With these options, the `nisclient -i` option will not ask for any passwords.

During the client initialization process, files that are being modified are backed up as `files.no_nisplus`. The files that are usually modified during a client initialization are: `/etc/defaultdomain`, `/etc/nsswitch.conf`, `/etc/inet/hosts`, and, if it exists, `/var/nis/NIS_COLD_START`. Notice that a file will not be saved if a backup file already exists.

The `-i` option does not set up a NIS+ client to resolve hostnames using DNS. Please refer to the DNS documentation for information on setting up DNS. (See `resolv.conf(4)`).

It is not necessary to initialize either NIS+ root master servers or machines that were installed as NIS+ clients using `suninstall(1M)`.

Use the third synopsis (`-u` option) to initialize a NIS+ user. You must be logged in as the user on a NIS+ client machine in the domain where your NIS+ credentials have been created. Your administrator should have already created the NIS+ credential for your username using `nisclient -c` or `nispopulate(1M)`. You will need the network password your administrator used to create the NIS+ credential for your username. `nisclient` will prompt you for this network password to decrypt your secret key and then for your login password to generate a new set of secret/public keys.

Use the fourth synopsis (`-r` option) to restore the network service environment to whatever you were using before `nisclient -i` was executed. You must be logged in as super-user on the machine that is to be restored. The restore will only work if the machine was initialized with `nisclient -i` because it uses the backup files created by the `-i` option.

Reboot the machine after initializing a machine or restoring the network service.

OPTIONS

The following options are supported:

<code>-a <NIS+_server_addr></code>	Specifies the IP address for the NIS+ server. This option is used <i>only</i> with the <code>-i</code> option.
<code>-c</code>	Adds DES credentials for NIS+ principals.
<code>-d <NIS+_domain></code>	Specifies the NIS+ domain where the credential should be created when used in conjunction with the <code>-c</code> option. It specifies the name for the new NIS+ domain when used in conjunction with the <code>-i</code> option. The default is your current domainname.

nisclient(1M)

-h <NIS+_server_host>	Specifies the NIS+ server's hostname. This option is used <i>only</i> with the -i option.
-i	Initializes a NIS+ client machine.
-l <network_password>	Specifies the network password for the clients. This option is used <i>only</i> with the -c option. If this option is not specified, the script will prompt you for the network password.
-k <key_domain>	This option specifies the domain where root's credentials are stored. If a domain is not specified, then the system default domain is assumed.
-o	Overwrites existing credential entries. The default is not to overwrite. This is used <i>only</i> with the -c option.
-r	Restores the network service environment.
-s 0 2	Specifies the authentication level for the NIS+ client. Level 0 is for unauthenticated clients and level 2 is for authenticated (DES) clients. The default is to set up with level 2 authentication. This is used <i>only</i> with the -i option. <code>nisclient</code> always uses level 2 authentication (DES) for both -c and -u options. There is no need to run <code>nisclient</code> with -u and -c for level 0 authentication. To configure authentication mechanisms other than DES at security level 2, use <code>nisauthconf(1M)</code> before running <code>nisclient</code> .
-u	Initializes a NIS+ user.
-v	Runs the script in verbose mode.
-x	Turns the "echo" mode on. The script just prints the commands that it would have executed. Notice that the commands are not actually executed. The default is off.

EXAMPLES

EXAMPLE 1 Adding the DES Credential in the Local Domain

To add the DES credential for host `sunws` and user `fred` in the local domain:

```
example% /usr/lib/nis/nisclient -c sunws fred
```

EXAMPLE 2 Adding the DES Credential in a Specified Domain

To add the DES credential for host `sunws` and user `fred` in domain `xyz.sun.com.`:

```
example% /usr/lib/nis/nisclient -c -d xyz.sun.com. sunws fred
```

EXAMPLE 3 Initializing the Host in a Specific Domain

To initialize host sunws as a NIS+ client in domain xyz.sun.com. where nisplus_server is a server for the domain xyz.sun.com.:

```
example# /usr/lib/nis/nisclient -i -h nisplus_server -d xyz.sun.com
```

The script will prompt you for the IP address of nisplus_server if the server is not found in the /etc/hosts file. The -d option is needed only if your current domain name is different from the new domain name.

EXAMPLE 4 Initializing the Host as an Unauthenticated Client in a Specific Domain

To initialize host sunws as an unauthenticated NIS+ client in domain xyz.sun.com. where nisplus_server is a server for the domain xyz.sun.com:

```
example# /usr/lib/nis/nisclient -i -S 0 \
-h nisplus_server -d xyz.sun.com. -a 129.140.44.1
```

EXAMPLE 5 Initializing the User as a NIS+ principal

To initialize user fred as a NIS+ principal, log in as user fred on a NIS+ client machine.

```
example% /usr/lib/nis/nisclient -u
```

FILES	/var/nis/NIS_COLD_START	This file contains a list of servers, their transport addresses, and their Secure RPC public keys that serve the machines default domain.
	/etc/defaultdomain	The system default domainname.
	/etc/nsswitch.conf	Configuration file for the name-service switch.
	/etc/inet/hosts	Local host name database.

NAME	nisinit – NIS+ client and server initialization utility
SYNOPSIS	nisinit -r nisinit -pY D Nparent_domain host... nisinit -c [-k <key_domain>] -H host -B -C coldstart
DESCRIPTION	nisinit initializes a machine to be a NIS+ client or an NIS+ root master server. It may be easier to use nisclient(1M) or nisserver(1M) to accomplish this same task.
OPTIONS	-r Initialize the machine to be a NIS+ root server. This option creates the file /var/nis/data/root.object and initialize it to contain information about this machine. It uses the sysinfo(2) system call to retrieve the name of the default domain. To initialize the machine as an NIS+ root server, it is advisable to use the “-r” option of nisserver(1M), instead of using “nisinit -r”. -p Y D N parent_domain host ... This option is used on a root server to initialize a /var/nis/data/parent.object to make this domain a part of the namespace above it. Only root servers can have parent objects. A parent object describes the namespace “above” the NIS+ root. If this is an isolated domain, this option should not be used. The argument to this option tells the command what type of name server is serving the domain above the NIS+ domain. When clients attempt to resolve a name that is outside of the NIS+ namespace, this object is returned with the error NIS_FOREIGNNS indicating that a name space boundary has been reached. It is up to the client to continue the name resolution process. The parameter <i>parent_domain</i> is the name of the parent domain in a syntax that is native to that type of domain. The list of host names that follow the domain parameter are the names of hosts that serve the parent domain. If there is more than one server for a parent domain, the first host specified should be the master server for that domain. Y Specifies that the parent directory is a NIS version 2 domain. D Specifies that the parent directory is a DNS domain. N Specifies that the parent directory is another NIS+ domain. This option is useful for connecting a pre-existing NIS+ subtree into the global namespace. Note that in the current implementation, the NIS+ clients do not take advantage of the -p feature. Also, since the parent object is currently not replicated on root replica servers, it is recommended that this option not be used. -c Initializes the machine to be a NIS+ client. There are three initialization options available: initialize by coldstart, initialize by hostname, and initialize by broadcast.

nisinit(1M)

The most secure mechanism is to initialize from a trusted coldstart file. The second option is to initialize using a hostname that you specify as a trusted host. The third method is to initialize by broadcast and it is the least secure method.

- C *coldstart* Causes the file *coldstart* to be used as a prototype coldstart file when initializing a NIS+ client. This coldstart file can be copied from a machine that is already a client of the NIS+ namespace. For maximum security, an administrator can encrypt and encode (with `uuencode(1C)`) the coldstart file and mail it to an administrator bringing up a new machine. The new administrator would then decode (with `uudecode`), decrypt, and then use this file with the `nisinit` command to initialize the machine as an NIS+ client. If the coldstart file is from another client in the same domain, the `nisinit` command may be safely skipped and the file copied into the `/var/nis` directory as `/var/nis/NIS_COLD_START`.
- H *hostname* Specifies that the host *hostname* should be contacted as a trusted NIS+ server. The `nisinit` command will iterate over each transport in the `NETPATH` environment variable and attempt to contact `rpcbind(1M)` on that machine. This hostname *must* be reachable from the client without the name service running. For IP networks this means that there must be an entry in `/etc/hosts` for this host when `nisinit` is invoked.
- B Specifies that the `nisinit` command should use an IP broadcast to locate a NIS+ server on the local subnet. Any machine that is running the NIS+ service may answer. No guarantees are made that the server that answers is a server of the organization's namespace. If this option is used, it is advisable to check with your system administrator that the server and domain served are valid. The binding information can be dumped to the standard output using the `nisshowcache(1M)` command.

Note that `nisinit -c` will just enable navigation of the NIS+ name space from this client. To make NIS+ your name service, modify the file `/etc/nsswitch.conf` to reflect that. See `nsswitch.conf(4)` for more details.

-k *<key_domain>*

This option specifies the domain where root's credentials are stored. If it is not specified, then the system default domain is assumed. This domain name is used to create the `/var/nis/NIS_COLD_START` file.

RETURN VALUES

`nisinit` returns 0 on success and 1 on failure.

EXAMPLES	EXAMPLE 1 Initializing the Machine as a NIS+ Client using the Host <i>freddy</i> as a Trusted Server This example initializes the machine as an NIS+ client using the host <i>freddy</i> as a trusted server. <pre>example# nisinit -cH freddy</pre>	
	EXAMPLE 2 Setting up a Client using a Trusted Coldstart File This example sets up a client using a trusted coldstart file. <pre>example# nisinit -cC /tmp/colddata</pre>	
	EXAMPLE 3 Setting up a Client Using an IP Broadcast This example sets up a client using an IP broadcast. <pre>example# nisinit -cB</pre>	
	EXAMPLE 4 Setting up a Root Server This example sets up a root server. <pre>example# nisinit -r</pre>	
ENVIRONMENT VARIABLES	NETPATH	This environment variable may be set to the transports to try when contacting the NIS+ server (see <code>netconfig(4)</code>). The client library will only attempt to contact the server using connection oriented transports.
FILES	/var/nis/NIS_COLD_START	This file contains a list of servers, their transport addresses, and their Secure RPC public keys that serve the machine's default domain.
	/var/nis/data/root.object	This file describes the root object of the NIS+ namespace. It is a standard XDR-encoded NIS+ directory object that can be modified by authorized clients using the <code>nis_modify()</code> interface.
	/var/nis/data/parent.object	This file describes the namespace that is logically above the NIS+ namespace. The most common type of parent object is a DNS object. This object contains contact information for a server of that domain.
	/etc/hosts	Internet host table.

NAME	nisldapmaptest – test NIS+ and LDAP mapping configuration files
SYNOPSIS	nisldapmaptest [-s -r -d] [-l -t <i>object</i>] [-v] [-i] [-o] [-m <i>conf</i> file] [-x attr=val...] [col=val...]
DESCRIPTION	Use the <code>nisldapmaptest</code> utility to test NIS+ to LDAP mapping configuration files. See <code>NIS+LDAPmapping(4)</code>. The <code>nisldapmaptest</code> utility uses much of the same internal interface as the <code>rpc.nisd(1M)</code> does to read, add, modify, or delete LDAP data, as specified by the column name and value operand pairs. <code>nisldapmaptest</code> does not read or modify any of the <code>rpc.nisd(1M)</code> database files. See NOTES for details on important differences between the ways that <code>nisldapmaptest</code> and <code>rpc.nisd(1M)</code> operate on LDAP data.
OPTIONS	The <code>nisldapmaptest</code> utility supports the following options: -d Delete data in LDAP. -i Ignore failures when obtaining information from the NIS+ server. This enables <code>nisldapmaptest</code> to work to some extent, even if the NIS+ server is unreachable, or if the system is not a NIS+ client. However, NIS+ lookups are still attempted, so there may be NIS+ error messages. In this mode, <code>nisldapmaptest</code> also tries to guess things such as NIS+ object types and derives table column information from the mapping rules in the configuration files. Avoid using the <code>-i</code> option to add, modify, or delete, until you have determined that the <code>nisldapmaptest</code>'s guesses are adequate for your needs. -l Parse the configuration file into internal data structures, and then print out the configuration per those structures. Note that the printed data is not in configuration file format. Either <code>-l</code> or <code>-t</code> must be specified. If both are present, <code>-l</code> is ignored. -m <i>conf</i>file Specify the name of the <code>NIS+LDAPmapping(4)</code> configuration file. The default directory is <code>/var/nis</code>, and the default mapping file is <code>NIS+LDAPmapping</code>. -o For NIS+ tables, work on the NIS+ object itself, specified by means of the <code>-t</code> option, not on the table entries. -r Replace or add data in LDAP. -s Search for data in LDAP. This is the default. -t <i>object</i> Specify the NIS+ object on which to operate. If the object name is not fully qualified, that is, it does not end in a dot, the value of the <code>nisplusLDAPbaseDomain</code> attribute is appended.

nislmaptest(1M)

	-v	Set the verbose flag. This flag produces extra diagnostic information.
	-x attr=val...	Specify mapping attribute and value pairs to override those obtained by means of the configuration file. Although any attributes defined on NIS+LDAPmapping(4) or rpc.nisd(4) can be specified, the ones that control rpc.nisd(1M) operation have no effect on nislmaptest.
OPERANDS	The following operands are supported:	
	col=val...	NIS+ column and value pairs used to specify which entries should be looked up, added, modified, or deleted. For additions and modifications, use col=val to specify the new values.
EXAMPLES	EXAMPLE 1 Searching for a User	
	Use the following example to search for the user xyzzy in the LDAP container specified for the passwd.org_dir table.	
	example% nislmaptest -t passwd.org_dir name=xyzzy	
	EXAMPLE 2 Listing Table Entries	
	Use the following example to list all entries in the container specified for the services.org_dir table.	
	example% nislmaptest -t services.org_dir	
	EXAMPLE 3 Listing an Object	
	Use the following example to list the services.org_dir object itself, as it is stored in LDAP.	
	example% nislmaptest -o -t services.org_dir	
	EXAMPLE 4 Modifying a Table Entry	
	Use the following example to modify the membership list of the group grp, in the container specified for the group.org_dir table, to be mem1, mem2, and mem3.	
	example% nislmaptest -r -t group.org_dir name=grp \ members=mem1,mem2,mem3	
	EXAMPLE 5 Deleting a Table Entry	
	Use the following example to delete the host called bad from the container specified for the hosts.org_dir table.	
	example% nislmaptest -d -t hosts.org_dir name=bad	

EXIT STATUS	The following exit values are returned: <table><tr><td>0</td><td>The requested operation was successful.</td></tr><tr><td>!= 0</td><td>An error occurred.</td></tr></table>	0	The requested operation was successful.	!= 0	An error occurred.												
0	The requested operation was successful.																
!= 0	An error occurred.																
FILES	/var/nis/NIS+LDAPmapping.template /etc/default/rpd.nisd																
ATTRIBUTES	See attributes(5) for descriptions of the following attributes: <table><tr><th>ATTRIBUTE TYPE</th><th>ATTRIBUTE VALUE</th></tr><tr><td>Availability</td><td>SUNWnisd</td></tr><tr><td>Interface Stability</td><td>Obsolete</td></tr></table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	Availability	SUNWnisd	Interface Stability	Obsolete										
ATTRIBUTE TYPE	ATTRIBUTE VALUE																
Availability	SUNWnisd																
Interface Stability	Obsolete																
SEE ALSO	rpc.nisd(1M), NIS+LDAPmapping(4), rpc.nisd(4), attributes(5)																
NOTES	There are several differences between the ways that nisldapmaptest and rpc.nisd operate: 1. nisldapmaptest obtains information about NIS+ by means of the NIS+ API calls, while rpc.nisd looks in its internal database. Thus, if the NIS+ server is not available, nisldapmaptest may be unable to determine NIS+ object types or table column information. 2. While nisldapmaptest can add, modify, or delete LDAP data, it does not modify any NIS+ data. 3. When operating on table entries, if nisldapmaptest is unable to obtain the entry from NIS+, it composes LDAP operations using only the supplied col=val operands. Depending on the mapping used, this can result in extra LDAP operations, for example, attempting to obtain a DN for add, modify, or delete. 4. The default value for nisplusLDAPbaseDomain is the system domain name per sysinfo(2) in nisldapmaptest, but the internal notion of the domain it serves in rpc.nisd. While the two usually are the same, this is not necessarily always the case. 5. When more than one NIS+ entry maps to a single LDAP entry, nisldapmaptest may be unable to perform a complete update, unless you make sure that the col=val specification picks up all relevant NIS+ entries. For example, if you have the services.org_dir NIS+ entries: <table><tr><td>cname</td><td>name</td><td>proto</td><td>port</td></tr><tr><td>x</td><td>x</td><td>tcp</td><td>12345</td></tr><tr><td>x</td><td>y</td><td>tcp</td><td>12345</td></tr><tr><td>x</td><td>z</td><td>tcp</td><td>12345</td></tr></table>	cname	name	proto	port	x	x	tcp	12345	x	y	tcp	12345	x	z	tcp	12345
cname	name	proto	port														
x	x	tcp	12345														
x	y	tcp	12345														
x	z	tcp	12345														

`nisldapmaptest(1M)`

then specifying `cname=x` will pick up all three entries and create or modify the corresponding LDAP entry to have three CN values: `x`, `y`, and `z`. However, specifying `name=x` will match just the first NIS+ entry, and create or modify the LDAP entry to have just one CN: `x`.

NAME	nislog – display the contents of the NIS+ transaction log					
SYNOPSIS	/usr/sbin/nislog [-h num -t num] [-v] [directory...]					
DESCRIPTION	nislog displays the contents of the NIS+ server transaction log on the standard output. This command can be used to track changes in the namespace. The /var/nis/trans.log file contains the transaction log maintained by the NIS+ server. When updates occur, they are logged to this file and then propagated to replicas as log transactions. When the log is checkpointed, updates that have been propagated to the replicas are removed. The nislog command can only be run on an NIS+ server by superuser. It displays the log entries for that server only. If <i>directory</i> is not specified, the entire log is searched. Otherwise, only those logs entries that correspond to the specified directories are displayed.					
OPTIONS	-h num	Display num transactions from the “head” of the log. If the numeric parameter is 0, only the log header is displayed.				
	-t num	Display num transactions from the “tail” of the log. If the numeric parameter is 0, only the log header is displayed.				
	-v	Verbose mode.				
FILES	/var/nis/trans.log	transaction log

nisping(1M)

NAME	nisping – send ping to NIS+ servers								
SYNOPSIS	<pre>/usr/lib/nis/nisping [-uf] [-H <i>hostname</i>] [-r <i>directory</i>] /usr/lib/nis/nisping -C [-a] [-H <i>hostname</i>] [<i>directory</i>]</pre>								
DESCRIPTION	In the first SYNOPSIS line, the <code>nisping</code> command sends a “ping” to all replicas of a NIS+ directory. Once a replica receives a ping, it will check with the master server for the directory to get updates. Prior to pinging the replicas, this command attempts to determine the last update “seen” by a replica and the last update logged by the master. If these two timestamps are the same, the ping is not sent. The <code>-f</code> (force) option will override this feature. Under normal circumstances, NIS+ replica servers get the new information from the master NIS+ server within a short time. Therefore, there should not be any need to use <code>nisping</code>. In the second SYNOPSIS line, the <code>nisping -C</code> command sends a checkpoint request to the servers. If no <i>directory</i> is specified, the home domain, as returned by <code>nisdefaults(1)</code>, is checkpointed. If all directories, served by a given server, have to be checkpointed, then use the <code>-a</code> option. On receiving a checkpoint request, the servers would commit all the updates for the given <i>directory</i> from the table log files to the database files. This command, if sent to the master server, will also send updates to the replicas if they are out of date. This option is needed because the database log files for NIS+ are not automatically checkpointed. <code>nisping</code> should be used at frequent intervals (such as once a day) to checkpoint the NIS+ database log files. This command can be added to the <code>crontab(1)</code> file. If the database log files are not checkpointed, their sizes will continue to grow. If the server specified by the <code>-H</code> option does not serve the directory, then no ping is sent. Per-server and per-directory access restrictions may apply; see <code>nisopaccess(1)</code>. <code>nisping</code> uses <code>NIS_CPTIME</code> and <code>NIS_PING</code> (resync (ping) of replicas), or <code>NIS_CHECKPOINT</code> (for checkpoint). Since the <code>NIS_PING</code> operation does not return a status, the <code>nisping</code> command is typically unable to indicate success or failure for resyncs.								
OPTIONS	<table><tr><td>-a</td><td>Checkpoint all directories on the server.</td></tr><tr><td>-C</td><td>Send a request to checkpoint, rather than a ping, to each server. The servers schedule to commit all the transactions to stable storage.</td></tr><tr><td>-H <i>hostname</i></td><td>Only the host <i>hostname</i> is sent the ping, checked for an update time, or checkpointed.</td></tr><tr><td>-f</td><td>Force a ping, even though the timestamps indicate there is no reason to do so. This option is useful for debugging.</td></tr></table>	-a	Checkpoint all directories on the server.	-C	Send a request to checkpoint, rather than a ping, to each server. The servers schedule to commit all the transactions to stable storage.	-H <i>hostname</i>	Only the host <i>hostname</i> is sent the ping, checked for an update time, or checkpointed.	-f	Force a ping, even though the timestamps indicate there is no reason to do so. This option is useful for debugging.
-a	Checkpoint all directories on the server.								
-C	Send a request to checkpoint, rather than a ping, to each server. The servers schedule to commit all the transactions to stable storage.								
-H <i>hostname</i>	Only the host <i>hostname</i> is sent the ping, checked for an update time, or checkpointed.								
-f	Force a ping, even though the timestamps indicate there is no reason to do so. This option is useful for debugging.								

RETURN VALUES	-r	This option can be used to update or get status about the root object from the root servers, especially when new root replicas are added or deleted from the list. If used without -u option, -r will send a ping request to the servers serving the root domain. When the replicas receive a ping, they will update their root object if needed. The -r option can be used with all other options except with the -C option; the root object need not be checkpointed.				
	-u	Display the time of the last update; no servers are sent a ping.				
	-1	No servers were contacted, or the server specified by the -H switch could not be contacted.				
	0	Success.				
	1	Some, but not all, servers were successfully contacted.				
EXAMPLES	EXAMPLE 1 Using <code>nisping</code> This example pings all replicas of the default domain: <pre>example% nisping</pre> Note that this example will not ping the the <code>org_dir</code> and <code>groups_dir</code> subdirectories within this domain. This example pings the server <i>example</i> which is a replica of the <i>org_dir.foo.com</i>. directory: <pre>example% nisping -H example org_dir.foo.com.</pre> This example checkpoints all servers of the <i>org_dir.bar.com</i>. directory. <pre>example% nisping -C org_dir.bar.com.</pre>					
ENVIRONMENT VARIABLES	NIS_PATH	If this variable is set, and the NIS+ directory name is not fully qualified, each directory specified will be searched until the directory is found.

NAME	nispopulate – populate the NIS+ tables in a NIS+ domain
SYNOPSIS	<pre> /usr/lib/nis/nispopulate -Y [-x] [-f] [-n] [-u] [-v] [-S 0 2] [-l <network_passwd>] [-d <NIS+_domain>] -h <NIS_server_host> [-a <NIS_server_addr>] -y <NIS_domain> [table] ... /usr/lib/nis/nispopulate -F [-x] [-f] [-u] [-v] [-S 0 2] [-d <NIS+_domain>] [-l <network_passwd>] [-p <directory_path>] [table] ... /usr/lib/nis/nispopulate -C [-x] [-f] [-v] [-d <NIS+_domain>] [-l <network_passwd>] [hosts passwd] </pre>
DESCRIPTION	The nispopulate shell script can be used to populate NIS+ tables in a specified domain from their corresponding files or NIS maps. nispopulate assumes that the tables have been created either through nisserver(1M) or nissetup(1M). The table argument accepts standard names that are used in the administration of Solaris systems and non-standard <i>key-value</i> type tables. See nisaddent(1M) for more information on <i>key-value</i> type tables. If the table argument is not specified, nispopulate will automatically populate each of the standard tables. These standard (default) tables are: auto_master, auto_home, ethers, group, hosts, ipnodes, networks, passwd, protocols, services, rpc, netmasks, bootparams, netgroup, aliases and shadow. Note that the shadow table is only used when populating from files. The non-standard tables that nispopulate accepts are those of <i>key-value</i> type. These tables must first be created manually with the nistbladm(1) command. Use the first synopsis (-Y) to populate NIS+ tables from NIS maps. nispopulate uses ypxfr(1M) to transfer the NIS maps from the NIS servers to the /var/yp/<NIS_domain> directory on the local machine. Then, it uses these files as the input source. Note that <NIS_domain> is case sensitive. Make sure there is enough disk space for that directory. Use the second synopsis (-F) to populate NIS+ tables from local files. nispopulate will use those files that match the table name as input sources in the current working directory or in the specified directory. Note that when populating the hosts, ipnodes, and passwd tables, nispopulate will automatically create the NIS+ credentials for all users and hosts (ipnodes) that are defined in the hosts, ipnodes, and passwd tables, respectively. A network passwd is required to create these credentials. This network password is used to encrypt the secret key for the new users and hosts. This password can be specified using the -l option or it will use the default password, "nisplus". nispopulate will not overwrite any existing credential entries in the credential table. Use nisclient(1M) to overwrite the entries in the cred table. It creates both LOCAL and DES credentials for users, and only DES credentials for hosts. To disable automatic credential creation, specify the "-S 0" option. The third synopsis (-C) is used to populate NIS+ credential table with level 2 authentication (DES) from the hosts, ipnodes and passwd tables of the specified domain. The valid table arguments for this operation are hosts, ipnodes and

nispopulate(1M)

passwd. If this argument is not specified then it will use `hosts`, `ipnodes` and `passwd` as the input source. If other authentication mechanisms are configured using `nisauthconf(1M)`, the NIS+ credential table will be loaded with credentials for those mechanisms.

If `nispopulate` was earlier used with `"-S 0"` option, then no credentials were added for the hosts or the users. If later the site decides to add credentials for all users and hosts, then this `(-C)` option can be used to add credentials.

OPTIONS

<code>-a <NIS_server_addr></code>	Specifies the IP address for the NIS server. This option is only used with the <code>-Y</code> option.
<code>-C</code>	Populate the NIS+ credential table from <code>hosts</code> , <code>ipnodes</code> , and <code>passwd</code> tables using DES authentication (security level 2). If other authentication mechanisms are configured using <code>nisauthconf(1M)</code> , the NIS+ credential table will be populated with credentials for those mechanisms.
<code>-d <NIS+_domain.></code>	Specifies the NIS+ domain. The default is the local domain.
<code>-F</code>	Populates NIS+ tables from files.
<code>-f</code>	Forces the script to populate the NIS+ tables without prompting for confirmation.
<code>-h <NIS_server_host></code>	Specifies the NIS server hostname from where the NIS maps are copied from. This is only used with the <code>-Y</code> option. This hostname must be present in the NIS+ <code>hosts</code> or <code>ipnodes</code> table, or in the <code>/etc/hosts</code> or <code>/etc/inet/ipnodes</code> file. If the hostname is not defined, the script will prompt you for its IP address, or you can use the <code>-a</code> option to specify the address manually.
<code>-l <network_passwd></code>	Specifies the network password for populating the NIS+ credential table. This is only used when you are populating the <code>hosts</code> , <code>ipnodes</code> , and <code>passwd</code> tables. The default <code>passwd</code> is <code>"nisplus"</code> .
<code>-n</code>	Does not overwrite local NIS maps in <code>/var/yp/<NISdomain></code> directory if they already exist. The default is to overwrite the existing NIS maps in the local <code>/var/yp/<NISdomain></code> directory. This is only used with the <code>-Y</code> option.
<code>-p <directory_path></code>	Specifies the directory where the files are stored. This is only used with the <code>-F</code> option. The default is the current working directory.

<code>-s 0 2</code>	Specifies the authentication level for the NIS+ clients. Level 0 is for unauthenticated clients and no credentials will be created for users and hosts in the specified domain. Level 2 is for authenticated (DES) clients and DES credentials will be created for users and hosts in the specified domain. The default is to set up with level 2 authentication (DES). There is no need to run <code>nispopulate</code> with <code>-C</code> for level 0 authentication. Also, if other authentication mechanisms are configured with <code>nisauthconf(1M)</code> , credentials for those mechanisms will also be populated for the NIS+ clients.
<code>-u</code>	Updates the NIS+ tables (ie., adds, deletes, modifies) from either files or NIS maps. This option should be used to bring an NIS+ table up to date when there are only a small number of changes. The default is to add to the NIS+ tables without deleting any existing entries. Also, see the <code>-n</code> option for updating NIS+ tables from existing maps in the <code>/var/yp</code> directory.
<code>-v</code>	Runs the script in verbose mode.
<code>-x</code>	Turns the "echo" mode on. The script just prints the commands that it would have executed. Note that the commands are not actually executed. The default is off.
<code>-Y</code>	Populate the NIS+ tables from NIS maps.
<code>-y <NIS_domain></code>	Specifies the NIS domain to copy the NIS maps from. This is only used with the <code>-Y</code> option. The default domainname is the same as the local domainname.

EXAMPLES**EXAMPLE 1** Using `nispopulate`

To populate all the NIS+ standard tables in the domain *xyz.sun.com*. from NIS maps of the *yp.sun.COM* domain as input source where host *yp_host* is a YP server of *yp.sun.COM*:

```
nis_server# /usr/lib/nis/nispopulate -Y -y yp.sun.COM \
-h yp_host -d xyz.sun.com.
```

To update all of the NIS+ standard tables from the same NIS domain and hosts shown above:

```
nis_server# /usr/lib/nis/nispopulate -Y -u -y yp.sun.COM -h yp_host \
-d xyz.sun.com.
```

To populate the `hosts` table in domain *xyz.sun.com*. from the `hosts` file in the `/var/nis/files` directory and using "somepasswd" as the network password for key encryption:

nispopulate(1M)

EXAMPLE 1 Using nispopulate (Continued)

```
nis_server# /usr/lib/nis/nispopulate -F -p \  
/var/nis/files -l somepasswd hosts
```

To populate the passwd table in domain *xyz.sun.com*. from the passwd file in the */var/nis/files* directory without automatically creating the NIS+ credentials:

```
nis_server# /usr/lib/nis/nispopulate -F -p /var/nis/files \  
-d xys.sun.com. -S 0 passwd
```

To populate the credential table in *domain xyz.sun.com*. for all users defined in the passwd table.

```
nis_server# /usr/lib/nis/nispopulate -C -d xys.sun.com. passwd
```

To create and populate a non-standard key-value type NIS+ table, "private", from the file */var/nis/files/private*: (nispopulate assumes that the private.org_dirkey-value type table has already been created).

```
nis_server# /usr/bin/nistbladm -D access=og=rmcd,nw=r \  
-c private key=S,nogw= value=,nogw= private.org.dir  
nis_server# /usr/lib/nis/nispopulate -F -p /var/nis/files private
```

ENVIRONMENT VARIABLES

nispopulate normally creates temporary files in the directory */tmp*. You may specify another directory by setting the environment variable *TMPDIR* to your chosen directory. If *TMPDIR* is not a valid directory, then nispopulate will use */tmp*.

FILES

<i>/etc/inet/hosts</i>	local host name database
<i>/etc/inet/ipnodes</i>	local database associating names of nodes with IP addresses
<i>/var/yp</i>	NIS (YP) domain directory
<i>/var/nis</i>	NIS+ domain directory
<i>/tmp</i>

nisprefadm(1M)

NAME	nisprefadm – NIS+ utility to set server preferences for NIS+ clients
SYNOPSIS	<pre> /usr/bin/nisprefadm -a {-L -G} [-o opt-string] [-d domain] [-C client] server... /usr/bin/nisprefadm -m {-L -G} [-o opt-string] [-d domain] [-C client] oldserver=newserver... /usr/bin/nisprefadm -r {-L -G} [-o opt-string] [-d domain] [-C client] server... /usr/bin/nisprefadm -u {-L -G} [-o opt-string] [-d domain] [-C client] server... /usr/bin/nisprefadm -x {-L -G} [-d domain] [-C client] /usr/bin/nisprefadm -l {-L -G} [-d domain] [-C client] /usr/bin/nisprefadm -F </pre>
DESCRIPTION	nisprefadm defines which servers are to be preferred by NIS+ clients. This information is used by <code>nis_cachemgr(1M)</code> to control the order in which it selects which server to use for a particular domain. On a client system, the cache manager first looks for a local preferred server list in <code>/var/nis</code>. If it doesn't find one, it looks for an entry with its host name in the NIS+ table. Finally, if it doesn't find it there, it looks for an entry for its subnet. By default, <code>nis_cachemgr</code> puts all servers that are on the same subnet as the client system (that is, local servers) are on the preferred server list. In some cases this default preferred server list is inadequate. For example, if all of the servers for a domain are remote, but some are <i>closer</i> than others, the cache manager should try to select the closer one. Because the cache manager has no reliable way to determine the distance to remote servers, <code>nisprefadm</code> is used to provide this information. The preferred server information is stored either globally in a NIS+ table (with the <code>-G</code> option) or locally in a file, <code>/var/nis/client_info</code> (with the <code>-L</code> option). It is preferable to store the information globally so that it can be used by all clients on a subnet. The <code>nis_cachemgr</code> process on a client machine reloads the preferred server information periodically, depending on the machine's setup. If the local file is used, the information is reloaded every 12 hours. If the global table is used, the information is reloaded based on the TTL value of the client information table. This TTL value can be changed using <code>nischttl(1)</code>. If you want your changes to take effect immediately, use the <code>nisprefadm -F</code> command. When changing local information (<code>-L</code>), <code>nisprefadm</code> automatically forces <code>nis_cachemgr</code> to reload the information. The cache manager assigns weights to all of the servers on the preferred list. By default, local servers (that is, servers on the same subnet) are given a weight of 0. Other servers are given the weight, "infinite". This can be changed by using the <code>nisprefadm</code> command and giving a weight in parentheses after the server name. When selecting a server for a domain, the cache manager first tries to contact the

servers with the lowest weight. If it doesn't get a response, it tries the servers with the next lowest weight, and so on. If it fails to get a response from any of the preferred servers, it tries to contact the non-preferred servers.

The use of weights gives fine control over the server selection process, but care must be given to avoid assigning too many different weights. For example, if weights 0, 1, 2, and 3 are used, but all of the servers with weight 0, 1, and 2, are unavailable, then there will be a noticeable delay in selecting a server. This is because the cache manager waits 5 seconds for a response at each weight level before moving on to the next one. As a general rule, one or two weight levels provides a good balance of server selection control and performance.

When specifying a server name, it is not necessary to fully qualify the name. When the cache manager tries to access a domain, it compares the list of servers for the domain with the list of preferred servers. It will find a match if a preferred server name is a prefix of the name of a server for the domain. If a domain is served by two servers with the same prefix, the preferred server name must include enough of the domain name to distinguish the two.

The `nis_cachemgr(1M)` process automatically adds local servers (same subnet as the client) to the preferred server list with a weight of 0. Thus, it is not necessary to specify them, though it does no harm.

If you specify a weight for a server, you probably should quote the parentheses to avoid having the shell interpret them. The following command illustrates this:

```
example% nisprefadm -G -a -C client1 "srv1(2)"
```

In general, `nis_cachemgr` does a fairly good job of selecting servers on its own. Therefore, the use of `nisprefadm` is not usually necessary. Some situations in which it is recommended are:

No local servers, many remote servers

In this case, `nis_cachemgr` needs to choose one of the remote servers. Because it doesn't have information on which is closest, it sends a ping to all of them and then selects the one that responds fastest. This may not always select the best server. If some of the servers are closer to the client than the others, they should be listed as preferred servers so that `nis_cachemgr` will try them first. This reduces the amount of network traffic for selecting a server.

Very remote servers

In some networks there are NIS+ servers that are only reachable through very slow network connections. It is usually best to avoid unnecessary traffic over that connection. If the `pref_type=pref_only` option is set along with preferred servers, then only the preferred servers are contacted for domains they serve. The non-preferred servers are not tried at all; even if all of the preferred servers are unavailable. For domains that are not served by any of the preferred servers, the `pref_only` option is ignored.

nisprefadm(1M)

OPTIONS	In the SYNOPSIS, when several options are surrounded by braces (that is, by '{' and '}') one of the options must be specified.
-a	Add the specified servers to the preferred server list.
-C <i>client</i>	Store the preferred server information with the key, <i>client</i> . The <i>client</i> can be either a hostname or a subnet number. When a hostname is specified, the preferred server information applies to that host only. When a subnet is specified, the preferred server information applies to all clients on that subnet. The cache manager searches for host specific entries first. It only searches for subnet entries if no host entry is found. If this option is not specified, then the hostname of the machine on which the command is run is used.
-d <i>domain</i>	Specify the <i>domain</i> to which the command is to apply.
-F	Tells <i>nis_cachemgr</i> (1M) to refresh its preferred server information. The program periodically does this anyway, but this option forces it to do the refresh immediately. When updating the local information, <i>nis_cachemgr</i> automatically refreshes the preferred server information.
	This option must be executed as <i>root</i> .
-l	List the current preferred server information.
-L -G	Store the preferred server information locally in the file, <i>/var/nis/client_info</i> (the -L option), or globally in a NIS+ table <i>client.info.org-dir.domain</i> (the -G option). If the information is stored locally, then it only applies to the system on which the command is run. If it is stored globally then it can apply to all systems on a subnet (depending on the value of the -C option).
	The -L option must be run as <i>root</i> .
-m	Modify the preferred server list. The server specified by <i>oldserver</i> is replaced by <i>newserver</i> . This is typically used to change the weight for a server.
-o	Specify additional options to control server selection. Currently the only valid option is <i>pref_type</i> , which can have a value of either <i>all</i> (the default) or <i>pref_only</i> . If the value is <i>all</i> , then the cache manager tries to contact non-preferred servers if all of the preferred servers fail to respond. If <i>pref_only</i> is specified, then it won't try non-preferred servers. The only exception to this is when a domain is not served by any of the preferred servers. In this case, the cache manager ignores the option. This is to avoid requiring that preferred servers be defined for every domain.
-r	Remove the specified servers from the preferred server list.

	-u Clear the list of preferred servers and then add the specified servers to the preferred server list. -x Remove the preferred server information completely.				
RETURN VALUES	nisprefadm returns the following values: 0 On success. 1 On failure.				
EXAMPLES	EXAMPLE 1 Using <code>nisprefadm</code> This command sets the preferred server list for the system on which it is run: <pre>example% nisprefadm -L -a srv1 srv2</pre> The information is stored in a file, <code>/var/nis/client_info</code>, so it will only affect this one system. The following command has the same effect, but the information is stored in a NIS+ table in the default domain. <pre>example% nisprefadm -G -a srv1 srv2</pre> As a system administrator, you might want to set the preferred server information for a client system other than the one you are running the command on. The following command sets the preferred server information for a client system named <code>client1</code>: <pre>example% nisprefadm -G -a -C client1 srv1 srv2</pre> It is common for all client systems on a subnet to use the same set of preferred servers. The following command sets a preferred server list that applies to all clients on subnet, 192.85.18.0: <pre>example% nisprefadm -G -a -C 192.85.18.0 srv1 srv2</pre>

nisrestore(1M)

NAME	nisrestore – restore NIS+ directory backup
SYNOPSIS	nisrestore [-fv] <i>backup-dir directory...</i> nisrestore [-fv] -a <i>backup-dir</i> nisrestore -t <i>backup-dir</i>
DESCRIPTION	nisrestore restores an existing backup of a NIS+ directory object that was created using nisbackup(1M). The <i>backup-dir</i> is the UNIX directory that contains the NIS+ backup on the server being restored. The nisrestore command can be used to restore a NIS+ directory object or a complete NIS+ database. It also can be used as an "out of band" fast replication for a new replica server being initialized. The rpc.nisd(1M) daemon must be stopped before running nisrestore. The first synopsis is used to restore a single directory object or a specified list of directory objects. The directory can be partially qualified or fully qualified. The server being restored will be verified against the list of servers serving the directory. If this server is not configured to serve this object, nisrestore will exit with an error. The -f option will override this check and force the operation. The second synopsis will restore all of the directory objects contained in the <i>backup-dir</i>. Again, the server will be validated against the serving list for each of the directory objects in the <i>backup-dir</i>. If one of the objects in the <i>backup-dir</i> are not served by this server, nisrestore will exit with an error. The -f option will override this check and force the operation. The -a option will attempt to restore all NIS+ objects contained in the <i>backup-dir</i>. If any of these objects are not served by the server, nisrestore will exit with an error. If the <i>backup-dir</i> contains objects that are not served by the server, nisrestore must be executed without the -a option and the specific directory objects listed. The -f option will disable verification of the server being configured to serve the objects being restored. This option should be used with care, as data could be inadvertently restored to a server that doesn't serve the restored data. This option is required in the case of restoring a single server domain (master server only) or if the other NIS+ servers are unavailable for NIS+ lookups. The combination of options -f and -a should be used with caution, as no validation of the server serving the restored objects will be done. New replicas can be quickly added to a namespace with the nisrestore command. The steps are as follows. Configure the new replica on the master server (see nisserver(1M)): <pre>master# nisserver -R -h replica</pre> Kill the rpc.nisd server process on the new replica server: <pre>replica# kill rpc.nisd-pid</pre>

Create a backup of the NIS+ database on the master, which will include the new replica information. See `nisbackup(1M)`. The `/backup` will need to be exported to the new replica. See `share_nfs(1M)`.

```
master# nisbackup -a /backup
```

Restore the backup of the NIS+ database on the new replica. Use the `-f` option if `nisrestore` is unable to lookup the NIS+ objects being restored. The backup should be available through `nfs` or similar means. See `share_nfs(1M)`.

```
replica# nisrestore -f -a //nfs-mnt/backup
```

Restart the `rpc.nisd(1M)` process on the new replica, and the server will immediately be available for service.

OPTIONS	<code>-a</code> Restores all directory objects included in the <i>backup-dir</i> partition. <code>-f</code> Forces the restoration of a directory without the validation of the server in the directory object's serving list. <code>-t</code> Lists all directory objects contained in <i>backup-dir</i>. <code>-v</code> Verbose option. Additional output will be produced upon execution of the command.

OPERANDS	<i>backup-dir</i> The UNIX directory that contains the data files for the NIS+ directory objects to be restored. <i>directory</i> The NIS+ directory object(s) to be restored. This can be a fully or partially qualified name.

EXAMPLES **EXAMPLE 1** Restoring the Directory Object on a Replica Server from a Local UFS Partition

To restore the `org_dir` directory object of the domain `foo.com` on a replica server from a local `ufs` partition named `/var/backup`:

```
replica_server# nisrestore /var/backup org_dir.foo.com.
```

EXAMPLE 2 Forcing the Restore of a Backed up NIS+ Namespace to a Replica Server From the Backup Partition

To force the restore of an entire backed up NIS+ namespace to a replica server from the backup partition named `/var/backup`:

```
replica_server# nisrestore -f -a /var/backup
```

EXAMPLE 3 Restoring the Subdomain on a Master Server From a Backup that Includes Other Directory Objects

To restore the subdomain `sub.foo.com` on a master server, from a backup that includes other directory objects:

nisrestore(1M)

EXAMPLE 3 Restoring the Subdomain on a Master Server From a Backup that Includes Other Directory Objects (Continued)

```
master_server# nisrestore /var/backup sub.foo.com. \
org_dir.sub.foo.com. groups_dir.sub.foo.com.
```

EXIT STATUS

0	Successful completion.
1	An error occurred.

FILES

- `/backup-dir/backup_list`
This ASCII file contains a list of all the objects contained in this *backup-dir* directory. This information can be displayed with the `-t` option.
- `/backup-dir/directory-object`
A subdirectory that is created in the *backup-dir* which contains the directory-object backup.
- `/backup-dir/directory-object/data`
A subdirectory that contains the data files that are part of the directory-object backup.
- `/backup-dir/directory-object/last.upd`
This data file contains timestamp information about the directory-object.
- `/backup-dir/directory-object/data.dict`
A NIS+ data dictionary for all of the objects contained in this directory-object backup.

NAME	nisserver – set up NIS+ servers	
SYNOPSIS	<pre> /usr/lib/nis/nisserver -r [-x] [-f] [-v] [-Y] [-d NIS+_domain] [-g NIS+_groupname] [-l network_password] /usr/lib/nis/nisserver -M [-x] [-f] [-v] [-Y] -d NIS+_domain [-g NIS+_groupname] [-h NIS+_server_host] /usr/lib/nis/nisserver -R [-x] [-f] [-v] [-Y] [-d NIS+_domain] [-h NIS+_server_host] </pre>	
DESCRIPTION	The <code>nisserver</code> shell script can be used to set up a root master, non-root master, and replica NIS+ server with level 2 security (DES). If other authentication mechanisms are configured with <code>nisauthconf(1M)</code>, <code>nisserver</code> will set up a NIS+ server using those mechanisms. <code>nisauthconf(1M)</code> should be used before <code>nisserver</code>. When setting up a new domain, this script creates the NIS+ directories (including <code>groups_dir</code> and <code>org_dir</code>) and system table objects for the domain specified. It does not populate the tables. <code>nispopulate(1M)</code> must be used to populate the tables.	
OPTIONS	-d <i>NIS+_domain</i> Specifies the name for the NIS+ domain. The default is your local domain. -f Forces the NIS+ server setup without prompting for confirmation. -g <i>NIS+_groupname</i> Specifies the NIS+ group name for the new domain. This option is not valid with -R option. The default group is <code>admin.<domain></code>. -h <i>NIS+_server_host</i> Specifies the hostname for the NIS+ server. It must be a valid host in the local domain. Use a fully qualified hostname (for example, <i>hostx.xyz.sun.com.</i>) to specify a host outside of your local domain. This option is <i>only</i> used for setting up non-root master or replica servers. The default for non-root master server setup is to use the same list of servers as the parent domain. The default for replica server setup is the local hostname. -l <i>network_password</i> Specifies the network password with which to create the credentials for the root master server. This option is <i>only</i> used for master root server setup (-r option). If this option is not specified, the script prompts you for the login password. -M Sets up the specified host as a master server. Make sure that <code>rpc.nisd(1M)</code> is running on the new master server before this command is executed. -R Sets up the specified host as a replica server. Make sure that <code>rpc.nisd</code> is running on the new replica server.	

nisserver(1M)

	-r Sets up the server as a root master server. Use the -R option to set up a root replica server. -v Runs the script in verbose mode. -x Turns the echo mode on. The script just prints the commands that it would have executed. Note that the commands are not actually executed. The default is off. -Y Sets up a NIS+ server with NIS-compatibility mode. The default is to set up the server without NIS-compatibility mode.
USAGE	Use the first synopsis of the command (-r) to set up a root master server. To run the command, you must be logged in as super-user on the server machine. Use the second synopsis of the command (-M) to set up a non-root master server for the specified domain. To run the command, you must be logged in as a NIS+ principal on a NIS+ machine and have write permission to the parent directory of the domain that you are setting up. The new non-root master server machine must already be an NIS+ client (see <code>niscclient(1M)</code>) and have the <code>rpc.nisd(1M)</code> daemon running. Use the third synopsis of the command (-R) to set up a replica server for both root and non-root domains. To run the command, you must be logged in as a NIS+ principal on a NIS+ machine and have write permission to the parent directory of the domain that you are replicating. The new non-root replica server machine must already be an NIS+ client and have the <code>rpc.nisd</code> daemon running.
EXAMPLES	EXAMPLE 1 Setting up Servers To set up a root master server for domain <code>sun.com.</code>: <pre>root_server# /usr/lib/nis/nisserver -r -d sun.com.</pre> For the following examples make sure that the new servers are NIS+ clients and that <code>rpc.nisd</code> is running on these hosts before executing <code>nisserver</code>. To set up a replica server for the <code>sun.com.</code> domain on host <i>sunreplica</i>: <pre>root_server# /usr/lib/nis/nisserver -R -d sun.com. -h sunrep</pre> To set up a non-root master server for domain <i>xyz.sun.com.</i> on host <i>sunxyz</i> with the NIS+ groupname as <i>admin-mgr.xyz.sun.com.</i>: <pre>root_server# /usr/lib/nis/nisserver -M -d xyz.sun.com. -h sunxyz \ -g admin-mgr.xyz.sun.com.</pre> To set up a non-root replica server for domain <i>xyz.sun.com.</i> on host <i>sunabc</i>: <pre>sunxyz# /usr/lib/nis/nisserver -R -d xyz.sun.com. -h sunabc</pre>

nissetup(1M)

NAME	nissetup – initialize a NIS+ domain				
SYNOPSIS	/usr/lib/nis/nissetup [-Y] [<i>domain</i>]				
DESCRIPTION	nissetup is a shell script that sets up a NIS+ domain to service clients that wish to store system administration information in a domain named <i>domain</i>. This domain should already exist prior to executing this command. See nismkdir(1) and nisinit(1M). A NIS+ domain consists of a NIS+ directory and its subdirectories: org_dir and groups_dir. org_dir stores system administration information and groups_dir stores information for group access control. nissetup creates the subdirectories org_dir and groups_dir in <i>domain</i>. Both subdirectories will be replicated on the same servers as the parent domain. After the subdirectories are created, nissetup creates the default tables that NIS+ serves. These are auto_master, auto_home, bootparams, cred, ethers, group, hosts, mail_aliases, netmasks, networks, passwd, protocols, rpc, services, and timezone. The nissetup script uses the nistbladm(1) command to create these tables. The script can be easily customized to add site specific tables that are created at setup time. This command is normally executed just once per domain. While this command creates the default tables, it does not initialize them with data. This is accomplished with the nisaddent(1M) command. It is easier to use the nisserver(1M) script to create subdirectories and the default tables.				
OPTIONS	-Y Specify that the domain will be served as both a NIS+ domain as well as an NIS domain using the backward compatibility flag. This will set up the domain to be less secure by making all the system tables readable by unauthenticated clients as well.

NAME	nissshowcache – NIS+ utility to print out the contents of the shared cache file				
SYNOPSIS	<code>/usr/lib/nis/nissshowcache [-v]</code>				
DESCRIPTION	nissshowcache prints out the contents of the per-machine NIS+ directory cache that is shared by all processes accessing NIS+ on the machine. By default, nissshowcache only prints out the directory names in the cache along with the list of active servers. The shared cache is maintained by nis_cachemgr(1M).				
OPTIONS	-v Verbose mode. Print out the contents of each directory object, including the information on the server name and its universal addresses.				
FILES	/var/nis/NIS_SHARED_DIRCACHE

nisstat(1M)

NAME	nisstat – report NIS+ server statistics																
SYNOPSIS	<code>/usr/lib/nis/nisstat</code> [-H <i>host</i>] [<i>directory</i>]																
DESCRIPTION	The <code>nisstat</code> command queries a NIS+ server for various statistics about its operations. These statistics may vary between implementations and from release to release. Not all statistics are available from all servers. If you request a statistic from a server that does not support that statistic, it is never a fatal error. The message “unknown statistic” is returned. By default, statistics are fetched from the server(s) of the NIS+ directory for the default domain. If <i>directory</i> is specified, servers for that directory are queried. Supported statistics for this release are as follows: <table><tr><td><i>root server</i></td><td>This reports whether the server is a root server.</td></tr><tr><td><i>NIS compat mode</i></td><td>This reports whether the server is running in NIS compat mode.</td></tr><tr><td><i>DNS forwarding in NIS mode</i></td><td>This reports whether the server in NIS compat mode will forward host lookup calls to DNS.</td></tr><tr><td><i>security level</i></td><td>This reports the security level of this server.</td></tr><tr><td><i>serves directories</i></td><td>This lists the directories served by this server.</td></tr><tr><td><i>Operations</i></td><td>This statistic returns results in the form: <code>OP=opname : C=calls : E=errors : T=micros</code> Where <i>opname</i> is replaced by the RPC procedure name or operation, <i>calls</i> is the number of calls to this procedure that have been made since the server started running. <i>errors</i> is the number of errors that have occurred while processing a call, and <i>micros</i> is the average time in microseconds to complete the last 16 calls.</td></tr><tr><td><i>Directory Cache</i></td><td>This statistic reports the number of calls to the internal directory object cache, the number of hits on that cache, the number of misses, and the hit rate percentage.</td></tr><tr><td><i>Group Cache</i></td><td>This statistic reports the number of calls to the internal NIS+ group object cache, the number of hits on that cache, the number of misses, and the hit rate percentage.</td></tr></table>	<i>root server</i>	This reports whether the server is a root server.	<i>NIS compat mode</i>	This reports whether the server is running in NIS compat mode.	<i>DNS forwarding in NIS mode</i>	This reports whether the server in NIS compat mode will forward host lookup calls to DNS.	<i>security level</i>	This reports the security level of this server.	<i>serves directories</i>	This lists the directories served by this server.	<i>Operations</i>	This statistic returns results in the form: <code>OP=opname : C=calls : E=errors : T=micros</code> Where <i>opname</i> is replaced by the RPC procedure name or operation, <i>calls</i> is the number of calls to this procedure that have been made since the server started running. <i>errors</i> is the number of errors that have occurred while processing a call, and <i>micros</i> is the average time in microseconds to complete the last 16 calls.	<i>Directory Cache</i>	This statistic reports the number of calls to the internal directory object cache, the number of hits on that cache, the number of misses, and the hit rate percentage.	<i>Group Cache</i>	This statistic reports the number of calls to the internal NIS+ group object cache, the number of hits on that cache, the number of misses, and the hit rate percentage.
<i>root server</i>	This reports whether the server is a root server.																
<i>NIS compat mode</i>	This reports whether the server is running in NIS compat mode.																
<i>DNS forwarding in NIS mode</i>	This reports whether the server in NIS compat mode will forward host lookup calls to DNS.																
<i>security level</i>	This reports the security level of this server.																
<i>serves directories</i>	This lists the directories served by this server.																
<i>Operations</i>	This statistic returns results in the form: <code>OP=opname : C=calls : E=errors : T=micros</code> Where <i>opname</i> is replaced by the RPC procedure name or operation, <i>calls</i> is the number of calls to this procedure that have been made since the server started running. <i>errors</i> is the number of errors that have occurred while processing a call, and <i>micros</i> is the average time in microseconds to complete the last 16 calls.																
<i>Directory Cache</i>	This statistic reports the number of calls to the internal directory object cache, the number of hits on that cache, the number of misses, and the hit rate percentage.																
<i>Group Cache</i>	This statistic reports the number of calls to the internal NIS+ group object cache, the number of hits on that cache, the number of misses, and the hit rate percentage.																

Static Storage

This statistic reports the number of bytes the server has allocated for its static storage buffers.

Dynamic Storage

This statistic reports the amount of heap the server process is currently using.

Uptime

This statistic reports the time since the service has been running.

Per-server and per-directory access restrictions may apply. See `nisopaccess(1)`. `nisstat` uses `NIS_STATUS`.

OPTIONS

`-H host`

Normally all servers for the directory are queried. With this option, only the machine named *host* is queried. If the named machine does not serve the directory, no statistics are returned.

ENVIRONMENT VARIABLES

`NIS_PATH`

If this variable is set, and the NIS+ directory name is not fully qualified, each directory specified will be searched until the directory is found. See `nisdefaults(1)`.

ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWnisu

NOTES

NIS+ might not be supported in future releases of the Solaris™ Operating Environment. Tools to aid the migration from NIS+ to LDAP are available in the Solaris 9 operating environment. For more information, visit <http://www.sun.com/directory/nisplus/transition.html>.

nisupdkeys(1M)

NAME	nisupdkeys – update the public keys in a NIS+ directory object								
SYNOPSIS	<pre>/usr/lib/nis/nisupdkeys [-a -C] [-H <i>host</i>] [<i>directory</i>]</pre> <pre>/usr/lib/nis/nisupdkeys -s [-a -C] -H <i>host</i></pre>								
DESCRIPTION	This command updates the public keys in an NIS+ directory object. When the public key(s) for a NIS+ server are changed, <i>nisupdkeys</i> reads a directory object and attempts to get the public key data for each server of that directory. These keys are placed in the directory object and the object is then modified to reflect the new keys. If <i>directory</i> is present, the directory object for that directory is updated. Otherwise the directory object for the default domain is updated. The new key must be propagated to all directory objects that reference that server. On the other hand, <i>nisupdkeys -s</i> gets a list of all the directories served by <i>host</i> and updates those directory objects. This assumes that the caller has adequate permission to change all the associated directory objects. The list of directories being served by a given server can also be obtained by <i>nisstat</i>(1M). Before you do this operation, make sure that the new address/public key has been propagated to all replicas. If multiple authentication mechanisms are configured using <i>nisauthconf</i>(1M), then the keys for those mechanisms will also be updated or cleared. The user executing this command must have modify access to the directory object for it to succeed. The existing directory object can be displayed with the <i>niscat</i>(1) command using the <i>-o</i> option. This command does not update the directory objects stored in the <i>NIS_COLD_START</i> file on the NIS+ clients. If a server is also the root master server, then <i>nisupdkeys -s</i> cannot be used to update the root directory.								
OPTIONS	<table> <tr> <td>-a</td><td>Update the universal addresses of the NIS+ servers in the directory object. Currently, this only works for the TCP/IP family of transports. This option should be used when the IP address of the server is changed. The server's new address is resolved using <i>getipnodebyname</i>(3SOCKET) on this machine. The <i>/etc/nsswitch.conf</i> file must point to the correct source for <i>ipnodes</i> and <i>hosts</i> for this resolution to work.</td></tr> <tr> <td>-C</td><td>Specify to clear rather than set the public key(s). Communication with a server that has no public key(s) does not require the use of secure RPC.</td></tr> <tr> <td>-H <i>host</i></td><td>Limit key changes only to the server named <i>host</i>. If the hostname is not a fully qualified NIS+ name, then it is assumed to be a host in the default domain. If the named host does not serve the directory, no action is taken.</td></tr> <tr> <td>-s</td><td>Update all the NIS+ directory objects served by the specified server. This assumes that the caller has adequate access rights to</td></tr> </table>	-a	Update the universal addresses of the NIS+ servers in the directory object. Currently, this only works for the TCP/IP family of transports. This option should be used when the IP address of the server is changed. The server's new address is resolved using <i>getipnodebyname</i> (3SOCKET) on this machine. The <i>/etc/nsswitch.conf</i> file must point to the correct source for <i>ipnodes</i> and <i>hosts</i> for this resolution to work.	-C	Specify to clear rather than set the public key(s). Communication with a server that has no public key(s) does not require the use of secure RPC.	-H <i>host</i>	Limit key changes only to the server named <i>host</i> . If the hostname is not a fully qualified NIS+ name, then it is assumed to be a host in the default domain. If the named host does not serve the directory, no action is taken.	-s	Update all the NIS+ directory objects served by the specified server. This assumes that the caller has adequate access rights to
-a	Update the universal addresses of the NIS+ servers in the directory object. Currently, this only works for the TCP/IP family of transports. This option should be used when the IP address of the server is changed. The server's new address is resolved using <i>getipnodebyname</i> (3SOCKET) on this machine. The <i>/etc/nsswitch.conf</i> file must point to the correct source for <i>ipnodes</i> and <i>hosts</i> for this resolution to work.								
-C	Specify to clear rather than set the public key(s). Communication with a server that has no public key(s) does not require the use of secure RPC.								
-H <i>host</i>	Limit key changes only to the server named <i>host</i> . If the hostname is not a fully qualified NIS+ name, then it is assumed to be a host in the default domain. If the named host does not serve the directory, no action is taken.								
-s	Update all the NIS+ directory objects served by the specified server. This assumes that the caller has adequate access rights to								

change all the associated directory objects. If the NIS+ principal making this call does not have adequate permissions to update the directory objects, those particular updates will fail and the caller will be notified. If the `rpc.nisd` on *host* cannot return the list of servers it serves, the command will print an error message. The caller would then have to invoke `nisupdkeys` multiple times (as in the first synopsis), once per NIS+ directory that it serves.

EXAMPLES**EXAMPLE 1** Using `nisupdkeys`

The following example updates the keys for servers of the *foo.bar.* domain.

```
example% nisupdkeys foo.bar.
```

This example updates the key(s) for host *fred* that serves the *foo.bar.* domain.

```
example% nisupdkeys -H fred foo.bar.
```

This example clears the public key(s) for host *wilma* in the *foo.bar.* directory.

```
example% nisupdkeys -CH wilma foo.bar.
```

This example updates the public key(s) in all directory objects that are served by the host *wilma*.

```
example% nisupdkeys -s -H wilma
```

h1>nlsadmin(1M)

NAME	nlsadmin – network listener service administration						
SYNOPSIS	<pre> /usr/sbin/nlsadmin -x /usr/sbin/nlsadmin [options] net_spec /usr/sbin/nlsadmin [options] -N port_monitor_tag /usr/sbin/nlsadmin -V /usr/sbin/nlsadmin -c cmd -o streamname [-p modules] [-A address -D] [-R prognum : versnum] </pre>						
DESCRIPTION	nlsadmin is the administrative command for the network listener process(es) on a machine. Each network has at least one instance of the network listener process associated with it; each instance (and thus, each network) is configured separately. The listener process “listens” to the network for service requests, accepts requests when they arrive, and invokes servers in response to those service requests. The network listener process may be used with any network (more precisely, with any connection-oriented transport provider) that conforms to the transport provider specification. nlsadmin can establish a listener process for a given network, configure the specific attributes of that listener, and start and kill the listener process for that network. nlsadmin can also report on the listener processes on a machine, either individually (per network) or collectively. <i>net_spec</i> represents a particular listener process. Specifically, <i>net_spec</i> is the relative path name of the entry under /dev for a given network (that is, a transport provider). <i>address</i> is a transport address on which to listen and is interpreted using a syntax that allows for a variety of address formats. By default, <i>address</i> is interpreted as the symbolic ASCII representation of the transport address. An <i>address</i> preceded by \x will let you enter an address in hexadecimal notation. Note that <i>address</i> must appear as a single word to the shell, thus it must be quoted if it contains any blanks. Changes to the list of services provided by the listener or the addresses of those services are put into effect immediately.						
OPTIONS	nlsadmin may be used with the following combinations of options and arguments: <table> <tr> <td>-x</td><td>Report the status of all of the listener processes installed on this machine.</td></tr> <tr> <td><i>net_spec</i></td><td>Print the status of the listener process for <i>net_spec</i>.</td></tr> <tr> <td>-q <i>net_spec</i></td><td>Query the status of the listener process for the specified network, and reflects the result of that query in its exit code. If a listener process is active, nlsadmin will exit with a status of 0; if no process is active, the exit</td></tr> </table>	-x	Report the status of all of the listener processes installed on this machine.	<i>net_spec</i>	Print the status of the listener process for <i>net_spec</i> .	-q <i>net_spec</i>	Query the status of the listener process for the specified network, and reflects the result of that query in its exit code. If a listener process is active, nlsadmin will exit with a status of 0; if no process is active, the exit
-x	Report the status of all of the listener processes installed on this machine.						
<i>net_spec</i>	Print the status of the listener process for <i>net_spec</i> .						
-q <i>net_spec</i>	Query the status of the listener process for the specified network, and reflects the result of that query in its exit code. If a listener process is active, nlsadmin will exit with a status of 0; if no process is active, the exit						

	code will be 1; the exit code will be greater than 1 in case of error.
<code>-v net_spec</code>	Print a verbose report on the servers associated with <i>net_spec</i> , giving the service code, status, command, and comment for each. It also specifies the <code>uid</code> the server will run as and the list of modules to be pushed, if any, before the server is started.
<code>-z service_code net_spec</code>	Print a report on the server associated with <i>net_spec</i> that has service code <i>service_code</i> , giving the same information as in the <code>-v</code> option.
<code>-q -z service_code net_spec</code>	Query the status of the service with service code <i>service_code</i> on network <i>net_spec</i> , and exits with a status of 0 if that service is enabled, 1 if that service is disabled, and greater than 1 in case of error.
<code>-l address net_spec</code>	Change or set the transport address on which the listener listens (the general listener service). This address can be used by remote processes to access the servers available through this listener (see the <code>-a</code> option, below). If <i>address</i> is just a dash ("<code>-</code>"), <code>nlsadmin</code> reports the address currently configured, instead of changing it. A change of address takes effect immediately.
<code>-t address net_spec</code>	Change or set the address on which the listener listens for requests for terminal service but is otherwise similar to the <code>-l</code> option above. A terminal service address should not be defined unless the appropriate remote login software is available; if such software is available, it must be configured as service code 1 (see the <code>-a</code> option, below).
<code>-i net_spec</code>	Initialize an instance of the listener for the network specified by <i>net_spec</i> ; that is, create and initialize the files required by the listener as well as starting that instance of the listener. Note that a particular instance

-a service_code

of the listener should be initialized only once. The listener must be initialized before assigning addresses or services.

[*-p modules*] [*-w name*] *-c cmd -y comment net_spec*

Add a new service to the list of services available through the indicated listener. *service_code* is the code for the service, *cmd* is the command to be invoked in response to that service code, comprised of the full path name of the server and its arguments, and *comment* is a brief (free-form) description of the service for use in various reports. Note that *cmd* must appear as a single word to the shell; if arguments are required, the *cmd* and its arguments must be enclosed in quotation marks. The *comment* must also appear as a single word to the shell. When a service is added, it is initially enabled (see the *-e* and *-d* options, below).

Service codes are alphanumeric strings, and are administered by AT&T. The numeric service codes 0 through 100 are reserved for internal use by the listener. Service code 0 is assigned to the nlps server, which is the service invoked on the general listening address. In particular, code 1 is assigned to the remote login service, which is the service automatically invoked for connections to the terminal login address.

If the *-p* option is specified, then *modules* will be interpreted as a list of STREAMS modules for the listener to push before starting the service being added. The modules are pushed in the order they are specified. *modules* should be a comma-separated list of modules, with no white space included.

If the *-w* option is specified, then *name* is interpreted as the user name from */etc/passwd* that the listener should look up. From the user name, the listener obtains

the user ID, the group ID(s), and the home directory for use by the server. If `-w` is not specified, the default is to use the user name `listen`.

A service must explicitly be added to the listener for each network on which that service is to be available. This operation will normally be performed only when the service is installed on a machine, or when populating the list of services for a new network.

`-r service_code net_spec`

Remove the entry for the *service_code* from that listener's list of services. This is normally done only in conjunction with the de-installation of a service from a machine.

`-e service_code net_spec`

`-d service_code net_spec`

Enable or disable (respectively) the service indicated by *service_code* for the specified network. The service must previously have been added to the listener for that network (see the `-a` option, above). Disabling a service will cause subsequent service requests for that service to be denied, but the processes from any prior service requests that are still running will continue unaffected.

`-s net_spec`

`-k net_spec`

Start and kill (respectively) the listener process for the indicated network. These operations are normally performed as part of the system startup and shutdown procedures. Before a listener can be started for a particular network, it must first have been initialized (see the `-i` option, above). When a listener is killed, processes that are still running as a result of prior service requests will continue unaffected.

Under the Service Access Facility, it is possible to have multiple instances of the listener on a single *net_spec*. In any of the above commands, the option `-N port_monitor_tag` may be used in place of the *net_spec* argument. This argument specifies the tag by which an instance of the listener is identified by the Service Access Facility. If the `-N` option is not specified (that is, the *net_spec* is specified in the invocation), then it will be assumed that the last component of the *net_spec* represents

nlsadmin(1M)

the tag of the listener for which the operation is destined. In other words, it is assumed that there is at least one listener on a designated *net_spec*, and that its tag is identical to the last component of the *net_spec*. This listener may be thought of as the primary, or default, listener for a particular *net_spec*.

nlsadmin is also used in conjunction with the Service Access Facility commands. In that capacity, the following combinations of options can be used:

-V

Write the current version number of the listener's administrative file to the standard output. It is used as part of the *sacadm* command line when *sacadm* adds a port monitor to the system.

-c *cmd* | -o *streamname* [-p *modules*] [-A *address* | -D] [-R *prognum* : *versnum*]
Format the port monitor-specific information to be used as an argument to *pmadm*(1M)

The -c option specifies the full path name of the server and its arguments. *cmd* must appear as a single word to the shell, and its arguments must therefore be surrounded by quotes.

The -o option specifies the full path name of a FIFO or named STREAM through which a standing server is actually receiving the connection.

If the -p option is specified, then *modules* will be interpreted as a list of STREAMS modules for the listener to push before starting the service being added. The modules are pushed in the order in which they are specified. *modules* must be a comma-separated list, with no white space included.

If the -A option is specified, then *address* will be interpreted as the server's private address. The listener will monitor this address on behalf of the service and will dispatch all calls arriving on this address directly to the designated service. This option may not be used in conjunction with the -D option.

If the -D option is specified, then the service is assigned a private address dynamically, that is, the listener will have the transport provider select the address each time the listener begins listening on behalf of this service. For RPC services, this option will be often be used in conjunction with the -R option to register the dynamically assigned address with the *rpcbinder*. This option may not be used in conjunction with the -A option.

When the -R option is specified, the service is an RPC service whose address, program number, and version number should be registered with the *rpcbinder* for this transport provider. This registration is performed each time the listener begins listening on behalf of the service. *prognum* and *versnum* are the program number and version number, respectively, of the RPC service.

nlsadmin may be invoked by any user to generate reports; all operations that affect a listener's status or configuration may only be run by a super-user.

The options specific to the Service Access Facility may not be used together with any other options.

ERRORS If successful, nlsadmin exits with a status of 0. If nlsadmin fails for any reason, it exits with a status greater than or equal to 2. See -q option for a return status of 1.

NOTES Dynamically assigned addresses are not displayed in reports as statically assigned addresses are.

nscd(1M)

NAME	nscd – name service cache daemon								
SYNOPSIS	/usr/sbin/nscd [-f <i>configuration-file</i>] [-g] [-e <i>cachename</i> , yes no] [-i <i>cachename</i>]								
DESCRIPTION	nscd is a process that provides a cache for the most common name service requests. It starts up during multi-user boot. The default <i>configuration-file</i> <code>/etc/nscd.conf</code> determines the behavior of the cache daemon. See <code>nscd.conf(4)</code>. nscd provides caching for the <code>passwd(4)</code>, <code>group(4)</code>, <code>hosts(4)</code>, <code>ipnodes(4)</code>, <code>exec_attr(4)</code>, <code>prof_attr(4)</code>, and <code>user_attr(4)</code> databases through standard libc interfaces, such as <code>gethostbyname(3NSL)</code>, <code>getipnodebyname(3SOCKET)</code>, <code>gethostbyaddr(3NSL)</code>, and others. Each cache has a separate time-to-live for its data; modifying the local database (<code>/etc/hosts</code>, <code>/etc/resolv.conf</code>, and so forth) causes that cache to become invalidated upon the next call to nscd. The shadow file is specifically not cached. <code>getspnam(3C)</code> calls remain uncached as a result. nscd also acts as its own administration tool. If an instance of nscd is already running, commands are passed to the running version transparently. In order to preserve NIS+ security, the startup script for nscd (<code>/etc/init.d/nscd</code>) checks the permissions on the <code>passwd</code> table if NIS+ is being used. If this table cannot be read by unauthenticated users, then nscd will make sure that any encrypted password information returned from the NIS+ server is supplied only to the owner of that password.								
OPTIONS	Several of the options described below require a <i>cachename</i> specification. Supported values are <code>passwd</code>, <code>group</code>, <code>hosts</code>, <code>ipnodes</code>, <code>exec_attr</code>, <code>prof_attr</code>, and <code>user_attr</code>. <table> <tr> <td>-f <i>configuration-file</i></td><td>Causes nscd to read its configuration data from the specified file.</td></tr> <tr> <td>-g</td><td>Prints current configuration and statistics to standard output. This is the only option executable by non-root users.</td></tr> <tr> <td>-e <i>cachename</i>, yes no</td><td>Enables or disables the specified cache.</td></tr> <tr> <td>-i <i>cachename</i></td><td>Invalidate the specified cache.</td></tr> </table>	-f <i>configuration-file</i>	Causes nscd to read its configuration data from the specified file.	-g	Prints current configuration and statistics to standard output. This is the only option executable by non-root users.	-e <i>cachename</i> , yes no	Enables or disables the specified cache.	-i <i>cachename</i>	Invalidate the specified cache.
-f <i>configuration-file</i>	Causes nscd to read its configuration data from the specified file.								
-g	Prints current configuration and statistics to standard output. This is the only option executable by non-root users.								
-e <i>cachename</i> , yes no	Enables or disables the specified cache.								
-i <i>cachename</i>	Invalidate the specified cache.								
EXAMPLES	EXAMPLE 1 Stopping and restarting the nscd daemon. <pre>example# /etc/init.d/nscd stop</pre> <pre>example# /etc/init.d/nscd start</pre>								
FILES	<code>/etc/nscd.conf</code> determines the behavior of the cache daemon

nslookup(1M)

NAME	nslookup – query name servers interactively	
SYNOPSIS	nslookup [- option]... <i>host</i> [<i>server</i>] nslookup [- option]... - [<i>server</i>] nslookup	
DESCRIPTION	nslookup sends queries to Internet domain name servers. It has two modes: interactive and non-interactive. Interactive mode allows the user to contact servers for information about various hosts and domains or to display a list of hosts in a domain. Non-interactive mode is used to display just the name and requested information for a host or domain.	
OPTIONS	-option	Set the permissible options, as shown in the following list. These are the same options that the set command supports in interactive mode (see set in the Commands section for more complete descriptions). all

Entering and Leaving Interactive Mode

Within non-interactive mode, space-separated options can be specified. They must be entered before the host name, to be queried. Each option must be prefixed with a hyphen.

For example, to request extensive host information and to set the timeout to 10 seconds when inquiring about *gypsy*, enter:

```
example% nslookup -query=hinfo -timeout=10 gypsy
```

To avoid repeated entry of an option that you almost always use, place a corresponding `set` command in a `.nslookuprc` file located inside your home directory. (See **Commands** for more information about `set`.) The `.nslookuprc` file can contain several `set` commands if each is followed by a RETURN.

Interactive mode is selected when

- No arguments are supplied.
- A '-' (hyphen) character is supplied as the *host* argument.

To exit from an interactive nslookup session, type `Control-d` or type the command `exit` followed by RETURN.

Supported Command Interactions

The commands associated with interactive mode are subject to various limitations and run-time conventions.

The maximum length of a command line is 255 characters. When the RETURN key is pressed, command-line execution begins. While a command is running, its execution can be interrupted by typing `Control-c`.

The first word entered on the command line must be the name of a nslookup command unless you wish to enter the name of a host to inquire about. Any unrecognized command is handled as a host name to inquire about. To force a command to be treated as a host name to be inquired about, precede it with a backslash character.

Commands

`exit`

Exit the nslookup program.

`help`

`?`

Display a brief summary of commands.

`host [ server ]`

Look up information for *host* using the current default server, or using *server* if it is specified.

If the *host* supplied is an Internet address and the query type is `A` or `1PTR`, the name of the host is returned. If the *host* supplied is a name and it does not have a trailing period, the default domain name is appended to the name. (This behavior depends on the state of the `set` options `domain`, `srchlist`, `defname`, and `search`).

nslookup(1M)

To look up a host that is not in the current domain, append a period to the name.

`finger [ name ] [ >> filename ]`

Connect with the finger server on the current host, which is defined by the most recent successful host lookup.

If no *name* value is specified, a list of login account names on the current host is generated.

Similar to a shell command interpreter, output can be redirected to a file using the usual redirection symbols: `>` and `>>`.

`ls [ -options ] domain [ >> filename ]`

List the information available for *domain*, optionally creating or appending to *filename*. The default output contains host names and their Internet addresses.

Output can be redirected to *filename* using the `>` and `>>` redirection symbols. When output is directed to a file, hash marks are shown for every 50 records received from the server. The permissible values for *options* are:

<code>a</code>	Lists aliases of hosts in the domain. This is a synonym for the command <code>ls -t CNAME</code> .
<code>d</code>	Lists all records for the domain. This is a synonym for the command <code>ls -t ANY</code> .
<code>h</code>	Lists CPU and operating system information for the domain. This is a synonym for the command <code>ls -t HINFO</code> .
<code>s</code>	Lists well-known services of hosts in the domain. This is a synonym for the command <code>ls -t WKS</code> .
<code>t querytype-value</code>	lists all records of the specified type (see <i>querytype</i> within the discussion of the <code>set</code> command).

`set token=value`

`set keyword`

Establish a preferred mode of search operation. Permissible *token* and *keyword* values are:

<code>all</code>	Display the current values of frequently-used options. Information about the current default server and host is also displayed.				
<code>cl[ass]=classname</code>	Limit the search according to the protocol group (<i>classname</i>) for which lookup information is desired. Permissible <i>classname</i> values are: <table><tr><td><code>ANY</code></td><td>A wildcard selecting all classes</td></tr><tr><td><code>IN</code></td><td>The Internet class (the default)</td></tr></table>	<code>ANY</code>	A wildcard selecting all classes	<code>IN</code>	The Internet class (the default)
<code>ANY</code>	A wildcard selecting all classes				
<code>IN</code>	The Internet class (the default)				

	CHAOS	The Chaos class.
	HESIOD	The MIT Athena Hesiod class.
d2 nod2		Enable or disable exhaustive debugging mode. Essentially all fields of every packet are displayed. By default, this option is disabled.
deb[ug] nodeb[ug]		Enable or disable debugging mode. When debugging mode is enabled, much more information is produced about the packet sent to the server and the resulting answer. By default, this option is disabled.
def[name] nodef[name]		Enable or disable appending the default domain name to a single-component lookup request (one that lacks a dot). By default, this option is enabled for nslookup. The default value for the domain name is the value given in <code>/etc/resolv.conf</code> , unless: there is an environmental value for <code>LOCALDOMAIN</code> when nslookup is run; a recent value has been specified through the <code>srchlist</code> command or the <code>set domain</code> command.
do[main]=string		Change the default domain name to be appended to all lookup requests to <i>string</i> . For this option to have any effect, the <code>defname</code> option must also be enabled and the <code>search</code> option must be set in a compatible way. The domain search list contains the parents of the default domain if it has at least two components in its name. For example, if the default domain is <code>CC.Berkeley.EDU</code> , the search list is <code>CC.Berkeley.EDU</code> and <code>Berkeley.EDU</code> . Use the <code>set srchlist</code> command to specify a different list. Use the <code>set all</code> command to display the list.
ignoretc noignoretc		Ignore packet truncation errors. By default, this option is disabled.
srch[list]=name1/name2/...		Change the default domain name to <i>name1</i> and the domain search list to <i>name1</i> , <i>name2</i> , etc. A maximum of 6 names can be specified, along with slash characters to separate them. For example, example% set srchlist=lcs.MIT.EDU/ai.MIT.EDU/MIT.EDU

nslookup(1M)

sets the domain to `lcs.MIT.EDU` and the search list to all three names. This command overrides the default domain name and search list of the `set domain` command. Use the `set all` command to display the list.

`search`

`nosearch`

Enable or disable having the domain names in the domain search list appended to the request, generating a series of lookup queries if necessary until an answer is received. To take effect, the lookup request must contain at least one dot (period); yet it must not contain a trailing period. By default, this option is enabled.

`po[rt]=value`

Specify the default TCP/UDP name server port. By default, this value is 53.

`q[ue]rytype=value`

`ty[pe]=value`

Change the type of information returned from a query to one of:

<code>A</code>	The Internet address of the host
<code>CNAME</code>	The canonical name for an alias
<code>HINFO</code>	The host CPU and operating system type
<code>MD</code>	The mail destination
<code>MX</code>	The mail exchanger
<code>MB</code>	The mailbox domain name
<code>MG</code>	The mail group member
<code>MINFO</code>	The mailbox or mail list information
<code>NS</code>	The name server
<code>PTR</code>	The host name if the query is in the form of an Internet address; otherwise the pointer to other information
<code>SOA</code>	The domain's start-of-authority information
<code>TXT</code>	The text information
<code>UINFO</code>	The user information
<code>WKS</code>	The supported well-known services

(Other types specified in the *RFC 1035* document are valid, but they are not as useful.)

`recurse`

`norecurse`

Enable or disable having to query other name servers before abandoning a search. By default, this feature is enabled.

`ret[ry]=count`

Set the maximum number of times to retry a request before abandoning a search.

When a reply to a request is not received within a certain amount of time (changed

with `set timeout`), the timeout period is doubled and the request is resent. The `retry` value controls how many times a request is resent before the request is aborted. The default for `count` is 4.

`ro[ot]=host`

Change the name of the root server to *host*. This affects the `root` command. The default root server is `ns.internic.net`.

`t[imeout]=interval`

Change the amount of time to wait for a reply to *interval* seconds. Each retry doubles the timeout period. The default *interval* is 5 seconds.

`vc`

`novc`

Enable or disable the use of a virtual circuit when sending requests to the server. By default, this feature is disabled.

`root`

Change the default server to the server for the root of the domain name space. Currently, the host `ns.internic.net` is used; this command is a synonym for `server ns.internic.net`. The name of the root server can be changed with the `set root` command.

`server domain`

`lserver domain`

Change the default server to *domain*. `lserver` uses the initial server to look up information about *domain* while `server` uses the current default server. If an authoritative answer can not be found, the names of servers that might have the answer are returned.

EXAMPLES

EXAMPLE 1 Searching the Internet Domain Namespace

To effectively search the Internet domain namespace, it helps to know its structure. At present, the Internet domain name-space is tree-structured, with one top level domain for each country except the United States.. There are also some traditional top level domains, not explicitly tied to any particular country. These include:

COM	Commercial establishments
EDU	Educational institutions
ORG	Not-for-profit organizations
GOV	Government agencies
MIL	MILNET hosts

If you are looking for a specific host, you need to know something about the host's organization in order to determine the top-level domain that it belongs to. For instance, if you want to find the Internet address of a machine at UCLA, do the following:

- Connect with the root server using the `root` command. The root server of the name space has knowledge of the top-level domains.

nslookup(1M)

EXAMPLE 1 Searching the Internet Domain Namespace (Continued)

- Since UCLA is a university, its domain name is `ucla.edu`. Connect with a server for the `ucla.edu` domain with the command `server ucla.edu`. The response produces the names of hosts that act as servers for that domain. Note: the root server does not have information about `ucla.edu`, but knows the names and addresses of hosts that do. Once located by the root server, all future queries will be sent to the UCLA name server.
- To request information about a particular host in the domain (for instance, `locus`), just type the host name. To request a listing of hosts in the UCLA domain, use the `ls` command. The `ls` command requires a domain name, (in this case, `ucla.edu`, as an argument.

If you are connected with a name server that handles more than one domain, all lookups for host names must be fully specified with its domain. For instance, the domain `harvard.edu` is served by `seismo.css.gov`, which also services the `css.gov` and `cornell.edu` domains. A lookup request for the host `aiken` in the `harvard.edu` domain must be specified as `aiken.harvard.edu`. However, the `set domain=name` and `set defname` commands can be used to automatically append a domain name to each request.

After a successful lookup of a host, use the `finger(1)` command to see who is on the system, or to finger a specific person. (`finger` requires the type to be A.)

To get other information about the host, use the `set querytype=value` command to change the type of information desired and request another lookup.

ENVIRONMENT VARIABLES

HOSTALIASES	References the file containing host aliases
LOCALDOMAIN	Overrides default domain

EXIT STATUS

The process returns the following values:

0	On success.
1	On failure.

FILES

<code>/etc/resolv.conf</code>	Initial domain name and name server addresses
<code>\$HOME/.nslookuprc</code>	Initial option commands
<code>/usr/lib/nslookup.help</code>	Summary of commands

ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu
Interface Stability	Standard BIND 8.2.4

SEE ALSO `finger(1)`, `more(1)`, `in.named(1M)`, `nstest(1M)`, `resolver(3RESOLV)`, `resolv.conf(4)`, `attributes(5)`

Mockapetris, Paul. *RFC 1034, Domain Names - Concepts and Facilities*. Network Working Group. November 1987.

Mockapetris, Paul. *RFC 1035, Domain Names - Implementation and Specification*. Network Working Group. November 1987.

DIAGNOSTICS If the lookup request is successful, an error message is produced. Possible errors are:

Timed out	The server did not respond to a request after a certain amount of time (changed with <code>set timeout=value</code>) and a certain number of retries (changed with <code>set retry=value</code>).
No response from server	No name server is running on the server machine.
No records	The server does not have resource records of the current query type for the host, although the host name is valid. The query type is specified with the <code>set querytype</code> command.
Non-existent domain	The host or domain name does not exist.
Connection refused Network is unreachable	The connection to the name or finger server can not be made at the current time. This error commonly occurs with <code>ls</code> and <code>finger</code> requests.
Server failure	The name server found an internal inconsistency in its database and could not return a valid answer.
Refused	The name server refused to service the request.
Format error	The name server found that the request packet was not in the proper format. This may indicate an error in <code>nslookup</code> .

nctest(1M)

NAME	nstest – DNS test shell																								
SYNOPSIS	nstest [-d] [-i] [-r] [-v] [-p <i>port</i>] [<i>inet_addr</i> [<i>logfile</i>]]																								
DESCRIPTION	nstest is an interactive DNS test program. Queries are formed and sent by user command; any reply received is printed on the standard output. <i>inet_addr</i> is the Internet address of the DNS resolver to which nstest should send its queries. If <i>inet_addr</i> is not included, nstest first tries to contact a DNS server on the local host; if that fails, it tries the servers listed in the <code>/etc/resolv.conf</code> file. If a <i>logfile</i> is supplied, nstest uses it to log the queries sent and replies received.																								
OPTIONS	-d Causes nstest to create a file named <code>ns_packet.dump</code> (if it does not exist) and write into it a raw (binary) copy of each packet sent. If <code>ns_packet.dump</code> does exist, nstest will truncate it. -i Sets the <code>RES_IGNTC</code> flag on the queries it makes. See <code>resolver(3RESOLV)</code> for a description of the <code>RES_IGNTC</code> flag. -r Turns off the <code>RES_RECURSE</code> flag on the queries it makes. See <code>resolver(3RESOLV)</code> for a description of the <code>RES_RECURSE</code> flag. -v Turns on the <code>RES_USEVC</code> and <code>RES_STAYOPEN</code> flags on the <code>res_send()</code> calls made. See <code>resolver(3RESOLV)</code> for a description of the <code>RES_USEVC</code> and <code>RES_STAYOPEN</code> flags. -p Causes nstest to use the supplied <i>port</i> instead of the default name server port.																								
USAGE	When nstest starts, it prints a prompt (">") and waits for user input. DNS queries are formed by typing a <i>key letter</i> followed by the appropriate <i>argument</i>. Each <i>key letter</i> results in a call to <code>res_mkquery()</code> with <i>op</i> set to either <code>IQUERY</code> or <code>QUERY</code> and <i>type</i> set to one of the type values (defined in <code><arpa/nameser.h></code>). (Any other key letter than those listed below causes nstest to print a summary of the following table.) <table><tr><th colspan="3">Key Letter &</th></tr><tr><th>Argument</th><th>Op</th><th>Type</th></tr><tr><td><i>ahost</i></td><td>QUERY</td><td>T_A</td></tr><tr><td><i>Aaddr</i></td><td>IQUERY</td><td>T_A</td></tr><tr><td><i>Buser</i></td><td>QUERY</td><td>T_MG</td></tr><tr><td><i>buser</i></td><td>QUERY</td><td>T_MB</td></tr><tr><td><i>chost</i></td><td>QUERY</td><td>T_CNAME</td></tr><tr><td><i>fhost</i></td><td>QUERY</td><td>T_UINFO</td></tr></table>	Key Letter &			Argument	Op	Type	<i>ahost</i>	QUERY	T_A	<i>Aaddr</i>	IQUERY	T_A	<i>Buser</i>	QUERY	T_MG	<i>buser</i>	QUERY	T_MB	<i>chost</i>	QUERY	T_CNAME	<i>fhost</i>	QUERY	T_UINFO
Key Letter &																									
Argument	Op	Type																							
<i>ahost</i>	QUERY	T_A																							
<i>Aaddr</i>	IQUERY	T_A																							
<i>Buser</i>	QUERY	T_MG																							
<i>buser</i>	QUERY	T_MB																							
<i>chost</i>	QUERY	T_CNAME																							
<i>fhost</i>	QUERY	T_UINFO																							

<i>Ggid</i>	IQUERY	T_GID
<i>ghost</i>	QUERY	T_GID
<i>hhost</i>	QUERY	T_HINFO
<i>ihost</i>	QUERY	T_MINFO
<i>Mhost</i>	QUERY	T_MAILB
<i>mhost</i>	QUERY	T_MX
<i>nhost</i>	QUERY	T_NS
<i>phost</i>	QUERY	T_PTR
<i>rhost</i>	QUERY	T_MR
<i>shost</i>	QUERY	T_SOA
<i>Thost</i>	QUERY	T_TXT
<i>Uuid</i>	IQUERY	T_UID
<i>uhost</i>	QUERY	T_UID
<i>whost</i>	QUERY	T_WKS
<i>xhost</i>	QUERY	T_AXFR

After the query is successfully formed, `res_send()` is called to send it and wait for a reply. `nctest` then prints the following on the standard output:

- a summary of the request and reply packets, including the `HEADER` structure (defined in `<arpa/nameser.h>`) used in the request
- the question being asked of the name server
- an enumeration of the name server(s) being polled
- a summary of the `HEADER` structure received in the reply
- the question the name server answered
- the answer itself

EXAMPLES

EXAMPLE 1 Fetching the address of host `playground.sun.com` from the Sun name server.

