About This Guide

This guide describes how to create and run Java 2 Platform, Enterprise Edition (J2EE) applications that follow the new open Java standards model for Servlets and JavaServer Pages (JSPs) on the Sun™ Open Net Environment (Sun ONE) Application Server 7. In addition to describing programming concepts and tasks, this guide offers implementation tips and reference material.

This preface contains information about the following topics:

• Who Should Use This Guide
• Using the Documentation
• How This Guide Is Organized
• Documentation Conventions
• Related Information
• Product Support

Who Should Use This Guide

The intended audience for this guide is the person who develops, assembles, and deploys web applications (servlets and JSPs) in a corporate enterprise.

This guide assumes you are familiar with the following topics:

• J2EE specification
• HTML
• Java programming
• Java APIs as defined in servlet, JSP, EJB, and JDBC specifications
Using the Documentation

- Structured database query languages such as SQL
- Relational database concepts
- Software development processes, including debugging and source code control

Using the Documentation

The Sun ONE Application Server manuals are available as online files in Portable Document Format (PDF) and Hypertext Markup Language (HTML) formats, at:

http://docs.sun.com/

The following table lists tasks and concepts described in the Sun ONE Application Server manuals. The left column lists the tasks and concepts, and the right column lists the corresponding manuals.

Sun ONE Application Server Documentation Roadmap

How This Guide Is Organized

This guide provides a Sun ONE Application Server environment overview for designing web applications. The content is as follows:

- Chapter 1, “Web Applications”
  
  This chapter introduces web applications and describes how they are supported in Sun ONE Application Server.

- Chapter 2, “Using Servlets”
  
  This chapter describes how to create and use servlets.

- Chapter 3, “Using JavaServer Pages”
  
  This chapter describes how to create and use JavaServer Pages (JSPs).

- Chapter 4, “Creating and Managing User Sessions”
  
  This chapter describes how to create and manage a session that allows users and transaction information to persist between interactions.
• Chapter 5, “Securing Web Applications”
  This chapter describes how to write a secure web application for the Sun ONE Application Server.

• Chapter 6, “Assembling and Deploying Web Modules”
  This chapter describes how web modules are assembled and deployed in Sun ONE Application Server.

• Chapter 7, “Using Server-Parsed HTML”
  This chapter describes how to use server-parsed HTML with the Sun ONE Application Server.

• Chapter 8, “Using CGI”
  This chapter describes how to use CGI with the Sun ONE Application Server.

Finally, an Index is provided.

Documentation Conventions

This section describes the types of conventions used throughout this guide:

• General Conventions
• Conventions Referring to Directories

General Conventions

The following general conventions are used in this guide:

• **File and directory paths** are given in UNIX® format (with forward slashes separating directory names). For Windows versions, the directory paths are the same, except that backslashes are used to separate directories.

• **URLs** are given in the format:
  
  http://server.domain/path/file.html

  In these URLs, *server* is the server name where applications are run; *domain* is your Internet domain name; *path* is the server’s directory structure; and *file* is an individual filename. Italic items in URLs are placeholders.

• **Font conventions** include:
The monospace font is used for sample code and code listings, API and language elements (such as function names and class names), file names, pathnames, directory names, and HTML tags.

Italic type is used for code variables.

Italic type is also used for book titles, emphasis, variables and placeholders, and words used in the literal sense.

Bold type is used as either a paragraph lead-in or to indicate words used in the literal sense.

- **Installation root directories** for most platforms are indicated by `install_dir` in this document. Exceptions are noted in “Conventions Referring to Directories” on page 15.

  By default, the location of `install_dir` on most platforms is:

  - Solaris 8 non-package-based Evaluation installations:
    
    ```
    user's home directory/sun/appserver7
    ```

  - Solaris unbundled, non-evaluation installations:
    
    ```
    /opt/SUNWappserver7
    ```

  - Windows, all installations:
    
    ```
    C:\Sun\AppServer7
    ```

  For the platforms listed above, `default_config_dir` and `install_config_dir` are identical to `install_dir`. See “Conventions Referring to Directories” on page 15 for exceptions and additional information.

- **Instance root directories** are indicated by `instance_dir` in this document, which is an abbreviation for the following:

  ```
  default_config_dir/domains/domain/instance
  ```

- **UNIX-specific descriptions** throughout this manual apply to the Linux operating system as well, except where Linux is specifically mentioned.

---

**NOTE**  
Forte for Java 4.0 has been renamed to Sun ONE Studio 4 throughout this manual.
Conventions Referring to Directories

By default, when using the Solaris 8 and 9 package-based installation and the Solaris 9 bundled installation, the application server files are spread across several root directories. These directories are described in this section.

- **For Solaris 9 bundled installations**, this guide uses the following document conventions to correspond to the various default installation directories provided:
  - *install_dir* refers to `/usr/appserver/`, which contains the static portion of the installation image. All utilities, executables, and libraries that make up the application server reside in this location.
  - *default_config_dir* refers to `/var/appserver/domains`, which is the default location for any domains that are created.
  - *install_config_dir* refers to `/etc/appserver/config`, which contains installation-wide configuration information such as licenses and the master list of administrative domains configured for this installation.

- **For Solaris 8 and 9 package-based, non-evaluation, unbundled installations**, this guide uses the following document conventions to correspond to the various default installation directories provided:
  - *install_dir* refers to `/opt/SUNWappserver7`, which contains the static portion of the installation image. All utilities, executables, and libraries that make up the application server reside in this location.
  - *default_config_dir* refers to `/var/opt/SUNWappserver7/domains`, which is the default location for any domains that are created.
  - *install_config_dir* refers to `/etc/opt/SUNWappserver7/config`, which contains installation-wide configuration information such as licenses and the master list of administrative domains configured for this installation.

Related Information

You can find a directory of URLs for the official specifications at `install_dir/docs/index.htm`. Additionally, we recommend the following resources:

**Programming with Servlets and JSPs:**

*Java Servlet Programming*, by Jason Hunter, O'Reilly Publishing

Programming with JDBC:

*Database Programming with JDBC and Java*, by George Reese, O'Reilly Publishing

*JDBC Database Access With Java: A Tutorial and Annotated Reference (Java Series)*, by Graham Hamilton, Rick Cattell, & Maydene Fisher

**Product Support**

If you have problems with your system, contact customer support using one of the following mechanisms:

- The online support web site at:
  

- The telephone dispatch number associated with your maintenance contract

Please have the following information available prior to contacting support. This helps to ensure that our support staff can best assist you in resolving problems:

- Description of the problem, including the situation where the problem occurs and its impact on your operation
- Machine type, operating system version, and product version, including any patches and other software that might be affecting the problem
- Detailed steps on the methods you have used to reproduce the problem
- Any error logs or core dumps
Web Applications

This chapter describes how web applications are supported in Sun ONE Application Server, and includes the following sections:

- Introducing Web Applications
- Creating a Web Application
- Deploying a Web Application
- Debugging a Web Application
- Internationalization Issues
- Virtual Servers
- Default Web Modules
- Servlet and JSP Caching
- Database Connection Pooling
- Configuring the Web Container
- Web Application Examples

Introducing Web Applications

Sun ONE Application Server 7 supports the Servlet 2.3 API specification, which allows servlets and JSPs to be included in web applications.

A web application is a collection of servlets, JavaServer Pages, HTML documents, and other web resources which might include image files, compressed archives, and other data. A web application may be packaged into an archive (a WAR file) or exist in an open directory structure.
The following figure illustrates details of the J2EE environment. Web applications are in the presentation layer. Two web applications are running in the web container: one of them is part of a full application that includes EJB modules and connectors, while the other is an individually deployed web module.

Web applications in the J2EE environment
In addition, Sun ONE Application Server 7 supports SHTML and CGI, which are non-J2EE application components.

This section includes summaries of the following topics:

- Servlets
- JavaServer Pages
- SHTML
- CGI

### Servlets

Java servlets are server-side Java programs that application servers can run to generate content in response to a client request. Servlets can be thought of as applets that run on the server side without a user interface. Servlets are invoked through URL invocation or by other servlets.

Sun ONE Application Server 7 supports the Java Servlet Specification version 2.3.

**NOTE** Servlet API version 2.3 is fully backward compatible with versions 2.1 and 2.2, so all existing servlets will continue to work without modification or recompilation.

To develop servlets, use Sun Microsystems’ Java Servlet API. For information about using the Java Servlet API, see the documentation provided by Sun Microsystems at:

For information about developing servlets in Sun ONE Application Server, see Chapter 2, “Using Servlets.”
JavaServer Pages

Sun ONE Application Server 7 supports JavaServer Pages (JSP) Specification version 1.2.

A JSP is a page, much like an HTML page, that can be viewed in a web browser. However, in addition to HTML tags, it can include a set of JSP tags and directives intermixed with Java code that extend the ability of the web page designer to incorporate dynamic content in a page. These additional features provide functionality such as displaying property values and using simple conditionals.

One of the main benefits of JSPs is that they are like HTML pages. The web page designer simply writes a page that uses HTML and JSP tags and puts it on their application server. The page is compiled automatically when it is deployed. What the web page designer needs to know about Java classes and Java compilers is minimal.

Sun ONE Application Server supports precompilation of JSPs, however, and this is recommended for production servers.

JSP pages can access full Java functionality in the following ways:
• by embedding Java code directly in scriptlets in the page
• by accessing Java beans
• by using server-side tags that include Java servlets

Both beans and servlets are Java classes that need to be compiled, but they can be defined and compiled by a Java programmer, who then publishes the interface to the bean or the servlet. The web page designer can access a pre-compiled bean or servlet from a JSP page.

Sun ONE Application Server 7 supports JSP tag libraries and standard portable tags.

For information about creating JSPs, see Sun Microsystem’s JavaServer Pages web site at:

For information about Java Beans, see Sun Microsystem’s JavaBeans web page at:

http://java.sun.com/beans/index.html

For information about developing JSPs in Sun ONE Application Server, see Chapter 3, “Using JavaServer Pages.”
SHTML

HTML files can contain tags that are executed on the server. In addition to supporting the standard server-side tags, or SSIs, Sun ONE Application Server 7 allows you to embed servlets and define your own server-side tags. For more information, see Chapter 7, “Using Server-Parsed HTML.”

CGI

Common Gateway Interface (CGI) programs run on the server and generate a response to return to the requesting client. CGI programs can be written in various languages, including C, C++, Java, Perl, and as shell scripts. CGI programs are invoked through URL invocation. Sun ONE Application Server complies with the version 1.1 CGI specification. For more information, see Chapter 8, “Using CGI.”

Creating a Web Application

To create a web application:

1. Create a directory for all the web application’s files. This is the web application’s document root.
2. Create any needed HTML files, image files, and other static content. Place these files in the document root directory or a subdirectory where they can be accessed by other parts of the application.
3. Create any needed JSP files. For more information, see Chapter 3, “Using JavaServer Pages.”
4. Create any needed servlets. For more information, see Chapter 2, “Using Servlets.”
5. Compile the servlets. For details about precompiling JSPs, see “Compiling JSPs: The Command-Line Compiler,” on page 59.
6. Organize the web application as described in “Web Application Structure,” on page 84.
7. Create the deployment descriptor files. For more information, see Chapter 6, “Assembling and Deploying Web Modules.”
Deploying a Web Application

8. Package the web application in a WAR file if desired. This is optional. For example:

   jar -cvf module_name.war *

9. Deploy the web application. For more information, see Chapter 6, “Assembling and Deploying Web Modules.”

You can create a web application by hand, or you can use Sun ONE Studio 4. For more information about Sun ONE Studio, see the Sun ONE Studio 4, Enterprise Edition Tutorial.

Deploying a Web Application

Web application deployment descriptor files are created by the Sun ONE Application Server Administration interface during deployment. You can also create these by hand. These descriptor files are packaged within Web Application aRchive (.war) files. They contain metadata, plus information that identifies the servlet or JSP and establishes its application role. For more information about these descriptor files, see Chapter 6, “Assembling and Deploying Web Modules.”

Debugging a Web Application

For information about debugging applications, see the Sun ONE Application Server Developer’s Guide.

Internationalization Issues

This section covers internationalization as it applies to the following:

- The Server
- Servlets
- JSPs
The Server

To set the default locale of the entire Sun ONE Application Server, which determines the locale of the Administration interface, the logs, and so on, do one of the following:

• Go to the server instance page of the Administration interface, click on the Advanced tab, type a value in the Locale field, click on the Save button, click on the General tab, and select the Apply Changes button.
• Set the locale attribute of the server element in the server.xml file, then restart the server. For more information about this file, see the Sun ONE Application Server Administrator’s Configuration File Reference.

Servlets

This section explains how the Sun ONE Application Server determines the character encoding for the servlet request and the servlet response.

For encodings you can use, see:

http://java.sun.com/j2se/1.4/docs/guide/intl/encoding.doc.html

Servlet Request

When processing a servlet request, the server uses the following order of precedence, first to last, to determine the request character encoding:

• The setCharacterEncoding() method.
• A hidden field in the form, specified by the parameter-encoding element in the sun-web.xml file. For more information, see “parameter-encoding,” on page 123.
• The character encoding set in the locale-charset-info element in the sun-web.xml file. For more information about this element, see “Internationalization Elements,” on page 121.
• The default, which is ISO-8859-1.

Servlet Response

When processing a servlet response, the server uses the following order of precedence, first to last, to determine the response character encoding:

• The setContentType() method.
The `setLocale()` method.

The default, which is ISO-8859-1.

**JSPs**

For encodings you can use, see:

http://java.sun.com/j2se/1.4/docs/guide/intl/encoding.doc.html

To set the character encoding of a JSP, use the `page` directive. For example:

```jsp
<%@ page contentType="text/html; charset=Shift_JIS" %>
```

The `contentType` attribute defines the following:

- The character encoding for the JSP page.
- The character encoding for the response of the JSP page.
- The MIME type for the response of the JSP page.

The default value is `text/html; charset=ISO-8859-1`.

When processing a JSP page, the server uses the following order of precedence, first to last, to determine the character encoding:

- The `page` directive and `contentType` attribute of JSP file.
- The default, which is ISO-8859-1.

Some JSP pages can deliver content using different content types and character encodings depending on the request time input. Dynamic setting of content type relies on an underlying invocation of `response.setContentType()` method. This method can be invoked as long as no content has been sent to the response stream.

**Virtual Servers**

A virtual server, also called a virtual host, is a virtual web server that serves content targeted for a specific URL. Multiple virtual servers may serve content using the same or different host names, port numbers, or IP addresses. The HTTP service can direct incoming web requests to different virtual servers based on the URL.
When you first install Sun ONE Application Server, a default virtual server is created. (You can also assign a default virtual server to each new HTTP listener you create. For details, see the Sun ONE Application Server Administrator’s Guide.)

Web applications and J2EE applications containing web components can be assigned to virtual servers. You can assign virtual servers in either of these ways:

- Using the Administration Interface
- Editing the server.xml File

### Using the Administration Interface

You can assign a virtual server to a web module during deployment as described in “Deploying Web Applications,” on page 86.

To use the Administration interface to configure a default web module for a virtual server:

1. Deploy the web application or J2EE application as described in “Deploying Web Applications,” on page 86.
2. Open the HTTP Server component under your server instance.
3. Open the Virtual Servers component under the HTTP Server component.
4. Select the virtual server to which you want to assign the web application.
5. Select the web module from the Default Web Module drop-down list.
6. Select the Save button.
7. Go to the server instance page and select the Apply Changes button.

For more information, see “Default Web Modules,” on page 26.

### Editing the server.xml File

When a web module is deployed as part of an application, a j2ee-application element is created for it in server.xml during deployment. When a web module is deployed as an individual module, a web-module element is created for it in server.xml during deployment. The j2ee-application and web-module elements both have a virtual-servers attribute, which specifies a list of virtual server IDs. The virtual-servers attribute is empty by default, which means that the web application is assigned to all virtual servers.
Each `virtual-server` element in `server.xml` has a `default-web-module` attribute, which allows you to configure a default web module for each virtual server. A default web module for the default virtual server is provided at installation. For more information, see “Default Web Modules,” on page 26.

For more information about `server.xml` and virtual servers, see the Sun ONE Application Server Administrator’s Configuration File Reference.

**Default Web Modules**

You can assign a default web module to the default virtual server and to each new virtual server you create. For details, see “Virtual Servers,” on page 24. To access the default web module for a virtual server, point your browser to the URL for the virtual server, but do not supply a context root. For example:

```
http://myvserver:3184/
```

If you do not assign a default web module to a virtual server, the virtual server serves HTML or JSP content from its document root, which is usually `instance_dir/docroot`. To access this HTML or JSP content, point your browser to the URL for the virtual server, do not supply a context root, but specify the target file. For example:

```
http://myvserver:3184/hellothere.jsp
```

**Servlet and JSP Caching**

The Sun ONE Application Server has the ability to cache servlet or JSP results in order to make subsequent calls to the same servlet or JSP faster. The Sun ONE Application Server caches the request results for a specific amount of time. In this way, if another data call occurs the Sun ONE Application Server can return the cached data instead of performing the operation again. For example, if your servlet returns a stock quote that updates every 5 minutes, you set the cache to expire after 300 seconds.