To fetch the address of host `playground.sun.com` from the Sun name server, the user would enter:

```
$ nctest 192.9.5.1
> aplayground.sun.com
```

The utility `nctest` would return the following:

```
res_mkquery(0, playground.sun.com, 1, 1)
res_send()
HEADER:
```

nstest(1M)

EXAMPLE 1 Fetching the address of host playground.sun.com from the Sun name server. *(Continued)*

```
opcode = QUERY, id = 1, rcode = NOERROR
header flags:  rd
qdcount = 1, ancount = 0, nscount = 0, arcount = 0
```

QUESTIONS:

```
playground.sun.com, type = A, class = IN
```

Querying server (# 1) address = 192.9.5.1

got answer:

HEADER:

```
opcode = QUERY, id = 1, rcode = NOERROR
header flags:  qr aa rd ra
qdcount = 1, ancount = 1, nscount = 0, arcount = 0
```

QUESTIONS:

```
playground.sun.com, type = A, class = IN
```

ANSWERS:

```
playground.sun.com
type = A, class = IN, ttl = 1 day, dlen = 4
internet address = 192.9.5.5
```

EXAMPLE 2 Looking up a PTR record.

To look up a PTR record, enter:

```
$ nstest 192.9.5.1
```

```
> p5.5.9.192.in-addr.arpa
```

The utility nstest would return the following:

```
res_mkquery(0, 5.5.9.192.in-addr.arpa, 1, 12)
```

```
res_send()
```

HEADER:

```
opcode = QUERY, id = 2, rcode = NOERROR
header flags:  rd
qdcount = 1, ancount = 0, nscount = 0, arcount = 0
```

QUESTIONS:

```
5.5.9.192.in-addr.arpa, type = PTR, class = IN
```

Querying server (# 1) address = 192.9.5.1

got answer:

HEADER:

```
opcode = QUERY, id = 2, rcode = NOERROR
header flags:  qr aa rd ra
qdcount = 1, ancount = 1, nscount = 0, arcount = 0
```

QUESTIONS:

```
5.5.9.192.in-addr.arpa, type = PTR, class = IN
```

ANSWERS:

```
5.5.9.192.in-addr.arpa
type = PTR, class = IN, ttl = 7 hours 47 mins 2 secs, dlen = 23
domain name = playground.sun.com
```

EXAMPLE 2 Looking up a PTR record. (Continued)

nsupdate(1M)

NAME	nsupdate – update Internet name servers interactively
SYNOPSIS	nsupdate [-k <i>keydir:keyname</i>] [-d] [-v] [<i>filename</i>]
DESCRIPTION	The nsupdate program can be used to update Internet domain name servers that support dynamic update. nsupdate uses the DNS resolver library to pass messages to the DNS server requesting the addition or deletion of DNS resource records (RR's). nsupdate reads input from <i>filename</i> or from standard input.
OPTIONS	nsupdate supports the following options: -d Debug mode. -k Sign updates with Secret Key Transaction Authentication for DNS (TSIG). -v Virtual circuit. Make use of TCP to communicate with the server. The default is UDP.
USAGE	nsupdate reads input records, one per line. Each line contributes a resource record to an update request. All domain names used in a single update request must belong to the same DNS zone. Updates are sent to the master server as defined in the SOA MNAME field. A blank line causes the accumulated records to be formatted into a single update request and transmitted to the zone's authoritative name servers. Additional records may follow, which are formed into additional, but completely independent, update requests. End the input with a blank line in order to transmit the last request. Records take one of two general forms. Prerequisite records specify conditions that must be satisfied before the request will be processed. Update records specify changes to be made to the DNS database. An update request consists of zero or more prerequisites and one or more updates. Each update request is processed atomically. All prerequisites must be satisfied, then all updates will be performed. nsupdate understands the following input record formats: prereq nxdomain domain-name This format requires that no RR of any type exist with name <i>domain-name</i>. prereq yxdomain domain-name This format requires that at least one RR names <i>domain-name</i> must exist. prereq nxrrset domain-name [class] type This format requires that no RR exist of the specified type and <i>domain-name</i>. prereq yxrrset domain-name [class] type [data ...] This format requires that an RR exist of the specified type and <i>domain-name</i>. If data is specified, it must match exactly. update delete domain-name [class] [type [data ...]]

This format deletes RR's names *domain-name*. If *type* (and possibly *data*) are specified, only matching records will be deleted.

```
update add domain-name ttl [class] type data ...
```

This format adds a new RR of specified *ttl*, *type* and *data*.

EXAMPLES

EXAMPLE 1 Using nsupdate Interactively To Change an IP Address

The following example shows the interactive use of `nsupdate` to change an IP address. It deletes any existing A records for a domain name and then inserts a new address. Since no prerequisites are specified, the new record will be added even if there are no existing records to delete. A trailing blank line is required to process the request.

```
example$ nsupdate
>update delete test.example.com A
>update add test.example.com 3600 A 10.1.1.1
>
```

EXAMPLE 2 Using nsupdate Interactively to Add a CNAME (Alias)

In the following example, a CNAME (alias) is added to the database only if there are no existing A or CNAME records for the domain name.

```
example$ nsupdate
>prereq nxrrset www.example.com A
>prereq nxrrset www.example.com CNAME
>update add www.example.com 3600 CNAME test.test.com
>
```

EXAMPLE 3 Using nsupdate Interactively With a Key

In the following example, `nsupdate` is signed with the key `mykey`, which is located in the directory `/var/named/keys`.

```
example$ nsupdate -k /var/named/keys:mykey
>update add ftp.example.com 60 A 192.168.5.1
>
```

DIAGNOSTICS

`Qq send error`

This message typically indicates that authoritative name servers could not be reached.

`Qq failed update packet`

This message typically indicates that the name server has rejected the update. Either the name server does not support dynamic update, or there was an authentication failure.

`Qq res_mkupdate: packet size = size`

If this is the only message sent, it indicates that the update was received and authenticated by the name server. However, the prerequisites may have prevented the update from being performed. Use debug mode (the `-d` option) to examine the status field in the name server's reply and determine if the update was performed.

NAME	ntpd – set the date and time by way of NTP
SYNOPSIS	/usr/sbin/ntpd [-bBdoqsuv] [-a <i>key#</i>] [-e <i>authdelay</i>] [-k <i>keyfile</i>] [-m] [-o <i>version</i>] [-p <i>samples</i>] [-t <i>timeout</i>] [-w] <i>server...</i>
DESCRIPTION	The <code>ntpd</code> utility sets the local date and time. To determine the correct time, it polls the Network Time Protocol (NTP) servers on the hosts given as arguments. This utility must be run as root on the local host. It obtains a number of samples from each of the servers and applies the standard NTP clock filter and selection algorithms to select the best of these. The reliability and precision of <code>ntpd</code> improve dramatically with a greater number of servers. While a single server may be used, better performance and greater resistance to inaccuracy on the part of any one server can be obtained by providing at least three or four servers, if not more. The <code>ntpd</code> utility makes time adjustments in one of two ways. If it determines that your clock is off by more than 0.5 seconds it simply steps the time by calling <code>gettimeofday(3C)</code>. If the error is less than 0.5 seconds, by default, it slews the clock's time with the offset, by way of a call to <code>adjtime(2)</code>. The latter technique is less disruptive and more accurate when the offset is small; it works quite well when <code>ntpd</code> is run by <code>cron</code> every hour or two. The adjustment made in the latter case is actually 50% larger than the measured offset. This adjustment tends to keep a badly drifting clock more accurate, at some expense to stability. This tradeoff is usually advantageous. At boot time, however, it is usually better to step the time. This can be forced in all cases by specifying the <code>-b</code> option on the command line. The <code>ntpd</code> utility declines to set the date if an NTP server daemon like <code>xntpd(1M)</code> is running on the same host. It can be run on a regular basis from <code>cron(1M)</code> as an alternative to running a daemon. Doing so once every one to two hours results in precise enough timekeeping to avoid stepping the clock.
OPTIONS	The following options are supported: -a <i>key#</i> Authenticate transactions, using the key number, <i>key#</i>. -b Step the time by calling <code>gettimeofday(3C)</code>. -B Force the time to always be slewed using the <code>adjtime(2)</code> system call, even if the measured offset is greater than +128 ms. The default is to step the time using <code>settimeofday(3C)</code> if the offset is greater than +128 ms. If the offset is much greater than +128 ms in this case, that it can take a long time (hours) to slew the clock to the correct value. During this time the host should not be used to synchronize clients. -d Display what will be done without actually doing it. Information useful for general debugging is also printed. -e <i>authdelay</i> Specify an authentication processing delay, <i>authdelay</i> in seconds. See <code>xntpd(1M)</code> for details. This number is usually small enough to

ntpd(1M)

	be negligible for purposes of <code>ntpd</code> . However, specifying a value may improve timekeeping on very slow CPU's.
<code>-k keyfile</code>	Read keys from the file <i>keyfile</i> instead of the default file, <code>/etc/ntp.keys</code> . <i>keyfile</i> should be in the format described in <code>xntpd(1M)</code> .
<code>-m</code>	Join multicast group specified in <i>server</i> and synchronize to multicast NTP packets. The standard NTP group is 224.0.1.1.
<code>-o version</code>	Force the program to poll as a version 1 or version 2 implementation. By default <code>ntpd</code> claims to be an NTP version 3 implementation in its outgoing packets. However, some older software declines to respond to version 3 queries. This option can be used in these cases.
<code>-p samples</code>	Set the number of samples <code>ntpd</code> acquires from each server. <i>samples</i> can be between 1 and 8 inclusive. The default is 4.
<code>-q</code>	Query only. Do not set the clock.
<code>-s</code>	Log actions by way of the <code>syslog(3C)</code> facility rather than to the standard output — a useful option when running the program from <code>cron(1M)</code> .
<code>-t timeout</code>	Set the time <code>ntpd</code> spends, waiting for a response. <i>timeout</i> is rounded to a multiple of 0.2 seconds. The default is 1 second, a value suitable for polling across a LAN.
<code>-u</code>	Use an unprivileged port to send the packets from. This option is useful when you are behind a firewall that blocks incoming traffic to privileged ports, and you want to synchronize with hosts beyond the firewall. The <code>-d</code> option always uses unprivileged ports.
<code>-v</code>	Be verbose. This option causes <code>ntpd</code> 's version identification string to be logged.
<code>-w</code>	Wait until able to synchronize with a server. When the <code>-w</code> option is used together with <code>-m</code> , <code>ntpd</code> waits until able to join the group and synchronize.

FILES `/etc/inet/ntp.keys` Contains the encryption keys used by `ntpd`.

NOTES The technique of compensating for clock oscillator errors to improve accuracy is inadequate. However, to further improve accuracy would require the program to save *state* from previous runs.

ntpq(1M)

NAME	ntpq – standard Network Time Protocol query program								
SYNOPSIS	/usr/sbin/ntpq [-inp] [-c <i>command</i>] [<i>host</i>] [...]								
DESCRIPTION	ntpq queries NTP servers which implement the recommended NTP mode 6 control message format, about current state. It can also request changes in that state. The program can be run in interactive mode; or it can be controlled using command line arguments. Requests to read and write arbitrary variables can be assembled, with raw and pretty-printed output options available. By sending multiple queries to the server, ntpq can also obtain and print a list of peers in a common format. If one or more request options are included on the command line, ntpq sends each of the requests to NTP servers running on each of the hosts given as command line arguments. By default, ntpq sends its requests to localhost, if hosts are not included on the command line. If no request options are given, ntpq attempts to read commands from the standard input and execute them on the NTP server running on the first host given on the command line. Again, ntpq defaults to localhost if no other host is specified. ntpq uses NTP mode 6 packets to communicate with an NTP server. Thus, it can be used to query any compatible server on the network that permits queries. Since NTP is a UDP protocol, this communication will be somewhat unreliable, especially over large distances. ntpq makes one attempt to retransmit requests; requests timeout if the remote host is not heard from within a suitable period.								
OPTIONS	Command line options are described below. Specifying a command line option other than -i or -n causes the specified query (queries) to be sent, immediately to the indicated host(s). Otherwise, ntpq attempts to read interactive format commands from standard input. <table><tr><td>-c</td><td>Interpret the next argument as an interactive format command and add it to the list of commands to be executed on the specified host(s). Multiple -c options may be given.</td></tr><tr><td>-i</td><td>Operate in interactive mode; write prompts to standard output and read commands from standard input.</td></tr><tr><td>-n</td><td>Output all host addresses in dotted-quad numeric format rather than converting them to canonical host names.</td></tr><tr><td>-p</td><td>Print a list of the peers known to the server as well as a summary of their state. This is equivalent to the peers interactive command. See USAGE below.</td></tr></table>	-c	Interpret the next argument as an interactive format command and add it to the list of commands to be executed on the specified host(s). Multiple -c options may be given.	-i	Operate in interactive mode; write prompts to standard output and read commands from standard input.	-n	Output all host addresses in dotted-quad numeric format rather than converting them to canonical host names.	-p	Print a list of the peers known to the server as well as a summary of their state. This is equivalent to the peers interactive command. See USAGE below.
-c	Interpret the next argument as an interactive format command and add it to the list of commands to be executed on the specified host(s). Multiple -c options may be given.								
-i	Operate in interactive mode; write prompts to standard output and read commands from standard input.								
-n	Output all host addresses in dotted-quad numeric format rather than converting them to canonical host names.								
-p	Print a list of the peers known to the server as well as a summary of their state. This is equivalent to the peers interactive command. See USAGE below.								
USAGE	Interactive format commands consist of a keyword followed by up to four arguments. Only enough characters of the full keyword to uniquely identify the command need be typed. Normally, the output of a command is sent to standard output; but this output may be written to a file by appending a '>', followed by a file name, to the command line.								

**Interactive
Commands**

A number of interactive format commands are executed entirely within the ntpq program itself. They do not result in NTP mode 6 requests being sent to a server. If no request options are included on the command line, and if the standard input is a terminal device, ntpq prompts for these commands. The interactive commands are described below:

? [*command_keyword*]

A '?' by itself prints a list of all the command keywords known to the current version of ntpq. A '?' followed by a command keyword prints function and usage information about the command.

timeout *milliseconds*

Specifies a time out period for responses to server queries. The default is about 5000 milliseconds. Since ntpq retries each query once after a time out, the total waiting time for a time out is twice the time out value that is set.

delay *milliseconds*

Specifies a time interval to be added to timestamps included in requests which require authentication. This command is used to enable (unreliable) server reconfiguration over long delay network paths or between machines whose clocks are unsynchronized. Currently, the server does not require time stamps in authenticated requests. Thus, this command may be obsolete.

host *hostname*

Set the name of the host to which future queries are to be sent. *Hostname* may be either a host name or a numeric address.

keyid #

Specify of a key number to be used to authenticate configuration requests. This number must correspond to a key number the server has been configured to use for this purpose.

passwd

Prompts the user to type in a password which will be used to authenticate configuration requests. If an authenticating key has been specified (see *keyid* above), this password must correspond to this key. ntpq does not echo the password as it is typed.

hostnames *yes* | *no*

If "yes" is specified, host names are printed in information displays. If "no" is given, numeric addresses are printed instead. The default is "yes" unless modified using the command line -n switch.

raw

Print all output from query commands exactly as it is received from the remote server. The only formatting/filtering done on the data is to transform non- ASCII data into printable form.

ntpq(1M)

`cooked`

Causes output from query commands to be “cooked”. The values of variables recognized by the server are reformatted, so that they can be more easily read. Variables which `ntpq` thinks should have a decodable value, but do not, are marked with a trailing ‘?’.

`ntpversion [ 1 | 2 | 3 ]`

Sets the NTP version number which `ntpq` claims in packets (defaults is 3). Note that mode 6 control messages (and modes, for that matter) did not exist in NTP version 1. There appear to be no servers left which demand version 1.

`authenticate [ yes | no ]`

The command `authenticate yes` instructs `ntpq` to send authentication with all requests it makes. Normally `ntpq` does not authenticate requests unless they are write requests. Authenticated requests cause some servers to handle requests slightly differently, and can occasionally cause a slowed response if you turn authentication on before doing a peer display. `addvars variable_name[=value] [ , ... ] rmvars variable_name [ , ... ] clearvars`

The data carried by NTP mode 6 messages consists of a list of items of the form `variable_name=value` where the “=value” is ignored, and can be omitted, in requests to the server to read variables. `ntpq` maintains an internal list in which data to be included in control messages can be assembled, and sent. This is accomplished with the `readlist` and `writelist` commands described below. The `addvars` command allows variables and their optional values to be added to the list. If more than one variable is to be added, the list should be comma-separated, and it should not contain white space. The `rmvars` command can be used to remove individual variables from the list; the `clearlist` command removes all variables from the list.

`debug [ more | less | off ]`

Turns internal query program debugging on and off.

`quit`

Exit `ntpq`.

Control Message Commands

Each peer known to an NTP server has a 16 bit integer *association identifier* assigned to it. NTP control messages which carry peer variables must identify the peer that the values correspond to, by including its association ID. An association ID of 0 is special. It indicates the variables are system variables, whose names are drawn from a separate name space.

Control message commands send one or more NTP mode 6 messages to the server, and cause the data returned to be printed in some format. Most commands currently implemented send a single message and expect a single response. The current exceptions are the peers `mreadlist` and `mreadvar` commands. The `peers` command sends a preprogrammed series of messages to obtain the data it needs. The `mreadlist` and `mreadvar` commands, iterate over a range of associations.

Control message commands are described below:

`associations`

Obtains and prints a list of association identifiers and peer statuses for in-spec peers of the server being queried. The list is printed in columns. The first of these is an index that numbers the associations from 1, for internal use. The second column contains the actual association identifier returned by the server and the third the status word for the peer. This is followed by a number of columns containing data decoded from the status word. Note that the data returned by the `associations` command is cached internally in `ntpq`. The index is then of use when dealing with “dumb” servers which use association identifiers that are hard for humans to type. For any subsequent commands which require an association identifier as an argument, the identifier can be specified by using the form, *&index*. Here *index* is taken from the previous list.

`lassociations`

Obtains and prints a list of association identifiers and peer statuses for all associations for which the server is maintaining *state*. This command differs from the `associations` command only for servers which retain *state* for out-of-spec client associations. Such associations are normally omitted from the display when the `associations` command is used, but are included in the output of `lassociations`.

`passociations`

Prints association data concerning in-spec peers from the internally cached list of associations. This command performs identically to the `associations` command except that it displays the internally stored data rather than making a new query.

`lpassociations`

Print data for all associations, including out-of-spec client associations, from the internally cached list of associations. This command differs from `passociations` only when dealing with servers which retain *state* for out-of-spec client associations.

`pstatus assocID`

Sends a read status request to the server for the given association. The names and values of the peer variables returned will be printed. Note that the status word from the header is displayed preceding the variables, both in hexadecimal and in pigeon English.

`readvar [ assoc ] [ variable_name[=value] [ , . . . ] ]`

Requests that the values of the specified variables be returned by the server by sending a read variables request. If the association ID is omitted or is given as zero the variables are system variables, otherwise they are peer variables and the values returned will be those of the corresponding peer. Omitting the variable list will send a request with no data which should induce the server to return a default display.

`rv [ assocID ] [ variable_name[=value] [ , . . . ] ]`

An easy-to-type short form for the `readvar` command.

`writevar assocID variable_name=value [ ,... ]`
 Like the `readvar` request, except the specified variables are written instead of read.

`readlist [ assocID ]`
 Requests that the values of the variables in the internal variable list be returned by the server. If the association ID is omitted or is 0 the variables are assumed to be system variables. Otherwise they are treated as peer variables. If the internal variable list is empty a request is sent without data, which should induce the remote server to return a default display.

`rl [ assocID ]`
 An easy-to-type short form of the `readlist` command.

`writelist [ assocID ]`
 Like the `readlist` request, except the internal list variables are written instead of read.

`mreadvar assocID assocID [ variable_name[=value] [ ,... ] ]`
 Like the `readvar` command except the query is done for each of a range of (nonzero) association IDs. This range is determined from the association list cached by the most recent `associations` command.

`mrvar assocID assocID [ variable_name[=value] [ ,... ] ]`
 An easy-to-type short form of the `mreadvar` command.

`mreadlist assocID assocID`
 Like the `readlist` command except the query is done for each of a range of (nonzero) association IDs. This range is determined from the association list cached by the most recent `associations` command.

`mrl assocID assocID`
 An easy-to-type short form of the `mreadlist` command.

`clockvar [ assocID ] [ variable_name[=value] [ ,... ] ]`
 Requests that a list of the server's clock variables be sent. Servers which have a radio clock or other external synchronization respond positively to this. If the association identifier is omitted or zero the request is for the variables of the "system clock". This request generally gets a positive response from all servers with a clock. Some servers may treat clocks as pseudo-peers and, hence, can possibly have more than one clock connected at once. For these servers, referencing the appropriate peer association ID shows the variables of a particular clock. Omitting the variable list causes the server to return a default variable display.

`cv [ assocID ] [ variable_name[=value] [ ,... ] ]`
 An easy-to-type short form of the `clockvar` command.

`peers`
 Obtains a list of in-spec peers of the server, along with a summary of each peer's state. Summary information includes:

- The address of the remote peer
- The reference ID (0.0.0.0 if the ref ID is unknown)

- The stratum of the remote peer
- The type of the peer (local, unicast, multicast or broadcast) when the last packet was received
- The polling interval in seconds
- The reachability register, in octal
- The current estimated delay offset and dispersion of the peer, all in milliseconds.

The character in the left margin indicates the fate of this peer in the clock selection process. The codes mean:

SPACE	Discarded due to high stratum and/or failed sanity checks.
x	Designated falsticker by the intersection algorithm.
.	Culled from the end of the candidate list.
–	Discarded by the clustering algorithm.
+	Included in the final selection set.
#	Selected for synchronization; but distance exceeds maximum.
*	Selected for synchronization.
o	Selected for synchronization, pps signal in use.

Since the `peers` command depends on the ability to parse the values in the responses it gets, it may fail to work from time to time with servers which poorly control the data formats.

The contents of the host field may be given in one of four forms. It may be a host name, an IP address, a reference clock implementation name with its parameter or, `REFCLK(implementation number, parameter)`. On “hostnames no” only IP-addresses will be displayed.

lpeers

Like `peers`, except a summary of all associations for which the server is maintaining state is printed. This can produce a much longer list of peers from inadequate servers.

opeers

An old form of the `peers` command with the reference ID replaced by the local interface address.

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWntpu

SEE ALSO `attributes(5)`

ntpq(1M)

BUGS	The <code>peers</code> command is non-atomic. It may occasionally result in spurious error messages about invalid associations occurring and terminating the command. The timeout value is a fixed constant. As a result, it often waits a long time to timeout, since the fixed value assumes sort of a worst case. The program should improve the time out estimate as it sends queries to a particular host; but it does not.

NAME	ntptrace – trace a chain of NTP hosts back to their master time source				
SYNOPSIS	/usr/sbin/ntptrace [-vdm] [-r <i>retries</i>] [-t <i>timeout</i>] [<i>server</i>]				
DESCRIPTION	ntptrace determines where a given Network Time Protocol (NTP) server gets its time from, and follows the chain of NTP servers back to their master time source. If given no arguments, it starts with <i>localhost</i> .				
OPTIONS	The following options are supported: -d Turns on some debugging output. -n Turns off the printing of host names; instead, host IP addresses are given. This may be necessary if a nameserver is down. -r <i>retries</i> Sets the number of retransmission attempts for each host. -t <i>timeout</i> Sets the retransmission timeout (in seconds); default = 2. -v Prints verbose information about the NTP servers.				
EXAMPLES	EXAMPLE 1 Sample Output From the ntptrace Command The following example shows the output from the ntptrace command: <pre>% ntptrace localhost: stratum 4, offset 0.0019529, synch distance 0.144135 server2.bozo.com: stratum 2, offset 0.0124263, synch distance 0.115784 usndh.edu: stratum 1, offset 0.0019298, synch distance 0.011993, refid 'WWVB'</pre> On each line, the fields are (left to right): ■ The server's host name ■ The server's stratum ■ The time offset between that server and the local host (as measured by ntptrace; this is why it is not always zero for <i>localhost</i>) ■ The host's synchronization distance ■ The reference clock ID (only for stratum-1 servers) All times are given in seconds. Synchronization distance is a measure of the goodness of the clock's time.

BUGS	This program makes no attempt to improve accuracy by doing multiple samples.

NAME	obpsym – Kernel Symbolic Debugging for OpenBoot Firmware
SYNOPSIS	modload -p misc/obpsym
DESCRIPTION	obpsym is a kernel module that installs OpenBoot callback handlers that provide kernel symbol information to OpenBoot. OpenBoot firmware user interface commands use the callbacks to convert numeric <i>addresses</i> to kernel symbol names for display purposes, and to convert kernel symbol names to numeric <i>literals</i> allowing symbolic names to be used as input arguments to user interface commands. Once obpsym is installed, kernel symbolic names may be used anywhere at the OpenBoot firmware's user interface command prompt in place of a literal (numeric) string. For example, if obpsym is installed, the OpenBoot firmware commands <i>ctrace</i> and <i>dis</i> typically display symbolic names and offsets in the form <i>modname:symbolname + offset</i>. User interface Commands such as <i>dis</i> can be given a kernel symbolic name such as <i>ufs:ufs_mount</i> instead of a numeric address. Placing the command <pre>forceload: misc/obpsym</pre> into the <i>system(4)</i> file forces the kernel module <i>misc/obpsym</i> to be loaded and activates the kernel callbacks during the kernel startup sequence. obpsym may be useful as a kernel debugger in situations where other kernel debuggers are not useful. For example, on SPARC machines, if obpsym is loaded, you may be able to use the OpenBoot firmware's <i>ctrace</i> command to display symbolic names in the stack backtrace after a watchdog reset. The syntax for a kernel symbolic name is: <pre>[<i>module-name</i> :] <i>symbol-name</i></pre> Where <i>module-name</i> is the name of the kernel module that the symbol <i>symbol-name</i> appears in. A NULL module name is taken as "all modules, in no particular order" by obpsym. The module name <i>unix</i> is equivalent to a NULL module name, so that conflicts with words defined in the firmware's vocabulary can be avoided. Typically, OpenBoot firmware reads a word from the input stream and looks the word up in its internal <i>vocabulary</i> before checking if the word is a <i>literal</i>. Thus, kernel symbols, such as <i>reset</i> may be given as <i>unix:reset</i> to avoid the unexpected side effect of the firmware finding and executing a matching word in its vocabulary.
Kernel Symbolic Name Syntax

OpenBoot 2.x Command Reference Manual

WARNINGS

Some OpenBoot firmware user interface commands may use system resources incompatibly with the way they are used by the Unix kernel. These commands and the use of this feature as a kernel debugger may cause interactions that the Unix kernel is not prepared to deal with. If this occurs, the Unix kernel and/or the OpenBoot firmware user interface commands may react unpredictably and may panic the system, or may hang or may cause other unpredictable results. For these reasons, the use of this feature is only minimally supported and recommended to be used only as a kernel debugger of "last resort".

If a breakpoint or watchpoint is triggered while the console frame buffer is powered off, the system can crash and be left in a state from which it is difficult to recover. If one of these is triggered while the monitor is powered off, you will not be able to see the debugger output.

NOTES

platform-name can be found using the `-i` option of `uname(1)`

obpsym is supported only on architectures that support OpenBoot firmware.

On some systems, OpenBoot must be completely RAM resident so the obpsym symbol callback support can be added to the firmware, if the firmware doesn't include support for the symbol callbacks. On these systems, obpsym may complain that it requires that "you must use ramforth to use this module".

See the *OpenBoot 2.x Command Reference Manual* for details on how to use the *ramforth* command, how to place the command into *nvrामrc*, and how to set *use-nvrामrc?* to `true`. On systems with version 1.x OpenBoot firmware, *nvrामrc* doesn't exist, and the *ramforth* command must be typed manually after each reset, in order to use this module.

Once installed, the symbol table callbacks can be disabled by using the following OpenBoot firmware command:

```
0 0 set-symbol-lookup
```

NAME	ocfserv – OCF server				
SYNOPSIS	ocfserv [-D] [-p <i>path</i>]				
DESCRIPTION	The OCF server, <i>ocfserv</i>, is a per-host daemon that acts as the central point of communications with all smartcards connected to the host. Applications that need to use a smartcard can do so by using the APIs in <i>libsmartcard.so</i> or <i>smartcard.jar</i>. The internal implementation of these APIs communicates with <i>ocfserv</i> to perform the requested function. <i>inetd</i>(1M) automatically starts the <i>ocfserv</i> command when it is needed. Once started, <i>ocfserv</i> runs forever. If <i>ocfserv</i> is killed or crashes, it restarts automatically if necessary. Because <i>ocfserv</i> is run automatically, there really is not a reason to run it by manually. You must have root privileges to execute this utility.				
OPTIONS	The following options are supported: -D Run <i>ocfserv</i> in debug mode. -p <i>path</i> Specify property file name.				
EXIT STATUS	The following exit values are returned: 0 Successful completion. >0 An error occurred.				
FILES	/etc/smartcard/opencard.properties File where server stores properties				
ATTRIBUTES	See <i>attributes</i>(5) for descriptions of the following attributes: <table border="1"> <thead> <tr> <th>ATTRIBUTE TYPE</th><th>ATTRIBUTE VALUE</th></tr> </thead> <tbody> <tr> <td>Availability</td><td>SUNWocf</td></tr> </tbody> </table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	Availability	SUNWocf
ATTRIBUTE TYPE	ATTRIBUTE VALUE				
Availability	SUNWocf				
SEE ALSO	<i>inetd</i> (1M), <i>smartcard</i> (1M), <i>attributes</i> (5), <i>smartcard</i> (5)				

parse_dynamic_clustertoc(1M)

NAME	parse_dynamic_clustertoc – parse clustertoc file based on dynamic entries				
SYNOPSIS	<code>cdrom/export/exec/sparc.Solaris_2.x/sbin/install.d/parse_dynamic_clustertoc</code> <code>cdrom/export/exec/i386.Solaris_2.x/sbin/install.d/parse_dynamic_clustertoc</code>				
DESCRIPTION	This script parses the <code>clustertoc</code> file before the <code>suninstall(1M)</code> process is run. <code>parse_dynamic_clustertoc</code> is called by a modified <code>sysconfig</code> script on the install CD. When <code>parse_dynamic_clustertoc</code> runs, it reads the <code>clustertoc</code> and when it encounters <code>SUNW_CSRMBRIFF</code> lines, it either checks the platform using the script's builtin function, or calls an external script. The script exits with a 0 if the cluster entry is included, otherwise it will be ignored. If the cluster entry is to be included, the <code>SUNW_CSRMBRIFF = (test test_arg) cluster</code> line is converted to <code>SUNW_CSRMEMBER =cluster</code>.				
EXAMPLES	EXAMPLE 1 Checking For an SX Framebuffer The following is an example of a simple external test to check for an SX Framebuffer. The entry in the <code>clustertoc</code> file is shown and following that is the script that must be placed in the <code>install.d/dynamic_test</code> directory. <pre>SUNW_CSRMBRIFF=(smcc.dctoc sx)SUNWCsx #!/bin/sh # # Likewise, this file is expected to live under \$(TESTDIR). # case "\$1" in sx) prtconf -p grep 'SUNW,sx' 1> /dev/null;; esac</pre>				
FILES	<code>cdrom/Solaris_2.x/locale/C/.clustertoc.dynamic</code> Dynamic version of the <code>clustertoc</code> file <code>cdrom/export/exec/sparc.Solaris_2.x/sbin/install.d/dynamic_test</code> Directory that contains any additional tests <code>cdrom/export/exec/i386.Solaris_2.x/sbin/install.d/dynamic_test</code> Directory that contains any additional tests				
ATTRIBUTES	See <code>attributes(5)</code> for descriptions of the following attributes: <table><thead><tr><th>ATTRIBUTE TYPE</th><th>ATTRIBUTE VALUE</th></tr></thead><tbody><tr><td>Availability</td><td>SHWPCdrom (Solaris CD)</td></tr></tbody></table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	Availability	SHWPCdrom (Solaris CD)
ATTRIBUTE TYPE	ATTRIBUTE VALUE				
Availability	SHWPCdrom (Solaris CD)				
SEE ALSO	<code>suninstall(1M)</code> , <code>clustertoc(4)</code> , <code>attributes(5)</code>				

NAME	passmgmt – password files management	
SYNOPSIS	passmgmt -a <i>options name</i> passmgmt -m <i>options name</i> passmgmt -d <i>name</i>	
DESCRIPTION	The passmgmt command updates information in the password files. This command works with both <code>/etc/passwd</code> and <code>/etc/shadow</code>. passmgmt -a adds an entry for user <i>name</i> to the password files. This command does not create any directory for the new user and the new login remains locked (with the string <code>*LK*</code> in the password field) until the <code>passwd(1)</code> command is executed to set the password. passmgmt -m modifies the entry for user <i>name</i> in the password files. The name field in the <code>/etc/shadow</code> entry and all the fields (except the password field) in the <code>/etc/passwd</code> entry can be modified by this command. Only fields entered on the command line will be modified. passmgmt -d deletes the entry for user <i>name</i> from the password files. It will not remove any files that the user owns on the system; they must be removed manually. passmgmt can be used only by the super-user.	
OPTIONS	-c <i>comment</i> A short description of the login, enclosed in quotes. It is limited to a maximum of 128 characters and defaults to an empty field. -h <i>homedir</i> Home directory of <i>name</i>. It is limited to a maximum of 256 characters and defaults to <code>/usr/name</code>. -u <i>uid</i> UID of the <i>name</i>. This number must range from 0 to the maximum non-negative value for the system. It defaults to the next available UID greater than 99. Without the -o option, it enforces the uniqueness of a UID. -o This option allows a UID to be non-unique. It is used only with the -u option. -g <i>gid</i> GID of <i>name</i>. This number must range from 0 to the maximum non-negative value for the system. The default is 1. -s <i>shell</i> Login shell for <i>name</i>. It should be the full pathname of the program that will be executed when the user logs in. The maximum size of <i>shell</i> is 256 characters. The default is for this field to be empty and to be interpreted as <code>/usr/bin/sh</code>. -l <i>logname</i> This option changes the <i>name</i> to <i>logname</i>. It is used only with the -m option. The total size of each login entry is limited to a maximum of 511 bytes in each of the password files.	
FILES	<code>/etc/passwd</code> <code>/etc/shadow</code>	

passmgmt(1M)

/etc/opasswd
/etc/oshadow

ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

SEE ALSO

`passwd(1)`, `useradd(1M)`, `userdel(1M)`, `usermod(1M)`, `passwd(4)`, `shadow(4)`, `attributes(5)`

EXIT STATUS

The `passmgmt` command exits with one of the following values:

0	Success.
1	Permission denied.
2	Invalid command syntax. Usage message of the <code>passmgmt</code> command is displayed.
3	Invalid argument provided to option.
4	UID in use.
5	Inconsistent password files (for example, <i>name</i> is in the <code>/etc/passwd</code> file and not in the <code>/etc/shadow</code> file, or vice versa).
6	Unexpected failure. Password files unchanged.
7	Unexpected failure. Password file(s) missing.
8	Password file(s) busy. Try again later.
9	<i>name</i> does not exist (if <code>-m</code> or <code>-d</code> is specified), already exists (if <code>-a</code> is specified), or <code>logname</code> already exists (if <code>-m -l</code> is specified).

NOTES

Do not use a colon (:) or RETURN as part of an argument. It is interpreted as a field separator in the password file. The `passmgmt` command will be removed in a future release. Its functionality has been replaced and enhanced by `useradd`, `userdel`, and `usermod`. These commands are currently available.

This command only modifies password definitions in the local `/etc/passwd` and `/etc/shadow` files. If a network nameservice such as NIS or NIS+ is being used to supplement the local files with additional entries, `passmgmt` cannot change information supplied by the network nameservice.

NAME	patchadd – apply a patch package to a system running the Solaris operating environment
SYNOPSIS	<pre> patchadd [-d] [-u] [-B <i>backout_dir</i>] [-C <i>net_install_image</i>] [-R <i>client_root_path</i> -S <i>service</i>] <i>patch</i> patchadd [-d] [-u] [-B <i>backout_dir</i>] [-C <i>net_install_image</i>] [-R <i>client_root_path</i> -S <i>service</i>] -M <i>patch_dir</i> <i>patch_id...</i> <i>patch_dir</i><i>patch_list</i> patchadd [-C <i>net_install_image</i>] [-R <i>client_root_path</i>] [-S <i>service</i>] -p </pre>
DESCRIPTION	patchadd applies a patch package to a system running the Solaris 2.x operating environment or later Solaris environments (such as Solaris 8) that are compatible with Solaris 2.x. This patch installation utility cannot be used to apply Solaris 1 patches. patchadd must be run as root. There are three forms of the patchadd command. The first form of patchadd installs <i>one</i> patch to a system, client, service, or the mini root of a Net Install Image. The second form of patchadd installs <i>more than one</i> patch to a system, client, service, or the mini root of a Net Install Image. The third form of patchadd <i>displays</i> installed patches on the client, service, or the mini root of a Net Install Image.
OPTIONS	The following options are supported: -B <i>backout_dir</i> Saves backout data to a directory other than the package database. Specify <i>backout_dir</i> as an absolute path name. -C <i>net_install_image</i> Patches the files located on the mini root on a Net Install Image created by <i>setup_install_server</i>. Specify <i>net_install_image</i> as the absolute path name to a Solaris 2.6 or compatible version boot directory. See EXAMPLES. -d Does not back up the files to be patched. <i>The patch cannot be removed.</i> -M <i>patch_dir patch_id ... patch_dir patch_list</i> Specifies the patches to be installed. Specify patches to the -M option in one of the following ways: 1. By directory location <i>and</i> patch number. To use the directory location and patch number, specify <i>patch_dir</i> as the absolute path name of the directory that contains spooled patches. Specify <i>patch_id</i> as the patch number of a given patch. Specifying multiple <i>patch_id</i>'s is recommended. 2. By directory location <i>and</i> the name of a file containing a patch list.

patchadd(1M)

To use the directory location and a file containing a patch list, specify *patch_dir* as the absolute path name of the directory containing the file with a list of patches to be installed. Specify *patch_list* as the name of the file containing the patches to be installed.

-p

Displays a list of the patches currently applied.

-R *client_root_path*

Locates all patch files generated by patchadd under the directory *client_root_path*. *client_root_path* is the directory that contains the bootable root of a client from the server's perspective. Specify *client_root_path* as the absolute path name to the beginning of the directory tree under which all patch files generated by patchadd are to be located. -R cannot be specified with the -S option. See NOTES.

-S *service*

Specifies an alternate service (for example, Solaris_2.3). This service is part of the server and client model, and can only be used from the server's console. Servers can contain shared /usr file systems that are created by Host Manager. These service areas can then be made available to the clients they serve. -S cannot be specified with the -R option. See NOTES.

-u

Turns off file validation. Applies the patch even if some of the files to be patched have been modified since their original installation.

OPERANDS The following operands are supported:

<i>patch</i>	The absolute path name to <i>patch_id</i> . /var/sadm/spool/patch/104945-02 is an example of a patch.
<i>patch_dir</i>	The absolute path name to the directory that contains all the spooled patches. /var/sadm/spool/patch is an example of a <i>patch_dir</i> .
<i>patch_id</i>	The patch number of a given patch. 104945-02 is an example of a <i>patch_id</i> .
<i>patch_list</i>	The name of a file that contains a list of patches to install. <i>patch_list</i> files contain one <i>patch_id</i> on each line.

EXAMPLES The examples in this section are all relative to the /usr/sbin directory.

EXAMPLE 1 Installing a Patch to a Standalone Machine

The following example installs a patch to a standalone machine:

```
example# patchadd /var/spool/patch/104945-02
```

EXAMPLE 1 Installing a Patch to a Standalone Machine *(Continued)***EXAMPLE 2** Installing a Patch to a Client From the Server's Console

The following example installs a patch to a client from the server's console:

```
example# patchadd -R /export/root/client1 /var/spool/patch/104945-02
```

EXAMPLE 3 Installing a Patch to a Service From the Server's Console

The following example installs a patch to a service from the server's console:

```
example# patchadd -S Solaris_2.3 /var/spool/patch/104945-02
```

EXAMPLE 4 Installing Multiple Patches in a Single Invocation of patchadd

The following example installs multiple patches in a single patchadd invocation:

```
example# patchadd -M /var/spool/patch 104945-02 104946-02 102345-02
```

EXAMPLE 5 Installing Multiple Patches Specifying a File with the List of Patches to Install

The following example installs multiple patches specifying a file with the list of patches to install:

```
example# patchadd -M /var/spool/patch patchlist
```

EXAMPLE 6 Installing Multiple Patches to a Client and Saving the Backout Data to a Directory Other Than the Default

The following example installs multiple patches to a client and saves the backout data to a directory other than the default:

```
example# patchadd -M /var/spool/patch -R /export/root/client1
          -B /export/backoutrepository 104945-02 104946-02 102345-02
```

EXAMPLE 7 Installing a Patch to a Solaris 2.6 or Compatible Version Net Install Image

The following example installs a patch to a Solaris 2.6 or compatible version Net Install Image:

```
example# patchadd -C /export/Solaris_2.6/Tools/Boot
          /var/spool/patch/104945-02
```

EXAMPLE 8 Displaying the Patches Installed on a Client

The following example displays the patches installed on a client:

```
example# patchadd -R /export/root/client1 -p
```

EXIT STATUS

The following exit values are returned:

patchadd(1M)

0 Successful completion.
>0 An error occurred.

ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWswmt, SUNWcsu

DIAGNOSTICS

The following messages may help in determining some of the most common problems associated with installing a patch.

Patch Installation errors

Message

```
The prepatch script exited with return code retcode.
patchadd is terminating.
```

Explanation and Recommended Action

The prepatch script supplied with the patch exited with a return code other than 0. Run a script trace of the prepatch script and find out why the prepatch had a bad return code. Add the `-x` option to the first line of the prepatch script to fix the problem and run `patchadd` again.

Message

```
The postpatch script exited with return code retcode.
Backing out patch.
```

Explanation and Recommended Action

The postpatch script provided with the patch exited with an error code other than 0. This script is mostly used to cleanup files (that is, when a package is known to have ownership or permission problems) attributes that don't correspond to the patch package's objects. After the user has noted all validation errors and taken the appropriate action for each one, the user should re-run `patchadd` using the `-u` (unconditional) option. This time, the patch installation will ignore validation errors and install the patch anyway.

Message

```
Insufficient space in /var/sadm/patch to save old files.
(For 2.4 systems and previous)
```

Explanation and Recommended Action

There is insufficient space in the `/var/sadm/patch` directory to save old files. The user has three options for handling this problem: Use the `-B` option while invoking `patchadd`. This option will direct `patchadd` to: save the backout data to the user specified file system, generate additional disk space by deleting unneeded files, or override the saving of the old files by using the `-d` (do not save) option when running `patchadd`.

If the user elects not to save the old versions of the files to be patched, `patchrm` cannot be used. One way to regain space on a system is to remove the save area for previously applied patches. Once the user has decided that it is unlikely that a patch will be backed out, the user can remove the files that were saved by `patchadd`. The following commands should be executed to remove the saved files for patch `patch_id`:

```
cd /var/sadm/patch/patch_id
rm -r save/*
rm .oldfilessaved
```

After these commands have been executed, patch `patch_id` can no longer be backed out.

Message

```
Insufficient space in /var/sadm/pkg/PKG/save to save old files.
(For 2.5 systems and later)
```

Explanation and Recommended Action

There is insufficient space in the `/var/sadm/pkg/PKG/save` directory to save old files. The user has three options for handling this problem: (1) Use the `-B` option while invoking `patchadd`. This option will direct `patchadd` to save the backout data to the user specified file system. (See above synopsis) (2) Generate additional disk space by deleting unneeded files, or (3) override the saving of the old files by using the `-d` (do not save) option when running `patchadd`.

However if the user elects not to save the old versions of the files to be patched, `patchrm` cannot be used. One way to regain space on a system is to remove the save area for previously applied patches. Once the user has decided that it is unlikely that a patch will be backed out, the user can remove the files that were saved by `patchadd`. The following commands should be executed to remove the saved files for patch `patch_id`:

```
cd /var/sadm/pkg/pkgabbrev/save
rm -r patch_id
```

After these commands have been executed, patch `patch_id` can no longer be backed out.

Message

```
Save of old files failed.
(For 2.4 systems and previous)
```

Explanation and Recommended Action

Before applying the patch, the patch installation script uses `cpio` to save the old versions of the files to be patched. This error message means that the `cpio` failed. The output of the `cpio` would have been preceded this message. The user should take the appropriate action to correct the `cpio` failure. A common reason for failure will be insufficient disk space to save the old versions of the files. The user has two options for handling insufficient disk space: (1) generate additional disk space by deleting unneeded files, or (2) override the saving of the old files by using the `-d` option when running `patchadd`. However if the user elects not to save the old versions of the files to be patched, the patch cannot be backed out.

patchadd(1M)

Message

```
Pkgadd of pkgname package failed with error code code.  
See /tmp/log.patch_id for reason for failure.
```

Explanation and Recommended Action

The installation of one of the patch packages failed. `patchadd` will backout the patch to leave the system in its pre-patched state. See the log file for the reason for failure. Correct the problem and reapply the patch.

Message

```
Pkgadd of pkgname package failed with error code code.  
Will not backout patch...patch re-installation.  
Warning: The system may be in an unstable state!  
See /tmp/log.patch_id for reason for failure.
```

Explanation and Recommended Action

The installation of one of the patch packages failed. `patchadd` will *not* backout the patch. You may manually backout the patch using `patchrm`, then re-apply the entire patch. Look in the log file for the reason `pkgadd` failed. Correct the problem and re-apply the patch.

Message

```
patchadd is unable to find the INST_RELEASE file. This file  
must be present for patchadd to function correctly.
```

Explanation and Recommended Action

The `INST_RELEASE` file is missing from the system. This file is created during either initial installation or during an update.

Message

```
A previous installation of patch patch_id was invoked  
that saved files that were to be patched. Since files  
were saved, you must run this instance of patchadd  
without the -d option.
```

Explanation and Recommended Action

If a patch was previously installed without using the `-d` option, then the re-installation attempt must also be invoked without the `-d` option. Execute `patchadd` without the `-d` option.

Message

```
A previous installation of patch patch_id was invoked  
with the -d option. (i.e. Do not save files that would  
be patched) Therefore, this invocation of patchadd  
must also be run with the -d option.
```

Explanation and Recommended Action

If a patch was previously installed using the `-d` option, then the re-installation attempt must also be invoked with the `-d` option. Execute `patchadd` with the `-d` option.

**Diagnostic
Reference**

The patch installation messages listed below are not necessarily considered errors as indicated in the explanations given. These messages are, however, recorded in the patch installation log for diagnostic reference.

Message

```
Package not patched:
PKG=SUNxxxx
Original package not installed
```

Explanation and Recommended Action

One of the components of the patch would have patched a package that is not installed on your system. This is not necessarily an error. A patch may fix a related bug for several packages.

For example, suppose a patch fixes a bug in both the online-backup and fddi packages. If you had online-backup installed but didn't have fddi installed, you would get the message :

```
Package not patched:
PKG=SUNWbf
Original package not installed
```

This message only indicates an error if you thought the package was installed on your system. If this is the case, take the necessary action to install the package, backout the patch (if it installed other packages) and re-install the patch.

Message

```
Package not patched:
PKG=SUNxxx
ARCH=xxxxxxx
VERSION=xxxxxxx
Architecture mismatch
```

Explanation and Recommended Action

One of the components of the patch would have patched a package for an architecture different from your system. This is not necessarily an error. Any patch to one of the architecture-specific packages might contain one element for each of the possible architectures. For example, assume you are running on a sun4m. If you were to install a patch to package SUNWcar, you would see the following (or similar) messages:

```
Package not patched:
PKG=SUNWcar
ARCH=sparc.sun4c
VERSION=11.5.0, REV=2.0.18
Architecture mismatch
```

```
Package not patched:
PKG=SUNWcar
ARCH=sparc.sun4u
VERSION=11.5.0, REV=2.0.18
Architecture mismatch
```

```
Package not patched:
```

patchadd(1M)

```
PKG=SUNWcar
ARCH=sparc.sun4e
VERSION=11.5.0,REV=2.0.18
Architecture mismatch
```

```
Package not patched:
PKG=SUNWcar
ARCH=sparc.sun4
VERSION=11.5.0,REV=2.0.18
Architecture mismatch
```

These messages indicate an error condition only if patchadd does not correctly recognize your architecture.

Message

```
Package not patched:
PKG=SUNxxxx
ARCH=xxxx
VERSION=xxxxxxx
Version mismatch
```

Explanation and Recommended Action

The version of software to which the patch is applied is not installed on your system. For example, if you were running Solaris 5.5, and you tried to install a patch against Solaris 5.6, you would see the following (or similar) message:

```
Package not patched:
PKG=SUNWcsu
ARCH=sparc
VERSION=10.0.2
Version mismatch
```

This message does not necessarily indicate an error. If the version mismatch was for a package you needed patched, either get the correct patch version or install the correct package version. Then backout the patch (if necessary) and re-apply.

Message

```
Re-installing Patch.
```

Explanation and Recommended Action

The patch has already been applied, but there is at least one package in the patch that could be added. For example, if you applied a patch that had both Openwindows and Answerbook components, but your system did not have Answerbook installed, the Answerbook parts of the patch would not have been applied. If, at a later time, you pkgadd Answerbook, you could re-apply the patch, and the Answerbook components of the patch would be applied to the system.

Message

```
patchadd Interrupted.
patchadd is terminating.
```

Explanation and Recommended Action

patchadd was interrupted during execution (usually through pressing CTRL-c). patchadd will clean up its working files and exit.

Message

```
patchadd Interrupted.
Backing out Patch...
```

Explanation and Recommended Action

patchadd was interrupted during execution (usually through pressing CTRL-c). patchadd will clean up its working files, backout the patch, and exit.

SEE ALSO cpio(1), pkginfo(1), patchrm(1M), pkgadd(1M), pkgchk(1M), pkgrm(1M), smpatch(1M), showrev(1M), attributes(5)

NOTES To successfully install a patch to a client or server, patchadd must be issued twice, once with the -R option and once with the -S option. This guarantees that the patch is installed to both the /usr and root partitions. This is necessary if there are both /usr and root packages in the patch.

pkgadd is invoked by patchadd and executes the installation scripts in the *pkg/install* directory. The checkinstall script is executed with its ownership set to user install, if there is no user install then pkgadd executes the checkinstall script as nobody. The SVR4 ABI states that the checkinstall shall only be used as an information gathering script. If the permissions for the checkinstall script are changed to something other than the initial settings, pkgadd may not be able to open the file for reading, thus causing the patch installation to abort with the following error:

```
pkgadd: ERROR: checkinstall script did not complete successfully.
```

The permission for the checkinstall script should not be changed. Contents of log file for a successful installation: patchadd redirects pkgadd's output to the patch installation log file. For a successful installation, pkgadd will produce the following message that gets inserted into the log file:

```
This appears to be an attempt to install the same architecture
and version of a package which is already installed. This
installation will attempt to overwrite this package.
```

This message does not indicate a failure, it represents the correct behavior by pkgadd when a patch installs correctly.

On client server machines the patch package is *not* applied to existing clients or to the client root template space. Therefore, when appropriate, *all client machines will need the patch applied directly using this same patchadd method on the client*. See instructions above for applying patches to a client. A bug affecting a package utility (for example, pkgadd, pkgrm, pkgchk) could affect the reliability of patchadd or patchrm which use package utilities to install and backout the patch package. It is recommended that any patch that fixes package utility problems be reviewed and, if necessary, applied before other patches are applied. Existing patches are:

Solaris 2.1:
patch 100901

Solaris 2.2:

NAME	patchrm – remove a Solaris patch package and restore previously saved files
SYNOPSIS	patchrm [-f] [-B <i>backout_dir</i>] [-C <i>net_install_image</i> -R <i>client_root_path</i> -S <i>service</i>] <i>patch_id</i>
DESCRIPTION	patchrm removes a patch package and restores previously saved files to a system running the Solaris 2.x operating environment or later Solaris environments (such as Solaris 8) that are compatible with Solaris 2.x. patchrm cannot be used with Solaris 1 patches. patchrm must be run as root.
OPTIONS	The following options are supported: -B <i>backout_dir</i> Removes a patch whose backout data has been saved to a directory other than the package database. This option is only needed if the original backout directory, supplied to the patchadd command at installation time, has been moved. Specify <i>backout_dir</i> as an absolute path name. -C <i>net_install_image</i> Removes the patched files located on the mini root on a Net Install Image created by <i>setup_install_server</i>. Specify <i>net_install_image</i> as the absolute path name to a Solaris 2.6 or compatible version boot directory. See EXAMPLES. -f Forces the patch removal regardless of whether the patch was superseded by another patch. -R <i>client_root_path</i> Locates all patch files generated by patchrm under the directory <i>client_root_path</i>. <i>client_root_path</i> is the directory that contains the bootable root of a client from the server's perspective. Specify <i>client_root_path</i> as the absolute path name to the beginning of the directory tree under which all patch files generated from patchrm will be located. -R cannot be specified with the -S option. -S <i>service</i> Specifies an alternate service (for example, Solaris_2.3). This service is part of the server and client model, and can only be used from the server's console. Servers can contain shared /usr file systems that are created by Host Manager. These service areas can then be made available to the clients they serve. -S cannot be specified with the -R option..
OPERANDS	The following operands are supported: <i>patch_id</i> The patch number of a given patch. 104945-02 is an example of a <i>patch_id</i>.

patchrm(1M)

EXAMPLES

The examples in this section assume that patch 104945-02 has been installed to the system prior to removal. All of the examples are relative to the `/usr/sbin` directory.

EXAMPLE 1 Removing a Patch From a Stand-alone System

The following example removes a patch from a standalone system:

```
example# patchrm 104945-02
```

EXAMPLE 2 Removing a Patch From a Client's System From the Server's Console

The following example removes a patch from a client's system from the server's console:

```
example# patchrm -R /export/root/client1 104945-02
```

EXAMPLE 3 Removing a Patch From a Server's Service Area

The following example removes a patch from a server's service area:

```
example# patchrm -S Solaris_2.3 104945-02
```

EXAMPLE 4 Removing a Patch From a Net Install Image

The following example removes a patch from a Net Install Image:

```
example# patchrm -C /export/Solaris_2.6/Tools/Boot 104945-02
```

EXIT STATUS

The following exit values are returned:

0	Successful completion.
>0	An error occurred.

ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWswmt, SUNWcsu

DIAGNOSTICS

The following messages may help in determining some of the most common problems associated with backing out a patch.

Message

```
prebackout patch exited with return code code.
patchrm exiting.
```

Explanation and Recommended Action

The prebackout script supplied with the patch exited with a return code other than 0. Generate a script trace of the prebackout script to determine why the

prebackout script failed. Add the `-x` option to the first line of the prepatch script to fix the problem and run `patchadd` again.

Message

```
postbackout patch exited with return code code.
patchrm exiting.
```

Explanation and Recommended Action

The postbackout script supplied with the patch exited with a return code other than 0. Look at the postbackout script to determine why it failed. Add the `-x` option to the first line of the prepatch script to fix the problem, and, if necessary, *re-execute the postbackout script only*.

Message

```
Only one service may be defined.
```

Explanation and Recommended Action

You have attempted to specify more than one service from which to backout a patch. Different services must have their patches backed out with different invocations of `patchrm`.

Message

```
The -S and -R arguments are mutually exclusive.
```

Explanation and Recommended Action

You have specified both a non-native service and a *client_root_path* from which to backout a patch. These two arguments are mutually exclusive. If backing out a patch from a non-native `usr` partition, the `-S` option should be used. If backing out a patch from a client's root partition (either native or non-native), the `-R` option should be used.

Message

```
The service service cannot be found on this system
```

Explanation and Recommended Action

You have specified a non-native service from which to backout a patch, but the specified service is not installed on your system. Correctly specify the service when backing out the patch.

Message

```
Only one client_root_path may be defined.
```

Explanation and Recommended Action

You have specified more than one *client_root_path* using the `-R` option. The `-R` option may be used only once per invocation of `patchrm`.

Message

```
The dir directory cannot be found on this system.
```

patchrm(1M)

Explanation and Recommended Action

You have specified a directory using the `-R` option which is either not mounted, or does not exist on your system. Verify the directory name and re-backout the patch.

Message

Patch *patch_id* has not been successfully installed to this system.

Explanation and Recommended Action

You have attempted to backout a patch that is not installed on this system. If you must restore previous versions of patched files, you may have to restore the original files from the initial installation CD.

Message

Patch *patch_id* has not been successfully applied to this system.
Will remove directory *dir*.

Explanation and Recommended Action

You have attempted to back out a patch that is not applied to this system. While the patch has not been applied, a residual `/var/sadm/patch/patch_id` (perhaps from an unsuccessful `patchadd`) directory still exists. The patch cannot be backed out. If you must restore old versions of the patched files, you may have to restore them from the initial installation CD.

Message

This patch was obsoleted by patch *patch_id*.
Patches must be backed out in the reverse order in which they were installed. Patch backout aborted.

Explanation and Recommended Action

You are attempting to backout patches out of order. Patches should never be backed-out out of sequence. This could undermine the integrity of the more current patch.

Message

Patch *patch_id* is required to be installed by an already installed *patch_id*.
It cannot be backed out until the required patch is backed out first.

Explanation and Recommended Action

Backout the patch that is required to be installed then backout the desired patch.

Message

The installation of patch *patch_id* was interrupted.

Explanation and Recommended Action

A previous installation was interrupted. The interrupted patch needs to be installed before backing out the desired patch.

Message

Patch *patch_id* was installed without backing up the original files. It cannot be backed out.

Explanation and Recommended Action

Either the `-d` option of `patchadd` was set when the patch was applied, or the save area of the patch was deleted to regain space. As a result, the original files are not saved and `patchrm` cannot be used. The original files can only be recovered from the original installation CD.

Message

`pkgadd` of *pkgname* package failed return code *code*.
See `/var/sadm/patch/patch_id/log` for reason for failure.

Explanation and Recommended Action

The installation of one of patch packages failed. See the log file for the reason for failure. Correct the problem and run the backout script again.

Message

Restore of old files failed.

Explanation and Recommended Action

The backout script uses the `cpio` command to restore the previous versions of the files that were patched. The output of the `cpio` command should have preceded this message. The user should take the appropriate action to correct the `cpio` failure. This is for Solaris 2.4 or previous versions.

SEE ALSO `cpio(1)`, `pkginfo(1)`, `patchadd(1M)`, `pkgadd(1M)`, `pkgchk(1M)`, `pkgrm(1M)`, `showrev(1M)`, `attributes(5)`

NOTES On client server machines the patch package is *not* removed from existing clients or from client root template space. Therefore, when appropriate, *all client machines will need the patch removed directly using this same patchrm method on the client*. A bug affecting a package utility (for example, `pkgadd`, `pkgrm`, `pkgchk`) could affect the reliability of `patchadd` or `patchrm` which use package utilities to install and backout the patch package. It is recommended that any patch that fixes package utility problems be reviewed and, if necessary, applied before other patches are applied. Existing patches are:

NAME	pbind – control and query bindings of processes to processors						
SYNOPSIS	pbind -b <i>processor_id</i> <i>pid</i>... pbind -u <i>pid</i>... pbind [-q] [<i>pid</i>...]						
DESCRIPTION	pbind controls and queries bindings of processes to processors. pbind binds all the LWPs (lightweight processes) of a process to a processor, or removes or displays the bindings. When an LWP is bound to a processor, it will be executed only by that processor except when the LWP requires a resource that is provided only by another processor. The binding is not exclusive, that is, the processor is free execute other LWPs as well. Bindings are inherited, so new LWPs and processes created by a bound LWP will have the same binding. Binding an interactive shell to a processor, for example, binds all commands executed by the shell. Superusers may bind or unbind any process, and other users can use pbind to bind or unbind any process for which the user has permission to signal, that is, any process that has the same effective user ID as the user.						
OPTIONS	The following options are supported: <table> <tr> <td>-b <i>processor_id</i></td><td>Binds all the LWPs of the specified processes to the processor <i>processor_id</i>. Specify <i>processor_id</i> as the processor ID of the processor to be controlled or queried. <i>processor_id</i> must be present and on-line. Use the psrinfo command to determine whether or not <i>processor_id</i> is present and on-line. See psrinfo(1M).</td></tr> <tr> <td>-q</td><td>Displays the bindings of the specified processes, or of all processes. If a process is composed of multiple LWPs, which have different bindings, the bindings of only one of the bound LWPs will be displayed.</td></tr> <tr> <td>-u</td><td>Removes the bindings of all LWPs of the specified processes, allowing them to be executed on any on-line processor.</td></tr> </table>	-b <i>processor_id</i>	Binds all the LWPs of the specified processes to the processor <i>processor_id</i> . Specify <i>processor_id</i> as the processor ID of the processor to be controlled or queried. <i>processor_id</i> must be present and on-line. Use the psrinfo command to determine whether or not <i>processor_id</i> is present and on-line. See psrinfo(1M).	-q	Displays the bindings of the specified processes, or of all processes. If a process is composed of multiple LWPs, which have different bindings, the bindings of only one of the bound LWPs will be displayed.	-u	Removes the bindings of all LWPs of the specified processes, allowing them to be executed on any on-line processor.
-b <i>processor_id</i>	Binds all the LWPs of the specified processes to the processor <i>processor_id</i> . Specify <i>processor_id</i> as the processor ID of the processor to be controlled or queried. <i>processor_id</i> must be present and on-line. Use the psrinfo command to determine whether or not <i>processor_id</i> is present and on-line. See psrinfo(1M).						
-q	Displays the bindings of the specified processes, or of all processes. If a process is composed of multiple LWPs, which have different bindings, the bindings of only one of the bound LWPs will be displayed.						
-u	Removes the bindings of all LWPs of the specified processes, allowing them to be executed on any on-line processor.						
OPERANDS	The following operands are supported: <i>pid</i> The process ID of the process to be controlled or queried.						
EXAMPLES	EXAMPLE 1						
Binding processes	The following example binds processes 204 and 223 to processor 2. <pre>example% pbind -b 2 204 223</pre>						

pbind(1M)

	This command displays the following output: <pre>process id 204: was 2, now 2 process id 223: was 3, now 2</pre>				
Unbinding a process	The following example unbinds process 204. <pre>example% pbind -u 204</pre>				
Querying Bindings	The following example demonstrates that process 1 is bound to processor 0, process 149 has at least one LWP bound to CPU3, and process 101 has no bound LWPs. <pre>example% pbind -q 1 149 101</pre> This command displays the following output: <pre>process id 1: 0 process id 149: 3 process id 101: not bound</pre>				
ATTRIBUTES	See attributes(5) for descriptions of the following attributes: <table><thead><tr><th>ATTRIBUTE TYPE</th><th>ATTRIBUTE VALUE</th></tr></thead><tbody><tr><td>Availability</td><td>SUNWcsu</td></tr></tbody></table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	Availability	SUNWcsu
ATTRIBUTE TYPE	ATTRIBUTE VALUE				
Availability	SUNWcsu				
EXIT STATUS	The following exit values are returned: <table><tbody><tr><td>0</td><td>Successful completion.</td></tr><tr><td>>0</td><td>An error occurred.</td></tr></tbody></table>	0	Successful completion.	>0	An error occurred.
0	Successful completion.				
>0	An error occurred.				
SEE ALSO	psradm(1M), psrinfo(1M), psrset(1M), processor_bind(2), processor_info(2), sysconf(3C), attributes(5)				
DIAGNOSTICS	pbind: cannot query pid 31: No such process The process specified did not exist or has exited. pbind: cannot bind pid 31: Not owner The user does not have permission to bind the process. pbind: cannot bind pid 31: Invalid argument The specified processor is not on-line.				

NAME	pcmciad – PCMCIA user daemon				
SYNOPSIS	/usr/lib/pcmciad				
DESCRIPTION	The PCMCIA user daemon provides user-level services for the PCMCIA nexus driver and PCMCIA card client drivers. There are no user-configurable options for this daemon.				
ATTRIBUTES	See attributes(5) for descriptions of the following attributes: <table><tr><th>ATTRIBUTE TYPE</th><th>ATTRIBUTE VALUE</th></tr><tr><td>Availability</td><td>SUNWpcmcu</td></tr></table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	Availability	SUNWpcmcu
ATTRIBUTE TYPE	ATTRIBUTE VALUE				
Availability	SUNWpcmcu				
SEE ALSO	pcmcia(4), attributes(5)				
DIAGNOSTICS	pcmciad: can't open /dev/pem: No such file or directory The user daemon could not communicate with the PCMCIA event management driver.				

pfinstall(1M)

NAME	pfinstall – tests installation profiles						
SYNOPSIS	<code>/usr/sbin/install.d/pfinstall -D -d disk_config [-c CDpath] profile</code>						
DESCRIPTION	After you create a profile, you can use the <code>pfinstall</code> command to test the profile and see if it does what you want before using it to install or upgrade a system. <code>pfinstall</code> enables you to test a profile against: ■ The system's disk configuration where <code>pfinstall</code> is being run. ■ Other disks by using a disk configuration file that represents a structure of a disk. See NOTES on how to create a disk configuration file. To successfully and accurately test a profile for a particular Solaris release, you must test a profile within the Solaris environment of the same release. For example, if you want to test a profile for Solaris 2.6, you have to run the <code>pfinstall</code> command on a system running Solaris 2.6. So, on a system running Solaris 2.6, you can test Solaris 2.6 initial installation profiles. However, if you want to test a Solaris 2.6 upgrade profile on a system running a previous version of Solaris, or if you don't have a Solaris 2.6 system installed yet to test Solaris 2.6 initial installation profiles, you have to boot a system from a Solaris 2.6 CD image and temporarily create a Solaris 2.6 install environment. Then, you can run <code>pfinstall</code> in the Solaris 2.6 install environment to test your profiles. To create a temporary Solaris 2.6 install environment, boot a system from a Solaris 2.6 CD image (just as you would to install), answer any system identification questions, choose the Solaris Interactive Installation program, and exit out of the first screen that is presented. Then, from the shell, you can execute the <code>pfinstall</code> command.						
OPTIONS	The following options are supported: <table> <tr> <td><code>-D</code></td><td><code>pfinstall</code> uses the system's disk configuration to test the profile. You must specify either this option or the <code>-d</code> option to test the profile (see WARNINGS).</td></tr> <tr> <td><code>-d disk_config</code></td><td><code>pfinstall</code> uses a disk configuration file, <i>disk_config</i>, to test the profile. See NOTES on how to create a disk configuration file. You must specify either this option or the <code>-D</code> option to test the profile (see WARNINGS). This option cannot be used with an upgrade profile (<code>install_type upgrade</code>). You must always test an upgrade profile against a system's disk configuration (<code>-D</code> option).</td></tr> <tr> <td><code>-c CDpath</code></td><td>The path to the Solaris 2 installation image. This is required if the image is not mounted on <code>/cdrom</code>. (For example, use this option if you copied the installation image to disk or mounted the CD-ROM on a directory other than <code>/cdrom</code>.)</td></tr> </table>	<code>-D</code>	<code>pfinstall</code> uses the system's disk configuration to test the profile. You must specify either this option or the <code>-d</code> option to test the profile (see WARNINGS).	<code>-d disk_config</code>	<code>pfinstall</code> uses a disk configuration file, <i>disk_config</i> , to test the profile. See NOTES on how to create a disk configuration file. You must specify either this option or the <code>-D</code> option to test the profile (see WARNINGS). This option cannot be used with an upgrade profile (<code>install_type upgrade</code>). You must always test an upgrade profile against a system's disk configuration (<code>-D</code> option).	<code>-c CDpath</code>	The path to the Solaris 2 installation image. This is required if the image is not mounted on <code>/cdrom</code> . (For example, use this option if you copied the installation image to disk or mounted the CD-ROM on a directory other than <code>/cdrom</code> .)
<code>-D</code>	<code>pfinstall</code> uses the system's disk configuration to test the profile. You must specify either this option or the <code>-d</code> option to test the profile (see WARNINGS).						
<code>-d disk_config</code>	<code>pfinstall</code> uses a disk configuration file, <i>disk_config</i> , to test the profile. See NOTES on how to create a disk configuration file. You must specify either this option or the <code>-D</code> option to test the profile (see WARNINGS). This option cannot be used with an upgrade profile (<code>install_type upgrade</code>). You must always test an upgrade profile against a system's disk configuration (<code>-D</code> option).						
<code>-c CDpath</code>	The path to the Solaris 2 installation image. This is required if the image is not mounted on <code>/cdrom</code> . (For example, use this option if you copied the installation image to disk or mounted the CD-ROM on a directory other than <code>/cdrom</code> .)						
OPERANDS	The following operand is supported: <table> <tr> <td><i>profile</i></td><td>The file name of the profile to test. If <i>profile</i> is not in the directory where <code>pfinstall</code> is being run, you must specify the path.</td></tr> </table>	<i>profile</i>	The file name of the profile to test. If <i>profile</i> is not in the directory where <code>pfinstall</code> is being run, you must specify the path.				
<i>profile</i>	The file name of the profile to test. If <i>profile</i> is not in the directory where <code>pfinstall</code> is being run, you must specify the path.						

EXAMPLES**EXAMPLE 1** Testing an Upgrade Profile

The following example tests an upgrade profile, `upgrade.prof`, on a system with a previous version of the Solaris software installed.

1. Boot the system to be upgraded from a Solaris 2.6 image (just as you would to install). The image can be located in the system's local CD-ROM or on an install server.
2. Answer the system configuration questions, if prompted.
3. If you are presented with a choice of installation options, choose the Solaris Interactive Installation program.
4. Exit from the first screen of the Solaris Interactive Installation program.
After the Solaris Interactive Installation program exits, a shell prompt is displayed.
5. Create a temporary mount point:

```
example# mkdir /tmp/mnt
```

6. Mount the directory that contains the profile(s) you want to test.

If you want to mount a remote NFS file system (for systems on the network), enter:

```
mount -F nfs server_name:path /tmp/mnt
```

If you want to mount a UFS-formatted diskette, enter:

```
mount -F ufs /dev/diskette /tmp/mnt
```

If you want to mount a PCFS-formatted diskette, enter:

```
mount -F pcfs /dev/diskette /tmp/mnt
```

7. Change directory to `/tmp/mnt` where the profile resides:

```
example# cd /tmp/mnt
```

8. Test the `upgrade.prof` profile:

```
/usr/sbin/install.d/pfinstall -D upgrade.prof
```

EXAMPLE 2 Testing the `basic.prof` Profile

The following example tests the `basic.prof` profile against the disk configuration on a Solaris 2.6 system where `pfinstall` is being run. The path to the Solaris CD image is specified because Volume Management is being used.

```
example# /usr/sbin/install.d/pfinstall -D -c /cdrom/cdrom0/s0 basic.prof
```

EXAMPLE 3 Testing the `basic.prof` Profile

The following example tests the `basic.prof` profile against the `535_test` disk configuration file. This example uses a Solaris CD image located in the `/export/install` directory, and `pfinstall` is being run on a Solaris 2.6 system.

```
example# /usr/sbin/install.d/pfinstall -d 535_test \
-c /export/install basic.prof
```

pfinstall(1M)

EXIT STATUS	0	Successful (system rebooted).
	1	Successful (system not rebooted).
	2	An error occurred.

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWinst

SEE ALSO `fdisk(1M)`, `prtvtoc(1M)`, `attributes(5)`

Solaris 9 Installation Guide

WARNINGS If the `-d` or `-D` option is not specified, `pfinstall` may perform an actual installation on the system by using the specified profile, and the data on the system may be overwritten.

NOTES You have to test a profile on a system with the same platform type for which the profile was created.

SPARC To create a disk configuration file (`-d` option) for a SPARC based system:

1. Locate a SPARC based system with a disk that you want to test.
2. Create a disk configuration file by redirecting the output of the `prtvtoc(1M)` command to a file.

```
example# prtvtoc /dev/rdisk/c0t3d0s2 > 535_disk
```

3. (Optional.) Concatenate disk configuration files into a single file to test a profile against multiple disks. The target numbers in the disk device names must be unique.

```
example# cat 535_disk 1G_disk > mult_disks
```

IA To create a disk configuration file (`-d` option) for an IA based system:

1. Locate an IA based system with a disk that you want to test.
2. Create part of the disk configuration file by saving the output of the `fdisk(1M)` command to a file:

```
example# fdisk -R -W 535_disk /dev/rdisk/c0t3d0p0
```

3. Append the output of the `prtvtoc(1M)` command to the disk configuration file.

```
example# prtvtoc /dev/rdisk/c0t3d0s2 >> 535_disk
```

`pfinstall(1M)`

4. (Optional.) Concatenate disk configuration files into a single file to test a profile against multiple disks. The target numbers in the disk device names must be unique.

```
example# cat 535_disk 1G_disk > mult_disks
```

To test a profile with a specific system memory size, set `SYS_MEMSIZE` to the specific memory size (in Mbytes) before running `pfinstall`:

```
example# SYS_MEMSIZE=memory_size
```

```
example# export SYS_MEMSIZE
```

pgxconfig(1M)

NAME	pgxconfig, GFXconfig – configure the PGX32 (Raptor GFX) Graphics Accelerator
SYNOPSIS	<pre>/usr/sbin/pgxconfig [-dev <i>device-filename</i>] [-res <i>video-mode</i> [try noconfirm nocheck]] [-file machine system] [-depth 8 24] [-24only true false] [-cachedpixmap true false] [-defaults] /usr/sbin/pgxconfig [-propt] [-prconf] /usr/sbin/pgxconfig [-help] [-res ?] /usr/sbin/pgxconfig [-i]</pre>
DESCRIPTION	The <code>pgxconfig</code> utility configures the PGX32 (Raptor GFX) Graphics Accelerator and some of the X11 window system defaults for PGX32 (Raptor GFX). A previous version of this utility was named <code>GFXconfig</code>. The first form of <code>pgxconfig</code> shown in the synopsis above stores the specified options in the <code>OWconfig</code> file. These options are used to initialize the PGX32 (Raptor GFX) device the next time the window system is run on that device. Updating options in the <code>OWconfig</code> file provides persistence of these options across window system sessions and system reboots. The second, third, and fourth forms, which invoke only the <code>-prconf</code>, <code>-propt</code>, <code>-help</code>, and <code>-res ?</code> options, do not update the <code>OWconfig</code> file. For the third form all other options are ignored. The <code>-i</code> option starts <code>pgxconfig</code> in interactive mode. Options may be specified for only one PGX32 (Raptor GFX) device at a time. Only PGX32 (Raptor GFX)-specific options can be specified through <code>pgxconfig</code>. The normal window system options for specifying default depth, default visual class and so forth are still specified as device modifiers on the <code>openwin</code> command line. See the <code>Xsun(1)</code> manual page available with the <code>SUNWxwman</code> package. The user can also specify the <code>OWconfig</code> file that is to be updated. By default, the machine-specific file in the <code>/usr/openwin</code> directory tree is updated. The <code>-file</code> option can be used to specify an alternate file to use. For example, the system-global <code>OWconfig</code> file in the <code>/etc/openwin</code> directory tree can be updated instead. Both of these standard <code>OWconfig</code> files can only be written by root.
OPTIONS	The following options are supported: <code>-cachedpixmap true false</code> When set to <code>false</code>, it forces the PGX32 (Raptor GFX) device to use 24-bit only when running OpenWindows. The default value is <code>true</code>.

Certain applications make use of a cached pixmap when writing to the display device. Such a technique can cause garbled output and can cause the X server to crash. If you experience such behavior, try setting the `-cachedpixmap` option to `false`.

-defaults

Reset all option values to their default values.

-depth 8 | 24

Sets the screen depth to 8 or 24 bits per pixel. 24 bits per pixel enables TrueColor graphics in the window system.

-dev *device-filename*

Specify the PGX32 (Raptor GFX) special file. The default is `/dev/fbs/gfxp0`, or `/dev/fbs/raptor0` if applicable.

-file *machine* | *system*

Specify which OWconfig file to update. If `machine`, the machine-specific OWconfig file in the `/etc/openwin` directory tree is used. If `system`, the global OWconfig file in the `/usr/openwin` directory tree is used. If the file does not exist, it is created.

-help

Print a list of the `pgxconfig` command line options, along with a brief explanation of each.

-i

Start `pgxconfig` in interactive mode.

-prconf

Print the PGX32 (Raptor GFX) hardware configuration. The following is a typical display:

```
--- Hardware Configuration for /dev/fbs/gfxp0 ---
DAC: version 0x0
Type:
Board:
PROM: version 0x0

                              640x480x67, 640x480x72, 640x480x75, 800x600x56,
                              800x600x60, 800x600x72, 800x600x75, 832x624x75,
                              1024x768x87, 1024x768x60, 1024x768x70, 1024x768x75,
                              1280x1024x75, 1280x1024x76, 1152x900x66, 1152x900x76,
                              1280x1024x67, 960x680x112S, vga, svga, 1152, 1280
                              stereo
```

pgxconfig(1M)

```
Current resolution setting: 1280x1024x76
Possible depths: 8, 24, 8+24
Current depth: 8
```

-propt

Print the current values of all PGX32 (Raptor GFX) options in the OWconfig file specified by the `-file` option for the device specified by the `-dev` option. Print the values of options as they would be in the OWconfig file after the call to `pgxconfig` would have completed. The following is a typical display:

```
--- OpenWindows Configuration for /dev/fbs/gfxp0 ---
OWconfig: machine
Video Mode: not set
Depth: 8+24
```

-res *video-mode* [*try* | *noconfirm* | *nocheck*]

Specify the built-in video mode used to drive the monitor connected to the specified PGX32 (Raptor GFX) device.

The format for *video-mode* can be one of the following:

widthxheightxrate

The *width* is the screen width in pixels, *height* is the screen height in pixels, and *rate* is the vertical frequency of the screen refresh. As a convenience, `-res` also accepts formats with `@` prepended to the refresh rate rather than `x`. For example: `1280x1024@76`. The list can be obtained by running `pgxconfig` with the `-res ?` option (the third form shown in the command synopsis above). Note that not all resolutions are supported by both the video board and by the monitor. The `pgxconfig` utility will not permit you to set a resolution not supported by the board unless the `noconfirm` or `nocheck` option is specified. It will also request confirmation before setting a resolution not supported by the monitor if the `nocheck` option is not specified.

Symbolic names

For convenience, the video modes listed below have symbolic names defined. Rather than the form *widthxheightxrate*, the symbolic name may be supplied as the argument to `-res`. If the symbolic name is `none`, the screen resolution will be the video mode that is currently programmed in the device when the window system is run.

svga	1024x768x60
1152	1152x900x76
1280	1280x1024x76
vga	640x480x60

none default console resolution

The `-res` option also accepts additional, optional arguments immediately following the video mode specification. Any or all of these may be present.

`noconfirm` Using the `-res` option, the user could put the system into an unusable state, a state where there is no video output. This can happen if there is ambiguity in the monitor sense codes for the particular code read. To reduce the chance of this occurring, the default behavior of `pgxconfig` is to print a warning message to this effect and to prompt the user to find out if it is okay to continue. The `noconfirm` option instructs `pgxconfig` to bypass this confirmation and to program the requested video mode anyway. This option is useful when `pgxconfig` is being run from a shell script.

`nocheck` If present, normal error checking based on the monitor sense code is suspended. The video mode specified by the user will be accepted regardless of whether it is appropriate for the currently attached monitor. (This option is useful if a different monitor is to be connected to the PGX32 (Raptor GFX) device). Use of this option implies `noconfirm` as well.

`try` This option allows the user to test the specified resolution before committing it. It displays a pattern on the screen with the specified resolution. If the test pattern appears correctly, the user may answer "y" to the query. The other permissible answer is "n".

`-res ?`

Print the list of possible resolutions supported by the PGX32 and the monitor.

`-24only`

Force the PGX32 (Raptor GFX) device to use 24 bit only when running Openwindows.

DEFAULTS

For a given invocation of `pgxconfig`, if an option does not appear on the command line, the corresponding `OWconfig` option is not updated; it retains its previous value, except for `-depth` and `-24only`.

A default value is used if a PGX32 (Raptor GFX) option has not been specified with `pgxconfig` when the window system is run. The option defaults are as follows:

`-dev` `/dev/fbs/gfxp0`
`-file` `system`
`-res` `none`

pgxconfig(1M)

The default of none for the `-res` option indicates that when the window system is run, the screen resolution will be the video mode that is currently programmed in the device.

EXAMPLES

EXAMPLE 1 Switching the Resolution on the Monitor Type

The following example switches the monitor type to the resolution of 1280 x 1024 at 76 Hz:

```
example# /usr/sbin/pgxconfig -res 1280x1024x76
```

NAME	picld – PICL daemon
SYNOPSIS	<code>/usr/lib/picl/picld</code>
DESCRIPTION	The Platform Information and Control Library (PICL) provides a mechanism to publish platform-specific information for clients to access in a platform-independent way. <code>picld</code> maintains and controls access to the PICL information from clients and plug-in modules. The daemon is started in both single-user and multi-user boot mode. Upon startup, the PICL daemon loads and initializes the plug-in modules. These modules use the <code>libpicltree(3PICLTREE)</code> interface to create nodes and properties in the PICL tree to publish platform configuration information. After the plug-in modules are initialized, the daemon opens the PICL daemon door to service client requests to access information in the PICL tree.
PICL Tree	The PICL tree is the repository of all the nodes and properties created by the plug-in modules to represent the platform configuration. Every node in the PICL tree is an instance of a well-defined PICL class. The name of the base PICL class is <code>picl</code>, which defines a basic set of properties that all nodes in the tree must possess. Two of those properties are <code>name</code> and <code>_class</code>, where <code>name</code> contains the name of the node, and the <code>_class</code> contains the PICL class name of the node. Certain nodes in the PICL tree have well-known names. For example, the name of the root node of the PICL tree is <code>/</code> and the name of the root node of the sub-tree containing platform device nodes is <code>platform</code>.
PICL plug-in Modules	The PICL plug-in modules are shared objects that publish platform-specific data in the PICL tree. They are located in well-known directories so that the daemon can locate and load them. Plug-in modules are located in one of the following plug-in directories depending on the platform-specific nature of the data that they collect and publish: <pre> /usr/platform/'uname -i'/lib/picl/plugins /usr/platform/'uname -m'/lib/picl/plugins </pre> A plug-in module can specify its dependency on another plug-in module using the <code>-l</code> or <code>-R</code> linker option. The plug-ins are loaded by the daemon using <code>dlopen(3DL)</code> according to the specified dependencies. Each plug-in module must define a <code>.init</code> section, which is executed when the plug-in module is loaded, to register themselves with the daemon. See <code>picld_plugin_register(3PICLTREE)</code> for additional information on plug-in registration. The plug-in modules use the <code>libpicltree(3PICLTREE)</code> interface to publish nodes and properties in the PICL tree so that clients can access them. When the PICL daemon invokes the initialization routine of the plug-in module, the plug-in collects the platform information and creates nodes and/or properties to represent the configuration in the PICL tree. A plug-in can create additional threads to monitor the platform configuration and update the PICL tree with any changes. This enables a PICL plug-in to operate as a daemon within the PICL framework.

picld(1M)

An environmental monitor is an example of a plug-in module that uses a thread to monitor the temperatures and fan speeds of the platform, then publishes the environmental information in the PICL tree so clients can access them.

Clients use the `libpicl(3PICL)` interface to send requests to `picld` for accessing the PICL tree.

EXIT STATUS `picld` does not return an exit status.