For more information about response caching as it pertains to servlets, see “Caching Servlet Results,” on page 45. For more information about JSP caching, see “JSP Caching,” on page 56.
Database Connection Pooling

Database connection pooling enhances the performance of servlet or JSP database interactions. There are several JDBC 2.0 compatible drivers that support connection pooling, for example Pointbase (provided with Sun ONE Application Server except for Solaris 9 bundled installations), Oracle 8i update, and CloudScape 3.0. For more information about JDBC, see the Sun ONE Application Server Developer’s Guide to J2EE Features and Services.

Configuring the Web Container

You can configure logging in the web container for the entire server in these ways:

- By using the Administration interface; see the Sun ONE Application Server Administrator’s Guide.
- By editing the server.xml file; see the Sun ONE Application Server Administrator’s Configuration File Reference.

Web Application Examples

Sample web applications that you can examine and deploy are included in Sun ONE Application Server, in the install_dir/samples/webapps directory. Each sample has its own documentation.
Web Application Examples
This chapter describes how to create effective servlets to control application interactions running on a Sun ONE Application Server, including standard servlets. In addition, this chapter describes the Sun ONE Application Server features to use to augment the standards.

This chapter contains the following sections:

• About Servlets
• Creating Servlets
• Invoking Servlets
• Servlet Output
• Caching Servlet Results
• About the Servlet Engine

About Servlets

Servlets, like applets, are reusable Java applications. However, servlets run on an application server or web server rather than in a web browser.

Servlets supported by the Sun ONE Application Server are based on the Java Servlet Specification v2.3. All relevant specifications are accessible from install_dir/docs/index.htm, where install_dir is the directory where the Sun ONE Application Server is installed.
Servlets are used for an application’s presentation logic. A servlet acts as an application’s central dispatcher by processing form input, invoking business logic components encapsulated in EJB components, and formatting web page output using JSPs. Servlets control the application flow from one user interaction to the next by generating content in response to user requests.

The fundamental characteristics are:

- Servlets are created and managed at runtime by the Sun ONE Application Server servlet engine.
- Servlets operate on input data that is encapsulated in a request object.
- Servlets respond to a query with data encapsulated in a response object.
- Servlets call EJB components to perform business logic functions.
- Servlets call JSPs to perform page layout functions.
- Servlets are extensible; use the APIs provided with the Sun ONE Application Server to add functionality.
- Servlets provide user session information persistence between interactions.
- Servlets can be part of an application or they can reside discretely on the application server so they are available to multiple applications.
- Servlets can be dynamically reloaded while the server is running.
- Servlets are addressable with URLs; buttons on an application’s pages often point to servlets.
- Servlets can call other servlets.

**Servlet Data Flow**

When a user clicks a Submit button, information entered in a display page is sent to a servlet. The servlet processes the incoming data and orchestrates a response by generating content, often through business logic components, which are EJB components. Once the content is generated, the servlet creates a response page, usually by forwarding the content to a JSP. The response is sent back to the client, which sets up the next user interaction.

The following illustration shows the information flow to and from the servlet, as:

1. Servlet processes the client request
2. Servlet generates content
3. Servlet creates response and either:
   a. Sends it back directly to the client
   or
   b. Dispatches the task to a JSP

The servlet remains in memory, available to process another request.

Servlet Data Flow Steps

Servlet Types

There are two main servlet types:

- Generic servlets
  - Extend `javax.servlet.GenericServlet`.
  - Are protocol independent; they contain no inherent HTTP support or any other transport protocol.
Creating Servlets

- HTTP servlets
  - Extend `javax.servlet.HttpServlet`.
  - Have built-in HTTP protocol support and are more useful in a Sun ONE Application Server environment.

For both servlet types, implement the constructor method `init()` and the destructor method `destroy()` to initialize or deallocate resources, respectively.

All servlets must implement a `service()` method, which is responsible for handling servlet requests. For generic servlets, simply override the service method to provide routines for handling requests. HTTP servlets provide a service method that automatically routes the request to another method in the servlet based on which HTTP transfer method is used. So, for HTTP servlets, override `doPost()` to process POST requests, `doGet()` to process GET requests, and so on.

Creating Servlets

To create a servlet, perform the following tasks:

- Design the servlet into your application, or, if accessed in a generic way, design it to access no application data.
- Create a class that extends either `GenericServlet` or `HttpServlet`, overriding the appropriate methods so it handles requests.
- Use the Sun ONE Application Server Administration interface to create a web application deployment descriptor. For details, see Chapter 6, “Assembling and Deploying Web Modules.”

The rest of this section discusses the following topics:

- Creating the Class Declaration
- Overriding Methods
- Accessing Parameters and Storing Data
- Handling Sessions and Security
- Accessing Business Logic Components
- Handling Threading Issues
- Delivering Client Results
Creating the Class Declaration

To create a servlet, write a public Java class that includes basic I/O support as well as the package `javax.servlet`. The class must extend either `GenericServlet` or `HttpServlet`. Since Sun ONE Application Server servlets exist in an HTTP environment, the latter class is recommended. If the servlet is part of a package, you must also declare the package name so the class loader can properly locate it.

The following example header shows the HTTP servlet declaration called `myServlet`:

```java
import java.io.*;
import javax.servlet.*;
import javax.servlet.http.*;

public class myServlet extends HttpServlet {
    ...servlet methods...
}
```

Overriding Methods

Next, override one or more methods to provide servlet instructions to perform its intended task. All processing by a servlet is done on a request-by-request basis and happens in the service methods, either `service()` for generic servlets or one of the `doOperation()` methods for HTTP servlets. This method accepts incoming requests, processing them according to the instructions you provide, and directs the output appropriately. You can create other methods in a servlet as well.

Business logic may involve database access to perform a transaction or passing the request to an EJB component.

Overriding Initialize

Override the class initializer `init()` to initialize or allocate resources for the servlet instance’s life, such as a counter. The `init()` method runs after the servlet is instantiated but before it accepts any requests. For more information, see the servlet API specification.

**NOTE**

All `init()` methods must call `super.init(ServletConfig)` to set their scope. This makes the servlet’s configuration object available to other servlet methods. If this call is omitted, a 500 `SC_INTERNAL_SERVER_ERROR` appears in the browser when the servlet starts up.
The following example of the `init()` method initializes a counter by creating a public integer variable called `thisMany`:

```java
public class myServlet extends HttpServlet {
    int thisMany;

    public void init (ServletConfig config) throws ServletException {
        super.init(config);
        thisMany = 0;
    }
}
```

Now other servlet methods can access the variable.

**Overriding Destroy**

Override the class destructor `destroy()` to write log messages or to release resources that have been opened in the servlet’s life cycle. Resources should be appropriately closed and dereferenced so that they are recycled or garbage collected. The `destroy()` method runs just before the servlet itself is deallocated from memory. For more information, see the servlet API specification.

For example, the `destroy()` method could write a log message like the following, based on the example for “Overriding Initialize” above:

```java
out.println("myServlet was accessed " + thisMany " times.\n");
```

**Overriding Service, Get, and Post**

When a request is made, the Sun ONE Application Server hands the incoming data to the servlet engine to process the request. The request includes form data, cookies, session information, and URL name-value pairs, all in a type `HttpServletRequest` object called the request object. Client metadata is encapsulated as a type `HttpServletResponse` object called the response object. The servlet engine passes both objects as the servlet’s `service()` method parameters.

**NOTE**

A web application is not started if any of its components, such as a filter, throws a `ServletException` during initialization. This is to ensure that if any part of the web application runs, all of it runs. It is especially important that a web application fail if security components fail.
The default service() method in an HTTP servlet routes the request to another method based on the HTTP transfer method (POST, GET, and so on). For example, HTTP POST requests are routed to the doPost() method, HTTP GET requests are routed to the doGet() method, and so on. This enables the servlet to perform different request data processing depending on the transfer method. Since the routing takes place in service(), there is no need to generally override service() in an HTTP servlet. Instead, override doGet(), doPost(), and so on, depending on the expected request type.

The automatic routing in an HTTP servlet is based simply on a call to request.getMethod(), which provides the HTTP transfer method. In a Sun ONE Application Server, request data is already preprocessed into a name-value list by the time the servlet sees the data, so simply overriding the service() method in an HTTP servlet does not lose any functionality. However, this does make the servlet less portable, since it is now dependent on preprocessed request data.

Override the service() method (for generic servlets) or the doGet() or doPost() methods (for HTTP servlets) to perform tasks needed to answer the request. Very often, this means accessing EJB components to perform business transactions, collating the needed information (in the request object or in a JDBC result set object), and then passing the newly generated content to a JSP for formatting and delivery back to the client.

Most operations that involve forms use either a GET or a POST operation, so for most servlets you override either doGet() or doPost(). Note that implementing both methods to provide for both input types or simply pass the request object to a central processing method, as shown in the following example:

```java
public void doGet (HttpServletRequest request,
HttpServletResponse response)
    throws ServletException, IOException {
    doPost(request, response);
}
```

All request-by-request traffic in an HTTP servlet is handled in the appropriate doOperation() method, including session management, user authentication, dispatching EJB components and JSPs, and accessing Sun ONE Application Server features.

If a servlet intends to call the RequestDispatcher method include() or forward(), be aware the request information is no longer sent as HTTP POST, GET, and so on. In other words, if a servlet overrides doPost(), it may not process anything if another servlet calls it, if the calling servlet happens to receive its data through HTTP GET. For this reason, be sure to implement routines for all possible input types, as explained above. RequestDispatcher methods always call service().
For more information, see “Calling a Servlet Programatically,” on page 43.

| NOTE | Arbitrary binary data, such as uploaded files or images, can be problematic, since the web connector translates incoming data into name-value pairs by default. You can program the web connector to properly handle these kinds of data and package them correctly in the request object. |

### Accessing Parameters and Storing Data

Incoming data is encapsulated in a request object. For HTTP servlets, the request object type is `HttpServletRequest`. For generic servlets, the request object type is `ServletRequest`. The request object contains all request parameters, including your own request values called attributes.

To access all incoming request parameters, use the `getParameter()` method. For example:

```java
String username = request.getParameter("username");
```

Set and retrieve values in a request object using `setAttribute()` and `getAttribute()`, respectively. For example:

```java
request.setAttribute("favoriteDwarf", "Dwalin");
```

This shows one way to transfer data to a JSP, since JSPs have access to the request object as an implicit bean.

### Handling Sessions and Security

From a web or application server’s perspective, a web application is a series of unrelated server hits. There is no automatic recognition if a user has visited the site before, even if their last interaction were seconds before. A session provides a context between multiple user interactions by remembering the application state. Clients identify themselves during each interaction by a cookie, or, in the case of a cookie-less browser, by placing the session identifier in the URL.

A session object can store objects, such as tabular data, information about the application’s current state, and information about the current user. Objects bound to a session are available to other components that use the same session.

For more information, see Chapter 4, “Creating and Managing User Sessions.”
After a successful login, you should direct a servlet to establish the user’s identity in a standard object called a session object that holds information about the current session, including the user’s login name and whatever additional information to retain. Application components can then query the session object to obtain user authentication.

To provide a secure user session for your application, see Chapter 5, “Securing Web Applications.”

**Accessing Business Logic Components**

In the Sun ONE Application Server programming model, you implement business logic, including database or directory transactions and complex calculations, in EJB components. A request object reference can be passed as an EJB parameter to perform the specified task.

Store the results from database transactions in JDBC ResultSet objects and pass object references to other components for formatting and delivery to the client. Also, store request object results by using the request.setAttribute() method, or in the session by using the session.setAttribute() method. Objects stored in the request object are valid only for the request length, or in other words for this particular servlet thread. Objects stored in the session persist for the session duration, which can span many user interactions.

This example shows a servlet accessing an EJB component called ShoppingCart. The servlet creates a cart handle by casting the user’s session ID as a cart after importing the cart’s remote interface. The cart is stored in the user’s session.

```java
import cart.ShoppingCart;

// Get the user’s session and shopping cart
HttpSession session = request.getSession(true);
ShoppingCart cart = (ShoppingCart)session.getAttribute(session.getId());

// If the user has no cart, create a new one
if (cart == null) {
    String jndiNm = "java:comp/env/ejb/ShoppingCart";
    javax.naming.Context initCtx = null;
    Object home = null;
    try {
        initCtx = new javax.naming.InitialContext(env);
        java.util.Properties props = null;
        home = initCtx.lookup(jndiNm);
        cart = ((IShoppingCartHome) home).create();
    } catch (Exception e) {
        // Handle exception
    }
}
```
Access EJB components from servlets by using the Java Naming Directory Interface (JNDI) to establish a handle, or proxy, to the EJB component. Next, refer to the EJB component as a regular object; overhead is managed by the bean’s container.

This example shows JNDI looking up a proxy for the shopping cart:

```java
String jndiNm = "java:comp/env/ejb/ShoppingCart";
javax.naming.Context initCtx;
Object home;
try {
    initCtx = new javax.naming.InitialContext(env);
} catch (Exception ex) {
    return null;
} try {
    java.util.Properties props = null;
    home = initCtx.lookup(jndiNm);
} catch(javax.naming.NameNotFoundException e) {
    return null;
} catch(javax.naming.NamingException e) {
    return null;
} try {
    IShoppingCart cart = ((IShoppingCartHome) home).create();
} catch (...) {...}
```

For more information on EJB components, see the Sun ONE Application Server Developer’s Guide to Enterprise JavaBeans Technology.
Handling Threading Issues

By default, servlets are not thread-safe. The methods in a single servlet instance are usually executed numerous times simultaneously (up to the available memory limit). Each execution occurs in a different thread though only one servlet copy exists in the servlet engine.

This is efficient system resource usage, but is dangerous because of how Java manages memory. Because variables belonging to the servlet class are passed by reference, different threads can overwrite the same memory space as a side effect. To make a servlet (or a block within a servlet) thread-safe, do one of the following:

- Synchronize write access to all instance variables, as in `public synchronized void method() (whole method) or synchronized(this) {...} (block only).` Because synchronizing slows response time considerably, synchronize only blocks, or make sure that the blocks in the servlet do not need synchronization.

For example, this servlet has a thread-safe block in `doGet()` and a thread-safe method called `mySafeMethod()`:

```
import java.io.*;
import javax.servlet.*/;
import javax.servlet.http.*/;

public class myServlet extends HttpServlet {

public void doGet (HttpServletRequest request,
    HttpServletResponse response)
    throws ServletException, IOException {
    //pre-processing
    synchronized (this) {
        //code in this block is thread-safe
    }
    //other processing;
}

public synchronized int mySafeMethod (HttpServletRequest request)
```
{  
    //everything that happens in this method is thread-safe  
}  

• Use the SingleThreadModel class to create a single-threaded servlet. When a single-threaded servlet is deployed to the Sun ONE Application Server, the servlet engine creates a servlet instance pool used for incoming requests (multiple copies of the same servlet in memory). You can change the number of servlet instances in the pool by setting the singleThreadedServletPoolSize property in the Sun ONE Application Server specific web application deployment descriptor. For more information on the Sun ONE Application Server web application deployment descriptor, see Chapter 6, “Assembling and Deploying Web Modules.” A single-threaded servlet is slower under load because new requests must wait for a free instance in order to proceed, but this is not a problem with distributed, load-balanced applications since the load automatically shifts to a less busy process.

For example, this servlet is completely single-threaded:

```java
import java.io.*;
import javax.servlet.*;
import javax.servlet.http.*;

public class myServlet extends HttpServlet
    implements SingleThreadModel {
    servlet methods...
}
```

**Delivering Client Results**

The final user interaction activity is to provide a response page to the client. The response page can be delivered in two ways:

• Creating a Servlet Response Page

• Creating a JSP Response Page

**Creating a Servlet Response Page**

Generate the output page within a servlet by writing to the output stream. The recommended way to do this depends on the output type.
Creating Servlets

Always specify the output MIME type using `setContentType()` before any output commences, as in this example:

```java
response.setContentType("text/html");
```

For textual output, such as plain HTML, create a PrintWriter object and then write to it using `println`. For example:

```java
PrintWriter output = response.getWriter();
output.println("Hello, World\n");
```

For binary output, write to the output stream directly by creating a ServletOutputStream object and then write to it using `print()`. For example:

```java
ServletOutputStream output = response.getOutputStream();
output.print(binary_data);
```

Creating a JSP Response Page

Servlets can invoke JSPs in two ways:

- The `include()` method in the RequestDispatcher interface calls a JSP and waits for it to return before continuing to process the interaction. The `include()` method can be called multiple times within a given servlet.

  This example shows a JSP using `include()`:

  ```java
  RequestDispatcher dispatcher =
  getServletContext().getRequestDispatcher("JSP_URI");
  dispatcher.include(request, response);
  ...
  //processing continues
  ```

- The `forward()` method in the RequestDispatcher interface hands the JSP interaction control. The servlet is no longer involved with the current interaction’s output after invoking `forward()`, thus only one call to the `forward()` method can be made in a particular servlet.

  This example shows a JSP using `forward()`:

  ```java
  RequestDispatcher dispatcher =
  getServletContext().getRequestDispatcher("JSP_URI");
  dispatcher.forward(request, response);
  ```

**NOTE** You cannot use the `forward()` method if you have already defined a PrintWriter or ServletOutputStream object.
Invoking Servlets

You can invoke a servlet by directly addressing it from an application page with a URL or calling it programmatically from an already running servlet. See the following sections:

• Calling a Servlet with a URL
• Calling a Servlet Programmatically

Calling a Servlet with a URL

You can call servlets by using URLs embedded as links in an application’s HTML or JSP pages. The format of these URLs is as follows:

http://server:port/context_root/servlet/servlet_name?name=value

The following table describes each URL section. The left column lists the URL elements, and the right column lists descriptions of each URL element.

<table>
<thead>
<tr>
<th>URL element</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>server:port</td>
<td>The IP address (or host name) and optional port number.</td>
</tr>
<tr>
<td></td>
<td>To access the default web module for a virtual server, specify only this</td>
</tr>
<tr>
<td></td>
<td>URL section. You do not need to specify the context_root or servlet_name</td>
</tr>
<tr>
<td></td>
<td>unless you also wish to specify name-value parameters.</td>
</tr>
</tbody>
</table>

For more information about JSPs, see Chapter 3, “Using JavaServer Pages.”
Invoking Servlets

In this example, leMort is the host name, MortPages is the context root, and calcMortgage is the servlet name:

http://www.leMort.com/MortPages/servlet/calcMortgage?rate=8.0&per=360&bal=180000

Calling a Servlet Programmatically

First, identify which servlet to call by specifying a URI. This is normally a path relative to the current application. For example, if your servlet is part of an application with a context root called OfficeFrontEnd, the URL to a servlet called ShowSupplies from a browser is as follows:

http://server:port/OfficeApp/OfficeFrontEnd/servlet/ShowSupplies?name=value

You can call this servlet programmatically from another servlet in one of two ways, as described below.

- To include another servlet’s output, use the include() method from the RequestDispatcher interface. This method calls a servlet by its URI and waits for it to return before continuing to process the interaction. The include() method can be called multiple times within a given servlet.

  For example:

  RequestDispatcher dispatcher =
  getServletContext().getRequestDispatcher("/ShowSupplies");
  dispatcher.include(request, response);

- To hand interaction control to another servlet, use the RequestDispatcher interface’s forward() method with the servlet’s URI as a parameter.
This example shows a servlet using `forward()`:

```java
RequestDispatcher dispatcher =
        getServletContext().getRequestDispatcher("/ShowSupplies");
dispatcher.forward(request, response);
```

**NOTE**

Forwarding a request means the original servlet is no longer involved with the current interaction output after `forward()` is invoked. Therefore, only one `forward()` call can be made in a particular servlet.

ServletContext.log messages are sent to the server log.

By default, the `System.out` and `System.err` output of servlets are sent to the server log, and during start-up server log messages are echoed to the `System.err` output. Also by default, there is no Windows-only console for the `System.err` output. You can change these defaults in these ways:

- Using the Administration Interface
- Editing the server.xml File

**Using the Administration Interface**

Use the Administration interface as follows:

1. Click on the Logging tab of the server instance page in the Administration interface.

2. Check or uncheck these boxes:
   - Log stdout content to event log - If true, `System.out` output is sent to the server log.
   - Log stderr content to event log - If true, `System.err` output is sent to the server log.
   - Echo to stderr - If true, server log messages are echoed to `System.err`.
   - Create console - Creates a Windows-only console for `System.err` output.
3. Click on the Save button.

4. Go to the server instance page and select the Apply Changes button.

For more information, see the Sun ONE Application Server Administrator’s Guide.

Editing the server.xml File

Edit the server.xml file as follows, then restart the server:

```xml
<log-service
  log-stdout=false
  log-stderr=false
  echo-log-messages-to-stderr=false
  create-console=true />
```

The create-console attribute is Windows-only. For more information about server.xml, see the Sun ONE Application Server Administrator’s Configuration File Reference.

Caching Servlet Results

The Sun ONE Application Server can cache the results of invoking a servlet, a JSP, or any URL pattern to make subsequent invocations of the same servlet, JSP, or URL pattern faster. The Sun ONE Application Server caches the request results for a specific amount of time. In this way, if another data call occurs, the Sun ONE Application Server can return the cached data instead of performing the operation again. For example, if your servlet returns a stock quote that updates every 5 minutes, you set the cache to expire after 300 seconds.

Whether to cache results and how to cache them depends on the data involved. For example, it makes no sense to cache the results of a quiz submission, because the input to the servlet is different each time. However, you could cache a high level report showing demographic data taken from quiz results that is updated once an hour.

You can define how a Sun ONE Application Server web application handles response caching by editing specific fields in the sun-web.xml file. In this way, you can create programmatically standard servlets that still take advantage of this valuable Sun ONE Application Server feature.

For more information about JSP caching, see “JSP Caching,” on page 56.
The rest of this section covers the following topics:

- Caching Features
- Default Cache Configuration
- Caching Example
- CacheHelper Interface
- CacheKeyGenerator Interface

Caching Features

Sun ONE Application Server 7 has the following web application response caching capabilities:

- Caching is configurable based on the servlet name or the URI.
- When caching is based on the URI, this includes user specified parameters in the query string. For example, a response from 
  \[/garden/catalog?category=roses\] is different from a response from 
  \[/garden/catalog?category=lilies\]. These responses are stored under different keys in the cache.
- Cache size, entry timeout, and other caching behaviors are configurable.
- Entry timeout is measured from the time an entry is created or refreshed. You can override this timeout for an individual cache mapping by specifying the \[cache-mapping\] subelement \[timeout\].
- You can determine caching criteria programmatically by writing a cache helper class. For example, if a servlet only knows when a back end data source was last modified, you can write a helper class to retrieve the last modified timestamp from the data source and decide whether to cache the response based on that timestamp. See “CacheHelper Interface,” on page 48.
- You can determine cache key generation programmatically by writing a cache key generator class. See “CacheKeyGenerator Interface,” on page 50.

NOTE

For information about caching static file content, see the \[nsfc.conf\] file, described in the Sun ONE Application Server Administrator’s Configuration File Reference.
• All non-ASCII request parameter values specified in cache key elements must be URL encoded. The caching subsystem attempts to match the raw parameter values in the request query string.

• Since newly updated classes impact what gets cached, the web container clears the cache during dynamic deployment or reloading of classes.

• The following HttpServletRequest request attributes are exposed:
  o com.sun.appserv.web.cachedServletName, the cached servlet target
  o com.sun.appserv.web.cachedURLPattern, the URL pattern being cached

Default Cache Configuration

If you enable caching but do not provide any special configuration for a servlet or JSP, the default cache configuration is as follows:

• The default cache timeout is 30 seconds.

• Only the HTTP GET method is eligible for caching.

• HTTP requests with cookies or sessions automatically disable caching.

• No special consideration is given to Pragma:, Cache-control:, or Vary: headers.

• The default key consists of the Servlet Path (minus pathInfo and the query string).

• A “least recently used” list is maintained to evict cache entries if the maximum cache size is exceeded.

• Key generation concatenates the servlet path with key field values, if any are specified.

Caching Example

Here is an example cache element in the sun-web.xml file:

```xml
<cache max-capacity="8192" timeout="60">
  <cache-helper name="myHelper" class-name="MyCacheHelper"/>
  <cache-mapping>
    <servlet-name>myservlet</servlet-name>
    <timeout name="timefield">120</timeout>
    <http-method>GET</http-method>
  </cache-mapping>
</cache>
```
<http-method>POST</http-method>
</cache-mapping>
<cache-mapping>
  <url-pattern>/catalog/*</url-pattern>
  <!-- cache the best selling category; cache the responses to
  -- this resource only when the given parameters exist. cache
  -- only when the catalog parameter has 'lilies' or 'roses'
  -- but no other catalog varieties:
  -- /orchard/catalog?best&category='lilies'
  -- /orchard/catalog?best&category='roses'
  -- but not the result of
  -- /orchard/catalog?best&category='wild'
  -->
  <constraint-field name='best' scope='request.parameter'/>
  <constraint-field name='category' scope='request.parameter'>
    <value>roses</value>
    <value>lilies</value>
  </constraint-field>
  <!-- Specify that a particular field is of given range but the
  -- field doesn't need to be present in all the requests -->
  <constraint-field name='SKUnum' scope='request.parameter'>
    <value match-expr='in-range'>1000 - 2000</value>
  </constraint-field>
  <!-- cache when the category matches with any value other than
  -- a specific value -->
  <constraint-field name='category' scope='request.parameter'>
    <value match-expr='equals' cache-on-match-failure='true'>bogus</value>
  </constraint-field>
</cache-mapping>
<cache-mapping>
  <servlet-name>InfoServlet</servlet-name>
  <cache-helper-ref>myHelper</cache-helper-ref>
</cache-mapping>

For more information about the sun-web.xml caching settings, see “Caching Elements,” on page 108.

CacheHelper Interface

Here is the CacheHelper interface:

package com.sun.appserv.web.cache;

import java.util.Map
import javax.servlet.ServletContext;
import javax.servlet.http.HttpServletRequest;

/** CacheHelper interface is an user-extensible interface to customize:
   * a) the key generation b) whether to cache the response.
   */
public interface CacheHelper {

    // name of request attributes
    public static final String ATTR_CACHE_MAPPED_SERVLET_NAME =
        "com.sun.appserv.web.cachedServletName";
    public static final String ATTR_CACHE_MAPPED_URL_PATTERN =
        "com.sun.appserv.web.cachedURLPattern";

    public static final int TIMEOUT_VALUE_NOT_SET = -2;

    /** initialize the helper
     * @param context the web application context this helper belongs to
     * @exception Exception if a startup error occurs
     */
    public void init(ServletContext context, Map props) throws Exception;

    /** getCacheKey: generate the key to be used to cache this request
     * @param request incoming <code>HttpServletRequest</code> object
     * @returns the generated key for this requested cacheable resource.
     */
    public String getCacheKey(HttpServletRequest request);

    /** isCacheable: is the response to given request cachebale?
     * @param request incoming <code>HttpServletRequest</code> object
     * @returns <code>true</code> if the response could be cached. or
     * <code>false</code> if the results of this request must not be cached.
     */
    public boolean isCacheable(HttpServletRequest request);

    /** isRefreshNeeded: is the response to given request be refreshed?
     * @param request incoming <code>HttpServletRequest</code> object
     * @returns <code>true</code> if the response needs to be refreshed.
     * or return <code>false</code> if the results of this request
     * don’t need to be refreshed.
     */
    public boolean isRefreshNeeded(HttpServletRequest request);

    /** get timeout for the cached response.
     * @param request incoming <code>HttpServletRequest</code> object
     * @returns the timeout in seconds for the cached response; a return
     * value of -1 means the response never expires and a value of -2 indicates
Caching Servlet Results

* helper cannot determine the timeout (container assigns default timeout)
*/
public int getTimeout(HttpServletRequest request);

/**
 * Stop the helper from active use
 * @exception Exception if an error occurs
 */
public void destroy() throws Exception;
}

CacheKeyGenerator Interface

The built-in default CacheHelper implementation allows web applications to customize the key generation. An application component (in a servlet or JSP) can set up a custom CacheKeyGenerator implementation as an attribute in the ServletContext.

The name of the context attribute is configurable as the value of the cacheKeyGeneratorAttrName property in the default-helper element of the sun-web.xml deployment descriptor. For more information, see “default-helper,” on page 111.

Here is the CacheKeyGenerator interface:

package com.sun.appserv.web.cache;

import javax.servlet.ServletContext;
import javax.servlet.http.HttpServletRequest;

/** CacheKeyGenerator: a helper interface to generate the key that
 *  is used to cache this request.
 *
 *  Name of the ServletContext attribute implementing the
 *  CacheKeyGenerator is configurable via a property of the
 *  default-helper in sun-web.xml:
 *  <default-helper>
 *   <property
 *    name="cacheKeyGeneratorAttrName"
 *    value="com.acme.web.MyCacheKeyGenerator" />
 *  </default-helper>
 *
 *  Caching engine looks up the specified attribute in the servlet
 *  context; the result of the lookup must be an implementation of the
 *  CacheKeyGenerator interface.
 */
public interface CacheKeyGenerator {

/** getCacheKey: generate the key to be used to cache the
 * response.
 * @param context the web application context
 * @param request incoming HttpServletRequest
 * @returns key string used to access the cache entry.
 * if the return value is null, a default key is used.
 */
 public String getCacheKey(ServletContext context,
 HttpServletRequest request);
}

About the Servlet Engine

Servlets exist in and are managed by the servlet engine in the Sun ONE Application Server. The servlet engine is an internal object that handles all servlet meta functions. These functions include instantiation, initialization, destruction, access from other components, and configuration management.

Instantiating and Removing Servlets

After the servlet engine instantiates the servlet, the servlet engine runs its `init()` method to perform any necessary initialization. Override this method to perform an initialize a function for the servlet’s life, such as initializing a counter.

When a servlet is removed from service, the server engine calls the `destroy()` method in the servlet so that the servlet can perform any final tasks and deallocate resources. Override this method to write log messages or clean up any lingering connections that won’t be caught in garbage collection.

Request Handling

When a request is made, the Sun ONE Application Server hands the incoming data to the servlet engine. The servlet engine processes the request’s input data, such as form data, cookies, session information, and URL name-value pairs, into an `HttpServletRequest` request object type.

The servlet engine also creates an `HttpServletResponse` response object type. The engine then passes both as parameters to the servlet’s `service()` method.
In an HTTP servlet, the default `service()` method routes requests to another method based on an HTTP transfer method, such as `POST`, `GET`, and so on. For example, HTTP `POST` requests are sent to the `doPost()` method, HTTP `GET` requests are sent to the `doGet()` method, and so on. This enables the servlet to process request data differently, depending on which transfer method is used. Since the routing takes place in the service method, you generally do not override `service()` in an HTTP servlet. Instead, override `doGet()`, `doPost()`, and so on, depending on the request type you expect.

To perform the tasks to answer a request, override the `service()` method for generic servlets, and the `doGet()` or `doPost()` methods for HTTP servlets. Very often, this means accessing EJB components to perform business transactions, collating the information in the request object or in a JDBC `ResultSet` object, and then passing the newly generated content to a JSP for formatting and delivery back to the user.

### Allocating Servlet Engine Resources

By default, the servlet engine creates a thread for each new request. This is less resource intensive than instantiating a new servlet copy in memory for each request. Avoid threading issues, since each thread operates in the same memory space where servlet object variables can overwrite each other.

If a servlet is specifically written as a single thread, the servlet engine creates a pool of servlet instances to be used for incoming requests. If a request arrives when all instances are busy, it is queued until an instance becomes available. The number of pool instances is configurable in the `sun-web.xml` file, in the `singleThreadedServletPoolSize` property of the `sun-web-app` element.

For more information about the `sun-web.xml` file, see Chapter 6, “Assembling and Deploying Web Modules.” For more information on threading issues, see “Handling Threading Issues,” on page 39.
This chapter describes how to use JavaServer Pages (JSPs) as page templates in a Sun ONE Application Server web application.

This chapter contains the following sections:

• Introducing JSPs
• Creating JSPs
• JSP Tag Libraries and Standard Portable Tags
• JSP Caching
• Compiling JSPs: The Command-Line Compiler
• Debugging JSPs

Introducing JSPs

JSPs are browser pages in HTML or XML. They also contain Java code, which enables them to perform complex processing, conditionalize output, and communicate with other application objects. JSPs in Sun ONE Application Server are based on the JSP 1.2 specification. This specification is accessible from install_dir/docs/index.htm; install_dir is where the Sun ONE Application Server is installed.

In a Sun ONE Application Server application, JSPs are the individual pages that make up an application. You can call a JSP from a servlet to handle the user interaction output, or, since JSPs have the same application environment access as any other application component, you can use a JSP as an interaction destination.
JSPs are made up of JSP elements and template data. Template data is anything not in the JSP specification, including text and HTML tags. For example, the minimal JSP requires no processing by the JSP engine and is a static HTML page.

The Sun ONE Application Server compiles JSPs into HTTP servlets the first time they are called (or they can be precompiled for better performance). This makes them available to the application environment as standard objects and enables them to be called from a client using a URL.