NAME	ping – send ICMP (ICMP6) ECHO_REQUEST packets to network hosts		
SYNOPSIS	<pre> /usr/sbin/ping host [timeout] /usr/sbin/ping -s [-l -U] [-adlLnRv] [-A addr_family] [-c traffic_class] [-g gateway [-g gateway...]] [-F flow_label] [-I interval] [-i interface] [-P tos] [-p port] [-t ttl] host [data_size] [npackets] </pre>		
DESCRIPTION	The utility <code>ping</code> utilizes the ICMP (ICMP6 in IPv6) protocol's ECHO_REQUEST datagram to elicit an ICMP (ICMP6) ECHO_RESPONSE from the specified <i>host</i> or network <i>gateway</i>. If <i>host</i> responds, <code>ping</code> will print: <pre> host is alive </pre> on the standard output and exit. Otherwise, after <i>timeout</i> seconds, it will write: <pre> no answer from host </pre> The default value of <i>timeout</i> is 20 seconds. When you specify the <code>s</code> flag, sends one datagram per second (adjust with <code>-I</code>) and prints one line of output for every ECHO_RESPONSE that it receives. <code>ping</code> produces no output if there is no response. In this second form, <code>ping</code> computes round trip times and packet loss statistics; it displays a summary of this information upon termination or timeout. The default <i>data_size</i> is 56 bytes, or you can specify a size with the <i>data_size</i> command-line argument. If you specify the optional <i>npackets</i>, <code>ping</code> sends <code>ping</code> requests until it either sends <i>npackets</i> requests or receives <i>npackets</i> replies. When using <code>ping</code> for fault isolation, first <code>ping</code> the local host to verify that the local network interface is running.		
OPTIONS	The following options are supported: <table> <tr> <td><code>-A addr_family</code></td><td> Specify the address family of the target host. <i>addr_family</i> can be either <code>inet</code> or <code>inet6</code>. Address family determines which protocol to use. For an argument of <code>inet</code>, IPv4 is used. For <code>inet6</code>, IPv6 is used. By default, if the name of a host is provided, not the literal IP address, and a valid IPv6 address exists in the name service database, <code>ping</code> will use this address. Otherwise, if the name service database contains an IPv4 address, it will try the IPv4 address. Specify the address family <code>inet</code> or <code>inet6</code> to override the default behavior. If the argument specified is <code>inet</code>, <code>ping</code> will use the IPv4 address associated with the host </td></tr> </table>	<code>-A addr_family</code>	Specify the address family of the target host. <i>addr_family</i> can be either <code>inet</code> or <code>inet6</code>. Address family determines which protocol to use. For an argument of <code>inet</code>, IPv4 is used. For <code>inet6</code>, IPv6 is used. By default, if the name of a host is provided, not the literal IP address, and a valid IPv6 address exists in the name service database, <code>ping</code> will use this address. Otherwise, if the name service database contains an IPv4 address, it will try the IPv4 address. Specify the address family <code>inet</code> or <code>inet6</code> to override the default behavior. If the argument specified is <code>inet</code>, <code>ping</code> will use the IPv4 address associated with the host
<code>-A addr_family</code>	Specify the address family of the target host. <i>addr_family</i> can be either <code>inet</code> or <code>inet6</code>. Address family determines which protocol to use. For an argument of <code>inet</code>, IPv4 is used. For <code>inet6</code>, IPv6 is used. By default, if the name of a host is provided, not the literal IP address, and a valid IPv6 address exists in the name service database, <code>ping</code> will use this address. Otherwise, if the name service database contains an IPv4 address, it will try the IPv4 address. Specify the address family <code>inet</code> or <code>inet6</code> to override the default behavior. If the argument specified is <code>inet</code>, <code>ping</code> will use the IPv4 address associated with the host		

ping(1M)

	name. If none exists, <code>ping</code> will state that the host is unknown and exit. It does not try to determine if an IPv6 address exists in the name service database. If the specified argument is <code>inet6</code>, <code>ping</code> uses the IPv6 address that is associated with the host name. If none exists, <code>ping</code> states that the host is unknown and exits.
-F <i>flow_label</i>	Specify the flow label of probe packets. The value must be an integer in the range from 0 to 1048575. This option is valid only on IPv6.
-I <i>interval</i>	Turn on the statistics mode and specify the interval between successive transmissions. The default is one second. See the discussion of the <code>-s</code> option.
-L	Turn off loopback of multicast packets. Normally, members are in the host group on the outgoing interface, a copy of the multicast packets will be delivered to the local machine.
-P <i>tos</i>	Set the type of service (<i>tos</i>) in probe packets to the specified value. The default is zero. The value must be an integer in the range from 0 to 255. Gateways also in the path can route the probe packet differently, depending upon the value of <i>tos</i> that is set in the probe packet. This option is valid only on IPv4.
-R	Record route. Sets the IPv4 record route option, which stores the route of the packet inside the IPv4 header. The contents of the record route are only printed if the <code>-v</code> and <code>-s</code> options are given. They are only set on return packets if the target host preserves the record route option across echos, or the <code>-l</code> option is given. This option is valid only on IPv4.
-U	Send UDP packets instead of ICMP (ICMP6) packets. <code>ping</code> sends UDP packets to consecutive ports expecting to receive back ICMP (ICMP6) <code>PORT_UNREACHABLE</code> from the target host.
-a	<code>ping</code> all addresses, both IPv4 and IPv6, of the multihomed destination. The output appears as if <code>ping</code> has been run once for each IP address of the destination. If this option is used together with <code>-A</code>, <code>ping</code> probes only the addresses that are of the specified address family. When used with the <code>-s</code> option and <i>npackets</i> is not specified, <code>ping</code> continuously probes the destination addresses in a round robin

	fashion. If <i>npackets</i> is specified, <i>ping</i> sends <i>npackets</i> number of probes to each IP address of the destination and then exits.
<code>-c traffic_class</code>	Specify the traffic class of probe packets. The value must be an integer in the range from 0 to 255. Gateways along the path can route the probe packet differently, depending upon the value of <i>traffic_class</i> set in the probe packet. This option is valid only on IPv6.
<code>-d</code>	Set the <code>SO_DEBUG</code> socket option.
<code>-g gateway</code>	Specify a loose source route gateway so that the probe packet goes through the specified host along the path to the target host. The maximum number of gateways is 8 for IPv4 and 127 for IPv6. Note that some factors such as the link MTU can further limit the number of gateways for IPv6.
<code>-i interface_address</code>	Specify the outgoing interface address to use for multicast packets for IPv4 and both multicast and unicast packets for IPv6. The default interface address for multicast packets is determined from the (unicast) routing tables. <i>interface_address</i> can be a literal IP address, for example, 10.123.100.99, or an interface name, for example, <code>le0</code> , or an interface index, for example 2.
<code>-l</code>	Use to send the probe packet to the given host and back again using loose source routing. Usually specified with the <code>-R</code> option. If any gateways are specified using <code>-g</code> , they are visited twice, both to and from the destination. This option is ignored if the <code>-U</code> option is used.
<code>-n</code>	Show network addresses as numbers. <i>ping</i> normally does a reverse name lookup on the IP addresses it extracts from the packets received. The <code>-n</code> option blocks the reverse lookup, so <i>ping</i> prints IP addresses instead of host names.
<code>-p port</code>	Set the base UDP <i>port</i> number used in probes. This option is used with the <code>-U</code> option. The default base <i>port</i> number is 33434. The <i>ping</i> utility starts setting the destination port number of UDP packets to this base and increments it by one at each probe.
<code>-r</code>	Bypass the normal routing tables and send directly to a host on an attached network. If the host is not on a directly attached network, an error is returned. This

ping(1M)

	option can be used to ping a local host through an interface that has been dropped by the router daemon. See <code>in.routed(1M)</code>. <code>-s</code> Send one datagram per second and collect statistics. <code>-t ttl</code> Specify the IPv4 time to live, or IPv6 hop limit, for unicast and multicast packets. The default time to live (hop limit) for unicast packets can be set with <code>ndd(1M)</code> using the <code>icmp_ipv4_ttl</code> variable for IPv4 and the <code>icmp_ipv6_ttl</code> variable for IPv6. The default time to live (hop limit) for multicast is one hop. <code>-v</code> Verbose output. List any ICMP (ICMP6) packets, other than replies from the target host.				
OPERANDS	<i>host</i> The network host				
EXAMPLES	EXAMPLE 1 Using ping With IPv6 This example shows ping sending probe packets to all the IPv6 addresses of the host london, one at a time. It sends an ICMP6 ECHO_REQUEST every second until the user interrupts it. <pre>istanbul% ping -s -A inet6 -a london PING london: 56 data bytes 64 bytes from london (4::114:a00:20ff:ab3d:83ed): icmp_seq=0. time=2. ms 64 bytes from london (fec0::114:a00:20ff:ab3d:83ed): icmp_seq=1. time=1. ms 64 bytes from london (4::114:a00:20ff:ab3d:83ed): icmp_seq=2. time=1. ms 64 bytes from london (fec0::114:a00:20ff:ab3d:83ed): icmp_seq=3. time=1. ms 64 bytes from london (4::114:a00:20ff:ab3d:83ed): icmp_seq=4. time=1. ms 64 bytes from london (fec0::114:a00:20ff:ab3d:83ed): icmp_seq=5. time=1. ms ^C ----london PING Statistics---- 6 packets transmitted, 6 packets received, 0% packet loss round-trip (ms) min/avg/max = 1/1/2</pre>				
EXIT STATUS	The following exit values are returned: 0 Successful operation; the machine is alive. non-zero An error has occurred. Either a malformed argument has been specified, or the machine was not alive.

pkgadd(1M)

NAME	pkgadd – Transfer software packages to the system
SYNOPSIS	pkgadd [-nv] [-a <i>admin</i>] [-d <i>device</i>] [[-M] -R <i>root_path</i>] [-r <i>response</i>] [-V <i>fs_file</i>] [pkginst... -Y <i>category</i> [, <i>category</i>...]] pkgadd -s <i>spool</i> [-d <i>device</i>] [pkginst... -Y <i>category</i> [, <i>category</i>...]]
DESCRIPTION	pkgadd transfers the contents of a software package from the distribution medium or directory to install it onto the system. Used without the -d option, pkgadd looks in the default spool directory for the package (<i>var/spool/pkg</i>). Used with the -s option, it writes the package to a spool directory instead of installing it. Certain unbundled and third-party packages are no longer entirely compatible with the latest version of pkgadd. These packages require user interaction throughout the installation and not just at the very beginning. To install these older packages (released prior to Solaris 2.4), set the following environment variable: <code>NONABI_SCRIPTS=TRUE</code> pkgadd permits keyboard interaction throughout the installation as long as this environment variable is set.
OPTIONS	The following options are supported: -a <i>admin</i> Define an installation administration file, <i>admin</i>, to be used in place of the default administration file. The token <i>none</i> overrides the use of any <i>admin</i> file, and thus forces interaction with the user. Unless a full path name is given, pkgadd first looks in the current working directory for the administration file. If the specified administration file is not in the current working directory, pkgadd looks in the <code>/var/sadm/install/admin</code> directory for the administration file. -d <i>device</i> Install or copy a package from <i>device</i>. <i>device</i> can be a full path name to a directory or the identifiers for tape, floppy disk, or removable disk (for example, <code>/var/tmp</code> or <code>/floppy/floppy_name</code>). It can also be a device alias (for example, <code>/floppy/floppy0</code>) or a datastream created by pkgtrans (see pkgtrans(1)). -M Instruct pkgadd not to use the <code>\$root_path/etc/vfstab</code> file for determining the client's mount points. This option assumes the mount points are correct on the server and it behaves consistently with Solaris 2.5 and earlier releases. -n Installation occurs in non-interactive mode. Suppress output of the list of installed files. The default mode is interactive. -r <i>response</i> Identify a file or directory which contains output from a previous pkgask(1M) session. This file supplies the interaction responses that would be requested by the package in interactive mode. <i>response</i> must be a full pathname.

	-R <i>root_path</i> Define the full path name of a directory to use as the <i>root_path</i>. All files, including package system information files, are relocated to a directory tree starting in the specified <i>root_path</i>. The <i>root_path</i> may be specified when installing to a client from a server (for example, <code>/export/root/client1</code>). -s <i>spool</i> Write the package into the directory <i>spool</i> instead of installing it. -v Trace all of the scripts that get executed by pkgadd, located in the <i>pkginst/install</i> directory. This option is used for debugging the procedural and non-procedural scripts. -V <i>fs_file</i> Specify an alternative <i>fs_file</i> to map the client's file systems. For example, used in situations where the <code>\$root_path/etc/vfstab</code> file is non-existent or unreliable. -Y <i>category</i> Install packages based on the value of the CATEGORY parameter stored in the package's <code>pkginfo(4)</code> file. When executed without options or operands, pkgadd uses <code>/var/spool/pkg</code> (the default spool directory).														
OPERANDS	The following operands are supported: <i>pkginst</i> The package instance or list of instances to be installed. The token <code>all</code> may be used to refer to all packages available on the source medium. The format <i>pkginst</i>. * can be used to indicate all instances of a package. The asterisk character (*) is a special character to some shells and may need to be escaped. In the C-Shell, "*" must be surrounded by single quotes (') or preceded by a backslash (\).														
EXAMPLES	EXAMPLE 1 Installing a Package from a Solaris CD-ROM. The following example installs a package from a Solaris CD-ROM. You are prompted for the name of the package you want to install. <pre>example% pkgadd -d /cdrom/cdrom0/s0/Solaris_2.6</pre>														
EXIT STATUS	<table> <tr> <td>0</td><td>Successful completion</td></tr> <tr> <td>1</td><td>Fatal error.</td></tr> <tr> <td>2</td><td>Warning.</td></tr> <tr> <td>3</td><td>Interruption.</td></tr> <tr> <td>4</td><td>Administration.</td></tr> <tr> <td>5</td><td>Administration. Interaction is required. Do not use pkgadd -n.</td></tr> <tr> <td>10</td><td>Reboot after installation of all packages.</td></tr> </table>	0	Successful completion	1	Fatal error.	2	Warning.	3	Interruption.	4	Administration.	5	Administration. Interaction is required. Do not use pkgadd -n.	10	Reboot after installation of all packages.
0	Successful completion														
1	Fatal error.														
2	Warning.														
3	Interruption.														
4	Administration.														
5	Administration. Interaction is required. Do not use pkgadd -n.														
10	Reboot after installation of all packages.														

pkgadd(1M)

20 Reboot after installation of this package.

Application Packaging Developer's Guide

NOTES When transferring a package to a spool directory, the `-r`, `-n`, and `-a` options cannot be used.

The `-r` option can be used to indicate a directory name as well as a filename. The directory can contain numerous response files, each sharing the name of the package with which it should be associated. This would be used, for example, when adding multiple interactive packages with one invocation of `pkgadd`. In this situation, each package would need a response file. If you create response files with the same name as the package (for example, `pkinst1` and `pkinst2`), then name the directory in which these files reside after the `-r`.

The `-n` option causes the installation to halt if any interaction is needed to complete it.

If the default *admin* file is too restrictive, the administration file may need to be modified to allow for total non-interaction during a package installation. See `admin(4)` for details.

NAME	pkgask – stores answers to a request script				
SYNOPSIS	pkgask [-d <i>device</i>] [-R <i>root_path</i>] -r <i>response</i> <i>pkginst...</i>				
DESCRIPTION	pkgask allows the administrator to store answers to an interactive package (one with a request script, that is, a user-created file that must be named <i>request</i>). Invoking this command generates a response file that is then used as input at installation time. The use of this response file prevents any interaction from occurring during installation since the file already contains all of the information the package needs.				
OPTIONS	The following options are supported -d <i>device</i> Run the request script for a package on <i>device</i>. <i>device</i> can be a directory pathname or the identifiers for tape, floppy disk or removable disk (for example, /var/tmp, /dev/diskette, and /dev/dsk/c1d0s0). The default device is the installation spool directory. -R <i>root_path</i> Define the full path name of a directory to use as the <i>root_path</i>. All files, including package system information files, are relocated to a directory tree starting in the specified <i>root_path</i>. -r <i>response</i> Identify a file or directory which should be created to contain the responses to interaction with the package. The name must be a full pathname. The file, or directory of files, can later be used as input to the pkgadd(1M) command.				
OPERANDS	The following operands are supported: <i>pkginst</i> Specify the package instance, or list of instances for which request scripts will be created. The token <i>all</i> may be used to refer to all packages available on the source medium.				
EXIT STATUS	0 Successful completion. >0 An error occurred.				
ATTRIBUTES	See attributes(5) for descriptions of the following attributes: <table border="1"> <thead> <tr> <th>ATTRIBUTE TYPE</th><th>ATTRIBUTE VALUE</th></tr> </thead> <tbody> <tr> <td>Availability</td><td>SUNWcsu</td></tr> </tbody> </table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	Availability	SUNWcsu
ATTRIBUTE TYPE	ATTRIBUTE VALUE				
Availability	SUNWcsu				
SEE ALSO	pkginfo(1), pkgmk(1), pkgparam(1), pkgproto(1), pkgtrans(1), installf(1M), pkgadd(1M), pkgchk(1M), pkgrm(1M), removef(1M), admin(4), attributes(5) <i>Application Packaging Developer's Guide</i>				
NOTES	The -r option can be used to indicate a directory name as well as a filename. The directory name is used to create numerous response files, each sharing the name of the package with which it should be associated. This would be used, for example, when				

pkgask(1M)

you will be adding multiple interactive packages with one invocation of `pkgadd(1M)`. Each package would need a response file. To create multiple response files with the same name as the package instance, name the directory in which the files should be created and supply multiple instance names with the `pkgask` command. When installing the packages, you will be able to identify this directory to the `pkgadd(1M)` command.

If the default `admin` file is too restrictive, the administration file may need to be modified to allow for total non-interaction during a package installation. See `admin(4)` for details.

NAME	pkgchk – check package installation accuracy
SYNOPSIS	pkgchk [-l -acfnqv] [-i <i>file</i>] [-p <i>path...</i>] [-R <i>root_path</i>] [[-m <i>pkgmap</i> [-e <i>envfile</i>]] pkginst... -Y <i>category,category...</i>] pkgchk -d <i>device</i> [-l -fv] [-i <i>file</i>] [-M] [-p <i>path...</i>] [-V <i>fs_file</i>] [pkginst... -Y <i>category[,category...]</i>]
DESCRIPTION	pkgchk checks the accuracy of installed files or, by using the -l option, displays information about package files. pkgchk checks the integrity of directory structures and files. Discrepancies are written to standard error along with a detailed explanation of the problem. The first synopsis defined above is used to list or check the contents and/or attributes of objects that are currently installed on the system, or in the indicated pkgmap. Package names may be listed on the command line, or by default, the entire contents of a machine will be checked. The second synopsis is used to list or check the contents of a package which has been spooled on the specified device, but not installed. Note that attributes cannot be checked for spooled packages.
OPTIONS	The following options are supported: -a Audit the file attributes only and do not check file contents. Default is to check both. -c Audit the file contents only and do not check file attributes. Default is to check both. -d <i>device</i> Specify the device on which a spooled package resides. <i>device</i> can be a directory path name or the identifiers for tape, floppy disk, or removable disk (for example, /var/tmp or /dev/diskette). -e <i>envfile</i> Request that the package information file named as <i>envfile</i> be used to resolve parameters noted in the specified pkgmap file. -f Correct file attributes if possible. If used with the -x option, this option removes hidden files. When pkgchk is invoked with this option, it creates directories, named pipes, links, and special devices if they do not already exist. If the -d option calls out an uninstalled package, the -f option will only take effect if the package is in directory (not stream) format. All file attributes will be set to agree with the entries in the pkgmap file except that setuid, setgid, and sticky bits will not be set in the mode. -i <i>file</i> Read a list of path names from <i>file</i> and compare this list against the installation software database or the indicated pkgmap file. Path names which are not contained in <i>file</i> are not checked. -l List information on the selected files that make up a package. This option is not compatible with the -a, -c, -f, -g, and -v options.

pkgchk(1M)

	-m pkgmap	Check the package against the package map file, pkgmap.
	-M	Instruct pkgchk not to use the <i>\$root_path/etc/vfstab</i> file for determining the client's mount points. This option assumes the mount points are correct on the server and it behaves consistently with Solaris 2.5 and earlier releases.
	-n	Do not check volatile or editable files' contents. This should be used for most post-installation checking.
	-p <i>path</i>	Only check the accuracy of the path name or path names listed. <i>path</i> can be one or more path names separated by commas (or by white space, if the list is quoted).
	-q	Quiet mode. Do not give messages about missing files.
	-R <i>root_path</i>	Define the full name of a directory to use as the <i>root_path</i> . All files, including package system information files, are relocated to a directory tree starting in the specified <i>root_path</i> . The <i>root_path</i> may be specified when installing to a client from a server (for example, <i>/export/root/client1</i>).
	-v	Verbose mode. Files are listed as processed.
	-V <i>fs_file</i>	Specify an alternative <i>fs_file</i> to map the client's file systems. For example, used in situations where the <i>\$root_path/etc/vfstab</i> file is non-existent or unreliable.
	-x	Search exclusive directories, looking for files which exist that are not in the installation software database or the indicated pkgmap file.
	-Y <i>category</i>	Check packages based on the value of the CATEGORY parameter stored in the installed or spooled package's pkginfo(4) file.
OPERANDS	<i>pkginst</i>	The package instance or instances to be checked. The format <i>pkginst</i> . * can be used to check all instances of a package. The default is to display all information about all installed packages. The asterisk character (*) is a special character to some shells and may need to be escaped. In the C-Shell, "*" must be surrounded by single quotes (') or preceded by a backslash (\);
EXAMPLES	EXAMPLE 1 Using pkgchk for Displaying Package Installation Information The following example displays package installation information for <i>/usr/bin/ls</i>: <pre>example% pkgchk -l -p /usr/bin/ls</pre>	
EXIT STATUS	0	Successful completion.
	>0	An error occurred.

pkgchk(1M)

Application Packaging Developer's Guide

pkgrm(1M)

NAME	pkgrm – remove a package from the system
SYNOPSIS	<pre>pkgrm [-nv] [-a <i>admin</i>] [[-A -M] -R <i>root_path</i>] [-V <i>fs_file</i>] [pkginst... -Y <i>category</i> [, <i>category</i>...]] pkgrm -s <i>spool</i> [pkginst... -Y <i>category</i> [, <i>category</i>...]]</pre>
DESCRIPTION	pkgrm will remove a previously installed or partially installed package from the system. A check is made to determine if any other packages depend on the one being removed. If a dependency exists, the action taken is defined in the <i>admin</i> file. The default state for the command is in interactive mode, meaning that prompt messages are given during processing to allow the administrator to confirm the actions being taken. Non-interactive mode can be requested with the <i>-n</i> option. The <i>-s</i> option can be used to specify the directory from which spooled packages should be removed. Certain unbundled and third-party packages are no longer entirely compatible with the latest version of pkgrm. These packages require user interaction throughout the removal and not just at the very beginning. To remove these older packages (released prior to Solaris 2.4), set the following environment variable: <i>NONABI_SCRIPTS=TRUE</i> pkgrm permits keyboard interaction throughout the removal as long as this environment variable is set.
OPTIONS	The following options are supported: -a <i>admin</i> Use the installation administration file, <i>admin</i>, in place of the default <i>admin</i> file. pkgrm first looks in the current working directory for the administration file. If the specified administration file is not in the current working directory, pkgrm looks in the <i>/var/sadm/install/admin</i> directory for the administration file. -A Remove the package files from the client's file system, absolutely. If a file is shared with other packages, the default behavior is to not remove the file from the client's file system. -M Instruct pkgrm not to use the <i>\$root_path/etc/vfstab</i> file for determining the client's mount points. This option assumes the mount points are correct on the server and it behaves consistently with Solaris 2.5 and earlier releases. -n Non-interactive mode. If there is a need for interaction, the command will exit. Use of this option requires that at least one package instance be named upon invocation of the command. Certain conditions must exist for a package to be removed non-interactively or a non-restrictive <i>admin</i> file needs to be used.

	-R <i>root_path</i> Defines the full path name of a directory to use as the <i>root_path</i>. All files, including package system information files, are relocated to a directory tree starting in the specified <i>root_path</i>. -s <i>spool</i> Remove the specified package(s) from the directory <i>spool</i>. The default directory for spooled packages is <code>/var/sadm/pkg</code>. -v Trace all of the scripts that get executed by <code>pkgrm</code>, located in the <i>pkginst/install</i> directory. This option is used for debugging the procedural and non-procedural scripts. -V <i>fs_file</i> Specify an alternative <i>fs_file</i> to map the client's file systems. Used in situations where the <code>\$root_path/etc/vfstab</code> file is non-existent or unreliable. -Y <i>category</i> Remove packages based on the value of the <code>CATEGORY</code> parameter stored in the installed or spooled package's <code>pkginfo(4)</code> file. No package with the <code>CATEGORY</code> value of <code>system</code> can be removed from the file system with this option.														
OPERANDS	The following operand is supported: <i>pkginst</i> Specifies the package to be removed. The format <i>pkginst</i>.<code>*</code> can be used to remove all instances of a package. The asterisk character (<code>*</code>) is a special character to some shells and may need to be escaped. In the C-Shell, <code>"*"</code> must be surrounded by single quotes (<code>'</code>) or preceded by a backslash (<code>\</code>).														
EXAMPLES	EXAMPLE 1 Removing All instances of SUNWjunk From <code>client1</code> The following example removes all instances of SUNWjunk from <code>client1</code>: <pre>example% pkgrm -R /export/root/client1 SUNWjunk*</pre>														
EXIT STATUS	The following exit values are returned: <table> <tr> <td>0</td><td>Successful completion.</td></tr> <tr> <td>1</td><td>Fatal error.</td></tr> <tr> <td>2</td><td>Warning.</td></tr> <tr> <td>3</td><td>Interruption.</td></tr> <tr> <td>4</td><td>Administration.</td></tr> <tr> <td>10</td><td>Reboot after removal of all packages.</td></tr> <tr> <td>20</td><td>Reboot after removal of this package.</td></tr> </table>	0	Successful completion.	1	Fatal error.	2	Warning.	3	Interruption.	4	Administration.	10	Reboot after removal of all packages.	20	Reboot after removal of this package.
0	Successful completion.														
1	Fatal error.														
2	Warning.														
3	Interruption.														
4	Administration.														
10	Reboot after removal of all packages.														
20	Reboot after removal of this package.

Application Packaging Developer's Guide

NAME	pmadm – port monitor administration
SYNOPSIS	<pre>pmadm -a [-p <i>pmtag</i> -t <i>type</i>] -s <i>svctag</i> -i <i>id</i> -m <i>pmspecific</i> -v <i>ver</i> [-f <i>xu</i>] [-y <i>comment</i>] [-z <i>script</i>] pmadm -r -p <i>pmtag</i> -s <i>svctag</i> pmadm -e -p <i>pmtag</i> -s <i>svctag</i> pmadm -d -p <i>pmtag</i> -s <i>svctag</i> pmadm -l [-t <i>type</i> -p <i>pmtag</i>] [-s <i>svctag</i>] pmadm -L [-t <i>type</i> -p <i>pmtag</i>] [-s <i>svctag</i>] pmadm -g -p <i>pmtag</i> -s <i>svctag</i> [-z <i>script</i>] pmadm -g -s <i>svctag</i> -t <i>type</i> -z <i>script</i></pre>
DESCRIPTION	pmadm is the administrative command for the lower level of the Service Access Facility hierarchy, that is, for service administration. A port may have only one service associated with it although the same service may be available through more than one port. In order to uniquely identify an instance of a service, the pmadm command must identify both the port monitor or port monitors through which the service is available (-p or -t) and the service (-s). See OPTIONS. pmadm performs the following functions: ■ adds or removes a service ■ enables or disables a service ■ installs or replaces a per-service configuration script ■ prints requested service information Any user on the system may invoke pmadm to request service status (-l or -L) or to print per-service configuration scripts (-g without the -z option). pmadm with other options may be executed only by a privileged user.
OPTIONS	The following options are supported: -a Add a service. pmadm adds an entry for the new service to the port monitor's administrative file. Because of the complexity of the options and arguments that follow the -a option, it may be convenient to use a command script or the menu system to add services. -d Disable a service. Add x to the flag field in the entry for the service <i>svctag</i> in the port monitor's administrative file. This is the entry used by port monitor <i>pmtag</i>. See the -f option, below, for a description of the flags available. -e Enable a service. Remove x from the flag field in the entry for the service <i>svctag</i> in the port monitor administrative file. This is the entry used by port monitor <i>pmtag</i>. See the -f option, below, for a description of the flags available.

pmadm(1M)

-f xu	The -f option specifies one or both of the following two flags which are then included in the flag field of the entry for the new service in the port monitor's administrative file. If the -f option is not included, no flags are set and the default conditions prevail. By default, a new service is enabled and no utmpx entry is created for it. An -f option without a following argument is illegal. x Do not enable the service <i>svctag</i> available through port monitor <i>pmtag</i>. u Create a utmpx entry for service <i>svctag</i> available through port monitor <i>pmtag</i>.
-g	Print, install, or replace a per-service configuration script. The -g option with a -p option and a -s option prints the per-service configuration script for service <i>svctag</i> available through port monitor <i>pmtag</i>. The -g option with a -p option, a -s option, and a -z option installs the per-service configuration script contained in the file <i>script</i> as the per-service configuration script for service <i>svctag</i> available through port monitor <i>pmtag</i>. The -g option with a -s option, a -t option, and a -z option installs the file <i>script</i> as the per-service configuration script for service <i>svctag</i> available through any port monitor of type <i>type</i>. Other combinations of options with -g are invalid.
-i <i>id</i>	<i>id</i> is the identity that is to be assigned to service <i>svctag</i> when it is started. <i>id</i> must be an entry in <i>/etc/passwd</i>.
-l	The -l option requests service information. Used by itself and with the options described below, it provides a filter for extracting information in several different groupings. -l By itself, the -l option lists all services on the system. -l -p <i>pmtag</i> Lists all services available through port monitor <i>pmtag</i>. -l -s <i>svctag</i> Lists all services with tag <i>svctag</i>. -l -p <i>pmtag</i>-<i>svctag</i> Lists service <i>svctag</i>. -l -t <i>type</i> Lists all services available through port monitors of type <i>type</i>. -l -t <i>type</i>-<i>svctag</i> Lists all services with tag <i>svctag</i> available through a port monitor of type <i>type</i>. Other combinations of options with -l are invalid.
-L	The -L option is identical to the -l option except that output is printed in a condensed format.

-m <i>pmspecific</i>	<i>pmspecific</i> is the port monitor-specific portion of the port monitor administrative file entry for the service.
-p <i>pmtag</i>	Specifies the tag associated with the port monitor through which a service (specified as -s <i>svctag</i>) is available.
-r	Remove a service. When pmadm removes a service, the entry for the service is removed from the port monitor's administrative file.
-s <i>svctag</i>	Specifies the service tag associated with a given service. The service tag is assigned by the system administrator and is part of the entry for the service in the port monitor's administrative file.
-t <i>type</i>	Specifies the the port monitor type.
-v <i>ver</i>	Specifies the version number of the port monitor administrative file. The version number may be given as -v ' <i>pmspec</i> -V' where <i>pmspec</i> is the special administrative command for port monitor <i>pmtag</i> . This special command is ttyadm for ttymon and nlsadmin for listen. The version stamp of the port monitor is known by the command and is returned when <i>pmspec</i> is invoked with a -V option.
-y <i>comment</i>	Associate <i>comment</i> with the service entry in the port monitor administrative file.
-z <i>script</i>	Used with the -g option to specify the name of the file that contains the per-service configuration script. Modifying a configuration script is a three-step procedure. First a copy of the existing script is made (-g alone). Then the copy is edited. Finally, the copy is put in place over the existing script (-g with -z).

Options that request information write the requested information to the standard output. A request for information using the -l option prints column headers and aligns the information under the appropriate headings. In this format, a missing field is indicated by a hyphen. A request for information in the condensed format using the -L option prints the information in colon-separated fields; missing fields are indicated by two successive colons. # is the comment character.

EXAMPLES

EXAMPLE 1 Adding a Service to a Port Monitor with the Tag pmtag

The following command adds a service to a port monitor with tag pmtag and gives the service the tag svctag. The port monitor-specific information is generated by specpm. The service defined by svctag will be invoked with identity root.

```
pmadm -a -p pmtag -s svctag -i root -m 'specpm -a arg1 -b arg2' -v 'specpm -V'
```

pmadm(1M)

EXAMPLE 2 Adding a Service with Service Tag `svctag`

The following command adds a service with service tag `svctag`, identity `guest`, and port monitor-specific information generated by `specpm` to all port monitors of type `type`:

```
pmadm -a -s svctag -i guest -t type -m 'specpm -a arg1 -b arg2' -v 'specpm -V'
```

EXAMPLE 3 Removing a Service

The following command removes the service `svctag` from port monitor `pmtag`:

```
pmadm -r -p pmtag -s svctag
```

EXAMPLE 4 Enabling a Service

The following command enables the service `svctag` available through port monitor `pmtag`:

```
pmadm -e -p pmtag -s svctag
```

EXAMPLE 5 Disabling a Service

The following command disables the service `svctag` available through port monitor `pmtag`:

```
pmadm -d -p pmtag -s svctag
```

EXAMPLE 6 Listing Status Information

The following command lists status information for all services:

```
pmadm -l
```

EXAMPLE 7 Listing Status Information

The following command lists status information for all services available through the port monitor with tag `ports`:

```
pmadm -l -p ports
```

EXAMPLE 8 Listing Status Information in Condensed Format

The following command lists the status information for all services available through the port monitor with tag `ports` in condensed format:

```
pmadm -L -p ports
```

EXAMPLE 9

List status information for all services available through port monitors of type `listen`:

```
pmadm -l -t listen
```

EXAMPLE 10 Printing the per-service Configuration

The following command prints the per-service configuration script associated with the service `svctag` available through port monitor `pmtag`:

```
pmadm -g -p pmtag -s svctag
```

EXIT STATUS The following exit values are returned:

0 Successful operation.

>0 Operation failed.

FILES `/etc/saf/pmtag/_config`

`/etc/saf/pmtag/svctag`

`/var/saf/pmtag/*`

pmconfig(1M)

NAME	pmconfig – Configure the Power Management system									
SYNOPSIS	/usr/sbin/pmconfig [-r]									
DESCRIPTION	The pmconfig utility sets the Power Management and suspend-resume configuration. User has permission to change Power Management configuration using pmconfig only if he is allowed to do so according to PMCHANGEPERM keyword of /etc/default/power. User has permission to change the suspend-resume configuration using pmconfig only if he is allowed to do so according to the CPRCHANGEPERM keyword of /etc/default/power. See FILES section below for a description of the PMCHANGEPERM and CPRCHANGEPERM keywords of /etc/default/power. Based on user permissions, pmconfig first resets the Power Management and/or suspend-resume state back to its default and then reads the new Power Management and/or suspend-resume configuration from /etc/power.conf and issues the commands to activate the new configuration. The pmconfig utility is run at system boot. This utility can also be run from the command line after manual changes have been made to the /etc/power.conf file. For editing changes made to the /etc/power.conf file to take effect, users must run pmconfig. The preferred interface for changing Power Management and suspend-resume configuration is dtpower(1M).									
OPTIONS	The following options are supported: -r Reset Power Management and suspend-resume state to default and exit. User must have both Power Management and suspend-resume configuration permission for this option.									
EXIT STATUS	The following exit values are returned: <table><tr><td>0</td><td>Upon successful completion</td></tr><tr><td>>0</td><td>An error occurred</td></tr></table>		0	Upon successful completion	>0	An error occurred				
0	Upon successful completion									
>0	An error occurred									
FILES	<table><tr><td>/etc/power.conf</td><td>System Power Management configuration file</td></tr><tr><td>/etc/default/power</td><td>File that controls permissions for system’s Power Management and suspend-resume features. The PMCHANGEPERM keyword controls the Power Management configuration permissions, while the CPRCHANGEPERM keyword controls the suspend-resume configuration permissions.</td></tr></table> Allowed values are: <table><tr><td>all</td><td>Any user can change the configuration.</td></tr><tr><td>-</td><td>No one except super-user can change the configuration.</td></tr></table>	/etc/power.conf	System Power Management configuration file	/etc/default/power	File that controls permissions for system’s Power Management and suspend-resume features. The PMCHANGEPERM keyword controls the Power Management configuration permissions, while the CPRCHANGEPERM keyword controls the suspend-resume configuration permissions.	all	Any user can change the configuration.	-	No one except super-user can change the configuration.	
/etc/power.conf	System Power Management configuration file									
/etc/default/power	File that controls permissions for system’s Power Management and suspend-resume features. The PMCHANGEPERM keyword controls the Power Management configuration permissions, while the CPRCHANGEPERM keyword controls the suspend-resume configuration permissions.									
all	Any user can change the configuration.									
-	No one except super-user can change the configuration.									

`<user1, user2, ...>` A user in this user list or a super-user can change the configuration. The user list is a space and/or comma (,) separated list. You must enclose the list in `<` and `>` characters.

`console-owner` A user who owns the system console device node or a super-user can change the configuration.

The default values are `PMCHANGEPERM=console-owner` and `CPRCHANGEPERM=console-owner`.

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWpmu
Interface stability	Unstable

SEE ALSO `powerd(1M)`, `power.conf(4)`, `attributes(5)`, `cpr(7)`, `pm(7D)`

Using Power Management

DIAGNOSTICS If the program cannot open the configuration file, it prints an error message to standard error. If the program encounters a syntax error in the configuration file, it prints an error message and the line number of the error in the configuration file. It then skips the rest of the information on that line and processes the next line. Any configuration information already processed on the line containing the error is used. If user does not have permission to change Power Management and/or suspend-resume configuration, and configuration file has entries for which user doesn't have permission, it process the entries for which user has permissions and prints error on rest.

pntadm(1M)

NAME	pntadm – DHCP network table management utility
SYNOPSIS	pntadm -C [-r <i>resource</i>] [-p <i>path</i>] [-u <i>uninterpreted</i>] <i>network</i> pntadm -A <i>name_IP_address</i> [-c <i>comment</i>] [-e <i>mm/dd/yyyy</i>] [-f <i>num</i> <i>keywords</i>] [-h <i>client_hostname</i>] [-i [-a] <i>client_ID</i>] [-m [-y] <i>macro</i>] [-s <i>server</i>] [-r <i>resource</i>] [-p <i>path</i>] [-u <i>uninterpreted</i>] <i>network</i> pntadm -M <i>name_IP_address</i> [-c <i>comment</i>] [-e <i>mm/dd/yyyy</i>] [-f <i>num</i> <i>keywords</i>] [-h <i>client_hostname</i>] [-i [-a] <i>client_ID</i>] [-m [-y] <i>macro</i>] [-n <i>new_client_IP_address</i>] [-s <i>server</i>] [-r <i>resource</i>] [-p <i>path</i>] [-u <i>uninterpreted</i>] <i>network</i> pntadm -D <i>name_IP_address</i> [-y] [-r <i>resource</i>] [-p <i>path</i>] [-u <i>uninterpreted</i>] <i>network</i> pntadm -P [-v] [-x] [-r <i>resource</i>] [-p <i>path</i>] [-u <i>uninterpreted</i>] <i>network</i> pntadm -R [-r <i>resource</i>] [-p <i>path</i>] [-u <i>uninterpreted</i>] <i>network</i> pntadm -L [-r <i>resource</i>] [-p <i>path</i>] [-u <i>uninterpreted</i>] pntadm -B [-v] [<i>batchfile</i>]
DESCRIPTION	The pntadm command is used to manage the Dynamic Host Configuration Protocol (DHCP) network tables. It is used to add and remove networks under DHCP management, and add, delete, or modify IP address records within network tables, or to view tables. For a description of the format of DHCP network tables, see dhcp_network(4). pntadm can be run as root or by other users assigned to the DHCP Management profile. See rbac(5) and user_attr(4). If the networks you want to add are subnetted, you need to update the netmasks(4) table. One of the following options (function flags) must be specified with the pntadm command: -A, -B, -C, -D, -L, -M, -P, or -R.
OPTIONS	The following options are supported: -A <i>name_IP_address</i> Add a client entry with hostname or client IP address, <i>name_IP_address</i>, to the named DHCP network table. The following sub-options are optional: -c <i>comment</i> Comment text. The default is NULL. -e <i>mm/dd/yyyy</i> Absolute lease. The default is 0. -f <i>num</i> <i>keywords</i> Flag value. The default is 00.

The flag (-f) option can be specified either as a single number denoting the intended flag value, or as a series of the following keywords, combined using the plus (+) symbol:

DYNAMIC or 00

Server manager's assignment.

PERMANENT or 01

Lease on entry is permanent.

MANUAL or 02

Administrator managed assignment.

UNUSABLE or 04

Entry is not valid.

BOOTP or 08

Entry reserved for BOOTP clients.

For a more detailed description of the flag values, see `dhcp_network(4)`.

-h *client_hostname*

Client hostname. The default is NULL.

When the -h option is used in this mode, the *client_hostname* is added to the hosts table within the resource used for storing host names (files, NIS+ or DNS). The command will fail if this *client_hostname* is already present in the hosts table.

-i *client_ID* [-a]

Client identifier [-a]. The default is 00.

The -i option modified with -a specifies that the client identifier is in ASCII format, and thus needs to be converted to hexadecimal format before insertion into the table.

-m *macro* [-y]

Macro name. Default is UNKNOWN.

The -m option modified with -y verifies the existence of the named macro in the `dhcptab` table before adding the entry.

-s *server*

Server IP or name. Default is system name (uname -n).

-B

Activate batch mode. `pntadm` will read from the specified file or from standard input a series of `pntadm`

pntadm(1M)

	commands and execute them within the same process. Processing many pntadm commands using this method is much faster than running an executable batchfile itself. Batch mode is recommended for using pntadm in scripts. The following sub-option is optional: -v Display commands to standard output as they are processed.
-C	Create the DHCP network table for the network specified by <i>network</i>. See OPERANDS. For details, see dhcp_network(4) and networks(4).
-D <i>name_IP_address</i>	Delete the specified client entry with hostname or client IP address, <i>name_IP_address</i>, in the named DHCP network table. (See dhcp_network(4).) The following sub-option is optional: -y Remove associated host table entry. The -y option requests that all hostnames associated with the IP address in the hosts table in the resource be removed.
-L	List the DHCP network tables presently configured, one per line, on standard output. If none are found, no output is printed and an exit status of 0 is returned.
-M <i>name_IP_address</i>	Modify the specified client entry with hostname or client IP address, <i>name_IP_address</i>, in the named DHCP network table. See dhcp_network(4). The default for the sub-options is what they currently are set to. The following sub-options are optional. -c <i>comment</i> New comment text. -e <i>mm/dd/yy</i> New absolute lease expiration date. Time defaults to 12:00 AM of the day specified. -f <i>num keyboard</i> New flag value, see explanation following the description of the -A option. -h <i>host_name</i> New client hostname.

The `-h` option allows you to change the current *hostname* associated with the IP address or to add a new *hostname* to the hosts table if an entry associated with this IP address does not exist.

- `-i client_ID`
New client identifier [`-a`].
- `-m macro [-y]`
Macro name defined in `dhcptab`.
- `-n new_client_IP_address`
New IP address.
- `-s server`
New server IP or name.

For more detailed description of the sub-options and flag values, see `dhcp_network(4)`.

`-P`

Display the named DHCP network table.

The following sub-options are optional:

- `-v` Display lease time in full verbose format.
- `-x` Display lease time in raw format.

These flag codes are used with the `-P` sub-options:

<code>-v</code>	<code>-x</code>	Description
D	00	DYNAMIC
P	01	PERMANENT
M	02	MANUAL
U	04	UNUSABLE
B	08	BOOTP

See `dhcp_network(4)` for information on these sub-options and associated flag codes.

`-p path`

Override the `dhcpsvc.conf(4)` configuration value for data store resource path, *path* See `dhcpsvc.conf(4)`

`-R`

Remove the named DHCP network table. See `dhcp_network(4)`.

pntadm(1M)

<code>-r data_store_resource</code>	Override the <code>/etc/inet/dhcpsvc.conf</code> configuration value for <code>RESOURCE=</code> with the <code>data_store_resource</code> specified. See the <code>dhcpsvc.conf(4)</code> man page for more details on resource type, and the <i>Solaris DHCP Service Developer's Guide</i> for more information about adding support for other data stores.
<code>-u uninterpreted</code>	Data which will be ignored by <code>pntadm</code> , but passed to the currently configured public module to be interpreted by the data store. This might be used for a database account name or other authentication or authorization parameters required by a particular data store.

OPERANDS The following operand is supported:

<code>network</code>	The network address or network name which corresponds to the <code>dhcp_network</code> table. See <code>dhcp_network(4)</code> .

EXAMPLES **EXAMPLE 1** Creating a Table for the 10.0.0.0 DHCP Network

The following command creates a table for the 10.0.0.0 (subnetted to class C) DHCP network table. Note that if you have an alias for this network in your `networks(4)` table, you can use that value rather than the dotted Internet Address notation.

```
example# pntadm -C 10.0.0.0
```

EXAMPLE 2 Adding an Entry to the 10.0.0.0 Table

The following command adds an entry to the 10.0.0.0 table in the `files` resource in the `/var/mydhcp` directory:

```
example# pntadm -r SUNWfiles -p /var/mydhcp -A 10.0.0.1 10.0.0.0
```

EXAMPLE 3 Modifying the 10.0.0.1 Entry of the 10.0.0.0 Table

The following command modifies the 10.0.0.1 entry of the 10.0.0.0 table, changing the macro name to `Green`, setting the `flags` field to `MANUAL` and `PERMANENT`:

```
example# pntadm -M 10.0.0.1 -m Green -f 'PERMANENT + MANUAL' 10.0.0.0
```

EXAMPLE 4 Changing the 10.0.0.1 Entry to 10.0.0.2

The following command changes the 10.0.0.1 entry to 10.0.0.2, making an entry in the `hosts(4)` table called `myclient`:

```
example# pntadm -M 10.0.0.1 -n 10.0.0.2 -h myclient 10.0.0.0
```

EXAMPLE 5 Setting the Client ID as ASCII

The following command sets the client ID as ASCII `aruba.foo.com` for the `myclient` entry:

```
example# pntadm -M myclient -i 'aruba.foo.com' -a 10.0.0.0
```

EXAMPLE 6 Deleting the `myclientEntry` from the `10.0.0.0` Table

The following command deletes the `myclient (10.0.0.2)` entry from the `10.0.0.0` table:

```
example# pntadm -D myclient 10.0.0.0
```

EXAMPLE 7 Removing the Named DHCP Network Table

The following command removes the named DHCP network table in the NIS+ directory specified:

```
example# pntadm -r SUNWnisplus -p Test.Nis.Plus. -R 10.0.0.0
```

EXAMPLE 8 Listing the Configured DHCP Network Tables

The following command lists the configured DHCP network tables:

```
example# pntadm -L
192.168.0.0
10.0.0.0
```

EXAMPLE 9 Executing `pntadm` Commands in Batch Mode

The following command runs a series of `pntadm` commands contained in a batch file:

```
example# pntadm -B addclients
```

EXIT STATUS	0	Successful completion.
	1	Object already exists.
	2	Object does not exist.
	3	Non-critical error.
	4	Critical error.

pntadm(1M)

NAME	pooladm – activate and deactivate the resource pools facility
SYNOPSIS	<code>/usr/sbin/pooladm [-n] [-c <i>filename</i>] -x]</code>
DESCRIPTION	The <code>pooladm</code> command provides administrative operations on pools and sets. <code>pooladm</code> reads the specified <i>filename</i> and attempts to activate the pool configuration contained in it. Before updating the current pool run-time configuration, <code>pooladm</code> validates the configuration for correctness. Without options, <code>pooladm</code> prints out the current running pools configuration.
OPTIONS	The following options are supported: -c Instantiate the configuration at the given location. If a filename is not specified, it defaults to <code>/etc/pooladm.conf</code>. -n Validate the configuration without actually updating the current active files. -x Remove the currently active pool configuration. Destroy all defined resources, and return all formerly partitioned components to their default resources.
OPERANDS	The following operands are supported: <i>filename</i> Use the configuration contained within this file.
EXAMPLES	EXAMPLE 1 Instantiating a Configuration The following command instantiates the configuration contained at <code>/home/admin/newconfig</code>: <pre>example# /usr/sbin/pooladm -c /home/admin/newconfig</pre> EXAMPLE 2 Validating the Configuration Without Instantiating It The following command attempts to instantiate the configuration contained at <code>/home/admin/newconfig</code>. It displays any error conditions that it encounters, but does not actually modify the active configuration. <pre>example# /usr/sbin/pooladm -n -c /home/admin/newconfig</pre> EXAMPLE 3 Removing the Current Configuration The following command removes the current pool configuration: <pre>example# /usr/sbin/pooladm -x</pre>

System Administration Guide: Resource Management and Network Services

NOTES Resource bindings that are not presented in the form of a binding to a partitionable resource, such as the scheduling class, are not necessarily be modified in a pooladm -x operation.

NAME	poolbind – bind processes, tasks, or projects or query binding of processes to resource pools
SYNOPSIS	<pre>/usr/sbin/poolbind -p poolname [-i idtype] id... /usr/sbin/poolbind -q pid... /usr/sbin/poolbind -Q pid...</pre>
DESCRIPTION	The poolbind command allows an authorized user to bind projects, tasks, and processes to pools. It can also allow a user to query a process to determine which pool the process is bound to.
OPTIONS	The following options are supported: <i>-i idtype</i> This option, together with the <i>idlist</i> arguments, specifies one or more processes to which the poolbind command is to apply. The interpretation of <i>idlist</i> depends on the value of <i>idtype</i>. The valid <i>idtype</i> arguments and corresponding interpretations of <i>idlist</i> are as follows: <i>pid</i> <i>idlist</i> is a list of process IDs. Binds the specified processes to the specified pool. This is the default behavior if no <i>idtype</i> is specified. <i>taskid</i> <i>idlist</i> is a list of task IDs. Bind all processes within the list of task IDs to the specified pool. <i>projid</i> <i>idlist</i> is a list of project IDs. Bind all processes within the list of projects to the specified pool. Each project ID can be specified as either a project name or a numerical project ID. See <code>project(4)</code>. <i>-q pid ...</i> Queries the pool bindings for a given list of process IDs. If the collection of resources associated with the process does not correspond to any currently existing pool, or if there are multiple pools with the set of resources that the process is bound to, the query fails for that particular process ID. <i>-Q pid ...</i> Queries the resource bindings for a given list of process IDs. The resource bindings are each reported on a separate line.
OPERANDS	The following operands are supported: <i>poolname</i> The name of a pool to which the specified project, tasks or processes are to be bound.
EXAMPLES	EXAMPLE 1 Binding All Processes The following command binds all processes in projects 5 and 7 to pool web_app: <pre>example# /usr/sbin/poolbind -p web_app -i projid 5 7</pre>

poolbind(1M)

EXAMPLE 2 Binding the Running Shell

The following command binds the running shell to pool web_app:

```
example# /usr/sbin/poolbind -p web_app $$
```

EXAMPLE 3 Querying the Pool Bindings

The following command queries the bindings to verify that the shell is bound to the given pool:

```
example# /usr/sbin/poolbind -q $$
```

EXAMPLE 4 Querying the Resource Bindings

The following command queries the bindings to verify that the shell is bound to the given resources:

```
example# /usr/sbin/poolbind -Q $$
```

EXIT STATUS

The following exit values are returned:

- 0 Successful completion.
- 1 Requested operation could not be completed.
- 2 Invalid command line options were specified.

System Administration Guide: Resource Management and Network Services

NAME	poolcfg – create and modify resource pool configuration files													
SYNOPSIS	<pre>/usr/sbin/poolcfg -c <i>command filename</i></pre> <pre>/usr/sbin/poolcfg -f <i>command_file filename</i></pre> <pre>/usr/sbin/poolcfg -h</pre>													
DESCRIPTION	The <code>poolcfg</code> command provides configuration operations on pools and sets. These operations are performed upon an existing configuration and take the form of modifications to the specified configuration file. The special <code>discover</code> command does not require an existing configuration. Actual activation of the resulting configuration is achieved by way of the <code>pooladm(1M)</code> command. Pools configuration files are structured files that must have been constructed using <code>poolcfg</code> itself or <code>libpool(3LIB)</code> directly. The configurations which are created by this tool may be used by <code>pooladm</code> to instantiate the configuration upon a target host.													
OPTIONS	The following options are supported: <table><tr><td><code>-c <i>command</i></code></td><td>Specify <i>command</i> as an editing command. See <code>USAGE</code>.</td></tr><tr><td><code>-f <i>command_file</i></code></td><td>Take the commands from <i>command_file</i>. <i>command_file</i> consists of editing commands, one per line.</td></tr><tr><td><code>-h</code></td><td>Display extended information about the syntax of editing commands.</td></tr></table>		<code>-c <i>command</i></code>	Specify <i>command</i> as an editing command. See <code>USAGE</code> .	<code>-f <i>command_file</i></code>	Take the commands from <i>command_file</i> . <i>command_file</i> consists of editing commands, one per line.	<code>-h</code>	Display extended information about the syntax of editing commands.						
<code>-c <i>command</i></code>	Specify <i>command</i> as an editing command. See <code>USAGE</code> .													
<code>-f <i>command_file</i></code>	Take the commands from <i>command_file</i> . <i>command_file</i> consists of editing commands, one per line.													
<code>-h</code>	Display extended information about the syntax of editing commands.													
Scripts	A script consists of editing commands, one per line, of the following: <table><tr><td><code>info [<i>entity-name</i>]</code></td><td>Display configuration (or specified portion) in human readable form to standard output. If no entity is specified, system information is displayed. Therefore, <code>poolcfg -c 'info' afile</code> is an equivalent invocation to <code>poolcfg -c 'info system name' afile</code>.</td></tr><tr><td><code>create <i>entity-name</i> [<i>property-list</i>]</code></td><td>Make an entity of the specified type and name.</td></tr><tr><td><code>destroy <i>entity-name</i></code></td><td>Remove the specified entity.</td></tr><tr><td><code>modify <i>entity-name</i> [<i>property-list</i>]</code></td><td>Change the listed properties on the named entity.</td></tr><tr><td><code>associate <i>pool-name</i> [<i>resource-list</i>]</code></td><td>Connect one or more resources to a pool, or replace one or more existing connections.</td></tr><tr><td><code>discover</code></td><td>Create a system entity, with one pool entity and resources to match current system configuration. All discovered resources of each resource type are recorded in the file, with the single pool referring to the default resource for each resource type.</td></tr></table>		<code>info [<i>entity-name</i>]</code>	Display configuration (or specified portion) in human readable form to standard output. If no entity is specified, system information is displayed. Therefore, <code>poolcfg -c 'info' afile</code> is an equivalent invocation to <code>poolcfg -c 'info system name' afile</code> .	<code>create <i>entity-name</i> [<i>property-list</i>]</code>	Make an entity of the specified type and name.	<code>destroy <i>entity-name</i></code>	Remove the specified entity.	<code>modify <i>entity-name</i> [<i>property-list</i>]</code>	Change the listed properties on the named entity.	<code>associate <i>pool-name</i> [<i>resource-list</i>]</code>	Connect one or more resources to a pool, or replace one or more existing connections.	<code>discover</code>	Create a system entity, with one pool entity and resources to match current system configuration. All discovered resources of each resource type are recorded in the file, with the single pool referring to the default resource for each resource type.
<code>info [<i>entity-name</i>]</code>	Display configuration (or specified portion) in human readable form to standard output. If no entity is specified, system information is displayed. Therefore, <code>poolcfg -c 'info' afile</code> is an equivalent invocation to <code>poolcfg -c 'info system name' afile</code> .													
<code>create <i>entity-name</i> [<i>property-list</i>]</code>	Make an entity of the specified type and name.													
<code>destroy <i>entity-name</i></code>	Remove the specified entity.													
<code>modify <i>entity-name</i> [<i>property-list</i>]</code>	Change the listed properties on the named entity.													
<code>associate <i>pool-name</i> [<i>resource-list</i>]</code>	Connect one or more resources to a pool, or replace one or more existing connections.													
<code>discover</code>	Create a system entity, with one pool entity and resources to match current system configuration. All discovered resources of each resource type are recorded in the file, with the single pool referring to the default resource for each resource type.													

poolcfg(1M)

	rename <i>entity-name</i> to <i>new-name</i> Change the name of an entity on the system to its new name.
Property Lists	The property list is specified by: <pre>(proptype name = value [; proptype name = value]*)</pre> where the last definition in the sequence for a given proptype, name pair is the one that holds. For property deletion, use ~ proptype name.
Resource Lists	A resource list is specified by <pre>(resourcetype name [; resourcetype name]*)</pre> where the last specification in the sequence for a resource is the one that holds. There is no deletion syntax for resource lists.
Recognized Entities	system Machine level entity pool Named collection of resource associations
Resource Types	pset Processor set resource
Property Types	boolean Takes one of two values true or false. int A 64-bit signed integer value. uint A 64-bit unsigned integer value. string Strings are delimited by quotes ("), and support the character escape sequences defined in <code>formats(5)</code>. float Scientific notation is not supported.
EXAMPLES	EXAMPLE 1 Creating an Initial Configuration File The following command creates an initial configuration file for this host. By not supplying a file name, <code>/etc/pooladm.conf</code> is assumed. <pre>\$ poolcfg -c discover</pre> EXAMPLE 2 Creating an Initial Configuration File The following command creates an initial configuration file for this host and writes it to <code>/home/admin/new_config</code>: <pre>\$ poolcfg -c discover /home/admin/new_config</pre> EXAMPLE 3 Writing a poolcfg Script The following <code>poolcfg</code> script creates a pool named <code>Accounting</code>, and a processor set, <code>small-1</code>. The processor set is created first, then the pool is created and associated with the set.

EXAMPLE 3 Writing a poolcfg Script (Continued)

```
create pset small-1 ( uint pset.min = 1 ; uint pset.max = 4)
create pool Accounting
associate pool Accounting ( pset small-1 )
```

EXAMPLE 4 Reporting on pool_0

The following command reports on pool_0 to standard output in human readable form:

```
# poolcfg -c 'info pool pool_0' /etc/pooladm.conf
```

EXAMPLE 5 Destroying pool_0 and Its Associations

The following command destroys pool_0 and associations, but not the formerly associated resources:

```
# poolcfg -c 'destroy pool pool_0' /etc/pooladm.conf
```

EXAMPLE 6 Displaying the Current Configuration

The following command displays the current configuration:

```
$ poolcfg -c 'info' /etc/pooladm.conf
system muskoka
    int system.version 1
    boolean system.bind-default true
    string system.comment Discovered by libpool

    pool pool_default
        boolean pool.default true
        boolean pool.active true
        int pool.importance 5
        string pool.comment
        string pool.scheduler FSS
        pset pset_default

    pset pset_default
        int pset.sys_id -1
        string pset.units population
        boolean pset.default true
        uint pset.max 4294967295
        uint pset.min 1
        string pset.comment
        boolean pset escapable false
        uint pset.load 0
        uint pset.size 2

    cpu
        int cpu.sys_id 0
        string cpu.comment
```

poolcfg(1M)

EXAMPLE 6 Displaying the Current Configuration *(Continued)*

```
cpu
    int cpu.sys_id 2
    string cpu.comment
```

System Administration Guide: Resource Management and Network Services

NAME	ports – creates /dev entries and inittab entries for serial lines
SYNOPSIS	/usr/sbin/ports [-r <i>rootdir</i>]
DESCRIPTION	devfsadm(1M) is now the preferred command for /dev and /devices and should be used instead of ports. The ports command creates symbolic links in the /dev/term and /dev/cua directories to the serial-port character device files in /devices and adds new entries in /etc/inittab for non-system ports found. System-board ports are given single lower-case letters for names (such as a and b) while other ports are named numerically. ports searches the kernel device tree to find the serial devices attached to the system. It also checks /dev/term and /dev/cua to see what symbolic links to serial devices already exist. ports then performs the following: 1. Assigns new numbers (or letters for system-board ports) to ports that are attached to the system but do not have /dev/term and /dev/cua entries. The numbers or letters assigned are the lowest-unused numbers or letters. 2. Removes dangling links: links from /dev/term and /dev/cua pointing to no-longer-existing ports. 3. Creates new /dev/term and /dev/cua links for new serial devices. 4. Invokes sacadm(1M) to make new port monitor entries for the new devices. This is not done automatically for on-board ports; on workstations these ports are often not used for dial-in sessions, so a port-monitor for one of these ports must be created explicitly. If the configuration has not changed, ports exits without doing anything. ports is run each time a reconfiguration-boot is performed, or when add_drv(1M) is executed. When invoking ports manually, first run drvconfig(1M) to ensure /devices is consistent with the current device configuration.
Notice to Driver Writers	ports considers devices with a node type of DDI_NT_SERIAL, DDI_NT_SERIAL_MB, DDI_NT_SERIAL_DO, or DDI_NT_SERIAL_MB_DO to be serial port devices. Devices with one of these node types must create minor device names that obey the following conventions when calling ddi_create_minor_node(9F). ■ The minor name for non-system port devices (DDI_NT_SERIAL) consists of an ASCII numeric string, where the first port on the device is named 0, the second named 1, the third named 2, up to the number of ports provided by the device. ■ The minor name for non-system dialout devices (DDI_NT_SERIAL_DO) is the ASCII numeric port name, concatenated with ,cu. For example, the minor name for the first dialout port on the serial board is 0,cu. ■ The minor name for system-board port devices (DDI_NT_SERIAL_MB) consists of a string containing a single ASCII lowercase character, where the first port on the device is named a, the second is named b, the third is named c, for all ports on the

ports(1M)

device (or up through port z).

- The minor name for system-board dialout devices (DDI_NT_SERIAL_MB_DO) consists of the lowercase character port name, concatenated with , cu. For example, the minor name for the first dialout port on the on-board serial device is a, cu.

To prevent disks from attempting to automatically generate links for a device, drivers must specify a private node type and refrain from using one of the above node types when calling `ddi_create_minor_node(9F)`.

OPTIONS The following options are supported:

`-r rootdir` Causes ports to presume that the `/dev/term`, `/dev/cua`, and `/devices` directories are found under *rootdir*, not directly under `/`. If this argument is specified, `sacadm(1M)` is not invoked, since it would update terminal administration files under `/etc` without regard to the *rootdir*.

EXAMPLES **EXAMPLE 1** Creating the Serial and Dialout Minor Device Nodes

The following example creates the serial and dialout minor device nodes from the `xkserial` driver's `attach(9E)` function:

```
/*
 * Create the minor number by combining the instance number
 * with the port number.
 */ #define XKNUMPORTS      8
#define XKMINORNUM(i, p)  ((i) < 4 | (p))
#define XKMINORNUM_DO(i, p) ((i) < 4 | (p) | 0x80)
int
xkserialattach(dev_info_t *dip, ddi_attach_cmd_t cmd)
{
    int instance, portnum;
    char name[8];
    /* other stuff in attach... */
    instance = ddi_get_instance(dip);
    for (portnum = 0; portnum < XKNUMPORTS; portnum++) {
        /*
         * create the serial port device
         */
        sprintf(name, "%d", portnum);
        ddi_create_minor_node(dip, name, S_IFCHR,
            XKMINORNUM(instance, portnum), DDI_NT_SERIAL, 0);

        /*
         * create the dialout device
         */
        sprintf(name, "%d,cu", portnum);
        ddi_create_minor_node(dip, name, S_IFCHR,
            XKMINORNUM_DO(instance, portnum), DDI_NT_SERIAL_DO, 0);
    }
}
```

EXAMPLE 2 Installing the xkserial Port Driver on a SPARCstation 20

The following example installs the xkserial port driver on a SPARCstation 20 (with the driver controlling the fictional XKSerial 8 port serial board) and performs a reconfiguration-boot. It creates the following special files in /devices.

```
# ls -l /devices/iommu@f,e0000000/sbus@f,e0001000/xkserial@f,800000/
crw-r----- 1 root sys 32, 16 Aug 29 00:02 xkserial@2000:0
crw-r----- 1 root sys 32, 144 Aug 29 00:02 xkserial@2000:0,cu
crw-r----- 1 root sys 32, 17 Aug 29 00:02 xkserial@2000:1
crw-r----- 1 root sys 32, 145 Aug 29 00:02 xkserial@2000:1,cu
crw-r----- 1 root sys 32, 18 Aug 29 00:02 xkserial@2000:2
crw-r----- 1 root sys 32, 146 Aug 29 00:02 xkserial@2000:2,cu
crw-r----- 1 root sys 32, 19 Aug 29 00:02 xkserial@2000:3
crw-r----- 1 root sys 32, 147 Aug 29 00:02 xkserial@2000:3,cu
crw-r----- 1 root sys 32, 20 Aug 29 00:02 xkserial@2000:4
crw-r----- 1 root sys 32, 148 Aug 29 00:02 xkserial@2000:4,cu
crw-r----- 1 root sys 32, 21 Aug 29 00:02 xkserial@2000:5
crw-r----- 1 root sys 32, 149 Aug 29 00:02 xkserial@2000:5,cu
crw-r----- 1 root sys 32, 22 Aug 29 00:02 xkserial@2000:6
crw-r----- 1 root sys 32, 150 Aug 29 00:02 xkserial@2000:6,cu
crw-r----- 1 root sys 32, 23 Aug 29 00:02 xkserial@2000:7
crw-r----- 1 root sys 32, 151 Aug 29 00:02 xkserial@2000:7,cu
```

/dev/term contain symbolic links to the serial port device nodes in /devices

```
# ls -l /dev/term
/dev/term/0 -> ../../devices/[...]/xkserial@2000:0
/dev/term/1 -> ../../devices/[...]/xkserial@2000:1
/dev/term/2 -> ../../devices/[...]/xkserial@2000:2
/dev/term/3 -> ../../devices/[...]/xkserial@2000:3
/dev/term/4 -> ../../devices/[...]/xkserial@2000:4
/dev/term/5 -> ../../devices/[...]/xkserial@2000:5
/dev/term/6 -> ../../devices/[...]/xkserial@2000:6
/dev/term/7 -> ../../devices/[...]/xkserial@2000:7
```

and /dev/cua contain symbolic links to the dialout port device nodes in /devices

```
# ls -l /dev/cua
/dev/cua/0 -> ../../devices/[...]/xkserial@2000:0,cu
/dev/cua/1 -> ../../devices/[...]/xkserial@2000:1,cu
/dev/cua/2 -> ../../devices/[...]/xkserial@2000:2,cu
/dev/cua/3 -> ../../devices/[...]/xkserial@2000:3,cu
/dev/cua/4 -> ../../devices/[...]/xkserial@2000:4,cu
/dev/cua/5 -> ../../devices/[...]/xkserial@2000:5,cu
/dev/cua/6 -> ../../devices/[...]/xkserial@2000:6,cu
/dev/cua/7 -> ../../devices/[...]/xkserial@2000:7,cu
```

NAME	powerd – Power manager daemon						
SYNOPSIS	<code>/usr/lib/power/powerd [-n]</code>						
DESCRIPTION	The powerd daemon is started by pmconfig(1M) to monitor system activity and perform an automatic shutdown using the suspend-resume feature. When the system is suspended, complete current state is saved on the disk before power is removed. On reboot, the system automatically starts a resume operation and the system is restored to the same state it was in immediately prior to suspend. Immediately prior to system shutdown, the daemon notifies syslogd(1M) of the shutdown, which broadcasts a notification.						
OPTIONS	The following option is supported: <code>-n</code> No broadcast mode. The daemon silently shuts down the system without notifying syslogd(1M).						
FILES	<code>/etc/power.conf</code> Power Management configuration information file

pppd(1M)

NAME	pppd – point to point protocol daemon	
SYNOPSIS	pppd [<i>tty_name</i>] [<i>speed</i>] [<i>options</i>]	
DESCRIPTION	The point-to-point protocol (PPP) provides a method for transmitting datagrams over serial point-to-point links. PPP is composed of three components: a facility for encapsulating datagrams over serial links, an extensible link control protocol (LCP), and a family of network control protocols (NCP) for establishing and configuring different network-layer protocols. The encapsulation scheme is provided by driver code in the kernel. pppd provides the basic LCP authentication support and several NCPs for establishing and configuring the Internet Protocol (referred to as the IP Control Protocol or “IPCP”) and IPv6 (IPV6CP).	
OPTIONS	The following sections discuss the pppd options:	
Options Files	Options are taken from files and the command line. pppd reads options from the files <code>/etc/ppp/options</code>, <code>\$HOME/.ppprc</code> and <code>/etc/ppp/options.ttyname</code> (in that order) before processing the options on the command line. (Command-line options are scanned for the terminal name before the <code>options.ttyname</code> file is read.) To form the name of the <code>options.ttyname</code> file, the initial <code>/dev/</code> is removed from the terminal name, and any remaining forward slash characters (/) are replaced with dots. For example, with serial device <code>/dev/cua/a</code>, option file <code>/etc/ppp/options.cua.a</code> is read. An options file is parsed into a series of words that are delimited by whitespace. Whitespace can be included in a word by enclosing the word in double-quotes ("). A backslash (\) quotes the succeeding character. A hash (#) starts a comment, which continues until the end of the line. There is no restriction on using the <code>file</code> or <code>call</code> options within an options file.	
Frequently Used Options	<tty_name> <speed> asynctest <map>	Communicate over the named device. The string <code>/dev/</code> is prepended if necessary. If no device name is given, or if the name of the terminal connected to the standard input is given, pppd uses that terminal and does not fork to put itself in the background. A value for this option from a privileged source cannot be overridden by a non-privileged user. Set the baud rate to <speed> (a decimal number). The default is to leave the baud rate unchanged. This option is normally needed for dial-out only. Set the async character map to <map>. The map describes which control characters cannot be successfully received over the serial line. pppd asks the peer to send these characters as a 2-byte escape sequence. The argument is a 32 bit hex number, with each bit representing a character to escape. Bit 0

	(00000001) represents the character 0x00; bit 31 (80000000) represents the character 0x1f or ^_. If multiple <code>asyncmap</code> options are given, the values are ORed together. If no <code>asyncmap</code> option is given, <code>pppd</code> attempts to negotiate a value of 0. If the peer agrees, this disables escaping of the standard control characters. Use the <code>default-asyncmap</code> option to disable negotiation and escape all control characters.
<code>auth</code>	Require the peer to authenticate itself before allowing network packets to be sent or received. This option is the default if the system has a default route. If the <code>auth</code> or the <code>noauth</code> option is not specified, <code>pppd</code> allows the peer to use only those IP addresses to which the system does not already have a route.
<code>call name</code>	Read options from the file <code>/etc/ppp/peers/name</code> . This file may contain privileged options, including <code>noauth</code> , even if <code>pppd</code> is not being run by root. The <i>name</i> string may not begin with a slash ("/") or include consecutive periods (" . . ") as a pathname component.
<code>callback number</code>	Request a callback to the given telephone number using Microsoft CBCP.
<code>connect script</code>	Use the executable or shell command specified by <i>script</i> to set up the serial line. This script would typically use the <code>chat(1M)</code> program to dial the modem and start the remote PPP session. A value for this option originating from a privileged source cannot be overridden by a non-privileged user.
<code>crtcts</code>	Use hardware flow control, that is, RTS/CTS, to control the flow of data on the serial port. If the <code>crtcts</code> , <code>nocrtcts</code> , <code>cdtrcts</code> or <code>nocdtrcts</code> option is not provided, the hardware flow control setting for the serial port is left unchanged. Some serial ports lack a true RTS output and use this mode to implement unidirectional flow control. The serial port suspends transmission when requested by the modem by means of CTS but cannot request the modem to stop sending to the computer. This mode allows the use of DTR as a modem control line.
<code>defaultroute</code>	Add a default route to the system routing tables when IPCP negotiation successfully completes, using the peer as the gateway. This entry is removed when the PPP connection is broken. This option is privileged if the <code>nodefaultroute</code> option is specified.

pppd(1M)

<i>disconnect script</i>	Run the executable or shell command specified by <i>script</i> after pppd terminates the link. Typically, this script is used to command the modem to hang up if hardware modem control signals are not available. <i>disconnect</i> is not run if the modem has already hung up. A value for this option originating from a privileged source cannot be overridden by a non-privileged user.
<i>escape xx,yy,...</i>	Specifies that certain characters be escaped on transmission regardless of whether the peer requests them to be escaped with its <i>async</i> control character map. The characters to be escaped are specified as a list of hex numbers separated by commas. Note that almost any character can be specified for the <i>escape</i> option, unlike the <i>asyncmap</i> option which allows only control characters to be specified. Characters that cannot be escaped are those containing hex values 0x20 through 0x3f and 0x5e.
<i>file name</i>	Read options from file <i>name</i> . If this option is used on the command line or in <i>\$HOME/.ppprc</i> , the file must be readable by the user invoking pppd. See Options Files for a list of files that pppd always reads, regardless of the use of this option.
<i>init script</i>	Run the executable or shell command specified by <i>script</i> to initialize the serial line. This script would typically use the <i>chat(1M)</i> program to configure the modem to enable auto-answer. A value for this option from a privileged source cannot be overridden by a non-privileged user.
<i>lock</i>	Directs pppd to create a UUCP-style lock file for the serial device to ensure exclusive access to the device.
<i>mru n</i>	Set the Maximum Receive Unit (MRU) value to <i>n</i> . pppd asks the peer to send packets of no more than <i>n</i> bytes. Minimum MRU value is 128. Default MRU value is 1500. A value of 296 is recommended for slow links (40 bytes for TCP/IP header + 256 bytes of data). For IPv6, MRU must be at least 1280.
<i>mtu n</i>	Set the Maximum Transmit Unit (MTU) value to <i>n</i> . Unless the peer requests a smaller value via MRU negotiation, pppd requests the kernel networking code to send data packets of no more than <i>n</i> bytes through the PPP network interface. For IPv6, MTU must be at least 1280.

Options

<code>passive</code>	Enables the "passive" option in the LCP. With this option, pppd attempts to initiate a connection; if no reply is received from the peer, pppd waits passively for a valid LCP packet instead of exiting, as it would without this option.
<code><local_IP_address>:<remote_IP_address></code>	Set the local and/or remote interface IP addresses. Either one may be omitted, but the colon is required. The IP addresses are specified with a host name or in decimal dot notation, for example: <code>:10.1.2.3</code> . The default local address is the first IP address of the system unless the <code>noipdefault</code> option is provided. The remote address is obtained from the peer if not specified in any option. Thus, in simple cases, this option is not required. If a local and/or remote IP address is specified with this option, pppd will not accept a different value from the peer in the IPCP negotiation unless the <code>ipcp-accept-local</code> and/or <code>ipcp-accept-remote</code> options are given, respectively.
<code>allow-fcs fcs-type</code>	Set allowable FCS type(s) for data sent to the peer. The <i>fcs-type</i> is a comma-separated list of "crc16", "crc32", "null", or integers. By default, all known types are allowed. If this option is specified and the peer requests a type not listed, a LCP Configure-Nak is sent to request only the listed types.
<code>allow-ip address(es)</code>	Allow peers to use the given IP address or subnet without authenticating themselves. The parameter is parsed in the same manner as each element of the list of allowed IP addresses is parsed in the secrets files. See the Authentication section more more details.
<code>bsdcomp nr,nt</code>	Request that the peer compress packets that it sends using the BSD-Compress scheme, with a maximum code size of <i>nr</i> bits, and agree to compress packets sent to the peer with a maximum code size of <i>nt</i> bits. If <i>nt</i> is not specified, it defaults to the value given for <i>nr</i> . Values in the range 9 to 15 may be used for <i>nr</i> and <i>nt</i> ; larger values provide better compression but consume more kernel memory for compression dictionaries. Alternatively, a value of 0 for <i>nr</i> or <i>nt</i> disables compression in the corresponding direction. Use <code>nobsdcomp</code> or <code>bsdcomp 0</code> to disable BSD-Compress compression entirely. If this option is read from a privileged source, a nonprivileged user may not specify a code size larger than the value from the privileged source.
<code>cdtrcts</code>	Use a non-standard hardware flow control such as DTR/CTS to control the flow of data on the serial port. If the <code>crtsets</code> , <code>nocrtsets</code> , <code>cdtrcts</code> or <code>nocdtrcts</code> option is not specified, the hardware flow control setting for the serial port is left unchanged. Some serial ports lack a true RTS output. Such serial ports use this mode to implement true bi-directional flow control. Note that this flow control mode does not permit using DTR as a modem control line.
<code>chap-interval n</code>	If this option is given, pppd will rechallenge the peer every <i>n</i> seconds.

pppd(1M)

`chap-max-challenge n`

Set the maximum number of CHAP challenge transmissions to *n* (default 10).

`chap-restart n`

Set the CHAP restart interval (retransmission timeout for challenges) to *n* seconds. The default is 3.

`connect-delay n`

Wait for up to *n* milliseconds after the connect script finishes for a valid PPP packet from the peer. When the wait period elapses or when a valid PPP packet is received from the peer, `pppd` begins negotiation by sending its first LCP packet. The default value is 1000 (1 second). A wait period applies only if the `connect` or `pty` option is used.

`datarate n`

Set maximum data rate to *n* (in bytes per second) when using the `pty`, `notty`, `record`, or `socket` options.

`debug`

Enables connection debugging facilities. If this option is given, `pppd` logs the contents of all control packets sent or received in a readable form. The packets are logged through `syslog` with facility `daemon` and level `debug`. This information can be directed to a file by configuring `/etc/syslog.conf` appropriately.

`default-asynctest`

Disable `asynctest` negotiation, forcing all control characters to be escaped for both the transmit and the receive direction.

`default-fcs`

Disable FCS Alternatives negotiation entirely. By default, no FCS Alternatives option is sent to the peer, but the option is accepted. If this option is specified by the peer, then LCP Configure-Reject is sent.

`default-mru`

Disable MRU [Maximum Receive Unit] negotiation. With this option, `pppd` uses the default MRU value of 1500 bytes for the transmit and receive directions.

`deflate nr,nt,e`

Request that the peer compress packets that it sends, using the `deflate` scheme, with a maximum window size of 2^{*nr} bytes, and agree to compress packets sent to the peer with a maximum window size of 2^{*nt} bytes and effort level of *e* (1 to 9). If *nt* is not specified, it defaults to the value given for *nr*. If *e* is not specified, it defaults to 6. Values in the range 9 to 15 may be used for *nr* and *nt*; larger values provide better compression but consume more kernel memory for compression dictionaries. (Value 8 is not permitted due to a `zlib` bug.) Alternatively, a value of 0 for *nr* or *nt* disables compression in the corresponding direction. Use `nodeflate` or `deflate 0` to disable `deflate` compression entirely. (Note: `pppd` requests `deflate` compression in preference to `BSD-Compress` if the peer can do either.) If this option is read from a privileged source, a nonprivileged user may not specify a code size larger than the value from the privileged source.

demand

Initiate the link only on demand, that is, when data traffic is present. With this option, the remote IP address must be specified by the user on the command line or in an options file. `pppd` initially configures and enables the interface for IP traffic without connecting to the peer. When traffic is available, `pppd` connects to the peer and performs negotiation, authentication and other actions. When completed, `pppd` passes data packets across the link. The `demand` option implies the `persist` option. If this behavior is not desired, use the `nopersist` option after the `demand` option. The `idle` and `holdoff` options can be used in conjunction with the `demand` option.

domain *d*

Append the domain name *d* to the local host name for authentication purposes. For example, if `gethostname()` returns the name `porsche`, but the fully qualified domain name is `porsche.Quotron.COM`, you could specify `domain Quotron.COM`. With this configuration, `pppd` uses the name `porsche.Quotron.COM` for accessing secrets in the secrets file and as the default name when authenticating to the peer. This option is privileged.

endpoint *endpoint-value*

Set the endpoint discriminator (normally used for RFC 1990 Multilink PPP operation). The *endpoint-value* consists of a class identifier and a class-dependent value. The class identifier is one of "null," "local," "IP," "MAC," "magic," "phone," or a decimal integer. If present, the class-dependent value is separated from the identifier by a colon (":") or period ("."). This value may be a standard dotted-decimal IP address for class "IP," an optionally colon-or-dot separated hex Ethernet address for class "MAC" (must have 6 numbers), or an arbitrary string of bytes specified in hex with optional colon or dot separators between bytes. Although this option is available, this implementation does not support multilink.

fcs *fcs-type*

Set FCS type(s) desired for data sent by the peer. The *fcs-type* is a comma-separated list of `crc16`, `crc32`, `null`, or integers. By default, an FCS Alternatives option is not specified, and the medium-dependent FCS type is used. If this option is specified and the peer sends an LCP Configure-Nak, only the listed types are used. If none are in common, the FCS Alternatives option is omitted from the next LCP Configure-Request to drop back to the default.

hide-password

When logging the contents of PAP packets, this option causes `pppd` to exclude the password string from the log. This is the default.

holdoff *n*

Specifies how many seconds to wait before re-initiating the link after it terminates. This option is effective only if the `persist` or `demand` option is used. The `holdoff` period is not applied if the link is terminated because it was idle.

ident *string*

Set the LCP Identification string. The default value is a version string similar to that displayed by the `--version` option.

pppd(1M)

`idle n`
Specifies that pppd must disconnect if the link is idle for *n* seconds. The link is idle when no data packets (i.e. IP packets) are being sent or received. Do not use this option with the `persist` option but without the `demand` option.

`ipcp-accept-local`
With this option, pppd accepts the peer's idea of the local IP address, even if the local IP address is specified in an option.

`ipcp-accept-remote`
With this option, pppd accepts the peer's idea of its remote IP address, even if the remote IP address is specified in an option.

`ipcp-max-configure n`
Set the maximum number of IPCP Configure-Request transmissions to *n* (default 10).

`ipcp-max-failure n`
Set the maximum number of IPCP Configure-NAKs sent before sending Configure-Rejects instead to *n* (default 10).

`ipcp-max-terminate n`
Set the maximum number of IPCP terminate-request transmissions to *n* (default 3).

`ipcp-restart n`
Set the IPCP restart interval (retransmission timeout) to *n* seconds (default 3).

`ipparam string`
Provides an extra parameter to the ip-up and ip-down scripts. When this option is given, the *string* supplied is given as the sixth parameter to those scripts. See the Scripts section.

`ipv6 <local_interface_identifier>, <remote_interface_identifier>`
Set the local and/or remote 64-bit interface identifier. Either one may be omitted. The identifier must be specified in standard ASCII notation of IPv6 addresses (for example: ::dead:beef). If the `ipv6cp-use-ipaddr` option is given, the local and remote identifiers are derived from the respective IPv4 addresses (see above). The `ipv6cp-use-persistent` option can be used instead of the `ipv6 <local>, <remote>` option.

`ipv6cp-accept-local`
Accept peer's interface identifier for the local link identifier.

`ipv6cp-max-configure n`
Set the maximum number of IPv6CP Configure-Request transmissions to *n* (default 10).

`ipv6cp-max-failure n`
Set the maximum number of IPv6CP Configure-NAKs sent before sending Configure-Rejects instead to *n* (default 10).

`ipv6cp-max-terminate n`
Set the maximum number of IPv6CP terminate-request transmissions to *n* (default 3).

ipv6cp-restart *n*

Set the IPv6CP restart interval (retransmission timeout) to *n* seconds (default 3).

ipv6cp-use-ipaddr

If either the local or remote IPv6 address is unspecified, use the corresponding configured IPv4 address as a default interface identifier. (This option uses the configured addresses, not the negotiated addresses. Do not use it with `ipcp-accept-local` if the local IPv6 identifier is unspecified or with `ipcp-accept-remote` if the remote IPv6 identifier is unspecified.)

ipv6cp-use-persistent

Use uniquely-available persistent value for link local address.

kdebug *n*

Enable debugging code in the kernel-level PPP driver. Argument *n* is the sum of the following values: 1 to enable general debug messages, 2 to request that contents of received packets be printed, and 4 to request contents of transmitted packets be printed. Messages printed by the kernel are logged by `syslogd(1M)` to a file directed in the `/etc/syslog.conf` configuration file. Do not use the `kdebug` option to debug failed links. Use the `debug` option instead.

lcp-echo-failure *n*

If this option is given, `pppd` presumes the peer to be dead if *n* LCP Echo-Requests are sent without receiving a valid LCP Echo-Reply. If this happens, `pppd` terminates the connection. This option requires a non-zero value for the `lcp-echo-interval` parameter. This option enables `pppd` to terminate after the physical connection is broken (for example, if the modem has hung up) in situations where no hardware modem control lines are available.

lcp-echo-interval *n*

If this option is given, `pppd` sends an LCP Echo-Request frame to the peer every *n* seconds. Normally the peer responds to the Echo-Request by sending an Echo-Reply. This option can be used with the `lcp-echo-failure` option to detect that the peer is no longer connected.

lcp-max-configure *n*

Set the maximum number of LCP Configure-Request transmissions to *n* (default 10).

lcp-max-failure *n*

Set the maximum number of LCP Configure-NAKs sent before starting to send Configure-Rejects instead to *n* (default 10).

lcp-max-terminate *n*

Set the maximum number of LCP Terminate-Request transmissions to *n* (default 3).

lcp-restart *n*

Set the LCP restart interval (retransmission timeout) to *n* seconds (default 3).

pppd(1M)

linkname *name*

Sets the logical name of the link to *name*. pppd creates a file named `ppp-name.pid` in `/var/run` containing its process ID. This is useful in determining which instance of pppd is responsible for the link to a given peer system. This is a privileged option.

local

Do not use modem control lines. With this option, pppd ignores the state of the CD (Carrier Detect) signal from the modem and does not change the state of the DTR (Data Terminal Ready) signal.

logfd *n*

Send log messages to file descriptor *n*. pppd sends log messages to (at most) one file or file descriptor (as well as sending the log messages to syslog), so this option and the `logfile` option are mutually exclusive. By default pppd sends log messages to `stdout` (file descriptor 1) unless the serial port is open on `stdout`.

logfile *filename*

Append log messages to the file *filename* (and send the log messages to syslog). The file is opened in append mode with the privileges of the user who invoked pppd.

login

Use the system password database for authenticating the peer using PAP, and record the user in the system `wtmp` file. Note that the peer must have an entry in the `/etc/ppp/pap-secrets` file and the system password database to be allowed access.

maxconnect *n*

Terminate the connection after it has been available for network traffic for *n* seconds (that is, *n* seconds after the first network control protocol starts). An LCP Time-Remaining message is sent when the first NCP starts, and again when 5, 2, and 0.5 minutes are remaining.

maxfail *n*

Terminate after *n* consecutive failed connection attempts. A value of 0 means no limit. The default value is 10.

modem

Use the modem control lines. This option is the default. With this option, pppd waits for the CD (Carrier Detect) signal from the modem to be asserted when opening the serial device (unless a connect script is specified), and drops the DTR (Data Terminal Ready) signal briefly when the connection is terminated and before executing the connect script.

ms-dns <*addr*>

If pppd is acting as a server for Microsoft Windows clients, this option allows pppd to supply one or two DNS (Domain Name Server) addresses to the clients. The first instance of this option specifies the primary DNS address; the second instance (if given) specifies the secondary DNS address. If the first instance specifies a name that resolves to multiple IP addresses, then the first two addresses are used. (This option is present in some older versions of pppd under the name `dns-addr`.)

ms-lanman

If `pppd` connects as a client to a Microsoft server and uses MS-CHAPv1 for authentication, this option selects the LAN Manager password style instead of Microsoft NT.

ms-wins <addr>

If `pppd` acts as a server for Microsoft Windows or Samba clients, this option allows `pppd` to supply one or two WINS (Windows Internet Name Services) server addresses to the clients. The first instance of this option specifies the primary WINS address; the second instance (if given) specifies the secondary WINS address. As with `ms-dns`, if the name specified resolves to multiple IP addresses, then the first two will be taken as primary and secondary.

name *name*

Set the name of the local system for authentication purposes to *name*. This is a privileged option. With this option, `pppd` uses lines in the secrets files that have *name* as the second field to look for a secret to use in authenticating the peer. In addition, unless overridden with the `user` option, *name* is used as the name to send to the peer when authenticating the local system. (Note that `pppd` does not append the domain name to *name*.)

no-accm-test

Disable use of `asynctest` (ACCM) checking using LCP Echo-Request messages. If the `lcp-echo-failure` is used on an asynchronous line, `pppd` includes all control characters in the first *n* LCP Echo-Request messages. If the `asynctest` is set incorrectly, the link drops rather than continue operation with random failures. This option disables that feature.

noaccomp

Disable HDLC Address/Control compression in both directions (send and receive).

noauth

Do not require the peer to authenticate itself. This option is privileged.

nobsdcomp

Disables BSD-Compress compression; `pppd` will not request or agree to compress packets using the BSD-Compress scheme. This option is not necessary if `noccp` is specified.

noccp

Disable CCP (Compression Control Protocol) negotiation. This option should only be required if the peer has bugs or becomes confused by requests from `pppd` for CCP negotiation. If CCP is disabled, then BSD and deflate compression do not need to be separately disabled.

nocrtscts

Disable hardware flow control (i.e. RTS/CTS) on the serial port. If the `crtscts`, `nocrtscts`, `cdtrcts` or `nocdtrcts` options are not given, the hardware flow control setting for the serial port is left unchanged.

pppd(1M)

`nocdtrcts`

This option is a synonym for `nocrtscts`. Either option will disable both forms of hardware flow control.

`nodefaultroute`

Disable the `defaultroute` option. You can prevent non-root users from creating default routes with `pppd` by placing this option in the `/etc/ppp/options` file.

`nodeflate`

Disables deflate compression; `pppd` will not request or agree to compress packets using the deflate scheme. This option is not necessary if `noccp` is specified.

`nodeflatedraft`

Do not use Internet Draft (incorrectly assigned) algorithm number for deflate compression. This option is not necessary if `noccp` is specified.

`nodetach`

Do not detach from the controlling terminal. Without this option, `pppd` forks to become a background process if a serial device other than the terminal on the standard input is specified.

`noendpoint`

Do not send or accept the Multilink Endpoint Discriminator option.

`noident`

Disable use of LCP Identification. LCP Identification messages will not be sent to the peer, but received messages will be logged. (Specify this option twice to completely disable LCP Identification. In this case, `pppd` sends LCP Code-Reject in response to received LCP Identification messages.)

`noip`

Disable IPCP negotiation and IP communication. Use this option only if the peer has bugs or becomes confused by requests from `pppd` for IPCP negotiation.

`noipv6`

Disable IPv6CP negotiation and IPv6 communication. IPv6 is not enabled by default.

`noipdefault`

Disables the default behavior when no local IP address is specified, which is to determine (if possible) the local IP address from the hostname. With this option, the peer must supply the local IP address during IPCP negotiation (unless it specified explicitly on the command line or in an options file).

`nolog`

Do not send log messages to a file or file descriptor. This option cancels the `logfd` and `logfile` options. `nologfd` acts as an alias for this option.

`nomagic`

Disable magic number negotiation. With this option, `pppd` cannot detect a looped-back line. Use this option only if the peer has bugs. Do not use this option to work around the "Serial line is looped back" error message.

nopam

This privileged option disables use of pluggable authentication modules. If this option is specified, pppd reverts to standard authentication mechanisms. The default is not to use PAM.

nopcomp

Disable protocol field compression negotiation in the receive and the transmit direction.

nopersist

Exit once a connection has been made and terminated. This is the default unless the **persist** or **demand** option is specified.

noplunk

Cause pppd to use **L_LINK** instead of **L_PLINK**. This is the default. When **L_LINK** is used, the system cleans up terminated interfaces (even when **SIGKILL** is used) but does not allow **ifconfig(1M)** to unplumb PPP streams or insert or remove modules dynamically. Use the **plink** option if **ifconfig(1M)** **modinsert**, **modremove** or **unplumb** support is needed.

nopredictor1

Do not accept or agree to Predictor-1 compression. (This option is accepted for compatibility. The implementation does not support Predictor-1 compression.)

noproxyarp

Disable the **proxyarp** option. If you want to prevent users from creating proxy ARP entries with pppd, place this option in the `/etc/ppp/options` file.

notty

Normally, pppd requires a terminal device. With this option, pppd allocates itself a pseudo-tty master/slave pair and uses the slave as its terminal device. pppd creates a child process to act as a character shunt to transfer characters between the pseudo-tty master and its standard input and output. Thus, pppd transmits characters on its standard output and receives characters on its standard input even if they are not terminal devices. This option increases the latency and CPU overhead of transferring data over the ppp interface as all of the characters sent and received must flow through the character shunt process. An explicit device name may not be given if this option is used.

novj

Disable Van Jacobson style TCP/IP header compression in both the transmit and the receive direction.

novjccomp

Disable the connection-ID compression option in Van Jacobson style TCP/IP header compression. With this option, pppd does not omit the connection-ID byte from Van Jacobson compressed TCP/IP headers, nor does it ask the peer to do so. This option is unnecessary if **novj** is specified.

pppd(1M)

pam

This privileged option enables use of PAM. If this is specified, `pppd` uses the `pam(3PAM)` framework for user authentication with a service name of "ppp" if the `login` option and PAP authentication are used. The default is not to use PAM.

papcrypt

Indicates that `pppd` should not accept a password which, before encryption, is identical to the secret from the `/etc/ppp/pap-secrets` file. Use this option if the secrets in the `pap-secrets` file are in `crypt(3C)` format.

pap-max-authreq *n*

Set the maximum number of PAP authenticate-request transmissions to *n* (default 10).

pap-restart *n*

Set the PAP restart interval (retransmission timeout) to *n* seconds (default 3).

pap-timeout *n*

Set the maximum time that `pppd` waits for the peer to authenticate itself with PAP to *n* seconds (0= no limit). The default is 30 seconds.

password *string*

Password string for authentication to the peer.

persist

Do not exit after a connection is terminated; instead try to reopen the connection.

plink

Cause `pppd` to use `I_PLINK` instead of `I_LINK`. The default is to use `I_LINK`, which cleans up terminated interface (even if `SIGKILL` is used), but does not allow `ifconfig(1M)` to unplumb PPP streams or insert or remove modules dynamically. Use this option if `ifconfig(1M)` `modinsert/modremove/unplumb` support is needed. See also the `plumbed` option.

plugin *filename*

Load the shared library object file *filename* as a plugin. This is a privileged option. Unless the filename specifies an explicit path, `/etc/ppp/plugins` and `/usr/lib/inet/ppp` will be searched for the object to load in that order.

plumbed

This option indicates that `pppd` should find a plumbed interface and use that for the session. If IPv4 addresses or IPv6 interface IDs or link MTU are otherwise unspecified, they are copied from the interface selected. This mode mimics some of the functionality of the older `aspppd` implementation and may be helpful when `pppd` is used with external applications that use `ifconfig(1M)`.

pppmux *timer*

Enable PPP Multiplexing option negotiation and set transmit multiplexing timeout to *timer* microseconds.

privgroup *group-name*

Allows members of group *group-name* to use privileged options. This is a privileged option. Because there is no guarantee that members of *group-name* cannot use `pppd`

to become root themselves, you should be careful using this option. Consider it equivalent to putting the members of *group-name* in the *root* or *sys* group.

proxyarp

Add an entry to the system's Address Resolution Protocol (ARP) table with the IP address of the peer and the Ethernet address of this system. When you use this option, the peer appears to other systems to be on the local Ethernet. The remote address on the PPP link must be in the same subnet as assigned to an Ethernet interface.

pty *script*

Specifies that the command *script*, and not a specific terminal device is used for serial communication. pppd allocates itself a pseudo-tty master/slave pair and uses the slave as its terminal device. *script* runs in a child process with the pseudo-tty master as its standard input and output. An explicit device name may not be given if this option is used. (Note: if the *record* option is used in conjunction with the *pty* option, the child process will have pipes on its standard input and output.)

receive-all

With this option, pppd accepts all control characters from the peer, including those marked in the *receive asyncmap*. Without this option, pppd discards those characters as specified in *RFC 1662*. This option should be used only if the peer has bugs, as is often found with dial-back implementations.

record *filename*

Directs pppd to record all characters sent and received to a file named *filename*. *filename* is opened in append mode, using the user's user-ID and permissions. Because this option uses a pseudo-tty and a process to transfer characters between the pseudo-tty and the real serial device, it increases the latency and CPU overhead of transferring data over the PPP interface. Characters are stored in a tagged format with timestamps that can be displayed in readable form using the *pppdump(1M)* program. This option is generally used when debugging the kernel portion of pppd (especially CCP compression algorithms) and not for debugging link configuration problems. See the *debug* option.

remotename *name*

Set the assumed name of the remote system for authentication purposes to *name*. Microsoft WindowsNT does not provide a system name in its CHAP Challenge messages, and this option is often used to work around this problem.

refuse-chap

With this option, pppd will not agree to authenticate itself to the peer using standard Challenge Handshake Authentication Protocol (CHAP). (MS-CHAP is not affected.)

refuse-mschap

Do not agree to authenticate to peer with MS-CHAPv1. If this option is specified, requests for MS-CHAPv1 authentication from the peer are declined with LCP Configure-Nak. That option does not disable any other form of CHAP.

pppd(1M)

refuse-mschapv2

Do not agree to authenticate to peer with MS-CHAPv2. If specified, this option requests that MS-CHAPv2 authentication from the peer be declined with LCP Configure-Nak. That option does not disable any other form of CHAP.

refuse-pap

With this option, pppd will not agree to authenticate itself to the peer using Password Authentication Protocol (PAP).

require-chap

Require the peer to authenticate itself using standard CHAP authentication. MS-CHAP is not affected.

require-mschap

Require the peer to authenticate itself using MS-CHAPv1 authentication.

require-mschapv2

Require the peer to authenticate itself using MS-CHAPv2 authentication.

require-pap

Require the peer to authenticate itself using PAP authentication.

show-password

When logging contents of PAP packets, this option causes pppd to show the password string in the log message.

silent

With this option, pppd will not transmit LCP packets to initiate a connection until a valid LCP packet is received from the peer. This is like the “passive” option with older versions of pppd and is retained for compatibility, but the current *passive* option is preferred.

small-accm-test

When checking the *asynctest* (ACCM) setting, pppd uses all 256 possible values by default. See *no-accm-test*. This option restricts the test so that only the 32 values affected by standard ACCM negotiation are tested. This option is useful on very slow links.

socket *host:port*

Connect to given host and port using TCP and run PPP over this connection.

sync

Use synchronous HDLC serial encoding instead of asynchronous. The device used by pppd with this option must have sync support. Currently supports *zs*, *se*, and *hsi* drivers.

unit *n*

Set PPP interface unit number to *n*, if possible.

updetach

With this option, pppd detaches from its controlling terminal after establishing the PPP connection. When this is specified, messages sent to *stderr* by the connect script, usually *chat(1M)*, and debugging messages from the *debug* option are directed to pppd's standard output.

usehostname

Enforce the use of the hostname with domain name appended, if given, as the name of the local system for authentication purposes. This overrides the name option. Because the name option is privileged, this option is normally not needed.

usepeerdns

Ask the peer for up to two DNS server addresses. Addresses supplied by the peer, if any, are passed to the `/etc/ppp/ip-up` script in the environment variables DNS1 and DNS2. In addition, pppd creates an `/etc/ppp/resolv.conf` file containing one or two nameserver lines with the address(es) supplied by the peer.

user *name*

Sets the name used for authenticating the local system to the peer to *name*.

vj-max-slots *n*

Sets the number of connection slots to be used by the Van Jacobson TCP/IP header compression and decompression code to *n*, which must be between 2 and 16 (inclusive).

welcome *script*

Run the executable or shell command specified by *script* before initiating PPP negotiation, after the connect script, if any, has completed. A value for this option from a privileged source cannot be overridden by a non-privileged user.

xonxoff

Use software flow control, that is, XON/XOFF, to control the flow of data on the serial port.

Obsolete Options

The following options are obsolete:

+ua *name*

Read a PAP user name and password from the file *name*. This file must have two lines for name and password. Name and password are sent to the peer when the peer requests PAP authentication.

+ipv6

Enable IPv6 and IPv6CP without specifying interface identifiers.

--version

Show version number and exit.

--help

Show brief help message and exit.

**EXTENDED
DESCRIPTION**
Security

The following sections discuss miscellaneous features of pppd:

pppd allows system administrators to provide legitimate users with PPP access to a server machine without fear of compromising the security of the server or the network it runs on. Access control is provided by restricting IP addresses the peer may use based on its authenticated identity (if any), and through restrictions on options a non-privileged user may use. Options that permit potentially insecure configurations are privileged. Privileged options are accepted only in files that are under the control of the system administrator or when pppd is being run by root.

pppd(1M)

By default, `pppd` allows an unauthenticated peer to use a given IP address only if the system does not already have a route to that IP address. For example, a system with a permanent connection to the wider Internet will normally have a default route, meaning all peers must authenticate themselves to set up a connection. On such a system, the `auth` option is the default. Conversely, a system with a PPP link that comprises the only connection to the Internet probably does not possess a default route, so the peer can use virtually any IP address without authenticating itself.

Security-sensitive options are privileged and cannot be accessed by a non-privileged user running `pppd`, either on the command line, in the user's `$HOME/.ppprc` file, or in an options file read using the `file` option. Privileged options may be used in `/etc/ppp/options` file or in an options file read using the `call` option. If `pppd` is run by the root user, privileged options can be used without restriction. If the `/etc/ppp/options` file does not exist, then only root may invoke `pppd`. The `/etc/ppp/options` file must be created (but may be empty) to allow ordinary non-root users to access `pppd`.

When opening the device, `pppd` uses the invoking user's user ID or the root UID (that is, 0), depending if the device name was specified by the user or the system administrator. If the device name comes from a privileged source, that is, `/etc/ppp/options` or an options file read using the `call` option, `pppd` uses full root privileges when opening the device. Thus, by creating an appropriate file under `/etc/ppp/peers`, the system administrator can allow users to establish a PPP connection via a device that they would not normally have access to. Otherwise `pppd` uses the invoking user's real UID when opening the device.

Authentication

During the authentication process, one peer convinces the other of its identity by sending its name and some secret information to the other. During authentication, the first peer becomes the "client" and the second becomes the "server." Authentication names can (but are not required to) correspond to the peer's Internet hostnames.

`pppd` supports four authentication protocols: the Password Authentication Protocol (PAP) and three forms of the Challenge Handshake Authentication Protocol (CHAP). With the PAP protocol, the client sends its name and a cleartext password to the server to authenticate itself. With CHAP, the server initiates the authentication exchange by sending a challenge to the client who must respond with its name and a hash value derived from the shared secret and the challenge.

The PPP protocol is symmetrical, meaning that each peer may be required to authenticate itself to the other. Different authentication protocols and names can be used for each exchange.

By default, `pppd` authenticates if requested and does not require authentication from the peer. However, `pppd` does not authenticate itself with a specific protocol if it has no secrets that can do so.

pppd stores authentication secrets in the `/etc/ppp/pap-secrets` (for PAP), and `/etc/ppp/chap-secrets` (for CHAP) files. Both files use the same format. pppd uses secrets files to authenticate itself to other systems and to authenticate other systems to itself.

Secrets files contain one secret per line. Secrets are specific to a particular combination of client and server and can only be used by that client to authenticate itself to that server. Each line in a secrets file has a minimum of three fields that contain the client and server names followed by the secret. Often, these three fields are followed by IP addresses that are used by clients to connect to a server.

A secrets file is parsed into words, with client name, server name and secrets fields allocated one word each. Embedded spaces or other special characters within a word must be quoted or escaped. Case is significant in all three fields.

A secret beginning with an at sign ("`@`") is followed by the name of a file containing the secret. An asterisk (*) as the client or server name matches any name. When choosing a match, pppd selects the one with the fewest wildcards. Succeeding words on a line are interpreted by pppd as acceptable IP addresses for that client. IP Addresses are disallowed if they appear in lines that contain only three words or lines whose first word begins with a hyphen ("`-`"). To allow any address, use "`*`". An address starting with an exclamation point ("`!`") indicates that the specified address is not acceptable. An address may be followed by "`/`" and a number *n* to indicate a whole subnet (all addresses that have the same value in the most significant *n* bits). In this form, the address may be followed by a plus sign ("`+`") to indicate that one address from the subnet is authorized, based on the ppp network interface unit number in use. In this case, the host part of the address is set to the unit number, plus one.

When authenticating the peer, pppd chooses a secret with the peer's name in the first field of the secrets file and the name of the local system in the second field. The local system name defaults to the hostname, with the domain name appended if the `domain` option is used. The default can be overridden with the `name` option unless the `usehostname` option is used.

When authenticating to the peer, pppd first determines the name it will use to identify itself to the peer. This name is specified with the `user` option. If the `user` option is not used, the name defaults to the host name of the local system. pppd then selects a secret from the secrets file by searching for an entry with a local name in the first field and the peer's name in the second field. pppd will know the name of the peer if standard CHAP authentication is used because the peer will have sent it in the Challenge packet. However, if MS-CHAP or PAP is being used, pppd must determine the peer's name from the options specified by the user. The user can specify the peer's name directly with the `remotename` option. Otherwise, if the remote IP address was specified by a name, rather than in numeric form, that name will be used as the peer's name. If that fails, pppd uses the null string as the peer's name.

pppd(1M)

When authenticating the peer with PAP, the supplied password is compared with data in the secrets file. If the password and secret do not match, the password is encrypted using `crypt()` and checked against the secret again. If the `papcrypt` option is given, the first unencrypted comparison is omitted for better security, and entries must thus be in encrypted `crypt(3C)` form.

If the `login` option is specified, the username and password are also checked against the system password database. This allows you to set up the `pap-secrets` file to enable PPP access only to certain users, and to restrict the set of IP addresses available to users. Typically, when using the `login` option, the secret in `/etc/ppp/pap-secrets` would be `"`, which matches any password supplied by the peer. This makes having the same secret in two places unnecessary. When `login` is used, the `pam` option enables access control through `pam(3PAM)`.

Authentication must be completed before IPCP (or other network protocol) can be started. If the peer is required to authenticate itself and fails, `pppd` closes LCP and terminates the link. If IPCP negotiates an unacceptable IP address for the remote host, IPCP is closed. IP packets are sent or received only when IPCP is open.

To allow hosts that cannot authenticate themselves to connect and use one of a restricted set of IP addresses, add a line to the `pap-secrets` file specifying the empty string for the client name and secret.

Additional `pppd` options for a given peer may be specified by placing them at the end of the secrets entry, separated by two dashes (`—`). For example

```
peername servername secret ip-address -- novj
```

Routing

When IPCP negotiation is complete, `pppd` informs the kernel of the local and remote IP addresses for the PPP interface and creates a host route to the remote end of the link that enables peers to exchange IP packets. Communication with other machines generally requires further modification to routing tables and/or Address Resolution Protocol (ARP) tables. In most cases the `defaultroute` and/or `proxyarp` options are sufficient for this, but further intervention may be necessary. If further intervention is required, use the `/etc/ppp/ip-up` script or a routing protocol daemon.

To add a default route through the remote host, use the `defaultroute` option. This option is typically used for “client” systems; that is, end-nodes that use the PPP link for access to the general Internet.

In some cases it is desirable to use proxy ARP, for example on a server machine connected to a LAN, to allow other hosts to communicate with the remote host. `proxyarp` instructs `pppd` to look for a network interface on the same subnet as the remote host. That is, an interface supporting broadcast and ARP that is not a point-to-point or loopback interface and that is currently up. If found, `pppd` creates a permanent, published ARP entry with the IP address of the remote host and the hardware address of the network interface.

Scripts

When the demand option is used, the interface IP addresses are already set at the time when IPCP comes up. If pppd cannot negotiate the same addresses it used to configure the interface, it changes the interface IP addresses to the negotiated addresses. This may disrupt existing connections. Using demand dialing with peers that perform dynamic IP address assignment is not recommended.

pppd invokes scripts at various stages during processing that are used to perform site-specific ancillary processing. These scripts may be shell scripts or executable programs. pppd does not wait for the scripts to finish. The scripts are executed as root (with the real and effective user-id set to 0), enabling them to update routing tables, run privileged daemons, or perform other tasks. Be sure that the contents of these scripts do not compromise your system's security. pppd runs the scripts with standard input, output and error redirected to /dev/null, and with an environment that is empty except for some environment variables that give information about the link. The pppd environment variables are:

DEVICE	Name of the serial tty device.
IFNAME	Name of the network interface.
IPLOCAL	IP address for the link's local end. This is set only when IPCP has started.
IPREMOTE	IP address for the link's remote end. This is set only when IPCP has started.
PEERNAME	Authenticated name of the peer. This is set only if the peer authenticates itself.
SPEED	Baud rate of the tty device.
ORIG_UID	Real user-id of user who invoked pppd.
PPPLOGNAME	Username of the real user-id who invoked pppd. This is always set.

pppd also sets the following variables for the ip-down and auth-down scripts:

CONNECT_TIME	Number of seconds between the start of PPP negotiation and connection termination.
BYTES_SENT	Number of bytes sent at the level of the serial port during the connection.
BYTES_RCVD	Number of bytes received at the level of the serial port during the connection.
LINKNAME	Logical name of the link, set with the linkname option.

If they exist, pppd invokes the following scripts. It is not an error if they do not exist.

/etc/ppp/auth-up	Program or script executed after the remote system successfully authenticates itself. It is executed with five command-line arguments: interface-name

pppd(1M)

	peer-name user-name tty-device speed. Note that this script is not executed if the peer does not authenticate itself, for example, when the noauth option is used.
/etc/ppp/auth-down	Program or script executed when the link goes down if /etc/ppp/auth-up was previously executed. It is executed in the same manner with the same parameters as /etc/ppp/auth-up.
/etc/ppp/ip-up	A program or script that is executed when the link is available for sending and receiving IP packets (that is, IPCP has come up). It is executed with six command-line arguments: interface-name tty-device speed local-IP-address remote-IP-address ipparam.
/etc/ppp/ip-down	A program or script which is executed when the link is no longer available for sending and receiving IP packets. This script can be used for undoing the effects of the /etc/ppp/ip-up script. It is invoked in the same manner and with the same parameters as the ip-up script.
/etc/ppp/ipv6-up	Similar to /etc/ppp/ip-up, except that it is executed when the link is available for sending and receiving IPv6 packets. Executed with six command-line arguments: interface-name tty-device speed local-link-local-address remote-link-local-address ipparam.
/etc/ppp/ipv6-down	Similar to /etc/ppp/ip-down, but executed when IPv6 packets can no longer be transmitted on the link. Executed with the same parameters as the ipv6-up script.

EXAMPLES

EXAMPLE 1 Using the auth Option

The following examples assume that the /etc/ppp/options file contains the auth option.

pppd is commonly used to dial out to an ISP. You can do this using the “pppd call isp” command where the /etc/ppp/peers/isp file is set up to contain a line similar to the following:

```
cua/a 19200 crtscts connect '/usr/bin/chat -f /etc/ppp/chat-isp' noauth
```

For this example, chat(1M) is used to dial the ISP's modem and process any login sequence required. The /etc/ppp/chat-isp file is used by chat and could contain the following:

EXAMPLE 1 Using the auth Option (Continued)

```

ABORT "NO CARRIER"
ABORT "NO DIALTONE"
ABORT "ERROR"
ABORT "NO ANSWER"
ABORT "BUSY"
ABORT "Username/Password Incorrect"
"" "at"
OK "at&f&d2&c1"
OK "atdt2468135"
"name:" "^Umyuserid"
"word:" "\qmypassword"
"ispts" "\q^Uppp"
"^^^Uppp^^"

```

See the chat(1M) man page for details of chat scripts.

EXAMPLE 2 Using pppd with proxyarp

pppd can also provide a dial-in ppp service for users. If the users already have login accounts, the simplest way to set up the ppp service is to let the users log in to their accounts and run pppd as shown in the following example:

```
example% pppd proxyarp
```

EXAMPLE 3 Providing a User with Access to PPP Facilities

To provide a user with access to the PPP facilities, allocate an IP address for the user's machine, create an entry in /etc/ppp/pap-secrets or /etc/ppp/chap-secrets. This enables the user's machine to authenticate itself. For example, to enable user "Joe" using machine "joespc" to dial in to machine "server" and use the IP address "joespc.my.net," add the following entry to the /etc/ppp/pap-secrets or /etc/ppp/chap-secrets files:

```
joespc      server      "joe's secret"      joespc.my.net
```

Alternatively, you can create another username, for example "ppp," whose login shell is /usr/bin/pppd and whose home directory is /etc/ppp. If you run pppd this way, add the options to the /etc/ppp/.ppprc file.

If your serial connection is complex, it may be useful to escape such control characters as XON (^Q) and XOFF (^S), using `asynmap a0000`. If the path includes a telnet, escape ^] (`asynmap 200a0000`). If the path includes a `rlogin` command, add escape `ff` option to the options, because `rlogin` removes the window-size-change sequence [0xff, 0xff, 0x73, 0x73, followed by any 8 bytes] from the stream.

EXIT STATUS

The pppd exit status indicates errors or specifies why a link was terminated. Exit status values are:

pppd(1M)

- 0 pppd has detached or the connection was successfully established and terminated at the peer's request.
- 1 An immediately fatal error occurred. For example, an essential system call failed.
- 2 An error was detected in the options given. For example, two mutually exclusive options were used, or `/etc/ppp/options` is missing and the user is not root.
- 3 pppd is not `setuid-root` and the invoking user is not root.
- 4 The kernel does not support PPP. For example, the PPP kernel driver is not included or cannot be loaded.
- 5 pppd terminated because it was sent a SIGINT, SIGTERM or SIGHUP signal.
- 6 The serial port could not be locked.
- 7 The serial port could not be opened.
- 8 The connect script failed and returned a non-zero exit status.
- 9 The command specified as the argument to the `pty` option could not be run.
- 10 The PPP negotiation failed because no network protocols were able to run.
- 11 The peer system failed or refused to authenticate itself.
- 12 The link was established successfully, but terminated because it was idle.
- 13 The link was established successfully, but terminated because the connect time limit was reached.
- 14 Callback was negotiated and an incoming call should arrive shortly.
- 15 The link was terminated because the peer is not responding to echo requests.
- 16 The link was terminated by the modem hanging up.
- 17 The PPP negotiation failed because serial loopback was detected.
- 18 The init script failed because a non-zero exit status was returned.
- 19 Authentication to the peer failed.

FILES	<code>/var/run/spppn.pid</code>	Process-ID for pppd process on PPP interface unit <i>n</i> .
	<code>/var/run/ppp-name.pid</code>	Process-ID for pppd process for logical link name (see the <code>linkname</code> option).
	<code>/etc/ppp/pap-secrets</code>	Username, passwords and IP addresses for PAP authentication. This file should be

	owned by root and not readable or writable by any other user, otherwise pppd will log a warning.
/etc/ppp/chap-secrets	Names, secrets and IP addresses for all forms of CHAP authentication. The /etc/ppp/pap-secrets file should be owned by root should not readable or writable by any other user, otherwise, pppd will log a warning.
/etc/ppp/options	System default options for pppd, read before user default options or command-line options.
\$HOME/.ppprc	User default options, read before /etc/ppp/options.ttyname.
/etc/ppp/options.ttyname	System default options for the serial port in use; read after \$HOME/.ppprc. The ttyname component of this filename is formed when the initial /dev/ is stripped from the port name (if present), and slashes (if any) are converted to dots.
/etc/ppp/peers	Directory with options files that may contain privileged options, even if pppd was invoked by a user other than root. The system administrator can create options files in this directory to permit non-privileged users to dial out without requiring the peer to authenticate, but only to certain trusted peers.

NOTES

These signals affect pppd behavior:

SIGINT, SIGTERM	Terminate the link, restore the serial device settings and exit.
SIGHUP	Terminate the link, restore the serial device settings and close the serial device. If the <code>persist</code> or <code>demand</code> option is specified, pppd attempts to reopen the serial device and start another connection after the holdoff period. Otherwise pppd exits. If received during the holdoff period, SIGHUP causes pppd to end the holdoff period immediately.
SIGUSR1	Toggles the state of the debug option and prints link status information to the log.
SIGUSR2	Causes pppd to renegotiate compression. This is useful to re-enable compression after it has been disabled as a result of a fatal decompression error. (Fatal decompression errors generally indicate a bug in an implementation.)

DIAGNOSTICS

Messages are sent to the syslog daemon using facility LOG_DAEMON. To see error and debug messages, edit the `/etc/syslog.conf` file to direct the messages to the desired output device or file, or use the `updetach` or `logfile` options.

The debug option causes the contents of all LCP, PAP, CHAP or IPCP control packets sent or received to be logged. This is useful if PPP negotiation does not succeed or if authentication fails.

Debugging can also be enabled or disabled by sending a SIGUSR1 signal, which acts as a toggle to the pppd process.

NAME	pppoe – PPPoE chat utility								
SYNOPSIS	<pre>pppoe [-omillsecs] [-smillsecs] [-v] device [service [[except] server... [only]]] pppoe [-omillsecs] [-v] -i [device]</pre>								
DESCRIPTION	The pppoe utility implements the client-side negotiation of PPPoE. It is intended to be used with the pppd(1M) connect option, in the same manner as the chat(1M) utility is used for asynchronous dial-up PPP. When given with the <i>-i</i> flag, pppoe sends out a broadcast query on the given interface named by the <i>device</i> parameter. You can specify no other arguments in this mode. All responding PPPoE servers and the offered services are displayed on standard output. Otherwise, when given without the <i>-i</i> flag, pppoe does the full PPPoE client-side negotiation. The <i>device</i> parameter is the intended Ethernet interface, and must already be plumbed with sppptun(1M). The optional <i>service</i> parameter specifies a particular service desired; other offered services will be ignored. The optional <i>server</i> parameter specifies a specific server desired. You can specify <i>server</i> as an Ethernet address in the usual x:x:x:x:x:x format (with "*" in any of the six byte positions interpreted to mean "any"), or as a symbolic name resolved through <i>/etc/ethers</i> (or <i>NIS</i>), or as a PPPoE access concentrator name. The sense of the match (true or false) can be inverted by specifying the keyword <i>except</i> before this string. This parameter can be specified more than once, and the first match is taken. If you specify the <i>server</i> parameter, then the selected servers become "preferred." If no preferred server responds, then the first responding server is used instead. To exclude non-matching servers entirely, append the keyword <i>only</i>.								
OPTIONS	<table> <tr> <td><i>-i</i></td><td>Sends out broadcast query over interface specified by <i>device</i>.</td></tr> <tr> <td><i>-o</i></td><td>Sets the initial wait time in milliseconds for PADO from the server before PADI is retried. The default is 500 milliseconds for normal operation, or 3000 milliseconds (3 seconds) for inquiry (<i>-i</i>) mode.</td></tr> <tr> <td><i>-s</i></td><td>Sets the initial wait time in milliseconds for PADS from the server before PADR is retried. The default is 2000 milliseconds (2 seconds).</td></tr> <tr> <td><i>-v</i></td><td>Displays verbose progress messages, including all PPPoE messages sent, and all state machine transitions.</td></tr> </table> You normally do not need to adjust the parameters set with <i>-o</i> and <i>-s</i>. They are provided for coping with unusually slow servers.	<i>-i</i>	Sends out broadcast query over interface specified by <i>device</i> .	<i>-o</i>	Sets the initial wait time in milliseconds for PADO from the server before PADI is retried. The default is 500 milliseconds for normal operation, or 3000 milliseconds (3 seconds) for inquiry (<i>-i</i>) mode.	<i>-s</i>	Sets the initial wait time in milliseconds for PADS from the server before PADR is retried. The default is 2000 milliseconds (2 seconds).	<i>-v</i>	Displays verbose progress messages, including all PPPoE messages sent, and all state machine transitions.
<i>-i</i>	Sends out broadcast query over interface specified by <i>device</i> .								
<i>-o</i>	Sets the initial wait time in milliseconds for PADO from the server before PADI is retried. The default is 500 milliseconds for normal operation, or 3000 milliseconds (3 seconds) for inquiry (<i>-i</i>) mode.								
<i>-s</i>	Sets the initial wait time in milliseconds for PADS from the server before PADR is retried. The default is 2000 milliseconds (2 seconds).								
<i>-v</i>	Displays verbose progress messages, including all PPPoE messages sent, and all state machine transitions.								
OPERANDS	The following operands are supported: <table> <tr> <td><i>device</i></td><td>plumbed Ethernet interface</td></tr> </table>	<i>device</i>	plumbed Ethernet interface						
<i>device</i>	plumbed Ethernet interface								

pppoe(1M)

server preferred server or, if you specify only, the specified server

service desired service; other available services are ignored

EXAMPLES

EXAMPLE 1 Connecting to Any Service on hme0

The following command enables you to connect to any PPPoE service on hme0:

```
# /usr/bin/pppd sppptun plugin pppoe.so \
connect "/usr/lib/inet/pppoe hme0" debug
```

Often, a command such as the preceding is specified in an `/etc/ppp/peers` file instead. For example, enter the following in `/etc/ppp/peers/myisp`:

```
sppptun
plugin pppoe.so
connect "/usr/lib/inet/pppoe hme0"
debug
```

To invoke the PPP connection described in the file, enter:

```
% /usr/bin/pppd call myisp
```

Note that, because the `/etc/ppp/peers` files are considered privileged by `pppd`, you need not be root to invoke the preceding command.

EXAMPLE 2 Connecting to a Particular Service

A more complex example: on hme0, connect to only the internet service offered by PPPoE servers with access concentrator name `isp`, but not to any Ethernet addresses starting with `40:0:1a`.

```
# /usr/lib/inet/pppoe hme0 internet except 40:0:1a:*:*:* isp only
```

Note that the `except 40:0:1a:*:*:*` filter must come before `isp`, because the filters are first-match.

EXIT STATUS

The following exit values are returned:

```
0          Successful completion.
>0         An error occurred.
```

FILES

```
/usr/lib/inet/pppoe
    executable command

/dev/sppptun
    Solaris PPP tunneling device driver.

/etc/ppp/connect-errors
    usual location of error output (see DIAGNOSTICS, below)
```

ATTRIBUTES See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWpppd

SEE ALSO pppd(1M), sppptun(1M), pppoed(1M), sppptun(7M)

RFC 2516, Method for Transmitting PPP Over Ethernet (PPPoE), Mamakos et al, February 1999

DIAGNOSTICS Error messages are written to standard error, which is normally redirected by pppd to /etc/ppp/connect-errors. The errors can also be redirected to pppd's standard output by using the updetach option.

If you specify the -v, verbose progress messages are displayed, including all PPPoE messages sent, and all state machine transitions. Specifying the updetach or nodetach pppd option is helpful when using verbose mode.

pppoed(1M)

NAME	pppoed – PPPoE server daemon				
SYNOPSIS	pppoed [<i>options</i>]				
DESCRIPTION	The pppoed daemon implements the server-side negotiation of PPPoE. When a client requests service from this daemon, a copy of pppd(1M) is invoked to handle the actual PPP communication. At startup, options are read from the command line and the <code>/etc/ppp/pppoe</code> file. After these options have been read, options in the per-device <code>/etc/ppp/pppoe.device</code> files are read, using the device names specified on the command line or in <code>/etc/ppp/pppoe</code>. (Device names are not permitted in the per-device files.) It is not an error if any of these files are absent; missing files are ignored. Options are reread in the same order on <code>SIGHUP</code>. Except for the possibility of short delays due to the processing time, <code>SIGHUP</code> does not interfere with any client operations. Current status, including options read, is dumped to <code>/tmp/pppoed.pid</code> on <code>SIGINT</code>. The options are used to set up a list of services to be offered to PPPoE clients on the broadcast domains (Ethernet subnets) specified by the named devices. Option parsing is always in one of two modes, either global mode or service mode. The initial mode at the beginning of each file (and the command line) is global mode. Options specified in global mode serve as default values for subsequently defined services. Service mode is entered by the <code>service name</code> option. In this mode, the named option is defined. Options that appear in this mode override any global mode definitions for the current service. The option parsing follows standard shell tokenizing rules, using whitespace to delimit tokens, quotes to enclose strings that can contain whitespace, and escape sequences for special characters. Environment variables are substituted using familiar <code>\$VAR</code> and <code>\${VAR}</code> syntax and set using <code>NEWVAR=string</code>. Variables are both usable in subsequent options and provided to the pppd(1M) processes spawned for each client, but they are interpreted as they are encountered during option processing. Thus, all set variables are seen by all processes spawned; position in the configuration files has no effect on this.				
OPTIONS	The pppoed daemon supports the following options: <table><tr><td><code>client [except] client-list</code></td><td>This option restricts the clients that may receive the service. If the <code>except</code> keyword is given, then the clients on the list cannot access the service, but others can. If this keyword is not given, then only the listed clients can access the service.</td></tr><tr><td></td><td>This option can be specified more than once for a given service. For a given client, first match among all listed options encountered specifies the handling. If it</td></tr></table>	<code>client [except] client-list</code>	This option restricts the clients that may receive the service. If the <code>except</code> keyword is given, then the clients on the list cannot access the service, but others can. If this keyword is not given, then only the listed clients can access the service.		This option can be specified more than once for a given service. For a given client, first match among all listed options encountered specifies the handling. If it
<code>client [except] client-list</code>	This option restricts the clients that may receive the service. If the <code>except</code> keyword is given, then the clients on the list cannot access the service, but others can. If this keyword is not given, then only the listed clients can access the service.				
	This option can be specified more than once for a given service. For a given client, first match among all listed options encountered specifies the handling. If it				

	matches an option with <code>except</code> specified, then access is denied. Otherwise, it is granted. The <code>client</code> list within a service is prepended to any list specified in the global context. If no <code>client</code> options are given or if all options are specified with <code>except</code>, then all clients are permitted by default. If any <code>client</code> options without <code>except</code> are specified, then no clients are permitted by default. The <i>client-list</i> is a comma-separated list of client identifiers. The match is made if any client on the list matches; thus, these are logically "ORed" together. Each client identifier can be either a symbolic name (resolved through <code>/etc/ethers</code> or NIS, as defined by <code>/etc/nsswitch.conf</code>) or a hexadecimal Ethernet address in the format <code>x:x:x:x:x:x</code>. In the latter case, any byte of the address can be "*", which matches any value in that position. For example, <code>40:0:1a:*:*:</code> matches Ethernet adapters from the manufacturer assigned block <code>40:0:1a</code>.
debug	Increase debug logging detail level by one. The detail levels are 0 (no logging), 1 (errors only; the default), 2 (warnings), 3 (informational messages), and 4 (debug messages). Log messages are written by default to <code>syslog(3C)</code> using facility <i>daemon</i> (see the <code>log</code> option below). When specified on the command line or in the global context of the <code>/etc/ppp/pppoe</code> file, this option also sets the daemon's default (non-service-related) detail level.
device <i>device-list</i>	Specify the devices on which the service is available. The <i>device-list</i> is a comma-separated list of logical device names (without the leading <code>/dev/</code>), such as <code>hme0</code>. This option is ignored if encountered in the per-device <code>/etc/ppp/pppoe.device</code> files.
extra <i>string</i>	Specifies extra options to <code>pppd(1M)</code>. It defaults to <code>"plugin pppoe.so directtty"</code> and usually does not need to be overridden.
file <i>path</i>	Suspends parsing of the current file, returns to global mode, and reads options from <i>path</i>. This file must be present and readable; if it is not, an error is logged. When the end of that file is reached, processing returns to the current file and the mode is reset to global again.

pppoed(1M)

	The global mode options specified in files read by this command use the options set in the current file's global mode; this condition extends to any file included by those files. All files read are parsed as though the command line had specified this option, and thus inherit the command line's global modes. This option can be used to revert to global mode at any point in an option file by specifying <code>file /dev/null</code>.
<i>group name</i>	Specifies the group ID (symbolic or numeric) under which <code>pppd</code> is executed. If <code>pppoed</code> is not run as root, this option is ignored.
<i>log path</i>	Specifies an alternate debug logging file. Debug messages are sent to this file instead of <code>syslog</code> . The special name <code>syslog</code> is recognized to switch logging back to <code>syslog</code> . When specified on the command line or in the global context of the <code>/etc/ppp/pppoe</code> file, this option also sets the daemon's default (non-service-related) log file.
<i>nodebug</i>	Set debug logging detail level to 0 (no logging). When specified on the command line or in the global context of the <code>/etc/ppp/pppoe</code> file, this option also sets the daemon's default (non-service-related) detail level.
<i>nowildcard</i>	Specifies that the current service should not be included in response to clients requesting "any" service. The client must ask for this service by name. When specified on the command line or in the global context of the <code>/etc/ppp/pppoe</code> file, this option causes <code>pppoed</code> to ignore all wildcard service requests.
<i>path path</i>	Specifies the path to the <code>pppd</code> executable. Defaults to <code>/usr/bin/pppd</code> .
<i>pppd string</i>	Passes command-line arguments to <code>pppd</code> . It can be used to set the IP addresses or configure security for the session. The default value is the empty string.
<i>server string</i>	Specifies the PPPoE Access Concentrator name to be sent to the client. It defaults to "Solaris PPPoE".
<i>service name</i>	Closes any service being defined and begins definition of a new service. The same service name can be used without conflict on multiple devices. If the same service name is used on a single device, then the last definition encountered during parsing overrides all previous definitions.

<i>user name</i>	Specifies the user ID (symbolic or numeric) under which <code>pppd</code> is executed. If <code>pppoed</code> is not run as root, this option is ignored.
<i>wildcard</i>	Specifies that the service should be included in responses to client queries that request "any" service (which is done by requesting a service name of length zero). When specified on the command line or in the global context of the <code>/etc/ppp/pppoe</code> file, this option causes <code>pppoed</code> to ignore all wildcard service requests. This is the default.

EXAMPLES **EXAMPLE 1** Configuring for Particular Services

In the `/etc/ppp/pppoe` file:

```
service internet
  device $DEV
  pppd "proxyarp 192.168.1.1:"
service debugging
  device hme0,$DEV
  pppd "debug proxyarp 192.168.1.1:"
```

You then invoke the daemon with:

```
% /usr/lib/inet/pppoed DEV=le0
```

The lines in `/etc/ppp/pppoe` and the preceding command result in offering services "internet" and "debugging" (and responding to wildcard queries) on interface `le0`, and offering only service "debugging" on interface `hme0`.

SIGNALS The pppoed daemon responds to the following signals:

SIGHUP	Causes <code>pppoed</code> to reparse the original command line and all configuration files, and close and reopen any log files.
SIGINT	Causes a snapshot of the state of the <code>pppoed</code> daemon to be written to <code>/tmp/pppoed.pid</code> (where <i>pid</i> is the decimal process ID of the daemon).

FILES	<code>/usr/lib/inet/pppoed</code>	executable command
	<code>/dev/sppptun</code>	Solaris PPP tunneling device driver
	<code>/etc/ppp/pppoe</code>	main configuration option file
	<code>/etc/ppp/pppoe.device</code>	per-device configuration option file
	<code>/etc/ppp/pppoe-errors</code>	location of output from <code>pppd</code> 's stderr
	<code>/etc/ppp/pppoe.if</code>	list of Ethernet interfaces to be plumbed at boot time
	<code>/tmp/pppoed.pid</code>	ASCII text file containing dumped <code>pppoed</code> state information

pppoed(1M)

ATTRIBUTES

See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE

SEE ALSO

pppd(1M), pppoec(1M), sppptun(1M), sppptun(7M)

RFC 2516, Method for Transmitting PPP Over Ethernet (PPPoE), Mamakos et al, February 1999

NOTES

Because pppd is installed setuid root, this daemon need not be run as root. However, if it is not run as root, the user and group options are ignored.

The Ethernet interfaces to be used must be plumbed for PPPoE using the sppptun(1M) utility before services can be offered.

The daemon operate runs even if there are no services to offer. If you want to modify a configuration, it is not necessary to terminate the daemon. Simply use `kill -HUP pppoed` after updating the configuration files.

The PPPoE protocol is far from perfect. Because it runs directly over Ethernet, there is no possibility of security and the MTU is limited to 1492 (violating RFC 1661's default value of 1500). It is also not possible to run the client and the server of a given session on a single machine with a single Ethernet interface for testing purposes. The client and server portions of a single session must be run on separate Ethernet interfaces with different MAC addresses.

NAME	pppstats – print PPP statistics												
SYNOPSIS	pppstats [-a] [-v] [-r] [-z] [-c <count>] [-w <secs>] [<i>interface</i>]												
DESCRIPTION	The pppstats utility reports PPP-related statistics at regular intervals for the specified PPP interface. If the interface is unspecified, pppstats defaults to sppp0 . The display is split horizontally into input and output sections containing columns of statistics describing the properties and volume of packets received and transmitted by the interface.												
OPTIONS	The pppstats options are: -a Display absolute values rather than deltas. With this option, all reports show statistics for the time elapsed since the link was initiated. Without this option, the second and subsequent reports show statistics for the time since the last report. -c <i>count</i> Repeat the display <i>count</i> times. If this option is not specified, the default repeat count is 1 if the -w option is not specified, otherwise infinity. -r Display additional statistics summarizing the compression ratio achieved by the packet compression algorithm in use. -v Display additional statistics relating to the performance of the Van Jacobson TCP header compression algorithm. -w <i>wait</i> Pause <i>wait</i> seconds between each display. If this option is not specified, the default interval is five seconds. -z Instead of the standard display, show statistics indicating the performance of the packet compression algorithm in use.												
EXTENDED DESCRIPTION	The following fields are printed on the input side when the -z option is not used: <table> <tr> <td>IN</td><td>Total number of bytes received by this interface.</td></tr> <tr> <td>PACK</td><td>Total number of packets received by this interface.</td></tr> <tr> <td>VJCOMP</td><td>Number of header-compressed TCP packets received by this interface.</td></tr> <tr> <td>VJUNC</td><td>Number of header-uncompressed TCP packets received by this interface. Not reported when the -r option is specified.</td></tr> <tr> <td>VJERR</td><td>Number of corrupted or bogus header-compressed TCP packets received by this interface. Not reported when the -r option is specified.</td></tr> <tr> <td>VJTOSS</td><td>Number of VJ header-compressed TCP packets dropped on reception by this interface because of preceding errors. Only reported when the -v option is specified.</td></tr> </table>	IN	Total number of bytes received by this interface.	PACK	Total number of packets received by this interface.	VJCOMP	Number of header-compressed TCP packets received by this interface.	VJUNC	Number of header-uncompressed TCP packets received by this interface. Not reported when the -r option is specified.	VJERR	Number of corrupted or bogus header-compressed TCP packets received by this interface. Not reported when the -r option is specified.	VJTOSS	Number of VJ header-compressed TCP packets dropped on reception by this interface because of preceding errors. Only reported when the -v option is specified.
IN	Total number of bytes received by this interface.												
PACK	Total number of packets received by this interface.												
VJCOMP	Number of header-compressed TCP packets received by this interface.												
VJUNC	Number of header-uncompressed TCP packets received by this interface. Not reported when the -r option is specified.												
VJERR	Number of corrupted or bogus header-compressed TCP packets received by this interface. Not reported when the -r option is specified.												
VJTOSS	Number of VJ header-compressed TCP packets dropped on reception by this interface because of preceding errors. Only reported when the -v option is specified.												

pppstats(1M)

NON-VJ	Total number of non-TCP packets received by this interface. Only reported when the -v option is specified.
RATIO	Compression ratio achieved for received packets by the packet compression scheme in use, defined as the uncompressed size divided by the compressed size. Only reported when the -r option is specified.
UBYTE	Total number of bytes received, after decompression of compressed packets. Only reported when the -r option is specified.
The following fields are printed on the output side:	
OUT	Total number of bytes transmitted from this interface.
PACK	Total number of packets transmitted from this interface.
VJCOMP	Number of TCP packets transmitted from this interface with VJ-compressed TCP headers.
VJUNC	Number of TCP packets transmitted from this interface with VJ-uncompressed TCP headers. Not reported when the -r option is specified.
NON-VJ	Total number of non-TCP packets transmitted from this interface. Not reported when the -r option is specified.
VJSRCH	Number of searches for the cached header entry for a VJ header compressed TCP packet. Only reported when the -v option is specified.
VJMISS	Number of failed searches for the cached header entry for a VJ header compressed TCP packet. Only reported when the -v option is specified.
RATIO	Compression ratio achieved for transmitted packets by the packet compression scheme in use, defined as the size before compression divided by the compressed size. Only reported when the -r option is specified.
UBYTE	Total number of bytes to be transmitted before packet compression is applied. Only reported when the -r option is specified.
When the -z option is specified, pppstats displays the following fields relating to the packet compression algorithm currently in use. If packet compression is not in use, these fields display zeroes. The fields displayed on the input side are:	
COMPRESSED BYTE	Number of bytes of compressed packets received.
COMPRESSED PACK	Number of compressed packets received.

pppstats(1M)

INCOMPRESSIBLE BYTE	Number of bytes of incompressible packets (that is, those which were transmitted in uncompressed form) received.
INCOMPRESSIBLE PACK	Number of incompressible packets received.
COMP RATIO	Recent compression ratio for incoming packets, defined as the uncompressed size divided by the compressed size (including both compressible and incompressible packets).

The fields displayed on the output side are:

COMPRESSED BYTE	Number of bytes of compressed packets transmitted.
COMPRESSED PACK	Number of compressed packets transmitted.
INCOMPRESSIBLE BYTE	Number of bytes of incompressible packets received; that is, those that were transmitted by the peer in uncompressed form.
INCOMPRESSIBLE PACK	Number of incompressible packets transmitted.
COMP RATIO	Recent compression ratio for outgoing packets.

praudit(1M)

NAME	praudit – print contents of an audit trail file				
SYNOPSIS	praudit [-lrs] [-ddel] [filename...]				
DESCRIPTION	praudit reads the listed <i>filenames</i> (or standard input, if no <i>filename</i> is specified) and interprets the data as audit trail records as defined in <code>audit.log(4)</code> . By default, times, user and group IDs (UIDs and GIDs, respectively) are converted to their ASCII representation. Record type and event fields are converted to their ASCII representation. A maximum of 100 audit files can be specified on the command line.				
OPTIONS	The following options are supported: -ddel Use <i>del</i> as the field delimiter instead of the default delimiter, which is the comma. If <i>del</i> has special meaning for the shell, it must be quoted. The maximum size of a delimiter is four characters. -l Print one line per record. -r Print records in their raw form. Times, UIDs, GIDs, record types, and events are displayed as integers. This option and the -s option are exclusive. If both are used, a format usage error message is output. -s Print records in their short form. All numeric fields are converted to ASCII and displayed. The short ASCII representations for the record type and event fields are used. This option and the -r option are exclusive. If both are used, a format usage error message is output.				
FILES	/etc/security/audit_event /etc/security/audit_class

NAME	printmgr – Solaris Print Manager is a graphical user interface for managing printers in a network
SYNOPSIS	<code>/usr/sadm/admin/bin/printmgr</code>
DESCRIPTION	Solaris Print Manager is a Java-based graphical user interface that enables you to manage local and remote printer access. This tool can be used in the following name service environments: LDAP, NIS, NIS+, NIS+ with Federated Naming Service (FNS), and files. You must be logged in as superuser to use this tool. Using Solaris Printer Manager is the preferred method for managing printer access instead of <code>admintool:printers</code> because Solaris Print Manager centralizes printer information when it is used in a name service environment. Adding printer information to a name service makes access to printers available to all systems on the network and generally makes printer administration easier because all the information about printers is centralized. Solaris Print Manager may be run on a remote system with the display sent to the local system. See the <i>System Administration Guide: Advanced Administration</i> for instructions on setting the <code>DISPLAY</code> environment variable. Using Solaris Print Manager to perform printer-related tasks automatically updates the appropriate printer databases. Solaris Print Manager also includes a command-line console that displays the <code>lp</code> command line for the add, modify, and delete printer operations. Errors and warnings may also be displayed when Printer Manager operations are performed. Help is available by clicking the Help button.
USAGE	Solaris Print Manager enables you to do the following tasks: - Select a Name Service - Select a name service for retrieving or changing printer information. - Add Access to a Printer - Add printer access on a printer client using Solaris Print Manager. - Add an Attached Printer - After physically attaching the printer to a system, use Solaris Print Manager to install a local printer and make it available for printing. - Add a Network Printer - After physically attaching the printer to a system, use Solaris Print Manager to install a local printer and make it available for printing. - Modify Printer Properties - After adding access to a printer or adding an attached or network printer, you can modify certain printer attributes. - Delete a Printer - Delete access to a printer from the print client or delete a printer from the print server or from the name service environment.

printmgr(1M)

ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWppm

SEE ALSO

`ldap(1)`, `lpget(1M)`, `lpset(1M)`, `attributes(5)`

System Administration Guide: Advanced Administration

NOTES

Be mindful of the following if the LDAP database is used as the name service.

1. Because the domain information for the printer being updated is extracted from the `ldapclient(1M)` configuration, the LDAP server being updated must host the same domain that is used by the current `ldapclient(1M)` server.
2. If the LDAP server being updated is a replica LDAP server, the updates will be referred to the master LDAP server and completed there. The updates might be out of sync and not appear immediately, as the replica server may not have been updated by the master server. For example, a printer that you deleted by using `lpset` may still appear in the printer list you display with `lpget` until the replica is updated from the master. Replica servers vary as to how often they are updated from the master. See *System Administration Guide: Advanced Administration* for information on LDAP server replication.
3. Although users can use the LDAP command line utilities `ldapadd(1)` and `ldapmodify(1)` to update printer entries in the directory, the preferred method is to use `lpset`. Otherwise, if the `lpadd` and `lpmodify` utilities are used, the administrator must ensure that the `printer-name` attribute value is unique within the `ou=printers` container on the LDAP server. If the value is not unique, the result of modifications done using `lpset` or the Solaris Print Manager, `printmgr(1M)` may be unpredictable.

NAME	privatepw – administer FTP Server enhanced group access file
SYNOPSIS	privatepw [-c] [-f <i>ftpgroups</i>] [-g <i>real_group_name</i>] <i>accessgroup</i> privatepw -d [-f <i>ftpgroups</i>] <i>accessgroup</i> privatepw -l [-f <i>ftpgroups</i>] privatepw -v
DESCRIPTION	The <i>privatepw</i> utility is an administrative tool to add, delete and list enhanced access group information in the <i>ftpgroups</i> file. See <i>ftpgroups</i>(4). When <i>privatepw</i> is used without options, the help usage message is displayed. The <i>privatepw</i> utility prompts for a password when adding an enhanced access group entry or modifying an existing one.
OPTIONS	The following options are supported by the <i>privatepw</i> utility: -c Create a new <i>ftpgroups</i> file for the specified <i>accessgroup</i>. -d Delete information about the specified <i>accessgroup</i> from the <i>ftpgroups</i> file. -f <i>ftpgroups</i> Use the specified <i>ftpgroups</i> file for all updates. -g <i>group</i> Set the real system group to the <i>group</i> specified. <i>group</i> is a valid group name returned by <i>getgrnam</i>(3C). If the real system group is not supplied with the -g option when adding an enhanced access group entry, the <i>privatepw</i> utility prompts for it. -l List the contents of the <i>ftpgroups</i> file. -v Display program copyright and version information, then terminate.
OPERANDS	The following operands are supported: <i>accessgroup</i> The name of the enhanced access group to create or update. It consists of an arbitrary string of alphanumeric and punctuation characters. See <i>ftpgroups</i>(4).
EXIT STATUS	The following exit values are returned: 0 Successful completion. >0 An error occurred.

NAME	prodreg – GUI viewer for Solaris Product Registry								
SYNOPSIS	/usr/bin/prodreg [<i>subcommand</i>]								
DESCRIPTION	The prodreg command is the viewer for the Solaris Product Registry (ProdReg), a system for maintaining records of the software products installed on a given Solaris system.								
OPERANDS	The following operands are supported: <table> <tr> <td><i>subcommand</i></td><td>A ProdReg subcommand name. The subcommand name is optional; if omitted, it is equivalent to the swing subcommand.</td></tr> </table>	<i>subcommand</i>	A ProdReg subcommand name. The subcommand name is optional; if omitted, it is equivalent to the swing subcommand.						
<i>subcommand</i>	A ProdReg subcommand name. The subcommand name is optional; if omitted, it is equivalent to the swing subcommand.								
USAGE	The following subcommands are supported: <table> <tr> <td>swing</td><td>Starts up the viewer using the default Java 2, SDK, Standard Edition, Swing GUI. This is the same as prodreg with no arguments.</td></tr> <tr> <td>awt</td><td>Starts up the viewer using a Java AWT GUI.</td></tr> <tr> <td>help</td><td>Prints a usage message.</td></tr> <tr> <td>version</td><td>Prints the current version of the prodreg program.</td></tr> </table>	swing	Starts up the viewer using the default Java 2, SDK, Standard Edition, Swing GUI. This is the same as prodreg with no arguments.	awt	Starts up the viewer using a Java AWT GUI.	help	Prints a usage message.	version	Prints the current version of the prodreg program.
swing	Starts up the viewer using the default Java 2, SDK, Standard Edition, Swing GUI. This is the same as prodreg with no arguments.								
awt	Starts up the viewer using a Java AWT GUI.								
help	Prints a usage message.								
version	Prints the current version of the prodreg program.								
ENVIRONMENT VARIABLES	The following environment variable affects the operation of prodreg: <table> <tr> <td>PKG_INSTALL_ROOT</td><td>If present, defines the full path name of a directory to use as the system's PKG_INSTALL_ROOT path. All product and package information files are then looked for in the directory tree, starting with the specified PKG_INSTALL_ROOT path. If not present, the default system path of "/" is used.</td></tr> </table>	PKG_INSTALL_ROOT	If present, defines the full path name of a directory to use as the system's PKG_INSTALL_ROOT path. All product and package information files are then looked for in the directory tree, starting with the specified PKG_INSTALL_ROOT path. If not present, the default system path of "/" is used.						
PKG_INSTALL_ROOT	If present, defines the full path name of a directory to use as the system's PKG_INSTALL_ROOT path. All product and package information files are then looked for in the directory tree, starting with the specified PKG_INSTALL_ROOT path. If not present, the default system path of "/" is used.

projadd(1M)

NAME	projadd – administer a new project on the system
SYNOPSIS	projadd [-c <i>comment</i>] [-U <i>user</i> [, <i>user</i> ...]] [-G <i>group</i> [, <i>group</i> ...]] [-p <i>projid</i> [<i>projid</i> ...]] <i>project</i>
DESCRIPTION	projadd adds a new project entry to the /etc/project file. If the files backend is being used for the project database, the new project is available for use immediately upon the completion of the projadd command.
OPTIONS	The following options are supported: -c <i>comment</i> Add a project comment. Comments are stored in the project's entry in the /etc/project file. Generally, comments contain a short description of the project and are used as the field for the project's full name. - Specify <i>comment</i> as a text string. <i>comment</i> cannot contain a colon (:) or NEWLINE. -G <i>group</i> Make <i>group</i> a member group of project. - Specify <i>group</i> as a group ID or name. -o Enable duplication of a project ID. -p <i>projid</i> Set the project ID of the new project. - Specify <i>projid</i> as a non-negative decimal integer below UID_MAX as defined in limits.h. <i>projid</i> defaults to the next available unique number above the highest number currently assigned. For example, if <i>projids</i> 100, 105, and 200 are assigned, the next default <i>projid</i> is 201. <i>projids</i> between 0-99 are reserved by SunOS. -U Add the existing users (as specified either by user ID or name), to member users of project.
OPERANDS	The following operands are supported: <i>project</i> The name of the project to create. The <i>project</i> operand is a string consisting of characters from the set of alphabetic characters, numeric characters, underline (_), and hyphen (-). The period ('.') is reserved for projects with special meaning to the operating system. The first character of the project name must be a letter. A warning message is displayed if these restrictions are not met.
EXIT STATUS	The following exit values are returned: 0 Successful completion. 2 The command syntax was invalid. A usage message for projadd is displayed. 3 An invalid argument was provided to an option.

- 4 The *projid* given with the *-p* option is already in use.
- 5 The project files contain an error. See *project*(4).
- 6 The project to be modified, group, or user does not exist.
- 9 The project is already in use.
- 10 Cannot update the */etc/project* file.

FILES */etc/project* System project file

ATTRIBUTES See *attributes*(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWesu

SEE ALSO *projects*(1), *groupadd*(1M), *groupdel*(1M), *groupmod*(1M), *grpchk*(1M), *projdel*(1M), *projmod*(1M), *useradd*(1M), *userdel*(1M), *usermod*(1M), *project*(4), *attributes*(5)

NOTES In case of an error, *projadd* prints an error message and exits with a non-zero status.

projadd adds a project definition only on the local system. If a network name service such as NIS or LDAP is being used to supplement the local */etc/project* file with additional entries, *projadd* cannot change information supplied by the network name service.

projdel(1M)

NAME	projdel – delete a project from the system				
SYNOPSIS	projdel <i>project</i>				
DESCRIPTION	The projdel utility deletes a project from the system and makes the appropriate changes to the system file.				
OPERANDS	The following operands are supported: <i>project</i> The name of the project to be deleted.				
EXIT STATUS	The following exit values are returned: 0 Successful completion. 2 The command syntax was invalid. A usage message for projdel is displayed. 3 An invalid argument was provided to an option. 4 The <i>projid</i> given with the -p option is already in use. 5 The project files contain an error. See project(4) . 6 The project to be modified, group, or user does not exist. 9 The project is already in use. 10 Cannot update the /etc/project file.				
FILES	/etc/project System project file				
ATTRIBUTES	See attributes(5) for descriptions of the following attributes: <table><thead><tr><th>ATTRIBUTE TYPE</th><th>ATTRIBUTE VALUE</th></tr></thead><tbody><tr><td>Availability</td><td>SUNWesu</td></tr></tbody></table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	Availability	SUNWesu
ATTRIBUTE TYPE	ATTRIBUTE VALUE				
Availability	SUNWesu				
SEE ALSO	projects(1) , groupadd(1M) , groupdel(1M) , groupmod(1M) , grpchk(1M) , logins(1M) , projadd(1M) , projmod(1M) , useradd(1M) , userdel(1M) , usermod(1M) , project(4) , attributes(5)				
DIAGNOSTICS	In case of an error, projdel prints an error message and exits with a non-zero status.				
NOTES	projdel deletes a project definition only on the local system. If a network name service such as NIS or LDAP is being used to supplement the local /etc/project file with additional entries, projdel cannot change information supplied by the network name service.				

NAME	projmod – modify a project’s information on the system
SYNOPSIS	projmod [-p <i>projid</i> [-o] [-a -r]] [-U <i>user</i> [, <i>user</i> ...]] [-G <i>group</i> [, <i>group</i> ...]] [-c <i>comment</i>] [-l <i>new_projectname</i>] <i>project</i>
DESCRIPTION	The projmod utility modifies a project’s definition on the system. projmod changes the definition of the specified project and makes the appropriate project-related system file and file system changes.
OPTIONS	The following options are supported: -c <i>comment</i> Specify <i>comment</i> as a text string. Generally, <i>comment</i> contains a short description of the project. This information is stored in the project’s <code>/etc/project</code> entry. -G <i>group</i> [,<i>group</i>...] Specify a replacement list of member groups of the project, or with -a or -r, a list of groups to be added or removed from the project. -l <i>new_projectname</i> Specify the new project name for the project. The <i>new_projectname</i> argument is a string consisting of characters from the set of alphabetic characters, numeric characters, period (.), underline (_), and hyphen (-). The first character should be alphabetic. A warning message is written if these restrictions are not met. -o This option allows the specified project ID to be duplicated (non-unique). -a This option specifies that the users or groups specified by the -U or -G flags should be added to the project, rather than replacing the existing member list. -r This option specifies that the users or groups specified by the -U or -G flags should be removed from the project, rather than replacing the existing member list. -p <i>projid</i> Specify a new project ID for the project. It must be a non-negative decimal integer less than MAXUID as defined in <code>param.h</code>. -U <i>user</i> [,<i>user</i>...] Specify a replacement list of member users of the project, or with -a or -r, a list of users to be added or removed from the project.
OPERANDS	The following operands are supported: <i>project</i> An existing project name to be modified.
EXIT STATUS	In case of an error, projmod prints an error message and exits with one of the following values:

projmod(1M)

The following exit values are returned:

0	Successful completion.
2	The command syntax was invalid. A usage message for <code>projmod</code> is displayed.
3	An invalid argument was provided to an option.
4	The <i>projid</i> given with the <code>-p</code> option is already in use.
5	The project files contain an error. See <code>project(4)</code> .
6	The project to be modified, group, or user does not exist.
9	The project is already in use.
10	Cannot update the <code>/etc/project</code> file.

FILES	<code>/etc/group</code>	System file containing group definitions
	<code>/etc/project</code>	System project file
	<code>/etc/passwd</code>	System password file
	<code>/etc/shadow</code>	System file containing users' encrypted passwords and related information

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWesu

SEE ALSO `groupadd(1M)`, `groupdel(1M)`, `groupmod(1M)`, `projadd(1M)`, `projdel(1M)`, `useradd(1M)`, `userdel(1M)`, `usermod(1M)`, `passwd(4)`, `project(4)`, `attributes(5)`

NOTES The `projmod` utility modifies project definitions only in the local `/etc/project` file. If a network name service such as NIS or LDAP is being used to supplement the local files with additional entries, *projmod* cannot change information supplied by the network name service. However `projmod` verifies the uniqueness of project name and project ID against the external name service.

NAME	prstat – report active process statistics
SYNOPSIS	prstat [-acJLmRtTv] [-C <i>psrsetlist</i>] [-j <i>projlist</i>] [-k <i>tasklist</i>] [-n <i>ntop</i> [, <i>nbottom</i>]] [-p <i>pidlist</i>] [-P <i>cpulist</i>] [-s <i>key</i> -S <i>key</i>] [-u <i>euidlist</i>] [-U <i>uidlist</i>] [<i>interval</i> [<i>count</i>]]
DESCRIPTION	The prstat utility iteratively examines all active processes on the system and reports statistics based on the selected output mode and sort order. prstat provides options to examine only processes matching specified PIDs, UIDs, CPU IDs, and processor set IDs. The -j, -k, -C, -p, -P, -u, and -U options accept lists as arguments. Items in a list can be either separated by commas or enclosed in quotes and separated by commas or spaces. If you do not specify an option, prstat examines all processes and reports statistics sorted by CPU usage.
OPTIONS	The following options are supported: -a Report information about processes and users. In this mode prstat displays separate reports about processes and users at the same time. -c Print new reports below previous reports instead of overprinting them. -C <i>psrsetlist</i> Report only processes or lwps that are bound to processor sets in the given list. Each processor set is identified by an integer as reported by psrset(1M). The load averages displayed are the sum of the load averages of the specified processor sets (see pset_getloadavg(3C)). -j <i>projlist</i> Report only processes or lwps whose project ID is in the given list. Each project ID can be specified as either a project name or a numerical project ID. See project(4). -J Report information about processes and projects. In this mode prstat displays separate reports about processes and projects at the same time. -k <i>tasklist</i> Report only processes or lwps whose task ID is in <i>tasklist</i>. -L Report statistics for each light-weight process (LWP). By default, prstat reports only the number of LWPs for each process. -m Report microstate process accounting information. In addition to all fields listed in -v mode, this mode also

prstat(1M)

	includes the percentage of time the process has spent processing system traps, text page faults, data page faults, waiting for user locks and waiting for CPU (latency time).
<code>-n ntop[,nbottom]</code>	Restrict number of output lines. The <i>ntop</i> argument determines how many lines of process or lwp statistics are reported, and the <i>nbottom</i> argument determines how many lines of user, task, or projects statistics are reported if the <code>-a</code> , <code>-t</code> , <code>-T</code> , or <code>-J</code> options are specified. By default, <code>prstat</code> displays as many lines of output that fit in a window or terminal. When you specify the <code>-c</code> option or direct the output to a file, the default values for <i>ntop</i> and <i>nbottom</i> are 15 and 5.
<code>-p pidlist</code>	Report only processes whose process ID is in the given list.
<code>-P cpulist</code>	Report only processes or lwps which have most recently executed on a CPU in the given list. Each CPU is identified by an integer as reported by <code>psrinfo(1M)</code> .
<code>-R</code>	Put <code>prstat</code> in the real time scheduling class. When this option is used, <code>prstat</code> is given priority over time-sharing and interactive processes. This option is available only for superuser.
<code>-s key</code>	Sort output lines (that is, processes, lwps, or users) by <i>key</i> in descending order. Only one <i>key</i> can be used as an argument. There are five possible key values: <code>cpu</code> Sort by process CPU usage. This is the default. <code>pri</code> Sort by process priority. <code>rss</code> Sort by resident set size. <code>size</code> Sort by size of process image. <code>time</code> Sort by process execution time.
<code>-S key</code>	Sort output lines by <i>key</i> in ascending order. Possible <i>key</i> values are the same as for the <code>-s</code> option. See <code>-s</code> .

	-t	Report total usage summary for each user. The summary includes the total number of processes or LWPs owned by the user, total size of process images, total resident set size, total cpu time, and percentages of recent cpu time and system memory.
	-T	Report information about processes and tasks. In this mode <code>prstat</code> displays separate reports about processes and tasks at the same time.
	-u <i>euidlist</i>	Report only processes whose effective user ID is in the given list. Each user ID may be specified as either a login name or a numerical user ID.
	-U <i>uidlist</i>	Report only processes whose real user ID is in the given list. Each user ID may be specified as either a login name or a numerical user ID.
	-v	Report verbose process usage. This output format includes the percentage of time the process has spent in user mode, in system mode, and sleeping. It also includes the number of voluntary and involuntary context switches, system calls and the number of signals received. Statistics that are not reported are marked with the - sign.
OUTPUT	The following list defines the column headings and the meanings of a <code>prstat</code> report:	
	PID	The process ID of the process.
	USERNAME	The real user (login) name or real user ID.
	SIZE	The total virtual memory size of the process, including all mapped files and devices, in kilobytes (K), megabytes (M), or gigabytes (G). The resident set size of the process (RSS), in kilobytes (K), megabytes (M), or gigabytes (G).
	STATE	The state of the process: cpuN Process is running on CPU N. sleep Sleeping: process is waiting for an event to complete. run Runnable: process in on run queue. zombie Zombie state: process terminated and parent not waiting. stop Process is stopped.

prstat(1M)

PRI	The priority of the process. Larger numbers mean higher priority.
NICE	Nice value used in priority computation. Only processes in certain scheduling classes have a nice value.
TIME	The cumulative execution time for the process.
CPU	The percentage of recent CPU time used by the process.
PROCESS	The name of the process (name of executed file).
LWPID	The lwp ID of the lwp being reported.
NLWP	The number of lwps in the process.

The following columns are displayed when the -v or -m option is specified

USR	The percentage of time the process has spent in user mode.
SYS	The percentage of time the process has spent in system mode.
TRP	The percentage of time the process has spent in processing system traps.
TFL	The percentage of time the process has spent processing text page faults.
DFL	The percentage of time the process has spent processing data page faults.
LCK	The percentage of time the process has spent waiting for user locks.
SLP	The percentage of time the process has spent sleeping.
LAT	The percentage of time the process has spent waiting for CPU.
VCX	The number of voluntary context switches.
ICX	The number of involuntary context switches.
SCL	The number of system calls.
SIG	The number of signals received.

Under the -l option, one line is printed for each lwp in the process and some reporting fields show the values for the lwp, not the process.

OPERANDS The following operands are supported:

<i>count</i>	Specifies the number of times that the statistics are repeated. By default, <code>prstat</code> reports statistics until a termination signal is received.
<i>interval</i>	Specifies the sampling interval in seconds; the default interval is 5 seconds.

EXAMPLES **EXAMPLE 1** Reporting the Five Most Active Super-User Processes

The following command reports the five most active super-user processes running on CPU1 and CPU2:

EXAMPLE 1 Reporting the Five Most Active Super-User Processes (Continued)

```
example% prstat -u root -n 5 -P 1,2 1 1
```

```
PID  USERNAME  SIZE  RSS STATE PRI  NICE      TIME  CPU PROCESS/LWP
306   root    3024K 1448K sleep  58   0    0:00.00 0.3% sendmail/1
102   root    1600K  592K sleep  59   0    0:00.00 0.1% in.rdisc/1
250   root    1000K  552K sleep  58   0    0:00.00 0.0% utmpd/1
288   root    1720K 1032K sleep  58   0    0:00.00 0.0% sac/1
  1   root     744K  168K sleep  58   0    0:00.00 0.0% init/1
TOTAL:          25, load averages:  0.05, 0.08, 0.12
```

EXAMPLE 2 Displaying Verbose Process Usage Information

The following command displays verbose process usage information about processes with lowest resident set sizes owned by users root and john.

```
example% prstat -S rss -n 5 -vc -u root,john
```

```
PID USERNAME USR SYS TRP TFL DFL LCK SLP LAT VCX ICX SCL SIG PROCESS/LWP
  1 root      0.0 0.0 - - - - - 100 - 0 0 0 0 init/1
102 root      0.0 0.0 - - - - - 100 - 0 0 3 0 in.rdisc/1
250 root      0.0 0.0 - - - - - 100 - 0 0 0 0 utmpd/1
1185 john     0.0 0.0 - - - - - 100 - 0 0 0 0 csh/1
240 root      0.0 0.0 - - - - - 100 - 0 0 0 0 powerd/4
TOTAL:          71, load averages:  0.02, 0.04, 0.08
```

EXIT STATUS The following exit values are returned:

```
0              Successful completion.
1              An error occurred.
```

ATTRIBUTES See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

SEE ALSO proc(1), psrinfo(1M), psrset(1M), sar(1M), pset_getloadavg(3C), proc(4), project(4), attributes(5)

NOTES The snapshot of system usage displayed by prstat is true only for a split-second, and it may not be accurate by the time it is displayed. When the -m option is specified, prstat tries to turn on microstate accounting for each process; the original state is restored when prstat exits. See proc(4) for additional information about the microstate accounting facility.

prtconf(1M)

NAME	prtconf – print system configuration
SPARC	<code>/usr/sbin/prtconf [-V] [-F] [-x] [-vpPD]</code>
IA	<code>/usr/sbin/prtconf [-V] [-x] [-vpPD]</code>
DESCRIPTION	The <code>prtconf</code> command prints the system configuration information. The output includes the total amount of memory, and the configuration of system peripherals formatted as a device tree.
OPTIONS	The following options are supported: -D For each system peripheral in the device tree, displays the name of the device driver used to manage the peripheral. -F Returns the device path name of the console frame buffer, if one exists. If there is no frame buffer, <code>prtconf</code> returns a non-zero exit code. This flag must be used by itself. It returns only the name of the console, frame buffer device or a non-zero exit code. For example, if the console frame buffer on a SPARCstation 1 is <code>cgthree</code> in SBus slot #3, the command returns: <code>/sbus@1,f80000000/cgthree@3,0</code>. This option could be used to create a symlink for <code>/dev/fb</code> to the actual console device. -p Displays information derived from the device tree provided by the firmware (PROM) on SPARC platforms or the booting system on IA platforms. The device tree information displayed using this option is a snapshot of the initial configuration and may not accurately reflect reconfiguration events that occur later. -P Includes information about pseudo devices. By default, information regarding pseudo devices is omitted. -v Specifies verbose mode. -V Displays platform-dependent PROM (on SPARC platforms) or booting system (on IA platforms) version information. This flag must be used by itself. The output is a string. The format of the string is arbitrary and platform-dependent. -x Reports if the firmware on this system is 64-bit ready. Some existing platforms may need a firmware upgrade in order to run the 64-bit kernel. If the operation is not applicable to this platform or the firmware is already 64-bit ready, it exits silently with a return code of zero. If the operation is applicable to this platform and the firmware is not 64-bit ready, it displays a descriptive message on the standard output and exits with a non-zero return code. The hardware platform documentation contains more information about the platforms that may need a firmware upgrade in order to run the 64-bit kernel. This flag overrides all other flags and must be used by itself.
EXIT STATUS	The following exit values are returned:

0	No error occurred.
non-zero	With the -F option (SPARC only), a non-zero return value means that the output device is not a frame buffer. With the -x option, a non-zero return value means that the firmware is not 64-bit ready. In all other cases, a non-zero return value means that an error occurred.

ATTRIBUTES See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWesu (32-bit) SUNWesxu (64-bit)

SEE ALSO modinfo(1M), sysdef(1M), attributes(5)

Sun Hardware Platform Guide

SPARC Only openprom(7D)

NOTES The output of the prtconf command is highly dependent on the version of the PROM installed in the system. The output will be affected in potentially all circumstances.

The driver not attached message means that no driver is currently attached to that instance of the device. In general, drivers are loaded and installed (and attached to hardware instances) on demand, and when needed, and may be uninstalled and unloaded when the device is not in use.

prtdiag(1M)

NAME	prtdiag – display system diagnostic information				
SYNOPSIS	<code>/usr/platform/platform-name/sbin/prtdiag [-v] [-l]</code>				
DESCRIPTION	prtdiag displays system configuration and diagnostic information on sun4u systems. The diagnostic information lists any failed field replaceable units (FRUs) in the system. The interface, output, and location in the directory hierarchy for prtdiag are uncommitted and subject to change in future releases. <i>platform-name</i> is the name of the platform implementation and can be found using the <code>-i</code> option of <code>uname(1)</code>. Note – prtdiag does not display diagnostic information and environmental status when executed on the Sun Enterprise 10000 server. See the <code>/var/opt/SUNWssp/adm/\${SUNW_HOSTNAME}/messages</code> file on the system service processor (SSP) to obtain such information for this server.				
OPTIONS	The following options are supported: -l Log output. If failures or errors exist in the system, output this information to <code>syslogd(1M)</code> only. -v Verbose mode. Displays the time of the most recent AC Power failure, and the most recent hardware fatal error information, and (if applicable) environmental status. The hardware fatal error information is useful to repair and manufacturing for detailed diagnostics of FRUs.				
EXIT STATUS	The following exit values are returned: 0 No failures or errors are detected in the system. 1 Failures or errors are detected in the system. 2 An internal prtdiag error occurred, for example, out of memory.				
ATTRIBUTES	See <code>attributes(5)</code> for descriptions of the following attributes: <table><thead><tr><th>ATTRIBUTE TYPE</th><th>ATTRIBUTE VALUE</th></tr></thead><tbody><tr><td>Availability</td><td>SUNWkvm</td></tr></tbody></table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	Availability	SUNWkvm

NAME	prtfru – print FRUID-specific information about the FRUs on a system or domain				
SYNOPSIS	<code>/usr/sbin/prtfru [-d] [-clx] [container]</code>				
DESCRIPTION	The <code>prtfru</code> utility is used to obtain FRUID data from the system or domain. Its output is that of a tree structure echoing the path in the FRU (Field-Replaceable Unit) tree to each container. When a container is found, the data from that container is printed in a tree-like structure as well. <code>prtfru</code> without any arguments will print the FRU hierarchy and all of the FRUID container data. <code>prtfru</code> prints to stdout which may be redirected to a file.				
OPTIONS	The following options are supported: -c Prints <i>only</i> the containers and their data. This option does not print the FRU tree hierarchy. -d Prints a DTD for the current registry to stdout. -l Prints <i>only</i> the FRU tree hierarchy. This option does not print the container data. -x Prints in XML format with a system identifier (SYSTEM) of <code>prtfrureg.dtd</code>. Options <code>-c</code> and <code>-l</code> can be used together to obtain a list of the containers.				
OPERANDS	The following operand is supported: <i>container</i> The name of a particular container in the FRU hierarchy, that is, either the name or path/name of a container as displayed in the <code>-l</code> option.				
EXIT STATUS	The following exit values are returned: 0 All information was found and printed successfully. >0 An error has occurred.				
ATTRIBUTES	See <code>attributes(5)</code> for descriptions of the following attributes: <table border="1"> <thead> <tr> <th>ATTRIBUTE TYPE</th><th>ATTRIBUTE VALUE</th></tr> </thead> <tbody> <tr> <td>Availability</td><td>SUNWfruid</td></tr> </tbody> </table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	Availability	SUNWfruid

prtpicl(1M)

NAME	prtpicl – print PICL tree				
SYNOPSIS	prtpicl [-c <i>picl_class</i>] [-v]				
DESCRIPTION	The <code>prtpicl</code> command prints the PICL tree maintained by the PICL daemon. The output of <code>prtpicl</code> includes the name and PICL class of the nodes.				
OPTIONS	The following options are supported: -c <i>picl_class</i> Print only the nodes of the named PICL class. -v Print in verbose mode. In verbose mode, <code>prtpicl</code> prints a list of properties and values for each node. Verbose mode is disabled by default.				
EXIT STATUS	The following exit values are returned: 0 Successful completion. non-zero An error occurred.				
ATTRIBUTES	See <code>attributes(5)</code> for descriptions of the following attributes: <table><thead><tr><th>ATTRIBUTE TYPE</th><th>ATTRIBUTE VALUE</th></tr></thead><tbody><tr><td>Availability</td><td>SUNWpiclu</td></tr></tbody></table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	Availability	SUNWpiclu

Availability	SUNWpiclu				
SEE ALSO	<code>picld(1M)</code> , <code>attributes(5)</code>				

NAME	prtvtoC – report information about a disk geometry and partitioning				
SYNOPSIS	prtvtoC [-fhs] [-t <i>vfstab</i>] [-m <i>mnttab</i>] <i>device</i>				
DESCRIPTION	The prtvtoC command allows the contents of the VTOC (volume table of contents) to be viewed. The command can be used only by the super-user. The <i>device</i> name can be the file name of a raw device in the form of <i>/dev/rdisk/c?t?d?s2</i> or can be the file name of a block device in the form of <i>/dev/dsk/c?t?d?s2</i>.				
OPTIONS	The following options are supported: -f Report on the disk free space, including the starting block address of the free space, number of blocks, and unused partitions. -h Omit the headers from the normal output. -s Omit all headers but the column header from the normal output. -t <i>vfstab</i> Use <i>vfstab</i> as the list of filesystem defaults, in place of <i>/etc/vfstab</i>. -m <i>mnttab</i> Use <i>mnttab</i> as the list of mounted filesystems, in place of <i>/etc/mnttab</i>.				
EXAMPLES	EXAMPLE 1 The prtvtoC command. The command line entry and system response shown below are for a 424-megabyte hard disk: <pre>example# prtvtoC /dev/rdisk/c0t3d0s2 * /dev/rdisk/c0t3d0s2 partition map * * Dimension: * 512 bytes/sector * 80 sectors/track * 9 tracks/cylinder * 720 sectors/cylinder * 2500 cylinders * 1151 accessible cylinders * * Flags: * 1: unmountable * 10: read-only *</pre> The data in the Tag column above indicates the type of partition, as follows: <table> <tr> <th>Name</th><th>Number</th></tr> <tr> <td>UNASSIGNED</td><td>0x00</td></tr> </table>	Name	Number	UNASSIGNED	0x00
Name	Number				
UNASSIGNED	0x00				

prvtoc(1M)

NAME	psradm – change processor operational status
SYNOPSIS	psradm -f -i -n [-v] <i>processor_id</i> ... psradm -a-f -i -n [-v]
DESCRIPTION	The psradm utility changes the operational status of processors. The legal states for the processor are <i>on-line</i>, <i>off-line</i>, and <i>no-intr</i>. An <i>on-line</i> processor processes LWPs (lightweight processes) and may be interrupted by I/O devices in the system. An <i>off-line</i> processor does not process any LWPs. Usually, an <i>off-line</i> processor is not interruptible by I/O devices in the system. On some processors or under certain conditions, it may not be possible to disable interrupts for an <i>off-line</i> processor. Thus, the actual effect of being <i>off-line</i> may vary from machine to machine. A <i>no-intr</i> processor processes LWPs but is not interruptible by I/O devices. A processor may not be taken <i>off-line</i> if there are LWPs that are bound to the processor. On some architectures, it might not be possible to take certain processors <i>off-line</i> if, for example, the system depends on some resource provided by the processor. At least one processor in the system must be able to process LWPs. At least one processor must also be able to be interrupted. Since an <i>off-line</i> processor may be interruptible, it is possible to have an operational system with one processor <i>no-intr</i> and all other processors <i>off-line</i> but with one or more accepting interrupts. If any of the specified processors are powered off, psradm may power on one or more processors. Only superusers can use the psradm utility.
OPTIONS	The following options are supported: -a Perform the action on all processors, or as many as possible. -f Take the specified processors <i>off-line</i>. -i Set the specified processors <i>no-intr</i>. -n Bring the specified processors <i>on-line</i>. -v Output a message giving the results of each attempted operation.
OPERANDS	The following operands are supported: <i>processor_id</i> The processor ID of the processor to be set <i>on-line</i> or <i>off-line</i> or <i>no-intr</i>. Specify <i>processor_id</i> as an individual processor number (for example, 3), multiple processor numbers separated by spaces (for example, 1 2 3), or a range of processor numbers (for example,

psradm(1M)

1-4). It is also possible to combine ranges and (individual or multiple) *processor_ids* (for example, 1-3 5 7-8 9).

EXAMPLES

EXAMPLE 1 Examples of psradm.

The following example sets processors 2 and 3 off-line.

```
psradm -f 2 3
```

The following example sets processors 1 and 2 no-intr.

```
psradm -i 1 2
```

The following example sets all processors on-line.

```
psradm -a -n
```

EXIT STATUS

The following exit values are returned:

0 Successful completion.
>0 An error occurred.

FILES

/etc/wtmpx records logging processor status changes

DIAGNOSTICS

psradm: processor 4: Invalid argument
The specified processor does not exist in the configuration.

psradm: processor 3: Device busy
The specified processor could not be taken off-line because it either has LWPs bound to it, is the last on-line processor in the system, or is needed by the system because it provides some essential service.

psradm: processor 3: Device busy
The specified processor could not be set no-intr because it is the last interruptible processor in the system, or or it is the only processor in the system that can service interrupts needed by the system.

psradm: processor 3: Device busy
The specified processor is powered off, and it cannot be powered on because some platform-specific resource is unavailable.

psradm: processor 0: Not owner
The user does not have permission to change processor status.

psradm(1M)

psradm: processor 2: Operation not supported

The specified processor is powered off, and the platform does not support power on of individual processors.

psrinfo(1M)

NAME	psrinfo – displays information about processors						
SYNOPSIS	psrinfo [-v] [<i>processor_id</i> ...] psrinfo -s <i>processor_id</i>						
DESCRIPTION	psrinfo displays information about processors. Without the <i>processor_id</i> operand, psrinfo displays one line for each configured processor, displaying whether it is on-line, non-interruptible (designated by <i>no-intr</i>), off-line, or powered off, and when that status last changed. Use the <i>processor_id</i> operand to display information about a specific processor. See OPERANDS.						
OPTIONS	The following options are supported: <table><tr><td>-s <i>processor_id</i></td><td>Silent mode. Displays 1 if the specified processor is fully on-line, and 0 if the specified processor is non-interruptible, off-line, or powered off.</td></tr><tr><td></td><td>Use silent mode when using psrinfo in shell scripts.</td></tr><tr><td>-v</td><td>Verbose mode. Displays additional information about the specified processors, including: processor type, floating point unit type and clock speed. If any of this information cannot be determined, psrinfo displays unknown.</td></tr></table>	-s <i>processor_id</i>	Silent mode. Displays 1 if the specified processor is fully on-line, and 0 if the specified processor is non-interruptible, off-line, or powered off.		Use silent mode when using psrinfo in shell scripts.	-v	Verbose mode. Displays additional information about the specified processors, including: processor type, floating point unit type and clock speed. If any of this information cannot be determined, psrinfo displays unknown.
-s <i>processor_id</i>	Silent mode. Displays 1 if the specified processor is fully on-line, and 0 if the specified processor is non-interruptible, off-line, or powered off.						
	Use silent mode when using psrinfo in shell scripts.						
-v	Verbose mode. Displays additional information about the specified processors, including: processor type, floating point unit type and clock speed. If any of this information cannot be determined, psrinfo displays unknown.						
OPERANDS	The following operands are supported: <table><tr><td><i>processor_id</i></td><td>The processor ID of the processor about which information is to be displayed.</td></tr><tr><td></td><td>Specify <i>processor_id</i> as an individual processor number (for example, 3), multiple processor numbers separated by spaces (for example, 1 2 3), or a range of processor numbers (for example, 1-4). It is also possible to combine ranges and (individual or multiple) <i>processor_ids</i> (for example, 1-3 5 7-8 9).</td></tr></table>	<i>processor_id</i>	The processor ID of the processor about which information is to be displayed.		Specify <i>processor_id</i> as an individual processor number (for example, 3), multiple processor numbers separated by spaces (for example, 1 2 3), or a range of processor numbers (for example, 1-4). It is also possible to combine ranges and (individual or multiple) <i>processor_ids</i> (for example, 1-3 5 7-8 9).		
<i>processor_id</i>	The processor ID of the processor about which information is to be displayed.						
	Specify <i>processor_id</i> as an individual processor number (for example, 3), multiple processor numbers separated by spaces (for example, 1 2 3), or a range of processor numbers (for example, 1-4). It is also possible to combine ranges and (individual or multiple) <i>processor_ids</i> (for example, 1-3 5 7-8 9).						
EXAMPLES	EXAMPLE 1 Displaying Information About All Configured Processors in Verbose Mode The following example displays information about all configured processors in verbose mode. <pre>psrinfo -v</pre> EXAMPLE 2 Determining If a Processor is On-line The following example uses psrinfo in a shell script to determine if a processor is on-line. <pre>if ["`psrinfo -s 3 2> /dev/null`" -eq 1] then echo "processor 3 is up" fi</pre>						

EXIT STATUS The following exit values are returned:

0 Successful completion.
>0 An error occurred.

DIAGNOSTICS psrinfo: processor 9: Invalid argument
The specified processor does not exist.

psrset(1M)

NAME	psrset – creation and management of processor sets
SYNOPSIS	<pre>psrset -a <i>processor_set_id</i> <i>processor_id...</i> psrset -b <i>processor_set_id</i> <i>pid...</i> psrset -c [<i>processor_id...</i>] psrset -d <i>processor_set_id</i> psrset -e <i>processor_set_id</i> <i>command</i> [<i>argument(s)</i>] psrset -f <i>processor_set_id</i> psrset [-i] [<i>processor_set_id...</i>] psrset -n <i>processor_set_id</i> psrset -p [<i>processor_id...</i>] psrset -q [<i>pid...</i>] psrset -r <i>processor_id...</i> psrset -u <i>pid...</i></pre>
DESCRIPTION	The <code>psrset</code> utility controls the management of processor sets. Processor sets allow the binding of processes to groups of processors, rather than just a single processor. There are two types of processor sets, those created by the user using the <code>psrset</code> command or the <code>pset_create(2)</code> system call, and those automatically created by the system. Processors assigned to user-created processor sets will run only LWPs that have been bound to that processor set, but system processor sets may run other LWPs as well. System-created processor sets will not always exist on a given machine. When they exist, they will generally represent particular characteristics of the underlying machine, such as groups of processors that can communicate more quickly with each other than with other processors in the system. These processor sets cannot be modified or removed, but processes may be bound to them.
OPTIONS	The following options are supported: -a Assigns the specified processors to the specified processor set. Processor sets automatically created by the system cannot have processors assigned to them. However, processors belonging to system processor sets may be assigned to user-created processor sets. This option is restricted to use by the super-user. -b Binds all the LWPs of the specified processes to the specified processor set. LWPs bound to a processor set will be restricted to run only on the processors in that set unless they require resources available only on another processor. Processes may only be bound to non-empty processor sets, that is, processor sets that have had processors assigned to them.

- Bindings are inherited, so new LWPs and processes created by a bound LWP will have the same binding. Binding an interactive shell to a processor, for example, binds all commands executed by the shell.
- c** Creates a new processor set and displays the new processor set ID.
- If a list of processors is given, it also attempts to assign those processors to the processor set. If this succeeds, the processors will be idle until LWPs are bound to the processor set. This option is restricted to use by the super-user.
- Only a limited number of processor sets may be active (created and not destroyed) at a given time. This limit will always be greater than the number of processors in the system. If the **-c** option is used when the maximum number of processor sets is already active, the command will fail.
- The following format will be used for the first line of output of the **-c** option when the `LC_MESSAGES` locale category specifies the "C" locale. In other locales, the strings `created`, `processor`, and `set` may be replaced with more appropriate strings corresponding to the locale.
- ```
"created processor set %d\n" processor set ID
```
- d** Removes the specified processor set, releasing all processors and processes associated with it.
- Processor sets automatically created by the system cannot be removed. This option is restricted to use by the super-user.
- e** Executes a command (with optional arguments) in the specified processor set.
- The command process and any child processes are executed only by processors in the processor set.
- The super-user may execute a command in any active processor set. Other users may only execute commands in system processor sets.
- f** Disables interrupts for all processors within the specified processor set.
- See `psradm(1M)`. If some processors in the set cannot have their interrupts disabled, the other processors will still have their interrupts disabled, and the command will report an error and return non-zero exit status. This option is restricted to use by the super-user.
- i** Displays a list of processors assigned to each named processor set. If no argument is given, a list of all processor sets and the processors assigned to them is displayed. This is also the default operation if the `psrset` command is not given an option.