JSPs run inside the server’s JSP engine, which is responsible for interpreting JSP specific tags and performing the actions they specify in order to generate dynamic content. This content, along with any template data surrounding it, is assembled into an output page and is returned to the caller.

Creating JSPs

You create JSPs in basically the same way you create HTML files. You can use an HTML editor to create pages and edit the page layout. You make a page a JSP by inserting JSP-specific tags into the raw source code where needed, and by giving the file a .jsp extension.

JSPs that adhere to the JSP 1.2 specification follow XML syntax for the most part, which is consistent with HTML. For a summary of the JSP tags you can use, see “JSP Tag Libraries and Standard Portable Tags,” on page 55.

JSPs are compiled into servlets, so servlet design considerations also apply to JSPs. JSPs and servlets can perform the same tasks, but each excels at one task at the expense of the other. Servlets are strong in processing and adaptability. However, performing HTML output from them involves many cumbersome println statements that must be coded by hand. Conversely, JSPs excel at layout tasks because they are simply HTML files and can be created with HTML editors, though performing complex computational or processing tasks with them is awkward. For information about servlets, see Chapter 2, “Using Servlets.”

Here are a few additional JSP design tips:

• Designing for Ease of Maintenance
• Designing for Portability
• Handling Exceptions
Designing for Ease of Maintenance

Each JSP can call or include any other JSP. For example, you can create a generic corporate banner, a standard navigation bar, and a left-side column table of contents, where each element is in a separate JSP and is included for each page built. The page can be constructed with a JSP functioning as a frameset, dynamically determining the pages to load into each subframe. A JSP can also be included when the JSP is compiled into a servlet or when a request arrives.

Designing for Portability

JSPs can be completely portable between different applications and different servers. A disadvantage is that they have no particular application data knowledge, but this is only a problem if they require that kind of data.

One possible use for generic JSPs is for portable page elements, such as navigation bars or corporate headers and footers, which are meant to be included in other JSPs. You can create a library of reusable generic page elements to use throughout an application, or even among several applications.

For example, the minimal generic JSP is a static HTML page with no JSP-specific tags. A slightly less minimal JSP might contain some Java code that operates on generic data, such as printing the date and time, or that makes a change to the page’s structure based on a standard value set in the request object.

Handling Exceptions

If an uncaught exception occurs in a JSP file, Sun ONE Application Server generates an exception, usually a 404 or 500 error. To avoid this problem, set the errorPage attribute of the <%@ page %> tag.

JSP Tag Libraries and Standard Portable Tags

Sun ONE Application Server supports tag libraries and standard portable tags. For more information about tag libraries, see the JSP 1.2 specification at:

For a handy summary of JSP 1.2 tag syntax, see the following PDF file:

JSP Caching

JSP caching lets you cache JSP page fragments within the Java engine. Each can be cached using different cache criteria. For example, suppose you have page fragments to view stock quotes, weather information, and so on. The stock quote fragment can be cached for 10 minutes, the weather report fragment for 30 minutes, and so on.

For more information about response caching as it pertains to servlets, see “Caching Servlet Results,” on page 45.

JSP caching uses the custom tag library support provided by JSP 1.2. JSP caching is implemented by a tag library packaged into the install_dir/lib/appserv-tags.jar file, which you can copy into the WEB-INF/lib directory of your web application. The appserv-tags.tld tag description file is in this JAR file and in the install_dir/lib/tlds directory.

You refer to these tags in your JSP files as follows:

```jsp
<%@ taglib prefix="prefix" uri="Sun ONE Application Server Tags" %>
```

Subsequently, the cache tags are available as `<prefix:cache>` and `<prefix:flush>`. For example, if your `prefix` is `mypfx`, the cache tags are available as `<mypfx:cache>` and `<mypfx:flush>`.

If you wish to use a different URI for this tag library, you can use an explicit `<taglib>` element in your web.xml file.

The tags are as follows:

- cache
- flush

**cache**

The cache tag caches the body between the beginning and ending tags according to the attributes specified. The first time the tag is encountered, the body content is executed and cached. Each subsequent time it is run, the cached content is checked to see if it needs to be refreshed and if so, it is executed again, and the cached data is refreshed. Otherwise, the cached data is served.

**Attributes**

The following table describes attributes for the `cache` tag. The left column lists the attribute name, the middle column indicates the default value, and the right column describes what the attribute does.
Example

The following example represents a cached JSP page:

```jsp
<%@ taglib prefix="mypfx" uri="Sun ONE Application Server Tags" %>

<%
    String cacheKey = null;
    if (session != null)
        cacheKey = (String) session.getAttribute("loginId");

    // check for nocache
    boolean noCache = false;
    String nc = request.getParameter("nocache");
    if (nc != null)
        noCache = "true";

    // force reload
    boolean reload = false;
    String refresh = request.getParameter("refresh");
```
if (refresh != null)
    reload = true;
%

<myfx:cache key="<%= cacheKey %>", nocache="<%= noCache %>",
refresh="<%= reload %>", timeout="10m">
<%
    String page = request.getParameter("page");
    if (page.equals("frontPage") { // get headlines from database
        ....
    } else {
        ....
}%>
</myfx:cache>

<myfx:cache timeout="1h">
<h2>Local News</h2>
<%
    // get the headline news and cache them
    %>
</myfx:cache>

flush
Forces the cache to be flushed. If a key is specified, only the entry with that key is flushed. If no key is specified, the entire cache is flushed.

Attributes
The following table describes attributes for the flush tag. The left column lists the attribute name, the middle column indicates the default value, and the right column describes what the attribute does.

flush attributes

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Default</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>key</td>
<td>ServletPath_Suffix</td>
<td>(optional) The name used by the container to access the cached entry. The cache key is suffixed to the servlet path to generate a key to access the cached entry. If no key is specified, a number is generated according to the position of the tag in the page.</td>
</tr>
</tbody>
</table>
Examples
To flush the entry with key="foobar":

```xml
<mypfx:flush key="foobar"/>
```

To flush the entire cache:

```jsp
<% if (session != null && session.getAttribute("clearCache") != null) { %>
    <mypfx:flush />
<% } %>
```

Compiling JSPs: The Command-Line Compiler

Sun ONE Application Server provides the following ways of compiling JSP 1.2 compliant source files into servlets:

- JSPs are automatically compiled at runtime.
- The `asadmin deploy` command has a `precompilejsp` option; see the *Sun ONE Application Server Developer’s Guide*.
- The `sun-appserv-jspc` Ant task allows you to precompile JSPs; see the *Sun ONE Application Server Developer’s Guide*.
- The `jspc` command line tool, described in this section, allows you to precompile JSPs at the command line.

To allow the JSP container to pick up the precompiled JSPs from a JAR file, you must disable dynamic reloading of JSPs. To do this, set the `reload-interval` property to `-1` in the `jsp-config` element of the `sun-web.xml` file. See “JSP Elements,” on page 119.

The `jspc` command line tool is located under `install_dir/bin` (make sure this directory is in your path). The format of the `jspc` command is as follows:

```bash
jspc [options] file_specifier
```

The following table shows what `file_specifier` can be in the `jspc` command. The left column lists file specifiers, and the right column lists descriptions of those file specifiers.

File specifiers for the `jspc` command

<table>
<thead>
<tr>
<th>File Specifier</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>files</code></td>
<td>One or more JSP files to be compiled.</td>
</tr>
</tbody>
</table>
File specifiers for the jspc command

<table>
<thead>
<tr>
<th>File Specifier</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-webapp dir</td>
<td>A directory containing a web application. All JSPs in the directory and its subdirectories are compiled. You cannot specify a WAR, JAR, or ZIP file; you must first extract it to an open directory structure.</td>
</tr>
</tbody>
</table>

The following table shows the basic options for the jspc command. The left column lists options, and the right column lists descriptions of those options.

Basic jspc options

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-q</td>
<td>Enables quiet mode (same as -v0). Only fatal error messages are displayed.</td>
</tr>
<tr>
<td>-d dir</td>
<td>Specifies the output directory for the compiled JSPs. Package directories are automatically generated based on the directories containing the uncompiled JSPs. The default top-level directory is the directory from which jspc is invoked.</td>
</tr>
<tr>
<td>-p name</td>
<td>Specifies the name of the target package for all specified JSPs, overriding the default package generation performed by the -d option.</td>
</tr>
<tr>
<td>-c name</td>
<td>Specifies the target class name of the first JSP compiled. Subsequent JSPs are unaffected.</td>
</tr>
<tr>
<td>-uribase dir</td>
<td>Specifies the URI directory to which compilations are relative. Applies only to JSP files listed in the command, and not to JSP files specified with -webapp. This is the location of each JSP file relative to the uriroot. If this cannot be determined, the default is /.</td>
</tr>
<tr>
<td>-urioot dir</td>
<td>Specifies the root directory against which URI files are resolved. Applies only to JSP files listed in the command, and not to JSP files specified with -webapp. If this option is not specified, all parent directories of the first JSP page are searched for a WEB-INF subdirectory. The closest directory to the JSP page that has one is used. If none of the JSP’s parent directories have a WEB-INF subdirectory, the directory from which jspc is invoked is used.</td>
</tr>
</tbody>
</table>
The following table shows the advanced options for the \texttt{jspc} command. The left column lists options, and the right column lists descriptions of those options.

**Advanced \texttt{jspc} options**

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>\texttt{-v[level]}</td>
<td>Enables verbose mode. The \textit{level} is optional; the default is 2. Possible \textit{level} values are:</td>
</tr>
<tr>
<td></td>
<td>• 0 - fatal error messages only</td>
</tr>
<tr>
<td></td>
<td>• 1 - error messages only</td>
</tr>
<tr>
<td></td>
<td>• 2 - error and warning messages only</td>
</tr>
<tr>
<td></td>
<td>• 3 - error, warning, and informational messages</td>
</tr>
<tr>
<td></td>
<td>• 4 - error, warning, informational, and debugging messages</td>
</tr>
<tr>
<td>\texttt{-mapped}</td>
<td>Generates separate \texttt{write} calls for each HTML line and comments that describe the location of each line in the JSP file. By default, all adjacent \texttt{write} calls are combined and no location comments are generated.</td>
</tr>
<tr>
<td>\texttt{-die[code]}</td>
<td>Returns the error number specified by \textit{code} if an error occurs. If the \textit{code} is absent or unparsable it defaults to 1.</td>
</tr>
<tr>
<td>\texttt{-webinc file}</td>
<td>Creates partial servlet mappings for the \texttt{-webapp} option, which can be pasted into a \texttt{web.xml} file.</td>
</tr>
<tr>
<td>\texttt{-webxml file}</td>
<td>Creates an entire \texttt{web.xml} file for the \texttt{-webapp} option.</td>
</tr>
<tr>
<td>\texttt{-ieplugin class_id}</td>
<td>Specifies the Java plugin COM class ID for Internet Explorer. Used by the \texttt{<a href="">jsp:plugin</a>} tags.</td>
</tr>
</tbody>
</table>

For example, this command compiles the \texttt{hello} JSP file and writes the compiled JSP under \texttt{hellodir}:

```
jspc -d hellodir -genclass hello.jsp
```
Debugging JSPs

This command compiles all the JSP files in the web application under `webappdir` into class files under `jspclassdir`:

```
jspc -d jspclassdir -genclass -webapp webappdir
```

To use either of these precompiled JSPs in a web application, put the classes under `hellodir` or `jspclassdir` into a JAR file, place the JAR file under `WEB-INF/lib`, and set the `reload-interval` property to `-1` in the `sun-web.xml` file.

Debugging JSPs

When you use Sun ONE Studio 4 to debug JSPs, you can set breakpoints in either the JSP code or the generated servlet code, and you can switch between them and see the same breakpoints in both.

To set up debugging in Sun ONE Studio, see the *Sun ONE Application Server Developer's Guide*. For further details, see the *Sun ONE Studio 4, Enterprise Edition Tutorial*. 
Creating and Managing User Sessions

Introducing Sessions

The term user session refers to a series of user application interactions that are tracked by the server. Sessions are used for maintaining user specific state, including persistent objects (like handles to EJB components or database result sets) and authenticated user identities, among many interactions. For example, a session could be used to track a validated user login followed by a series of directed activities for a particular user.

The session itself resides in the server. For each request, the client transmits the session ID in a cookie or, if the browser does not allow cookies, the server automatically writes the session ID into the URL.

The Sun ONE Application Server supports the servlet standard session interface, called HttpSession, for all session activities. This interface enables you to write portable, secure servlets.
Introducing Sessions

Sessions and Cookies

A cookie is a small collection of information that can be transmitted to a calling browser, which retrieves it on each subsequent call from the browser so that the server can recognize calls from the same client. A cookie is returned with each call to the site that created it, unless it expires.

Sessions are maintained automatically by a session cookie that is sent to the client when the session is first created. The session cookie contains the session ID, which identifies the client to the browser on each successive interaction. If a client does not support or allow cookies, the server rewrites the URLs where the session ID appears in the URLs from that client.

You can configure whether and how sessions use cookies. See the session-properties and cookie-properties elements in the sun-web.xml file, described in Chapter 6, “Assembling and Deploying Web Modules.”

Sessions and URL Rewriting

There are two situations in which the Sun ONE Application Server plugin performs implicit URL rewriting:

- When a response comes back from the Sun ONE Application Server; if implicit URL rewriting has been chosen, the plugin rewrites the URLs in the response before passing the response on to the client.

- When the request given by a client need not be sent to the Sun ONE Application Server and can be served on the web server side. Such requests may occur in the middle of a session and the response may need to be rewritten.

You can configure whether sessions use URL rewriting. See the session-properties element in the sun-web.xml file, described in Chapter 6, “Assembling and Deploying Web Modules.”

Sessions and Security

The Sun ONE Application Server security model is based on an authenticated user session. Once a session has been created the application user is authenticated (if authentication is used) and logged in to the session. Each interaction step from the servlet that receives an EJB request does two things: generates content for a JSP to format the output, and checks that the user is properly authenticated.
Additionally, you can specify that a session cookie is only passed on a secured connection (that is, HTTPS), so the session can only remain active on a secure channel.

For more information about security, see Chapter 5, “Securing Web Applications.”

How to Use Sessions

To use a session, first create a session using the HttpServletRequest method getSession(). Once the session is established, examine and set its properties using the provided methods. If desired, set the session to time out after being inactive for a defined time period or invalidate it manually. You can also bind objects to the session which store them for use by other components.