## psrset(1M)

|                         |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |            |                                     |                     |                                                                                                                                                                                                                                                                                                                              |                         |                                                        |
|-------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------|-------------------------------------|---------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------|--------------------------------------------------------|
|                         | <p>-n Enables interrupts for all processors within the specified processor set.</p> <p>See <code>psradm(1M)</code>. This option is restricted to use by the super-user.</p> <p>-p Displays the processor set assignments for the specified list of processors. If no argument is given, the processor set assignments for all processors in the system is given.</p> <p>-q Displays the processor set bindings of the specified processes. If a process is composed of multiple LWPs, which have different bindings, the bindings of only one of the bound LWPs will be shown. If no argument is given, the processor set bindings of all processes in the system is displayed.</p> <p>-r Removes a list of processors from their current processor sets. Processors that are removed will return to either the system processor set to which they previously belonged, or to the general pool of processors if they did not belong to a system processor set. This option is restricted to use by the super-user.</p> <p>Processors with LWPs bound to them using <code>pbind(1M)</code> cannot be assigned to or removed from processor sets.</p> <p>-u Removes the processor set bindings from all the LWPs of the specified processes, allowing them to be executed on any on-line processor if they are not bound to individual processors through <code>pbind</code>.</p> <p>The super-user can bind or unbind any process to any active processor set. Other users can only bind or unbind processes to system processor sets, and unbind only from processor sets that do not have the <code>PSET_NOESCAPE</code> attribute set. Furthermore, they can only bind or unbind processes for which they have permission to signal, that is, any process that has the same effective user ID as the user.</p> |            |                                     |                     |                                                                                                                                                                                                                                                                                                                              |                         |                                                        |

**DIAGNOSTICS**

psrset: cannot query pid 31: No such process  
The process specified did not exist or has exited.

psrset: cannot bind pid 31: Not owner  
The user does not have permission to bind the process.

psrset: cannot assign processor 4: Not owner  
The user does not have permission to assign the processor.

psrset: cannot assign processor 8: Invalid argument  
The specified processor is not on-line, or the specified processor does not exist.

psrset: cannot bind pid 67: Device busy  
An LWP in the specified process is bound to a processor and cannot be bound to a processor set that does not include that processor.

psrset: cannot assign processor 7: Device busy  
The specified processor could not be added to the processor set. This may be due to bound LWPs on that processor, or because that processor cannot be combined in the same processor set with other processors in that set, or because the processor is the last one in its current processor set.

psrset: cannot execute in processor set 8: Invalid argument  
The specified processor set does not exist.

psrset: cannot create processor set: Not enough space  
The maximum number of processor sets allowed in the system is already active.

| <b>DESCRIPTION</b>       | <p>putdev adds a new device to the device table, modifies an existing device description or removes a device entry from the table. The first synopsis is used to add a device. The second synopsis is used to modify existing entries by adding or changing attributes. If a specified attribute is not defined, this option adds that attribute to the device definition. If a specified attribute is already defined, it modifies the attribute definition. The third synopsis is used to delete either an entire device entry or, if the attribute argument is used, to delete an attribute assignment for a device.</p>                                                                                               |              |                                                                                                                                                                                                                                                                                                                                                         |                  |                                                                                                                                                                                                                                                              |               |                                                                                                      |              |                                                              |
| <b>OPTIONS</b>           | <p>The following options are supported:</p> <ul style="list-style-type: none"> <li>-a        Add a device to the device table using the specified attributes. The device must be referenced by its <i>alias</i>.</li> <li>-d        Remove a device from the device table, when executed without the <i>attributes</i> argument. Used with the <i>attribute</i> argument, it deletes the given attribute specification for <i>device</i> from the table.</li> <li>-m        Modify a device entry in the device table. If an entry already exists, it adds any specified attributes that are not defined. It also modifies any attributes which already have a value with the value specified by this command.</li> </ul> |              |                                                                                                                                                                                                                                                                                                                                                         |                  |                                                                                                                                                                                                                                                              |               |                                                                                                      |              |                                                              |
| <b>OPERANDS</b>          | <p>The following operands are supported:</p> <table> <tr> <td><i>alias</i></td><td>Designates the alias of the device to be added.</td></tr> <tr> <td><i>attribute</i></td><td>Designates a device attribute to be added, modified, or deleted. Can be any of the device attributes described under <b>DEVICE ATTRIBUTES</b> except <i>alias</i>. This prevents an accidental modification or deletion of a device's alias from the table.</td></tr> <tr> <td><i>device</i></td><td>Designates the pathname or alias of the device whose attribute is to be added, modified, or removed.</td></tr> <tr> <td><i>value</i></td><td>Designates the value to be assigned to a device's attribute.</td></tr> </table>          | <i>alias</i> | Designates the alias of the device to be added.                                                                                                                                                                                                                                                                                                         | <i>attribute</i> | Designates a device attribute to be added, modified, or deleted. Can be any of the device attributes described under <b>DEVICE ATTRIBUTES</b> except <i>alias</i> . This prevents an accidental modification or deletion of a device's alias from the table. | <i>device</i> | Designates the pathname or alias of the device whose attribute is to be added, modified, or removed. | <i>value</i> | Designates the value to be assigned to a device's attribute. |
| <i>alias</i>             | Designates the alias of the device to be added.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |              |                                                                                                                                                                                                                                                                                                                                                         |                  |                                                                                                                                                                                                                                                              |               |                                                                                                      |              |                                                              |
| <i>attribute</i>         | Designates a device attribute to be added, modified, or deleted. Can be any of the device attributes described under <b>DEVICE ATTRIBUTES</b> except <i>alias</i> . This prevents an accidental modification or deletion of a device's alias from the table.                                                                                                                                                                                                                                                                                                                                                                                                                                                              |              |                                                                                                                                                                                                                                                                                                                                                         |                  |                                                                                                                                                                                                                                                              |               |                                                                                                      |              |                                                              |

| <b>DEVICE ATTRIBUTES</b> | <p>The following list shows the standard device attributes, used by applications such as <code>ufsdump(1M)</code> and <code>ufsrestore(1M)</code>, which can be defined for a device. You are not limited to this list, you can define any attribute you like.</p> <table> <tr> <td><i>alias</i></td><td>The unique name by which a device is known. No two devices in the database may share the same alias name. The name is limited in length to 14 characters and should contain only alphanumeric characters and the following special characters if they are escaped with a backslash: underscore ( _ ), dollar sign (\$), hyphen ( - ), and period ( . ).</td></tr> </table>                                       | <i>alias</i> | The unique name by which a device is known. No two devices in the database may share the same alias name. The name is limited in length to 14 characters and should contain only alphanumeric characters and the following special characters if they are escaped with a backslash: underscore ( _ ), dollar sign (\$), hyphen ( - ), and period ( . ). |                  |                                                                                                                                                                                                                                                              |               |                                                                                                      |              |                                                              |
| <i>alias</i>             | The unique name by which a device is known. No two devices in the database may share the same alias name. The name is limited in length to 14 characters and should contain only alphanumeric characters and the following special characters if they are escaped with a backslash: underscore ( _ ), dollar sign (\$), hyphen ( - ), and period ( . ).                                                                                                                                                                                                                                                                                                                                                                   |              |                                                                                                                                                                                                                                                                                                                                                         |                  |                                                                                                                                                                                                                                                              |               |                                                                                                      |              |                                                              |

|           |                                                                                                                                                                                                                                                                                                                                                    |
|-----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| bdevice   | The pathname to the block special device node associated with the device, if any. The associated major/minor combination should be unique within the database and should match that associated with the cdevice field, if any. (It is the administrator's responsibility to ensure that these major/minor numbers are unique in the database.)     |
| capacity  | The capacity of the device or of the typical volume, if removable.                                                                                                                                                                                                                                                                                 |
| cdevice   | The pathname to the character special device node associated with the device, if any. The associated major/minor combination should be unique within the database and should match that associated with the bdevice field, if any. (It is the administrator's responsibility to ensure that these major/minor numbers are unique in the database.) |
| cyl       | Used by the command specified in the mkfscmd attribute.                                                                                                                                                                                                                                                                                            |
| desc      | A description of any instance of a volume associated with this device (such as floppy diskette).                                                                                                                                                                                                                                                   |
| dpartlist | The list of disk partitions associated with this device. Used only if type=disk. The list should contain device aliases, each of which must have type=dpart.                                                                                                                                                                                       |
| dparttype | The type of disk partition represented by this device. Used only if type=dpart. It should be either fs (for file system) or dp (for data partition).                                                                                                                                                                                               |
| erasescmd | The command string that, when executed, erases the device.                                                                                                                                                                                                                                                                                         |
| fmtcmd    | The command string that, when executed, formats the device.                                                                                                                                                                                                                                                                                        |
| fsname    | The file system name on the file system administered on this partition, as supplied to the /usr/sbin/labelit command. This attribute is specified only if type=dpart and dparttype=fs.                                                                                                                                                             |
| gap       | Used by the command specified in the mkfscmd attribute.                                                                                                                                                                                                                                                                                            |
| mkfscmd   | The command string that, when executed, places a file system on a previously formatted device.                                                                                                                                                                                                                                                     |
| mountpt   | The default mount point to use for the device. Used only if the device is mountable. For disk partitions where type=dpart and dparttype=fs, this attribute should specify the location where the partition is normally mounted.                                                                                                                    |
| nblocks   | The number of blocks in the file system administered on this partition. Used only if type=dpart and dparttype=fs.                                                                                                                                                                                                                                  |
| ninodes   | The number of inodes in the file system administered on this partition. Used only if type=dpart and dparttype=fs.                                                                                                                                                                                                                                  |

## putdev(1M)

|          |                                                                                                                                                                                                    |
|----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| norewind | The name of the character special device node that allows access to the serial device without rewinding when the device is closed.                                                                 |
| pathname | Defines the pathname to an i-node describing the device (used for non-block or character device pathnames, such as directories).                                                                   |
| type     | A token that represents inherent qualities of the device. Standard types include: 9-track, ctape, disk, directory, diskette, dpart, and qtape.                                                     |
| volname  | The volume name on the file system administered on this partition, as supplied to the <code>/usr/sbin/labelit</code> command. Used only if <code>type=dpart</code> and <code>dparttype=fs</code> . |
| volume   | A text string used to describe any instance of a volume associated with this device. This attribute should not be defined for devices which are not removable.                                     |

### EXIT STATUS

The following exit values are returned:

|   |                                                                                                                                                                                                                                                                       |
|---|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0 | Successful completion.                                                                                                                                                                                                                                                |
| 1 | Command syntax was incorrect, an invalid option was used, or an internal error occurred.                                                                                                                                                                              |
| 2 | The device table could not be opened for reading, or a new device table could not be created.                                                                                                                                                                         |
| 3 | If executed with the <code>-a</code> option, indicates that an entry in the device table with the alias <code>alias</code> already exists. If executed with the <code>-m</code> or <code>-d</code> options, indicates that no entry exists for device <i>device</i> . |
| 4 | Indicates that <code>-d</code> was requested and one or more of the specified attributes were not defined for the device.                                                                                                                                             |

| NAME        | putdgrp – edits device group table                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| SYNOPSIS    | <b>putdgrp</b> [-d] <i>dgroup</i> [ <i>device...</i> ]                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| DESCRIPTION | <p>putdgrp modifies the device group table. It performs two kinds of modification. It can modify the table by creating a new device group or removing a device group. It can also change group definitions by adding or removing a device from the group definition.</p> <p>When the command is invoked with only a <i>dgroup</i> specification, the command adds the specified group name to the device group table if it does not already exist. If the -d option is also used with only the <i>dgroup</i> specification, the command deletes the group from the table.</p> <p>When the command is invoked with both a <i>dgroup</i> and a <i>device</i> specification, it adds the given device name(s) to the group definition. When invoked with both arguments and the -d option, the command deletes the device name(s) from the group definition.</p> <p>When the command is invoked with both a <i>dgroup</i> and a <i>device</i> specification and the device group does not exist, it creates the group and adds the specified devices to that new group.</p> |
| OPTIONS     | <p>The following options are supported:</p> <p>-d        Delete the group or, if used with <i>device</i>, delete the device from a group definition.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| OPERANDS    | <p>The following operands are supported:</p> <p><i>dgroup</i>    Specify a device group name.</p> <p><i>device</i>    Specify the pathname or alias of the device that is to be added to, or deleted from, the device group.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| EXIT STATUS | <p>The following exit values are returned:</p> <p>0        Successful completion.</p> <p>1        Command syntax was incorrect, an invalid option was used, or an internal error occurred.</p> <p>2        Device group table could not be opened for reading or a new device group table could not be created.</p> <p>3        If executed with the -d option, indicates that an entry in the device group table for the device group <i>dgroup</i> does not exist and so cannot be deleted. Otherwise, indicates that the device group <i>dgroup</i> already exists and cannot be added.</p> <p>4        If executed with the -d option, indicates that the device group <i>dgroup</i> does not have as members one or more of the specified devices. Otherwise, indicates that the device group <i>dgroup</i> already has one or more of the specified devices as members.</p>                                                                                                                                                                                        |

## putdgrp(1M)

### EXAMPLES

**EXAMPLE 1** Adding a new device group.

The following example adds a new device group:

```
example# putdgrp floppies
```

**EXAMPLE 2** Adding a device to a device group.

The following example adds a device to a device group:

```
example# putdgrp floppies diskette2
```

**EXAMPLE 3** Deleting a device group.

The following example deletes a device group:

```
example# putdgrp -d floppies
```

**EXAMPLE 4** Deleting a device from a device group.

The following example deletes a device from a device group:

```
example# putdgrp -d floppies diskette2
```

| <b>SYNOPSIS</b>    | <pre>/usr/sbin/pwck [filename]</pre> <pre>/usr/sbin/grpck [filename]</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |                |                 |              |         |
| <b>DESCRIPTION</b> | <p>pwck scans the password file and notes any inconsistencies. The checks include validation of the number of fields, login name, user ID, group ID, and whether the login directory and the program-to-use-as-shell exist. The default password file is /etc/passwd.</p> <p>grpck verifies all entries in the group file. This verification includes a check of the number of fields, group name, group ID, whether any login names belong to more than NGROUPS_MAX groups and that all login names appear in the password file. The default group file is /etc/group.</p> |                |                 |              |         |

| <b>DIAGNOSTICS</b> | <p>Group entries in /etc/group with no login names are flagged.</p> <p>Group file '<i>filename</i>' is empty<br/> The /etc/passwd or /etc/group file is an empty file.</p> <p>cannot open file <i>filename</i>: No such file or directory<br/> The /etc/passwd or /etc/group file does not exist.</p>                                                                                                                                                                                                                                                                       |                |                 |              |         |
| <b>NOTES</b>       | <p>If no filename argument is given, grpck checks the local group file, /etc/group, and also makes sure that all login names encountered in the checked group file are known to the system getpwent(3C) routine. This means that the login names may be supplied by a network name service.</p>                                                                                                                                                                                                                                                                             |                |                 |              |         |

## pwconv(1M)

| NAME           | pwconv – installs and updates /etc/shadow with information from /etc/passwd                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |                |                 |              |                    |

| SYNOPSIS       | <b>pwconv</b>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |                |                 |              |                    |
| DESCRIPTION    | <p>The pwconv command creates and updates /etc/shadow with information from /etc/passwd.</p> <p>pwconv relies on a special value of 'x' in the password field of /etc/passwd. This value of 'x' indicates that the password for the user is already in /etc/shadow and should not be modified.</p> <p>If the /etc/shadow file does not exist, this command will create /etc/shadow with information from /etc/passwd. The command populates /etc/shadow with the user's login name, password, and password aging information. If password aging information does not exist in /etc/passwd for a given user, none will be added to /etc/shadow. However, the last changed information will always be updated.</p> <p>If the /etc/shadow file does exist, the following tasks will be performed:</p> <ul style="list-style-type: none"><li>Entries that are in the /etc/passwd file and not in the /etc/shadow file will be added to the /etc/shadow file.</li><li>Entries that are in the /etc/shadow file and not in the /etc/passwd file will be removed from /etc/shadow.</li><li>Password attributes (for example, password and aging information) that exist in an /etc/passwd entry will be moved to the corresponding entry in /etc/shadow.</li></ul> <p>The pwconv command can only be used by the super-user.</p> |                |                 |              |                    |

| SYNOPSIS    | <b>quot</b> [-acfhnv] <i>filesystem</i> . . .<br><b>quot</b> -a [-cfhnv]                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| DESCRIPTION | quot displays the number of blocks (1024 bytes) in the named <i>filesystem</i> (one or more) currently owned by each user. There is a limit of 2048 blocks. Files larger than this will be counted as a 2048 block file, but the total block count will be correct.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| OPTIONS     | <p>The following options are supported:</p> <ul style="list-style-type: none"><li>-a       Generate a report for all mounted file systems.</li><li>-c       Display three columns giving a file size in blocks, the number of files of that size, and a cumulative total of blocks containing files of that size or a smaller size.</li><li>-f       Display three columns giving, for each user, the number of blocks owned, the count of number of files, and the user name. This option is incompatible with the -c and -v options.</li><li>-h       Estimate the number of blocks in the file. This does not account for files with holes in them.</li><li>-n       Attach names to the list of files read from standard input. quot -n cannot be used alone, because it expects data from standard input. For example, the pipeline<br/><br/>ncheck myfilesystem   sort +0n   quot -n myfilesystem<br/><br/>will produce a list of all files and their owners. This option is incompatible with all other options.</li><li>-v       In addition to the default output, display three columns containing the number of blocks not accessed in the last 30, 60, and 90 days.</li></ul> |
| OPERANDS    | <i>filesystem</i> mount-point of the filesystem(s) being checked                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| USAGE       | See <i>largefile</i> (5) for the description of the behavior of quot when encountering files greater than or equal to 2 Gbyte ( 2 <sup>31</sup> bytes).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| EXIT STATUS | 0           Successful operation.<br>32          Error condition (bad or missing argument, bad path, or other error).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| FILES       | /etc/mnttab       Lists mounted file systems.<br>/etc/passwd       Used to obtain user names                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| ATTRIBUTES  | See <i>attributes</i> (5) for descriptions of the following attributes:                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

## quota(1M)

|                    |                                                                                                                                                                                                                                                                                                                                                                                                              |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>NAME</b>        | quota – display a user's ufs file system disk quota and usage                                                                                                                                                                                                                                                                                                                                                |
| <b>SYNOPSIS</b>    | <b>quota</b> [-v] [ <i>username</i> ]                                                                                                                                                                                                                                                                                                                                                                        |
| <b>DESCRIPTION</b> | <p>quota displays users' ufs disk usage and limits. Only the super-user may use the optional <i>username</i> argument to view the limits of other users.</p> <p>quota without options only display warnings about mounted file systems where usage is over quota. Remotely mounted file systems which do not have quotas turned on are ignored.</p> <p><i>username</i> can be the numeric UID of a user.</p> |
| <b>OPTIONS</b>     | -v            Display user's quota on all mounted file systems where quotas exist.                                                                                                                                                                                                                                                                                                                           |
| <b>USAGE</b>       | See largefile(5) for the description of the behavior of quota when encountering files greater than or equal to 2 Gbyte ( 2 <sup>31</sup> bytes).                                                                                                                                                                                                                                                             |
| <b>FILES</b>       | /etc/mnttab     list of currently mounted filesystems                                                                                                                                                                                                                                                                                                                                                        |
| <b>ATTRIBUTES</b>  | See attributes(5) for descriptions of the following attributes:                                                                                                                                                                                                                                                                                                                                              |

**SEE ALSO** edquota(1M), quotaon(1M), quotacheck(1M), repquota(1M), rquotad(1M), attributes(5), largefile(5)

**NOTES** quota will also display quotas for NFS mounted ufs-based file systems if the rquotad daemon is running. See rquotad(1M).

quota may display entries for the same file system multiple times for multiple mount points. For example,

```
quota -v user1
```

may display identical quota information for user1 at the mount points /home/user1, /home/user2, and /home/user, if all three mount points are mounted from the same file system with quotas turned on.

| <b>NAME</b>        | quotacheck – ufs file system quota consistency checker                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |                |                 |              |         |

| <b>SYNOPSIS</b>    | <b>quotacheck</b> [-fp] [-v] <i>filesystem...</i><br><b>quotacheck</b> -a [-fpv]                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |                |                 |              |         |
| <b>DESCRIPTION</b> | <p>quotacheck examines each mounted ufs file system, builds a table of current disk usage, and compares this table against the information stored in the file system's disk quota file. If any inconsistencies are detected, both the quota file and the current system copy of the incorrect quotas are updated.</p> <p><i>filesystem</i> is either a file system mount point or the block device on which the file system resides.</p> <p>quotacheck expects each file system to be checked to have a quota file named <i>quotas</i> in the root directory. If none is present, quotacheck will not check the file system.</p> <p>quotacheck accesses the character special device in calculating the actual disk usage for each user. Thus, the file systems that are checked should be quiescent while quotacheck is running.</p> |                |                 |              |         |
| <b>OPTIONS</b>     | <p>The following options are supported:</p> <ul style="list-style-type: none"> <li>-a Check the file systems which <i>/etc/mnttab</i> indicates are ufs file systems. These file systems must be read-write mounted with disk quotas enabled, and have an <i>rq</i> entry in the <i>mntopts</i> field in <i>/etc/vfstab</i>.</li> <li>-f Force check on file systems with logging enabled. Use in combination with the -p option.</li> <li>-p Check quotas of file systems in parallel. For file systems with logging enabled, no check is performed unless the -f option is also specified.</li> <li>-v Indicate the calculated disk quotas for each user on a particular file system. quotacheck normally reports only those quotas modified.</li> </ul>                                                                            |                |                 |              |         |
| <b>USAGE</b>       | See <i>largefile(5)</i> for the description of the behavior of quotacheck when encountering files greater than or equal to 2 Gbyte ( $2^{31}$ bytes).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |                |                 |              |         |

| DESCRIPTION | <p>quotaon turns on disk quotas for one or more ufs file systems.</p> <p>Before a file system may have quotas enabled, a file named <i>quotas</i>, owned by root, must exist in the root directory of the file system. See <i>edquota(1M)</i> for details on how to modify the contents of this file.</p> <p>quotaoff turns off disk quotas for one or more ufs file systems.</p> <p>The file systems specified must already be mounted.</p> <p>These commands update the <i>mntopts</i> field of the appropriate entries in <i>/etc/mnttab</i> to indicate when quotas are on or off for each file system. If quotas are on, the string <i>quota</i> will be added to <i>mntopts</i>; if quotas are off, the <i>quota</i> string is not present.</p> <p><i>filesystem</i> must be either the mount point of a file system, or the block device on which the file system resides.</p> <p><b>quotaon</b> -a This option is normally used at boot time to enable quotas. It applies only to those file systems in <i>/etc/vfstab</i> which have “rq” in the <i>mntopts</i> field, are currently mounted “rw”, and have a <i>quotas</i> file in the root directory.</p> <p>-v Display a message for each file system after quotas are turned on.</p> <p><b>quotaoff</b> -a Force all file systems in <i>/etc/mnttab</i> to have their quotas disabled.</p> <p>-v Display a message for each file system affected.</p> <p><b>USAGE</b> See <i>largefile(5)</i> for the description of the behavior of <i>quotaon</i> and <i>quotaoff</i> when encountering files greater than or equal to 2 Gbyte ( 2<sup>31</sup> bytes).</p> <p><b>FILES</b> <i>/etc/mnttab</i> mounted file systems<br/><i>/etc/vfstab</i> list of default parameters for each file system</p> <p><b>ATTRIBUTES</b> See <i>attributes(5)</i> for descriptions of the following attributes:</p> |

| <b>NAME</b>        | rctladm – display and/or modify global state of system resource controls                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>SYNOPSIS</b>    | <b>rctladm</b> [-lu] [-e <i>action</i> ] [-d <i>action</i> ] [ <i>name</i> ...]                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>DESCRIPTION</b> | The <b>rctladm</b> command allows the examination and modification of active resource controls on the running system. An instance of a resource control is referred to as an <i>rctl</i> . See <b>setrctl(2)</b> for further description of an <i>rctl</i> . Logging of <i>rctl</i> violations can be activated or deactivated system-wide and active <i>rtcls</i> (and their state) can be listed.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>OPTIONS</b>     | <p>The <b>rctladm</b> command supports the following options:</p> <p><b>-l</b> List available <i>rtcls</i> with event status. This option displays the global event actions available for each <i>rctl</i>, and by the action name used with the enable (<b>-e</b>) and disable (<b>-d</b>) options below. The global flag values for the control are also displayed. If one or more name operands are specified, only those <i>rtcls</i> matching the given names will be displayed.</p> <p>This is the default action if no options are specified.</p> <p><b>-e <i>action</i></b><br/> <b>-d <i>action</i></b> Enable or disable, respectively, the global action on the specified <i>rctl</i>(s). If no <i>rctl</i> is specified, no action is taken and an error status is returned. You can use the special token <b>all</b> with the disable option to deactivate all global actions on a resource control.</p> <p>You can set the syslog action to a specific degree by assigning a severity level. To do this, specify <b>syslog=level</b>, where <i>level</i> is one of the string tokens given as valid severity levels in <b>syslog(3C)</b>. You can omit the common <b>LOG_</b> prefix on the severity level.</p> <p><b>-u</b> Configure resource controls based on the contents of <b>/etc/rctladm.conf</b>. Any name operands are ignored.</p> |
| <b>OPERANDS</b>    | <p>The following operands are supported:</p> <p><b><i>name</i></b> The name of the <i>rctl</i> to operate on. You can specify multiple <i>rctl</i> names may be specified. If no names are specified, and the list action has been specified, then all <i>rtcls</i> are listed. If the enable or disable action is specified, one or more <i>rctl</i> names must be specified.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>EXAMPLES</b>    | <p><b>EXAMPLE 1</b> Activating System Logging for Specific Violations</p> <p>The following command activates system logging of all violations of <b>task.max-lwps</b>.</p> <pre># rctladm -e syslog task.max-lwps #</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

**EXAMPLE 1** Activating System Logging for Specific Violations (Continued)

**EXAMPLE 2** Examining Current Status of a Specific Resource

The following command examines the current status of the `task.max-lwps` resource.

```
$ rctladm -l task.max-lwps
task.max-lwps syslog=DEBUG
$
```

**EXIT STATUS** The following exit values are returned:

- 0 Successful completion.
- 1 Fatal error occurred.
- 2 Invalid command line options were specified

**FILES** `/etc/rctladm.conf` Each time `rctladm` is executed, it updates the contents of `rctladm.conf` with the current configuration.

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWesu         |

**SEE ALSO** `setrctl(2)`, `getrctl(2)`, `prctl(1)`, `rctlblk_get_global_flags(3C)`, `rctlblk_get_global_action(3C)`, `attributes(5)`

**NOTES** By default, the base operating system provides a variety of controls:

```
project.cpu-shares

task.max-lwps
task.max-cpu-time

process.max-cpu-time
process.max-file-size
process.max-data-size
process.max-stack-size
process.max-core-size
process.max-file-descriptor
process.max-address-space
```

The default properties of the process resource controls are described on `setrlimit(2)`. Task and project resource controls are unenforced by default.

rdate(1M)

| NAME           | rdate – set system date from a remote host                                                                                                                                                                                                                                                                                                                                                                                                                            |                |                 |              |           |

| SYNOPSIS       | <b>rdate</b> <i>hostname</i>                                                                                                                                                                                                                                                                                                                                                                                                                                          |                |                 |              |           |
| DESCRIPTION    | <p>rdate sets the local date and time from the <i>hostname</i> given as an argument. You must have the authorization <code>solaris.system.date</code> on the local system. Typically, <code>rdate</code> is used in a startup script.</p> <p>The <code>inetd</code> daemon responds to <code>rdate</code> requests. To enable <code>inetd</code> response, the lines invoking the <code>time</code> command in <code>inetd.conf</code> must not be commented out.</p> |                |                 |              |           |
| USAGE          | The <code>rdate</code> command is IPv6-enabled. See <code>ip6(7P)</code> .                                                                                                                                                                                                                                                                                                                                                                                            |                |                 |              |           |

| <b>DESCRIPTION</b> | <p>The reboot utility restarts the kernel. The kernel is loaded into memory by the PROM monitor, which transfers control to the loaded kernel.</p> <p>Although reboot can be run by the super-user at any time, shutdown(1M) is normally used first to warn all users logged in of the impending loss of service. See shutdown(1M) for details.</p> <p>The reboot utility performs a sync(1M) operation on the disks, and then a multi-user reboot is initiated. See init(1M) for details.</p> <p>The reboot utility normally logs the reboot to the system log daemon, syslogd(1M), and places a shutdown record in the login accounting file /var/adm/wtmpx. These actions are inhibited if the -n or -q options are present.</p> <p>Normally, the system reboots itself at power-up or after crashes.</p> |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

The form and list of arguments is described in the boot(1M) and kernel(1M) man pages. If multiple arguments are specified, they must be quoted for the shell, as shown in the EXAMPLES section. If the <i>boot_arguments</i> begin with a hyphen, they must be preceded by the – delimiter (two hyphens) to denote the end of the reboot argument list. |
| <b>EXAMPLES</b>    | <p><b>EXAMPLE 1</b> Passing the -r and -v Arguments to boot</p> <p>In the following example, the delimiter ‘—’ (two hyphens) must be used to separate the options of reboot from the arguments of boot(1M).</p> <pre>example# reboot -dl — -rv</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

## reboot(1M)

**EXAMPLE 1** Passing the -r and -v Arguments to boot (Continued)

**EXAMPLE 2** Rebooting Using a Specific Disk and Kernel

The following example reboots using a specific disk and kernel. Note that multiple boot arguments are quoted.

```
example# reboot "disk1 kernel.test/unix"
```

**FILES** /var/adm/wtmpx login accounting file

**ATTRIBUTES** See attributes(5) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWcsu         |

**SEE ALSO** mdb(1), boot(1M), dumpadm(1M), fsck(1M), halt(1M), init(1M), kernel(1M), shutdown(1M), sync(1M), syslogd(1M), sync(2), uadmin(2), reboot(3C), attributes(5)

**NOTES** The reboot utility does not execute the scripts in /etc/rcnum.d or execute shutdown actions in inittab(4). To ensure a complete shutdown of system services, use shutdown(1M) or init(1M) to reboot a Solaris system.

| <b>NAME</b>        | rem_drv – remove a device driver from the system                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |                |                 |              |         |

| <b>SYNOPSIS</b>    | <b>rem_drv</b> [-b <i>basedir</i> ] <i>device_driver</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |                |                 |              |         |
| <b>DESCRIPTION</b> | <p>The <code>rem_drv</code> command informs the system that the device driver <i>device_driver</i> is no longer valid. If possible, <code>rem_drv</code> unloads <i>device_driver</i> from memory. Entries for the device in the <code>/devices</code> namespace are removed. <code>rem_drv</code> also updates the system driver configuration files.</p> <p>If <code>rem_drv</code> has been executed, the next time the system is rebooted it automatically performs a reconfiguration boot (see <code>kernel(1M)</code>).</p> |                |                 |              |         |
| <b>OPTIONS</b>     | <p>The following options are supported:</p> <p>-b <i>basedir</i>                Sets the path to the root directory of the diskless client. Used on the server to execute <code>rem_drv</code> for a client. The client machine must be rebooted to unload the driver.</p>                                                                                                                                                                                                                                                        |                |                 |              |         |
| <b>EXAMPLES</b>    | <p><b>EXAMPLE 1</b> Removing the sd Driver</p> <p>The following example removes the <code>sd</code> driver from use:</p> <pre>example% rem_drv sd</pre> <p><b>EXAMPLE 2</b> Removing a Diskless Client</p> <p>The next example removes the driver from the <code>sun1</code> diskless client. The driver is not uninstalled or unloaded until the client machine is rebooted.</p> <pre>example% rem_drv -b /export/root/sun1 sd</pre>                                                                                             |                |                 |              |         |
| <b>ATTRIBUTES</b>  | <p>See <code>attributes(5)</code> for descriptions of the following attributes:</p> <table border="1"> <thead> <tr> <th>ATTRIBUTE TYPE</th><th>ATTRIBUTE VALUE</th></tr> </thead> <tbody> <tr> <td>Availability</td><td>SUNWcsu</td></tr> </tbody> </table>                                                                                                                                                                                                                                                                       | ATTRIBUTE TYPE | ATTRIBUTE VALUE | Availability | SUNWcsu |

| <b>SYNOPSIS</b>    | <pre><b>removef</b> [ [-M] -R <i>root_path</i>] [-V <i>fs_file</i>] <i>pkginst path...</i> <b>removef</b> [ [-M] -R <i>root_path</i>] [-V <i>fs_file</i>] -f <i>pkginst</i></pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>DESCRIPTION</b> | removef informs the system that the user, or software, intends to remove a pathname. Output from removef is the list of input pathnames that may be safely removed (no other packages have a dependency on them).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>OPTIONS</b>     | <p>The following options are supported:</p> <ul style="list-style-type: none"> <li>-f                   After all files have been processed, removef should be invoked with the -f option to indicate that the removal phase is complete.</li> <li>-M                   Instruct removef not to use the <i>\$root_path/etc/vfstab</i> file for determining the client's mount points. This option assumes the mount points are correct on the server and it behaves consistently with Solaris 2.5 and earlier releases.</li> <li>-R <i>root_path</i>       Define the full path name of a directory to use as the <i>root_path</i>. All files, including package system information files, are relocated to a directory tree starting in the specified <i>root_path</i>. The <i>root_path</i> may be specified when installing to a client from a server (for example, <i>/export/root/client1</i>).</li> <li>-V <i>fs_file</i>         Specify an alternative <i>fs_file</i> to map the client's file systems. For example, used in situations where the <i>\$root_path/etc/vfstab</i> file is non-existent or unreliable.</li> </ul> |
| <b>OPERANDS</b>    | <p>The following operands are supported:</p> <ul style="list-style-type: none"> <li><i>path</i>                The pathname to be removed.</li> <li><i>pkginst</i>            The package instance from which the pathname is being removed.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>EXAMPLES</b>    | <p><b>EXAMPLE 1</b> Using removef</p> <p>The following example uses the removef command in an optional pre-install script:</p> <pre>echo "The following files are no longer part of this package     and are being removed." removef \$PKGINST /dev/xt[0-9][0-9][0-9]   while read pathname do     echo "\$pathname"     rm -f \$pathname done removef -f \$PKGINST    exit 2</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>EXIT STATUS</b> | <ul style="list-style-type: none"> <li>0                   Successful completion.</li> <li>&gt;0                  An error occurred.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

## repquota(1M)

| NAME           | repquota – summarize quotas for a ufs file system                                                                                                                                                                                                                                                                                                                                           |                |                 |              |         |
|----------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------|-----------------|--------------|---------|
| SYNOPSIS       | <b>repquota</b> [-v] <i>filesystem</i> ...<br><b>repquota</b> -a [-v]                                                                                                                                                                                                                                                                                                                       |                |                 |              |         |
| DESCRIPTION    | <p>repquota prints a summary of the disk usage and quotas for the specified ufs file systems. The current number of files and amount of space (in kilobytes) is printed for each user along with any quotas created with edquota(1M).</p> <p>The <i>filesystem</i> must have the file quotas in its root directory.</p> <p>Only the super-user may view quotas which are not their own.</p> |                |                 |              |         |
| OPTIONS        | <p>The following options are supported:</p> <p>-a            Report on all mounted ufs file systems that have <i>rq</i> in the <i>mntopts</i> field of the <i>/etc/vfstab</i> file.</p> <p>-v            Report quotas for all users, even those who do not consume resources.</p>                                                                                                          |                |                 |              |         |
| USAGE          | See <i>largefile</i> (5) for the description of the behavior of <i>repquota</i> when encountering files greater than or equal to 2 Gbyte ( 2 <sup>31</sup> bytes).                                                                                                                                                                                                                          |                |                 |              |         |
| ATTRIBUTES     | <p>See <i>attributes</i>(5) for descriptions of the following attributes:</p> <table><thead><tr><th>ATTRIBUTE TYPE</th><th>ATTRIBUTE VALUE</th></tr></thead><tbody><tr><td>Availability</td><td>SUNWcsu</td></tr></tbody></table>                                                                                                                                                           | ATTRIBUTE TYPE | ATTRIBUTE VALUE | Availability | SUNWcsu |

| DESCRIPTION                      | <p>re-preinstall installs the JumpStart software (preinstall boot image) on a system, so you can power-on the system and have it automatically install the Solaris software (perform a JumpStart installation on the system). When you turn on a re-preinstalled system, the system looks for the JumpStart software on the system's default boot disk. All new SPARC systems have the JumpStart software already preinstalled. The XX in Solaris_XX is the version number of the Solaris release being used.</p> <p>You can use the re-preinstall command in several ways. The most common way is to run re-preinstall on a system to install the JumpStart software on its own default boot disk. This is useful if you want to restore a system to its original factory conditions. (See the first procedure described in EXAMPLES.)</p> <p>You can also run re-preinstall on a system to install JumpStart software on any attached disk (non-boot disk). After you install the JumpStart software on a disk, you can move the disk to a different system and perform a JumpStart installation on the different system. (See the second procedure described in EXAMPLES.)</p> <p>re-preinstall creates a standard file system on the specified <i>target-slice</i> (usually slice 0), and re-preinstall makes sure there is enough space on the <i>target-slice</i> for the JumpStart software. If sufficient space is not available, re-preinstall fails with the following message:</p> <pre>re-preinstall: target-slice too small xx Megabytes required</pre> <p>You can use the format(1M) command to create sufficient space on the <i>target-slice</i> for the JumpStart software.</p> |                               |                                                                                                                                                                                                                                     |                                  |                                                                                                                                                                                                                                                                  |
| OPTIONS                          | <p>The following options are supported:</p> <table> <tr> <td><code>-k platform_name</code></td><td>Platform name of the system that will use the disk with the JumpStart software. The default is the platform name of the system running re-preinstall. | <i>target-slice</i>              | Device name of the disk slice where the JumpStart software will be installed (usually slice 0), for example, c0t3d0s0.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |                               |                                                                                                                                                                                                                                     |                                  |                                                                                                                                                                                                                                                                  |

## re-preinstall(1M)

### EXAMPLES

#### EXAMPLE 1 Installing the JumpStart Software on a System's Own Default Boot Disk

The following procedure installs the JumpStart software on a system's own default boot disk:

1. From the `ok` prompt, boot the system from the Solaris media CD or DVD in single-user mode:
2. The following command installs the Jumpstart software on the System default boot disk, `c0t0d0s0` on a Solaris 9 system:

```
ok boot cdrom -s
```

```
example# /usr/sbin/install.d/re-preinstall c0t0d0s1
```

3. Reboot the slice:

```
example# reboot disk:b
```

#### EXAMPLE 2 Installing the JumpStart Software on a System's Attached (non-boot) Disk

The following procedure installs the JumpStart software on a system's attached (non-boot) disk:

1. Mount the Solaris CD or DVD if `vold(1M)` is not running or CD or DVD is not mounted.
2. Use the `format(1M)` command to determine the target-slice where JumpStart will be installed.
3. Use the `uname(1)` command (`-i` option) to determine the platform name of the system that will use the re-preinstalled disk
4. Run `re-preinstall` with the `-m Solaris_boot_dir` option if the Solaris CD or DVD is not mounted on `/cdrom`.

The following command installs the JumpStart software on the system's attached disk for a system with a Sun4u kernel architecture, and it uses the Solaris CD or DVD mounted with `vold(1M)` on a Solaris 9 system:

```
example# /cdrom/cdrom/s1/usr/bin/install.d/re-preinstall -m
/cdrom/cdrom/s1 -k sun4u c0t2d0s0
```

### EXIT STATUS

The following exit values are returned:

- |   |                        |
|---|------------------------|
| 0 | Successful completion. |
| 1 | An error has occurred. |

### ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

re-preinstall(1M)

| ATTRIBUTE TYPE | ATTRIBUTE VALUE                                |
|----------------|------------------------------------------------|
| Availability   | SUNWcdrom (Solaris CD, SPARC Platform Edition) |

| NAME        | rmmount – removable media mounter for CD-ROM, floppy, Jaz drive, and others                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| SYNOPSIS    | <code>/usr/sbin/rmmount [-D]</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| DESCRIPTION | <p>The <code>rmmount</code> utility is a removable media mounter that is executed by Volume Management whenever a removable medium, such as a CD-ROM or a floppy, is inserted. The Volume Management daemon, <code>vold(1M)</code>, manages removable media. <code>rmmount</code> can also be called by using <code>volrmmount(1)</code>.</p> <p>Upon insertion of a medium and following invocation of the <code>volcheck(1)</code> command, <code>rmmount</code> determines what type of file system (if any) is on that medium. If a file system is present, <code>rmmount</code> mounts the file system in one of the locations listed below.</p> <p>For a diskette (floppy):</p> <ul style="list-style-type: none"><li><code>/floppy/floppy0</code><br/>symbolic link to mounted floppy in local floppy drive</li><li><code>/floppy/floppy_name</code><br/>mounted named floppy</li><li><code>/floppy/unnamed_floppy</code><br/>mounted unnamed floppy</li></ul> <p>For a CD-ROM or a DVD-ROM:</p> <ul style="list-style-type: none"><li><code>/cdrom/cdrom0</code><br/>symbolic link to mounted CD-ROM in local CD-ROM drive</li><li><code>/cdrom/CD-ROM_name</code><br/>mounted named CD-ROM</li><li><code>/cdrom/CD-ROM_name/partition</code><br/>mounted named CD-ROM with partitioned file system</li><li><code>/cdrom/unnamed_cdrom</code><br/>mounted unnamed CD-ROM</li></ul> <p>For a Zip drive:</p> <ul style="list-style-type: none"><li><code>/rmdisk/zip0</code><br/>symbolic link to mounted Zip medium in local Zip drive</li><li><code>/rmdisk/Zip_name</code><br/>mounted named Zip medium</li><li><code>/rmdisk/Zip_name/partition</code><br/>mounted named Zip medium with partitioned file system</li><li><code>/rmdisk/unnamed_zip</code><br/>mounted unnamed Zip medium</li></ul> <p>For a Jaz drive:</p> |

```

/rmdisk/jaz0
 symbolic link to mounted Jaz medium in local Jaz drive
/rmdisk/Jaz_name
 mounted named Jaz medium
/rmdisk/Jaz_name/partition
 mounted named Jaz medium with partitioned file system
/rmdisk/unnamed_Jaz
 mounted unnamed Jaz medium

```

For a generic “rmdisk” drive:

```

/rmdisk/rmdisk0
 symbolic link to mounted removable medium in local removable medium drive
/rmdisk/rmdisk_name
 mounted named removable medium
/rmdisk/rmdisk_name/partition
 mounted named removable medium with partitioned file system
/rmdisk/unnamed_rmdisk
 mounted unnamed removable medium

```

If the media is read-only (for example, a CD-ROM or a floppy with write-protect tab set), the file system is mounted read-only.

If a file system is not identified, `rmmount` does not mount a file system. See the *System Administration Guide: Basic Administration* for more information on the location of CD-ROM, floppy, and other media without file systems. Also see `volfs(7FS)`.

If a file system type has been determined, it is then checked to see that it is “clean.” If the file system is “dirty,” `fsck -p` (see `fsck(1M)`) is run in an attempt to clean it. If `fsck` fails, the file system is mounted read-only.

After the mount is complete, “actions” associated with the media type are executed. These actions allow for the notification to other programs that new media are available. These actions are shared objects and are described in the configuration file, `/etc/rmmount.conf`. See `rmmount.conf(4)`.

Actions are executed in the order in which they appear in the configuration file. The action function can return either 1 or 0. If it returns 0, no further actions will be executed. This allows the function to control which applications are executed.

In order to execute an action, `rmmount` performs a `dlopen(3DL)` on the shared object and calls the action function defined within it. The definition of the interface to actions can be found in `/usr/include/rmmount.h`.

## rmmount(1M)

File systems mounted by `rmmount` are always mounted with the `nosuid` flag set, thereby disabling `setuid` programs and access to block or character devices in that file system. Upon ejection, `rmmount` unmounts mounted file systems and executes actions associated with the media type. If a file system is “busy” (that is, it contains the current working directory of a live process), the ejection will fail.

**OPTIONS**    `-D`            Turn on the debugging output from the `rmmount` `dprintf` calls.

**FILES**        `/etc/rmmount.conf`                      removable media mouter configuration file  
                `/usr/lib/rmmount/*.so.1`              shared objects used by `rmmount`.

**ATTRIBUTES**    See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWvolu        |

**SEE ALSO**    `volcancel(1)`, `volcheck(1)`, `volmissing(1)`, `volrmmount(1)`, `fsck(1M)`, `vold(1M)`, `dlopen(3DL)`, `rmmount.conf(4)`, `vold.conf(4)`, `attributes(5)`, `volfs(7FS)`

| DESCRIPTION                           | <p>rmt is a program used by the remote dump and restore programs in manipulating a magnetic tape drive through an interprocess communication connection. rmt is normally started up with an <code>rexec(3SOCKET)</code> or <code>rcmd(3SOCKET)</code> call.</p> <p>The rmt program accepts requests that are specific to the manipulation of magnetic tapes, performs the commands, then responds with a status indication. All responses are in ASCII and in one of two forms. Successful commands have responses of:</p> <p><i>A</i>number\n<br/>           where <i>number</i> is an ASCII representation of a decimal number.</p> <p>Unsuccessful commands are responded to with:</p> <p><i>E</i>error-number\n<i>e</i>rror-message\n<br/>           where <i>error-number</i> is one of the possible error numbers described in <code>intro(3)</code>, and <i>error-message</i> is the corresponding error string as printed from a call to <code>perror(3C)</code>.</p> <p>The protocol consists of the following commands:</p> <table> <tr> <td><i>S</i>\n</td><td>Return the status of the open device, as obtained with a <code>MTIOCGET ioctl</code> call. If the operation was successful, an “ack” is sent with the size of the status buffer, then the status buffer is sent (in binary).</td></tr> <tr> <td><i>C</i>device\n</td><td>Close the currently open device. The <i>device</i> specified is ignored.</td></tr> <tr> <td><i>I</i>operation\n<i>n</i>count\n</td><td>Perform a <code>MTIOCOP ioctl(2)</code> command using the specified parameters. The parameters are interpreted as the ASCII representations of the decimal values to place in the <i>mt_op</i> and <i>mt_count</i> fields of the structure used in the <code>ioctl</code> call. When the operation is successful the return value is the <i>count</i> parameter.</td></tr> <tr> <td><i>L</i>offset\n<i>n</i>whence\n</td><td>Perform an <code>lseek(2)</code> operation using the specified parameters. The response value is returned from the <code>lseek</code> call.</td></tr> <tr> <td><i>O</i>device\n<i>n</i>mode\n</td><td>Open the specified <i>device</i> using the indicated <i>mode</i>. <i>device</i> is a full pathname, and <i>mode</i> is an ASCII representation of a decimal number suitable for passing to <code>open(9E)</code>. If a device is already open, it is closed before a new open is performed.</td></tr> <tr> <td><i>R</i>count\n</td><td>Read <i>count</i> bytes of data from the open device. rmt performs the requested <code>read(9E)</code> and responds with <i>A</i>count-read\n if the read was successful; otherwise an</td></tr> </table> | <i>S</i> \n | Return the status of the open device, as obtained with a <code>MTIOCGET ioctl</code> call. If the operation was successful, an “ack” is sent with the size of the status buffer, then the status buffer is sent (in binary). | <i>C</i> device\n | Close the currently open device. The <i>device</i> specified is ignored. | <i>I</i> operation\n <i>n</i> count\n | Perform a <code>MTIOCOP ioctl(2)</code> command using the specified parameters. The parameters are interpreted as the ASCII representations of the decimal values to place in the <i>mt_op</i> and <i>mt_count</i> fields of the structure used in the <code>ioctl</code> call. When the operation is successful the return value is the <i>count</i> parameter. | <i>L</i> offset\n <i>n</i> whence\n | Perform an <code>lseek(2)</code> operation using the specified parameters. The response value is returned from the <code>lseek</code> call. | <i>O</i> device\n <i>n</i> mode\n | Open the specified <i>device</i> using the indicated <i>mode</i> . <i>device</i> is a full pathname, and <i>mode</i> is an ASCII representation of a decimal number suitable for passing to <code>open(9E)</code> . If a device is already open, it is closed before a new open is performed. | <i>R</i> count\n | Read <i>count</i> bytes of data from the open device. rmt performs the requested <code>read(9E)</code> and responds with <i>A</i> count-read\n if the read was successful; otherwise an |
| <i>S</i> \n                           | Return the status of the open device, as obtained with a <code>MTIOCGET ioctl</code> call. If the operation was successful, an “ack” is sent with the size of the status buffer, then the status buffer is sent (in binary).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |             |                                                                                                                                                                                                                              |                   |                                                                          |                                       |                                                                                                                                                                                                                                                                                                                                                                  |                                     |                                                                                                                                             |                                   |                                                                                                                                                                                                                                                                                               |                  |                                                                                                                                                                                         |

| <i>I</i> operation\n <i>n</i> count\n | Perform a <code>MTIOCOP ioctl(2)</code> command using the specified parameters. The parameters are interpreted as the ASCII representations of the decimal values to place in the <i>mt_op</i> and <i>mt_count</i> fields of the structure used in the <code>ioctl</code> call. When the operation is successful the return value is the <i>count</i> parameter.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |             |                                                                                                                                                                                                                              |                   |                                                                          |                                       |                                                                                                                                                                                                                                                                                                                                                                  |                                     |                                                                                                                                             |                                   |                                                                                                                                                                                                                                                                                               |                  |                                                                                                                                                                                         |
| <i>L</i> offset\n <i>n</i> whence\n   | Perform an <code>lseek(2)</code> operation using the specified parameters. The response value is returned from the <code>lseek</code> call.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |             |                                                                                                                                                                                                                              |                   |                                                                          |                                       |                                                                                                                                                                                                                                                                                                                                                                  |                                     |                                                                                                                                             |                                   |                                                                                                                                                                                                                                                                                               |                  |                                                                                                                                                                                         |
| <i>O</i> device\n <i>n</i> mode\n     | Open the specified <i>device</i> using the indicated <i>mode</i> . <i>device</i> is a full pathname, and <i>mode</i> is an ASCII representation of a decimal number suitable for passing to <code>open(9E)</code> . If a device is already open, it is closed before a new open is performed.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |             |                                                                                                                                                                                                                              |                   |                                                                          |                                       |                                                                                                                                                                                                                                                                                                                                                                  |                                     |                                                                                                                                             |                                   |                                                                                                                                                                                                                                                                                               |                  |                                                                                                                                                                                         |

rmt(1M)

error in standard format is returned. If the read was successful, the data read is sent.

*wcount* \n

Write data onto the open device. *rmt* reads *count* bytes from the connection, aborting if a premature EOF is encountered. The response value is returned from the *write(9E)* call.

Any other command causes *rmt* to exit.

**ATTRIBUTES** See *attributes(5)* for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|

| DESCRIPTION | <p>roleadd adds a role entry to the <code>/etc/passwd</code> and <code>/etc/shadow</code> and <code>/etc/user_attr</code> files. The <code>-A</code> and <code>-P</code> options respectively assign authorizations and profiles to the role. Roles cannot be assigned to other roles.</p> <p>roleadd also creates supplementary group memberships for the role (<code>-G</code> option) and creates the home directory (<code>-m</code> option) for the role if requested. The new role account remains locked until the <code>passwd(1)</code> command is executed.</p> <p>Specifying <code>roleadd -D</code> with the <code>-g</code>, <code>-b</code>, <code>-f</code>, or <code>-e</code> option (or any combination of these option) sets the default values for the respective fields. See the <code>-D</code> option. Subsequent <code>roleadd</code> commands without the <code>-D</code> option use these arguments.</p> <p>The system file entries created with this command have a limit of 512 characters per line. Specifying long arguments to several options can exceed this limit.</p> <p>The role (<code>role</code>) field accepts a string of no more than eight bytes consisting of characters from the set of alphabetic characters, numeric characters, period (<code>.</code>), underscore (<code>_</code>), and hyphen (<code>-</code>). The first character should be alphabetic and the field should contain at least one lower case alphabetic character. A warning message will be written if these restrictions are not met. A future Solaris release may refuse to accept role fields that do not meet these requirements.</p> <p>The <code>role</code> field must contain at least one character and must not contain a colon (<code>:</code>) or a newline (<code>\n</code>).</p> |
| OPTIONS     | <p>The following options are supported:</p> <ul style="list-style-type: none"> <li><code>-A <i>authorization</i></code>    One or more comma separated authorizations defined in <code>auth_attr(4)</code>. Only a user or role who has grant rights to the authorization can assign it to an account</li> <li><code>-b <i>base_dir</i></code>        The default base directory for the system if <code>-d <i>dir</i></code> is not specified. <i>base_dir</i> is concatenated with the account name to define the home directory. If the <code>-m</code> option is not used, <i>base_dir</i> must exist.</li> <li><code>-c <i>comment</i></code>        Any text string. It is generally a short description of the role. This information is stored in the role's <code>/etc/passwd</code> entry.</li> <li><code>-d <i>dir</i></code>             The home directory of the new role. It defaults to <code>base_dir/account_name</code>, where <i>base_dir</i> is the base directory for new login home directories and <i>account_name</i> is the new role name.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

| -e <i>expire</i>   | <p>Specify the expiration date for a role. After this date, no user will be able to access this role. The expire option argument is a date entered using one of the date formats included in the template file <i>/etc/datemsk</i>. See <i>getdate(3C)</i>.</p> <p>If the date format that you choose includes spaces, it must be quoted. For example, you can enter 10/6/90 or "October 6, 1990". A null value (" ") defeats the status of the expired date. This option is useful for creating temporary roles.</p>                                                                                                                                                 |       |                  |          |       |          |           |       |         |          |   |        |      |       |      |          |      |
| -f <i>inactive</i> | <p>The maximum number of days allowed between uses of a role ID before that ID is declared invalid. Normal values are positive integers. A value of 0 defeats the status.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |       |                  |          |       |          |           |       |         |          |   |        |      |       |      |          |      |
| -g <i>group</i>    | <p>An existing group's integer ID or character-string name. Without the <i>-D</i> option, it defines the new role's primary group membership and defaults to the default group. You can reset this default value by invoking <i>roleadd -D -g group</i>.</p>                                                                                                                                                                                                                                                                                                                                                                                                          |       |                  |          |       |          |           |       |         |          |   |        |      |       |      |          |      |
| -G <i>group</i>    | <p>An existing group's integer ID or character-string name. It defines the new role's supplementary group membership. Duplicates between <i>group</i> with the <i>-g</i> and <i>-G</i> options are ignored. No more than NGROUPS_MAX groups can be specified.</p>                                                                                                                                                                                                                                                                                                                                                                                                     |       |                  |          |       |          |           |       |         |          |   |        |      |       |      |          |      |
| -k <i>skel_dir</i> | <p>A directory that contains skeleton information (such as <i>.profile</i>) that can be copied into a new role's home directory. This directory must already exist. The system provides the <i>/etc/skel</i> directory that can be used for this purpose.</p>                                                                                                                                                                                                                                                                                                                                                                                                         |       |                  |          |       |          |           |       |         |          |   |        |      |       |      |          |      |
| -m                 | <p>Create the new role's home directory if it does not already exist. If the directory already exists, it must have read, write, and execute permissions by <i>group</i>, where <i>group</i> is the role's primary group.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                         |       |                  |          |       |          |           |       |         |          |   |        |      |       |      |          |      |

- o This option allows a UID to be duplicated (non-unique).
- P *profile* One or more comma-separated execution profiles defined in `prof_attr(4)`.
- s *shell* Full pathname of the program used as the user's shell on login. It defaults to an empty field causing the system to use `/bin/sh` as the default. The value of *shell* must be a valid executable file.
- u *uid* The UID of the new role. This UID must be a non-negative decimal integer below `MAXUID` as defined in `<sys/param.h>`. The UID defaults to the next available (unique) number above the highest number currently assigned. For example, if UIDs 100, 105, and 200 are assigned, the next default UID number will be 201. (UIDs from 0-99 are reserved for possible use in future applications.)

**FILES**

- `/etc/datemsk`
- `/etc/passwd`
- `/etc/shadow`
- `/etc/group`
- `/etc/skel`
- `/usr/include/limits.h`
- `/etc/user_attr`

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWcsu         |

**SEE ALSO** `passwd(1)`, `profiles(1)`, `roles(1)`, `users(1B)`, `groupadd(1M)`, `groupdel(1M)`, `groupmod(1M)`, `grpck(1M)`, `logins(1M)`, `pwck(1M)`, `userdel(1M)`, `usermod(1M)`, `getdate(3C)`, `auth_attr(4)`, `passwd(4)`, `prof_attr(4)`, `user_attr(4)`, `attributes(5)`

**DIAGNOSTICS** In case of an error, `roleadd` prints an error message and exits with a non-zero status.

The following indicates that login specified is already in use:

```
UX: roleadd: ERROR: login is already in use. Choose another.
```

The following indicates that the *uid* specified with the `-u` option is not unique:

```
UX: roleadd: ERROR: uid uid is already in use. Choose another.
```

## roleadd(1M)

The following indicates that the *group* specified with the *-g* option is already in use:

```
UX: roleadd: ERROR: group group does not exist. Choose another.
```

The following indicates that the *uid* specified with the *-u* option is in the range of reserved UIDs (from 0-99):

```
UX: roleadd: WARNING: uid uid is reserved.
```

The following indicates that the *uid* specified with the *-u* option exceeds MAXUID as defined in *<sys/param.h>*:

```
UX: roleadd: ERROR: uid uid is too big. Choose another.
```

The following indicates that the */etc/passwd* or */etc/shadow* files do not exist:

```
UX: roleadd: ERROR: Cannot update system files - login cannot be created.
```

**NOTES** If a network nameservice such as NIS or NIS+ is being used to supplement the local */etc/passwd* file with additional entries, *roleadd* cannot change information supplied by the network nameservice.

| NAME           | roledel – delete a role’s login from the system                                                                                                                                                                                                                                                                                                                                                                                                                                      |                |                 |              |         |

| SYNOPSIS       | <b>roledel</b> [-r] <i>role</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                      |                |                 |              |         |
| DESCRIPTION    | The <b>roledel</b> utility deletes a role account from the system and makes the appropriate account-related changes to the system file and file system. <b>roledel</b> also removes the role from each user’s list of assumable roles.                                                                                                                                                                                                                                               |                |                 |              |         |
| OPTIONS        | <p>The following options are supported:</p> <p>-r Remove the role’s home directory from the system. This directory must exist. The files and directories under the home directory will no longer be accessible following successful execution of the command.</p>                                                                                                                                                                                                                    |                |                 |              |         |
| OPERANDS       | <p>The following operands are supported:</p> <p><i>role</i> An existing role name to be deleted.</p>                                                                                                                                                                                                                                                                                                                                                                                 |                |                 |              |         |
| EXIT STATUS    | <p>The following exit values are returned:</p> <p>0 Successful completion.</p> <p>2 Invalid command syntax. A usage message for the <b>roledel</b> command is displayed.</p> <p>6 The account to be removed does not exist.</p> <p>8 The account to be removed is in use.</p> <p>10 Cannot update the <i>/etc/group</i> or <i>/etc/user_attr</i> file but the login is removed from the <i>/etc/passwd</i> file.</p> <p>12 Cannot remove or otherwise modify the home directory.</p> |                |                 |              |         |
| FILES          | <p><i>/etc/passwd</i> system password file</p> <p><i>/etc/shadow</i> system file containing roles’ encrypted passwords and related information</p> <p><i>/etc/group</i> system file containing group definitions</p> <p><i>/etc/user_attr</i> system file containing additional role attributes</p>                                                                                                                                                                                  |                |                 |              |         |

**NOTES** The roledel utility only deletes an account definition that is in the local /etc/group, /etc/passwd, /etc/shadow, and /etc/user\_attr file. If a network name service such as NIS or NIS+ is being used to supplement the local /etc/passwd file with additional entries, roledel cannot change information supplied by the network name service.

| DESCRIPTION | <p>The <b>rolemod</b> utility modifies a role’s login information on the system. It changes the definition of the specified login and makes the appropriate login-related system file and file system changes.</p> <p>The system file entries created with this command have a limit of 512 characters per line. Specifying long arguments to several options may exceed this limit.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| OPTIONS     | <p>The following options are supported:</p> <ul style="list-style-type: none"> <li>-A <i>authorization</i>                      One or more comma separated authorizations as defined in <code>auth_attr(4)</code>. Only role with grant rights to the <i>authorization</i> can assign it to an account. This replaces any existing authorization setting.</li> <li>-c <i>comment</i>                              Specify a comment string. <i>comment</i> can be any text string. It is generally a short description of the login, and is currently used as the field for the user’s full name. This information is stored in the user’s <code>/etc/passwd</code> entry.</li> <li>-d <i>dir</i>                                      Specify the new home directory of the role. It defaults to <i>base_dir/login</i>, where <i>base_dir</i> is the base directory for new login home directories, and <i>login</i> is the new login.</li> <li>-e <i>expire</i>                                  Specify the expiration date for a role. After this date, no role will be able to access this login. The expire option argument is a date entered using one of the date formats included in the template file <code>/etc/datemsk</code>. See <code>getdate(3C)</code>.<br/><br/>For example, you may enter <code>10/6/90</code> or <code>October 6, 1990</code>. A value of <code>''</code> defeats the status of the expired date.</li> <li>-f <i>inactive</i>                                Specify the maximum number of days allowed between uses of a login ID before that login ID is declared invalid. Normal values are positive integers. A value of 0 defeats the status.</li> <li>-g <i>group</i>                                    Specify an existing group’s integer ID or character-string name. It redefines the role’s primary group membership.</li> <li>-G <i>group</i>                                    Specify an existing group’s integer "ID" or character string name. It redefines the role’s supplementary</li> </ul> |

## rolemod(1M)

|                         |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|-------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                         | group membership. Duplicates between <i>group</i> with the -g and -G options are ignored. No more than NGROUPS_UMAX groups may be specified as defined in <param.h>.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| -l <i>new_loginname</i> | Specify the new login name for the role. The <i>new_loginname</i> argument is a string no more than eight bytes consisting of characters from the set of alphabetic characters, numeric characters, period (.), underline (_), and hyphen (-). The first character should be alphabetic and the field should contain at least one lower case alphabetic character. A warning message will be written if these restrictions are not met. A future Solaris release may refuse to accept login fields that do not meet these requirements. The <i>new_loginname</i> argument must contain at least one character and must not contain a colon (:) or NEWLINE (\n). |
| -m                      | Move the role's home directory to the new directory specified with the -d option. If the directory already exists, it must have permissions read/write/execute by <i>group</i> , where <i>group</i> is the role's primary group.                                                                                                                                                                                                                                                                                                                                                                                                                                |
| -o                      | This option allows the specified UID to be duplicated (non-unique).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| -P <i>profile</i>       | One or more comma-separated execution profiles defined in <i>auth_attr</i> (4). This replaces any existing profile setting.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| -s <i>shell</i>         | Specify the full pathname of the program that is used as the role's shell on login. The value of <i>shell</i> must be a valid executable file.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| -u <i>uid</i>           | Specify a new UID for the role. It must be a non-negative decimal integer less than MAXUID as defined in <param.h>. The UID associated with the role's home directory is not modified with this option; a role will not have access to their home directory until the UID is manually reassigned using <i>chown</i> (1M).                                                                                                                                                                                                                                                                                                                                       |
| OPERANDS                | The following operands are supported:<br><br>login     An existing login name to be modified.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| EXIT STATUS             | In case of an error, <i>rolemod</i> prints an error message and exits with one of the following values:<br><br>2            The command syntax was invalid. A usage message for the <i>rolemod</i> command is displayed.<br><br>3            An invalid argument was provided to an option.                                                                                                                                                                                                                                                                                                                                                                     |

- 4 The *uid* given with the *-u* option is already in use.
- 5 The password files contain an error. *pwconv*(1M) can be used to correct possible errors. See *passwd*(4).
- 6 The login to be modified does not exist, the *group* does not exist, or the login shell does not exist.
- 8 The login to be modified is in use.
- 9 The *new\_logname* is already in use.
- 10 Cannot update the */etc/group* or */etc/user\_attr* file. Other update requests will be implemented.
- 11 Insufficient space to move the home directory (*-m* option). Other update requests will be implemented.
- 12 Unable to complete the move of the home directory to the new home directory.

| <b>DESCRIPTION</b>   | <p>route manually manipulates the network routing tables. These tables are normally maintained by the system routing daemon, such as <code>in.routed(1M)</code> and <code>in.ripngd(1M)</code>.</p> <p>route supports a limited number of general options, but a rich command language. Users can specify an arbitrary request that can be delivered by means of the programmatic interface discussed in <code>route(7P)</code>.</p> <p>route uses a routing socket and the new message types RTM_ADD, RTM_DELETE, RTM_GET, and RTM_CHANGE. Only superusers can modify routing tables.</p>                                                                                                                                                                                                                                                            |                  |              |                     |                                                  |                     |                          |                    |                                                    |                  |                                                  |                      |                                                                                                                             |
| <b>OPTIONS</b>       | <p><b>-f</b> Flush the routing tables of all gateway entries. If you use the <b>-f</b> option in conjunction with any of the <code>route</code> sub-commands, <code>route</code> flushes the gateways before performing the sub-command. Specify the table to flush by placing the <b>-inet</b> or <b>-inet6</b> modifier immediately after the <b>-f</b> option. If unspecified, flushing IPv4 (<b>-inet</b>) routes is the default.</p> <p><b>-n</b> Prevent attempts to print host and network names symbolically when reporting actions. This option is useful when name servers are unavailable.</p> <p><b>-v</b> Print additional details in verbose mode.</p> <p><b>-q</b> Suppress all output.</p>                                                                                                                                            |                  |              |                     |                                                  |                     |                          |                    |                                                    |                  |                                                  |                      |                                                                                                                             |
| <b>Sub-commands</b>  | <p>The following sub—commands are supported:</p> <table> <tr> <td><code>add</code></td><td>Add a route.</td></tr> <tr> <td><code>change</code></td><td>Change aspects of a route (such as its gateway).</td></tr> <tr> <td><code>delete</code></td><td>Delete a specific route.</td></tr> <tr> <td><code>flush</code></td><td>Remove all gateway entries from the routing table.</td></tr> <tr> <td><code>get</code></td><td>Look up and display the route for a destination.</td></tr> <tr> <td><code>monitor</code></td><td>Continuously report any changes to the routing information base, routing lookup misses, or suspected network partitionings.</td></tr> </table> <p>The <code>add</code> and <code>delete</code> sub-commands have the following syntax:</p> <pre> route [ -fnvq ] cmd <i>destination gateway</i> [metric/netmask] </pre> | <code>add</code> | Add a route. | <code>change</code> | Change aspects of a route (such as its gateway). | <code>delete</code> | Delete a specific route. | <code>flush</code> | Remove all gateway entries from the routing table. | <code>get</code> | Look up and display the route for a destination. | <code>monitor</code> | Continuously report any changes to the routing information base, routing lookup misses, or suspected network partitionings. |
| <code>add</code>     | Add a route.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |                  |              |                     |                                                  |                     |                          |                    |                                                    |                  |                                                  |                      |                                                                                                                             |
| <code>change</code>  | Change aspects of a route (such as its gateway).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |                  |              |                     |                                                  |                     |                          |                    |                                                    |                  |                                                  |                      |                                                                                                                             |
| <code>delete</code>  | Delete a specific route.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |                  |              |                     |                                                  |                     |                          |                    |                                                    |                  |                                                  |                      |                                                                                                                             |
| <code>flush</code>   | Remove all gateway entries from the routing table.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |                  |              |                     |                                                  |                     |                          |                    |                                                    |                  |                                                  |                      |                                                                                                                             |
| <code>get</code>     | Look up and display the route for a destination.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |                  |              |                     |                                                  |                     |                          |                    |                                                    |                  |                                                  |                      |                                                                                                                             |
| <code>monitor</code> | Continuously report any changes to the routing information base, routing lookup misses, or suspected network partitionings.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |                  |              |                     |                                                  |                     |                          |                    |                                                    |                  |                                                  |                      |                                                                                                                             |

where *cmd* is `add` or `delete`, *destination* is the destination host or network, and *gateway* is the next-hop intermediary through which packets should be routed. Modifiers described in OPERANDS can be placed anywhere on the command line.

The `get` and `change` sub-commands have the following syntax:

```
route [-fnvq] cmd destination [gateway [metric/netmask]]
```

where *cmd* is `get` or `change`, *destination* is the destination host or network, and *gateway* is the next-hop intermediary through which packets should be routed. Modifiers described in OPERANDS can be placed anywhere on the command line.

The `monitor` sub-command has the following syntax:

```
route monitor [-inet | -inet6]
```

## OPERANDS

### Destinations and Gateways

`route` executes its sub-commands on routes to destinations by way of gateways.

By default, destination and gateway addresses are interpreted as IPv4 addresses. All symbolic names are tried first as a host name, using `getipnodebyname(3SOCKET)`. If this lookup fails in the `AF_INET` case, `getnetbyname(3SOCKET)` interprets the name as that of a network.

Including an optional modifier on the command line before the address changes how the `route` sub-command interprets it.

The following modifiers are supported:

- `-inet` Force the address to be interpreted as an IPv4 address, that is, under the `AF_INET` address family.
- `-inet6` Force the address to be interpreted as an IPv6 address, that is, under the `AF_INET6` address family.

For IPv4 addresses, routes to a particular host are by default distinguished from those to a network by interpreting the Internet address specified as the destination. If the destination has a *local address part* (that is, the portion not covered by the netmask) of 0, or if the destination is resolved as the symbolic name of a network, then the route is assumed to be to a network; otherwise, it is presumed to be a route to a host.

You can force this selection by using one of the following modifiers:

- `-host` Force the destination to be interpreted as a host.
- `-net` Force the destination to be interpreted as a network.

For example:

| Destination | Destination Equivalent        |
|-------------|-------------------------------|
| 128.32      | <code>-host 128.0.0.32</code> |

## route(1M)

| Destination     | Destination Equivalent |
|-----------------|------------------------|
| 128.32.130      | - host 128.32.0.130    |
| -net 128.32     | 128.32.0.0             |
| -net 128.32.130 | 128.32.130.0           |

Two modifiers avoid confusion between addresses and keywords (for example., *host* used as a symbolic host name). You can distinguish a *destination* by preceding it with the `-dst` modifier. You can distinguish a gateway address by using the `-gateway` modifier. If the destination is directly reachable by way of an interface requiring no intermediary IP router to act as a gateway, this can be indicated by using the `-interface` or `-iface` modifier.

In the following example, the route does not refer to an external gateway (router), but rather to one of the machine's interfaces. Packets with IP destination addresses matching the destination and mask on such a route are sent out on the interface identified by the gateway address. For interfaces using the ARP protocol, this type of route is used to specify that all matching destinations are local to the physical link. That is, a host could be configured to ARP for all addresses, without regard to the configured interface netmask, by adding a default route using this command. For example:

```
example# route add default hostname -interface
```

where gateway address *hostname* is the name or IP address associated with the network interface over which all matching packets should be sent. On a host with a single network interface, *hostname* is usually the same as the *nodename* returned by the `uname -n` command. See `uname(1)`.

For backward compatibility with older systems, directly reachable routes can also be specified by placing a 0 after the gateway address:

```
example# route add default hostname 0
```

This value was once a route metric, but this metric is no longer used. If the value is specified as 0, then the destination is directly reachable (equivalent to specifying `-interface`). If it is non-zero but cannot be interpreted as a subnet mask, then a gateway is used (default).

With the `AF_INET` address family or an IPv4 address, a separate subnet mask can be specified. This can be specified in one of the following ways:

- IP address following the gateway address . This is typically specified in *decimal dot* notation as for `inet_addr(3SOCKET)` rather than in symbolic form.
- IP address following the `-netmask` qualifier.
- Slash character and a decimal length appended to the destination address.

If a subnet mask is not specified, the mask used is the subnet mask of the output interface selected by the gateway address, if the classful network of the destination is the same as the classful network of the interface. Otherwise, the classful network mask for the destination address is used.

Each of the following examples creates an IPv4 route to the destination 192.0.2.32 subnet with a subnet mask of 255.255.255.224:

```
example# route add 192.0.2.32/27 somegateway
example# route add 192.0.2.32 -netmask 255.255.255.224 somegateway
example# route add 192.0.2.32 somegateway 255.255.255.224
```

For IPv6, only the slash format is accepted. The following example creates an IPv6 route to the destination 33fe:: with a netmask of 16 one-bits followed by 112 zero-bits.

```
example# route add -inet6 3ffe::/16 somegateway
```

In cases where the gateway does not uniquely identify the output interface (for example, when several interfaces have the same address), you can use the `-ifp ifname` modifier to specify the interface by name. For example, `-ifp lo0` associates the route with the `lo0` interface.

## Routing Flags

Routes have associated flags that influence operation of the protocols when sending to destinations matched by the routes. These flags can be set (and in some cases cleared, indicated by ~) by including the following modifiers on the command line:

| Modifier   | Flag          | Description                                         |
|------------|---------------|-----------------------------------------------------|
| -interface | ~RTF_GATEWAY  | Destination is directly reachable                   |
| -iface     | ~RTF_GATEWAY  | Alias for interface modifier                        |
| -static    | RTF_STATIC    | Manually added route                                |
| -nostatic  | ~RTF_STATIC   | Pretend route was added by kernel or routing daemon |
| -reject    | RTF_REJECT    | Emit an ICMP unreachable when matched               |
| -blackhole | RTF_BLACKHOLE | Silently discard packets during updates             |
| -proto1    | RTF_PROTO1    | Set protocol specific routing flag #1               |
| -proto2    | RTF_PROTO2    | Set protocol specific routing flag #2               |
| -private   | RTF_PRIVATE   | Do not advertise this route                         |
| -multirt   | RTF_MULTIRT   | Creates the specified redundant route               |
| -setsrc    | RTF_SETSRC    | Assigns the default source address                  |

## route(1M)

The optional modifiers `-rtt`, `-rttvar`, `-sendpipe`, `-recvpipe`, `-mtu`, `-hopcount`, `-expire`, and `-sssthresh` provide initial values to quantities maintained in the routing entry by transport level protocols, such as TCP. These can be individually locked either by preceding each modifier to be locked by the `-lock` meta-modifier, or by specifying that all ensuing metrics can be locked by the `-lockrest` meta-modifier.

Some transport layer protocols can support only some of these metrics. The following optional modifiers are supported:

|                         |                                                                            |
|-------------------------|----------------------------------------------------------------------------|
| <code>-expire</code>    | Lifetime for the entry. This optional modifier is not currently supported. |
| <code>-hopcount</code>  | Maximum hop count. This optional modifier is not currently supported.      |
| <code>-mtu</code>       | Maximum MTU in bytes.                                                      |
| <code>-recvpipe</code>  | Receive pipe size in bytes.                                                |
| <code>-rtt</code>       | Round trip time in microseconds.                                           |
| <code>-rttvar</code>    | Round trip time variance in microseconds.                                  |
| <code>-sendpipe</code>  | Send pipe size in bytes.                                                   |
| <code>-sssthresh</code> | Send pipe size threshold in bytes.                                         |

### Compatibility

The modifiers `host` and `net` are taken to be equivalent to `-host` and `-net`. To specify a symbolic address that matches one of these names, use the `dst` or `gateway` keyword to distinguish it. For example: `-dst host`

The following two flags are also accepted for compatibility with older systems, but have no effect.

| Modifier               | Flag         |
|------------------------|--------------|
| <code>-cloning</code>  | RTF_CLONING  |
| <code>-xresolve</code> | RTF_XRESOLVE |

The `-ifa` hostname modifier is also accepted, but has no effect.

### FILES

|                                 |                                      |
|---------------------------------|--------------------------------------|
| <code>/etc/defaultrouter</code> | List of default routers              |
| <code>/etc/hosts</code>         | List of host names and net addresses |
| <code>/etc/networks</code>      | List of network names and addresses  |

### ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWcsu         |

**SEE ALSO**

uname(1), in.ripngd(1M), in.routed(1M), netstat(1M), routed(1M), ioctl(2), getipnodebyname(3SOCKET), getnetbyname(3SOCKET), inet\_addr(3SOCKET), defaultrouter(4), hosts(4), networks(4), attributes(5), ARP(7P), ip(7P), route(7P), routing(7P)

**DIAGNOSTICS**

`add [ host | network ] destination:gateway flags`

The specified route is being added to the tables. The values printed are from the routing table entry supplied in the `ioctl(2)` call. If the gateway address used was not the primary address of the gateway (the first one returned by `getipnodebyname(3SOCKET)`) the gateway address is printed numerically as well as symbolically.

`delete [ host | network ] destination:gateway flags`

`change [ host | network ] destination:gateway flags`

As `add`, but when deleting or changing an entry.

*destination done*

When the `-f` flag is specified, or the `flush` sub-command is used, each routing table entry deleted is indicated with a message of this form.

*Network is unreachable*

An attempt to add a route failed because the gateway listed was not on a directly-connected network. Give the next-hop gateway instead.

*not in table*

A delete operation was attempted for an entry that is not in the table.

*entry exists*

An add operation was attempted for a route that already exists in the kernel.

*routing table overflow*

An operation was attempted, but the system was unable to allocate memory to create the new entry.

**NOTES**

Specifying that destinations are local (with the `-interface` modifier) assumes that the routers implement proxy ARP, meaning that they respond to ARP queries for all reachable destinations. Normally, using either router discovery or RIP is more reliable and scalable than using proxy ARP. See `in.routed(1M)` for information related to RIP.

Combining the all destinations are local route with subnet or network routes can lead to unpredictable results. The search order as it relates to the all destinations are local route are undefined and can vary from release to release.

## rpcbind(1M)

| NAME           | rpcbind – universal addresses to RPC program number mapper                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |                |                 |              |         |

| SYNOPSIS       | <b>rpcbind</b> [-d] [-w]                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |                |                 |              |         |
| DESCRIPTION    | <p>rpcbind is a server that converts RPC program numbers into universal addresses. It must be running on the host to be able to make RPC calls on a server on that machine.</p> <p>When an RPC service is started, it tells rpcbind the address at which it is listening, and the RPC program numbers it is prepared to serve. When a client wishes to make an RPC call to a given program number, it first contacts rpcbind on the server machine to determine the address where RPC requests should be sent.</p> <p>rpcbind should be started before any other RPC service. Normally, standard RPC servers are started by port monitors, so rpcbind must be started before port monitors are invoked.</p> <p>When rpcbind is started, it checks that certain name-to-address translation-calls function correctly. If they fail, the network configuration databases may be corrupt. Since RPC services cannot function correctly in this situation, rpcbind reports the condition and terminates.</p> <p>rpcbind can only be started by the super-user.</p> |                |                 |              |         |
| OPTIONS        | <p>The following options are supported:</p> <ul style="list-style-type: none"><li>-d Run in debug mode. In this mode, rpcbind will not fork when it starts, will print additional information during operation, and will abort on certain errors. With this option, the name-to-address translation consistency checks are shown in detail.</li><li>-w Do a warm start. If rpcbind aborts or terminates on SIGINT or SIGTERM, it will write the current list of registered services to /tmp/portmap.file and /tmp/rpcbind.file. Starting rpcbind with the -w option instructs it to look for these files and start operation with the registrations found in them. This allows rpcbind to resume operation without requiring all RPC services to be restarted.</li></ul>                                                                                                                                                                                                                                                                                       |                |                 |              |         |
| FILES          | <p>/tmp/portmap.file</p> <p>/tmp/rpcbind.file</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |                |                 |              |         |

**NOTES** Terminating `rpcbind` with `SIGKILL` will prevent the warm-start files from being written.

All RPC servers must be restarted if the following occurs: `rpcbind` crashes (or is killed with `SIGKILL`) and is unable to write the warm-start files; `rpcbind` is started without the `-w` option after a graceful termination; or, the warm-start files are not found by `rpcbind`.

## rpc.bootparamd(1M)

| <b>DESCRIPTION</b> | <p>rpc.bootparamd is a server process that provides information from a bootparams database to diskless clients at boot time. See bootparams(4)</p> <p>The source for the bootparams database is determined by the nsswitch.conf(4) file (on the machine running the rpc.bootparamd process).</p> <p>The rpc.bootparamd program can be invoked either by inetd(1M) or directly from the command line.</p>                                 |                 |                          |                    |                                                |
| <b>OPTIONS</b>     | -d            Display debugging information.                                                                                                                                                                                                                                                                                                                                                                                             |                 |                          |                    |                                                |

| <b>NOTES</b>       | <p>A diskless client requires service from at least one rpc.bootparamd process running on a server that is on the same IP subnetwork as the diskless client.</p> <p>Some routines that compare hostnames use case-sensitive string comparisons; some do not. If an incoming request fails, verify that the case of the hostname in the file to be parsed matches the case of the hostname called for, and attempt the request again.</p> |                 |                          |                    |                                                |

|             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |                                                                                                                                                                                                                                                                                                    |

| DESCRIPTION | <p>rpcinfo makes an RPC call to an RPC server and reports what it finds.</p> <p>In the first synopsis, <i>rpcinfo</i> lists all the registered RPC services with <i>rpcbind</i> on <i>host</i>. If <i>host</i> is not specified, the local host is the default. If <i>-s</i> is used, the information is displayed in a concise format.</p> <p>In the second synopsis, <i>rpcinfo</i> lists all the RPC services registered with <i>rpcbind</i>, version 2. Note that the format of the information is different in the first and the second synopsis. This is because the second synopsis is an older protocol used to collect the information displayed (version 2 of the <i>rpcbind</i> protocol).</p> <p>The third synopsis makes an RPC call to procedure 0 of <i>prognum</i> and <i>versnum</i> on the specified <i>host</i> and reports whether a response was received. <i>transport</i> is the transport which has to be used for contacting the given service. The remote address of the service is obtained by making a call to the remote <i>rpcbind</i>.</p> <p>The <i>prognum</i> argument is a number that represents an RPC program number (see <i>rpc(4)</i>).</p> <p>If a <i>versnum</i> is specified, <i>rpcinfo</i> attempts to call that version of the specified <i>prognum</i>. Otherwise, <i>rpcinfo</i> attempts to find all the registered version numbers for the specified <i>prognum</i> by calling version 0, which is presumed not to exist; if it does exist, <i>rpcinfo</i> attempts to obtain this information by calling an extremely high version number instead, and attempts to call each registered version. Note that the version number is required for <i>-b</i> and <i>-d</i> options.</p> <p>The EXAMPLES section describe other ways of using <i>rpcinfo</i>.</p> |                                                                                                                                                                                                                                                                                                    |
| OPTIONS     | -T <i>transport</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            | Specify the transport on which the service is required. If this option is not specified, <i>rpcinfo</i> uses the transport specified in the <i>NETPATH</i> environment variable, or if that is unset or <i>NULL</i> , the transport in the <i>netconfig(4)</i> database is used. This is a generic |

## rpcinfo(1M)

|                        |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                        | option, and can be used in conjunction with other options as shown in the SYNOPSIS.                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| -a <i>serv_address</i> | Use <i>serv_address</i> as the (universal) address for the service on <i>transport</i> to ping procedure 0 of the specified <i>prognum</i> and report whether a response was received. The -T option is required with the -a option. If <i>versnum</i> is not specified, <i>rpcinfo</i> tries to ping all available version numbers for that program number. This option avoids calls to remote <i>rpcbind</i> to find the address of the service. The <i>serv_address</i> is specified in universal address format of the given transport. |
| -b                     | Make an RPC broadcast to procedure 0 of the specified <i>prognum</i> and <i>versnum</i> and report all hosts that respond. If <i>transport</i> is specified, it broadcasts its request only on the specified transport. If broadcasting is not supported by any transport, an error message is printed. Use of broadcasting should be limited because of the potential for adverse effect on other systems.                                                                                                                                 |
| -d                     | Delete registration for the RPC service of the specified <i>prognum</i> and <i>versnum</i> . If <i>transport</i> is specified, unregister the service on only that transport, otherwise unregister the service on all the transports on which it was registered. Only the owner of a service can delete a registration, except the superuser, who can delete any service.                                                                                                                                                                   |
| -l                     | Display a list of entries with a given <i>prognum</i> and <i>versnum</i> on the specified <i>host</i> . Entries are returned for all transports in the same protocol family as that used to contact the remote <i>rpcbind</i> .                                                                                                                                                                                                                                                                                                             |
| -m                     | Display a table of statistics of <i>rpcbind</i> operations on the given <i>host</i> . The table shows statistics for each version of <i>rpcbind</i> (versions 2, 3 and 4), giving the number of times each procedure was requested and successfully serviced, the number and type of remote call requests that were made, and information about RPC address lookups that were handled. This is useful for monitoring RPC activities on <i>host</i> .                                                                                        |
| -n <i>portnum</i>      | Use <i>portnum</i> as the port number for the -t and -u options instead of the port number given by <i>rpcbind</i> . Use of this option avoids a call to the remote <i>rpcbind</i> to find out the address of the service. This option is made obsolete by the -a option.                                                                                                                                                                                                                                                                   |

|    |                                                                                                                                                                                                                                                                                                                                                                                                           |
|----|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -p | Probe <code>rpcbind</code> on <i>host</i> using version 2 of the <code>rpcbind</code> protocol, and display a list of all registered RPC programs. If <i>host</i> is not specified, it defaults to the local host. This option is not useful for IPv6; use <code>-s</code> (see below) instead. Note that version 2 of the <code>rpcbind</code> protocol was previously known as the portmapper protocol. |
| -s | Display a concise list of all registered RPC programs on <i>host</i> . If <i>host</i> is not specified, it defaults to the local host.                                                                                                                                                                                                                                                                    |
| -t | Make an RPC call to procedure 0 of <i>prognum</i> on the specified <i>host</i> using TCP, and report whether a response was received. This option is made obsolete by the <code>-T</code> option as shown in the third synopsis.                                                                                                                                                                          |
| -u | Make an RPC call to procedure 0 of <i>prognum</i> on the specified <i>host</i> using UDP, and report whether a response was received. This option is made obsolete by the <code>-T</code> option as shown in the third synopsis.                                                                                                                                                                          |

**EXAMPLES****EXAMPLE 1** RPC services.

To show all of the RPC services registered on the local machine use:

```
example% rpcinfo
```

To show all of the RPC services registered with `rpcbind` on the machine named *klaxon* use:

```
example% rpcinfo klaxon
```

The information displayed by the above commands can be quite lengthy. Use the `-s` option to display a more concise list:

```
example% rpcinfo -s klaxon
```

| program | vrsn  | netid(s)                        | service | owner     |
|---------|-------|---------------------------------|---------|-----------|
| 100000  | 2,3,4 | tcp,udp,ticlts,ticots,ticotsord | rpcbind | superuser |
| 100008  | 1     | ticotsord,ticots,ticlts,udp,tcp | walld   | superuser |
| 100002  | 2,1   | ticotsord,ticots,ticlts,udp,tcp | rusersd | superuser |
| 100001  | 2,3,4 | ticotsord,ticots,tcp,ticlts,udp | rstatd  | superuser |
| 100012  | 1     | ticotsord,ticots,ticlts,udp,tcp | sprayd  | superuser |
| 100007  | 3     | ticotsord,ticots,ticlts,udp,tcp | ypbind  | superuser |
| 100029  | 1     | ticotsord,ticots,ticlts         | keyserv | superuser |

## rpcinfo(1M)

### EXAMPLE 1 RPC services. (Continued)

|        |     |                                 |          |           |
|--------|-----|---------------------------------|----------|-----------|
| 100078 | 4   | ticotsord,ticots,ticlts         | -        | superuser |
| 100024 | 1   | ticotsord,ticots,ticlts,udp,tcp | status   | superuser |
| 100021 | 2,1 | ticotsord,ticots,ticlts,udp,tcp | nlockmgr | superuser |
| 100020 | 1   | ticotsord,ticots,ticlts,udp,tcp | llockmgr | superuser |

To show whether the RPC service with program number *prognum* and version *versnum* is registered on the machine named *klaxon* for the transport TCP use:

```
example% rpcinfo -T tcp klaxon prognum versnum
```

To show all RPC services registered with version 2 of the rpcbind protocol on the local machine use:

```
example% rpcinfo -p
```

To delete the registration for version 1 of the walld (program number 100008) service for all transports use:

```
example# rpcinfo -d 100008 1
```

or

```
example# rpcinfo -d walld 1
```

rpc.metamedd(1M)

**NAME** rpc.metamedd – remote mediator services

**SYNOPSIS** `/usr/sbin/rpc.metamedd`

**DESCRIPTION** `rpc.metamedd` is an `rpc(4)` server which is used to manage mediator information for use in 2-string HA configurations. The `rpc.metamedd` daemon is invoked by `inetd(1M)`.

**EXIT STATUS** The following exit values are returned:

|    |                        |
|----|------------------------|
| 0  | Successful completion. |
| >0 | An error occurred.     |

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| DESCRIPTION | <p>The <code>rpc.nisd</code> daemon is an RPC service that implements the NIS+ service. This daemon must be running on all machines that serve a portion of the NIS+ namespace.</p> <p><code>rpc.nisd</code> is usually started from a system startup script.</p> <p>The <code>-B</code> option causes <code>rpc.nisd</code> to start an auxiliary process, <code>rpc.nisd_resolv</code>, which provides ypserv compatible DNS forwarding for NIS host requests. <code>rpc.nisd_resolv</code> can also be started independently. See <code>rpc.nisd_resolv(1M)</code> for more information on using <code>rpc.nisd_resolv</code> independently.</p> <p>The <code>/etc/default/rpc.nisd</code> file contains the following default parameter settings. See FILES.</p> <p>ENABLE_NIS_YP_EMULATION Specifies whether the server is put into NIS (YP) compatibility mode.<br/>ENABLE_NIS_YP_EMULATION=YES is equivalent to the <code>-Y</code> command-line option. The default value for ENABLE_NIS_YP_EMULATION is NO.</p>                                                                                                                                                                                                                                                         |
| OPTIONS     | <p>-A Authentication verbose mode. The daemon logs all the authentication related activities to <code>syslogd(1M)</code> with LOG_INFO priority.</p> <p>-B Provide ypserv compatible DNS forwarding for NIS host requests. The DNS resolving process, <code>rpc.nisd_resolv</code>, is started and controlled by <code>rpc.nisd</code>. This option requires that the <code>/etc/resolv.conf</code> file be setup for communication with a DNS nameserver. The <code>nslookup</code> utility can be used to verify communication with a DNS nameserver. See <code>resolv.conf(4)</code> and <code>nslookup(1M)</code>.</p> <p>-C Open diagnostic channel on <code>/dev/console</code>.</p> <p>-D Debug mode. Do not fork.</p> <p>-d <i>dictionary</i> Specify an alternate dictionary for the NIS+ database. The primary use of this option is for testing. Note that the string is not interpreted, rather it is simply passed to the <code>db_initialize</code> function.&gt;</p> <p>-F Force the server to do a checkpoint of the database when it starts up. Forced checkpoints may be required when the server is low on disk space. This option removes updates from the transaction log that have propagated to all of the replicas.</p> <p>-h Print list of options.</p> |

|                             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |   |                                                                                                                                                                                                                                                         |   |                                                                                                                                                                                                                                                                                                                                                                                    |   |                                                                                                                                                                                                                                                                             |

| <code>-L number</code>      | Specify the “load” the NIS+ service is allowed to place on the server. The load is specified in terms of the <i>number</i> of child processes that the server may spawn. The value of <i>number</i> must be at least 1 for the callback functions to work correctly. The default is 128.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |   |                                                                                                                                                                                                                                                         |   |                                                                                                                                                                                                                                                                                                                                                                                    |   |                                                                                                                                                                                                                                                                             |
| <code>-m mappingfile</code> | <p>Specify the name of a configuration file that maps NIS+ objects (especially tables and columns) to LDAP (entries and attributes). See <code>NIS+LDAPmapping(4)</code>. The default path is <code>/var/nis</code>. The default mapping file is <code>NIS+LDAPmapping</code>. If this file exists, the <code>rpc.nisd</code> daemon will map data to and from LDAP. A template mapping file that covers the normal NIS+ directories and tables is installed as <code>/var/nis/NIS+LDAPmapping.template</code>.</p> <p>A NIS+ object must have a valid mapping entry in the mapping file in order to have data for that table read from or written to the LDAP repository.</p> <p>The <code>rpc.nisd(4)</code> file contains specifications for LDAP server addresses, LDAP authentication method, and the like. See <code>NIS+LDAPmapping(4)</code> for an overview of the setup you need to map NIS+ data to or from LDAP.</p>                                                                                                                                                                                                                                                    |   |                                                                                                                                                                                                                                                         |   |                                                                                                                                                                                                                                                                                                                                                                                    |   |                                                                                                                                                                                                                                                                             |
| <code>-S level</code>       | <p>Set the authorization security level of the service. The argument is a number between 0 and 2. By default, the daemon runs at security level 2.</p> <table> <tr> <td>0</td><td>Security level 0 is designed to be used for testing and initial setup of the NIS+ namespace. Security level 2 is the default if the <code>-S</code> option is not used.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |   |                                                                                                                                                                                                                                                         |   |                                                                                                                                                                                                                                                                                                                                                                                    |   |                                                                                                                                                                                                                                                                             |
| <code>-t netid</code>       | Use <i>netid</i> as the transport for communication between <code>rpc.nisd</code> and <code>rpc.nisd_resolv</code> . The default transport is <code>ticots(7D)</code> ( <code>tcp</code> on SunOS 4.x systems).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |   |                                                                                                                                                                                                                                                         |   |                                                                                                                                                                                                                                                                                                                                                                                    |   |                                                                                                                                                                                                                                                                             |

## rpc.nisd(1M)

|                           |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|---------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -v                        | Verbose. With this option, the daemon sends a running narration of what it is doing to the syslog daemon (see <code>syslogd(1M)</code> ) at <code>LOG_INFO</code> priority. This option is most useful for debugging problems with the service. See also <code>-A</code> option.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| -x <i>attribute=value</i> | <p>Specify the value of the named <i>attribute</i>. Attributes that control the NIS+ to LDAP mapping operation are derived as follows:</p> <ol style="list-style-type: none"><li>1. Retrieve from LDAP.</li><li>2. Override with values from the <i>mappingfile</i>, if any. See the <code>-m</code> option.</li><li>3. Override with values from the command line <code>-x</code> options.</li></ol> <p>See <code>NIS+LDAPmapping(4)</code> and <code>rpc.nisd(4)</code> for the recognized attributes and their syntax.</p> <p>As a special case, you can use the <code>nisplusLdapConfig*</code> attributes to derive additional information from LDAP. You can only specify the <code>nisplusLdapConfig*</code> attributes in <code>rpc.nisd(4)</code> or by means of the command line.</p> |
| -Y                        | Put the server into NIS (YP) compatibility mode. When operating in this mode, the NIS+ server will respond to NIS Version 2 requests using the version 2 protocol. Because the YP protocol is not authenticated, only those items that have read access to nobody (the unauthenticated request) will be visible through the V2 protocol. It supports only the standard Version 2 maps in this mode (see <code>-B</code> option and <code>NOTES</code> in <code>ypfiles(4)</code> ). See <code>FILES</code> .                                                                                                                                                                                                                                                                                    |
| -z <i>number</i>          | Specify the maximum RPC record size that can be used over connection oriented transports. The default is 9000 bytes. If you specify a size less than the default value, the default value will be used instead.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

### EXAMPLES

#### EXAMPLE 1 Setting up the NIS+ Service

The following example sets up the NIS+ service.

```
example% rpc.nisd
```

#### EXAMPLE 2 Setting Up NIS+ Service Emulating YP With DNS Forwarding

The following example sets up the NIS+ service, emulating YP with DNS forwarding.

```
example% rpc.nisd -YB
```

**EXAMPLE 3** Specifying NIS+ and LDAP Mapping Information

The following example shows how to specify that all additional NIS+ and LDAP mapping information should be retrieved from DN “dc=x,dc=y,dc=z”, from the LDAP server at IP address 1.2.3.4, port 389. The examples uses the simple authentication method and the cn=nisplusAdmin,ou=People, proxy user. The -m option is omitted for clarity in this example..

```
-x nisplusLDAPconfigDN=dc=x,dc=y,dc=z \
-x nisplusLDAPconfigPreferredServerList=127.0.0.1:389 \
-x nisplusLDAPconfigAuthenticationMethod=simple \
-x nisplusLDAPconfigProxyUser=cn=nisplusAdmin,ou=People, \
-x nisplusLDAPconfigProxyPassword=xyzzz
```

**ENVIRONMENT  
VARIABLES**

**NETPATH** The transports that the NIS+ service will use can be limited by setting this environment variable. See `netconfig(4)`.

**FILES**

|                                          |                                                                                                                                                                                                             |
|------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>/var/nis/data/parent.object</code> | This file describes the namespace that is logically above the NIS+ namespace. The most common type of parent object is a DNS object. This object contains contact information for a server of that domain.  |
| <code>/var/nis/data/root.object</code>   | This file describes the root object of the NIS+ namespace. It is a standard XDR-encoded NIS+ directory object that can be modified by authorized clients using the <code>nis_modify(3NSL)</code> interface. |
| <code>/etc/init.d/rpc</code>             | Initialization script for NIS+.                                                                                                                                                                             |
| <code>/etc/default/rpc.nisd</code>       | LDAP connection and general <code>rpc.nisd</code> configuration. You can override some of the settings by command-line options.                                                                             |
| <code>/var/nis/NIS+LDAPmapping</code>    | Default path for LDAP mapping file. See the discussion of the -m option.                                                                                                                                    |

**ATTRIBUTES**

See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWnisu        |

| <b>DESCRIPTION</b> | <p>rpc.nisd_resolv is an auxiliary process which provides DNS forwarding service for NIS hosts requests to both ypserve and rpc.nisd that are running in the NIS compatibility mode. It is generally started by invoking rpc.nisd(1M) with the -B option or ypserve(1M) with the -d option. Although it is not recommended, rpc.nisd_resolv can also be started independently with the following options.</p> <p>This command requires that the /etc/resolv.conf file be setup for communication with a DNS nameserver. The nslookup utility can be used to verify communication with a DNS nameserver. See resolv.conf(4) and nslookup(1M).</p> |                |                 |              |          |
| <b>OPTIONS</b>     | <p>-F           Run in foreground.</p> <p>-C <i>fd</i>       Use <i>fd</i> for service xprt (from nisd).</p> <p>-v           Verbose. Send output to the syslog daemon.</p> <p>-V           Verbose. Send output to stdout.</p> <p>-t <i>xx</i>       Use transport <i>xx</i>.</p> <p>-p <i>yy</i>       Use transient program# <i>yy</i>.</p>                                                                                                                                                                                                                                                                                                   |                |                 |              |          |

| NAME        | rpc.nispasswd, nispasswd – NIS+ password update daemon                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |                                                                                                                                                                                                                                                                                                                            |
| SYNOPSIS    | <b>/usr/sbin/rpc.nispasswd</b> [-a <i>attempts</i> ] [-c <i>minutes</i> ] [-D] [-g] [-v]                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |                                                                                                                                                                                                                                                                                                                            |
| DESCRIPTION | <p>rpc.nispasswd daemon is an ONC+ RPC service that services password update requests from nispasswd(1) and yppasswd(1). It updates password entries in the NIS+ passwd table.</p> <p>rpc.nispasswd is normally started from a system startup script after the NIS+ server (rpc.nisd(1M)) has been started. rpc.nispasswd will determine whether it is running on a machine that is a master server for one or more NIS+ directories. If it discovers that the host is not a master server, then it will promptly exit. It will also determine if rpc.nisd(1M) is running in NIS (YP) compatibility mode (the -Yoption) and will register as yppasswd for NIS (YP) clients as well.</p> <p>rpc.nispasswd will syslog all failed password update attempts, which will allow an administrator to determine whether someone was trying to "crack" the passwords.</p> <p>rpc.nispasswd has to be run by a superuser.</p> |                                                                                                                                                                                                                                                                                                                            |
| OPTIONS     | -a <i>attempts</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   | Set the maximum number of attempts allowed to authenticate the caller within a password update request session. Failed attempts are syslogd(1M) and the request is cached by the daemon. After the maximum number of allowed attempts the daemon severs the connection to the client. The default value is set to 3.       |
|             | -c <i>minutes</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    | Set the number of minutes a failed password update request should be cached by the daemon. This is the time during which if the daemon receives further password update requests for the same user and authentication of the caller fails, then the daemon will simply not respond. The default value is set to 30minutes. |
|             | -D                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   | Debug. Run in debugging mode.                                                                                                                                                                                                                                                                                              |
|             | -g                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   | Generate DES credential. By default the DES credential is not generated for the user if they do not have one. By specifying this option, if the user does not have a credential, then one will be generated for them and stored in the NIS+ cred table.                                                                    |
|             | -v                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   | Verbose. With this option, the daemon sends a running narration of what it is doing to the syslog daemon. This option is useful for debugging problems.                                                                                                                                                                    |
| EXIT STATUS | 0                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    | success                                                                                                                                                                                                                                                                                                                    |

| <b>SYNOPSIS</b>    | <code>/usr/sbin/rpc.rexd [-s]</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |                |                 |              |          |
| <b>DESCRIPTION</b> | <p><code>rpc.rexd</code> is the Sun RPC server for remote program execution. This daemon is started by <code>inetd(1M)</code> whenever a remote execution request is made.</p> <p>For non-interactive programs, the standard file descriptors are connected directly to TCP connections. Interactive programs involve pseudo-terminals, in a fashion that is similar to the login sessions provided by <code>rlogin(1)</code>. This daemon may use NFS to mount file systems specified in the remote execution request.</p>                                                                                                                                                                                                                                                                                                                          |                |                 |              |          |
| <b>OPTIONS</b>     | <p>The following options are supported:</p> <p><code>-s</code>      Secure. When specified, requests must have valid DES credentials. If the request does not have a DES credential it is rejected. The default publickey credential is rejected. Only newer <code>on(1)</code> commands send DES credentials.</p> <p>If access is denied with an authentication error, you may have to set your publickey with the <code>chkey(1)</code> command.</p> <p>Specifying the <code>-s</code> option without presenting secure credentials will result in an error message: <code>Unix too weak auth (DesOnly)!</code></p>                                                                                                                                                                                                                                |                |                 |              |          |
| <b>SECURITY</b>    | <p><code>rpc.rexd</code> uses <code>pam(3PAM)</code> for account and session management. The PAM configuration policy, listed through <code>/etc/pam.conf</code>, specifies the modules to be used for <code>rpc.rexd</code>. Here is a partial <code>pam.conf</code> file with <code>rpc.rexd</code> entries for account and session management using the UNIX module.</p> <pre>rpc.rexd    account requisite    pam_roles.so.1 rpc.rexd    account required    pam_projects.so.1 rpc.rexd    account required    pam_unix_account.so.1  rpc.rexd    session required    pam_unix_session.so.1</pre> <p>If there are no entries for the <code>rpc.rexd</code> service, then the entries for the "other" service will be used. <code>rpc.rexd</code> uses the <code>getpwnuid()</code> call to determine whether the given user is a legal user.</p> |                |                 |              |          |
| <b>FILES</b>       | <p><code>/dev/pts/n</code>      Pseudo-terminals used for interactive mode</p> <p><code>/etc/passwd</code>      Authorized users</p> <p><code>/tmp_rex/rexd?????</code>      Temporary mount points for remote file systems</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |                |                 |              |          |

rpc.rexd(1M)

**SEE ALSO** chkey(1), on(1), rlogin(1), inetd(1M), pam(3PAM), inetd.conf(4), pam.conf(4), publickey(4), attributes(5), pam\_authtok\_check(5), pam\_authtok\_get(5), pam\_authtok\_store(5), pam\_dhkeys(5), pam\_passwd\_auth(5), pam\_unix(5), pam\_unix\_account(5), pam\_unix\_auth(5), pam\_unix\_session(5)

**DIAGNOSTICS** Diagnostic messages are normally printed on the console, and returned to the requestor.

**NOTES** Root cannot execute commands using rexd client programs such as on(1).

The pam\_unix(5) module might not be supported in a future release. Similar functionality is provided by pam\_authtok\_check(5), pam\_authtok\_get(5), pam\_authtok\_store(5), pam\_dhkeys(5), pam\_passwd\_auth(5), pam\_unix\_account(5), pam\_unix\_auth(5), and pam\_unix\_session(5).

rpc.rstatd(1M)

**NAME** rpc.rstatd, rstatd – kernel statistics server

**SYNOPSIS** `/usr/lib/netsvc/rstat/rpc.rstatd`

**DESCRIPTION** `rpc.rstatd` is a server which returns performance statistics obtained from the kernel. `rup(1)` uses `rpc.rstatd` to collect the uptime information that it displays.

`rpc.rstatd` is an RPC service.

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWrcmds       |

**SEE ALSO** `rup(1)`, `inetd(1M)`, `services(4)`, `attributes(5)`

rpc.rusersd(1M)

**NAME** rpc.rusersd, rusersd – network username server

**SYNOPSIS** /usr/lib/netsvc/rusers/rpc.rusersd

**DESCRIPTION** rpc.rusersd is a server that returns a list of users on the host. The rpc.rusersd daemon may be started by inetd(1M) or listen(1M).

**ATTRIBUTES** See attributes(5) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWrcmds       |

**SEE ALSO** inetd(1M), listen(1M), pmadm(1M), sacadm(1M), attributes(5)

rpc.rwalld(1M)

**NAME** rpc.rwalld, rwalld – network rwall server

**SYNOPSIS** /usr/lib/netsvc/rwall/rpc.rwalld

**DESCRIPTION** rpc.rwalld is a server that handles rwall(1M) requests. It is implemented by calling wall(1M) on all the appropriate network machines. The rpc.rwalld daemon may be started by inetd(1M) or listen(1M).

**ATTRIBUTES** See attributes(5) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWrcmds       |

**SEE ALSO** inetd(1M), listen(1M), rwall(1M), wall(1M), attributes(5)

| <b>NAME</b>        | rpc.smserverd – removable media device server                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |                |                 |              |          |

| <b>DESCRIPTION</b> | <p><code>rpc.smserverd</code> is a server that handles requests from client applications, including the Volume Management daemon (<code>vold(1M)</code>), for access to removable media devices. In addition to <code>vold</code>, <code>rmformat(1)</code> and the CDE Filemanager (when performing removable media operations) are <code>rpc.smserverd</code> clients. The <code>rpc.smserverd</code> daemon is started by <code>inetd(1M)</code> when a client makes a call to a Solaris-internal library to access a SCSI, IDE, or USB device. The daemon is not started if a client attempts to access a floppy or PCMCIA device. Once started, the daemon remains active until such time as it is idle for three minutes or more.</p> <p>The <code>rpc.smserverd</code> daemon is provided for the exclusive use of the client applications mentioned above. It has no external, customer-accessible interfaces, including no configuration file.</p> |                |                 |              |          |

| SYNOPSIS       | <b>/usr/lib/netsvc/spray/rpc.sprayd</b>                                                                                                                                                                                                                                                                                                                                                                                                                                                             |                |                 |              |           |
| DESCRIPTION    | <p>rpc.sprayd is a server that records the packets sent by spray(1M). The rpc.sprayd daemon may be started by inetd(1M) or listen(1M).</p> <p>The service provided by rpc.sprayd is not useful as a networking benchmark as it uses unreliable connectionless transports, (udp for example). It can report a large number of packets dropped when the drops were caused by the program sending packets faster than they can be buffered locally (before the packets get to the network medium).</p> |                |                 |              |           |
| ATTRIBUTES     | <p>See attributes(5) for descriptions of the following attributes:</p> <table><tr><th>ATTRIBUTE TYPE</th><th>ATTRIBUTE VALUE</th></tr><tr><td>Availability</td><td>SUNWrcmds</td></tr></table>                                                                                                                                                                                                                                                                                                      | ATTRIBUTE TYPE | ATTRIBUTE VALUE | Availability | SUNWrcmds |

| DESCRIPTION | <p>rpc.yppasswdd is a server that handles password change requests from yppasswd(1). It changes a password entry in the passwd, shadow, and security/passwd.adjunct files. The passwd and shadow files provide the basis for the passwd.byname and passwd.byuid maps. The passwd.adjunct file provides the basis for the passwd.adjunct.byname and passwd.adjunct.byuid maps. Entries in the passwd, shadow or passwd.adjunct files are changed only if the password presented by yppasswd(1) matches the encrypted password of the entry. All password files are located in the PWDIR directory.</p> <p>If the -D option is given, the passwd, shadow, or passwd.adjunct files are placed under the directory path that is the argument to -D.</p> <p>If the -noshell, -nogecos or -nopw options are given, these fields cannot be changed remotely using chfn, chsh, or passwd(1).</p> <p>If the -m option is given, a make(1) is performed in /var/yp after any of the passwd, shadow, or passwd.adjunct files are modified. All arguments following the flag are passed to make.</p> <p>The second of the listed syntaxes is provided only for backward compatibility. If the second syntax is used, the passwordfile is the full pathname of the password file and adjunctfile is the full pathname of the optional passwd.adjunct file. If a shadow file is found in the same directory as passwordfile, the shadowfile is used as described above. Use of this syntax and the discovery of a shadowfile file generates diagnostic output. The daemon, however, starts normally.</p> <p>The first and second syntaxes are mutually exclusive. You cannot specify the full pathname of the passwd, passwd.adjunct files and use the -D option at the same time.</p> <p>The daemon is started automatically on the master server of the passwd map by ypstart(1M), which is invoked at boot time by the /etc/init.d/rpc script.</p> <p>The server does not insist on the presence of a shadow file unless there is no -D option present or the directory named with the -D option is /etc. In addition, a passwd.adjunct file is not necessary. If the -D option is given, the server attempts to find a passwd.adjunct file in the security subdirectory of the named directory. For example, in the presence of "-D /var/yp" the server checks for a "/var/yp/security/passwd.adjunct" file.</p> |

## rpc.yppasswdd(1M)

If only a `passwd` file exists, then the encrypted password is expected in the second field. If both a `passwd` and a `passwd.adjunct` file exist, the encrypted password is expected in the second field of the adjunct file with `##username` in the second field of the `passwd` file. If all three files are in use, the encrypted password is expected in the shadow file. Any deviation causes a password update to fail.

If you remove or add a shadow or `passwd.adjunct` file after `rpc.yppasswdd` has started, you must stop and restart the daemon to enable it to recognize the change. See `ypstart(1m)` for information on restarting the daemon.

The `rpc.yppasswdd` daemon considers a shell that has a name that begins with 'r' to be a restricted shell. By default, the daemon does not check whether a shell begins with an 'r'. However, you can tell it to do so by uncommenting the `"check_restricted_shell_name=1"` line in `/etc/default/yppasswdd`. The result will be to restrict a user's ability to change from his default shell. See `yppasswdd(4)`.

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWypu         |

**SEE ALSO** `make(1)`, `passwd(1)`, `yppasswd(1)`, `inetd(1M)`, `ypmake(1M)`, `passwd(4)`, `shadow(4)`, `ypfiles(4)`, `yppasswdd(4)`, `attributes(5)`

**NOTES** If `make` has not been installed and the `-m` option is given, the daemon outputs a warning and proceeds, effectively ignoring the `-m` flag.

When using the `-D` option, you should make sure that the `PWDIR` of the `/var/yp/Makefile` is set accordingly.

The second listed syntax is supplied only for backward compatibility and might be removed in a future release of this daemon.

The Network Information Service (NIS) was formerly known as Sun Yellow Pages (YP). The functionality of the two remains the same; only the name has changed. The name Yellow Pages is a registered trademark in the United Kingdom of British Telecommunications PLC, and cannot be used without permission.

| <b>SYNOPSIS</b>    | <b>/usr/lib/netsvc/yp/rpc.yppupdated</b> [-is]                                                                                                                                                                                                                                                                                                                                                              |
| <b>DESCRIPTION</b> | <p>yppupdated is a daemon that updates information in the Network Information Service (NIS). yppupdated consults the <code>updaters(4)</code> file in the <code>/var/yp</code> directory to determine which NIS maps should be updated and how to change them.</p> <p>By default, the daemon requires the most secure method of authentication available to it, either DES (secure) or UNIX (insecure).</p> |
| <b>OPTIONS</b>     | <p>-i      Accept RPC calls with the insecure AUTH_UNIX credentials. This allows programmatic updating of the NIS maps in all networks.</p> <p>-s      Accept only calls authenticated using the secure RPC mechanism (AUTH_DES authentication). This disables programmatic updating of the NIS maps unless the network supports these calls.</p>                                                           |
| <b>FILES</b>       | <code>/var/yp/updaters</code> Configuration file for <code>rpc.yppupdated</code> command.                                                                                                                                                                                                                                                                                                                   |
| <b>ATTRIBUTES</b>  | See <code>attributes(5)</code> for descriptions of the following attributes:                                                                                                                                                                                                                                                                                                                                |

| NAME        | rpld – IA Network Booting RPL (Remote Program Load) Server                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| SYNOPSIS    | <pre>/usr/sbin/rpld [-fdDMblgz] interface /usr/sbin/rpld -a [-fdDMblgz]</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| DESCRIPTION | <p>The RPL server provides network booting functionality to IA clients by listening to boot requests from them according to the RPL protocol specifications. Boot requests can be generated by clients using the boot floppy supplied in the IA distribution. Once the request has been received, the server validates the client and adds it to its internal service list. Subsequent requests from the client to download bootfiles will result in the sending of data frames from the server to the client specifying where to load the boot program in memory. When all the bootfiles have been downloaded, the server specifies where to start execution to initiate the boot process.</p> <p>In the first synopsis, the interface parameter names the network interface upon which rpld is to listen for requests. For example:</p> <pre>/usr/sbin/rpld /dev/le0 /usr/sbin/rpld /dev/smc0</pre> <p>In the second synopsis, rpld locates all of the network interfaces present on the system and starts a daemon process for each one.</p> <p>The server starts by reading the default configuration file, or an alternate configuration file if one is specified. If no configuration file can be found, internal default values will be used. Alternatively, command line options are available to override any of the values in the configuration file. After the configuration options are set, it then opens the network interface as specified in the command line and starts listening to RPL boot requests.</p> <p>Network boot IA clients have to have information pre-configured on a server for the RPL server to validate and serve them. This involves putting configuration information in both the ethers(4) and the bootparams(4) databases. The ethers database contains a translation from the physical node address to the IP address of the clients and is normally used by the RARP server. The bootparams database stores all other information needed for booting off this client, such as the number of bootfiles and the file names of the various boot components. Both databases can be looked up by the RPL server through NIS. See the sub-section Client Configuration for information on how to set up these databases.</p> <p>To assist in the administration and maintenance of the network boot activity, there are two run-time signals that the server will accept to change some run-time parameters and print out useful status information. See the sub-section Signals for details.</p> <p>The RPL server is not limited to the ability to boot only IA clients. If properly configured, the server should be able to download any bootfiles to the clients.</p> <p><b>Client Configuration</b> The following configuration information is specific to booting IA clients.</p> |

In order to allow clients to boot IA from across the network, the client's information has to be pre-configured in two databases: `ethers(4)` and `bootparams(4)`. Both databases can be accessed through NIS. Refer to *Solaris 9 Installation Guide* for information on how to configure a diskless IA client. The discussion contained in the rest of this section is provided for your information only and should not be performed manually.

The `ethers` database contains a translation table to convert the physical node address to the IP address of the client. Therefore, an IP address must be assigned to the client (if this has not been done already), the node address of the client must be obtained, and then this information needs to be entered in the `ethers` database.

The bulk of the configuration is done in the `bootparams` database. This is a free-format database that essentially contains a number of keyword-value string pairs. A number of keywords have been defined for specific purposes, like the `bootparams` RPC in `bootparamd(1M)`. Three more keywords have been defined for the RPL server. They are `numbootfiles`, `bootfile`, and `bootaddr`. All three keywords must be in lowercase letters with no spaces before or after the equals symbol following the keyword.

`numbootfiles` Specifies the number of files to be downloaded to the network boot client. The format of this option is:

```
numbootfiles=n
```

Always use `numbootfiles=3` to boot IA across the network.

`bootfile` Specifies the path name of the bootfile to be downloaded and where in memory to start loading the bootfile. A complete path name should be used. For example, assuming the client's IP address is 129.181.32.15:

```
bootfile=/rplboot/129.181.32.15.hw.com:45000
bootfile=/rplboot/129.181.32.15.glue.com:35000
bootfile=/rplboot/129.181.32.15.inetboot=8000
```

The path name following the equals symbol specifies the bootfile to be downloaded, and the hex address following the colon (:) is the absolute address of the memory location to start loading that bootfile. These addresses should be in the range of 7c00 to a0000 (i.e., the base 640K range excluding the interrupt vector and BIOS data areas). Address 45000 for this `hw.com` bootfile is also a suggested value and if possible should not be changed. The address of 35000 for `glue.com` is a suggested value that, if possible, should not be changed. The address of 8000 for `inetboot` is an absolute requirement and should never be changed.

## rpld(1M)

These files, when created following the procedures in the *Solaris 9 Installation Guide* are actually symbolic links to the real file to be downloaded to the client. `hw.com` is linked to a special driver that corresponds to the network interface card of the client. `glue.com` and `inetboot` are generic to all network boot clients.

The order of these bootfile lines is not significant, but because problems have been found with certain boot PROMs, it is highly recommended that the bootfile lines be ordered in descending order of the load addresses.

`bootaddr`      The absolute address in memory to start executing after all the bootfiles have been downloaded. This address should always correspond to the address where `glue.com` is being loaded. If possible, always use:

```
bootaddr=35000
```

### OPTIONS

The following options are supported:

- |                                   |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|-----------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>-b background_mode</code>   | Specify 1 to run the server in the background and relinquish the controlling terminal, or 0 to run in the foreground without relinquishing the controlling terminal. This option corresponds to the <i>BackGround</i> setting in the configuration file. If you have specified that the error or warning messages be sent to standard output in the configuration file or by using the <code>-D</code> option above, the server cannot be run in background mode. Doing so will cause the server to exit after announcing the error. |
| <code>-d debug_level</code>       | Specify a level of 0 if you do not want any error or warning messages to be generated, or a level from 1 to 9 for increasing amounts of messages. This option corresponds to the <i>DebugLevel</i> setting in the configuration file. The default value is 0. Note that it is best to limit the level to 8 or below; use of level 9 may generate so many debug messages that the performance of the RPL server may be impacted.                                                                                                      |
| <code>-D debug_destination</code> | Specify 0 to send error or warning messages to standard output, 1 to <code>syslogd</code> , and 2 to the log file. This option corresponds to the <i>DebugDest</i> setting in the configuration file. The default value is 2.                                                                                                                                                                                                                                                                                                        |
| <code>-f config_filename</code>   | Use this to specify a configuration file name other than the system default <code>/etc/rpld.conf</code> file.                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <code>-g delay_granularity</code> | This corresponds to the <i>DelayGran</i> setting in the configuration file. If retransmission requests from clients do occur, the delay granularity factor will be used to adjust the delay count for this client upwards                                                                                                                                                                                                                                                                                                            |

|                                   |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|-----------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                   | <p>or downwards. If the retransmission request is caused by data overrun, the delay count will be incremented by delay granularity units to increase the delay between data frames. If the retransmission request is caused by sending data too slowly, this will be used to adjust the delay count downwards to shorten the delay. Eventually the server will settle at the delay count value that works best with the speed of the client and no retransmission request will be needed. The default value is 2.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <code>-l log_filename</code>      | <p>Specify an alternate log file name to hold the error or warning messages in connection with the <code>-D 2</code> option or the configuration file <code>DebugDest = 2</code> setting. This option corresponds to the <code>LogFile</code> setting in the configuration file. The default is <code>/var/spool/rpld.log</code>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <code>-M maximum_clients</code>   | <p>Specify the maximum number of simultaneous network boot clients to be served. This option corresponds to the <code>MaxClients</code> setting in the configuration file. A value of <code>-1</code> means unlimited, and the actual number will depend on available system resources. The default value is <code>-1</code>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <code>-s start_delay_count</code> | <p>This option corresponds to the <code>StartDelay</code> setting in the configuration file. Specify the number of delay units between outgoing data frames sent to clients to avoid retransmission requests from them. Using the LLC type 1 protocol, data transfer is a one-way, best-effort delivery mechanism. The server, without any type of delay mechanism, can overrun the client by sending data frames too quickly. Therefore, a variable delay is built into the server to limit the speed of sending data to the clients, thus avoiding the clients sending back retransmission requests. This value should be machine environment specific. If you have a fast server machine but slow client machines, you may want to set a large start delay count. If you have comparable server and client machines, the delay count may be set to 1. The delay is only approximate and should not be taken as an accurate measure of time. There is no specific correlation between the delay unit and the actual time of delay. The default value is 20.</p> |
| <code>-z frame_size</code>        | <p>This option corresponds to the <code>FrameSize</code> setting in the configuration file. This specifies the size of the data frames used to send data to the clients. This is limited by the underlying physical medium. For</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

## rpld(1M)

ethernet/802.3, the maximum physical frame size is 1500 octets. The default value is 1500. Note that the protocol overhead of LLC1 and RPL is 32 octets, resulting in a maximum data length of 1468 octets.

**Signals** The RPL server accepts two signals to change run-time parameters and display status information, respectively:

- HANGUP** This will cause the RPL server to reread the default configuration file `/etc/rpld.conf` or an alternate configuration file if one is specified when the server is started. New values of certain parameters can be used immediately, such as *DebugLevel*, *DebugDest*, *LogFile*, *DelayGran*, and *FrameSize*. For *MaxClients*, if the server is already serving more than the new value, the server will not accept additional boot requests until the number has fallen below the *MaxClients* parameter. For *StartDelay*, this will only affect new boot requests. All the existing delay counts for the various clients in service will not be affected. Finally, the *BackGround* parameter will have no effect once the server has been running. You cannot change the mode of service without first killing the server and then restarting it.
- USR1** This signal will cause the server to dump all the parameter values and the status of each individual boot client to the destination specified by *DebugDest*.

**FILES**

- `/usr/sbin/rpld`
- `/etc/rpld.conf`
- `/var/spool/rpld.log`
- `/etc/ethers`
- `/etc/bootparams`
- `/rplboot`

| <b>NAME</b>        | rquotad – remote quota server                                                                                                                                                                                                                                                |
| <b>SYNOPSIS</b>    | <b>/usr/lib/nfs/rquotad</b>                                                                                                                                                                                                                                                  |
| <b>DESCRIPTION</b> | rquotad is an rpc(4) server which returns quotas for a user of a local file system which is mounted by a remote machine over the NFS. The results are used by quota(1M) to display user quotas for remote file systems. The rquotad daemon is normally invoked by inetd(1M). |
| <b>USAGE</b>       | See largefile(5) for the description of the behavior of rquotad when encountering files greater than or equal to 2 Gbyte ( $2^{31}$ bytes).                                                                                                                                  |
| <b>FILES</b>       | quotas    quota file at the file system root                                                                                                                                                                                                                                 |
| <b>ATTRIBUTES</b>  | See attributes(5) for descriptions of the following attributes:                                                                                                                                                                                                              |

| DESCRIPTION | <p>rsh is a limiting version of the standard command interpreter sh, used to restrict logins to execution environments whose capabilities are more controlled than those of sh (see sh(1) for complete description and usage).</p> <p>When the shell is invoked, it scans the environment for the value of the environmental variable, SHELL. If it is found and rsh is the file name part of its value, the shell becomes a restricted shell.</p> <p>The actions of rsh are identical to those of sh, except that the following are disallowed:</p> <ul style="list-style-type: none"> <li>■ changing directory (see cd(1)),</li> <li>■ setting the value of \$PATH,</li> <li>■ specifying path or command names containing /,</li> <li>■ redirecting output (&gt; and &gt;&gt;).</li> </ul> <p>The restrictions above are enforced after .profile is interpreted.</p> <p>A restricted shell can be invoked in one of the following ways:</p> <ol style="list-style-type: none"> <li>1. rsh is the file name part of the last entry in the /etc/passwd file (see passwd(4));</li> <li>2. the environment variable SHELL exists and rsh is the file name part of its value; the environment variable SHELL needs to be set in the .login file;</li> <li>3. the shell is invoked and rsh is the file name part of argument 0;</li> <li>4. the shell is invoked with the -r option.</li> </ol> <p>When a command to be executed is found to be a shell procedure, rsh invokes sh to execute it. Thus, it is possible to provide to the end-user shell procedures that have access to the full power of the standard shell, while imposing a limited menu of commands; this scheme assumes that the end-user does not have write and execute permissions in the same directory.</p> <p>The net effect of these rules is that the writer of the .profile (see profile(4)) has complete control over user actions by performing guaranteed setup actions and leaving the user in an appropriate directory (probably <i>not</i> the login directory).</p> <p>The system administrator often sets up a directory of commands (that is, /usr/rbin) that can be safely invoked by a restricted shell. Some systems also provide a restricted editor, red.</p> |
| EXIT STATUS | Errors detected by the shell, such as syntax errors, cause the shell to return a non-zero exit status. If the shell is being used non-interactively execution of the shell file is abandoned. Otherwise, the shell returns the exit status of the last command executed.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

| SYNOPSIS       | <b>/usr/sbin/rtc</b> [-c] [-z <i>zone-name</i> ]                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |                                                                                                                                                                                                                                                                                                                                                                                                                     |                |                 |              |    |              |         |
| DESCRIPTION    | <p>The <b>rtc</b> command reconciles the difference in the way that time is established between UNIX and MS-DOS systems. UNIX systems utilize Greenwich Mean Time (GMT), while MS-DOS systems utilize local time.</p> <p>Without arguments, <b>rtc</b> displays the currently configured time zone string. The currently configured time zone string is based on what was last recorded by <b>rtc-z zone-name</b>.</p> <p>The <b>rtc</b> command is not normally run from a shell prompt; it is generally invoked by the system. Commands such as <b>date(1)</b> and <b>rdate(1M)</b>, which are used to set the time on a system, invoke <b>/usr/sbin/rtc -c</b> to ensure that daylight savings time (DST) is corrected for properly.</p> |                                                                                                                                                                                                                                                                                                                                                                                                                     |                |                 |              |    |              |         |

| DESCRIPTION             | <p>The <code>rtquery</code> command is used to query a RIP network routing daemon, <code>in.routed(1M)</code> or <code>GateD</code>, for its routing table by sending a request or poll command. The routing information in any routing response packets returned is displayed numerically and symbolically.</p> <p>By default, <code>rtquery</code> uses the request command. When the <code>-p</code> option is specified, <code>rtquery</code> uses the poll command, an undocumented extension to the RIP protocol supported by <code>GateD</code>. When querying <code>GateD</code>, the poll command is preferred over the request command because the response is not subject to Split Horizon and/or Poisoned Reverse, and because some versions of <code>GateD</code> do not answer the request command. <code>in.routed</code> does not answer the poll command, but recognizes requests coming from <code>rtquery</code> and so answers completely.</p> <p>The <code>rtquery</code> command is also used to turn tracing on or off in <code>in.routed</code>.</p>                                                                                                                                                                                                                                                                 |  |               |  |                         |                                                                           |    |                                                                                                  |    |                                                                                                                                                                           |                |                                                   |                     |                                                                                                                                                                                                                                                                                                |              |                                                                                                                                                                                       |      |                                |     |                    |

| -n                      | Displays only the numeric network and host addresses instead of both numeric and symbolic names.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |  |               |  |                         |                                                                           |    |                                                                                                  |    |                                                                                                                                                                           |                |                                                   |                     |                                                                                                                                                                                                                                                                                                |              |                                                                                                                                                                                       |      |                                |     |                    |
| -p                      | Uses the poll command to request full routing information from <code>GateD</code> . This is an undocumented extension RIP protocol supported only by <code>GateD</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |  |               |  |                         |                                                                           |    |                                                                                                  |    |                                                                                                                                                                           |                |                                                   |                     |                                                                                                                                                                                                                                                                                                |              |                                                                                                                                                                                       |      |                                |     |                    |
| -r <i>addr</i>          | Asks about the route to destination <i>addr</i> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |  |               |  |                         |                                                                           |    |                                                                                                  |    |                                                                                                                                                                           |                |                                                   |                     |                                                                                                                                                                                                                                                                                                |              |                                                                                                                                                                                       |      |                                |     |                    |
| -t <i>operation</i>     | Changes tracing, where <i>operation</i> is one of the actions listed below. Requests from processes not running with UID 0 or on distant networks are generally ignored by the daemon except for a message in the system log. <code>GateD</code> is likely to ignore these debugging requests.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |  |               |  |                         |                                                                           |    |                                                                                                  |    |                                                                                                                                                                           |                |                                                   |                     |                                                                                                                                                                                                                                                                                                |              |                                                                                                                                                                                       |      |                                |     |                    |
| on=tracefile            | Turns tracing on, directing tracing into the specified file. That file must have been specified when the daemon was started or have the name, <code>/var/log/in.routed.trace</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |  |               |  |                         |                                                                           |    |                                                                                                  |    |                                                                                                                                                                           |                |                                                   |                     |                                                                                                                                                                                                                                                                                                |              |                                                                                                                                                                                       |      |                                |     |                    |

rtquery(1M)

dump                Dumps the daemon's routing table to the current trace file.

-w *timeout*                Changes the delay for an answer from each host. By default, each host is given 15 seconds to respond.

-1                    Queries using RIP version 1 instead of RIP version 2.

**EXIT STATUS**        The following exit values are returned:

0                    Successful completion.

>0                  An error occurred.

**ATTRIBUTES**        See attributes(5) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWroute       |

**SEE ALSO**            in.routed(1M), route(1M), gateways(4), attributes(5), icmp(7P), inet(7P), udp(7P)

*Routing Information Protocol, RIPv1, RFC 1058*

*Routing Information Protocol, RIPv2, RFC 2453, STD 0056*

| DESCRIPTION | <p>runacct is the main daily accounting shell procedure. It is normally initiated using cron. runacct processes connect, fee, disk, and process accounting files. It also prepares summary files for prdaily or billing purposes. runacct is distributed only to source code licensees.</p> <p>runacct takes care not to damage active accounting files or summary files in the event of errors. It records its progress by writing descriptive diagnostic messages into active. When an error is detected, a message is written to /dev/console, mail (see mail(1)) is sent to root and adm, and runacct terminates. runacct uses a series of lock files to protect against re-invocation. The files lock and lock1 are used to prevent simultaneous invocation, and lastdate is used to prevent more than one invocation per day.</p> <p>runacct breaks its processing into separate, restartable <i>states</i> using statefile to remember the last <i>state</i> completed. It accomplishes this by writing the <i>state</i> name into statefile. runacct then looks in statefile to see what it has done and to determine what to process next. <i>states</i> are executed in the following order:</p> <table> <tr> <td>SETUP</td><td>Move active accounting files into working files.</td></tr> <tr> <td>WTMPFIX</td><td>Verify integrity of wtmpx file, correcting date changes if necessary.</td></tr> <tr> <td>CONNECT</td><td>Produce connect session records in tacct.h format.</td></tr> <tr> <td>PROCESS</td><td>Convert process accounting records into tacct.h format.</td></tr> <tr> <td>MERGE</td><td>Merge the connect and process accounting records.</td></tr> <tr> <td>FEES</td><td>Convert output of chargefee into tacct.h format, merge with connect, and process accounting records.</td></tr> <tr> <td>DISK</td><td>Merge disk accounting records with connect, process, and fee accounting records.</td></tr> <tr> <td>MERGETACCT</td><td>Merge the daily total accounting records in daytacct with the summary total accounting records in /var/adm/acct/sum/tacct.</td></tr> <tr> <td>CMS</td><td>Produce command summaries.</td></tr> <tr> <td>USEREXIT</td><td>Any installation dependent accounting programs can be included here.</td></tr> <tr> <td>CLEANUP</td><td>Clean up temporary files and exit. To restart runacct after a failure, first check the active file for diagnostics, then fix any corrupted data files, such as pacct or wtmpx. The lock, lock1, and lastdate files must be removed before runacct can be restarted. The argument <i>mmdd</i> is necessary if runacct is being restarted. <i>mmdd</i> specifies the month and day for which runacct will rerun the accounting. The entry point for processing is based</td></tr> </table> | SETUP | Move active accounting files into working files. | WTMPFIX | Verify integrity of wtmpx file, correcting date changes if necessary. | CONNECT | Produce connect session records in tacct.h format. | PROCESS | Convert process accounting records into tacct.h format. | MERGE | Merge the connect and process accounting records. | FEES | Convert output of chargefee into tacct.h format, merge with connect, and process accounting records. | DISK | Merge disk accounting records with connect, process, and fee accounting records. | MERGETACCT | Merge the daily total accounting records in daytacct with the summary total accounting records in /var/adm/acct/sum/tacct. | CMS | Produce command summaries. | USEREXIT | Any installation dependent accounting programs can be included here. | CLEANUP | Clean up temporary files and exit. To restart runacct after a failure, first check the active file for diagnostics, then fix any corrupted data files, such as pacct or wtmpx. | CLEANUP     | Clean up temporary files and exit. To restart runacct after a failure, first check the active file for diagnostics, then fix any corrupted data files, such as pacct or wtmpx. The lock, lock1, and lastdate files must be removed before runacct can be restarted. The argument <i>mmdd</i> is necessary if runacct is being restarted. <i>mmdd</i> specifies the month and day for which runacct will rerun the accounting. The entry point for processing is based                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |       |                                                  |         |                                                                       |         |                                                    |         |                                                         |       |                                                   |      |                                                                                                      |      |                                                                                  |            |                                                                                                                            |     |                            |          |                                                                      |         |                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

## runacct(1M)

on the contents of *statefile*; to override this, include the desired *state* on the command line to designate where processing should begin.

### EXAMPLES

#### EXAMPLE 1 Starting runacct

The following example starts runacct:

```
example% nohup runacct 2> /var/adm/acct/nite/fd2log &
```

#### EXAMPLE 2 Restarting runacct

The following example restarts runacct:

```
example% nohup runacct 0601 2>> /var/adm/acct/nite/fd2log &
```

#### EXAMPLE 3 Restarting runacct at a Specific State

The following example restarts runacct at a specific state:

```
example% nohup runacct 0601 MERGE 2>> /var/adm/acct/nite/fd2log &
```

### NOTES

It is not recommended to restart runacct in the *SETUP state*. Run *SETUP* manually and restart using:

`runacct mmd` WTMPFIX

If `runacct` failed in the *PROCESS state*, remove the last `ptacct` file because it will not be complete.

The `runacct` command can process a maximum of

- 6000 distinct sessions
- 1000 distinct terminal lines
- 2000 distinct login names

during a single invocation of the command. If at some point the actual number of any one of these items exceeds the maximum, the command will not succeed.

Do not invoke `runacct` at the same time as `ckpacct`, as there may be a conflict if both scripts attempt to execute `turnacct switch` simultaneously.

## rwall(1M)

| <b>NAME</b>        | rwall – write to all users over a network                                                                                                                                                                                                                                    |                |                 |              |           |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------|-----------------|--------------|-----------|
| <b>SYNOPSIS</b>    | <pre>/usr/sbin/rwall hostname...<br/>/usr/sbin/rwall -n netgroup...<br/>/usr/sbin/rwall -h hostname -n netgroup</pre>                                                                                                                                                        |                |                 |              |           |
| <b>DESCRIPTION</b> | <p>rwall reads a message from standard input until EOF. It then sends this message, preceded by the line:</p> <pre>Broadcast Message . . .</pre> <p>to all users logged in on the specified host machines. With the -n option, it sends to the specified network groups.</p> |                |                 |              |           |
| <b>OPTIONS</b>     | <p>-n <i>netgroup</i>      Send the broadcast message to the specified network groups.</p> <p>-h <i>hostname</i>      Specify the hostname, the name of the host machine.</p>                                                                                                |                |                 |              |           |
| <b>ATTRIBUTES</b>  | <p>See attributes(5) for descriptions of the following attributes:</p> <table><thead><tr><th>ATTRIBUTE TYPE</th><th>ATTRIBUTE VALUE</th></tr></thead><tbody><tr><td>Availability</td><td>SUNWrcmdc</td></tr></tbody></table>                                                 | ATTRIBUTE TYPE | ATTRIBUTE VALUE | Availability | SUNWrcmdc |
| ATTRIBUTE TYPE     | ATTRIBUTE VALUE                                                                                                                                                                                                                                                              |                |                 |              |           |
| Availability       | SUNWrcmdc                                                                                                                                                                                                                                                                    |                |                 |              |           |
| <b>SEE ALSO</b>    | inetd(1M), listen(1M), pmdm(1M), sacadm(1M), wall(1M), attributes(5)                                                                                                                                                                                                         |                |                 |              |           |
| <b>NOTES</b>       | The timeout is fairly short to allow transmission to a large group of machines (some of which may be down) in a reasonable amount of time. Thus the message may not get through to a heavily loaded machine.                                                                 |                |                 |              |           |

|                                                |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |         |                                                                                                                            |          |                                                                                                                                                       |          |                                                                                                                         |        |                                                          |          |                                                                                                                                                         |

| <b>DESCRIPTION</b>                             | The Service Access Controller (SAC) is the overseer of the server machine. It is started when the server machine enters multiuser mode. The SAC performs several important functions as explained below.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |         |                                                                                                                            |          |                                                                                                                                                       |          |                                                                                                                         |        |                                                          |          |                                                                                                                                                         |
| <b>Customizing the SAC Environment</b>         | When <b>sac</b> is invoked, it first looks for the per-system configuration script <code>/etc/saf/_sysconfig</code> . <b>sac</b> interprets <code>_sysconfig</code> to customize its own environment. The modifications made to the SAC environment by <code>_sysconfig</code> are inherited by all the children of the SAC. This inherited environment may be modified by the children.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |         |                                                                                                                            |          |                                                                                                                                                       |          |                                                                                                                         |        |                                                          |          |                                                                                                                                                         |
| <b>Starting Port Monitors</b>                  | After it has interpreted the <code>_sysconfig</code> file, the <b>sac</b> reads its administrative file <code>/etc/saf/_sactab</code> . <code>_sactab</code> specifies which port monitors are to be started. For each port monitor to be started, <b>sac</b> forks a child (see <code>fork(2)</code> ) and creates a <code>utmpx</code> entry with the <code>type</code> field set to <code>LOGIN_PROCESS</code> . Each child then interprets its per-port monitor configuration script <code>/etc/saf/pmtag/_config</code> , if the file exists. These modifications to the environment affect the port monitor and will be inherited by all its children. Finally, the child process <b>execs</b> the port monitor, using the command found in the <code>_sactab</code> entry. (See <b>sacadm</b> ; this is the command given with the <code>-c</code> option when the port monitor is added to the system.)                                                                                                                                                                                                                                                                                                                                      |         |                                                                                                                            |          |                                                                                                                                                       |          |                                                                                                                         |        |                                                          |          |                                                                                                                                                         |
| <b>Polling Port Monitors to Detect Failure</b> | The <code>-t</code> option sets the frequency with which <b>sac</b> polls the port monitors on the system. This time may also be thought of as half of the maximum latency required to detect that a port monitor has failed and that recovery action is necessary.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |         |                                                                                                                            |          |                                                                                                                                                       |          |                                                                                                                         |        |                                                          |          |                                                                                                                                                         |
| <b>Administrative functions</b>                | <p>The Service Access Controller represents the administrative point of control for port monitors. Its administrative tasks are explained below.</p> <p>When queried (<b>sacadm</b> with either <code>-l</code> or <code>-L</code>), the Service Access Controller returns the status of the port monitors specified, which <b>sacadm</b> prints on the standard output. A port monitor may be in one of six states:</p> <table> <tr> <td>ENABLED</td><td>The port monitor is currently running and is accepting connections. See <b>sacadm(1M)</b> with the <code>-e</code> option.</td></tr> <tr> <td>DISABLED</td><td>The port monitor is currently running and is not accepting connections. See <b>sacadm</b> with the <code>-d</code> option, and see NOTRUNNING, below.</td></tr> <tr> <td>STARTING</td><td>The port monitor is in the process of starting up. STARTING is an intermediate state on the way to ENABLED or DISABLED.</td></tr> <tr> <td>FAILED</td><td>The port monitor was unable to start and remain running.</td></tr> <tr> <td>STOPPING</td><td>The port monitor has been manually terminated but has not completed its shutdown procedure. STOPPING is an intermediate state on the way to NOTRUNNING.</td></tr> </table> | ENABLED | The port monitor is currently running and is accepting connections. See <b>sacadm(1M)</b> with the <code>-e</code> option. | DISABLED | The port monitor is currently running and is not accepting connections. See <b>sacadm</b> with the <code>-d</code> option, and see NOTRUNNING, below. | STARTING | The port monitor is in the process of starting up. STARTING is an intermediate state on the way to ENABLED or DISABLED. | FAILED | The port monitor was unable to start and remain running. | STOPPING | The port monitor has been manually terminated but has not completed its shutdown procedure. STOPPING is an intermediate state on the way to NOTRUNNING. |
| ENABLED                                        | The port monitor is currently running and is accepting connections. See <b>sacadm(1M)</b> with the <code>-e</code> option.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |         |                                                                                                                            |          |                                                                                                                                                       |          |                                                                                                                         |        |                                                          |          |                                                                                                                                                         |
| DISABLED                                       | The port monitor is currently running and is not accepting connections. See <b>sacadm</b> with the <code>-d</code> option, and see NOTRUNNING, below.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |         |                                                                                                                            |          |                                                                                                                                                       |          |                                                                                                                         |        |                                                          |          |                                                                                                                                                         |
| STARTING                                       | The port monitor is in the process of starting up. | FAILED                                         | The port monitor was unable to start and remain running.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |         |                                                                                                                            |          |                                                                                                                                                       |          |                                                                                                                         |        |                                                          |          |                                                                                                                                                         |
| STOPPING                                       | The port monitor has been manually terminated but has not completed its shutdown procedure. STOPPING is an intermediate state on the way to NOTRUNNING.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |         |                                                                                                                            |          |                                                                                                                                                       |          |                                                                                                                         |        |                                                          |          |                                                                                                                                                         |

## sac(1M)

**NOTRUNNING** The port monitor is not currently running. (See `sacadm` with `-k`.) This is the normal “not running” state. When a port monitor is killed, all ports it was monitoring are inaccessible. It is not possible for an external user to tell whether a port is not being monitored or the system is down. If the port monitor is not killed but is in the `DISABLED` state, it may be possible (depending on the port monitor being used) to write a message on the inaccessible port telling the user who is trying to access the port that it is disabled. This is the advantage of having a `DISABLED` state as well as the `NOTRUNNING` state.

When a port monitor terminates, the SAC removes the `utmpx` entry for that port monitor.

The SAC receives all requests to enable, disable, start, or stop port monitors and takes the appropriate action.

The SAC is responsible for restarting port monitors that terminate. Whether or not the SAC will restart a given port monitor depends on two things:

- The restart count specified for the port monitor when the port monitor was added by `sacadm`; this information is included in `/etc/saf/pmtag/_sactab`.
- The number of times the port monitor has already been restarted.

**SECURITY** `sac` uses `pam(3PAM)` for session management. The PAM configuration policy, listed through `/etc/pam.conf`, specifies the session management module to be used for `sac`. Here is a partial `pam.conf` file with entries for `sac` using the UNIX session management module.

```
sac session required pam_unix_session.so.1
```

If there are no entries for the `sac` service, then the entries for the “other” service will be used.

**OPTIONS** `-t sanity_interval` Sets the frequency (*sanity\_interval*) with which `sac` polls the port monitors on the system.

**FILES** `/etc/saf/_sactab`  
`/etc/saf/_sysconfig`  
`/var/adm/utmpx`  
`/var/saf/_log`

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWcsu         |

sac(1M)

**SEE ALSO** pmadm(1M), sacadm(1M), fork(2) pam(3PAM), pam.conf(4), attributes(5), pam\_authtok\_check(5), pam\_authtok\_get(5), pam\_authtok\_store(5), pam\_dhkeys(5), pam\_passwd\_auth(5), pam\_unix(5), pam\_unix\_account(5), pam\_unix\_auth(5), pam\_unix\_session(5)

**NOTES** The pam\_unix(5) module might not be supported in a future release. Similar functionality is provided by pam\_authtok\_check(5), pam\_authtok\_get(5), pam\_authtok\_store(5), pam\_dhkeys(5), pam\_passwd\_auth(5), pam\_unix\_account(5), pam\_unix\_auth(5), and pam\_unix\_session(5).

| DESCRIPTION | <p>sacadm is the administrative command for the upper level of the Service Access Facility hierarchy (port monitor administration). sacadm performs the following functions:</p> <ul style="list-style-type: none"> <li>■ adds or removes a port monitor</li> <li>■ starts or stops a port monitor</li> <li>■ enables or disables a port monitor</li> <li>■ installs or replaces a per-system configuration script</li> <li>■ installs or replaces a per-port monitor configuration script</li> <li>■ prints requested port monitor information</li> </ul> <p>Requests about the status of port monitors (-l and -L) and requests to print per-port monitor and per-system configuration scripts (-g and -G without the -z option) may be executed by any user on the system. Other sacadm commands may be executed only by the super-user.</p> |
| OPTIONS     | <p>-a                   Add a port monitor. When adding a port monitor, sacadm creates the supporting directory structure in /etc/saf and /var/saf and adds an entry for the new port monitor to /etc/saf/_sactab. The file _sactab already exists on the delivered system. Initially, it is empty except for a single line, which contains the version number of the Service Access Controller. Unless the command line that adds the new port monitor includes the -f option with the -x argument, the new port monitor will be started. Because of the complexity of the options and arguments that follow the -a option, it may be convenient to use a command script or the menu system to add port monitors.</p>                                                                                                                          |

|                 |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|-----------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -c <i>cmd</i>   | Execute the command string <i>cmd</i> to start a port monitor. The -c option may be used only with a -a. A -a option requires a -c.                                                                                                                                                                                                                                                                                                                                                                                  |
| -d              | Disable the port monitor <i>pmtag</i> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| -e              | Enable the port monitor <i>pmtag</i> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| -f <i>dx</i>    | <p>The -f option specifies one or both of the following two flags which are then included in the flags field of the <code>_sactab</code> entry for the new port monitor. If the -f option is not included on the command line, no flags are set and the default conditions prevail. By default, a port monitor is started. A -f option with no following argument is illegal.</p> <p>d            Do not enable the new port monitor.</p> <p>x            Do not start the new port monitor.</p>                     |
| -g              | The -g option is used to request output or to install or replace the per-port monitor configuration script <code>/etc/saf/<i>pmtag</i>/_config</code> . -g requires a -p option. The -g option with only a -p option prints the per-port monitor configuration script for port monitor <i>pmtag</i> . The -g option with a -p option and a -z option installs the file <i>script</i> as the per-port monitor configuration script for port monitor <i>pmtag</i> . Other combinations of options with -g are invalid. |
| -G              | The -G option is used to request output or to install or replace the per-system configuration script <code>/etc/saf/_sysconfig</code> . The -G option by itself prints the per-system configuration script. The -G option in combination with a -z option installs the file <i>script</i> as the per-system configuration script. Other combinations of options with a -G option are invalid.                                                                                                                        |
| -k              | Stop port monitor <i>pmtag</i> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| -l              | The -l option is used to request port monitor information. The -l by itself lists all port monitors on the system. The -l option in combination with the -p option lists only the port monitor specified by <i>pmtag</i> . A -l in combination with the -t option lists all port monitors of type <i>type</i> . Any other combination of options with the -l option is invalid.                                                                                                                                      |
| -L              | The -L option is identical to the -l option except that the output appears in a condensed format.                                                                                                                                                                                                                                                                                                                                                                                                                    |
| -n <i>count</i> | Set the restart count to <i>count</i> . If a restart count is not specified, count is set to 0. A count of 0 indicates that the port monitor is not to be restarted if it fails.                                                                                                                                                                                                                                                                                                                                     |
| -p <i>pmtag</i> | Specifies the tag associated with a port monitor.                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| -r              | Remove port monitor <i>pmtag</i> . <code>sacadm</code> removes the port monitor entry from <code>/etc/saf/_sactab</code> . If the removed port monitor is                                                                                                                                                                                                                                                                                                                                                            |

## sacadm(1M)

|                 |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|-----------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                 | <p>not running, then no further action is taken. If the removed port monitor is running, the Service Access Controller (SAC) sends it SIGTERM to indicate that it should shut down. Note that the port monitor's directory structure remains intact.</p> <p><b>-s</b> Start a port monitor. The SAC starts the port monitor <i>pmtag</i>.</p> <p><b>-t type</b> Specifies the port monitor type.</p> <p><b>-v ver</b> Specifies the version number of the port monitor. This version number may be given as</p> <p style="margin-left: 40px;"><i>-v 'pmspec -V'</i></p> <p>where <i>pmspec</i> is the special administrative command for port monitor <i>pmtag</i>. This special command is <i>ttysadm</i> for <i>ttymon</i> and <i>nlsadmin</i> for <i>listen</i>. The version stamp of the port monitor is known by the command and is returned when <i>pmspec</i> is invoked with a <i>-V</i> option.</p> <p><b>-x</b> The <i>-x</i> option by itself tells the SAC to read its database file (<i>_sactab</i>). The <i>-x</i> option with the <i>-p</i> option tells port monitor <i>pmtag</i> to read its administrative file.</p> <p><b>-y comment</b> Include <i>comment</i> in the <i>_sactab</i> entry for port monitor <i>pmtag</i>.</p> <p><b>-z script</b> Used with the <i>-g</i> and <i>-G</i> options to specify the name of a file that contains a configuration script. With the <i>-g</i> option, <i>script</i> is a per-port monitor configuration script; with <i>-G</i> it is a per-system configuration script. Modifying a configuration script is a three-step procedure. First a copy of the existing script is made (<i>-g</i> or <i>-G</i>). Then the copy is edited. Finally, the copy is put in place over the existing script (<i>-g</i> or <i>-G</i> with <i>-z</i>).</p> |
| <b>OUTPUT</b>   | <p>If successful, <i>sacadm</i> will exit with a status of 0. If <i>sacadm</i> fails for any reason, it will exit with a nonzero status. Options that request information will write the information on the standard output. In the condensed format (<i>-L</i>), port monitor information is printed as a sequence of colon-separated fields; empty fields are indicated by two successive colons. The standard format (<i>-l</i>) prints a header identifying the columns, and port monitor information is aligned under the appropriate headings. In this format, an empty field is indicated by a hyphen. The comment character is #.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>EXAMPLES</b> | <p><b>EXAMPLE 1</b> A sample output of the <i>sacadm</i> command.</p> <p>The following command line adds a port monitor. The port monitor tag is <i>npack</i>; its type is <i>listen</i>; if necessary, it will restart three times before failing; its administrative command is <i>nlsadmin</i>; and the configuration script to be read is in the file <i>script</i>:</p> <pre>sacadm -a -p npack -t listen -c /usr/lib/saf/listen npack -v 'nlsadmin -V' -n 3 -z script</pre> <p>Remove a port monitor whose tag is <i>pmtag</i>:</p> <pre>sacadm -r -p pmtag</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

**EXAMPLE 1** A sample output of the `sacadm` command. *(Continued)*

Start the port monitor whose tag is `pmtag`:

```
sacadm -s -p pmtag
```

Stop the port monitor whose tag is `pmtag`:

```
sacadm -k -p pmtag
```

Enable the port monitor whose tag is `pmtag`:

```
sacadm -e -p pmtag
```

Disable the port monitor whose tag is `pmtag`:

```
sacadm -d -p pmtag
```

List status information for all port monitors:

```
sacadm -l
```

List status information for the port monitor whose tag is `pmtag`:

```
sacadm -l -p pmtag
```

List the same information in condensed format:

```
sacadm -L -p pmtag
```

List status information for all port monitors whose type is `listen`:

```
sacadm -l -t listen
```

Replace the per-port monitor configuration script associated with the port monitor whose tag is `pmtag` with the contents of the file `file.config`:

```
sacadm -g -p pmtag -z file.config
```

**FILES**

- `/etc/saf/_sactab`
- `/etc/saf/_sysconfig`
- `/etc/saf/pmtag/_config`

| <b>DESCRIPTION</b> | <p>sadmind is the daemon used by Solstice AdminSuite applications to perform distributed system administration operations.</p> <p>The sadmind daemon is started automatically by the inetd daemon whenever a request to invoke an operation is received. The sadmind daemon process continues to run for 15 minutes after the last request is completed, unless a different idle-time is specified with the -i command line option. The sadmind daemon may be started independently from the command line, for example, at system boot time. In this case, the -i option has no effect; sadmind continues to run, even if there are no active requests.</p> <p>The sadmind daemon process can be configured to write tracing information into a log file by specifying the -c and -l command line options. The -c option specifies a comma-separated list of keywords indicating the types of information to be logged. The following keywords may be useful to administrators:</p> <table> <tr> <td>Errors</td><td>Includes messages about errors that occurred during the daemon execution.</td></tr> <tr> <td>Requests</td><td>Includes messages about which operations sadmind invoked and when.</td></tr> <tr> <td>System-Info</td><td>Includes messages about when the sadmind daemon was started and stopped.</td></tr> <tr> <td>*</td><td>Includes all possible log messages.</td></tr> </table> <p>The -l option enables logging and optionally specifies the path and file name of the log file. If no log file is specified, the default log file /var/adm/admin.log is used.</p> | Errors             | Includes messages about errors that occurred during the daemon execution.                                                         | Requests       | Includes messages about which operations sadmind invoked and when.                                                                                                                                                                                                                                                                                                                                                                                                                                       | System-Info | Includes messages about when the sadmind daemon was started and stopped. | * | Includes all possible log messages. |
| Errors             | Includes messages about errors that occurred during the daemon execution.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |                    |                                                                                                                                   |                |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |             |                                                                          |   |                                     |
| Requests           | Includes messages about which operations sadmind invoked and when.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |                    |                                                                                                                                   |                |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |             |                                                                          |   |                                     |
| System-Info        | Includes messages about when the sadmind daemon was started and stopped.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |                    |                                                                                                                                   |                |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |             |                                                                          |   |                                     |

You may want sadmind to run permanently (or for extended durations) on systems that are frequently administered by applications using sadmind (for example, a server managed through Host Manager) to improve application performance. |             |                                                                          |   |                                     |
| -c <i>keywords</i> | Specify the types of information to be logged as a comma-separated list of keywords. The default is to log all types of messages.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |                    |                                                                                                                                   |                |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |             |                                                                          |   |                                     |
| -i <i>secs</i>     | Specify the number of seconds for sadmind to stay up after the last request is completed. The default is 15 minutes (900 seconds). If <i>secs</i> is 0 or over 10,000,000, sadmind stays up forever. -i only applies when sadmind is started by the inetd daemon. You may want sadmind to run permanently (or for extended durations) on systems that are frequently administered by applications using sadmind (for example, a server managed through Host Manager) to improve application performance.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |                    |                                                                                                                                   |                |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |             |                                                                          |   |                                     |

|                   |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |   |                                                                                                                                                                                                                                                                                                                                           |   |                                                                                                                                                                                            |

| -l [logfile]      | Enable logging and optionally define the path name to the distributed system administration log file. The default log file is: /var/adm/admin.log                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |   |                                                                                                                                                                                                                                                                                                                                           |   |                                                                                                                                                                                            |
| -O OW_path_name   | Define the path name to the OpenWindows home directory. If this option is not specified, the <code>sadmind</code> daemon will use the OpenWindows home directory defined in the <code>OPENWINHOME</code> environment variable, if defined; the home directory specified in the <code>/etc/OPENWINHOME</code> file, if it exists; or the default directory <code>/usr/openwin</code> . When the <code>sadmind</code> daemon is started by the <code>inetd</code> daemon, the environment variable <code>OPENWINHOME</code> is typically not defined. If the OpenWindows home directory is not one of the path names specified ( <code>/usr/openwin</code> or in the file <code>/etc/OPENWINHOME</code> ), the <code>-O</code> option must be added to the <code>sadmind</code> entry in the <code>inetd.conf(4)</code> configuration file.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |   |                                                                                                                                                                                                                                                                                                                                           |   |                                                                                                                                                                                            |
| -S security_level | <p>Define the level of security to be used by the <code>sadmind</code> daemon when checking a client's right to perform an operation on the server system. Security level specifies the authentication mechanism used to provide and check the client's identity. The client's identity must be authenticated by the specified mechanism for <code>sadmind</code> to accept his or her request. The system-wide authentication requirements set by the security level may take precedence over any operation-specific requirements. Consequently, the security level can be used system-wide to ensure that all operations meet minimum authentication requirements, regardless of the requirements assigned specifically to an operation. In addition, the security level determines whether <code>sadmind</code> will perform authorization access control checking.</p> <p>Security level may be one of the following:</p> <table> <tr> <td>0</td><td>Set authentication type to <code>NONE</code>. All clients' user and group identities are set to the <code>nobody</code> identity by <code>sadmind</code> (see <i>Solstice AdminSuite 2.1 User's Guide</i>). If access is granted to <code>nobody</code>, <code>sadmind</code> executes the operation. Use this level only for testing.</td></tr> <tr> <td>1</td><td>Set authentication type to <code>WEAK</code>. Clients' user and group identities are set by <code>sadmind</code> from their authentication credentials. Client identities are accepted by</td></tr> </table> | 0 | Set authentication type to <code>NONE</code> . All clients' user and group identities are set to the <code>nobody</code> identity by <code>sadmind</code> (see <i>Solstice AdminSuite 2.1 User's Guide</i> ). If access is granted to <code>nobody</code> , <code>sadmind</code> executes the operation. Use this level only for testing. | 1 | Set authentication type to <code>WEAK</code> . | 1                 | Set authentication type to <code>WEAK</code> . Clients' user and group identities are set by <code>sadmind</code> from their authentication credentials. Client identities are accepted by                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |   |                                                                                                                                                                                                                                                                                                                                           |   |                                                                                                                                                                                            |

sadmind when they have satisfied either AUTH\_SYS or AUTH\_DES authentication mechanisms. The authenticated client identity is checked by `sadmind` for authorization to execute the operation. If an operation calls for a stronger security level, `sadmind` demotes the user identity to `nobody`, and then checks whether `nobody` is authorized to execute the operation. Since AUTH\_SYS client credentials are easily forged, this level should be used only in relatively secure environments. No check is done that the user ID of the client represents the same user on the server system as on the client system. It is assumed that user and group identities are set up consistently on the network. This security level is the default.

- 2 Set authentication type to `STRONG`. Clients' user and group identities are set by `sadmind` from their authentication credential mappings (effectively, user and group IDs from `netid.byname` for NIS, or `cred` table for NIS+). Client identities are accepted by `sadmind` only when they have satisfied the AUTH\_DES authentication mechanism. The `sadmind` daemon checks whether the client identity is authorized to execute the operation. This level provides the most secure environment for executing distributed administration operations. It overrides any weaker level specific to an operation. A DES credential must exist for the host running the `sadmind` daemon and all administration client user identities.

`-v` Enable the writing of log messages to the system logger, `syslogd`. Messages logged include fatal errors encountered while attempting to start the `sadmind` daemon process and those specified by the `-c` trace message keywords.

## EXAMPLES

### EXAMPLE 1 Using the `sadmind` command

By default, the line in `/etc/inetd.conf` that starts `sadmind` appears as follows:

```
100232/10 tli rpc/udp wait root
/usr/sbin/sadmind sadmind
```

**EXAMPLE 1** Using the `sadmind` command (Continued)

To make a network as secure as possible, change the line to:

```
100232/10 tli rpc/udp wait root
/usr/sbin/sadmind sadmind -S 2
```

To minimize delays due to starting up `sadmind`, change the line to include the `-i` option:

```
100232/10 tli rpc/udp wait root
/usr/sbin/sadmind sadmind -i 86400
```

In this example, the duration that `sadmind` remains up after the last operation request was completed is extended to 24 hours (86,400 seconds). Extending the timeout period may enhance performance on servers and workstations that frequently run or are administered by applications that use the `sadmind` daemon (for example, Solstice AdminSuite applications such as Host Manager).

- FILES** `/var/adm/admin.log` Distributed system administration default log file
- `/etc/inetd.conf` Internet servers database file

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWadmfw       |

**SEE ALSO** `inetd(1M)`, `rpcbind(1M)`, `inetd.conf(4)`, `attributes(5)`  
*Solstice AdminSuite 2.1 User's Guide*

**NOTES** Whenever `inetd` fails to start `sadmind`, re-register the RPC number for `sadmind`, 100232, with `rpcbind` by sending the `inetd` process a `SIGHUP` signal:

```
example% kill -HUP pid
```

or

```
example% kill -1
```

Sometimes `inetd` does not start `sadmind` in response to system administration requests, even though the `inetd.conf` file has the correct entry for the `sadmind` daemon. This can happen when `sadmind` is started manually from the command line and takes over the previous registration of the `sadmind` RPC number, 100232, by `inetd`. When the manually-started `sadmind` daemon is terminated, the `sadmind` RPC number, 100232, is de-registered with `rpcbind`. Consequently, system administration requests are ignored by `inetd`.

| <b>NAME</b>          | saf – Service Access Facility                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>DESCRIPTION</b>   | <p>The SAF generalizes the procedures for service access so that login access on the local system and network access to local services are managed in similar ways. Under the SAF, systems may access services using a variety of port monitors, including ttymon, the listener, and port monitors written expressly for a user's application. The manner in which a port monitor observes and manages access ports is specific to the port monitor and not to any component of the SAF. Users may therefore extend their systems by developing and installing their own port monitors. One of the important features of the SAF is that it can be extended in this way by users.</p> <p>Relative to the SAF, a service is a process that is started. There are no restrictions on the functions a service may provide. The SAF consists of a controlling process, the service access controller (SAC), and two administrative levels corresponding to two levels in the supporting directory structure. The top administrative level is concerned with port monitor administration, the lower level with service administration. The SAC is documented in the <code>sac(1M)</code> man page. The administrative levels and associated utilities are documented in the <i>System Administration Guide - Volume II</i>. The requirements for writing port monitors and the functions a port monitor must perform to run under the SAF and the SAC are documented here.</p>                                                                                            |
| <b>Port Monitors</b> | <p>A port monitor is a process that is responsible for monitoring a set of homogeneous, incoming ports on a machine. A port monitor's major purpose is to detect incoming service requests and to dispatch them appropriately.</p> <p>A port is an externally seen access point on a system. A port may be an address on a network (TSAP or PSAP), a hardwired terminal line, an incoming phone line, etc. The definition of what constitutes a port is strictly a function of the port monitor itself.</p> <p>A port monitor performs certain basic functions. Some of these are required to conform to the SAF; others may be specified by the requirements and design of the port monitor itself. Port monitors have two main functions: managing ports and monitoring ports for indications of activity.</p> <p><b>Port Management</b></p> <p>The first function of a port monitor is to manage a port. The actual details of how a port is managed are defined by the person who defines the port monitor. A port monitor is not restricted to handling a single port; it may handle multiple ports simultaneously.</p> <p>Some examples of port management are setting the line speed on incoming phone connections, binding an appropriate network address, reinitializing the port when the service terminates, outputting a prompt, etc.</p> <p><b>Activity Monitoring</b></p> <p>The second function of a port monitor is to monitor the port or ports for which it is responsible for indications of activity. Two types of activity may be detected.</p> |

## Other Port Monitor Functions

The first is an indication to the port monitor to take some port monitor-specific action. Pressing the break key to indicate that the line speed should be cycled is an example of a port monitor activity. Not all port monitors need to recognize and respond to the same indications. The indication used to attract the attention of the port monitor is defined by the person who defines the port monitor.

The second is an incoming service request. When a service request is received, a port monitor must be able to determine which service is being requested from the port on which the request is received. The same service may be available on more than one port.

This section briefly describes other port monitor functions.

### Restricting Access to the System

A port monitor must be able to restrict access to the system without disturbing services that are still running. In order to do this, a port monitor must maintain two internal states: enabled and disabled. The port monitor starts in the state indicated by the ISTATE environment variable provided by the sac. See sac(1M) for details. Enabling or disabling a port monitor affects all ports for which the port monitor is responsible. If a port monitor is responsible for a single port, only that port will be affected. If a port monitor is responsible for multiple ports, the entire collection of ports will be affected. Enabling or disabling a port monitor is a dynamic operation: it causes the port monitor to change its internal state. The effect does not persist across new invocations of the port monitor. Enabling or disabling an individual port, however, is a static operation: it causes a change to an administrative file. The effect of this change will persist across new invocations of the port monitor.

### Creating utmpx Entries

Port monitors are responsible for creating utmpx entries with the type field set to USER\_PROCESS for services they start. If this action has been specified, by using the -fu option in the pmadm command line that added the service, these utmpx entries may in turn be modified by the service. When the service terminates, the utmpx entry must be set to DEAD\_PROCESS.

### Port Monitor Process IDs and Lock Files

When a port monitor starts, it writes its process id into a file named \_pid in the current directory and places an advisory lock on the file.

### Changing the Service Environment: Running

doconfig(3NSL) Before invoking the service designated in the port monitor administrative file, \_pmtab, a port monitor must arrange for the per-service configuration script to be run, if one exists, by calling the library function doconfig(3NSL). Because the per-service configuration script may specify the execution of restricted commands, as well as for other security reasons, port monitors are invoked with root permissions. The details of how services are invoked are specified by the person who defines the port monitor.

### Terminating a Port Monitor

A port monitor must terminate itself gracefully on receipt of the signal SIGTERM. The termination sequence is the following:

saf(1M)

|                                       |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

|                                       | <ol style="list-style-type: none"><li>1. The port monitor enters the stopping state; no further service requests are accepted.</li><li>2. Any attempt to re-enable the port monitor will be ignored.</li><li>3. The port monitor yields control of all ports for which it is responsible. It must be possible for a new instantiation of the port monitor to start correctly while a previous instantiation is stopping.</li><li>4. The advisory lock on the process id file is released. Once this lock is released, the contents of the process id file are undefined and a new invocation of the port monitor may be started.</li></ol>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>SAF Files</b>                      | <p>This section briefly covers the files used by the SAF.</p> <p><b>The Port Monitor Administrative File</b><br/>A port monitor's current directory contains an administrative file named <code>_pmtab</code>; <code>_pmtab</code> is maintained by the <code>pmadm</code> command in conjunction with a port monitor-specific administrative command.</p> <p>The port monitor administrative command for a listen port monitor is <code>nlsadmin(1M)</code>; the port monitor administrative command for <code>ttymon</code> is <code>ttyadm(1M)</code>. Any port monitor written by a user must be provided with an administrative command specific to that port monitor to perform similar functions.</p> <p><b>Per-Service Configuration Files</b><br/>A port monitor's current directory also contains the per-service configuration scripts, if they exist. The names of the per-service configuration scripts correspond to the service tags in the <code>_pmtab</code> file.</p> <p><b>Private Port Monitor Files</b><br/>A port monitor may create private files in the directory <code>/var/saf/tag</code>, where <code>tag</code> is the name of the port monitor. Examples of private files are log files or temporary files.</p> |
| <b>The SAC/Port Monitor Interface</b> | <p>The SAC creates two environment variables for each port monitor it starts: <code>PMTAG</code> and <code>ISTATE</code>.</p> <p>This variable is set to a unique port monitor tag by the SAC. The port monitor uses this tag to identify itself in response to <code>sac</code> messages. <code>ISTATE</code> is used to indicate to the port monitor what its initial internal state should be. <code>ISTATE</code> is set to "enabled" or "disabled" to indicate that the port monitor is to start in the enabled or disabled state respectively.</p> <p>The SAC performs a periodic sanity poll of the port monitors. The SAC communicates with port monitors through FIFOs. A port monitor should open <code>_pmpipe</code>, in the current directory, to receive messages from the SAC and <code>./_sacpipe</code> to send return messages to the SAC.</p>                                                                                                                                                                                                                                                                                                                                                                              |
| <b>Message Formats</b>                | <p>This section describes the messages that may be sent from the SAC to a port monitor (<code>sac</code> messages), and from a port monitor to the SAC (port monitor messages). These messages are sent through FIFOs and are in the form of C structures.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

**sac Messages**

The format of messages from the SAC is defined by the structure `sacmsg`:

```
struct sacmsg
{
 int sc_size; /* size of optional data portion */
 char sc_type; /* type of message */
};
```

The SAC may send four types of messages to port monitors. The type of message is indicated by setting the `sc_type` field of the `sacmsg` structure to one of the following:

|                         |                                                                                    |
|-------------------------|------------------------------------------------------------------------------------|
| <code>SC_STATUS</code>  | status request                                                                     |
| <code>SC_ENABLE</code>  | enable message                                                                     |
| <code>SC_DISABLE</code> | disable message                                                                    |
| <code>SC_READDB</code>  | message indicating that the port monitor's <code>_pmtab</code> file should be read |

The `sc_size` field indicates the size of the optional data part of the message. See "Message Classes." For Solaris, `sc_size` should always be set to 0. A port monitor must respond to every message sent by the sac.

**Port Monitor Messages**

The format of messages from a port monitor to the SAC is defined by the structure `pmmsg`:

```
struct pmmsg {
 char pm_type; /* type of message */
 uchar_t pm_state; /* current state of port monitor */
 char pm_maxclass; /* maximum message class this port
 monitor understands */
 char pm_tag[PMTAGSIZE + 1]; /* port monitor's tag */
 int pm_size; /* size of optional data portion */
};
```

Port monitors may send two types of messages to the SAC. The type of message is indicated by setting the `pm_type` field of the `pmmsg` structure to one of the following:

|                         |                         |
|-------------------------|-------------------------|
| <code>PM_STATUS</code>  | state information       |
| <code>PM_UNKNOWN</code> | negative acknowledgment |

For both types of messages, the `pm_tag` field is set to the port monitor's tag and the `pm_state` field is set to the port monitor's current state. Valid states are:

|                          |          |
|--------------------------|----------|
| <code>PM_STARTING</code> | starting |
| <code>PM_ENABLED</code>  | enabled  |
| <code>PM_DISABLED</code> | disabled |

saf(1M)

|                                                                                                 |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|-------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                                                                                 | <div>PM_STOPPING</div> <div>stopping</div> <div>The current state reflects any changes caused by the last message from the SAC. The status message is the normal return message. The negative acknowledgment should be sent only when the message received is not understood. <code>pm_size</code> indicates the size of the optional data part of the message. <code>pm_maxclass</code> is used to specify a message class. Both are discussed under "Message Classes." In Solaris, always set <code>pm_maxclass</code> to 1 and <code>sc_size</code> to 0. Port monitors may never initiate messages; they may only respond to messages that they receive.</div>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <div>Message Classes</div>                                                                      | <div>The concept of message class has been included to accommodate possible SAF extensions. The messages described above are all class 1 messages. None of these messages contains a variable data portion; all pertinent information is contained in the message header. If new messages are added to the protocol, they will be defined as new message classes (for example, class 2). The first message the SAC sends to a port monitor will always be a class 1 message. Since all port monitors, by definition, understand class 1 messages, the first message the SAC sends is guaranteed to be understood. In its response to the SAC, the port monitor sets the <code>pm_maxclass</code> field to the maximum message class number for that port monitor. The SAC will not send messages to a port monitor from a class with a larger number than the value of <code>pm_maxclass</code>. Requests that require messages of a higher class than the port monitor can understand will fail. For Solaris, always set <code>pm_maxclass</code> to 1.</div> <div>For any given port monitor, messages of class <code>pm_maxclass</code> and messages of all classes with values lower than <code>pm_maxclass</code> are valid. Thus, if the <code>pm_maxclass</code> field is set to 3, the port monitor understands messages of classes 1, 2, and 3. Port monitors may not generate messages; they may only respond to messages. A port monitor's response must be of the same class as the originating message. Since only the SAC can generate messages, this protocol will function even if the port monitor is capable of dealing with messages of a higher class than the SAC can generate. <code>pm_size</code> (an element of the <code>pmmsg</code> structure) and <code>sc_size</code> (an element of the <code>sacmsg</code> structure) indicate the size of the optional data part of the message. The format of this part of the message is undefined. Its definition is inherent in the type of message. For Solaris, always set both <code>sc_size</code> and <code>pm_size</code> to 0.</div> |
| <div>Administrative Interface</div> <div>The SAC Administrative File <code>_sactab</code></div> | <div>This section discusses the port monitor administrative files available under the SAC.</div> <div>The service access controller's administrative file contains information about all the port monitors for which the SAC is responsible. This file exists on the delivered system. Initially, it is empty except for a single comment line that contains the version number of the SAC. Port monitors are added to the system by making entries in the SAC's administrative file. These entries should be made using the administrative command <code>sacadm(1M)</code> with a <code>-a</code> option. <code>sacadm(1M)</code> is also used to remove entries from the SAC's administrative file. Each entry in the SAC's administrative file contains the following information.</div>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

**PMTAG**

A unique tag that identifies a particular port monitor. The system administrator is responsible for naming a port monitor. This tag is then used by the SAC to identify the port monitor for all administrative purposes. PMTAG may consist of up to 14 alphanumeric characters.

**PMTYPE**

The type of the port monitor. In addition to its unique tag, each port monitor has a type designator. The type designator identifies a group of port monitors that are different invocations of the same entity. `ttymon` and `listen` are examples of valid port monitor types. The type designator is used to facilitate the administration of groups of related port monitors. Without a type designator, the system administrator has no way of knowing which port monitor tags correspond to port monitors of the same type. PMTYPE may consist of up to 14 alphanumeric characters.

**FLGS**

The flags that are currently defined are:

- `d`            When started, do not enable the port monitor.
- `x`            Do not start the port monitor.

If no flag is specified, the default action is taken. By default a port monitor is started and enabled.

**RCNT**

The number of times a port monitor may fail before being placed in a failed state. Once a port monitor enters the failed state, the SAC will not try to restart it. If a count is not specified when the entry is created, this field is set to 0. A restart count of 0 indicates that the port monitor is not to be restarted when it fails.

**COMMAND**

A string representing the command that will start the port monitor. The first component of the string, the command itself, must be a full path name.

**The Port Monitor  
Administrative  
File `_pmtab`**

Each port monitor will have two directories for its exclusive use. The current directory will contain files defined by the SAF (`_pmtab`, `_pid`) and the per-service configuration scripts, if they exist. The directory `/var/saf/pmtag`, where *pmtag* is the tag of the port monitor, is available for the port monitor's private files. Each port monitor has its own administrative file. The `pmadm(1M)` command should be used to add, remove, or modify service entries in this file. Each time a change is made using `pmadm(1M)`, the corresponding port monitor rereads its administrative file. Each entry in a port monitor's administrative file defines how the port monitor treats a specific port and what service is to be invoked on that port. Some fields must be present for all types of port monitors. Each entry must include a service tag to identify the service uniquely and an identity to be assigned to the service when it is started (for example, `root`).

The combination of a service tag and a port monitor tag uniquely define an instance of a service. The same service tag may be used to identify a service under a different port monitor. The record must also contain port monitor specific data (for example, for a

saf(1M)

ttymon port monitor, this will include the prompt string which is meaningful to ttymon). Each type of port monitor must provide a command that takes the necessary port monitor-specific data as arguments and outputs these data in a form suitable for storage in the file. The `ttysadm(1M)` command does this for ttymon and `nlsadmin(1M)` does it for listen. For a user-defined port monitor, a similar administrative command must also be supplied. Each service entry in the port monitor administrative file must have the following format and contain the information listed below:

```
svctag:flgs:id:reserved:reserved:reserved:pmspecific# comment
```

SVCTAG is a unique tag that identifies a service. This tag is unique only for the port monitor through which the service is available. Other port monitors may offer the same or other services with the same tag. A service requires both a port monitor tag and a service tag to identify it uniquely. SVCTAG may consist of up to 14 alphanumeric characters. The service entries are defined as:

#### FLGS

Flags with the following meanings may currently be included in this field:

- x Do not enable this port. By default the port is enabled.
- u Create a utmpx entry for this service. By default no utmpx entry is created for the service.