Creating or Accessing a Session

To create a new session or to gain access to an existing session, use the HttpServletRequest method getSession(), as shown in the following example:

```java
HttpSession mySession = request.getSession();
getSession() returns the valid session object associated with the request, identified in the session cookie which is encapsulated in the request object. Calling the method with no arguments, creates a session if one does not already exist which is associated with the request. Additionally, calling the method with a Boolean argument creates a session only if the argument is true.

The following example shows the doPost() method from a servlet which only performs the servlet’s main functions, if the session is present. Note that, the false parameter to getSession() prevents the servlet from creating a new session if one does not already exist:

```java
public void doPost (HttpServletRequest req, HttpServletResponse res) throws ServletException, IOException {
    if ( HttpSession session = req.getSession (false)  ) {
        // session retrieved, continue with servlet operations
    } else
```
// no session, return an error page

NOTE The `getSession()` method should be called before anything is written to the response stream. Otherwise the `SetCookie` string is placed in the HTTP response body instead of the HTTP header.

For more information about `getSession()`, see the Java Servlet Specification v2.3.

## Examining Session Properties

Once a session ID has been established, use the methods in the `HttpSession` interface to examine session properties, and methods in the `HttpServletRequest` interface to examine request properties that relate to the session.

The following table shows the methods to examine session properties. The left column lists `HttpSession` methods, and the right column lists descriptions of these methods.

<table>
<thead>
<tr>
<th>HttpSession Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>getCreationTime()</code></td>
<td>Returns the session time in milliseconds since January 1, 1970, 00:00:00 GMT.</td>
</tr>
<tr>
<td><code>getId()</code></td>
<td>Returns the assigned session identifier. An HTTP session's identifier is a unique string which is created and maintained by the server.</td>
</tr>
<tr>
<td><code>getLastAccessedTime()</code></td>
<td>Returns the last time the client sent a request carrying the assigned session identifier (or -1 if its a new session) in milliseconds since January 1, 1970, 00:00:00 GMT.</td>
</tr>
<tr>
<td><code>isNew()</code></td>
<td>Returns a Boolean value indicating if the session is new. Its a new session, if the server has created it and the client has not sent a request to it. This means, the client has not <code>acknowledged</code> or <code>joined</code> the session and may not return the correct session identification information when making its next request.</td>
</tr>
</tbody>
</table>
For example:

```java
String mySessionID = mySession.getId();
if (mySession.isNew()) {
    log.println(currentDate);
    log.println("client has not yet joined session " + mySessionID);
}
```

The following table shows the methods to examine servlet request properties. The left column lists `HttpServletRequest` methods, and the right column lists descriptions of these methods.

<table>
<thead>
<tr>
<th>HttpServletRequest Methods</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>getRemoteUser()</code></td>
<td>Gets the requesting user name (HTTP authentication can provide the information). Returns null if the request has no user name information.</td>
</tr>
<tr>
<td><code>getRequestedSessionId()</code></td>
<td>Returns the session ID specified with the request. This may differ from the session ID in the current session if the session ID given by the client is invalid and a new session was created. Returns null if the request does not have a session associated with it.</td>
</tr>
<tr>
<td><code>isRequestedSessionIdValid()</code></td>
<td>Checks if the request is associated to a currently valid session. If the session requested is not valid, it is not returned through the <code>getSession()</code> method.</td>
</tr>
<tr>
<td><code>isRequestedSessionIdFromCookie()</code></td>
<td>Returns true if the request’s session ID provided by the client is a cookie, or false otherwise.</td>
</tr>
<tr>
<td><code>isRequestedSessionIdFromURL()</code></td>
<td>Returns true if the request’s session ID provided by the client is a part of a URL, or false otherwise.</td>
</tr>
</tbody>
</table>

For example:

```java
if (request.isRequestedSessionIdValid()) {
    if (request.isRequestedSessionIdFromCookie()) {
        // this session is maintained in a session cookie
    }
    // any other tasks that require a valid session
} else {
    // log an application error
}
```
How to Use Sessions

Binding Data to a Session

You can bind objects to sessions in order to make them available across multiple user interactions.

The following table shows the HttpSession methods that provide support for binding objects to the session object. The left column lists HttpSession methods, and the right column lists descriptions of these methods.

<table>
<thead>
<tr>
<th>HttpSession Methods</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>getAttribute()</td>
<td>Returns the object bound to a given name in the session or null if there is no such binding.</td>
</tr>
<tr>
<td>getAttributeNames()</td>
<td>Returns an array of names of all attributes bound to the session.</td>
</tr>
<tr>
<td>setAttribute()</td>
<td>Binds the specified object into the session with the given name. Any existing binding with the same name is overwritten. For an object bound into the session to be distributed it must implement the Serializable interface.</td>
</tr>
<tr>
<td>removeAttribute()</td>
<td>Unbinds an object in the session with the given name. If there is no object bound to the given name this method does nothing.</td>
</tr>
</tbody>
</table>

Binding Notification with HttpSessionBindingListener

Some objects require you to know when they are placed in or removed from, a session. To obtain this information, implement the HttpSessionBindingListener interface in those objects. When your application stores or removes data with the session, the servlet engine checks whether the object being bound or unbound implements HttpSessionBindingListener. If it does, the Sun ONE Application Server notifies the object under consideration, through the HttpSessionBindingListener interface, that it is being bound into or unbound from the session.

Invalidating a Session

Specify the session to invalidate itself automatically after being inactive for a defined time period. Alternatively, invalidate the session manually with the HttpSession method invalidate().
Invalidating a Session Manually

To invalidate a session manually, simply call the following method:

```java
session.invalidate();
```

All objects bound to the session are removed.

Setting a Session Timeout

Session timeout is set using the `sun-web.xml` deployment descriptor file. For more information, see the `session-properties` element in Chapter 6, “Assembling and Deploying Web Modules.”

Session Managers

A session manager automatically creates new session objects whenever a new session starts. In some circumstances, clients do not join the session, for example, if the session manager uses cookies and the client does not accept cookies.

Sun ONE Application Server 7 gives you these session management options:

- `StandardManager`, the default session manager
- `PersistentManager`, a provided session manager that uses a persistent data store

### Tip

The session API does not provide an explicit session logout API, so any logout implementation must call the `session.invalidate()` API.

### Note

The session manager interface is Unstable. An unstable interface may be experimental or transitional, and hence may change incompatibly, be removed, or be replaced by a more stable interface in the next release.
StandardManager

The StandardManager is the default session manager.

Enabling StandardManager

You may want to specify StandardManager explicitly to change its default parameters. To do so, edit the sun-web.xml file for the web application as in the following example.

```xml
<sun-web-app>
  ...
  <session-config>
    <session-manager>
      <manager-properties>
        <property name="reapIntervalSeconds" value="20" />
      </manager-properties>
    </session-manager>
  ...
  </session-config>
  ...
</sun-web-app>
```

For more information about the sun-web.xml file, see Chapter 6, “Assembling and Deploying Web Modules.”

Manager Properties for StandardManager

The following table describes manager-properties properties for the StandardManager session manager. The left column lists the property name, the middle column indicates the default value, and the right column describes what the property does.

<table>
<thead>
<tr>
<th>Property Name</th>
<th>Default Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>reapIntervalSeconds</td>
<td>60</td>
<td>Specifies the number of seconds between checks for expired sessions.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Setting this value lower than the frequency at which session data changes is</td>
</tr>
<tr>
<td></td>
<td></td>
<td>recommended. For example, this value should be as low as possible (1 second)</td>
</tr>
<tr>
<td></td>
<td></td>
<td>for a hit counter servlet on a frequently accessed website, or you could</td>
</tr>
<tr>
<td></td>
<td></td>
<td>lose the last few hits each time you restart the server.</td>
</tr>
</tbody>
</table>
PersistentManager

The PersistentManager is the other session manager provided with Sun ONE Application Server. For session persistence, PersistentManager can use a file, to which each session is serialized. You can also create your own persistence mechanism.

Enabling PersistentManager

You may want to specify PersistentManager explicitly to change its default parameters. To do so, edit the sun-web.xml file for the web application as in the following example. Note that persistence-type must be set to file.

```xml
<sun-web-app>
    ...
    <session-config>
        <session-manager persistence-type=file>
            <manager-properties>
                <property name=reapIntervalSeconds value=20 />
            </manager-properties>
            <store-properties>
                <property name=directory value=sessions />
            </store-properties>
        </session-manager>
    ...
    </session-config>
    ...
</sun-web-app>
```

For more information about the sun-web.xml file, see Chapter 6, “Assembling and Deploying Web Modules.”
Manager Properties for PersistentManager

The following table describes `manager-properties` properties for the PersistentManager session manager. The left column lists the property name, the middle column indicates the default value, and the right column describes what the property does.

<table>
<thead>
<tr>
<th>Property Name</th>
<th>Default Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>reapIntervalSeconds</td>
<td>60</td>
<td>Specifies the number of seconds between checks for expired sessions. Setting this value lower than the frequency at which session data changes is recommended. For example, this value should be as low as possible (1 second) for a hit counter servlet on a frequently accessed website, or you could lose the last few hits each time you restart the server.</td>
</tr>
<tr>
<td>maxSessions</td>
<td>-1</td>
<td>Specifies the maximum number of active sessions, or -1 (the default) for no limit.</td>
</tr>
</tbody>
</table>

Store Properties for PersistentManager

The following table describes `store-properties` properties for the PersistentManager session manager. The left column lists the property name, the middle column indicates the default value, and the right column describes what the property does.

<table>
<thead>
<tr>
<th>Property Name</th>
<th>Default Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>reapIntervalSeconds</td>
<td>60</td>
<td>Specifies the number of seconds between checks for expired sessions for those sessions that are currently swapped out. Setting this value lower than the frequency at which session data changes is recommended. For example, this value should be as low as possible (1 second) for a hit counter servlet on a frequently accessed website, or you could lose the last few hits each time you restart the server.</td>
</tr>
</tbody>
</table>
### store-properties properties

<table>
<thead>
<tr>
<th>Property Name</th>
<th>Default Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>directory</td>
<td>directory specified by javax.servlet. context.tempdir context attribute</td>
<td>Specifies the absolute or relative pathname of the directory into which individual session files are written. A relative path is relative to the temporary work directory for this web application.</td>
</tr>
</tbody>
</table>
This chapter describes how to write a secure web application for the Sun ONE Application Server with components that perform user authentication and access authorization.

This chapter contains the following sections:

- User Authentication by Servlets
- User Authentication for Single Sign-on
- User Authorization by Servlets
- Fetching the Client Certificate
- Security for SHTML and CGI

User Authentication by Servlets

The web-based login mechanisms required by the J2EE Specification, v1.3 are supported by the Sun ONE Application Server. These mechanisms include:

- HTTP Basic Authentication
- SSL Mutual Authentication
- Form-Based Login

The <login-config> element in the web.xml deployment descriptor file describes the authentication method used, the application’s realm name displayed by the HTTP basic authentication, and the form login mechanism’s attributes.

The <login-config> element syntax is as follows:

```xml
<!ELEMENT login-config
(auth-method?,realm-name?,form-login-config?)>
```
For more information regarding web.xml elements, see Chapter 13, “Deployment Descriptor,” of the Java Servlet Specification, v2.3.

For more information regarding sun-web.xml elements, see Chapter 6, “Assembling and Deploying Web Modules.”

For information about programmatic login, see the Sun ONE Application Server Developer’s Guide.

HTTP Basic Authentication

HTTP basic authentication (RFC2068) is supported by the Sun ONE Application Server. Because passwords are sent with base64 encoding, this authentication type is not very secure. Use of SSL or another equivalent transport encryption is recommended to protect the password during transmission.

SSL Mutual Authentication

Secure Socket Layer (SSL) 3.0 and the means to perform mutual (client/server) certificate-based authentication is a J2EE Specification, v1.3 requirement. This security mechanism provides user authentication using HTTPS (HTTP over SSL).

The Sun ONE Application Server SSL mutual authentication mechanism (also known as HTTPS authentication) supports the following cipher suites:

- SSL_RSA_EXPORT_WITH_RC4_40_MD5
- SSL_RSA_EXPORT_WITH_RC2_CBC_40_MD5
- SSL_RSA_EXPORT_WITH_DES40_CBC_SHA
- SSL_DH_DSS_EXPORT_WITH_DES40_CBC_SHA
- SSL_DH_RSA_EXPORT_WITH_DES40_CBC_SHA
- SSL_DHE_DSS_EXPORT_WITH_DES40_CBC_SHA
- SSL_DHE_RSA_EXPORT_WITH_DES40_CBC_SHA

NOTE
The auth-method subelement of login-config is officially optional, but if it is not included, the server defaults to HTTP Basic Authentication, which is not very secure.
Form-Based Login

The login screen’s look and feel cannot be controlled with the HTTP browser’s built-in mechanisms. J2EE introduces the ability to package a standard HTML or Servlet/JSP based form for logging in. The login form is associated with a web protection domain (an HTTP realm) and is used to authenticate previously unauthenticated users.

Because passwords are sent in the clear (unless protected by the underlying transport), this authentication type is not very secure. Use of SSL or another equivalent transport encryption is recommended to protect the password during transmission.

In order for the authentication to proceed appropriately, the login form action must always be `j_security_check`.

The following is an HTML sample showing how to program the form in an HTML page:

```html
<form method="POST" action="j_security_check">
  <input type="text" name="j_username">
  <input type="password" name="j_password">
</form>
```

You can specify the parameter encoding for the form. For details, see “parameter-encoding,” on page 123.

User Authentication for Single Sign-on

The single sign-on across applications on the Sun ONE Application Server is supported by the Sun ONE Application Server servlets and JSPs. This feature allows multiple applications that require the same user sign-on information to share this information between them, rather than having the user sign-on separately for each application. These applications are created to authenticate the user one time, and when needed this authentication information is propagated to all other involved applications.

An example application using the single sign-on scenario could be a consolidated airline booking service that searches all airlines and provides links to different airline web sites. Once the user signs on to the consolidated booking service, the user information can be used by each individual airline site without requiring another sign-on.
Single sign-on operates according to the following rules:

- Single sign-on applies to web applications configured for the same realm and virtual server. The realm is defined by the `realm-name` element in the `web.xml` file. For information about virtual servers, see the *Sun ONE Application Server Administrator’s Guide* or the *Sun ONE Application Server Administrator’s Configuration File Reference*.

- As long as users access only unprotected resources in any of the web applications on a virtual server, they are not challenged to authenticate themselves.

- As soon as a user accesses a protected resource in any web application associated with a virtual server, the user is challenged to authenticate himself or herself, using the login method defined for the web application currently being accessed.

- Once authenticated, the roles associated with this user are used for access control decisions across all associated web applications, without challenging the user to authenticate to each application individually.

- When the user logs out of one web application (for example, by invalidating or timing out the corresponding session if form based login is used), the user’s sessions in all web applications are invalidated. Any subsequent attempt to access a protected resource in any application requires the user to authenticate himself or herself again.

The single sign-on feature utilizes HTTP cookies to transmit a token that associates each request with the saved user identity, so it can only be used in client environments that support cookies.

To configure single sign-on, set the following properties in the `virtual-server` element of the `server.xml` file:

- `sso-enabled` - If false, single sign-on is disabled for this virtual server, and users must authenticate separately to every application on the virtual server. The default is true.

- `sso-max-inactive-seconds` - Specifies the time after which a user’s single sign-on record becomes eligible for purging if no client activity is received. Since single sign-on applies across several applications on the same virtual server, access to any of the applications keeps the single sign-on record active. The default value is 5 minutes (300 seconds). Higher values provide longer single sign-on persistence for the users at the expense of more memory use on the server.
User Authorization by Servlets

Servlets can be configured to only permit access to users with the appropriate authorization level. This section covers the following topics:

- Defining Roles
- Defining Servlet Authorization Constraints

Defining Roles

You define roles in the J2EE deployment descriptor file, web.xml, and the corresponding role mappings in the Sun ONE Application Server deployment descriptor file, sun-application.xml (or sun-web.xml for individually deployed web modules). For more information about sun-web.xml, see Chapter 6, "Assembling and Deploying Web Modules."

Each security-role-mapping element in the sun-application.xml or sun-web.xml file maps a role name permitted by the web application to principals and groups. For example, a sun-web.xml file for an individually deployed web module might contain the following:

```
<security-role-mapping>
    <role-name>manager</role-name>
    <principal-name>jgarcia</principal-name>
    <principal-name>mwebster</principal-name>
    <group-name>team-leads</group-name>
</security-role-mapping>
```
<role-name>administrator</role-name>
<principal-name>dsmith</principal-name>
</security-role-mapping>
</sun-web-app>

Note that the role-name in this example must match the role-name in the security-role element of the corresponding web.xml file.

Note that for J2EE applications (EAR files), all security role mappings for the application modules must be specified in the sun-application.xml file. For individually deployed web modules, the roles are always specified in the sun-web.xml file. A role can be mapped to either specific principals or to groups (or both). The principal or group names used must be valid principals or groups in the current default realm.

**Defining Servlet Authorization Constraints**

On the servlet level, you define access permissions using the auth-constraint element of the web.xml file. The auth-constraint element on the resource collection must be used to indicate the user roles permitted to the resource collection. Refer to the Servlet specification for details on configuring servlet authorization constraints.

**Fetching the Client Certificate**

When you enable SSL and require client certificate authorization, your servlets have access to the client certificate as shown in the following example:

```java
if (request.isSecure()) {
    java.security.cert.X509Certificate[] certs;
    certs = request.getAttribute("javax.servlet.request.X509Certificate");
    if (certs != null) {
        clientCert = certs[0];
        if (clientCert != null) {
            // Get the Distinguished Name for the user.
            java.security.Principal userDN = clientCert.getSubjectDN();
            ...
        }
    }
}
```

The userDN is the fully qualified Distinguished Name for the user.
Security for SHTML and CGI

For security, server-parsed HTML tags and CGI scripts depend on the server’s security configuration. The following J2EE-only security features are not available for server-parsed HTML tags and CGI scripts:

- J2EE realms
- J2EE roles
- Form-based login
- Single sign-on
- Programmatic login
- J2EE authorization constraints

For more information about the server’s security configuration, see the Sun ONE Application Server Administrator’s Guide to Security.
Security for SHTML and CGI
This chapter describes how web modules are assembled and deployed in Sun ONE Application Server. For general assembly and deployment information, see the Sun ONE Application Server Developer’s Guide.

The following topics are presented in this chapter:

* Web Application Structure
* Creating Web Deployment Descriptors
* Deploying Web Applications
* Dynamic Reloading of Web Applications
* The sun-web-app_2_3-0.dtd File
* Elements in the sun-web.xml File
* Sample Web Module XML Files
Web Application Structure

Web Applications have a directory structure, all accessible from a mapping to the application’s document root (for example, /hello). The document root contains JSP files, HTML files, and static files such as image files.

A WAR (web application archive) file contains a complete web application in compressed form.

A special directory under the document root, WEB-INF, contains everything related to the application that is not in the public document tree of the application. No file contained in WEB-INF can be served directly to the client. The contents of WEB-INF include:

- /WEB-INF/classes/*, the directory for servlet and other classes.
- /WEB-INF/lib/*.jar, the directory for JAR files containing beans and other utility classes.
- /WEB-INF/web.xml and /WEB-INF/sun-web.xml, XML-based deployment descriptors that specify the web application configuration, including mappings, initialization parameters, and security constraints.

The web application directory structure follows the structure outlined in the J2EE specification. Here is an example directory structure of a simple web application.