#### ID

The identity under which the service is to be started. The identity has the form of a login name as it appears in `/etc/passwd`.

#### PMSPECIFIC

Examples of port monitor information are addresses, the name of a process to execute, or the name of a STREAMS pipe to pass a connection through. This information will vary to meet the needs of each different type of port monitor.

#### COMMENT

A comment associated with the service entry. Port monitors may ignore the *u* flag if creating a utmpx entry for the service is not appropriate to the manner in which the service is to be invoked. Some services may not start properly unless utmpx entries have been created for them (for example, login). Each port monitor administrative file must contain one special comment of the form:

```
VERSION=value
```

where *value* is an integer that represents the port monitor's version number. The version number defines the format of the port monitor administrative file. This comment line is created automatically when a port monitor is added to the system. It appears on a line by itself, before the service entries.

#### Monitor-Specific Administrative Command

Previously, two pieces of information included in the `_pmtab` file were described: the port monitor's version number and the port monitor part of the service entries in the port monitor's `_pmtab` file. When a new port monitor is added, the version number

### The Port Monitor/Service Interface

must be known so that the `_pmtab` file can be correctly initialized. When a new service is added, the port monitor part of the `_pmtab` entry must be formatted correctly. Each port monitor must have an administrative command to perform these two tasks. The person who defines the port monitor must also define such an administrative command and its input options. When the command is invoked with these options, the information required for the port monitor part of the service entry must be correctly formatted for inclusion in the port monitor's `_pmtab` file and must be written to the standard output. To request the version number the command must be invoked with a `-V` option; when it is invoked in this way, the port monitor's current version number must be written to the standard output. If the command fails for any reason during the execution of either of these tasks, no data should be written to standard output.

The interface between a port monitor and a service is determined solely by the service. Two mechanisms for invoking a service are presented here as examples.

#### New Service Invocations

The first interface is for services that are started anew with each request. This interface requires the port monitor to first `fork(2)` a child process. The child will eventually become the designated service by performing an `exec(1)`. Before the `exec(1)` happens, the port monitor may take some port monitor-specific action; however, one action that must occur is the interpretation of the per-service configuration script, if one is present. This is done by calling the library routine `doconfig(3NSL)`.

#### Standing Service Invocations

The second interface is for invocations of services that are actively running. To use this interface, a service must have one end of a stream pipe open and be prepared to receive connections through it.

### Port Monitor Requirements

To implement a port monitor, several generic requirements must be met. This section summarizes these requirements. In addition to the port monitor itself, an administrative command must be supplied.

#### Initial Environment

When a port monitor is started, it expects an initial execution environment in which:

- It has no file descriptors open
- It cannot be a process group leader
- It has an entry in `/etc/utmpx` of type `LOGIN_PROCESS`
- An environment variable, `ISTATE`, is set to "enabled" or "disabled" to indicate the port monitor's correct initial state
- An environment variable, `PMTAG`, is set to the port monitor's assigned tag
- The directory that contains the port monitor's administrative files is its current directory
- The port monitor is able to create private files in the directory `/var/saf/tag`, where `tag` is the port monitor's tag
- The port monitor is running with user id 0 (root)

saf(1M)

|                                        |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

On the other hand, some services may not start properly unless <code>utmpx</code> entries have been created for them.</li><li>■ Interpret the per-service configuration script for the requested service, if it exists, by calling the <code>doconfig(3NSL)</code> library routine</li></ul> |
| <b>Configuration Files and Scripts</b> | <p>The library routine <code>doconfig(3NSL)</code>, defined in <code>libnsl.so</code>, interprets the configuration scripts contained in the files <code>/etc/saf/_sysconfig</code> (the per-system configuration file), and <code>/etc/saf/pmtag/_config</code> (per-port monitor configuration files); and in <code>/etc/saf/pmtag/svctag</code> (per-service configuration files). Its syntax is:</p> <pre>#include &lt;sac.h&gt; int doconfig (int fd, char *script, long rflag);</pre> <p><code>script</code> is the name of the configuration script; <code>fd</code> is a file descriptor that designates the stream to which stream manipulation operations are to be applied; <code>rflag</code> is a bitmask that indicates the mode in which script is to be interpreted. <code>rflag</code> may take two values, <code>NORUN</code> and <code>NOASSIGN</code>, which may be or'd. If <code>rflag</code> is zero, all commands in</p>                                                                                                                                                                              |

the configuration script are eligible to be interpreted. If *rflag* has the NOASSIGN bit set, the assign command is considered illegal and will generate an error return. If *rflag* has the NORUN bit set, the run and runwait commands are considered illegal and will generate error returns. If a command in the script fails, the interpretation of the script ceases at that point and a positive integer is returned; this number indicates which line in the script failed. If a system error occurs, a value of -1 is returned. If a script fails, the process whose environment was being established should not be started. In the example, doconfig(3NSL) is used to interpret a per-service configuration script.

```
. . .
 if ((i = doconfig (fd, svctag, 0)) != 0){
 error ("doconfig failed on line %d of script %s",i,svctag);
 }
```

#### The Per-System Configuration File

The per-system configuration file, `/etc/saf/_sysconfig`, is delivered empty. It may be used to customize the environment for all services on the system by writing a command script in the interpreted language described in this chapter and on the `doconfig(3NSL)` manpage. When the SAC is started, it calls the `doconfig(3NSL)` function to interpret the per-system configuration script. The SAC is started when the system enters multiuser mode.

#### Per-Port Monitor Configuration Files

Per-port monitor configuration scripts (`/etc/saf/pmtag/_config`) are optional. They allow the user to customize the environment for any given port monitor and for the services that are available through the ports for which that port monitor is responsible. Per-port monitor configuration scripts are written in the same language used for per-system configuration scripts. The per-port monitor configuration script is interpreted when the port monitor is started. The port monitor is started by the SAC after the SAC has itself been started and after it has run its own configuration script, `/etc/saf/_sysconfig`. The per-port monitor configuration script may override defaults provided by the per-system configuration script.

#### Per-Service Configuration Files

Per-service configuration files allow the user to customize the environment for a specific service. For example, a service may require special privileges that are not available to the general user. Using the language described in the `doconfig(3NSL)` manpage, you can write a script that will grant or limit such special privileges to a particular service offered through a particular port monitor. The per-service configuration may override defaults provided by higher-level configuration scripts. For example, the per-service configuration script may specify a set of STREAMS modules other than the default set.

### The Configuration Language

The language in which configuration scripts are written consists of a sequence of commands, each of which is interpreted separately. The following reserved keywords are defined: `assign`, `push`, `pop`, `runwait`, and `run`. The comment character is `#`. Blank lines are not significant. No line in a command script may exceed 1024 characters.

saf(1M)

`assign variable=value`

Used to define environment variables; *variable* is the name of the environment variable and *value* is the value to be assigned to it. The value assigned must be a string constant; no form of parameter substitution is available. *value* may be quoted. The quoting rules are those used by the shell for defining environment variables. `assign` will fail if space cannot be allocated for the new variable or if any part of the specification is invalid.

`push module1 [, module2, module3, ...]`

Used to push STREAMS modules onto the stream designated by `fd`; *module1* is the name of the first module to be pushed, *module2* is the name of the second module to be pushed, and so on. The command will fail if any of the named modules cannot be pushed. If a module cannot be pushed, the subsequent modules on the same command line will be ignored and modules that have already been pushed will be popped.

`pop [module]`

Used to pop STREAMS modules off the designated stream. If `pop` is invoked with no arguments, the top module on the stream is popped. If an argument is given, modules will be popped one at a time until the named module is at the top of the stream. If the named module is not on the designated stream, the stream is left as it was and the command fails. If *module* is the special keyword `ALL`, then all modules on the stream will be popped. Only modules above the topmost driver are affected.

`runwait command`

The `runwait` command runs a command and waits for it to complete; *command* is the path name of the command to be run. The command is run with `/bin/sh -c` prepended to it; shell scripts may thus be executed from configuration scripts. The `runwait` command will fail if *command* cannot be found or cannot be executed, or if *command* exits with a nonzero status.

`run command`

The `run` command is identical to `runwait` except that it does not wait for *command* to complete; *command* is the path name of the command to be run. `run` will not fail unless it is unable to create a child process to execute the command. Although they are syntactically indistinguishable, some of the commands available to `run` and `runwait` are interpreter built-in commands. Interpreter built-ins are used when it is necessary to alter the state of a process within the context of that process. The `doconfig` interpreter built-in commands are similar to the shell special commands and, like these, they do not spawn another process for execution. See the `sh(1)` man page. The initial set of built-in commands is: `cd`, `ulimit`, `umask`.

#### Sample Port Monitor Code

This example shows an example of a "null" port monitor that simply responds to messages from the SAC.

```
include <stdlib.h>
include <stdio.h>
include <unistd.h>
include <fcntl.h>
include <signal.h>
```

```

include <sac.h>

char Scratch[BUFSIZ]; /* scratch buffer */
char Tag[PMTAGSIZE + 1]; /* port monitor's tag */
FILE *Fp; /* file pointer for log file */
FILE *Tfp; /* file pointer for pid file */
char State; /* portmonitor's current state*/

main(argc, argv)
 int argc;
 char *argv[];
{
 char *istate;
 strcpy(Tag, getenv("PMTAG"));
 /*
 * open up a log file in port monitor's private directory
 */
 sprintf(Scratch, "/var/saf/%s/log", Tag);
 Fp = fopen(Scratch, "a+");
 if (Fp == (FILE *)NULL)
 exit(1);
 log(Fp, "starting");
 /*
 * retrieve initial state (either "enabled" or "disabled") and set
 * State accordingly
 */
 istate = getenv("ISTATE");
 sprintf(Scratch, "ISTATE is %s", istate);
 log(Fp, Scratch);
 if (!strcmp(istate, "enabled"))
 State = PM_ENABLED;
 else if (!strcmp(istate, "disabled"))
 State = PM_DISABLED;
 else {
 log(Fp, "invalid initial state");
 exit(1);
 }
 sprintf(Scratch, "PMTAG is %s", Tag);
 log(Fp, Scratch);
 /*
 * set up pid file and lock it to indicate that we are active
 */
 Tfp = fopen("_pid", "w");
 if (Tfp == (FILE *)NULL) {
 log(Fp, "couldn't open pid file");
 exit(1);
 }
 if (lockf(fileno(Tfp), F_TEST, 0) < 0) {
 log(Fp, "pid file already locked");
 exit(1);
 }

 log(Fp, "locking file");
 if (lockf(fileno(Tfp), F_LOCK, 0) < 0) {
 log(Fp, "lock failed");
 exit(1);
 }
 fprintf(Tfp, "%d", getpid());

```

## saf(1M)

```

 fflush(Tfp);

/*
 * handle poll messages from the sac ... this function never returns
 */
 handlepoll();
 pause();
 fclose(Tfp);
 fclose(Fp);
}

handlepoll()
{
 int pfd; /* file descriptor for incoming pipe */
 int sfd; /* file descriptor for outgoing pipe */
 struct sacmsg sacmsg; /* incoming message */
 struct pmmsg pmmsg; /* outgoing message */
/*
 * open pipe for incoming messages from the sac
 */
 pfd = open("_pmpipe", O_RDONLY|O_NONBLOCK);
 if (pfd < 0) {
 log(Fp, "_pmpipe open failed");
 exit(1);
 }
/*
 * open pipe for outgoing messages to the sac
 */
 sfd = open("../_sacpipe", O_WRONLY);
 if (sfd < 0) {
 log(Fp, "_sacpipe open failed");
 exit(1);
 }
/*
 * start to build a return message; we only support class 1 messages
 */
 strcpy(pmmsg.pm_tag, Tag);
 pmmsg.pm_size = 0;
 pmmsg.pm_maxclass = 1;
/*
 * keep responding to messages from the sac
 */
 for (;;) {
 if (read(pfd, &sacmsg, sizeof(sacmsg)) != sizeof(sacmsg)) {
 log(Fp, "_pmpipe read failed");
 exit(1);
 }
/*
 * determine the message type and respond appropriately
 */
 switch (sacmsg.sc_type) {
 case SC_STATUS:
 log(Fp, "Got SC_STATUS message");
 pmmsg.pm_type = PM_STATUS;
 pmmsg.pm_state = State;
 break;
 case SC_ENABLE:
 /*note internal state change below*/

```

```

 log(Fp, "Got SC_ENABLE message");
 pmmsg.pm_type = PM_STATUS;
 State = PM_ENABLED;
 pmmsg.pm_state = State;
 break;

### The sac.h Header File

The following example shows the sac.h header file.

```

/* length in bytes of a utmpx id */
define IDLEN 4
/* wild character for utmpx ids */
define SC_WILDC 0xff
/* max len in bytes for port monitor tag */
define PMTAGSIZE 14
/*

```

saf(1M)

```
* values for rflag in doconfig()
*/
/* don't allow assign operations */
define NOASSIGN 0x1
/* don't allow run or runwait operations */
define NORUN 0x2
/*
 * message to SAC (header only). This header is forever fixed. The
 * size field (pm_size) defines the size of the data portion of the
 * message, which follows the header. The form of this optional data
 * portion is defined strictly by the message type (pm_type).
 */
struct pmmsg {
 char pm_type; /* type of message */
 uchar_t pm_state; /* current state of pm */
 char pm_maxclass; /* max message class this port monitor
 understands */
 char pm_tag[PMTAGSIZE + 1]; /* pm's tag */
 int pm_size; /* size of opt data portion */
};
/*
 * pm_type values
 */
define PM_STATUS 1 /* status response */
define PM_UNKNOWN 2 /* unknown message was received */
/*
 * pm_state values
 */
/*
 * Class 1 responses
 */
define PM_STARTING 1 /* monitor in starting state */
define PM_ENABLED 2 /* monitor in enabled state */
define PM_DISABLED 3 /* monitor in disabled state */
define PM_STOPPING 4 /* monitor in stopping state */
/*
 * message to port monitor
 */
struct sacmsg {
 int sc_size; /* size of optional data portion */
 char sc_type; /* type of message */
};
/*
 * sc_type values
 * These represent commands that the SAC sends to a port monitor.
 * These commands are divided into "classes" for extensibility. Each
 * subsequent "class" is a superset of the previous "classes" plus
 * the new commands defined within that "class". The header for all
 * commands is identical; however, a command may be defined such that
 * an optional data portion may be sent in addition to the header.
 * The format of this optional data piece is self-defining based on
 * the command. The first message sent by the SAC
 * will always be a class 1 message. The port monitor response
 * indicates the maximum class that it is able to understand. Another
 * note is that port monitors should only respond to a message with
 * an equivalent class response (i.e. a class 1 command causes a
 * class 1 response).
 */
```

```

/*
 * Class 1 commands (currently, there are only class 1 commands)
 */
define SC_STATUS 1 /* status request */
define SC_ENABLE 2 /* enable request */
define SC_DISABLE 3 /* disable request */
define SC_READDB 4 /* read pmtab request */
/*
 * 'errno' values for Safereno, note that Safereno is used by both
 * pmadm and sacadm and these values are shared between them
 */
define E_BADARGS 1 /* bad args/ill-formed cmd line */
define E_NOPRIV 2 /* user not priv for operation */
define E_SAFERR 3 /* generic SAF error */
define E_SYSERR 4 /* system error */
define E_NOEXIST 5 /* invalid specification */
define E_DUP 6 /* entry already exists */
define E_PMRUN 7 /* port monitor is running */
define E_PMNOTRUN 8 /* port monitor is not running */
define E_RECOVER 9 /* in recovery */

```

## Directory Structure

This section gives a description of the SAF files and directories.

|                                     |                                                                                                                                            |
|-------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------|
| <code>/etc/saf/_sysconfig</code>    | The per-system configuration script.                                                                                                       |
| <code>/etc/saf/_sactab</code>       | The SAC's administrative file. Contains information about the port monitors for which the SAC is responsible.                              |
| <code>/etc/saf/pmtag</code>         | The home directory for port monitor <i>pmtag</i> .                                                                                         |
| <code>/etc/saf/pmtag/_config</code> | The per-port monitor configuration script for port monitor <i>pmtag</i> .                                                                  |
| <code>/etc/saf/pmtag/_pmtab</code>  | Port monitor <i>pmtag</i> 's administrative file. Contains information about the services for which <i>pmtag</i> is responsible.           |
| <code>/etc/saf/pmtag/svctag</code>  | The file in which the per-service configuration script for service <i>svctag</i> (available through port monitor <i>pmtag</i> ) is placed. |
| <code>/etc/saf/pmtag/_pid</code>    | The file in which a port monitor writes its process id in the current directory and places an advisory lock on the file.                   |
| <code>/etc/saf/pmtag/_pmpipe</code> | The file in which the port monitor receives messages from the SAC and <code>../_sacpipe</code> and sends return messages to the SAC.       |
| <code>/var/saf/_log</code>          | The SAC's log file.                                                                                                                        |
| <code>/var/saf/pmtag</code>         | The directory for files created by port monitor <i>pmtag</i> , for example its log file.                                                   |

saf(1M)

**LIST OF  
COMMANDS**

The following administrative commands relate to SAF.

sacadm(1M)      port monitor administrative command

pmadm(1M)      service administration command

**ATTRIBUTES**

See attributes(5) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWcsr         |

| NAME        | sar, sa1, sa2, sadc – system activity report package                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| SYNOPSIS    | <pre> /usr/lib/sa/sadc [t n] [ofile]  /usr/lib/sa/sa1 [t n]  /usr/lib/sa/sa2 [-aAbcdgkmpgruvwy] [-e time] [-f filename] [-i sec]                [-s time] </pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| DESCRIPTION | <p>System activity data can be accessed at the special request of a user (see <code>sar(1)</code>) and automatically, on a routine basis, as described here. The operating system contains several counters that are incremented as various system actions occur. These include counters for CPU utilization, buffer usage, disk and tape I/O activity, TTY device activity, switching and system-call activity, file-access, queue activity, inter-process communications, and paging. For more general system statistics, use <code>iostat(1M)</code>, <code>sar(1)</code>, or <code>vmstat(1M)</code>.</p> <p><code>sadc</code> and two shell procedures, <code>sa1</code> and <code>sa2</code>, are used to sample, save, and process this data.</p> <p><code>sadc</code>, the data collector, samples system data <i>n</i> times, with an interval of <i>t</i> seconds between samples, and writes in binary format to <i>ofile</i> or to standard output. The sampling interval <i>t</i> should be greater than 5 seconds; otherwise, the activity of <code>sadc</code> itself may affect the sample. If <i>t</i> and <i>n</i> are omitted, a special record is written. This facility can be used at system boot time, when booting to a multi-user state, to mark the time at which the counters restart from zero. For example, when accounting is enabled, the <code>/etc/init.d/perf</code> file writes the restart mark to the daily data file using the command entry:</p> <pre>su sys -c "/usr/lib/sa/sadc /var/adm/sa/sa`date +%d`"</pre> <p>The shell script <code>sa1</code>, a variant of <code>sadc</code>, is used to collect and store data in the binary file <code>/var/adm/sa/sadd</code>, where <code>dd</code> is the current day. The arguments <i>t</i> and <i>n</i> cause records to be written <i>n</i> times at an interval of <i>t</i> seconds, or once if omitted. The following entries in <code>/var/spool/cron/crontabs/sys</code> will produce records every 20 minutes during working hours and hourly otherwise:</p> <pre>0 * * * 0-6 /usr/lib/sa/sa1 20,40 8-17 * * 1-5 /usr/lib/sa/sa1</pre> <p>See <code>crontab(1)</code> for details.</p> <p>The shell script <code>sa2</code>, a variant of <code>sar</code>, writes a daily report in the file <code>/var/adm/sa/sardd</code>. See the <b>OPTIONS</b> section in <code>sar(1)</code> for an explanation of the various options. The following entry in <code>/var/spool/cron/crontabs/sys</code> will report important activities hourly during the working day:</p> <pre>5 18 * * 1-5 /usr/lib/sa/sa2 -s 8:00 -e 18:01 -i 1200 -A</pre> |

| NAME        | savecore – save a crash dump of the operating system                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| SYNOPSIS    | <b>/usr/bin/savecore</b> [-Lvd] [-f <i>dumpfile</i> ] [ <i>directory</i> ]                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| DESCRIPTION | <p>The savecore utility saves a crash dump of the kernel (assuming that one was made) and writes a reboot message in the shutdown log. It is invoked by the <code>/etc/init.d/savecore</code> file after the system boots, if savecore is enabled by way of <code>dumpadm(1M)</code>. savecore is enabled on reboot by default.</p> <p>The savecore utility checks the crash dump to be certain it corresponds with the version of the operating system currently running. If it does, savecore saves the crash dump data in the file <i>directory/vmcore.n</i> and the kernel's namelist in <i>directory/unix.n</i>. The trailing <i>.n</i> in the pathnames is replaced by a number which grows every time savecore is run in that directory.</p> <p>Before writing out a crash dump, savecore reads a number from the file <i>directory/minfree</i>. This is the minimum number of kilobytes that must remain free on the file system containing <i>directory</i>. If after saving the crash dump the file system containing <i>directory</i> would have less free space the number of kilobytes specified in <i>minfree</i>, the crash dump is not saved. If the <i>minfree</i> file does not exist, savecore assumes a <i>minfree</i> value of 1 megabyte.</p> <p>The savecore utility also logs a reboot message using facility <code>LOG_AUTH</code> (see <code>syslog(3C)</code>). If the system crashed as a result of a panic, savecore logs the panic string too.</p> |
| OPTIONS     | <p>The following options are supported:</p> <ul style="list-style-type: none"> <li>-d Disregard dump header valid flag. Force savecore to attempt to save a crash dump even if the header information stored on the dump device indicates the dump has already been saved.</li> <li>-f <i>dumpfile</i> Attempt to save a crash dump from the specified file instead of from the system's current dump device. This option may be useful if the information stored on the dump device has been copied to an on-disk file by means of the <code>dd(1M)</code> command.</li> <li>-L Save a crash dump of the live running Solaris system, without actually rebooting or altering the system in any way. This option forces savecore to save a live snapshot of the system to the dump device, and then immediately to retrieve the data and to write it out to a new set of crash dump files in the specified directory. Live system crash dumps can only be performed if you have configured your system to have a dedicated dump device using <code>dumpadm(1M)</code>.<br/><br/>savecore -L does not suspend the system, so the contents of memory continue to change while the dump is saved. This means that live crash dumps are not fully self-consistent.</li> <li>-v Verbose. Enables verbose error messages from savecore.</li> </ul>                                                                                                                                     |

## savecore(1M)

**OPERANDS** The following operands are supported:

*directory* Save the crash dump files to the specified directory. If *directory* is not specified, *savecore* saves the crash dump files to the default *savecore directory*, configured by *dumpadm(1M)*.

**FILES** *directory/vmcore.n*

*directory/unix.n*

*directory/bounds*

*directory/minfree*

*/dev/ksyms* the kernel namelist

*/etc/init.d/savecore*

*/var/crash/'uname -n'* default crash dump directory

**ATTRIBUTES** See *attributes(5)* for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE   |
|----------------|-------------------|
| Availability   | SUNWcsu (32-bit)  |
|                | SUNWcsxu (64-bit) |

**SEE ALSO** *adb(1)*, *mdb(1)*, *dd(1M)*, *dumpadm(1M)*, *syslog(3C)*, *attributes(5)*

**BUGS** If the dump device is also being used as a swap device, you must run *savecore* very soon after booting, before the swap space containing the crash dump is overwritten by programs currently running.

| <b>NAME</b>                           | sckmd – Sun Fire 15K key management daemon                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |                                       |                                                           |              |                      |              |                                     |

| <b>SYNOPSIS</b>                       | <code>/usr/platform/SUNW,Sun-Fire-15000/lib/sckmd</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |                                       |                                                           |              |                      |              |                                     |
| <b>DESCRIPTION</b>                    | <p>sckmd is a server process that resides on a Sun Fire 15K domain. sckmd maintains the Internet Protocol Security (IPsec) Security Associations (SAs) needed to secure the communication between the Sun Fire 15K System Controller (SC) and the cvcd(1M) and dcs(1M) daemons running on a Sun Fire 15K domain. See ipsec(7P) for a description of Security Associations.</p> <p>sckmd receives SAs from the SC and provides these SAs to the Security Association Databases (SADB) using pf_key(7P).</p> <p>sckmd normally starts up at system boot time. Each domain supports only one running sckmd process at a time.</p>                                                                                                                                                      |                                       |                                                           |              |                      |              |                                     |

| <b>NOTES</b>                          | <p>IPsec is used by Sun Fire 15K systems to secure the communication between the SC, and the cvcd(1M) and dcs(1M) daemons running on a domain. System-wide IPsec policies for these daemons are configured on a domain with ipsecconf(1M). Default policies are defined when the SUNWsckmr package is installed on a Sun Fire 15K domain at OS install time.</p> <p>Package SUNWsckmr configures default system-wide policies for cvcd(1M) and dcs(1M) by adding the following entries in <code>/etc/inet/ipsecinit.conf</code>:</p> <pre>{ dport sun-dr ulp tcp } permit   { auth_alg md5 } { sport sun-dr ulp tcp } apply   { auth_alg md5 sa unique } { dport cvc_hostd ulp tcp } permit   { auth_alg md5 } { sport cvc_hostd ulp tcp } apply   { auth_alg md5 sa unique }</pre> |                                       |                                                           |              |                      |              |                                     |

## sckmd(1M)

The `cvc_hostd` service represents `cvcd(1M)` and the `sun-dr` service represents `dcs(1M)` in the preceding entries.

These policies conform to the format defined by `ipsec(7P)` and require HMAC-MD5 authentication. See `authmd5h(7M)`.

System-wide policies for `cvcd(1M)` and `dcs(1M)` configured on a domain using `ipseccnf(1M)` must match the IPsec policies defined for these services on the SC. On an SC, IPsec policies for these services are defined by the SMS key management daemon. Refer to `thekmd(1M)` man page in the *Sun System Management Services (SMS) Reference Manual*.

IPsec encryption or authentication with encryption can be enabled on the domain using the `encr_algs` and `encr_auth_algs` properties, as described in the `ipseccnf(1M)` manual page. For example, the following `ipseccnf(1M)` entries require Triple-DES and HMAC-MD5 authentication for the network console `cvcd(1M)` service:

```
{ dport cvc_hostd ulp tcp } permit
 { encr_algs 3des encr_auth_algs md5 }
{ sport cvc_hostd ulp tcp } apply
 { encr_algs 3des encr_auth_algs md5 sa unique }
```

See `encr3des(7M)` for Triple-DES authentication and `authmd5h(7M)` for HMAC-M5 authentication.

|             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

| DESCRIPTION | <p>sendmail sends a message to one or more people, routing the message over whatever networks are necessary. sendmail does internetwork forwarding as necessary to deliver the message to the correct place.</p> <p>sendmail is not intended as a user interface routine; other programs provide user-friendly front ends. sendmail is used only to deliver pre-formatted messages.</p> <p>With no flags, sendmail reads its standard input up to an EOF, or a line with a single dot, and sends a copy of the letter found there to all of the addresses listed. It determines the network to use based on the syntax and contents of the addresses.</p> <p>Local addresses are looked up in the local <code>aliases(4)</code> file, or in a name service as defined by the <code>nsswitch.conf(4)</code> file, and aliased appropriately. In addition, if there is a <code>.forward</code> file in a recipient's home directory, sendmail forwards a copy of each message to the list of recipients that file contains. Refer to the NOTES section for more information about <code>.forward</code> files. Aliasing can be prevented by preceding the address with a backslash.</p> <p>There are several conditions under which the expected behavior is for the alias database to be either built or rebuilt. This cannot occur under any circumstances unless root owns <i>and</i> has exclusive write permission to the <code>/etc/mail/aliases*</code> files.</p> <p>If a message is found to be undeliverable, it is returned to the sender with diagnostics that indicate the location and nature of the failure; or, the message is placed in a <code>dead.letter</code> file in the sender's home directory.</p> |
| OPTIONS     | <p>The following options are supported:</p> <ul style="list-style-type: none"> <li>-Ac            Use <code>submit.cf</code> even if the operation mode does not indicate an initial mail submission.</li> <li>-Am            Use <code>sendmail.cf</code> even if the operation mode indicates an initial mail submission.</li> <li>-ba            Go into ARPANET mode. All input lines must end with a RETURN-LINEFEED, and all messages are generated with a RETURN-LINEFEED at the end. Also, the <code>From:</code> and <code>Sender:</code> fields are examined for the name of the sender.</li> <li>-bd            Run as a daemon in the background, waiting for incoming SMTP connections.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

## sendmail(1M)

|                         |                                                                                                                                                                                                                                                                                                                                                 |
|-------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -bD                     | Run as a daemon in the foreground, waiting for incoming SMTP connections.                                                                                                                                                                                                                                                                       |
| -bi                     | Initialize the <code>aliases(4)</code> database. Root must own <i>and</i> have exclusive write permission to the <code>/etc/mail/aliases*</code> files for successful use of this option.                                                                                                                                                       |
| -bm                     | Deliver mail in the usual way (default).                                                                                                                                                                                                                                                                                                        |
| -bp                     | Print a summary of the mail queues.                                                                                                                                                                                                                                                                                                             |
| -bP                     | Print the number of entries in the queues. This option is only available with shared memory support.                                                                                                                                                                                                                                            |
| -bs                     | Use the SMTP protocol as described in RFC 821. This flag implies all the operations of the <code>-ba</code> flag that are compatible with SMTP.                                                                                                                                                                                                 |
| -bt                     | Run in address test mode. This mode reads addresses and shows the steps in parsing; it is used for debugging configuration tables.                                                                                                                                                                                                              |
| -bv                     | Verify names only; do not try to collect or deliver a message. Verify mode is normally used for validating users or mailing lists.                                                                                                                                                                                                              |
| -B <i>type</i>          | Indicate body <i>type</i> (7BIT or 8BITMIME).                                                                                                                                                                                                                                                                                                   |
| -C <i>file</i>          | Use alternate configuration file.                                                                                                                                                                                                                                                                                                               |
| -d X                    | Set debugging value to X.                                                                                                                                                                                                                                                                                                                       |
| -F <i>fullname</i>      | Set the full name of the sender.                                                                                                                                                                                                                                                                                                                |
| -G                      | When accepting messages by way of the command line, indicate that they are for relay (gateway) submission. When this flag is set, <code>sendmail</code> might complain about syntactically invalid messages, for example, unqualified host names, rather than fixing them. <code>sendmail</code> does not do any canonicalization in this mode. |
| -f <i>name</i>          | Sets the name of the “from” person (that is, the sender of the mail).                                                                                                                                                                                                                                                                           |
| -h N                    | Set the hop count to N. The hop count is incremented every time the mail is processed. When it reaches a limit, the mail is returned with an error message, the victim of an aliasing loop.                                                                                                                                                     |
| -L <i>tag</i>           | Set the identifier used in <code>syslog</code> messages to the supplied <i>tag</i> .                                                                                                                                                                                                                                                            |
| -M <i>xvalue</i>        | Set macro <i>x</i> to the specified <i>value</i> .                                                                                                                                                                                                                                                                                              |
| -n                      | Do not do aliasing.                                                                                                                                                                                                                                                                                                                             |
| -N <i>notifications</i> | Tag all addresses being sent as wanting the indicated <i>notifications</i> , which consists of the word “NEVER” or a comma-separated list of “SUCCESS”, “FAILURE”, and “DELAY” for successful delivery, failure and a message that is stuck in a queue somewhere. The default is “FAILURE,DELAY”.                                               |

|                                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>-o<math>x</math>value</code> | Set option $x$ to the specified <i>value</i> . Processing Options are described below.                                                                                                                                                                                                                                                                                                                                                                                         |
| <code>-Ooption=value</code>        | Set <i>option</i> to the specified <i>value</i> (for long from names). Processing Options are described below.                                                                                                                                                                                                                                                                                                                                                                 |
| <code>-p protocol</code>           | Set the sending protocol. The <i>protocol</i> field can be in form <i>protocol: host</i> to set both the sending protocol and the sending host. For example: <code>-pUUCP:uunet</code> sets the sending <i>protocol</i> to UUCP and the sending host to uunet. (Some existing programs use <code>-oM</code> to set the $r$ and $s$ macros; this is equivalent to using <code>-p</code> ).                                                                                      |
| <code>-q[time]</code>              | Process saved messages in the queue at given intervals. If <i>time</i> is omitted, process the queue once. <i>time</i> is given as a tagged number, with $s$ being seconds, $m$ being minutes, $h$ being hours, $d$ being days, and $w$ being weeks. For example, <code>-q1h30m</code> or <code>-q90m</code> would both set the timeout to one hour thirty minutes.<br><br>By default, sendmail runs in the background. This option can be used safely with <code>-bd</code> . |
| <code>-qp [time]</code>            | Similar to <code>-qtime</code> , except that instead of periodically forking a child to process the queue, sendmail forks a single persistent child for each queue that alternates between processing the queue and sleeping. The sleep time ( <i>time</i> ) is specified as the argument; it defaults to 1 second. The process always sleeps at least 5 seconds if the queue was empty in the previous queue run.                                                             |
| <code>-qf</code>                   | Process saved messages in the queue once and do not <code>fork(2)</code> , but run in the foreground.                                                                                                                                                                                                                                                                                                                                                                          |
| <code>-qG name</code>              | Process jobs in queue group called <i>name</i> only.                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <code>-q[!]I substr</code>         | Limit processed jobs to those containing <i>substr</i> as a substring of the queue ID or not when <code>!</code> is specified.                                                                                                                                                                                                                                                                                                                                                 |
| <code>-q[!]R substr</code>         | Limit processed jobs to those containing <i>substr</i> as a substring of one of the recipients or not when <code>!</code> is specified.                                                                                                                                                                                                                                                                                                                                        |
| <code>--q[!]S substr</code>        | Limit processed jobs to those containing <i>substr</i> as a substring of the sender or not when <code>!</code> is specified.                                                                                                                                                                                                                                                                                                                                                   |
| <code>-r name</code>               | An alternate and obsolete form of the <code>-f</code> flag.                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <code>-R ret</code>                | Identify the information you want returned if the message bounces; <i>ret</i> can be "HDRS" for headers only or "FULL" for headers plus body.                                                                                                                                                                                                                                                                                                                                  |
| <code>-t</code>                    | Read message for recipients. <code>To:</code> , <code>Cc:</code> , and <code>Bcc:</code> lines are scanned for people to send to. The <code>Bcc:</code> line is deleted before transmission. Any addresses in the argument list is suppressed.                                                                                                                                                                                                                                 |

|                   | The NoRecipientAction Processing Option can be used to change the behaviour when no legal recipients are included in the message.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| -v                | Go into verbose mode. Alias expansions are announced, and so forth.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| -V <i>envid</i>   | The indicated <i>envid</i> is passed with the envelope of the message and returned if the message bounces.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| -X <i>logfile</i> | Log all traffic in and out of sendmail in the indicated <i>logfile</i> for debugging mailer problems. This produces a lot of data very quickly and should be used sparingly.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|                   | There are a number of "random" options that can be set from a configuration file. Options are represented by a single character or by multiple character names. The syntax for the single character names of is:<br><br><i>Oxvalue</i><br><br>This sets option <i>x</i> to be <i>value</i> . Depending on the option, <i>value</i> may be a string, an integer, a boolean (with legal values <i>t</i> , <i>T</i> , <i>f</i> , or <i>F</i> ; the default is TRUE), or a time interval.<br><br>The multiple character or long names use this syntax:<br><br>O <i>Longname=argument</i><br><br>This sets the option <i>Longname</i> to be <i>argument</i> . The long names are beneficial because they are easier to interpret than the single character names.<br><br>Not all processing options have single character names associated with them. In the list below the multiple character name is presented first followed by the single character syntax enclosed in parentheses.<br><br>AliasFile ( <i>Afile</i> )<br>Specify possible alias files.<br><br>AliasWait ( <i>a N</i> )<br>If set, wait up to <i>N</i> minutes for an "@:@" entry to exist in the <i>aliases(4)</i> database before starting up. If it does not appear in <i>N</i> minutes, issue a warning. Defaults to 10 minutes.<br><br>AllowBogusHELO<br>Allow a HELO SMTP command that does not include a host name. By default this option is disabled.<br><br>BadRcptThrottle= <i>N</i><br>If set and more than the specified number of recipients in a single SMTP envelope are rejected, sleep for one second after each rejected RCPT command. |

sendmail(1M)

BlankSub (Bc)

Set the blank substitution character to *c*. Unquoted spaces in addresses are replaced by this character. Defaults to SPACE (that is, no change is made).

CheckAliases (n)

Validate the RHS of aliases when rebuilding the `aliases(4)` database.

CheckpointInterval (CN)

Checkpoints the queue every *N* (default 10) addresses sent. If your system crashes during delivery to a large list, this prevents retransmission to any but the last *N* recipients.

ClassFactor (z*fact*)

The indicated factor *fact* is multiplied by the message class (determined by the `Precedence:` field in the user header and the `P` lines in the configuration file) and subtracted from the priority. Thus, messages with a higher `Priority:` are favored. Defaults to 1800.

ClientPortOptions

Set client SMTP options. The options are key=value pairs. Known keys are:

|                                |                                                                                                                                                                                                                                                                                                                                                                                     |                |                                                      |
|--------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------|------------------------------------------------------|
| <code>Addr Address Mask</code> | <i>Address Mask</i> defaults to <code>INADDR_ANY</code> . The address mask can be a numeric address in dot notation or a network name.                                                                                                                                                                                                                                              |                |                                                      |
| <code>Family</code>            | Address family (defaults to <code>INET</code> ).                                                                                                                                                                                                                                                                                                                                    |                |                                                      |
| <code>Listen</code>            | Size of listen queue (defaults to 10).                                                                                                                                                                                                                                                                                                                                              |                |                                                      |
| <code>Port</code>              | Name/number of listening port (defaults to <code>smtp</code> ).                                                                                                                                                                                                                                                                                                                     |                |                                                      |
| <code>RcvBufSize</code>        | The size of the TCP/IP receive buffer.                                                                                                                                                                                                                                                                                                                                              |                |                                                      |
| <code>SndBufSize</code>        | The size of the TCP/IP send buffer.                                                                                                                                                                                                                                                                                                                                                 |                |                                                      |
| <code>Modifier</code>          | Options (flags) for the daemon. Can be:<br><br><table><tr><td><code>h</code></td><td>Use name of interface for <code>HELO</code> command.</td></tr></table><br>If <code>h</code> is set, the name corresponding to the outgoing interface address (whether chosen by means of the <code>Connection</code> parameter or the default) is used for the <code>HELO/EHLO</code> command. | <code>h</code> | Use name of interface for <code>HELO</code> command. |
| <code>h</code>                 | Use name of interface for <code>HELO</code> command.                                                                                                                                                                                                                                                                                                                                |                |                                                      |

ColonOkInAddr

If set, colons are treated as a regular character in addresses. If not set, they are treated as the introducer to the RFC 822 “group” syntax. This option is on for version 5 and lower configuration files.

ConnectionCacheSize (k*N*)

The maximum number of open connections that are be cached at a time. The default is 1. This delays closing the current connection until either this invocation

## sendmail(1M)

of `sendmail` needs to connect to another host or it terminates. Setting it to 0 defaults to the old behavior, that is, connections are closed immediately.

### ConnectionCacheTimeout (*Ktimeout*)

The maximum amount of time a cached connection is permitted to idle without activity. If this time is exceeded, the connection is immediately closed. This value should be small (on the order of ten minutes). Before `sendmail` uses a cached connection, it always sends a NOOP (no operation) command to check the connection; if this fails, it reopens the connection. This keeps your end from failing if the other end times out. The point of this option is to be a good network neighbor and avoid using up excessive resources on the other end. The default is five minutes.

### ConnectionRateThrottle

The maximum number of connections permitted per second. After this many connections are accepted, further connections are delayed. If not set or  $\leq 0$ , there is no limit.

### ControlSocketName

Name of the control socket for daemon management. A running `sendmail` daemon can be controlled through this Unix domain socket. Available commands are: `help`, `restart`, `shutdown`, and `status`. The `status` command returns the current number of daemon children, the free disk space (in blocks) of the queue directory, and the load average of the machine expressed as an integer. If not set, no control socket is available. For the sake of security, this Unix domain socket must be in a directory which is accessible only by root; `/var/spool/mqueue/.smcontrol` is recommended for the socket name.

### DaemonPortOptions (*Options*)

Set server SMTP options. The options are *key=value* pairs. Known keys are:

|          |                                                                                                                                                                                                                                                                                                                                             |
|----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Name     | User-definable name for the daemon (defaults to "Daemon#"); used for error messages and logging.                                                                                                                                                                                                                                            |
| Addr     | Address mask (defaults <code>INADDR_ANY</code> )<br><br>The address mask may be a numeric address in dot notation or a network name.                                                                                                                                                                                                        |
| Family   | Address family (defaults to <code>INET</code> )                                                                                                                                                                                                                                                                                             |
| Listen   | Size of listen queue (defaults to 10)                                                                                                                                                                                                                                                                                                       |
| Modifier | Options (flags) for the daemon; can be a sequence (without any delimiters) of:<br><br>a        Require authentication.<br><br>b        Bind to interface through which mail has been received.<br><br>c        Perform hostname canonification ( <code>.cf</code> ).<br><br>f        Require fully qualified hostname ( <code>.cf</code> ). |

## sendmail(1M)

|                |                                                                                                              |
|----------------|--------------------------------------------------------------------------------------------------------------|
| <code>h</code> | Use name of interface for HELO command.                                                                      |
| <code>u</code> | Allow unqualified addresses ( <code>.cf</code> ).                                                            |
| <code>C</code> | Do not perform hostname canonification.                                                                      |
| <code>E</code> | Disallow ETRN (see RFC 2476).                                                                                |
| Name           | User-definable name for the daemon (defaults to <code>Daemon#</code> ); used for error messages and logging. |
| Port           | Name/number of listening port (defaults to <code>smtp</code> )                                               |
| ReceiveSize    | The size of the TCP/IP receive buffer.                                                                       |
| SendSize       | The size of the TCP/IP send buffer.                                                                          |

`sendmail` listens on a new socket for each occurrence of the `DaemonPortOptions` option in a configuration file.

### DataFileBufferSize

Set the threshold, in bytes, before a memory-based queue data file becomes disk-based. The default is 4096 bytes

### DeadLetterDrop

Defines the location of the system-wide `dead.letter` file, formerly hard-coded to `/var/tmp/dead.letter`. If this option is not set (the default), `sendmail` does not attempt to save to a system-wide `dead.letter` file in the event it cannot bounce the mail to the user or postmaster. Instead, it renames the `qf` file as it has in the past when the `dead.letter` file could not be opened.

### DefaultCharSet

Set the default character set to use when converting unlabeled 8 bit input to MIME.

### DefaultUser (*gid*) or (*uid*)

Set the default group ID for mailers to run in to *gid* or set the default userid for mailers to *uid*. Defaults to 1. The value can also be given as a symbolic group or user name.

### DelayLA=*LA*

When the system load average exceeds *LA*, `sendmail` sleeps for one second on most SMTP commands and before accepting connections.

### DeliverByMin=*time*

Set minimum time for Deliver By SMTP Service Extension (RFC 2852). If 0, no time is listed, if less than 0, the extension is not offered, if greater than 0, it is listed as minimum time for the EHLO keyword DELIVERBY.

### DeliveryMode (*dx*)

Deliver in mode *x*. Legal modes are:

- `i` Deliver interactively (synchronously).
- `b` Deliver in background (asynchronously).

## sendmail(1M)

|                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |                                                                           |

| <b>DontExpandCnames</b><br>If set, <code>\$( ... \$)</code> lookups that do DNS-based lookups do not expand CNAME records.                                                                                                                                                                                                                                                                                                                                                                                                                       |                                                                           |
| <b>DontInitGroups</b><br>If set, the <code>initgroups(3C)</code> routine is never be invoked. If you set this, agents run on behalf of users only have their primary ( <code>/etc/passwd</code> ) group permissions.                                                                                                                                                                                                                                                                                                                             |                                                                           |
| <b>DontProbeInterfaces</b><br>If set, <code>sendmail</code> does not insert the names and addresses of any local interfaces into the <code>\$=w class</code> . If set, you must also include support for these addresses, otherwise mail to addresses in this list bounce with a configuration error.                                                                                                                                                                                                                                            |                                                                           |
| <b>DontPruneRoutes (R)</b><br>If set, do not prune route-addr syntax addresses to the minimum possible.                                                                                                                                                                                                                                                                                                                                                                                                                                          |                                                                           |
| <b>DoubleBounceAddress</b><br>If an error occurs when sending an error message, send that “double bounce” error message to this address.                                                                                                                                                                                                                                                                                                                                                                                                         |                                                                           |
| <b>EightBitMode (8)</b><br>Use 8-bit data handling. This option requires one of the following keys. The key can selected by using just the first character, but using the full word is better for clarity.                                                                                                                                                                                                                                                                                                                                       |                                                                           |
| <code>mimify</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              | Do any necessary conversion of 8BITMIME to 7-bit.                         |
| <code>pass</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                | Pass unlabeled 8-bit input through as is.                                 |
| <code>strict</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              | Reject unlabeled 8-bit input.                                             |
| <b>ErrorHeader (Efile/message)</b><br>Append error messages with the indicated message. If it begins with a slash, it is assumed to be the pathname of a file containing a message (this is the recommended setting). Otherwise, it is a literal message. The error file might contain the name, email address, and/or phone number of a local postmaster who could provide assistance to end users. If the option is missing or <code>NULL</code> , or if it names a file which does not exist or which is not readable, no message is printed. |                                                                           |

**ErrorMode** (*ex*)

Dispose of errors using mode *x*. The values for *x* are:

- e** Mail back errors and give 0 exit status always.
- m** Mail back errors.
- p** Print error messages (default).
- q** No messages, just give exit status.
- w** Write back errors (mail if user not logged in).

**FallbackMXhost** (*Vfallbackhost*)

If specified, the *fallbackhost* acts like a very low priority MX on every host. This is intended to be used by sites with poor network connectivity.

**FastSplit**

If set to a value greater than zero (the default is one), it suppresses the MX lookups on addresses when they are initially sorted, that is, for the first delivery attempt. This usually results in faster envelope splitting unless the MX records are readily available in a local DNS cache. To enforce initial sorting based on MX records set **FastSplit** to zero. If the mail is submitted directly from the command line, then the value also limits the number of processes to deliver the envelopes; if more envelopes are created they are only queued up and must be taken care of by a queue run. Since the default submission method is by way of SMTP (either from a MUA or by way of the MSP), the value of **FastSplit** is seldom used to limit the number of processes to deliver the envelopes.

**ForkEachJob** (*Y*)

If set, deliver each job that is run from the queue in a separate process. Use this option if you are short of memory, since the default tends to consume considerable amounts of memory while the queue is being processed.

**ForwardPath** (*Jpath*)

Set the path for searching for users' `.forward` files. The default is `$z/.forward`. Some sites that use the automounter may prefer to change this to `/var/forward/$u` to search a file with the same name as the user in a system directory. It can also be set to a sequence of paths separated by colons; **sendmail** stops at the first file it can successfully and safely open. For example, `/var/forward/$u:$z/.forward` searches first in `/var/forward/username` and then in `~username/.forward` (but only if the first file does not exist). Refer to the NOTES section for more information.

**HelpFile** (*Hfile*)

Specify the help file for SMTP.

**HoldExpensive** (*c*)

If an outgoing mailer is marked as being expensive, don't connect immediately.

**HostsFile**

Set the file to use when doing "file" type access of host names.

## sendmail(1M)

### HostStatusDirectory

If set, host status is kept on disk between `sendmail` runs in the named directory tree. If a full path is not used, then the path is interpreted relative to the queue directory.

### IgnoreDots (i)

Ignore dots in incoming messages. This is always disabled (that is, dots are always accepted) when reading SMTP mail.

### LogLevel (Ln)

Set the default log level to *n*. Defaults to 9.

### (Mx value)

Set the macro *x* to *value*. This is intended only for use from the command line.

### MailboxDatabase

Type of lookup to find information about local mail boxes, defaults to `pw` which uses `getpwnam(3C)`. Other types can be introduced by adding them to the source code, see `libsm/mbdb.c` for details.

### MatchGECOS (G)

Try to match recipient names using the GECOS field. This allows for mail to be delivered using names defined in the GECOS field in `/etc/passwd` as well as the login name.

### MaxDaemonChildren

The maximum number of children the daemon permits. After this number, connections are rejected. If not set or  $\leq 0$ , there is no limit.

### MaxHopCount (hN)

The maximum hop count. Messages that have been processed more than *N* times are assumed to be in a loop and are rejected. Defaults to 25.

### MaxMessageSize

The maximum size of messages that are accepted (in bytes).

### MaxMimeHeaderLength=M[/N]

Sets the maximum length of certain MIME header field values to *M* characters. For some of these headers which take parameters, the maximum length of each parameter is set to *N* if specified. If `/N` is not specified, one half of *M* is used. By default, these values are 0, meaning no checks are done.

### MaxQueueChildren=N

When set, this limits the number of concurrent queue runner processes to *N*. This helps to control the amount of system resources used when processing the queue. When there are multiple queue groups defined and the total number of queue runners for these queue groups would exceed `MaxQueueChildren` then the queue groups are not all run concurrently. That is, some portion of the queue groups run concurrently such that `MaxQueueChildren` is not be exceeded, while the remaining queue groups are run later (in round robin order). See `MaxRunnersPerQueue`.

**MaxQueueRunSize**

If set, limit the maximum size of any given queue run to this number of entries. This stops reading the queue directory after this number of entries is reached; job priority is not used. If not set, there is no limit.

**MaxRunnersPerQueue=N**

This sets the default maximum number of queue runners for queue groups. Up to *N* queue runners work in parallel on a queue group's messages. This is useful where the processing of a message in the queue might delay the processing of subsequent messages. Such a delay can be the result of non-erroneous situations such as a low bandwidth connection. The can be overridden on a per queue group basis by setting the `Runners` option. The default is 1 when not set.

**MeToo (M)**

Send to me too, even if I am in an alias expansion.

**MaxRecipientsPerMessage**

If set, allow no more than the specified number of recipients in an SMTP envelope. Further recipients receive a 452 error code and are deferred for the next delivery attempt.

**MinFreeBlocks (bN/M)**

Insist on at least *N* blocks free on the file system that holds the queue files before accepting email by way of SMTP. If there is insufficient space, `sendmail` gives a 452 response to the `MAIL` command. This invites the sender to try again later. The optional *M* is a maximum message size advertised in the ESMTP EHLO response. It is currently otherwise unused.

**MinQueueAge**

The amount of time a job must sit in the queue between queue runs. This allows you to set the queue run interval low for better responsiveness without trying all jobs in each run. The default value is 0.

**MustQuoteChars**

Characters to be quoted in a full name phrase. `&`, `;`, `\`, `()`, `[]` are quoted automatically.

**NiceQueueRun**

The priority of queue runners. See `nice(1)`.

**NoRecipientAction**

Set action if there are no legal recipient files in the message. The legal values are:

|                                 |                                                                                                              |
|---------------------------------|--------------------------------------------------------------------------------------------------------------|
| <code>add-apparently-to</code>  | Add an <code>Apparently-to:</code> header with all the known recipients (which may expose blind recipients). |
| <code>add-bcc</code>            | Add an empty <code>Bcc:</code> header.                                                                       |
| <code>add-to</code>             | Add a <code>To:</code> header with all the known recipients (which may expose blind recipients).             |
| <code>add-to-undisclosed</code> | Add a <code>To: undisclosed-recipients:</code> header.                                                       |

## sendmail(1M)

| <code>OldStyleHeaders (o)</code>               | Assume that the headers may be in old format, that is, spaces delimit names. This actually turns on an adaptive algorithm: if any recipient address contains a comma, parenthesis, or angle bracket, it is assumed that commas already exist. If this flag is not on, only commas delimit names. Headers are always output with commas between the names.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |                           |                                                    |                     |                                               |                          |                                             |                           |                                             |                           |                                             |                     |                         |
| <code>OperatorChars</code> or <code>\$o</code> | Defines the list of characters that can be used to separate the components of an address into tokens.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |                           |                                                    |                     |                                               |                          |                                             |                           |                                             |                           |                                             |                     |                         |
| <code>PidFile</code>                           | Filename of the pid file. The default is <code>/var/run/sendmail.pid</code> . The filename is macro-expanded before it is opened.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |                           |                                                    |                     |                                               |                          |                                             |                           |                                             |                           |                                             |                     |                         |
| <code>PostmasterCopy (Ppostmaster)</code>      | If set, copies of error messages are sent to the named <i>postmaster</i> . Only the header of the failed message is sent. Since most errors are user problems, this is probably not a good idea on large sites, and arguably contains all sorts of privacy violations, but it seems to be popular with certain operating systems vendors.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |                           |                                                    |                     |                                               |                          |                                             |                           |                                             |                           |                                             |                     |                         |
| <code>PrivacyOptions (popt,opt,...)</code>     | <p>Set privacy options. Privacy is really a misnomer; many of these are just a way of insisting on stricter adherence to the SMTP protocol.</p> <p>The goaway pseudo-flag sets all flags except <code>noreceipts</code>, <code>restrictmailq</code>, <code>restrictqrun</code>, <code>restrictexpand</code>, <code>noetrn</code>, and <code>nobodyreturn</code>. If <code>mailq</code> is restricted, only people in the same group as the queue directory can print the queue. If queue runs are restricted, only root and the owner of the queue directory can run the queue. The <code>restrict-expand</code> pseudo-flag instructs sendmail to drop privileges when the <code>-bv</code> option is given by users who are neither root nor the <code>TrustedUser</code> so users cannot read private aliases, forwards, or <code>:include:</code> files. It adds the <code>NonRootSafeAddr</code> to the "DontBlame-Sendmail" option to prevent misleading unsafe address warnings. It also overrides the <code>-v</code> (verbose) command line option to prevent information leakage. Authentication Warnings add warnings about various conditions that may indicate attempts to fool the mail system, such as using an non-standard queue directory.</p> <p>The options can be selected from:</p> <table><tr><td><code>authwarnings</code></td><td>Put X-Authentication-Warning: headers in messages.</td></tr><tr><td><code>goaway</code></td><td>Disallow essentially all SMTP status queries.</td></tr><tr><td><code>needexphelo</code></td><td>Insist on HELO or EHLO command before EXPN.</td></tr><tr><td><code>needmailhelo</code></td><td>Insist on HELO or EHLO command before MAIL.</td></tr><tr><td><code>needvrfyhelo</code></td><td>Insist on HELO or EHLO command before VRFY.</td></tr><tr><td><code>noetrn</code></td><td>Disallow ETRN entirely.</td></tr></table> | <code>authwarnings</code> | Put X-Authentication-Warning: headers in messages. | <code>goaway</code> | Disallow essentially all SMTP status queries. | <code>needexphelo</code> | Insist on HELO or EHLO command before EXPN. | <code>needmailhelo</code> | Insist on HELO or EHLO command before MAIL. | <code>needvrfyhelo</code> | Insist on HELO or EHLO command before VRFY. | <code>noetrn</code> | Disallow ETRN entirely. |
| <code>authwarnings</code>                      | Put X-Authentication-Warning: headers in messages.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |                           |                                                    |                     |                                               |                          |                                             |                           |                                             |                           |                                             |                     |                         |

`ProcessTitlePrefix` *string*

Prefix the process title shown on “/usr/ucb/ps auxww” listings with *string*. The string is macro processed.

`QueueDirectory` (*Qdir*)

Use the named *dir* as the queue directory.

`QueueFactor` (*qfactor*)

Use *factor* as the multiplier in the map function to decide when to just queue up jobs rather than run them. This value is divided by the difference between the current load average and the load average limit (*xflag*) to determine the maximum message priority to be sent. Defaults to 600000.

`QueueFileMode`=*mode*

Default permissions for queue files (octal). If not set, sendmail uses 0600 unless its real and effective uid are different in which case it uses 0644.

`QueueLA` (*xLA*)

When the system load average exceeds *LA*, just queue messages (that is, do not try to send them). Defaults to eight times the number of processors online when sendmail starts.

`QueueSortOrder`=*algorithm*

Sets the algorithm used for sorting the queue. Only the first character of the value is used. Legal values are *host* (to order by the name of the first host name of the first recipient), *filename* (to order by the name of the queue file name), *time* (to order by the submission/creation time), *random* (to order randomly), *modification* (to order by the modification time of the *qf* file (older entries first)), and *priority* (to order by message priority). Host ordering makes better use of the connection cache, but may tend to process low priority messages that go to a single host over high priority messages that go to several hosts; it probably shouldn't be used on slow network links. Filename and modification time ordering saves the overhead of reading all of the queued items before starting the queue run. Creation (submission) time ordering is almost always a bad idea, since it allows large, bulk mail to go out before smaller, personal mail, but may have applicability on some hosts with very fast connections. Random is useful if several queue runners are started by hand which try to drain the same queue since odds are they are working on different parts of the queue at the same time. Priority ordering is the default.

## sendmail(1M)

### QueueTimeout (*Trtime/wtime*)

Set the queue timeout to *rtime*. After this interval, messages that have not been successfully sent are returned to the sender. Defaults to five days (5d). The optional *wtime* is the time after which a warning message is sent. If it is missing or 0, then no warning messages are sent.

### RecipientFactor (*yfact*)

The indicated factor *fact* is added to the priority (thus *lowering* the priority of the job) for each recipient, that is, this value penalizes jobs with large numbers of recipients. Defaults to 30000.

### RefuseLA (*XLA*)

When the system load average exceeds *LA*, refuse incoming SMTP connections. Defaults to 12 times the number of processors online when `sendmail` starts.

### ResolverOptions (*I*)

Tune DNS lookups.

### RetryFactor (*Zfact*)

The indicated factor *fact* is added to the priority every time a job is processed. Thus, each time a job is processed, its priority is decreased by the indicated value. In most environments this should be positive, since hosts that are down are all too often down for a long time. Defaults to 90000.

### RrtImpliesDsn

If this option is set, a "Return-Receipt-To:" header causes the request of a DSN, which is sent to the envelope sender as required by RFC 1891, not to the address given in the header.

### RunAsUser

If set, become this user when reading and delivering mail. Intended for use of firewalls where users do not have accounts.

### SafeFileEnvironment

If set, `sendmail` does a `chroot` into this directory before writing files.

### SaveFromLine (*f*)

Save Unix-style `From` lines at the front of headers. Normally they are assumed redundant and discarded.

### SendMimeErrors (*j*)

If set, send error messages in MIME format (see RFC 2045 and RFC 1344 for details). If disabled, `sendmail` does not return the DSN keyword in response to an EHLO and does not do Delivery Status Notification processing as described in RFC 1891.

### ServiceSwitchFile

Defines the path to the service-switch file. Since the service-switch file is defined in the Solaris operating environment this option is ignored.

### SevenBitInput (*7*)

Strip input to seven bits for compatibility with old systems. This should not be necessary.

SharedMemoryKey

Key to use for shared memory segment; if not set (or 0), shared memory is not be used. If this option is set, sendmail can share some data between different instances. For example, the number of entries in a queue directory or the available space in a file system. This allows for more efficient program execution, since only one process needs to update the data instead of each individual process gathering the data each time it is required.

SingleLineFromHeader

If set, From: lines that have embedded newlines are unwrapped onto one line.

SingleThreadDelivery

If this option and the HostStatusDirectory option are both set, use single thread deliveries to other hosts.

SmtpGreetingMessage or \$e

The initial SMTP greeting message.

StatusFile (*Sfile*)

Log statistics in the named file. By default, this is /etc/mail/sendmail.st. As root, you must touch(1) this file to enable mailstats(1).

SuperSafe (*s*)

This option can be set to True, False, or Interactive. If set to True, sendmail is set to super-safe when running things, that is, always instantiate the queue file, even if you are going to attempt immediate delivery. sendmail always instantiates the queue file before returning control to the client under any circumstances. This should really always be set to True. The Interactive value has been introduced in 8.12 and can be used together with DeliveryMode=i. It skips some synchronization calls which are effectively doubled in the code execution path for this mode.

TempFileMode (*Fmode*)

The file mode for queue files.

Timeout (*rtimeouts*)

Timeout reads after time interval. The *timeouts* argument is a list of *keyword=value* pairs. All but *command* apply to client SMTP. For backward compatibility, a timeout with no *keyword=* part is set all of the longer values. The recognized timeouts and their default values, and their minimum values specified in RFC 1123 section 5.3.2 are:

connect

all connections for a single delivery attempt [0, unspecified]

command

command read [1h, 5m]

connect

initial connect [0, unspecified]

control

complete control socket transaction [2m, none]

## sendmail(1M)

`datablock`  
data block read [1h, 3m]

`datafinal`  
reply to final . in data [1h, 10m]

`datainit`  
reply to DATA command [5m, 2m]

`fileopen`  
file open [60sec, none]

`helo`  
reply to HELO or EHLO command [5m, none]

`hoststatus`  
host retry [30m, unspecified]

`iconnect`  
first attempt to connect to a host [0, unspecified]

`ident`  
IDENT protocol timeout [5s, none]

`initial`  
wait for initial greeting message [5m, 5m]

`lhlo`  
wait for reply to an LMTP LHLO command [2m, unspecified].

`mail`  
reply to MAIL command [10m, 5m]

`misc`  
reply to NOOP and VERB commands [2m, none]

`queuereturn`  
undeliverable message returned [5d]

`queuewarn`  
deferred warning [4h]

`quit`  
reply to QUIT command [2m, none]

`rcpt`  
reply to RCPT command [1h, 5m]

`resolver.retrans`  
Resolver's retransmission time interval (in seconds) [varies]. Sets both  
`Timeout.resolver.retrans.first` and  
`Timeout.resolver.retrans.normal`.

`resolver.retrans.first`  
Resolver's retransmission time interval (in seconds) for the first attempt to  
deliver a message [varies].

`resolver.retrans.normal`

Resolver's retransmission time interval (in seconds) for all look-ups except the first delivery attempt [varies].

`resolver.retry`

Number of times to retransmit a resolver query [varies]. Sets both `Timeout.resolver.retry.first` and `Timeout.resolver.retry.normal`.

`resolver.retry.first`

Number of times to retransmit a resolver query for the first attempt to deliver a message [varies].

`resolver.retry.normal`

Number of times to retransmit a resolver query for all look-ups except the first delivery attempt [varies].

`rset`

reply to RSET command [5m, none]

`TimeZoneSpec (tzinfo)`

Set the local time zone info to *tzinfo*, for example, "PST8PDT ". Actually, if this is not set, the TZ environment variable is cleared (so the system default is used); if set but null, the user's TZ variable is used, and if set and non-null, the TZ variable is set to this value.

`TrustedUser`

The user parameter can be a user name (looked up in the passwd map) or a numeric user id. Trusted user for file ownership and starting the daemon. If set, generated alias databases and the control socket (if configured) are automatically owned by this user.

`TryNullMXList (w)`

If you are the "best" (that is, lowest preference) MX for a given host, you should normally detect this situation and treat that condition specially, by forwarding the mail to a UUCP feed, treating it as local, or whatever. However, in some cases (such as Internet firewalls) you may want to try to connect directly to that host as though it had no MX records at all. Setting this option causes `sendmail` to try this. The downside is that errors in your configuration are likely to be diagnosed as "host unknown" or "message timed out" instead of something more meaningful. This option is deprecated.

`UnixFromLine` or `$1`

The "From " line used when sending to files or programs.

`UnsafeGroupWrites`

If set, group-writable `:include:` and `.forward` files are considered "unsafe", that is, programs and files cannot be directly referenced from such files.

`UseErrorsTo (l)`

If there is an `Errors-To:` header, send error messages to the addresses listed there. They normally go to the envelope sender. Use of this option causes `sendmail` to violate RFC 1123. This option is not recommended and deprecated.

## sendmail(1M)

|                                |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |                          |                                         |                                |                           |                             |                                                   |                        |                          |                          |                                                   |                       |                                                          |                        |                           |                          |                                                        |

**NOTES** The sendmail program requires a fully qualified host name when starting. A script has been included to help verify if the host name is defined properly (see check-hostname(1M)).

The permissions and the ownership of several directories have been changed in order to increase security. In particular, access to /etc/mail and /var/spool/mqueue has been restricted.

Security restrictions have been placed users using .forward files to pipe mail to a program or redirect mail to a file. The default shell (as listed in /etc/passwd) of these users must be listed in /etc/shells. This restriction does not affect mail that is being redirected to another alias.

## sendmail(1M)

Additional restrictions have been put in place on `.forward` and `:include:` files. These files and the directory structure that they are placed in cannot be group- or world-writable (see `check-permissions(1M)`).

If you have interfaces that map to domains that have MX records that point to non-local destinations, you might need to enable the `DontProbeInterfaces` option to enable delivery to those destinations. In its default startup behavior, `sendmail` probes each interface and adds an interface's IP addresses, as well as any domains that those addresses map to, to its list of domains that are considered local. For domains thus added, being on the list of local domains is equivalent to having a 0-preference MX record, with `localhost` as the MX value. If this is not the result you want, enable `DontProbeInterfaces`.

| <b>NAME</b>        | setuname – change machine information                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |                |                 |              |                  |  |                   |

| <b>SYNOPSIS</b>    | <b>setuname</b> [-t] [-n <i>node</i> ] [-s <i>name</i> ]                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |                |                 |              |                  |  |                   |
| <b>DESCRIPTION</b> | <p>The <code>setuname</code> utility changes the parameter value for the system name and node name. Each parameter can be changed using <code>setuname</code> and the appropriate option.</p> <p>Either or both the <code>-s</code> and <code>-n</code> options must be given when invoking <code>setuname</code>.</p> <p>The system architecture may place requirements on the size of the system and network node name. The command will issue a fatal warning message and an error message if the name entered is incompatible with the system requirements.</p>                                                 |                |                 |              |                  |  |                   |
| <b>OPTIONS</b>     | <p>The following options are supported:</p> <ul style="list-style-type: none"> <li><code>-n <i>node</i></code> Changes the node name. <i>node</i> specifies the new network node name and can consist of alphanumeric characters and the special characters dash, underbar, and dollar sign.</li> <li><code>-s <i>name</i></code> Changes the system name. <i>name</i> specifies new system name and can consist of alphanumeric characters and the special characters dash, underbar, and dollar sign.</li> <li><code>-t</code> Temporary change. No attempt will be made to create a permanent change.</li> </ul> |                |                 |              |                  |  |                   |
| <b>ATTRIBUTES</b>  | <p>See <code>attributes(5)</code> for descriptions of the following attributes:</p> <table border="1"> <thead> <tr> <th>ATTRIBUTE TYPE</th><th>ATTRIBUTE VALUE</th></tr> </thead> <tbody> <tr> <td>Availability</td><td>SUNWcsu (32-bit)</td></tr> <tr> <td></td><td>SUNWcsxu (64-bit)</td></tr> </tbody> </table>                                                                                                                                                                                                                                                                                                  | ATTRIBUTE TYPE | ATTRIBUTE VALUE | Availability | SUNWcsu (32-bit) |  | SUNWcsxu (64-bit) |

| <b>SEE ALSO</b>    | <code>attributes(5)</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |                |                 |              |                  |  |                   |
| <b>NOTES</b>       | <code>setuname</code> attempts to change the parameter values in two places: the running kernel and, as necessary per implementation, to cross system reboots. A temporary change changes only the running kernel.                                                                                                                                                                                                                                                                                                                                                                                                  |                |                 |              |                  |  |                   |

sf880drd(1M)

| <b>DESCRIPTION</b> | <p>The Sun Fire 880 Dynamic Reconfiguration daemon, <code>sf880drd</code>, is part of the PCI and system bus hotplug framework. <code>sf880drd</code> starts at boot time. It has no configuration options and does not report any system status.</p> <p><code>sf880drd</code> implements the Sun Fire 880 console-less system administration (per-slot pushbuttons and LED status indicators). It also manages various aspects of CPU/memory hotplug.</p> |                |                 |              |            |

| <b>DESCRIPTION</b> | <p>sftp-server implements the server side of the SSH File Transfer Protocol as defined in the IETF draft-ietf-secsh-filexfer.</p> <p>sftp-server is a subsystem for sshd(1M) and must not be run directly. There are no options or config settings.</p> <p>To enable the sftp-server subsystem for sshd add the following to /etc/ssh/sshd_config:</p> <pre>Subsystem sftp /usr/lib/ssh/sftp-server</pre> <p>See sshd_config(4) for a description of the format and contents of that file.</p> <p>There is no relationship between the protocol used by sftp-server and the FTP protocol (RFC 959) provided by in.ftpd.</p> |                |                 |              |           |
| <b>EXIT STATUS</b> | <p>The following exit values are returned:</p> <p>0 Successful completion.</p> <p>&gt;0 An error occurred.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |                |                 |              |           |

| <b>DESCRIPTION</b> | The share command exports, or makes a resource available for mounting, through a remote file system of type <i>FSType</i> . If the option -F <i>FSType</i> is omitted, the first file system type listed in /etc/dfs/fstypes is used as default. For a description of NFS specific options, see share_nfs(1M). <i>pathname</i> is the pathname of the directory to be shared. When invoked with no arguments, share displays all shared file systems.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>OPTIONS</b>     | <div> <div>-F <i>FSType</i></div> <div>Specify the filesystem type.</div> </div> <div> <div>-o <i>specific_options</i></div> <div> <p>The <i>specific_options</i> are used to control access of the shared resource. (See share_nfs(1M) for the NFS specific options.) They may be any of the following:</p> <div> <div>rw</div> <div><i>pathname</i> is shared read/write to all clients. This is also the default behavior.</div> </div> <div> <div>rw=<i>client[:client]...</i></div> <div><i>pathname</i> is shared read/write only to the listed clients. No other systems can access <i>pathname</i>.</div> </div> <div> <div>ro</div> <div><i>pathname</i> is shared read-only to all clients.</div> </div> <div> <div>ro=<i>client[:client]...</i></div> <div><i>pathname</i> is shared read-only only to the listed clients. | <b>EXAMPLES</b>    | <p><b>EXAMPLE 1</b> Sharing a read-only filesystem</p> <p>This line will share the /disk file system read-only at boot time.</p> <pre>share -F nfs -o ro /disk</pre> <p><b>EXAMPLE 2</b> Invoking multiple options</p> <p>The following command shares the filesystem /export/manuals, with members of the netgroup having read-only access and users on the specified host having read-write access.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

**EXAMPLE 2** Invoking multiple options      *(Continued)*

```
share -F nfs -o ro=netgroup_name:rw=hostname /export/manuals
```

**FILES**

|                   |                                                    |
|-------------------|----------------------------------------------------|
| /etc/dfs/dfstab   | list of share commands to be executed at boot time |
| /etc/dfs/fstypes  | list of file system types, NFS by default          |
| /etc/dfs/sharetab | system record of shared file systems               |

**ATTRIBUTES** See attributes(5) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWcsu         |

**SEE ALSO** mountd(1M), nfsd(1M), share\_nfs(1M), shareall(1M), unshare(1M), attributes(5)

**NOTES** Export (old terminology): file system sharing used to be called exporting on SunOS 4.x, so the share command used to be invoked as exportfs(1B) or /usr/sbin/exportfs.

If share commands are invoked multiple times on the same filesystem, the last share invocation supersedes the previous—the options set by the last share command replace the old options. For example, if read-write permission was given to usera on /somefs, then to give read-write permission also to userb on /somefs:

```
example% share -F nfs -o rw=usera:userb /somefs
```

This behavior is not limited to sharing the root filesystem, but applies to all filesystems.

## shareall(1M)

| NAME           | shareall, unshareall – share, unshare multiple resources                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |                |                 |              |         |
|----------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------|-----------------|--------------|---------|
| SYNOPSIS       | <b>shareall</b> [-F <i>FSType</i> [, <i>FSType</i> ...]] [-   <i>file</i> ]<br><b>unshareall</b> [-F <i>FSType</i> [, <i>FSType</i> ...]]                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |                |                 |              |         |
| DESCRIPTION    | <p>When used with no arguments, <b>shareall</b> shares all resources from <i>file</i>, which contains a list of <b>share</b> command lines. If the operand is a hyphen (-), then the <b>share</b> command lines are obtained from the standard input. Otherwise, if neither a <i>file</i> nor a hyphen is specified, then the file <i>/etc/dfs/dfstab</i> is used as the default.</p> <p>Resources may be shared by specific file system types by specifying the file systems in a comma-separated list as an argument to -F.</p> <p><b>unshareall</b> unshares all currently shared resources. Without a -F flag, it unshares resources for all distributed file system types.</p> |                |                 |              |         |
| OPTIONS        | -F <i>FSType</i> Specify file system type. | NAME        | share_nfs – make local NFS file systems available for mounting by remote systems                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| SYNOPSIS    | <b>share</b> [-d <i>description</i> ] [-F <i>nfs</i> ] [-o <i>specific_options</i> ] <i>pathname</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| DESCRIPTION | <p>The share utility makes local file systems available for mounting by remote systems.</p> <p>If no argument is specified, then share displays all file systems currently shared, including NFS file systems and file systems shared through other distributed file system packages.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| OPTIONS     | <p>The following options are supported:</p> <ul style="list-style-type: none"> <li>-d <i>description</i>                      Provide a comment that describes the file system to be shared.</li> <li>-F <i>nfs</i>                                  Share NFS file system type.</li> <li>-o <i>specific_options</i>                  Specify <i>specific_options</i> in a comma-separated list of keywords and attribute-value-assertions for interpretation by the file-system-type-specific command. If <i>specific_options</i> is not specified, then by default sharing will be read-write to all clients. <i>specific_options</i> can be any combination of the following: <ul style="list-style-type: none"> <li>aclok <p>Allows the NFS server to do access control for NFS Version 2 clients (running SunOS 2.4 or earlier). When aclok is set on the server, maximal access is given to all clients. For example, with aclok set, if anyone has read permissions, then everyone does. If aclok is not set, minimal access is given to all clients.</p> </li> <li>anon=<i>uid</i> <p>Set <i>uid</i> to be the effective user ID of unknown users. By default, unknown users are given the effective user ID <code>UID_NOBODY</code>. If <i>uid</i> is set to <code>-1</code>, access is denied.</p> </li> <li>index=<i>file</i> <p>Load <i>file</i> rather than a listing of the directory containing this file when the directory is referenced by an NFS URL.</p> </li> <li>log=<i>tag</i> <p>Enables NFS server logging for the specified file system. The optional tag determines the location of the related log files. The tag is defined in <code>etc/nfs/nfslog.conf</code>. If no tag is specified, the default values associated with the “global” tag in <code>etc/nfs/nfslog.conf</code> will be used.</p> </li> </ul> </li> </ul> |

## share\_nfs(1M)

### nosub

Prevents clients from mounting subdirectories of shared directories. For example, if `/export` is shared with the `nosub` option on server *foeey* then a NFS client will not be able to do:

```
mount -F nfs foeey:/export/home/mnt
```

### nosuid

By default, clients are allowed to create files on the shared file system with the `setuid` or `setgid` mode enabled. Specifying `nosuid` causes the server file system to silently ignore any attempt to enable the `setuid` or `setgid` mode bits.

### public

Moves the location of the public file handle from root (`/`) to the exported directory for WebNFS-enabled browsers and clients. This option does not enable WebNFS service; WebNFS is always on. Only one file system per server may use this option. Any other option, including the `-ro=list` and `-rw=list` options can be included with the `public` option.

### ro

Sharing will be read-only to all clients.

### ro=*access\_list*

Sharing will be read-only to the clients listed in *access\_list*; overrides the `rw` suboption for the clients specified. See *access\_list* below.

### root=*access\_list*

Only root users from the hosts specified in *access\_list* will have root access. See *access\_list* below. By default, no host has root access, so root users are mapped to an anonymous user ID (see the `anon=uid` option described above). Netgroups can be used if the file system shared is using UNIX authentication (`AUTH_SYS`).

### rw

Sharing will be read-write to all clients.

### rw=*access\_list*

Sharing will be read-write to the clients listed in *access\_list*; overrides the `ro` suboption for the clients specified. See *access\_list* below.

`sec=mode[:mode]. . .`

Sharing will use one or more of the specified security modes. The *mode* in the `sec=mode` option must be a node name supported on the client. If the `sec=` option is not specified, the default security mode used is `AUTH_SYS`. Multiple `sec=` options can be specified on the command line, although each mode can appear only once. The security modes are defined in `nfssec(5)`.

Each `sec=` option specifies modes that apply to any subsequent `window=`, `rw`, `ro`, `rw=`, `ro=` and `root=` options that are provided before another `sec=` option. Each additional `sec=` resets the security mode context, so that more `window=`, `rw`, `ro`, `rw=`, `ro=` and `root=` options can be supplied for additional modes.

`sec=none`

If the option `sec=none` is specified when the client uses `AUTH_NONE`, or if the client uses a security mode that is not one that the file system is shared with, then the credential of each NFS request is treated as unauthenticated. See the `anon=uid` option for a description of how unauthenticated requests are handled.

`secure`

This option has been deprecated in favor of the `sec=dh` option.

`window=value`

When sharing with `sec=dh`, set the maximum life time (in seconds) of the RPC request's credential (in the authentication header) that the NFS server will allow. If a credential arrives with a life time larger than what is allowed, the NFS server will reject the request. The default value is 30000 seconds (8.3 hours).

|                    |                                                                                                                                                                                         |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>access_list</i> | The <i>access_list</i> argument is a colon-separated list whose components may be any number of the following:                                                                          |
| hostname           | The name of a host. With a server configured for DNS or LDAP naming in the <code>nsswitch "hosts"</code> entry, any hostname must be represented as a fully qualified DNS or LDAP name. |
| netgroup           | A netgroup contains a number of hostnames. With a server configured for DNS or LDAP naming in the                                                                                       |

|         |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|---------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|         | <p>nsswitch "hosts" entry, any hostname in a netgroup must be represented as a fully qualified DNS or LDAP name.</p> <p>domain name suffix</p> <p>To use domain membership the server must use DNS or LDAP to resolve hostnames to IP addresses; that is, the "hosts" entry in the <code>/etc/nsswitch.conf</code> must specify "dns" or "ldap" ahead of "nis" or "nisplus", since only DNS and LDAP return the full domain name of the host. Other name services like NIS or NIS+ cannot be used to resolve hostnames on the server because when mapping an IP address to a hostname they do not return domain information. For example,</p> <p>NIS or NIS+    129.144.45.9 --&gt; "myhost</p> <p>DNS or LDAP    129.144.45.9 --&gt;<br/>                  "myhost.mydomain.mycompany.com"</p> <p>The domain name suffix is distinguished from hostnames and netgroups by a prefixed dot. For example,</p> <p><code>rw=.mydomain.mycompany.com</code></p> <p>A single dot can be used to match a hostname with no suffix. For example,</p> <p><code>rw=.</code></p> <p>will match "mydomain" but not "mydomain.mycompany.com". This feature can be used to match hosts resolved through NIS and NIS+ rather than DNS and LDAP.</p> |
| network | <p>The network or subnet component is preceded by an at-sign (@). It can be either a name or a dotted address. If a name, it will be converted to a dotted address by <code>getnetbyname(3SOCKET)</code>. For example,</p> <p><code>=@mynet</code> would be equivalent to:</p> <p><code>=@129.144</code> or <code>=@129.144.0.0</code> The network prefix assumes an octet aligned netmask determined from the zero octets in the low-order part of the address. In the case where network prefixes are not byte-aligned, the</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

share\_nfs(1M)

syntax will allow a mask length to be specified explicitly following a slash (/) delimiter. For example,

=@theothernet/17 or =@129.144.132/22 where the mask is the number of leftmost contiguous significant bits in the corresponding IP address.

A prefixed minus sign (-) denies access to that component of *access\_list*. The list is searched sequentially until a match is found that either grants or denies access, or until the end of the list is reached. For example, if host "terra" is in the "engineering" netgroup, then

rw=-terra:engineering will deny access to terra but  
rw=engineering:-terra will grant access to terra.

**OPERANDS** The following operands are supported:  
*pathname* The pathname of the file system to be shared.

**EXAMPLES** **EXAMPLE 1** Sharing A File System With Logging Enabled

The following example shows the /export file system shared with logging enabled:

example% **share -o log /export**  
The default global logging parameters are used since no tag identifier is specified. The location of the log file, as well as the necessary logging work files, is specified by the global entry in /etc/nfs/nfslog.conf. Note that the nfslogd(1M) daemon will run only if at least one file system entry in /etc/dfs/dfstab is shared with logging enabled upon starting or rebooting the system. Simply sharing a file system with logging enabled from the command line will not start the nfslogd(1M).

**EXIT STATUS** The following exit values are returned:

0 Successful completion.  
>0 An error occurred.

**FILES** /etc/dfs/fstypes list of system types, NFS by default  
/etc/dfs/sharetab system record of shared file systems  
/etc/nfs/nfslogtab system record of logged file systems  
/etc/nfs/nfslog.conf logging configuration file

**ATTRIBUTES** See attributes(5) for descriptions of the following attributes:

## share\_nfs(1M)

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWnfsu        |

**SEE ALSO** mount(1M), mountd(1M), nfsd(1M), nfslogd(1M), share(1M), unshare(1M), getnetbyname(3SOCKET), nfslog.conf(4), netgroup(4), attributes(5), nfssec(5)

**NOTES** If the `sec=` option is presented at least once, all uses of the `window=`, `rw`, `ro`, `rw=`, `ro=` and `root=` options must come after the first `sec=` option. If the `sec=` option is not presented, then `sec=sys` is implied.

If one or more explicit `sec=` options are presented, `sys` must appear in one of the options mode lists for accessing using the `AUTH_SYS` security mode to be allowed. For example:

```
share -F nfs /var
share -F nfs -o sec=sys /var
```

will grant read-write access to any host using `AUTH_SYS`, but

```
share -F nfs -o sec=dh /var
```

will grant no access to clients that use `AUTH_SYS`.

Unlike previous implementations of `share_nfs(1M)`, access checking for the `window=`, `rw`, `ro`, `rw=`, and `ro=` options is done per NFS request, instead of per mount request.

Combining multiple security modes can be a security hole in situations where the `ro=` and `rw=` options are used to control access to weaker security modes. In this example,

```
share -F nfs -o sec=dh,rw,sec=sys,rw=hosta /var
```

an intruder can forge the IP address for `hosta` (albeit on each NFS request) to side-step the stronger controls of `AUTH_DES`. Something like:

```
share -F nfs -o sec=dh,rw,sec=sys,ro /var
```

is safer, because any client (intruder or legitimate) that avoids `AUTH_DES` will only get read-only access. In general, multiple security modes per `share` command should only be used in situations where the clients using more secure modes get stronger access than clients using less secure modes.

If `rw=`, and `ro=` options are specified in the same `sec=` clause, and a client is in both lists, the order of the two options determines the access the client gets. If client `hosta` is in two netgroups - `group1` and `group2` - in this example, the client would get read-only access:

```
share -F nfs -o ro=group1,rw=group2 /var
```

In this example `hosta` would get read-write access:

```
share -F nfs -o rw=group2,ro=group1 /var
```

share\_nfs(1M)

If within a `sec=` clause, both the `ro` and `rw=` options are specified, for compatibility, the order of the options rule is not enforced. All hosts would get read-only access, with the exception to those in the read-write list. Likewise, if the `ro=` and `rw` options are specified, all hosts get read-write access with the exceptions of those in the read-only list.

The `ro=` and `rw=` options are guaranteed to work over UDP and TCP but may not work over other transport providers.

The `root=` option with `AUTH_SYS` is guaranteed to work over UDP and TCP but may not work over other transport providers.

The `root=` option with `AUTH_DES` is guaranteed to work over any transport provider.

There are no interactions between the `root=` option and the `rw`, `ro`, `rw=`, and `ro=` options. Putting a host in the `root` list does not override the semantics of the other options. The access the host gets is the same as when the `root=` options is absent. For example, the following `share` command will deny access to `hostb`:

```
share -F nfs -o ro=hosta,root=hostb /var
```

The following will give read-only permissions to `hostb`:

```
share -F nfs -o ro=hostb,root=hostb /var
```

The following will give read-write permissions to `hostb`:

```
share -F nfs -o ro=hosta,rw=hostb,root=hostb /var
```

If the file system being shared is a symbolic link to a valid pathname, the canonical path (the path which the symbolic link follows) will be shared. For example, if `/export/foo` is a symbolic link to `/export/bar` (`/export/foo -> /export/bar`), the following `share` command will result in `/export/bar` as the shared pathname (and not `/export/foo`).

```
example# share -F nfs /export/foo
```

Note that an NFS mount of `server:/export/foo` will result in `server:/export/bar` really being mounted.

This line in the `/etc/dfs/dfstab` file will share the `/disk` file system read-only at boot time:

```
share -F nfs -o ro /disk
```

Note that the same command entered from the command line will not share the `/disk` file system unless there is at least one file system entry in the `/etc/dfs/dfstab` file. The `mountd(1M)` and `nfsd(1M)` daemons only run if there is a file system entry in `/etc/dfs/dfstab` when starting or rebooting the system.

showmount(1M)

| NAME           | showmount – show all remote mounts                                                                                                                                                                                                                                                                                                                                                                                                             |                |                 |              |           |
|----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------|-----------------|--------------|-----------|
| SYNOPSIS       | <b>/usr/sbin/showmount</b> [-ade] [ <i>hostname</i> ]                                                                                                                                                                                                                                                                                                                                                                                          |                |                 |              |           |
| DESCRIPTION    | showmount lists all the clients that have remotely mounted a filesystem from <i>host</i> . This information is maintained by the mountd(1M) server on <i>host</i> , and is saved across crashes in the file <i>/etc/rmtab</i> . The default value for <i>host</i> is the value returned by <i>hostname(1)</i> .                                                                                                                                |                |                 |              |           |
| OPTIONS        | <p>-a            Print all remote mounts in the format:</p> <p style="padding-left: 40px;"><i>hostname</i> : <i>directory</i></p> <p style="padding-left: 40px;">where <i>hostname</i> is the name of the client, and <i>directory</i> is the root of the file system that has been mounted.</p> <p>-d            List directories that have been remotely mounted by clients.</p> <p>-e            Print the list of shared file systems.</p> |                |                 |              |           |
| FILES          | <i>/etc/rmtab</i>                                                                                                                                                                                                                                                                                                                                                                                                                              |                |                 |              |           |
| ATTRIBUTES     | See <i>attributes(5)</i> for descriptions of the following attributes:                                                                                                                                                                                                                                                                                                                                                                         |                |                 |              |           |

| <b>NAME</b>        | showrev – show machine, software revision, and patch revision information                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>SYNOPSIS</b>    | <b>/usr/bin/showrev</b> [-a] [-p   -p -R <i>root_path</i> ] [-w] [-c <i>command</i> ]<br>[-s <i>hostname</i> ]                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>DESCRIPTION</b> | <p>showrev displays revision information for the current hardware and software. With no arguments, showrev shows the system revision information including hostname, hostid, release, kernel architecture, application architecture, hardware provider, domain, and kernel version.</p> <p>If a command is supplied with the -c option, showrev shows the PATH and LD_LIBRARY_PATH and finds out all the directories within the PATH that contain it. For each file found, its file type, revision, permissions, library information, and checksum are printed as well.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>OPTIONS</b>     | <p>The following options are supported:</p> <ul style="list-style-type: none"> <li>-a                   Print all system revision information available. Window system and patch information are added.</li> <li>-c <i>command</i>       Print the revision information about <i>command</i>.</li> <li>-p                   Print only the revision information about patches.</li> <li>-R <i>root_path</i>       Define the full path name of a directory to use as the <i>root_path</i>. By specifying the root path, showrev retrieves the revision information about the patch from package system information files located under a directory tree starting at <i>root_path</i>. The <i>root_path</i> can be specified when retrieving installed patch information in a client from a server, for example, /export/root/client1.</li> <li>-s <i>hostname</i>       Perform this operation on the specified <i>hostname</i>. The -s operation completes correctly only when <i>hostname</i> is running Solaris 2.5 or compatible versions.</li> <li>-w                   Print only the OpenWindows revision information.</li> </ul> |
| <b>OUTPUT</b>      | <p>Varies, based on flags passed. If no flags are passed, output similar to the following appears:</p> <pre> Hostname: system1 Hostid: 7233808e Release: 5.9 Kernel architecture: sun4u Application architecture: sparc Hardware provider: Sun_Microsystems Domain: a.network.COM Kernel version: SunOS 5.9 generic February 2001 </pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWadmc        |

**SEE ALSO** `arch(1)`, `ldd(1)`, `mcs(1)`, `sum(1)`, `patchadd(1M)`, `attributes(5)`

**BUGS** For the `-s` option to work when `hostname` is running a version of Solaris prior to 2.5, the Solstice AdminSuite must be installed on `hostname`.

| NAME                   | shutdown – shut down system, change system state                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |         |                                                                                           |                        |                                                                                                                                                                                                                                                                                                                                                                                                                                                 |            |                                                                                                                                                                                                                                                                                                                                      |         |                                                                                                                                                             |         |                                                                                                                                                       |
| SYNOPSIS               | <b>/usr/sbin/shutdown</b> [-y] [-g <i>grace-period</i> ] [-i <i>init-state</i> ] [ <i>message</i> ]                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |         |                                                                                           |                        |                                                                                                                                                                                                                                                                                                                                                                                                                                                 |            |                                                                                                                                                                                                                                                                                                                                      |         |                                                                                                                                                             |         |                                                                                                                                                       |
| DESCRIPTION            | <p>shutdown is executed by the super user to change the state of the machine. In most cases, it is used to change from the multi-user state (state 2) to another state.</p> <p>By default, shutdown brings the system to a state where only the console has access to the operating system. This state is called single-user.</p> <p>Before starting to shut down daemons and killing processes, shutdown sends a warning message and, by default, a final message asking for confirmation. <i>message</i> is a string that is sent out following the standard warning message "The system will be shut down in . . ." If the string contains more than one word, it should be contained within single ( ' ) or double ( " ) quotation marks.</p> <p>The warning message and the user provided <i>message</i> are output when there are 7200, 3600, 1800, 1200, 600, 300, 120, 60, and 30 seconds remaining before shutdown begins. See EXAMPLES.</p> <p>System state definitions are:</p> <table> <tr> <td>state 0</td><td>Stop the operating system.</td></tr> <tr> <td>state 1</td><td>State 1 is referred to as the administrative state. In state 1 file systems required for multi-user operations are mounted, and logins requiring access to multi-user file systems can be used. When the system comes up from firmware mode into state 1, only the console is active and other multi-user (state 2) services are unavailable. Note that not all user processes are stopped when transitioning from multi-user state to state 1.</td></tr> <tr> <td>state s, S</td><td>State s (or S) is referred to as the single-user state. All user processes are stopped on transitions to this state. In the single-user state, file systems required for multi-user logins are unmounted and the system can only be accessed through the console. Logins requiring access to multi-user file systems cannot be used.</td></tr> <tr> <td>state 5</td><td>Shut the machine down so that it is safe to remove the power. Have the machine remove power, if possible. The rc0 procedure is called to perform this task.</td></tr> <tr> <td>state 6</td><td>Stop the operating system and reboot to the state defined by the initdefault entry in /etc/inittab. The rc6 procedure is called to perform this task.</td></tr> </table> | state 0 | Stop the operating system.                                                                | state 1                | State 1 is referred to as the administrative state. In state 1 file systems required for multi-user operations are mounted, and logins requiring access to multi-user file systems can be used. When the system comes up from firmware mode into state 1, only the console is active and other multi-user (state 2) services are unavailable. Note that not all user processes are stopped when transitioning from multi-user state to state 1. | state s, S | State s (or S) is referred to as the single-user state. All user processes are stopped on transitions to this state. In the single-user state, file systems required for multi-user logins are unmounted and the system can only be accessed through the console. Logins requiring access to multi-user file systems cannot be used. | state 5 | Shut the machine down so that it is safe to remove the power. Have the machine remove power, if possible. The rc0 procedure is called to perform this task. | state 6 | Stop the operating system and reboot to the state defined by the initdefault entry in /etc/inittab. The rc6 procedure is called to perform this task. |
| state 0                | Stop the operating system.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |         |                                                                                           |                        |                                                                                                                                                                                                                                                                                                                                                                                                                                                 |            |                                                                                                                                                                                                                                                                                                                                      |         |                                                                                                                                                             |         |                                                                                                                                                       |
| state 1                | State 1 is referred to as the administrative state. In state 1 file systems required for multi-user operations are mounted, and logins requiring access to multi-user file systems can be used. When the system comes up from firmware mode into state 1, only the console is active and other multi-user (state 2) services are unavailable. Note that not all user processes are stopped when transitioning from multi-user state to state 1.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |         |                                                                                           |                        |                                                                                                                                                                                                                                                                                                                                                                                                                                                 |            |                                                                                                                                                                                                                                                                                                                                      |         |                                                                                                                                                             |         |                                                                                                                                                       |
| state s, S             | State s (or S) is referred to as the single-user state. All user processes are stopped on transitions to this state. In the single-user state, file systems required for multi-user logins are unmounted and the system can only be accessed through the console. Logins requiring access to multi-user file systems cannot be used.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |         |                                                                                           |                        |                                                                                                                                                                                                                                                                                                                                                                                                                                                 |            |                                                                                                                                                                                                                                                                                                                                      |         |                                                                                                                                                             |         |                                                                                                                                                       |
| state 5                | Shut the machine down so that it is safe to remove the power. Have the machine remove power, if possible. The rc0 procedure is called to perform this task.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |         |                                                                                           |                        |                                                                                                                                                                                                                                                                                                                                                                                                                                                 |            |                                                                                                                                                                                                                                                                                                                                      |         |                                                                                                                                                             |         |                                                                                                                                                       |
| state 6                | Stop the operating system and reboot to the state defined by the initdefault entry in /etc/inittab. The rc6 procedure is called to perform this task.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |         |                                                                                           |                        |                                                                                                                                                                                                                                                                                                                                                                                                                                                 |            |                                                                                                                                                                                                                                                                                                                                      |         |                                                                                                                                                             |         |                                                                                                                                                       |

## shutdown(1M)

**-i** *init-state*

If there are warnings, *init-state* specifies the state `init` is to be in. By default, system state 's' is used.

### EXAMPLES

#### EXAMPLE 1 Using shutdown

In the following example, `shutdown` is being executed on host `foo` and is scheduled in 120 seconds. The warning message is output 2 minutes, 1 minute, and 30 seconds before the final confirmation message.

```
example# shutdown -i S -g 120 "==== disk replacement ====="
Shutdown started. Tue Jun 7 14:51:40 PDT 1994

Broadcast Message from root (pts/1) on foo Tue Jun 7 14:51:41. . .
The system will be shut down in 2 minutes
==== disk replacement =====
Broadcast Message from root (pts/1) on foo Tue Jun 7 14:52:41. . .
The system will be shut down in 1 minutes
==== disk replacement =====
Broadcast Message from root (pts/1) on foo Tue Jun 7 14:53:41. . .
The system will be shut down in 30 seconds
==== disk replacement =====
Do you want to continue? (y or n):
```

### FILES

`/etc/inittab` controls process dispatching by `init`

### ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWcsu         |

### SEE ALSO

`boot(1M)`, `halt(1M)`, `init(1M)`, `killall(1M)`, `reboot(1M)`, `ufsdump(1M)`, `init.d(4)`, `inittab(4)`, `nologin(4)`, `attributes(5)`

### NOTES

When a system transitions down to the `S` or `s` state, the `/etc/nologin` file (see `nologin(4)`) is created. Upon subsequent transition to state 2 (multi-user state), this file is removed by a script in the `/etc/rc2.d` directory.

| <b>NAME</b>                       | slpd – Service Location Protocol Daemon                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |                 |                                                                                                                                                                                                                                                                                                                                                    |                      |                                                                                                                                                                                                                                             |                                   |                                                                                                                                                                                                                                                                                                                               |                    |                                                                                                                                                                                                                                              |
| <b>SYNOPSIS</b>                   | <code>/usr/lib/inet/slpd [-f <i>configuration-file</i>]</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |                 |                                                                                                                                                                                                                                                                                                                                                    |                      |                                                                                                                                                                                                                                             |                                   |                                                                                                                                                                                                                                                                                                                               |                    |                                                                                                                                                                                                                                              |
| <b>DESCRIPTION</b>                | <p>The <code>slpd</code> daemon provides common server functionality for the Service Location Protocol (“SLP”) versions 1 and 2, as defined by IETF in <i>RFC 2165</i> and <i>RFC 2608</i>. SLP provides a scalable framework for the discovery and selection of network services.</p> <p><code>slpd</code> provides the following framework services:</p> <table> <tr> <td>Directory Agent</td><td>This service automatically caches service advertisements from service agents to provide them to user agents, and makes directory agent advertisements of its services. This service is optional. <code>slpd</code> does not provide directory agent service by default. Directory agents are not databases, and they do not need to be maintained.</td></tr> <tr> <td>Service Agent Server</td><td>All service agents on the local host register and deregister with this server. This service responds to all requests for services, and forwards registrations to directory agents. By default, <code>slpd</code> is a service agent server.</td></tr> <tr> <td>Passive Directory Agent Discovery</td><td>This service listens for directory agent advertisements and maintains a table of active directory agents. When a user agent wishes to discover a directory agent, it can simply query <code>slpd</code>, obviating the need to perform discovery by means of multicast. By default, <code>slpd</code> performs this service.</td></tr> <tr> <td>Proxy Registration</td><td>This service can act as a proxy service agent for services that cannot register themselves. <code>slpd</code> reads the proxy registration file for information on services it is to proxy. By default, no services are registered by proxy.</td></tr> </table> <p>All configuration options are available from the configuration file. <code>slpd</code> reads its configuration file upon startup.</p> <p>Stop and start the <code>slpd</code> daemon by using the startup script: <code>/etc/init.d/slpd</code>. Use the command <code>/etc/init.d/slpd stop</code> to stop the <code>slpd</code> daemon. Use the command <code>/etc/init.d/slpd start</code> to start it.</p> <p>The file <code>/etc/inet/slp.conf</code> must exist before the startup script can start the daemon. Only the example file <code>/etc/inet/slp.conf.example</code> is present by default. To enable SLP, copy <code>/etc/inet/slp.conf.example</code> to <code>/etc/inet/slp.conf</code>.</p> | Directory Agent | This service automatically caches service advertisements from service agents to provide them to user agents, and makes directory agent advertisements of its services. This service is optional. <code>slpd</code> does not provide directory agent service by default. Directory agents are not databases, and they do not need to be maintained. | Service Agent Server | All service agents on the local host register and deregister with this server. This service responds to all requests for services, and forwards registrations to directory agents. By default, <code>slpd</code> is a service agent server. | Passive Directory Agent Discovery | This service listens for directory agent advertisements and maintains a table of active directory agents. When a user agent wishes to discover a directory agent, it can simply query <code>slpd</code> , obviating the need to perform discovery by means of multicast. By default, <code>slpd</code> performs this service. | Proxy Registration | This service can act as a proxy service agent for services that cannot register themselves. <code>slpd</code> reads the proxy registration file for information on services it is to proxy. By default, no services are registered by proxy. |
| Directory Agent                   | This service automatically caches service advertisements from service agents to provide them to user agents, and makes directory agent advertisements of its services. This service is optional. <code>slpd</code> does not provide directory agent service by default. Directory agents are not databases, and they do not need to be maintained.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |                 |                                                                                                                                                                                                                                                                                                                                                    |                      |                                                                                                                                                                                                                                             |                                   |                                                                                                                                                                                                                                                                                                                               |                    |                                                                                                                                                                                                                                              |
| Service Agent Server              | All service agents on the local host register and deregister with this server. This service responds to all requests for services, and forwards registrations to directory agents. By default, <code>slpd</code> is a service agent server.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |                 |                                                                                                                                                                                                                                                                                                                                                    |                      |                                                                                                                                                                                                                                             |                                   |                                                                                                                                                                                                                                                                                                                               |                    |                                                                                                                                                                                                                                              |
| Passive Directory Agent Discovery | This service listens for directory agent advertisements and maintains a table of active directory agents. When a user agent wishes to discover a directory agent, it can simply query <code>slpd</code> , obviating the need to perform discovery by means of multicast. By default, <code>slpd</code> performs this service.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |                 |                                                                                                                                                                                                                                                                                                                                                    |                      |                                                                                                                                                                                                                                             |                                   |                                                                                                                                                                                                                                                                                                                               |                    |                                                                                                                                                                                                                                              |
| Proxy Registration                | This service can act as a proxy service agent for services that cannot register themselves. <code>slpd</code> reads the proxy registration file for information on services it is to proxy. By default, no services are registered by proxy.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |                 |                                                                                                                                                                                                                                                                                                                                                    |                      |                                                                                                                                                                                                                                             |                                   |                                                                                                                                                                                                                                                                                                                               |                    |                                                                                                                                                                                                                                              |

## slpd(1M)

### OPTIONS

The following options are supported:

`-f configuration-file`                      Specify an alternate configuration file

### EXAMPLES

**EXAMPLE 1** Stopping the `slpd` daemon

The following command stops the `slpd` daemon:

```
example# /etc/init.d/slpd stop
```

**EXAMPLE 2** Restarting the `slpd` daemon

The following command restarts the `slpd` daemon:

```
example# /etc/init.d/slpd start
```

### FILES

`/etc/inet/slp.conf`                      The default configuration file

`slpd.reg`                                      The proxy registration file

### ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE      | ATTRIBUTE VALUE    |
|---------------------|--------------------|
| Availability        | SUNWslpu, SUNWslpr |
| CSI                 | Enabled            |
| Interface Stability | Evolving           |

### SEE ALSO

`slp_api(3SLP)`, `slp.conf(4)`, `slpd.reg(4)`, `attributes(5)`, `slp(7P)`

| DESCRIPTION   | <p>The smartcard utility is used for all configurations related to a smartcard. It comprises the following subcommands:</p> <ol style="list-style-type: none"> <li>Administration of OCF properties. (-c admin) <p>This subcommand is used to list and modify any of the OCF properties. With no arguments it will list all the current properties. It can only be executed by root. Some OCF properties are:</p> <table> <tr> <td>defaultcard</td><td># default card for an application</td></tr> <tr> <td>defaultreader</td><td># default reader for an application</td></tr> <tr> <td>authmechanism</td><td># authentication mechanism to</td></tr> <tr> <td>validcards</td><td># list of cards valid for an application</td></tr> </table> </li> </ol>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 | defaultcard | # default card for an application | defaultreader | # default reader for an application | authmechanism | # authentication mechanism to | validcards | # list of cards valid for an application |

## smartcard(1M)

A complete listing can be obtained by using the smartcard command as described in the EXAMPLES section.

2. Loading and Unloading of applets from the smartcard (-c load) and performing initial configuration of a non-Java card.

This subcommand administers the applets or properties on a smartcard. It can be used to load or unload applets and/or properties to and from a smartcard. The applet is a Java class file that has been run through a convertor to make the byte code JavaCard-compliant. This command can be used to load both an applet file in the standard format or a file converted to the capx format. If no -r option is specified, the loader tries to load to any connected reader, provided it has already been inserted using the smartcard -c admin command.

3. Converting card applets or properties to the capx format (-c bin2capx)

This subcommand is used to convert a Java card applet or properties into a new format called capx before downloading it onto the smartcard. Converting to this format enables the applet developer to add applet-specific information that is useful during the downloading process and identifies the applet.

In the following example,

```
smartcard -c bin2capx -i cyberflex.bin \
-T CyberFlex aidto-000102030405060708090A0B0C0D0E0F fileID=2222 \
instanceID=2223 and more.
```

if no output file is specified, a default file with the name *input\_filename.capx* is created in the current directory. The mandatory -T option requires the user to specify the card name for which the capx file is being generated.

The following example

```
smartcard -c bin2capx -T IButton
```

tells the loader eventually that the capx file contains the binary for IButton. A single capx file can hold binaries for multiple cards (1 per card.) Users can, for example, hold binary files for both CyberFlex and IButton in the same capx file as follows:

```
smartcard -c bin2capx -T IButton -i IButton.jib -o file.capx
```

In the following example,

```
smartcard -c bin2capx -T CyberFlex -i cyberflex.bin \
-l file.capx -o file.capx
```

the -l option is used to provide an already-generated capx file. The output is directed to the same capx file, resulting in capx file holding binaries for both cards.

4. Personalizing the smartcard (-c init)

This subcommand is used to set user-specific information required by an applet on a smartcard. For example, the Sun applet requires a user name to be set on the card. This subcommand is also used to personalize information for non-Java cars.

#### 5. Enabling and disabling the smartcard desktop login (-c {enable | disable})

### OPTIONS

The following options are supported:

|                                  |                                                                                                                                                                                                                                                                                   |
|----------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -a <i>application</i>            | Specify application name for the configuration parameter. Parameters may differ depending on the application. If no application name is specified, then <code>ocf</code> is the default application.                                                                              |
| -A <i>aid</i>                    | Specify a unique alphanumeric string that identifies the applet. The <i>aid</i> argument must be a minimum of 5 characters and can be a maximum of 16 characters in length. If an applet with an identical <i>aid</i> already exists on the card, a load will result in an error. |
| -c                               | Specify subcommand name. Valid options are: <code>admin</code> , <code>load</code> , <code>bin2capx</code> , <code>init</code> , <code>enable</code> and <code>disable</code> .                                                                                                   |
| -d <i>device</i>                 | Specify device on which the reader is connected (for example, <code>/dev/cua/a</code> ).                                                                                                                                                                                          |
| -D                               | Disable a system from using smartcards.                                                                                                                                                                                                                                           |
| -E                               | Export the keys to a file.                                                                                                                                                                                                                                                        |
| -i <i>filename</i>               | Specify input file name.                                                                                                                                                                                                                                                          |
| -I                               | Import from a file.                                                                                                                                                                                                                                                               |
| -j <i>classname</i>              | Specify fully-qualified class name.                                                                                                                                                                                                                                               |
| -k <i>keytype</i>                | Specify type of key (for example, <code>challenge_response</code> , <code>pki</code> .)                                                                                                                                                                                           |
| -l                               | Specify debug level (0–9), signifying level of debug information displayed.                                                                                                                                                                                                       |
| -L                               | List all properties configurable in an applet.                                                                                                                                                                                                                                    |
| -n <i>readername</i>             | Specify reader name as required by the driver.                                                                                                                                                                                                                                    |
| -o <i>filename</i>               | Specify output file name.                                                                                                                                                                                                                                                         |
| -p <i>propfile</i>               | Specify properties file name. This file could contain a list of property names and value pairs, in the format <i>propertyname=value</i> .                                                                                                                                         |
| -P <i>pin</i>                    | Specify pin used to validate to the card.                                                                                                                                                                                                                                         |
| -r <i>userfriendlyreadername</i> | Specify user-defined reader name where the card to be initialized is inserted.                                                                                                                                                                                                    |

## smartcard(1M)

|                    |                                                                                                                                                                                                                                                                                                                                                                    |         |                                           |          |                                          |       |                  |          |                                              |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------|-------------------------------------------|----------|------------------------------------------|-------|------------------|----------|----------------------------------------------|
| -R                 | Restart the ocf server.                                                                                                                                                                                                                                                                                                                                            |         |                                           |          |                                          |       |                  |          |                                              |
| -s <i>slot</i>     | Specify slot number. If a reader has multiple slots, this option specifies which slot to use for initialization. If a reader has only one slot, this option is not required. If no slot number is specified, by default the first slot of the reader is used.                                                                                                      |         |                                           |          |                                          |       |                  |          |                                              |
| -t                 | Specify type of property being updated. The valid values are: <table><tr><td>service</td><td>Updating a card service provider details.</td></tr><tr><td>terminal</td><td>Updating a card reader provider details.</td></tr><tr><td>debug</td><td>OCF trace level.</td></tr><tr><td>override</td><td>Override a system property of the same name.</td></tr></table> | service | Updating a card service provider details. | terminal | Updating a card reader provider details. | debug | OCF trace level. | override | Override a system property of the same name. |
| service            | Updating a card service provider details.                                                                                                                                                                                                                                                                                                                          |         |                                           |          |                                          |       |                  |          |                                              |
| terminal           | Updating a card reader provider details.                                                                                                                                                                                                                                                                                                                           |         |                                           |          |                                          |       |                  |          |                                              |
| debug              | OCF trace level.                                                                                                                                                                                                                                                                                                                                                   |         |                                           |          |                                          |       |                  |          |                                              |
| override           | Override a system property of the same name.                                                                                                                                                                                                                                                                                                                       |         |                                           |          |                                          |       |                  |          |                                              |
| -T <i>cardname</i> | Specify card name.                                                                                                                                                                                                                                                                                                                                                 |         |                                           |          |                                          |       |                  |          |                                              |
| -u                 | Unload the applet specified by the application ID from the card. If no application ID is specified, all applets are unloaded from the card.                                                                                                                                                                                                                        |         |                                           |          |                                          |       |                  |          |                                              |
| -v                 | Verbose mode ( displays helpful messages).                                                                                                                                                                                                                                                                                                                         |         |                                           |          |                                          |       |                  |          |                                              |
| -x                 | Specify action to be taken. Valid values are: add, delete, or modify.                                                                                                                                                                                                                                                                                              |         |                                           |          |                                          |       |                  |          |                                              |

### EXAMPLES

#### EXAMPLE 1 Viewing the Values of All Properties

Enter the following command to view the values of all the properties that are set:

```
% smartcard -c admin
```

#### EXAMPLE 2 Viewing the Values of Specific Properties

Enter the following command to view the values of specific properties:

```
% smartcard -c admin language country
```

#### EXAMPLE 3 Adding a Card Service

Enter the following command to add a card service factory for a CyberFlex card, available in the package `com.sun.services.cyberflex`, to the properties:

```
% smartcard -c admin -t service \
-j com.sun.services.cyberflex.CyberFlexCardServiceFactory -x add
```

**EXAMPLE 4** Adding a Reader

Enter the following command to add a SCM reader, available in the package `com.sun.services.scm`, to the properties on device `/dev/cua/a` and assign it a name of SCM:

```
% smartcard -c admin -t terminal \
-j com.sun.opencard.terminal.scm.SCMTc.SCMTcCardTerminalFactory \
-x add -d /dev/cua/a -r SCM -n SunSCRI
```

**EXAMPLE 5** Deleting a Reader

Enter the following command to delete the SCM reader, added in the previous example, from the properties:

```
% smartcard -c admin -t terminal -r SCM -x delete
```

**EXAMPLE 6** Changing the Debug Level

Enter the following command to change the debug level for all of the `com.sun` package to 9:

```
% smartcard -c admin -t debug -j com.sun -l 9 -x modify
```

**EXAMPLE 7** Setting the Default Card for an Application

Enter one of the following commands to set the default card for an application (`dtlogin`) to be `CyberFlex`.

If the property default card does not exist, enter the following command:

```
% smartcard -c admin -a dtlogin -x add defaultcard=CyberFlex
```

If the property default card exists, enter the following command:

```
% smartcard -c admin -a dtlogin -x modify defaultcard=CyberFlex
```

**EXAMPLE 8** Exporting Keys for a User into a File

Enter the following command to export the challenge-response keys for a user into a file:

```
% smartcard -c admin -k challenge_response -E -o /tmp/mykeys
```

**EXAMPLE 9** Importing Keys from a File

Enter the following command to import the challenge-response keys for a user from a file:

```
% smartcard -c admin -k challenge_response -I -i /tmp/mykeys
```

## smartcard(1M)

### **EXAMPLE 10** Downloading an Applet into a Java Card

Enter the following command to download an applet into a Java card or to configure a PayFlex (non-Java) card inserted into a SCM reader for the capx file supplied in the /usr/share/lib/smartcard directory:

```
% smartcard -c load -r SCM \
-i /usr/share/lib/smartcard/SolarisAuthApplet.capx
```

### **EXAMPLE 11** Downloading an Applet Binary

Enter the following command to download an applet binary from some place other than the capx file supplied with Solaris8 into an IButton (the AID and input file are mandatory, the remaining parameters are optional):

```
% smartcard -c load -A A000000062030400 -i newapplet.jib
```

### **EXAMPLE 12** Downloading an Applet on a CyberFlex Access Card

On a CyberFlex Access Card, enter the following command to download an applet newapplet.bin at fileID 2222, instanceID 3333 using the specified verifyKey and a heap size of 2000 bytes:

```
% smartcard -c load -A newAID -i newapplet.bin \
fileID=2222 instanceID=3333 verifyKey=newKey \
MAC=newMAC heapsize=2000
```

### **EXAMPLE 13** Configuring a PayFlex Card

Enter the following command to configure a PayFlex (non-Java) card with specific AID, transport key, and initial pin:

```
% smartcard -c load aid-A00000006203400 \
pin=242424246A617661 transportKey=4746584932567840
```

### **EXAMPLE 14** Unloading an Applet from a Card

Enter the following command to unload an applet from iButton:

```
% smartcard -c load -u
```

### **EXAMPLE 15** Displaying Usage of smartcard -c load

Enter the following command to display the usage of the smartcard -c load command:

```
% smartcard -c load
```

**EXAMPLE 16** Displaying All Configurable Parameters for an Applet

Enter the following command to display all the configurable parameters for an applet with aid 123456 residing on a card inserted into an SM reader:

```
% smartcard -c init -r SM -A 123456 -L
```

**EXAMPLE 17** Changing the Pin

Enter the following command to change the pin for the SolarisAuthApplet residing on a card or to change the pin for a PayFlex (non-Java) card inserted into an SM reader:

```
% smartcard -c init -A A000000062030400 -P oldpin pin=newpin
```

**EXAMPLE 18** Displaying All Configurable Parameters for the SolarisAuthApplet.

Enter the following command to display all the configurable parameters for the SolarisAuthApplet residing on a card inserted into an SM reader:

```
% smartcard -c init -A A000000062030400 -L
```

**EXAMPLE 19** Setting a Property to a Value on a Smartcard

Enter the following command to set properties called "user" to the value "james" and "application" to the value "login" on a card inserted into an SM reader that has a pin "testpin":

```
% smartcard -c init -A A000000062030400 -r CyberFlex -P testpin \
application=login user=james
```

**EXAMPLE 20** Converting an Applet for the CyberFlex Card into capx Format.

Enter the following command to convert an applet for the CyberFlex card into the capx format required for downloading the applet into the card:

```
% smartcard -c bin2capx \
-i /usr/share/lib/smartcard/SolarisAuthApplet.bin \
-T CyberFlex -o /home/CorporateCard.capx -v memory=128 heapsize=12
```

**EXAMPLE 21** Converting an Applet for the IButton Card into capx Format

Enter the following command to convert an applet for the IButton card into the capx format required for downloading the applet into the button:

```
% smartcard -c bin2capx -i /usr/share/lib/smartcard/SolarisAuthApplet.jib \
-T IButton -o /home/CorporateCard.capx -v
```

**EXIT STATUS**

The following exit values are returned:

0           Successful completion.

smartcard(1M)

1           An error occurred.

**ATTRIBUTES**    See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWocf         |

**SEE ALSO**      `ocfserv(1M)`, `attributes(5)`, `smartcard(5)`

**NOTES**         The command line options contain only alphanumeric input.

|             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

| NAME        | smattrpop – populate security attribute databases in a name service                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| SYNOPSIS    | <b>smattrpop</b> [-c ] [-f] [-m] [-p <i>policy</i> ] [-r] -s <i>scope</i> -t <i>scope</i> [-v] <i>database</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| DESCRIPTION | <p>The <b>smattrpop</b> command updates the <code>auth_attr(4)</code>, <code>exec_attr(4)</code>, <code>prof_attr(4)</code>, and <code>user_attr(4)</code> role-based access control databases in a target NIS, NIS+, LDAP, or local <code>/etc</code> files name service from the corresponding databases in a source name service or files.</p> <p>This command processes the table entries from the source database and merges each source entry field into the same field in the corresponding table entry in the target database. If a source entry does not exist in the target database, the entry is created. If the source entry exists in the target database, the fields are merged or replaced according to the command options.</p> <p>Any errors encountered while updating the target entry are reported to <code>stdout</code>, and the command continues with the next source database entry.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| OPTIONS     | <p>The following options are supported:</p> <p>-c                      Performs cross-table checking. If you specify this option and a check error occurs, a message identifying the check error is written to <code>stdout</code>.</p> <p>                        The target entry values are checked against entries in related databases:</p> <ul style="list-style-type: none"> <li>■ <code>auths</code> values — Each value must exist as the name of an authorization in the <code>auth_attr(4)</code> database.</li> <li>■ <code>profiles</code> values — Each value must exist as a name of a profile in the <code>prof_attr(4)</code> database.</li> <li>■ <code>roles</code> values — Each value must exist as the name of a role identity in the <code>user_attr(4)</code> database.</li> <li>■ For each <code>exec_attr(4)</code> entry in the source database, the name must exist as the name of a profile in the <code>prof_attr(4)</code> database.</li> </ul> <p>-f                      Specifies that the value in each field in the source entry replaces the value in the corresponding field in the target entry, if the source entry field has a non-empty value.</p> <p>-m                      For the <code>auths</code>, <code>profiles</code>, and <code>roles</code> attributes, specifies that the values in each field in the source entry are merged with the values in the corresponding target entry field. If a source value does not exist in the target field, the value is appended to the set of target values. If the target field is empty, the source values replace the target field. The attribute values that merge depend on the database being updated:</p> <ul style="list-style-type: none"> <li>■ <code>prof_attr(4)</code> — the <code>auths</code> and <code>profiles</code> attribute values are merged.</li> </ul> |

## smattrpop(1M)

|                        |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

| <code>-p policy</code> | Specifies the value of the <code>policy</code> field in the <code>exec_attr(4)</code> database. Valid values are <code>suser</code> (standard Solaris superuser) and <code>tsol</code> (Trusted Solaris). If you specify this option, only the entries in the source <code>exec_attr</code> database with the specified policy are processed. If you omit this option, all entries in the source <code>exec_attr</code> database are processed.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <code>-r</code>        | Specifies that role identities in the <code>user_attr(4)</code> database in the source name service are processed. If you omit this option, only the normal user entries in the <code>user_attr</code> source database are processed.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <code>-s scope</code>  | <p>Specifies the source name service or local file directory for database updates, using the following syntax:</p> <p><i>type</i> : <i>/server/domain</i></p> <p>where <i>type</i> indicates the type of name service. | <code>-t scope</code>  | <p>Specifies the target name service or local file directory for database updates, using the following syntax:</p> <p><i>type</i> : <i>/server/domain</i></p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

where *type* indicates the type of name service. Valid values for *type* are:

- *file* — local files
- *nis* — NIS name service
- *nisplus* — NIS+ name service
- *ldap* — LDAP name service

*server* indicates the local host name of the Solaris system on which the `smattrpop` command is executed, and on which both the source and target databases exist.

*domain* specifies the management domain name for the name service.

You can use two special cases of *scope* values:

- To indicate the databases in the `/etc/security` local system directory, use the scope `file:/server`, where *server* is the name of the local system.
- To update to databases in an arbitrary directory on the Solaris server, use the scope `file:/server/pathname`, where *server* is the name of the local system and *pathname* is the fully-qualified directory path name to the database files.

-v

Specifies that verbose messages are written. A message is written to `stdout` for each entry processed.

**OPERANDS** The following operands are supported:

*database*

Populates one or all databases. You can specify either the name of the database you want to process (for example, `auth_attr`), or `all` to process all databases. If you specify `all`, the databases are processed in the following order:

1. `auth_attr(4)`
2. `prof_attr(4)`
3. `exec_attr(4)`
4. `user_attr(4)`

**EXAMPLES** **EXAMPLE 1** Populating all tables in the NIS name service

The following example merges the values from all four attribute databases in the `/etc/security` directory of the local system into the corresponding tables in the NIS domain, `east.sun.com`. The command is executed on the master server, `hoosier`, for the NIS domain and the source files are in the `/etc` and `/etc/security` directories on the NIS master server. No cross-table checking is performed. A summary message indicating the number of entries processed and updated for each table is written to `stdout`.

## smattrpop(1M)

**EXAMPLE 1** Populating all tables in the NIS name service (Continued)

```
/usr/sadm/bin/smattrpop -s file:/hoosier \
-t nis:/hoosier/east.sun.com all
```

**EXAMPLE 2** Updating the authorization table in the NIS+ name service

This example merges new authorization data from a local system file in the `auth_attr` text format into the existing `auth_attr` database in the NIS+ domain, `east.sun.com`. The command is executed on the NIS+ master server, `foobar`. Values from the source `auth_attr` file replace the corresponding field values in the NIS+ tables for each entry. A message is written to `stdout` for each entry processed. Database cross-checking is performed and any check error is written to `stdout`. A summary message indicating the number of entries processed and updated for the `auth_attr` database is written to `stdout`.

```
/usr/sadm/bin/smattrpop -c -f -v -s file:/foobar/var/temp \
-t nisplus:/foobar/East.Sun.COM auth_attr
```

### ENVIRONMENT VARIABLES

See `environ(5)` for a description of the `JAVA_HOME` environment variable, which affects the execution of the `smattrpop` command. If this environment variable is not specified, the `/usr/java` location is used. See `smc(1M)`.

### EXIT STATUS

Any errors encountered while updating the target entry are reported to `stdout`. The following exit values are returned:

- 0 The specified tables were updated. Individual entries may have encountered checking errors.
- 1 A syntax error occurred in the command line.
- 2 A fatal error occurred and the tables were not completely processed. Some entries may have been updated before the failure.

| <b>DESCRIPTION</b> | <p>The <b>smc</b> command starts the Solaris Management Console. The Solaris Management Console is a graphical user interface that provides access to Solaris system administration tools. It relies on Solaris Management Console servers running on one or more computers to perform modifications and report data. Each of these servers is a repository for code which the console can retrieve after the user of the console has authenticated himself or herself to the server.</p> <p>The console can also retrieve toolboxes from the server. These toolboxes are descriptions of organized collections of tools available on that and possibly other servers. Once one of these toolboxes is loaded, the console will display it and the tools referenced in it.</p> <p>The console can also run in a terminal (non-graphically), for use over remote connections or non-interactively from a script.</p> <p>For information on the use of the graphical console, and for more detailed explanations of authentication, tools, and toolboxes, please refer to the Solaris Management Console online help available under the "Help" menu in the Solaris Management Console. To enable an NIS/NIS+ map to be managed from the Solaris Management Console, you must use the <b>smc edit</b> command to create a new toolbox for that map and enter the information about your NIS/NIS+ server where necessary. For instructions on creating a new toolbox, in the Solaris Management Console Help menu, select "Contents," then "About the Solaris Management Console Editor," then "To Create a Toolbox."</p> |
| <i>subcommands</i> | <p><b>smc subcommands</b> are:</p> <p><b>open</b>      The default subcommand for the Solaris Management Console is <b>open</b>. This will launch the console and allow you to run tools from the toolboxes you load. It does not need to be specified explicitly on the command line.</p> <p><b>edit</b>      The <b>edit</b> subcommand will also launch the console, like the <b>open</b> subcommand. However, after loading a toolbox, you will not be able to run the referenced tools. Instead, you will be able to edit that toolbox, that is, add, remove, or modify any tools or folders in that toolbox.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>OPTIONS</b>     | <p>The following options are supported. These letter options can also be specified by their equivalent option words preceded by a double dash. For example, you can use either -D or - -domain with the <i>domain</i> argument.</p> <p>If <i>tool_args</i> are specified, they must be preceded by the - - option and separated from the double dashes by a space.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

- **-auth-data** *file*

Specifies a file which the console can read to collect authentication data. When running the Solaris Management Console non-interactively, the console will still need to authenticate itself with the server to retrieve tools. This data can either be passed on the command line using the **-u**, **-p**, **-r**, and **-l** options (which is insecure, because any user can see this data), or it can be placed in a file for the console to read. For security reasons, this file should be readable only by the user running the console, although the console does not enforce this restriction.

The format of *file* is:

```
hostname=host name
username=user name
password=password for user name
rolename=role name
rolepassword=password for role name
```

Only one set of **hostname-username-password-rolename-rolepassword** may be specified in any one file. If the **rolename** is not specified, no role will be assumed.

-B | - **-toolbox** *toolbox*

Loads the specified toolbox. *toolbox* can be either a fully-qualified URL or a filename. If you specify an HTTP URL as, for example,

```
http://host_name:port/. . .
```

it must point to a *host\_name* and *port* on which an Solaris Management Console server is running. If you omit *port*, the default port, 898, is used. This option overrides the **-H** option.

-D | - **-domain** *domain*

Specifies the default domain that you want to manage. The syntax of *domain* is *type:/host\_name/domain\_name*, where *type* is **nis**, **nisplus**, **dns**, **ldap**, or **file**; *host\_name* is the name of the machine that serves the domain; and *domain\_name* is the name of the domain you want to manage. (Note: Do not use **nis+** for **nisplus**.) This option applies only to a single tool run in the terminal console.

If you do not specify this option, the Solaris Management Console assumes the **file** default domain on whatever server you choose to manage, meaning that changes are local to the server. Toolboxes can change the domain on a tool-by-tool basis; this option specifies the domain for all other tools.

-h | - **-help**

Prints a usage statement about the **smc** command and its subcommands to the terminal window. To print a usage statement for one of the subcommands, enter **-h** after the subcommand.

-H | - **-hostname** *host\_name:port*

Specifies the *host\_name* and *port* to which you want to connect. If you do not specify a *port*, the system connects to the default port, 898. If you do not specify *host\_name:port*, the Solaris Management Console connects to the local host on port

898. You may still have to choose a toolbox to load into the console. To override this behavior, use the `-B` option (see above), or set your console preferences to load a “home toolbox” by default.

`-Jjava_option`

Specifies an option that can be passed directly to the Java runtime (see `java(1)`). Do not enter a space between `-J` and the argument. This option is most useful for developers.

`-l | - --rolepassword role_password`

Specifies the password for the *role\_name*. If you specify a *role\_name* but do not specify a *role\_password*, the system prompts you to supply a *role\_password*. Passwords specified on the command line can be seen by any user on the system, hence this option is considered insecure.

`-p | - --password password`

Specifies the password for the *user\_name*. If you do not specify a password, the system prompts you for one. Passwords specified on the command line can be seen by any user on the system, hence this option is considered insecure.

`-r | - --rolename role_name`

Specifies a role name for authentication. If you are running the Solaris Management Console in a terminal and you do not specify this option, no role is assumed. The GUI console may prompt you for a role name, although you may not need to assume a role.

`-s | - --silent`

Disables informational messages printed to the terminal.

`-t`

Runs the Solaris Management Console in terminal mode. If this option is not given, the Solaris Management Console will automatically run in terminal mode if it cannot find a graphical display.

`- --trust`

Trusts all downloaded code implicitly. Use this option when running the terminal console non-interactively and you cannot let the console wait for user input.

`-T | - --tool tool_name`

Runs the tool with the Java class name that corresponds to *tool\_name*. If you do not specify this option and the Solaris Management Console is running in terminal mode, the system prompts you. If the Solaris Management Console is running in graphical mode, the system either loads a toolbox or prompts you for one (see options `-H` and `-B`).

`-u | - --username user_name`

Specifies the user name for authentication. If you do not specify this option, the user identity running the console process is assumed.

`-v | - --version`

Prints the version of the Solaris Management Console to the terminal. In the graphical console, this information can be found in the About box, available from the Help menu.

`-y | -yes`

Answers yes to all yes/no questions. Use this option when running the terminal console non-interactively and you cannot let the console wait for user input.

## EXAMPLES

### EXAMPLE 1 Printing a Usage Statement

The following prints a usage statement about the `smc` command to the terminal window:

```
smc --help
```

### EXAMPLE 2 Passing an Option to Java

The following passes an option through to the Java VM, which sets the `com.example.boolean` system property to `true`. This system property is only an example; the Solaris Management Console does not use it.

```
smc -J-Dcom.example.boolean=true
```

## ENVIRONMENT VARIABLES

See `environ(5)` for a description of the following environment variable that affects the execution of the `smc` command:

**JAVA\_HOME**      If you do not specify this environment variable, your `PATH` is searched for a suitable java. Otherwise, the `/usr/j2se` location is used.

## EXIT STATUS

The following exit values are returned. Other error codes may be returned if you specify a tool (using `-T tool_name`) that has its own error codes. See the documentation for the appropriate tool.

0            Successful completion.

1            An error occurred.

## ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWmcc         |

## SEE ALSO

| NAME                    | smccompile – build class list and compile Solaris Management Console service beans for remote use                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |     |                                                                                                                        |            |                                                                                                              |         |                                                                                                           |                         |                                                                                                                                                                                                                                                                                                                                                                                                 |                 |                                                                                                                                    |    |                                                                                                                                                                                                                                                                                   |

| DESCRIPTION             | <p>The <code>smccompile</code> command is used by developers of tools, services, and libraries for the Solaris Management Console. For information regarding the Solaris Management Console, see <code>smc(1M)</code>.</p> <p><code>smccompile</code> compiles service class files given by the bean name for use with the Solaris Management Console. This step builds the extra proxy and stub classes for services to be used with Solaris Management Console tools. Solaris Management Console requires running <code>smccompile -c</code> before creating service jar files, and <code>smccompile -j</code> after creating tool, service, and library jars.</p> <p><code>smccompile</code>, in conjunction with <code>smcregister(1M)</code>, is intended to replace the <code>smccconf</code> command as the preferred interface for managing the Solaris Management Console repository as well as toolboxes from within scripts, due to significant performance enhancements over <code>smccconf</code>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                  |     |                                                                                                                        |            |                                                                                                              |         |                                                                                                           |                         |                                                                                                                                                                                                                                                                                                                                                                                                 |                 |                                                                                                                                    |    |                                                                                                                                                                                                                                                                                   |
| OPTIONS                 | <p>The following options are supported:</p> <table> <tr> <td>ALL</td><td>Specify that the library being registered to or unregistered from the repository is for use by all tools and services.</td></tr> <tr> <td>ALLSERVICE</td><td>Specify that the library being registered to or unregistered from the repository is for use by all services.</td></tr> <tr> <td>ALLTOOL</td><td>Specify that the library being registered to or unregistered from the repository is for use by all tools.</td></tr> <tr> <td><i>attachedBeanname</i></td><td>Specify the name of a registered jar to which the library jarfile should be attached to (or detached from). This is typically the same as <i>altjarname</i> (if provided) or <i>jarfile</i> used to register the jar to which this library is being attached or detached. An attached library means the library is only available for use by the tool or service to which it is being attached.</td></tr> <tr> <td><i>beanname</i></td><td>The full package path of the bean name to be compiled. An example bean name is:<br/><code>com.mycompany.myproduct.MyService.</code></td></tr> <tr> <td>-c</td><td>Compile and build service class files for the specified bean name. This step builds the extra proxy and stub classes for services to be used with Solaris Management Console tools. You must run <code>smccompile</code> with this option before creating service type jar files.</td></tr> </table> | ALL | Specify that the library being registered to or unregistered from the repository is for use by all tools and services. | ALLSERVICE | Specify that the library being registered to or unregistered from the repository is for use by all services. | ALLTOOL | Specify that the library being registered to or unregistered from the repository is for use by all tools. | <i>attachedBeanname</i> | Specify the name of a registered jar to which the library jarfile should be attached to (or detached from). This is typically the same as <i>altjarname</i> (if provided) or <i>jarfile</i> used to register the jar to which this library is being attached or detached. An attached library means the library is only available for use by the tool or service to which it is being attached. | <i>beanname</i> | The full package path of the bean name to be compiled. An example bean name is:<br><code>com.mycompany.myproduct.MyService.</code> | -c | Compile and build service class files for the specified bean name. This step builds the extra proxy and stub classes for services to be used with Solaris Management Console tools. You must run <code>smccompile</code> with this option before creating service type jar files. |
| ALL                     | Specify that the library being registered to or unregistered from the repository is for use by all tools and services.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |     |                                                                                                                        |            |                                                                                                              |         |                                                                                                           |                         |                                                                                                                                                                                                                                                                                                                                                                                                 |                 |                                                                                                                                    |    |                                                                                                                                                                                                                                                                                   |

| <i>attachedBeanname</i> | Specify the name of a registered jar to which the library jarfile should be attached to (or detached from). This is typically the same as <i>altjarname</i> (if provided) or <i>jarfile</i> used to register the jar to which this library is being attached or detached. An attached library means the library is only available for use by the tool or service to which it is being attached.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |     |                                                                                                                        |            |                                                                                                              |         |                                                                                                           |                         |                                                                                                                                                                                                                                                                                                                                                                                                 |                 |                                                                                                                                    |    |                                                                                                                                                                                                                                                                                   |
| <i>beanname</i>         | The full package path of the bean name to be compiled. An example bean name is:<br><code>com.mycompany.myproduct.MyService.</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |     |                                                                                                                        |            |                                                                                                              |         |                                                                                                           |                         |                                                                                                                                                                                                                                                                                                                                                                                                 |                 |                                                                                                                                    |    |                                                                                                                                                                                                                                                                                   |
| -c                      | Compile and build service class files for the specified bean name. This step builds the extra proxy and stub classes for services to be used with Solaris Management Console tools. You must run <code>smccompile</code> with this option before creating service type jar files.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |     |                                                                                                                        |            |                                                                                                              |         |                                                                                                           |                         |                                                                                                                                                                                                                                                                                                                                                                                                 |                 |                                                                                                                                    |    |                                                                                                                                                                                                                                                                                   |

|                            |                                                                                                                                                                                                                                                                                                                                                                                                                           |
|----------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>-j</code>            | Build a list of classes in text format, suitable as input to <code>smcregister</code> for registration with the Solaris Management Console repository. The output is written to standard out and should be redirected to a file. You must run <code>smccompile</code> with this option after creating any tool, service, or library jar.                                                                                  |
| <code>jarfile</code>       | Specify the full path to the jar file to be registered. The name must be in the form <i>beanname.jar</i> , where <i>beanname</i> is the package path to the bean. If it is not, an alternate name must be given in that form using the <code>-n</code> option.                                                                                                                                                            |
| <code>-n altjarname</code> | Rename the jarfile in the repository to <i>altjarname</i> . Typically, this is the full bean name. For example, if the jarfile was <code>MyTool.jar</code> , then <i>altjarname</i> might be <code>com.mycompany.myproduct.MyTool.jar</code> . It is recommended that an <i>altjarname</i> containing the full package path be used. You must use this same name when registering the jar with <code>smcregister</code> . |

**EXAMPLES****EXAMPLE 1** Compiling a Service

The following command takes a Solaris Management Console service and builds its proxy and stub classes to make the service usable by Solaris Management Console tools:

```
/usr/sadm/bin/smccompile -c com.mycompany.myproject.MyServiceImpl
```

**EXAMPLE 2** Building a Class List for a Service

The following command builds the class list file (`classlist.txt`) for a service suitable for use with the `smcregister(1M)` command:

```
/usr/sadm/bin/smccompile -j service \
-n com.mycompany.myproject.MyServiceImpl.jar \
${HOME}/workarea/MyServiceImpl.jar > classlist.txt
```

The following command does the same thing without specifying an alternate name:

```
/usr/sadm/bin/smccompile -j service \
${HOME}/workarea/com.mycompany.myproject.MyServiceImpl.jar > classlist.txt
```

**EXAMPLE 3** Building a Class List for a Tool

The following command builds the class list file (`classlist.txt`) for a tool suitable for use with the `smcregister(1M)` command:

```
/usr/sadm/bin/smccompile -j tool \
-n com.mycompany.myproject.MyTool.jar \
${HOME}/workarea/MyTool.jar > classlist.txt
```

The following command does the same thing without specifying an alternate name:

## smccompile(1M)

### EXAMPLE 3 Building a Class List for a Tool (Continued)

```
/usr/sadm/bin/smccompile -j tool \
${HOME}/workarea/com.mycompany.myproject.MyTool.jar > classlist.txt
```

### EXAMPLE 4 Building a Class List for a Library Attached to All Tools

The following command builds the class list file (`classlist.txt`) for a library suitable for use with the `smcregister(1M)` command, and is attached to all tools:

```
/usr/sadm/bin/smccompile -j library \
-n com.mycompany.myproject.MyLibrary.jar \
ALLTOOL ${HOME}/workarea/MyLibrary.jar > classlist.txt
```

The following command does the same thing without specifying an alternate name:

```
/usr/sadm/bin/smccompile -j library \
ALLTOOL \
${HOME}/workarea/com.mycompany.myproject.MyLibrary.jar > classlist.txt
```

### EXAMPLE 5 Building a Class List for a Library Attached to a Specific Tool

The following command builds the class list file (`classlist.txt`) for a library suitable for use with the `smcregister(1M)` command, and is attached to a specific tool:

```
/usr/sadm/bin/smccompile -j library \
-n com.mycompany.myproject.MyLibrary.jar \
com.mycompany.myproject.MyTool.jar \
${HOME}/workarea/MyLibrary.jar > classlist.txt
```

The following command does the same thing without specifying an alternate name:

```
/usr/sadm/bin/smccompile -j library \
com.mycompany.myproject.MyTool.jar \
${HOME}/workarea/com.mycompany.myproject.MyLibrary.jar > classlist.txt
```

## ENVIRONMENT VARIABLES

See `environ(5)` for descriptions of the following environment variables that affect the execution of `smccompile`:

**JAVA\_HOME**      If you do not specify this environment variable, your `PATH` is searched for a suitable `java`. Otherwise, the `/usr/j2se` location is used.

## EXIT STATUS

The following exit values are returned:

|   |                        |
|---|------------------------|
| 0 | Successful completion. |
| 1 | An error occurred.     |

## ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

smccompile(1M)

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWMc          |

**SEE ALSO** smc(1M), smconf(1M), smcregister(1M), attributes(5), environ(5)

**NOTES** All standard shell quoting rules apply.

## smcconf(1M)

|                          |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

| NAME                     | smcconf – configure the Solaris Management Console                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| SYNOPSIS                 | <pre>/usr/sadm/bin/smcconf [-h] [-v] toolbox [action] [target] [parameters]                         [options]  /usr/sadm/bin/smcconf [-h] [-v] repository [action] [target]                         [parameters] [options]</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| DESCRIPTION              | <p>The <code>smcconf</code> command configures the Solaris Management Console. See <code>smc(1M)</code>. This command enables you to add to, remove from, and list the contents of the toolboxes and bean repository.</p> <p>Using <code>smcconf</code> to edit toolboxes is not as feature-rich as using the graphical editor in Solaris Management Console. The command line interface is intended for use in packaging scripts that do not require user interaction. To edit all the properties of a toolbox or to modify the hierarchy of folders in a toolbox, you must use the specialized graphical editor, that is, <code>smc edit</code>. See <code>smc(1M)</code>.</p> <p><code>smcregister</code> is intended to replace the <code>smcconf</code> command as the preferred interface for managing the Solaris Management Console repository as well as toolboxes from within scripts, due to significant performance enhancements over <code>smcconf</code>. See <code>smcregister(1M)</code>, <code>smccompile(1M)</code>, and the Solaris Management Console SDK Guide at <code>/usr/sadm/lib/smc/docs/sdkguide/index.html</code> for details.</p> |
| OPTIONS                  | <p>The following options are supported:</p> <ul style="list-style-type: none"> <li>-h            Prints out a usage summary for the command.</li> <li>-v            Verbose option. Displays the debugging output at any time.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| toolbox<br>configuration | <p><i>action</i>            Legal values are:</p> <ul style="list-style-type: none"> <li>add           <p>Adds a <i>target</i> to the toolbox. Specify the path to the toolbox using the <code>-B toolboxpath</code> option and, optionally, provide locale information with the <code>-L locale</code> option.</p> </li> <li>remove           <p>Removes a <i>target</i> from the toolbox. Specify the path to the toolbox using the <code>-B toolboxpath</code> option and, as an alternative, provide locale information with the <code>-L locale</code> option.</p> </li> <li>create           <p>Creates a new toolbox with no tools in it. The only <i>target</i> recognized is <code>toolbox</code>.</p> </li> <li>list           <p>Lists the contents of the toolbox. No <i>target</i> is recognized. If you specify a <i>parameter</i>, it is taken as the path to a toolbox and the contents of that toolbox are listed. If you do not specify a <i>parameter</i>, the contents of the default toolbox are listed.</p> </li> </ul>                                                                                                                   |

*target*

Legal values are:

*tool*

If the *action* is specified as `add`, this target adds a native Solaris Management Console tool from the toolbox. The required *parameter* is the full Java classname of the tool you are adding. If you specify a folder name with the `-F` option, the tool is placed inside that folder (the folder will not be created if it does not already exist). Otherwise, the tool is appended to the end of the toolbox and not placed inside any folder.

If the *action* is specified as `remove`, this target removes a native Solaris Management Console tool from the toolbox. The required *parameter* is the full Java classname of the tool you want to remove. If you specify a folder name with the `-F` option, any tool with the given name in that folder will be removed. If no folder name is specified, all tools with the given name in the toolbox are removed.

For the tool to appear in the console, the tool must also be registered in the repository. See the *repository configuration* section below for more information. If a tool is referenced in a toolbox but is not registered, it will not appear in the console when the toolbox is loaded.

Removing a tool from a toolbox does not remove the tool from the server repository.

*tbxURL*

If the *action* is specified as `add` or `remove`, this target adds to or removes from the toolbox a link to another toolbox. The required *parameter* is the URL to the other toolbox.

The properties of addition and removal are the same as for the *tool target*.

*toolbox*

If the *action* is specified as `create`, this target creates a skeleton toolbox with no tools. The required *parameters* are: the toolbox name, description, and small and large icon paths. These must be followed by the `-B toolboxpath` and `-D scope` options.

*legacy*

If the *action* is specified as `add` or `remove`, this target adds or removes legacy applications (command-line, X-windows, and web-based) to or from the toolbox. The `-N`, `-T`, `-E`, and `-B` options are required. The `-A` option is optional. Placement in the toolbox with the `-F` option follows the same rules as for the *tool* and *tbxURL* targets. See *NOTES* for more information about legacy applications.

|                   |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|-------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                   | <p><i>folder</i></p> <p>If the <i>action</i> is specified as <i>add</i>, this target adds a folder to the toolbox. The required <i>parameters</i> are: the folder name, description, and small and large icon paths.</p> <p>If the <i>action</i> is specified as <i>remove</i>, this target removes a folder from the toolbox. If the folder to be removed is itself inside a folder, the containing folder must be specified with the <i>-F</i> option.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <i>parameters</i> | Specifies values that might be required, depending on the combination of <i>action</i> and <i>target</i> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <i>options</i>    | <p>Supported options for various <i>action</i> and <i>target</i> combinations for the toolbox configuration are:</p> <ul style="list-style-type: none"> <li>-A <i>parameters</i><br/>Specifies the parameters to pass to the legacy application. This option is available only for the <i>legacy</i> target.</li> <li>-B <i>toolboxpath</i><br/>Specifies the path of the toolbox that is being modified. If this option is not given, the modifications will be performed on the default toolbox, "This Computer".</li> <li>-D <i>scope</i><br/>Specifies the scope (domain) in which the tool should be run. The legal values for <i>scope</i> are <i>file</i>, <i>nis</i>, <i>nisplus</i>, <i>dns</i>, and <i>ldap</i>. This can also be specified for a folder or a toolbox.</li> </ul> <p>In the former case, all tools in that folder and its subfolders are run in that scope; in the latter, all tools in the toolbox are run in that scope.</p> <ul style="list-style-type: none"> <li>-E <i>appPath</i><br/>Specifies the absolute executable path of the legacy application. This option is available only for the <i>legacy</i> target.</li> <li>-F <i>folder</i><br/>Specifies the full path of the container folder. If this option is not given, the default folder is the 'root' folder of the toolbox.</li> <li>-H [<i>host_name</i>][:<i>port</i>]<br/>Specifies the host and port from which a tool should be loaded. If <i>host_name</i> is not given, the default host is used. The default host is <i>localhost</i>, if the toolbox is loaded from the local file system, or the host from which the toolbox is loaded if loaded from a remote Solaris Management Console server. If <i>:port</i> is not given, the default port will be used. If this option is not given at all, both the default host and the default port are used.</li> </ul> |

**repository  
configuration**

The Solaris Management Console repository stores information about the registered tools and services, as well as libraries (for instance, resource jars) and properties attached to tools or services.

*action*

Legal values are:

*add*

Adds information to the repository. If the *-f* option is given to *add*, the information overwrites any information of the same name already in the repository. If the *-f* option is not given, an error might be returned if the information is already in the repository.

*remove*

Removes information from the repository.

*list*

Lists the contents of the repository:

- All registered tools
- All registered services
- All libraries attached to all tools
- All libraries attached to all services
- All libraries attached to all tools and services

*target*

Legal values are:

*bean*

If the *action* is specified as *add*, this target will add a tool or service bean (which kind is determined by the contents of the bean) to the repository. The required *parameter* is the path to the jar file that contains the bean to be added.

*-L locale*

Specifies the locale of the toolbox that is being modified. The default is the *C* locale.

*-N appName*

Specifies the name of the legacy application being registered. This is the name that appears in the console. This option is available only for the *legacy* target.

*-P key:value*

Specifies the key/value pairs that define parameters to a tool. Multiple key/value pairs can be specified at a time.

*-T appType*

Specifies the legacy application type. Legal values are *CLI*, *XAPP*, or *HTML*. This option is available only for the *legacy* target.

If the *action* is specified as `remove`, this target will remove a tool or service bean from the repository. The required *parameter* is the full Java classname of the desired bean.

#### library

If the *action* is specified as `add`, this target adds a “library” jar file to a tool or service bean. The two required *parameters* are the full Java classname of the desired bean and the path to the jar file to be attached. The bean name can also be one of the “pseudo-beans,” `ALL`, `ALLTOOL`, or `ALLSERVICE`, in which case the library is attached, respectively, to all beans, all tools, or all services in the repository.

If the *action* is specified as `remove`, this target detaches a “library” jar file from a tool or service bean. The two required *parameters* are the full Java classname of the desired bean and the name of the jar file that is attached. As with the `add` action, the three “pseudo-beans” `ALL`, `ALLTOOL`, or `ALLSERVICE` can be used.

#### property

If the *action* is specified as `add`, this target defines a property on a tool or service. One or more key/value pairs must be specified in the form,

**-P** *key=value* Following this property list is a “pseudo-bean name,” *pseudoBeanName*, as defined for the `library` target, on which the properties are defined. Optionally, a library name can follow the “pseudo-bean” name, in which case the properties are defined on the library that is attached to the named bean.

If the *action* is specified as `remove`, this target undefines a property on a tool or service. The key/value pairs, “pseudo-bean” name, and optional library are specified for the `add` action.

## EXAMPLES

### EXAMPLE 1 Adding Legacy Applications to a Toolbox

The following command adds to the default toolbox the command line interface (CLI) application, `/usr/bin/ls`, with arguments `-al -R`, giving it the name, `Directory Listing`:

```
/usr/sadm/bin/smcconf toolbox add legacy -N "Directory Listing" \
-T CLI -E /usr/bin/ls -A "-al -R"
```

### EXAMPLE 2 Adding a Folder to a Toolbox

The following command adds to the standard Management Tools toolbox a folder with the name, `New Folder`, the description, `This is a new folder`, and the small and large icons, `folder_s.gif` and `folder_l.gif`:

**EXAMPLE 2** Adding a Folder to a Toolbox (Continued)

```
/usr/sadm/bin/smccnf toolbox add folder "New Folder" \
 "This is a new folder" folder_s.gif folder_l.gif \
 -B /var/sadm/smc/toolboxes/smc/smc.tbx
```

**EXAMPLE 3** Adding a Native Solaris Management Console Tool to a Toolbox

The following command adds a native Solaris Management Console tool to the default toolbox. The Java classname of the tool is `HelloWorld.client>HelloTool` (the name, description, and icons visible in the console are provided by the tool itself). When loaded, it is run in the NIS domain, `syrix`, which is hosted by the machine, `temple`, and is retrieved from port 2112 on the machine from which the toolbox was loaded:

```
/usr/sadm/bin/smccnf toolbox add tool HelloWorld.client>HelloTool \
 -D nis:/temple/syrix -H :2112
```

**EXAMPLE 4** Adding an Solaris Management Console Tool to the Repository

The following command adds the Java bean found in `HelloWorld.jar` to the repository. The jar file contains information that the bean is a tool:

```
/usr/sadm/bin/smccnf repository add bean HelloWorld.jar
```

**EXAMPLE 5** Removing an Solaris Management Console Service from the repository

The following command removes a Java bean from the repository. Although the name of the bean implies that it is a service, that is merely a convention; the repository knows whether a particular registered bean is a tool or a service:

```
/usr/sadm/bin/smccnf repository remove bean \
 HelloWorld.server>HelloService
```

**EXAMPLE 6** Attaching a Library to a Tool

The following command adds the library jar file, `HelloWorld_fr.jar` (probably a French localized version of the `HelloTool`'s resources) to the bean, `HelloWorld.client>HelloTool`:

```
/usr/sadm/bin/smccnf repository add library \
 HelloWorld.client>HelloTool HelloWorld_fr.jar
```

**EXAMPLE 7** Attaching a Library to all Tools

The following command adds the library jar file, `widgets.jar`, to all tools in the repository. The library probably contains a widget set that might be useful to any registered tools:

```
/usr/sadm/bin/smccnf repository add library ALLTOOL widgets.jar
```

**ENVIRONMENT  
VARIABLES**

See `environ(5)` for descriptions of the following environment variables that affect the execution of the `smccnf` command:

## smcconf(1M)

|           |                                                                                                                                                                                                                         |
|-----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| JAVA_HOME | If you do not specify this environment variable, your PATH is searched for a suitable java. Otherwise, the /usr/j2se location is used.                                                                                  |
| DISPLAY   | If you do not set this environment variable, set it to null, or set it to an X(7) display to which you are not authorized to connect, the Solaris Management Console starts in terminal mode instead of graphical mode. |

**EXIT STATUS** The following exit values are returned:

|   |                        |
|---|------------------------|
| 0 | Successful completion. |
| 1 | An error occurred.     |

**ATTRIBUTES** See attributes(5) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWmc          |

**SEE ALSO** jar(1), java(1), javac(1), smc(1M), smccompile(1M), smcregister(1M), attributes(5), environ(5)

**NOTES** All standard shell quoting rules apply.

Legacy applications (X-windows, command-line, and web-based applications) are handled differently from “native” Solaris Management Console tools. Legacy tools are handled by an instantiation of a native Solaris Management Console tool, LegacyAppLauncher, which, through the toolbox, is given the necessary information to run the legacy application: path, options, and so forth. Thus, you do not register a legacy application into the repository as you would a native Solaris Management Console tool. Instead, legacy applications appear only in toolboxes.

| DESCRIPTION | <p>The <code>smcregister</code> command configures the Solaris Management Console. For information regarding the Solaris Management Console, see <code>smc(1M)</code>. This command enables you to add to, remove from, and list the contents of toolboxes and the Solaris Management Console repository.</p> <p><code>smcregister</code> also allows you to register scripts to perform registrations and unregistrations. Typically, a package containing one or more tools or services posts tool and service registrations immediately after installation. On Solaris, this is by way of invocations of <code>smcregister</code> from within a package post-install script. Similarly, unregistrations would be posted from within a package pre-remove script. These are per-machine registrations - that is, registration requests must be posted on each machine on which the Solaris Management Console server will be running. However, due to the way that diskless clients are installed, registration requests cannot be made at install time. Therefore, packages should include and install registration and unregistration scripts, and then register these scripts during installation by way of the <code>scripts</code> subcommand. These scripts should contain tool, toolbox, service, library or property configurations in any of its forms as listed in this man page. While these scripts function very much like package post-install and pre-remove scripts, do not assume the normal package environment is available. However, <code>PATH</code> can assumed to be <code>/usr/sbin:/usr/bin</code></p> |

## smcregister(1M)

Using `smcregister` to edit toolboxes is not as feature-rich as using the Solaris Management Console's graphical editor. The command line interface is intended for use in packaging scripts that do not require user interaction. To edit all the properties of a toolbox or to modify the hierarchy of folders in a toolbox, you must use the specialized graphical editor, that is, `smc edit`. See `smc(1M)`.

`smcregister` is intended to replace the `smcconf` command as the preferred interface for managing the Solaris Management Console repository as well as toolboxes from within scripts, due to significant performance enhancements over `smcconf`.

### OPTIONS

The following options are supported:

`-h` Prints out a usage summary for the command.

### Scripts Configuration

`regscript` The full path of a script containing registration commands. The script is executed upon the next restart of the Solaris Management Console server after the package containing the script is installed.

`unregscript` The full path of a script containing unregistration commands. The script is executed upon the next restart of the Solaris Management Console server after the package containing the script is removed.

### Toolbox Configuration

`action` Legal values are:

`add`

Adds a target to the toolbox. Specify the path to the toolbox using the `-B toolboxpath` option and, optionally, provide locale information with the `-L locale` option.

`create`

Creates a new toolbox with no tools in it. The only target recognized is `toolbox`.

`list`

Lists the contents of the toolbox. No target is recognized. If you specify a parameter, it is taken as the path to a toolbox and the contents of that toolbox are listed. If you do not specify a parameter, the contents of the default toolbox are listed.

`remove`

Removes a target from the toolbox. Specify the path to the toolbox using the `-B toolboxpath` option and, optionally, provide locale information with the `-L locale` option.

`-D`

Defers execution of the `toolbox` command until the Solaris Management Console server is restarted. This is a convenient option for use in packaging scripts during install and un-install. Additionally, the command runs much faster than if run interactively (without `-D`).

`target`

Legal values are:

**folder**

If the action is specified as `add`, this target adds a folder to the toolbox. There are four required parameters: the folder name, description, and small and large icon paths. If the action is specified as `remove`, this target removes a folder from the toolbox. If the folder to be removed is itself inside a folder, the containing folder must be specified with the `-F` option.

**legacy**

If the action is specified as `add` or `remove`, this target adds or removes legacy applications (command line, X-windows, and web-based) to or from the toolbox. The `-N`, `-T`, `-E`, and `-B` options are required, and the `-A` option is optional. Placement in the toolbox with the `-F` option follows the same rules as for the `tool` and `tbxURL` targets. See NOTES for more information about legacy applications.

**tbxURL**

If the action is specified as `add` or `remove`, this target adds to or removes from the toolbox a link to another toolbox. The required parameter is the URL to the other toolbox. The properties of addition and removal are the same as for the `tool` target.

**tool**

If the action is specified as `add`, this target adds a native Solaris Management Console tool from the toolbox. The required parameter is the full Java classname of the tool you are adding. If you specify a folder name with the `-F` option, the tool is placed inside that folder (the folder will not be created if it does not already exist). Otherwise, the tool is appended to the end of the toolbox and not placed inside any folder. If the action is specified as `remove`, this target removes a native Solaris Management Console tool from the toolbox. The required parameter is the full Java classname of the tool you wish to remove. If you specify a folder name with the `-F` option, any tool with the given name in that folder will be removed. If no folder name is specified, all tools with the given name in the toolbox will be removed. For the tool to show up in the console, the tool must also be registered in the repository. See the repository configuration section below for more information. If a tool is referenced in a toolbox but is not registered, it will not appear in the console when the toolbox is loaded. Removing a tool from a toolbox does not remove the tool from the server repository.

**toolbox**

If the action is specified as `create`, this target creates a skeleton toolbox with no tools. There are four required parameters: the toolbox name, description, and small and large icon paths. These must be followed by the `-B toolboxpath` and `-D scope` options.

| parameters | Specifies values that may be required depending on the combination of action and target.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| options    | <p>Supported options for various action and target combinations for the toolbox configuration are:</p> <ul style="list-style-type: none"><li>-A<br/>Specifies the parameters to pass to the legacy application. This option is available only for the legacy target.</li><li>-B<br/>Specifies the path of the toolbox that is being modified. If this option is not given, the modifications will be performed on the default toolbox, <i>This Computer</i>.</li><li>-D<br/>Specifies the scope (domain) in which the tool should be run. The legal values for scope are <i>file</i>, <i>nis</i>, <i>nisplus</i>, <i>dns</i>, and <i>ldap</i>. This may also be specified for a folder or a toolbox. In the former case, all tools in that folder and its subfolders will be run in that scope; in the latter, all tools in the toolbox will be run in that scope.</li><li>-E<br/>Specifies the absolute executable path of the legacy application. This option is available only for the legacy target.</li><li>-f<br/>If the <i>-f</i> option is given to add, the information will overwrite any information of the same name already in the toolbox. If the <i>-f</i> option is not given, an error may be returned if the information is already in the toolbox.</li><li>-F <i>folder</i><br/>Specifies the full path of the container folder. If this option is not given, the default folder is the <i>root</i> folder of the toolbox.</li><li>-H [<i>host_name</i>][:<i>port</i>]<br/>Specifies the host and port from which a tool should be loaded. If <i>host_name</i> is not given, the default host (<i>localhost</i>, if the toolbox is loaded from the local filesystem, or the host from which the toolbox is loaded if loaded from a remote Solaris Management Console server) will be used. If <i>:port</i> is not given, the default port will be used. If this option is not given at all, both the default host and the default port will be used.</li><li>-L <i>locale</i><br/>Specifies the locale of the toolbox which is being modified. The default is the <i>C</i> locale.</li><li>-N <i>appName</i><br/>Specifies the name of the legacy application being registered. This is the name that will appear in the console. This option is available only for the <i>legacy</i> target.</li></ul> |

|                         | -P <i>key:value</i><br>Specifies the key/value pairs that define parameters to a tool. Multiple key/value pairs can be specified at a time.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|                         | -T <i>appType</i><br>Specifies the legacy application type. Legal values are CLI, XAPP, or HTML. This option is available only for the legacy target.                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|                         | See NOTES for more information about registration and unregistration of tools, services, and libraries.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| ALL                     | Specify that the library being registered to or unregistered from the repository is for use by all tools and services.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| ALLSERVICE              | Specify that the library being registered to or unregistered from the repository is for use by all services.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| ALLTOOL                 | Specify that the library being registered to or unregistered from the repository is for use by all tools.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <i>attachedBeanname</i> | The name of a registered jar to which the library jarfile should be attached to (or detached from). This is typically the same as <i>altjarname</i> (if provided) or <i>jarfile</i> used to register the jar to which this library is being attached or detached. An attached library means the library is only available for use by the tool or service to which it is being attached.                                                                                                                                                                                                                                     |
| <i>classlistfile</i>    | The classlist text file generated from the smccompile(1M) command.<br><br>Library registration does not require that a classlist file be specified. Instead, you can substitute the keyword <i>none</i> in place of the classlist path argument to <i>smcregister</i> , in which case one will be generated automatically. Generating the classlist automatically during server startup will cause the next server restart to take longer, so it is strongly suggested that developers always provide a classlist file with their libraries. Auto-generation is more appropriately used to register 3rd-party library jars. |
| <i>jarfile</i>          | The full path to the jar file to be registered/unregistered. The name must be in the form <i>beanname.jar</i> , where <i>beanname</i> is the package path to the bean. If it is not, an alternate name must be given in that form using the -n option.                                                                                                                                                                                                                                                                                                                                                                      |
| -n <i>altjarname</i>    | Rename the jarfile in the repository to <i>altjarname</i> . This would typically be the full bean name. For example, if the jarfile was <i>MyTool.jar</i> , then <i>altjarname</i> might be <i>com.mycompany.myproduct.MyTool.jar</i> . It is recommended that an <i>altjarname</i> containing the full package path be used.                                                                                                                                                                                                                                                                                               |

## smregister(1M)

|                                 |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|---------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                 | <p><i>native_lib_list</i> List of up to 4 native libraries that can be associated with a service bean.</p> <p><i>-u</i> The operation will be to un-register the jar with the Solaris Management Console repository. The jarfile argument must be identical to the <i>altjarname</i> used to register the jar (if provided), or jarfile.</p> <p><i>xmlfile</i> The xml descriptor file that describes this jarfile. Every tool or services must have one. See the Solaris Management Console SDK Guide located at <code>/usr/sadm/lib/smc/docs/sdkguide/index.html</code>.</p>                                                                                                                         |
| <b>Repository Configuration</b> | <p>The Solaris Management Console repository stores information about the registered tools and services, as well as libraries (for instance, resource jars) and properties attached to tools or services.</p> <p><i>list</i> Lists the contents of the repository:</p> <ul style="list-style-type: none"> <li>■ All registered tools</li> <li>■ All registered services</li> <li>■ All libraries attached to all tools</li> <li>■ All libraries attached to all services</li> <li>■ All libraries attached to all tools and services</li> </ul>                                                                                                                                                        |
| <b>Property Configuration</b>   | <p>See NOTES for more information about registration and unregistration of properties. If registering a property, this defines a property on a tool or service. Only one key value pair at a time can be registered.</p> <p><i>beanname</i> The name of a registered jar on which the properties will be defined. Optionally, a library name may follow the bean name, in which case the properties are defined on the library that is attached to the named bean.</p> <p>If unregistering a property, this undefines a property from a tool or service. Only one key value pair at a time can be registered. The key, beanname, and optional library are specified as for registering a property.</p> |
| <b>EXAMPLES</b>                 | <p><b>EXAMPLE 1</b> Adding Legacy Applications to a Toolbox</p> <p>The following command adds to the default toolbox the Command Line Interface (CLI) application, <code>/usr/bin/ls</code> with arguments <code>-al -R</code>, giving it the name, Directory Listing:</p> <pre>/usr/sadm/bin/smregister toolbox add legacy -N "Directory Listing" \ -T CLI -E /usr/bin/ls -A "-al -R"</pre> <p>Use this variation to defer execution of this command until the Solaris Management Console server is restarted:</p> <pre>/usr/sadm/bin/smregister toolbox -D add legacy -N "Directory Listing" \ -T CLI -E /usr/bin/ls -A "-al -R"</pre>                                                               |

**EXAMPLE 2** Adding a Folder to a Toolbox

The following command adds to the standard Management Tools toolbox a folder with the name, New Folder, the description, This is a new folder, and the small and large icons, folder\_s.gif and folder\_l.gif:

```
/usr/sadm/bin/smregister toolbox add folder "New Folder" \
 "This is a new folder" folder_s.gif folder_l.gif \
 -B /var/sadm/smc/toolboxes/smc/smc.tbx
```

**EXAMPLE 3** Adding a Native Solaris Management Console Tool to a Toolbox

The following command adds a native Solaris Management Console tool to the default toolbox. The Java classname of the tool is

com.mycompany.myproject.client.MyTool (the name, description, and icons visible in the console are provided by the tool itself). When loaded, it will be run in the NIS domain, syrinx, which is hosted by the machine, temple, and will be retrieved from port 2112 on the machine from which the toolbox was loaded.

```
/usr/sadm/bin/smregister toolbox add tool \
 com.mycompany.myproject.client.MyTool \
 -D nis:/temple/syrinx -H :2112
```

**EXAMPLE 4** Adding an Solaris Management Console Tool to the Repository

The following command adds the Java bean found in MyTool.jar to the repository. The xml file contains information about the tool. The classlist file would have been generated by smccompile -j:

```
/usr/sadm/bin/smregister tool -n com.mycompany.myproject.client.MyTool.jar \
 ${HOME}/workarea/MyTool.jar \
 ${HOME}/workarea/MyTool_classlist.txt \
 ${HOME}/workarea/MyTool.xml
```

Use this variation to add an Solaris Management Console tool to the repository without specifying an alternate name:

```
/usr/sadm/bin/smregister tool \
 ${HOME}/workarea/com.mycompany.myproject.client.MyTool.jar \
 ${HOME}/workarea/MyTool_classlist.txt \
 ${HOME}/workarea/MyTool.xml
```

**EXAMPLE 5** Adding an Solaris Management Console Service to the Repository

The following command adds the Java bean found in MyServiceImpl.jar to the repository. The xml file contains information about the service. The classlist file would have been generated by smccompile -j. The extra proxy and stub classes included in the jar would have been generated by smccompile -c:

```
/usr/sadm/bin/smregister service \
 -n com.mycompany.myproject.server.MyServiceImpl.jar \
 ${HOME}/workarea/MyServiceImpl.jar \
```

## smregister(1M)

### **EXAMPLE 5** Adding an Solaris Management Console Service to the Repository (Continued)

```
${HOME}/workarea/MyServiceImpl_classlist.txt \
${HOME}/workarea/MyServiceImpl.xml
```

Use this variation to add a Solaris Management Console service to the repository without specifying an alternate name:

```
/usr/sadm/bin/smregister service \
 ${HOME}/workarea/com.mycompany.myproject.server.MyServiceImpl.jar \
 ${HOME}/workarea/MyServiceImpl_classlist.txt \
 ${HOME}/workarea/MyServiceImpl.xml
```

### **EXAMPLE 6** Removing an Solaris Management Console Tool From the Repository

The following command removes a Java tool bean from the repository:

```
/usr/sadm/bin/smregister tool \
 -u com.mycompany.myproject.client.MyTool.jar
```

### **EXAMPLE 7** Removing an Solaris Management Console Service From the Repository

The following command removes a Java service bean from the repository:

```
/usr/sadm/bin/smregister service \
 -u com.mycompany.myproject.server.MyServiceImpl.jar
```

### **EXAMPLE 8** Attaching a Library to a Specific Tool

The following command adds the library jar file, MyTool\_fr.jar (probably a French localized version of the MyTool's resources) to the bean, com.mycompany.myproject.client.MyTool:

```
/usr/sadm/bin/smregister library \
 -n MyTool_fr.jar \
 ${HOME}/workarea/MyTool_fr.jar \
 ${HOME}/workarea/MyTool_fr_classlist.txt \
 com.mycompany.myproject.client.MyTool
```

### **EXAMPLE 9** Attaching a Library to All Tools

The following command adds the library jar file, widgets.jar, to all tools in the repository. The library probably contains a widget set which might be useful to any registered tools. The classlist file would have been generated by `smccompile -j`.

```
/usr/sadm/bin/smregister library \
 ${HOME}/workarea/lib/widgets.jar\
 ${HOME}/workarea/lib/widgets_classlist.txt \
 ALLTOOL
```

**EXAMPLE 9** Attaching a Library to All Tools      *(Continued)*

Alternatively, to add a 3rd-party library jar to all tools, replace the classlist file with none:

```
/usr/sadm/bin/smcregister library \
/opt/lib/XYZwidgets.jar none ALLTOOL
```

**EXAMPLE 10** Detaching a Library from All Tools

The following command removes the Java library bean from the repository:

```
/usr/sadm/bin/smcregister library -u MyTool_fr.jar ALLTOOL
```

**EXAMPLE 11** Detaching a Library from a Specific Tool

The following command detaches the library jar file, MyTool\_fr.jar (probably a French localized version of the MyTool's resources) from the bean `com.mycompany.myproject.client.MyTool`, and removes it from the repository:

```
/usr/sadm/bin/smcregister library -u MyTool_fr.jar \
com.mycompany.myproject.client.MyTool
```

**EXAMPLE 12** Registering Scripts

The following command registers the following scripts containing registration and unregistration commands. `MyProduct_reg.sh` will be executed upon the next server restart after the file is installed by the owning package. `MyProduct_unreg.sh` will be executed upon the next server restart after the file is removed by the owning package:

```
/usr/sadm/bin/smcregister scripts \
/usr/sadm/lib/myProduct/MyProduct_reg.sh \
/usr/sadm/lib/myProduct/MyProduct_unreg.sh
```

**ENVIRONMENT  
VARIABLES**

See `environ(5)` for descriptions of the following environment variables that affect the execution of `smcregister`:

**JAVA\_HOME**      If you do not specify this environment variable, your `PATH` is searched for a suitable java. Otherwise, the `/usr/j2se` location is used.

**EXIT STATUS**

The following exit values are returned:

0                  Successful completion.  
1                  An error occurred.

**ATTRIBUTES**

See `attributes(5)` for descriptions of the following attributes:

smcregister(1M)

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWmc          |

**SEE ALSO** smc(1M), smcconf(1M), smccompile(1M), attributes(5), environ(5)

**NOTES** All standard shell quoting rules apply.

Legacy applications (X-windows, command-line, and web-based applications) are handled differently from native Solaris Management Console tools. Legacy tools are handled by an instantiation of a native Solaris Management Console tool, LegacyAppLauncher, which, through the toolbox, is given the necessary information to run the legacy application: path, options, and so forth. Thus, you do not register a legacy application into the repository as you would a native Solaris Management Console tool. Instead, legacy applications appear only in toolboxes.

Registration and unregistration of tools, services, libraries, and properties do not take effect until the Solaris Management Console server is restarted. Run `/etc/init.d/init.wbem stop` followed by `/etc/init.d/init.wbem start`

To modify a job in another user's crontab file, the administrator must have the <code>solaris.jobs.admin</code> authorization. |
| add                | Adds a job to the crontab(1) database. To add a job, the administrator must have the <code>solaris.jobs.user</code> authorization. To add a job to another user's crontab file, the administrator must have the <code>solaris.jobs.admin</code> authorization.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |     |                                                                                                                                                                                                                                                                |        |                                                                                                                                                                                                                                                                             |      |                                                                                                                                                                                                                                                                                                                                       |        |                                                                                                                                                                                                                                                                          |
| delete             | Deletes a job from the crontab(1) database. To delete a job, the administrator must have the <code>solaris.jobs.user</code> authorization. To delete a job from another user's crontab file, the administrator must have the <code>solaris.jobs.admin</code> authorization.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |     |                                                                                                                                                                                                                                                                |        |                                                                                                                                                                                                                                                                             |      |                                                                                                                                                                                                                                                                                                                                       |        |                                                                                                                                                                                                                                                                          |
| list               | Lists one or more jobs in the crontab(1) database. To list all jobs, the administrator must have the <code>solaris.jobs.user</code> authorization. To list a job in another user's crontab file, the administrator must have the <code>solaris.jobs.admin</code> authorization. No authorization is needed to list a user's own jobs.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |     |                                                                                                                                                                                                                                                                |        |                                                                                                                                                                                                                                                                             |      |                                                                                                                                                                                                                                                                                                                                       |        |                                                                                                                                                                                                                                                                          |
| modify             | Modifies a job in the crontab(1) database. To modify a job, the administrator must have the <code>solaris.jobs.user</code> authorization. To modify a job in another user's crontab file, the administrator must have the <code>solaris.jobs.admin</code> authorization.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |     |                                                                                                                                                                                                                                                                |        |                                                                                                                                                                                                                                                                             |      |                                                                                                                                                                                                                                                                                                                                       |        |                                                                                                                                                                                                                                                                          |
| <b>OPTIONS</b>     | <p>The smcron authentication arguments, <i>auth_args</i>, are derived from the smc(1M) arg set and are the same regardless of which subcommand you use. The smcron command requires the Solaris Management Console to be initialized for the command to succeed (see smc(1M)). After rebooting the Solaris Management Console server, the first Solaris Management Console connection might time out, so you might need to retry the command.</p> <p>The subcommand-specific options, <i>subcommand_args</i>, must come after the <i>auth_args</i> and must be separated from them by the - - option.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |     |                                                                                                                                                                                                                                                                |        |                                                                                                                                                                                                                                                                             |      |                                                                                                                                                                                                                                                                                                                                       |        |                                                                                                                                                                                                                                                                          |
| <i>auth_args</i>   | <p>The valid <i>auth_args</i> are -D, -H, -l, -p, -r, and -u; they are all optional. If no <i>auth_args</i> are specified, certain defaults will be assumed and the user may be prompted for additional information, such as a password for authentication purposes. These letter options can also be specified by their equivalent option words preceded by a double dash. For example, you can use either -D or - --domain with the <i>domain</i> argument.</p> <p>-D   - --domain <i>domain</i><br/>         Specifies the default domain that you want to manage. smcron accepts only <i>file</i> for this option. <i>file</i> is also the default value.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |     |                                                                                                                                                                                                                                                                |        |                                                                                                                                                                                                                                                                             |      |                                                                                                                                                                                                                                                                                                                                       |        |                                                                                                                                                                                                                                                                          |

## smcron(1M)

The file default domain means that changes are local to the server. Toolboxes can change the domain on a tool-by-tool basis; this option specifies the domain for all other tools.

**-H | -** *-hostname host\_name:port*

Specifies the *host\_name* and *port* to which you want to connect. If you do not specify a *port*, the system connects to the default port, 898. If you do not specify *host\_name:port*, the Solaris Management Console connects to the local host on port 898. You may still have to choose a toolbox to load into the console. To override this behavior, use the `smcron(1M)` **-B** option, or set your console preferences to load a "home toolbox" by default.

**-l | -** *-rolepassword role\_password*

Specifies the password for the *role\_name*. If you specify a *role\_name* but do not specify a *role\_password*, the system prompts you to supply a *role\_password*. Passwords specified on the command line can be seen by any user on the system, hence this option is considered insecure.

**-p | -** *-password password*

Specifies the password for the *user\_name*. If you do not specify a password, the system prompts you for one. Passwords specified on the command line can be seen by any user on the system, hence this option is considered insecure.

**-r | -** *-rolename role\_name*

Specifies a role name for authentication. If you do not specify this option, no role is assumed.

**-u | -** *-username user\_name*

Specifies the user name for authentication. If you do not specify this option, the user identity running the console process is assumed.

**- -**

This option is required and must always follow the preceding options. If you do not enter the preceding options, you must still enter the **- -** option.

### *subcommand\_args*

For the time-related subcommands described below, **-m**, **-M**, **-t**, and **-w**, you can enter multiple arguments, separated only by commas. `smcron` will construct `crontab` entries appropriate for your arguments. See **EXAMPLES**.

*Note:* Descriptions and other `arg` options that contain white spaces must be enclosed in double quotes.

#### ■ For subcommand `add`:

- |                               |                                                                                                                                                                                                                        |
|-------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>-c</b> <i>command</i>      | Specifies the command that you want to run.                                                                                                                                                                            |
| <b>-h</b>                     | (Optional) Displays the command's usage statement.                                                                                                                                                                     |
| <b>-m</b> <i>day_of_month</i> | (Optional) Specifies the day of the month you want to run the job. Valid values are 1–31. If you specify both <b>-t</b> and <b>-m</b> options, the job executes one day per month at the time specified by <b>-t</b> . |

- |                       |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|-----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -M <i>month</i>       | (Optional) Specifies the month that you want to run the job. Valid values are 1–12. If you specify both -t and -M options, the job executes during the specified month at the time specified by -t.                                                                                                                                                                                                                                                                                                                                       |
| -n <i>name</i>        | Specifies the unique name of the job.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| -o <i>owner</i>       | (Optional) Specifies the user name that is the owner of the job. If you do not specify this option, the user name specified by the -U option is assumed.                                                                                                                                                                                                                                                                                                                                                                                  |
| -t <i>time_of_day</i> | Specifies the time (in <i>hh:mm</i> ) that you want to execute the command. If no other time-related options are specified (-m, -M, or -w), the job executes every day at the time specified by -t. If you specify both -t and -w options, the job executes one day per week at the time specified by -t. If you specify both -t and -m options, the job executes one day per month at the time specified by -t. If you specify both -t and -M options, the job executes each day during the specified month at the time specified by -t. |
| -w <i>day_of_week</i> | (Optional) Specifies the day of the week you want to execute the command. Valid values are as follows: <ul style="list-style-type: none"> <li>■ 0=Sunday</li> <li>■ 1=Monday</li> <li>■ 2=Tuesday</li> <li>■ 3=Wednesday</li> <li>■ 4=Thursday</li> <li>■ 5=Friday</li> <li>■ 6=Saturday</li> </ul> <p>If you specify both -t and -w options, the job executes one day per week at the time specified by -t.</p>                                                                                                                          |
- For subcommand **delete**:
- |                 |                                                                                                                                                          |
|-----------------|----------------------------------------------------------------------------------------------------------------------------------------------------------|
| -h              | (Optional) Displays the command's usage statement.                                                                                                       |
| -n <i>name</i>  | Specifies the unique name of the job.                                                                                                                    |
| -o <i>owner</i> | (Optional) Specifies the user name that is the owner of the job. If you do not specify this option, the user name specified by the -U option is assumed. |
- For subcommand **list**:
- |                 |                                                                                                                                                                                                                                                                                                                                                                                  |
|-----------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -f <i>n s v</i> | (Optional) Specifies the format of the output. See EXAMPLES for examples of each output type. <ul style="list-style-type: none"> <li>■ <i>n</i> — Displays the data in native format, as it appears in the crontab(1) database.</li> <li>■ <i>s</i> — Default format. Displays the data in summary format.</li> <li>■ <i>v</i> — Displays the data in verbose format.</li> </ul> |
|-----------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

## smcron(1M)

|                                        |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