```
+ hello/
  |--- index.jsp
  |--- META-INF/
  |   |--- MANIFEST.MF
  |--- WEB-INF/
      |--- web.xml
      |--- sun-web.xml
```
Here is an example directory structure of a simple J2EE application containing a web module.

```plaintext
+ converter_1/
  |-- converterClient.jar
  |   +-- META-INF/
  |       |-- MANIFEST.MF
  |       |-- application.xml
  |       `-- sun-application.xml
  `-- war-ic_war/
      |-- index.jsp
      |   +-- META-INF/
      |       |-- MANIFEST.MF
      |       `-- WEB-INF/
      |           |-- web.xml
      |           `-- sun-web.xml
  `-- ejb-jar-ic_jar/
      |-- Converter.class
      |-- ConverterBean.class
      |-- ConverterHome.class
        +-- META-INF/
        |   |-- MANIFEST.MF
        |   |-- ejb-jar.xml
        |   `-- sun-ejb-jar.xml
        `-- app-client-ic_jar/
            |-- ConverterClient.class
            +-- META-INF/
                |-- MANIFEST.MF
                |-- application-client.xml
                `-- sun-application-client.xml
```

**Creating Web Deployment Descriptors**

Sun ONE Application Server web modules include two deployment descriptor files:

- A J2EE standard file (`web.xml`), described in the Java Servlet Specification, v2.3, Chapter 13, “Deployment Descriptors.” You can find the specification here:
  

- An optional Sun ONE Application Server specific file (`sun-web.xml`), described in this chapter.
Deploying Web Applications

The easiest way to create the web.xml and sun-web.xml files is to deploy a web module using the Administration interface or Sun ONE Studio 4. For more information, see the next section or the Sun ONE Application Server Developer’s Guide. For example web.xml and sun-web.xml files, see “Sample Web Module XML Files,” on page 124.

After you have created these files, you can edit them using the Administration interface or a combination of an editor and command line utilities such as Ant to reassemble and redeploy the updated deployment descriptor information. Apache Ant 1.4.1 is provided with Sun ONE Application Server. For more information, see the Sun ONE Application Server Developer’s Guide.

Deploying Web Applications

When you deploy, undeploy, or redeploy a web application, you do not need to restart the server. In other words, deployment is dynamic.

You can deploy a web application in these ways, which are described briefly:

- Using the Command Line
- Using the Administration Interface
- Using Sun ONE Studio

For more detailed information about deployment, see the Sun ONE Application Server Developer’s Guide.

You can keep the generated source for JSPs by adding the -keepgenerated property to the jsp-config element in sun-web.xml. If you include this property when you deploy the web application, the generated source is kept in instance_dir/generated/jsp/j2ee-apps/app_name/module_name if it is in an application or instance_dir/generated/jsp/j2ee-modules/module_name if it is in an individually deployed web module.

Using the Command Line

To deploy a web application using the command line:

1. Edit the deployment descriptor files (web.xml and sun-web.xml) by hand.
2. Execute an Ant build command (such as build war) to reassemble the WAR module.
3. Write the web application to a WAR file if desired. This is optional. For example:

```
jar -cvf module_name.war *
```

4. Use the `asadmin deploy` command to deploy the WAR module. The syntax is as follows:

```
```

For example, the following command deploys a web application as an individual module:

```
asadmin deploy --user jadams --password secret --host localhost --port 4848 --type web --instance server1 myWebApp.war
```

If `upload` is set to `false`, the `filepath` must be an absolute path on the server machine.

### Using the Administration Interface

To deploy a web application using the Administration interface:

1. Open the Applications component under your server instance.
2. Go to the Web Applications page.
3. Click on the Deploy button.
4. Enter the full path to the WAR module (or click on Browse to find it), then click on the OK button.
5. Enter the web application name and the context root.

   You can also redeploy the web application if it already exists by checking the appropriate box. This is optional.

6. Assign the web application to one or more virtual servers by checking the boxes next to the virtual server names.
7. Click on the OK button.
Using Sun ONE Studio

You can use Sun ONE Studio 4, to assemble and deploy web applications. For more information about using Sun ONE Studio, see the Sun ONE Studio 4, Enterprise Edition Tutorial.

NOTE In Sun ONE Studio, deploying web application is referred to as executing it.

Dynamic Reloading of Web Applications

If you make code changes to a web application and dynamic reloading is enabled, you do not need to redeploy the web application or restart the server. To enable dynamic reloading, you can do one of the following:

• Use the Administration interface:
  a. Open the Applications component under your server instance.
  b. Go to the Applications page.
  c. Check the Reload Enabled box to enable dynamic reloading.
  d. Enter a number of seconds in the Reload Poll Interval field to set the interval at which applications and modules are checked for code changes and dynamically reloaded.
  e. Click on the Save button.
  f. Go to the server instance page and select the Apply Changes button.

For details, see the Sun ONE Application Server Administrator’s Guide.

• Edit the following attributes of the server.xml file’s applications element, then restart the server:
  o dynamic-reload-enabled="true" enables dynamic reloading.
  o dynamic-reload-poll-interval-in-seconds sets the interval at which applications and modules are checked for code changes and dynamically reloaded.

For details about server.xml, see the Sun ONE Application Server Administrator’s Configuration File Reference.
In addition, to load new servlet files, reload EJB related changes, or reload deployment descriptor changes, you must do the following:

1. Create an empty file named `.reload` at the root of the deployed application:
   
   ```
   instance_dir/applications/j2ee-apps/app_name/.reload
   ```
   or individually deployed module:
   
   ```
   instance_dir/applications/j2ee-modules/module_name/.reload
   ```

2. Explicitly update the `.reload` file’s timestamp (`touch .reload` in UNIX) each time you make the above changes.

For JSPs, changes are reloaded automatically at a frequency set in the `reload-interval` property of the `jsp-config` element in the `sun-web.xml` file. To disable dynamic reloading of JSPs, set the `reload-interval` property to `-1`.

---

**The sun-web-app_2_3-0.dtd File**

The `sun-web-app_2_3-0.dtd` file defines the structure of the `sun-web.xml` file, including the elements it can contain and the subelements and attributes these elements can have. The `sun-web-app_2_3-0.dtd` file is located in the `install_dir/lib/dtds` directory.

**NOTE**

Do not edit the `sun-web-app_2_3-0.dtd` file; its contents change only with new versions of Sun ONE Application Server.

---

For general information about DTD files and XML, see the XML specification at:

[http://www.w3.org/TR/REC-xml](http://www.w3.org/TR/REC-xml)

Each element defined in a DTD file (which may be present in the corresponding XML file) can contain the following:

- Subelements
- Data
- Attributes
Subelements

Elements can contain subelements. For example, the following file fragment defines the cache element.

```xml
<!ELEMENT cache (cache-helper*, default-helper?, property*, cache-mapping*)>
```

The `ELEMENT` tag specifies that a cache element can contain cache-helper, default-helper, property, and cache-mapping subelements.

The following table shows how optional suffix characters of subelements determine the requirement rules, or number of allowed occurrences, for the subelements. The left column lists the subelement ending character, and the right column lists the corresponding requirement rule.

<table>
<thead>
<tr>
<th>Subelement Suffix</th>
<th>Requirement Rule</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>element*</code></td>
<td>Can contain zero or more of this subelement.</td>
</tr>
<tr>
<td><code>element?</code></td>
<td>Can contain zero or one of this subelement.</td>
</tr>
<tr>
<td><code>element+</code></td>
<td>Must contain one or more of this subelement.</td>
</tr>
<tr>
<td><code>element</code> (no suffix)</td>
<td>Must contain only one of this subelement.</td>
</tr>
</tbody>
</table>

If an element cannot contain other elements, you see `EMPTY` or `(#PCDATA)` instead of a list of element names in parentheses.

Data

Some elements contain character data instead of subelements. These elements have definitions of the following format:

```xml
<!ELEMENT element-name (#PCDATA)>
```

For example:

```xml
<!ELEMENT description (#PCDATA)>
```

In the `sun-web.xml` file, white space is treated as part of the data in a data element. Therefore, there should be no extra white space before or after the data delimited by a data element. For example:

```xml
<description>class name of session manager</description>
```
Attributes

Elements that have `ATTLIST` tags contain attributes (name-value pairs). For example:

```
<!ATTLIST cache max-capacity CDATA "4096"
 timeout CDATA "30"
 enabled %boolean; "false">
```

A `cache` element can contain `max-capacity`, `timeout`, and `enabled` attributes.

The `#REQUIRED` label means that a value must be supplied. The `#IMPLIED` label means that the attribute is optional, and that Sun ONE Application Server generates a default value. Wherever possible, explicit defaults for optional attributes (such as "true") are listed.

Attribute declarations specify the type of the attribute. For example, `CDATA` means character data, and `%boolean` is a predefined enumeration.

Elements in the sun-web.xml File

This section describes the XML elements in the `sun-web.xml` file. Elements are grouped as follows:

- General Elements
- Security Elements
- Session Elements
- Reference Elements
- Caching Elements
- Classloader Elements
- JSP Elements
- Internationalization Elements

**NOTE** Subelements must be defined in the order in which they are listed under each Subelements heading unless otherwise noted.
General Elements

General elements are as follows:

- sun-web-app
- property
- description

**sun-web-app**

Defines Sun ONE Application Server specific configuration for a web module. This is the root element; there can only be one sun-web-app element in a sun-web.xml file.

**Subelements**

The following table describes subelements for the sun-web-app element. The left column lists the subelement name, the middle column indicates the requirement rule, and the right column describes what the element does.

<table>
<thead>
<tr>
<th>Element</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>security-role-mapping</td>
<td>zero or more</td>
<td>Maps roles to users or groups in the currently active realm.</td>
</tr>
<tr>
<td>servlet</td>
<td>zero or more</td>
<td>Specifies a principal name for a servlet, which is used for the run-as role defined in web.xml.</td>
</tr>
<tr>
<td>session-config</td>
<td>zero or one</td>
<td>Specifies session manager, session cookie, and other session-related information.</td>
</tr>
<tr>
<td>resource-env-ref</td>
<td>zero or more</td>
<td>Maps the absolute JNDI name to the resource-env-ref in the corresponding J2EE XML file.</td>
</tr>
<tr>
<td>resource-ref</td>
<td>zero or more</td>
<td>Maps the absolute JNDI name to the resource-ref in the corresponding J2EE XML file.</td>
</tr>
<tr>
<td>ejb-ref</td>
<td>zero or more</td>
<td>Maps the absolute JNDI name to the ejb-ref in the corresponding J2EE XML file.</td>
</tr>
<tr>
<td>cache</td>
<td>zero or one</td>
<td>Configures caching for web application components.</td>
</tr>

<td>Specifies the maximum number of servlet instances allocated for each SingleThreadModel servlet in the web application.</td>
</tr>
</tbody>
</table>

Chapter 6  Assembling and Deploying Web Modules  93
**property**

Specifies a property, which has a name and a value. A property adds configuration information to its parent element that is one or both of the following:

- Optional with respect to Sun ONE Application Server
- Needed by a system or object that Sun ONE Application Server doesn’t have knowledge of, such as an LDAP server or a Java class

For example, a `manager-properties` element can include `property` subelements:

```xml
<manager-properties>
  <property name="reapIntervalSeconds" value="20" />
</manager-properties>
```

Which properties a `manager-properties` element uses depends on the value of the parent `session-manager` element’s `persistence-type` attribute. For details, see the description of the `session-manager` element.

**Subelements**

The following table describes subelements for the `property` element. The left column lists the subelement name, the middle column indicates the requirement rule, and the right column describes what the element does.

<table>
<thead>
<tr>
<th>Element</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>description</td>
<td>zero or one</td>
<td>Specifies an optional text description of a property.</td>
</tr>
</tbody>
</table>

**Attributes**

The following table describes attributes for the `property` element. The left column lists the attribute name, the middle column indicates the default value, and the right column describes what the attribute does.

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Default</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>none</td>
<td>Specifies the name of the property.</td>
</tr>
<tr>
<td>value</td>
<td>none</td>
<td>Specifies the value of the property.</td>
</tr>
</tbody>
</table>
description
Contains data that specifies a text description of the containing element.

Subelements
none

Attributes
none

Security Elements
Security elements are as follows:

- security-role-mapping
- servlet
- servlet-name
- role-name
- principal-name
- group-name

security-role-mapping
Maps roles to users or groups in the currently active realm. See the Sun ONE Application Server Developer’s Guide for how to define the currently active realm.

Subelements
The following table describes subelements for the security-role-mapping element. The left column lists the subelement name, the middle column indicates the requirement rule, and the right column describes what the element does.

<table>
<thead>
<tr>
<th>Element</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>role-name</td>
<td>only one</td>
<td>Contains the role name.</td>
</tr>
<tr>
<td>principal-name</td>
<td>requires at least one principal-name or group-name</td>
<td>Contains a principal (user) name in the current realm.</td>
</tr>
<tr>
<td>group-name</td>
<td>requires at least one principal-name or group-name</td>
<td>Contains a group name in the current realm.</td>
</tr>
</tbody>
</table>
Attributes
none

servlet
Specifies a principal name for a servlet, which is used for the run-as role defined in web-xml.

Subelements
The following table describes subelements for the servlet element. The left column lists the subelement name, the middle column indicates the requirement rule, and the right column describes what the element does.

<table>
<thead>
<tr>
<th>Element</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>servlet-name</td>
<td>only one</td>
<td>Contains the name of a servlet, which is matched to a servlet-name in web.xml.</td>
</tr>
<tr>
<td>principal-name</td>
<td>only one</td>
<td>Contains a principal (user) name in the current realm.</td>
</tr>
</tbody>
</table>

Attributes
none

servlet-name
Contains data that specifies the name of a servlet, which is matched to a servlet-name in web.xml. This name must be present in web.xml.

Subelements
none

Attributes
none

role-name
Contains data that specifies the role-name in the security-role element of the web.xml file.

Subelements
none
Attributes
none

principal-name
Contains data that specifies a principal (user) name in the current realm.

Subelements
none

Attributes
none

group-name
Contains data that specifies a group name in the current realm.

Subelements
none

Attributes
none

Session Elements
Session elements are as follows:

- session-config
- session-manager
- manager-properties
- store-properties
- session-properties
- cookie-properties

NOTE The session manager interface is Unstable. An unstable interface may be experimental or transitional, and hence may change incompatibly, be removed, or be replaced by a more stable interface in the next release.
session-config
Specifies session configuration information.

Subelements
The following table describes subelements for the session-config element. The left column lists the subelement name, the middle column indicates the requirement rule, and the right column describes what the element does.

session-config subelements

<table>
<thead>
<tr>
<th>Element</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>session-manager</td>
<td>zero or one</td>
<td>Specifies session manager configuration information.</td>
</tr>
<tr>
<td>session-properties</td>
<td>zero or one</td>
<td>Specifies session properties.</td>
</tr>
<tr>
<td>cookie-properties</td>
<td>zero or one</td>
<td>Specifies session cookie properties.</td>
</tr>
</tbody>
</table>

Attributes
none

session-manager
Specifies session manager information.

Subelements
The following table describes subelements for the session-manager element. The left column lists the subelement name, the middle column indicates the requirement rule, and the right column describes what the element does.

session-manager subelements

<table>
<thead>
<tr>
<th>Element</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>manager-properties</td>
<td>zero or one</td>
<td>Specifies session manager properties.</td>
</tr>
<tr>
<td>store-properties</td>
<td>zero or one</td>
<td>Specifies session persistence (storage) properties.</td>
</tr>
</tbody>
</table>
Attributes
The following table describes attributes for the session-manager element. The left column lists the attribute name, the middle column indicates the default value, and the right column describes what the attribute does.

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Default Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>persistence-type</td>
<td>memory</td>
<td>(optional) Specifies the session persistence mechanism. Allowed values are memory and file. The custom value is not implemented and should not be used.</td>
</tr>
</tbody>
</table>

manager-properties
Specifies session manager properties.

Subelements
The following table describes subelements for the manager-properties element. The left column lists the subelement name, the middle column indicates the requirement rule, and the right column describes what the element does.

<table>
<thead>
<tr>
<th>Element</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>property</td>
<td>zero or more</td>
<td>Specifies a property, which has a name and a value.</td>
</tr>
</tbody>
</table>

Attributes
none

Properties
The following table describes properties for the manager-properties element. The left column lists the property name, the middle column indicates the default value, and the right column describes what the property does.
store-properties

Specifies session persistence (storage) properties.

Subelements
The following table describes subelements for the store-properties element. The left column lists the subelement name, the middle column indicates the requirement rule, and the right column describes what the element does.

<table>
<thead>
<tr>
<th>Element</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>property</td>
<td>zero or more</td>
<td>Specifies a property, which has a name and a value.</td>
</tr>
</tbody>
</table>

Attributes
none
Properties
The following table describes properties for the store-properties element. The left column lists the property name, the middle column indicates the default value, and the right column describes what the property does.

<table>
<thead>
<tr>
<th>Property Name</th>
<th>Default Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>reapIntervalSeconds</td>
<td>60</td>
<td>Specifies the number of seconds between checks for expired sessions for those sessions that are currently swapped out.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Setting this value lower than the frequency at which session data changes is recommended. For example, this value should be as low as possible (1 second) for a hit counter servlet on a frequently accessed website, or you could lose the last few hits each time you restart the server.</td>
</tr>
<tr>
<td>directory</td>
<td>directory specified by javax.servlet.context.tempdir context attribute</td>
<td>Specifies the absolute or relative path name of the directory into which individual session files are written. A relative path is relative to the temporary work directory for this web module.</td>
</tr>
</tbody>
</table>

session-properties
Specifies session properties.

Subelements
The following table describes subelements for the session-properties element. The left column lists the subelement name, the middle column indicates the requirement rule, and the right column describes what the element does.

<table>
<thead>
<tr>
<th>session-properties subelements</th>
</tr>
</thead>
<tbody>
<tr>
<td>Element</td>
</tr>
<tr>
<td>property</td>
</tr>
</tbody>
</table>

Attributes
none
Properties
The following table describes properties for the `session-properties` element. The left column lists the property name, the middle column indicates the default value, and the right column describes what the property does.

<table>
<thead>
<tr>
<th>Property Name</th>
<th>Default Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>timeoutSeconds</td>
<td>600</td>
<td>Specifies the default maximum inactive interval (in seconds) for all sessions created in this web module. If set to 0 or less, sessions in this web module never expire. If a <code>session-timeout</code> element is specified in the <code>web.xml</code> file, the <code>session-timeout</code> value overrides any <code>timeoutSeconds</code> value. If neither <code>session-timeout</code> nor <code>timeoutSeconds</code> is specified, the <code>timeoutSeconds</code> default is used. Note that the <code>session-timeout</code> element in <code>web.xml</code> is specified in minutes, not seconds.</td>
</tr>
<tr>
<td>enableCookies</td>
<td>true</td>
<td>Uses cookies for session tracking if set to true.</td>
</tr>
<tr>
<td>enableURLRewriting</td>
<td>true</td>
<td>Enables URL rewriting. This provides session tracking via URL rewriting when the browser does not accept cookies. You must also use an <code>encodeURL</code> or <code>encodeRedirectURL</code> call in the servlet or JSP.</td>
</tr>
<tr>
<td>idLengthBytes</td>
<td>128</td>
<td>Specifies the number of bytes in this web module’s session ID.</td>
</tr>
</tbody>
</table>

cookie-properties
Specifies session cookie properties.

Subelements
The following table describes subelements for the `cookie-properties` element. The left column lists the subelement name, the middle column indicates the requirement rule, and the right column describes what the element does.

<table>
<thead>
<tr>
<th>Element</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>property</td>
<td>zero or more</td>
<td>Specifies a property, which has a name and a value.</td>
</tr>
</tbody>
</table>
Attributes
none

Properties
The following table describes properties for the `cookie-properties` element. The left column lists the property name, the middle column indicates the default value, and the right column describes what the property does.

<table>
<thead>
<tr>
<th>Property Name</th>
<th>Default Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>cookieName</td>
<td>JSESSIONID</td>
<td>Specifies the name of the cookie used for session tracking.</td>
</tr>
<tr>
<td>cookiePath</td>
<td>Context path at which the web module is installed.</td>
<td>Specifies the pathname that is set when the cookie is created. The browser sends the cookie if the pathname for the request contains this pathname. If set to / (slash), the browser sends cookies to all URLs served by the Sun ONE Application Server. You can set the path to a narrower mapping to limit the request URLs to which the browser sends cookies.</td>
</tr>
<tr>
<td>cookieMaxAgeSeconds</td>
<td>-1</td>
<td>Specifies the expiration time (in seconds) after which the browser expires the cookie.</td>
</tr>
<tr>
<td>cookieDomain</td>
<td>(unset)</td>
<td>Specifies the domain for which the cookie is valid.</td>
</tr>
<tr>
<td>cookieComment</td>
<td>Sun ONE Application Server Session Tracking Cookie</td>
<td>Specifies the comment that identifies the session tracking cookie in the cookie file. Applications can provide a more specific comment for the cookie.</td>
</tr>
</tbody>
</table>

Reference Elements
Reference elements are as follows:

- `resource-env-ref`
- `resource-env-ref-name`
- `resource-ref`
- `res-ref-name`
- `default-resource-principal`
- `name`
• password
• ejb-ref
• ejb-ref-name
• jndi-name

**resource-env-ref**
Maps the res-ref-name in the corresponding J2EE web.xml file resource-env-ref entry to the absolute jndi-name of a resource.

**Subelements**
The following table describes subelements for the resource-env-ref element. The left column lists the subelement name, the middle column indicates the requirement rule, and the right column describes what the element does.

<table>
<thead>
<tr>
<th>Subelement</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>resource-env-ref-name</td>
<td>only one</td>
<td>Specifies the res-ref-name in the corresponding J2EE web.xml file resource-env-ref entry.</td>
</tr>
<tr>
<td>jndi-name</td>
<td>only one</td>
<td>Specifies the absolute jndi-name of a resource.</td>
</tr>
</tbody>
</table>

**Attributes**
none

**resource-env-ref-name**
Contains data that specifies the res-ref-name in the corresponding J2EE web.xml file resource-env-ref entry.

**Subelements**
none

**Attributes**
none
resource-ref
Maps the res-ref-name in the corresponding J2EE web.xml file resource-ref entry to the absolute jndi-name of a resource.

Subelements
The following table describes subelements for the resource-ref element. The left column lists the subelement name, the middle column indicates the requirement rule, and the right column describes what the element does.

<table>
<thead>
<tr>
<th>Element</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>res-ref-name</td>
<td>only one</td>
<td>Specifies the res-ref-name in the corresponding J2EE web.xml file resource-ref entry.</td>
</tr>
<tr>
<td>jndi-name</td>
<td>only one</td>
<td>Specifies the absolute jndi-name of a resource.</td>
</tr>
<tr>
<td>default-resource-principal</td>
<td>zero or one</td>
<td>Specifies the default principal (user) for the resource.</td>
</tr>
</tbody>
</table>

Attributes
none

res-ref-name
Contains data that specifies the res-ref-name in the corresponding J2EE web.xml file resource-ref entry.

Subelements
none

Attributes
none
default-resource-principal
Specifications the default principal (user) for the resource.

If this element is used in conjunction with a JMS Connection Factory resource, the
name and password subelements must be valid entries in Sun ONE Message
Queue’s broker user repository. See the “Security Management” chapter in the Sun

Subelements
The following table describes subelements for the default-resource-principal
element. The left column lists the subelement name, the middle column indicates
the requirement rule, and the right column describes what the element does.

default-resource-principal subelements

<table>
<thead>
<tr>
<th>Element</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>only one</td>
<td>Contains the name of the principal.</td>
</tr>
<tr>
<td>password</td>
<td>only one</td>
<td>Contains the password for the principal.</td>
</tr>
</tbody>
</table>

Attributes
none

name
Contains data that specifies the name of the principal.

Subelements
none

Attributes
none

password
Contains data that specifies the password for the principal.

Subelements
none

Attributes
none
ejb-ref
Maps the ejb-ref-name in the corresponding J2EE ejb-jar.xml file ejb-ref entry to the absolute jndi-name of a resource.

Subelements
The following table describes subelements for the ejb-ref element. The left column lists the subelement name, the middle column indicates the requirement rule, and the right column describes what the element does.

<table>
<thead>
<tr>
<th>Element</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ejb-ref-name</td>
<td>only one</td>
<td>Specifies the ejb-ref-name in the corresponding J2EE ejb-jar.xml file ejb-ref entry.</td>
</tr>
<tr>
<td>jndi-name</td>
<td>only one</td>
<td>Specifies the absolute jndi-name of a resource.</td>
</tr>
</tbody>
</table>

Attributes
none

ejb-ref-name
Contains data that specifies the ejb-ref-name in the corresponding J2EE ejb-jar.xml file ejb-ref entry.

Subelements
none

Attributes
none

jndi-name
Contains data that specifies the absolute jndi-name of a URL resource or a resource in the server.xml file.

NOTE To avoid collisions with names of other enterprise resources in JNDI, and to avoid portability problems, all names in a Sun ONE Application Server application should begin with the string java:comp/env.
Elements in the sun-web.xml File

**Subelements**
none

**Attributes**
none

**Caching Elements**

For details about response caching as it pertains to servlets, see “Caching Servlet Results,” on page 45. For details about JSP caching, see “JSP Caching,” on page 56.

Caching elements are as follows:

- cache
- cache-helper
- default-helper
- cache-mapping
- url-pattern
- timeout
- http-method
- key-field
- constraint-field
- value

**cache**
Configures caching for web application components.

**Subelements**
The following table describes subelements for the cache element. The left column lists the subelement name, the middle column indicates the requirement rule, and the right column describes what the element does.
cache subelements

<table>
<thead>
<tr>
<th>Element</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>cache-helper</td>
<td>zero or more</td>
<td>Specifies a custom class that implements the CacheHelper interface.</td>
</tr>
<tr>
<td>default-helper</td>
<td>zero or one</td>
<td>Allows you to change the properties of the default, built-in cache-helper class.</td>
</tr>
<tr>
<td>property</td>
<td>zero or more</td>
<td>Specifies a cache property, which has a name and a value.</td>
</tr>
<tr>
<td>cache-mapping</td>
<td>zero or more</td>
<td>Maps a URL pattern or a servlet name to its cacheability constraints.</td>
</tr>
</tbody>
</table>

Attributes

The following table describes attributes for the cache element. The left column lists the attribute name, the middle column indicates the default value, and the right column describes what the attribute does.

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Default Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>max-entries</td>
<td>4096</td>
<td>(optional) Specifies the maximum number of entries the cache can contain. Must be a positive integer.</td>
</tr>
<tr>
<td>timeout-in-seconds</td>
<td>30</td>
<td>(optional) Specifies the maximum amount of time in seconds that an entry can remain in the cache after it is created or refreshed. Can be overridden by a timeout element.</td>
</tr>
<tr>
<td>enabled</td>
<td>false</td>
<td>(optional) Determines whether servlet and JSP caching is enabled. Legal values are on, off, yes, no, 1, 0, true, false.</td>
</tr>
</tbody>
</table>

Properties

The following table describes properties for the cache element. The left column lists the property name, the middle column indicates the default value, and the right column describes what the property does.
### Elements in the sun-web.xml File

#### cache properties

<table>
<thead>
<tr>
<th>Property</th>
<th>Default Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>cacheClassName</td>
<td>com.sun.appserv.web.cache.LruCache</td>
<td>Specifies the fully qualified name of the class that implements the cache functionality. The “cacheClassName values” table below lists possible values.</td>
</tr>
<tr>
<td>MultiLRUSegmentSize</td>
<td>4096</td>
<td>Specifies the number of entries in a segment of the cache table that should have its own LRU (least recently used) list. Applicable only if cacheClassName is set to com.sun.appserv.web.cache.MultiLruCache.</td>
</tr>
<tr>
<td>MaxSize</td>
<td>unlimited; Long.MAX_VALUE</td>
<td>Specifies an upper bound on the cache memory size in bytes (KB or MB units). Example values are 32 KB or 2 MB. Applicable only if cacheClassName is set to com.sun.appserv.web.cache.BoundedMultiLruCache.</td>
</tr>
</tbody>
</table>

#### Cache Class Names

The following table lists possible values of the cacheClassName property. The left column lists the value, and the right column describes the kind of cache the value specifies.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>com.sun.appserv.web.cache.LruCache</td>
<td>A bounded cache with an LRU (least recently used) cache replacement policy.</td>
</tr>
<tr>
<td>com.sun.appserv.web.cache.BaseCache</td>
<td>An unbounded cache suitable if the maximum number of entries is known.</td>
</tr>
<tr>
<td>com.sun.appserv.web.cache.BoundedMultiLruCache</td>
<td>A cache suitable for limiting the cache size by memory rather than number of entries. Uses the MaxSize property.</td>
</tr>
</tbody>
</table>
**cache-helper**
Specifies a class that implements the CacheHelper interface. For details, see “CacheHelper Interface,” on page 48.

**Subelements**
The following table describes subelements for the cache-helper element. The left column lists the subelement name, the middle column indicates the requirement rule, and the right column describes what the element does.

<table>
<thead>
<tr>
<th>Element</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>property</td>
<td>zero or more</td>
<td>Specifies a property, which has a name and a value.</td>
</tr>
</tbody>
</table>

**Attributes**
The following table describes attributes for the cache-helper element. The left column lists the attribute name, the middle column indicates the default value, and the right column describes what the attribute does.

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Default Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>default</td>
<td>Specifies a unique name for the helper class, which is referenced in the cache-mapping element.</td>
</tr>
<tr>
<td>class-name</td>
<td>none</td>
<td>Specifies the fully qualified class name of the cache helper, which must implement the com.sun.appserv.web.CacheHelper interface.</td>
</tr>
</tbody>
</table>

**default-helper**
Allows you to change the properties of the built-in default cache-helper class.

**Subelements**
The following table describes subelements for the default-helper element. The left column lists the subelement name, the middle column indicates the requirement rule, and the right column describes what the element does.
default-helper subelements

<table>
<thead>
<tr>
<th>Element</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>property</td>
<td>zero or more</td>
<td>Specifies a property, which has a name and a value.</td>
</tr>
</tbody>
</table>

Attributes

none

Properties

The following table describes properties for the default-helper element. The left column lists the property name, the middle column indicates the default value, and the right column describes what the property does.

default-helper properties

<table>
<thead>
<tr>
<th>Property</th>
<th>Default Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>cacheKeyGeneratorAttrName</td>
<td>Uses the built-in default cache-helper key generation, which concatenates the servlet path with key-field values, if any.</td>
<td>The caching engine looks in the ServletContext for an attribute with a name equal to the value specified for this property to determine whether a customized CacheKeyGenerator implementation is used. An application may provide a customized key generator rather than using the default helper. See “CacheKeyGenerator Interface,” on page 50.</td>
</tr>
</tbody>
</table>

cache-mapping

Maps a URL pattern or a servlet name to its cacheability constraints.

Subelements

The following table describes subelements for the cache-mapping element. The left column lists the subelement name, the middle column indicates the requirement rule, and the right column describes what the element does.
### cache-mapping subelements

<table>
<thead>
<tr>
<th>Element</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>servlet-name</td>
<td>requires one servlet-name or url-pattern</td>
<td>Contains the name of a servlet.</td>
</tr>
<tr>
<td>url-pattern</td>
<td>requires one servlet-name or url-pattern</td>
<td>Contains a servlet URL pattern for which caching is enabled.</td>
</tr>
<tr>
<td>cache-helper-ref</td>
<td>required if timeout, refresh-field, http-method, key-field, and constraint-field are not used</td>
<td>Contains the name of the cache-helper used by the parent cache-mapping element.</td>
</tr>
<tr>
<td>timeout</td>
<td>zero or one if cache-helper-ref is not used</td>
<td>Contains the cache-mapping specific maximum amount of time in seconds that an entry can remain in the cache after it is created or refreshed.</td>
</tr>
<tr>
<td>refresh-field</td>
<td>zero or one if cache-helper-ref is not used</td>
<td>Specifies a field that gives the application component a programmatic way to refresh a cached entry.</td>
</tr>
<tr>
<td>http-method</td>
<td>zero or more if cache-helper-ref is not used</td>
<td>Contains an HTTP method that is eligible for caching.</td>
</tr>
<tr>
<td>key-field</td>
<td>zero or more if cache-helper-ref is not used</td>
<td>Specifies a component of the key used to look up and extract cache entries.</td>
</tr>
<tr>
<td>constraint-field</td>
<td>zero or more if cache-helper-ref is not used</td>
<td>Specifies a cacheability constraint for the given url-pattern or servlet-name.</td>
</tr>
</tbody>
</table>

### Attributes

none
url-pattern
Contains data that specifies a servlet URL pattern for which caching is enabled. See
the Servlet 2.3 specification section SRV. 11.2 for applicable patterns.

Subelements
none

Attributes
none

cache-helper-ref
Contains data that specifies the name of the cache-helper used by the parent
cache-mapping element.

Subelements
none

Attributes
none

timeout
Contains data that specifies the cache-mapping specific maximum amount of time
in seconds that an entry can remain in the cache after it is created or refreshed. If
not specified, the default is the value of the timeout attribute of the cache element.

Subelements
none

Attributes
The following table describes attributes for the timeout element. The left column
lists the attribute name, the middle column indicates the default value, and the
right column describes what the attribute does.

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Default Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>none</td>
<td>Specifies the timeout input parameter, whose value is interpreted in seconds. The field’s type must be java.lang.Long or java.lang.Integer.</td>
</tr>
</tbody>
</table>
Elements in the sun-web.xml File

Chapter 6 Assembling and Deploying Web Modules 115

refresh-field
Specifies a field that gives the application component a programmatic way to refresh a cached entry.

Subelements
none

Attributes
The following table describes attributes for the refresh-field element. The left column lists the attribute name, the middle column indicates the default value, and the right column describes what the attribute does.

refresh-field attributes

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Default Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>none</td>
<td>Specifies the input parameter name.</td>
</tr>
<tr>
<td>scope</td>
<td>request.parameter</td>
<td>(optional) Specifies the scope in which the input parameter can be present. Allowed values are context.attribute, request.header, request.parameter, request.cookie, request.attribute, and session.attribute.</td>
</tr>
</tbody>
</table>

http-method
Contains data that specifies an HTTP method that is eligible for caching. The default is GET.

Subelements
none

Attributes
none
**key-field**

Specifies a component of the key used to look up and extract cache entries. The web container looks for the named parameter, or field, in the specified scope.

If this element is not present, the web container uses the Servlet Path (the path section that corresponds to the servlet mapping that activated the current request). See the Servlet 2.3 specification, section SRV 4.4, for details on the Servlet Path.

**Subelements**

none

**Attributes**

The following table describes attributes for the `key-field` element. The left column lists the attribute name, the middle column indicates the default value, and the right column describes what the attribute does.

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Default Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>none</td>
<td>Specifies the input parameter name.</td>
</tr>
<tr>
<td>scope</td>
<td>request.parameter</td>
<td>(optional) Specifies the scope in which the input parameter can be present. Allowed values are context.attribute, request.header, request.parameter, request.cookie, session.id, and session.attribute.</td>
</tr>
</tbody>
</table>

**constraint-field**

Specifies a cacheability constraint for the given `url-pattern` or `servlet-name`.

All `constraint-field` constraints must pass for a response to be cached. If there are `value` constraints, at least one of them must pass.

**Subelements**

The following table describes subelements for the `constraint-field` element. The left column lists the subelement name, the middle column indicates the requirement rule, and the right column describes what the element does.

<table>
<thead>
<tr>
<th>Element</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>value</td>
<td>zero or more</td>
<td>Contains a value to be matched to the input parameter value.</td>
</tr>
</tbody>
</table>
Attributes
The following table describes attributes for the constraint-field element. The left column lists the attribute name, the middle column indicates the default value, and the right column describes what the attribute does.

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Default Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>none</td>
<td>Specifies the input parameter name.</td>
</tr>
<tr>
<td>scope</td>
<td>request.parameter</td>
<td>(optional) Specifies the scope in which the input parameter can be present. Allowed values are context.attribute, request.header, request.parameter, request.cookie, request.attribute, and session.attribute.</td>
</tr>
<tr>
<td>cache-on-match</td>
<td>true</td>
<td>(optional) If true, caches the response if matching succeeds. Overrides the same attribute in a value subelement.</td>
</tr>
<tr>
<td>cache-on-match</td>
<td>false</td>
<td>(optional) If true, caches the response if matching fails. Overrides the same attribute in a value subelement.</td>
</tr>
</tbody>
</table>

value
Contains data that specifies a value to be matched to the input parameter value. The matching is case sensitive. For example:

<value match-expr="in-range">1-60</value>

Subelements
none

Attributes
The following table describes attributes for the value element. The left column lists the attribute name, the middle column indicates the default value, and the right column describes what the attribute does.
Elements in the sun-web.xml File

Classloader Elements

Classloader elements are as follows:

- class-loader

**class-loader**

Configures the classloader for the web module.

**Subelements**

none

**Attributes**

The following table describes attributes for the class-loader element. The left column lists the attribute name, the middle column indicates the default value, and the right column describes what the attribute does.

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Default Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>extra-class-path</td>
<td>null</td>
<td>(optional) Specifies additional classpath settings for this web module.</td>
</tr>
</tbody>
</table>
JSP Elements

JSP elements are as follows:

- **jsp-config**

### jsp-config

Specifies JSP configuration information.

#### Subelements

The following table describes subelements for the jsp-config element. The left column lists the subelement name, the middle column indicates the requirement rule, and the right column describes what the element does.

<table>
<thead>
<tr>
<th>jsp-config subelements</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>property</td>
<td>Specifies a property.</td>
</tr>
</tbody>
</table>

#### Attributes

- none
Properties

The following table describes properties for the jsp-config element. The left column lists the property name, the middle column indicates the default value, and the right column describes what the property does.

<table>
<thead>
<tr>
<th>Property Name</th>
<th>Default Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ieClassId</td>
<td>clsid:8AD9C840-044E-11D1-B3E9-00805F499D93</td>
<td>The Java plugin COM class ID for Internet Explorer. Used by the <a href="">jsp:plugin</a> tags.</td>
</tr>
<tr>
<td>javaCompilerPlugin</td>
<td>The internal JDK compiler (javac)</td>
<td>The fully qualified class name of the Java compiler plug-in to be used. Not needed for the default compiler. For example, to use the jikes compiler for JSP pages, set the javaCompilerPlugin property to org.apache.jasper.compiler.JikesJavaCompiler, then set the javaCompilerPath property to point to the jikes executable.</td>
</tr>
<tr>
<td>javaCompilerPath</td>
<td>none</td>
<td>Specifies the path to the executable of an out-of-process Java compiler such as jikes. Ignored for the default compiler. Needed only if the javaCompilerPlugin property is specified.</td>
</tr>
<tr>
<td>javaEncoding</td>
<td>UTF8</td>
<td>Specifies the encoding for the generated Java servlet. This encoding is passed to the Java compiler used to compile the servlet as well. By default, the web container tries to use UTF8. If that fails, it tries to use the javaEncoding value. For encodings you can use, see: <a href="http://java.sun.com/j2se/1.4/docs/guide/intl/encoding.doc.html">http://java.sun.com/j2se/1.4/docs/guide/intl/encoding.doc.html</a></td>
</tr>
<tr>
<td>classdebuginfo</td>
<td>false</td>
<td>Specifies whether the generated Java servlets should be compiled with the debug option set (-g for javac).</td>
</tr>
<tr>
<td>keepgenerated</td>
<td>true</td>
<td>If set to true, keeps the generated Java files. If false, deletes the Java files.</td>
</tr>
<tr>
<td>largefile</td>
<td>false</td>
<td>If set to true, static HTML is stored in a separate data file when a JSP is compiled. This is useful when a JSP is very large, because it minimizes the size of the generated servlet.</td>
</tr>
</tbody>
</table>
Internationalization Elements

Internationalization elements are as follows:

- locale-charset-info
- locale-charset-map
- parameter-encoding

locale-charset-info

Specifies information about the application’s internationalization settings.

Subelements

The following table describes subelements for the locale-charset-info element. The left column lists the subelement name, the middle column indicates the requirement rule, and the right column describes what the element does.

<table>
<thead>
<tr>
<th>Element</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>locale-charset-map</td>
<td>one or more</td>
<td>Maps a locale and an agent to a character set.</td>
</tr>
<tr>
<td>parameter-encoding</td>
<td>zero or one</td>
<td>Determines how the web container decodes parameters from forms for this web application according to a hidden field value.</td>
</tr>
</tbody>
</table>
Attributes
The following table describes attributes for the `locale-charset-info` element. The left column lists the attribute name, the middle column indicates the default value, and the right column describes what the attribute does.

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Default Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>default-locale</td>
<td>none</td>
<td>Specifies the default locale.</td>
</tr>
</tbody>
</table>

locale-charset-map
Maps locales and agents to character sets.

For encodings you can use, see:

http://java.sun.com/j2se/1.4/docs/guide/intl/encoding.doc.html

Subelements
The following table describes subelements for the `locale-charset-map` element. The left column lists the subelement name, the middle column indicates the requirement rule, and the right column describes what the element does.

<table>
<thead>
<tr>
<th>Element</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>description</td>
<td>zero or one</td>
<td>Specifies an optional text description of a mapping.</td>
</tr>
</tbody>
</table>

Attributes
The following table describes attributes for the `locale-charset-map` element. The left column lists the attribute name, the middle column indicates the default value, and the right column describes what the attribute does.

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Default Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>locale</td>
<td>none</td>
<td>Specifies the locale name.</td>
</tr>
</tbody>
</table>
Elements in the sun-web.xml File

Chapter 6 Assembling and Deploying Web Modules 123

Example Agents
The following table specifies example agent attribute values. The left column lists the agent, and the right column lists the corresponding attribute value.

<table>
<thead>
<tr>
<th>Agent</th>
<th>user-agent Header and agent Attribute Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Internet Explorer 5.00 for Windows 2000</td>
<td>Mozilla/4.0 (compatible; MSIE 5.01; Windows NT 5.0)</td>
</tr>
<tr>
<td>Netscape 4.7.7 for Windows 2000</td>
<td>Mozilla/4.77 [en] (Windows NT 5.0; U)</td>
</tr>
<tr>
<td>Netscape 4.7 for Solaris</td>
<td>Mozilla/4.7 [en] (X11; u; Sun OS 5.6 sun4u)</td>
</tr>
</tbody>
</table>

locale-charset-map attributes (Continued)

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Default Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>agent</td>
<td>none</td>
<td>(optional) Specifies the type of client that interacts with the application server. For a given locale, different agents may have different preferred character sets. The value of this attribute must exactly match the value of the user-agent HTTP request header sent by the client. See the “example agent attribute values” table for more information.</td>
</tr>
<tr>
<td>charset</td>
<td>none</td>
<td>Specifies the character set.</td>
</tr>
</tbody>
</table>

parameter-encoding
Specifies a hidden field that determines the character encoding the web container uses to decode parameters for request.getParameter calls when the charset is not set in the request’s content-type.

For encodings you can use, see:

http://java.sun.com/j2se/1.4/docs/guide/intl/encoding.doc.html

Subelements
none

Attributes
The following table describes attributes for the parameter-encoding element. The left column lists the attribute name, the middle column indicates the default value, and the right column describes what the attribute does.
Sample Web Module XML Files

Chapter 7

Using Server-Parsed HTML

HTML files can contain tags that are executed on the server. In addition to supporting the standard server-side tags, Sun ONE Application Server 7 allows you to embed servlets and define your own server-side tags.

You can create custom server-parsed HTML tags. For more information, see the Sun ONE Application Server NSAPI Developer's Guide.

For security, server-parsed HTML tags depend on the server’s security configuration. For more information, see “Security for SHTML and CGI,” on page 81 and the Sun ONE Application Server Administrator’s Guide to Security.

This chapter has the following sections:

• Server-Side HTML and J2EE Web Applications
• Enabling Server-Side HTML
• Using Server-Side HTML Commands
• Embedding Servlets
• Time Formats

Server-Side HTML and J2EE Web Applications

In Sun ONE Application Server, server-parsed HTML cannot interoperate with J2EE web applications. Specifically:

• Do not place server-parsed HTML within web application context roots.
• Do not include the output of server-parsed HTML in servlets or JSPs.
• Do not forward requests to server-parsed HTML from servlets or JSPs.
Enabling Server-Side HTML

You cannot apply J2EE security-constraint and filter-mapping features to server-parsed HTML.

Enabling Server-Side HTML

To enable server-side HTML:

1. Open the HTTP Server component under your server instance in the Administration interface.
2. Go to the Virtual Servers page.
3. Click on the name of the virtual server for which you are enabling server-side HTML.
4. Click on the HTTP/HTML tab.
5. Click on the Parse HTML option.
6. Choose a resource for which the server will parse HTML.
   Choose the virtual server or a specific directory within the virtual server.
   If you choose a directory, the server will parse HTML only when the server receives a URL for that directory or any file in that directory.
7. Choose whether to activate server-parsed HTML.
   You can activate for HTML files but not the exec tag, or for HTML files and the exec tag, which allows HTML files to execute other programs on the server.
8. Choose which files to parse.
   You can choose whether to parse only files with the .shtml extension, or all HTML files, which slows performance. If you are using UNIX, you can also choose to parse UNIX files with the execute permission turned on, though that can be unreliable.
9. Click on the OK button.
10. Go to the server instance page and select the Apply Changes button.

When you activate parsing, you need to be sure that the following directives are added to your init.conf file (note that native threads are turned off):

...
Note that you must set NativeThread="no" for Sun ONE Application Server 7. In addition, these functions now originate from Shtml.dll (or libShtml.so on UNIX), which is located in install_dir/bin for Windows (and install_dir/lib for UNIX).

In addition, be sure that the following directive is added to your obj.conf file:

```xml
<Object name="default">
  ...
  ...
  Service fn="shtml_send" type="magnus-internal/parsed-html" method="(GET|HEAD)"
  ...
</Object>
```

Using Server-Side HTML Commands

This section describes the HTML commands for including server-parsed tags in HTML files. These commands are embedded into HTML files, which are processed by the obj.conf file’s parse-html function.

The server replaces each command with data determined by the command and its attributes. The format for a command is:

```
<!--#command attribute1 attribute2 <Body>... -->
```

The format for each attribute is a name-value pair such as:

```
name="value"
```

Commands and attribute names should be in lower case.

The commands are “hidden” within HTML comments so they are ignored if not parsed by the server. The standard server-side commands are:

- config
- include
- echo
- fsize
Using Server-Side HTML Commands

- flastmod
- exec

**config**

The `config` command initializes the format for other commands.

- The `errmsg` attribute defines a message sent to the client when an error occurs while parsing the file. This error is also logged in the server log file.
- The `timefmt` attribute determines the format of the date for the `flastmod` command. It uses the same format characters as the `util_strftime` function. The default time format is: 

  `%A, %d-%b-%y %T`

  Refer to “Time Formats,” on page 137 for details about time formats.
- The `sizefmt` attribute determines the format of the file size for the `fsize` command. It can have one of these values:
  - `bytes` to report file size as a whole number in the format 12,345,678.
  - `abbrev` (the default) to report file size as a number of KB or MB.

**Example:**

```html
<!--#config timefmt="%r %a %b %e, %Y" sizefmt="abbrev-->"
```

This sets the date format to a value such as 08:23:15 AM Wed Apr 15, 1996, and the file size format to the number of KB or MB of characters used by the file.

**include**

The `include` command inserts a file into the parsed file. You can nest files by including another parsed file, which then includes another file, and so on. The client requesting the parsed document must also have access to the included file if your server uses access control for the directories where they reside.

In Sun ONE Application Server 7, you can use the `include` command with the `virtual` attribute to include a CGI program file. You must also use an `exec` command to execute the CGI program.

- The `virtual` attribute is the URI of a file on the server.
- The `file` attribute is a relative path name from the current directory. It cannot contain elements such as `../` and it cannot be an absolute path.
Using Server-Side HTML Commands

Example:

<!--#include file="bottle.gif"-->

echo

The `echo` command inserts the value of an environment variable. The `var` attribute specifies the environment variable to insert. If the variable is not found, “(none)” is inserted. For a list of environment variables, see the section “Environment Variables in Server-Side HTML Commands,” on page 136.

Example:

<!--#echo var="DATE_GMT"-->

fsize

The `fsize` command sends the size of a file. The attributes are the same as those for the `include` command (`virtual` and `file`). The file size format is determined by the `sizefmt` attribute in the `config` command.

Example:

<!--#fsize file="bottle.gif"-->

flastmod

The `flastmod` command prints the date a file was last modified. The attributes are the same as those for the `include` command (`virtual` and `file`). The date format is determined by the `timefmt` attribute in the `config` command.

Example:

<!--#flastmod file="bottle.gif"-->

exec

The `exec` command runs a shell command or CGI program.

- The `cmd` attribute (UNIX only) runs a command using `/bin/sh`. You may include any special environment variables in the command.
The `cgi` attribute runs a CGI program and includes its output in the parsed file.

Example:

```
<!--#exec cgi="workit.pl"-->
```

### Environment Variables in Server-Side HTML Commands

In addition to the normal set of environment variables used in CGI, you may include the following variables in your parsed commands:

- **DOCUMENT_NAME**
  
is the file name of the parsed file.

- **DOCUMENT_URI**
  
is the virtual path to the parsed file (for example, `/shtml/test.shtml`).

- **QUERY_STRING_UNESCAPED**
  
is the unescaped version of any search query the client sent with all shell-special characters escaped with the `\` character.

- **DATE_LOCAL**
  
is the current date and local time.

- **DATE_GMT**
  
is the current date and time expressed in Greenwich Mean Time.

- **LAST_MODIFIED**
  
is the date the file was last modified.

### Embedding Servlets

Sun ONE Application Server 7 supports the `<SERVLET>` tag as introduced by Java Web Server. This tag allows you to embed servlet output in an SHTML file. No configuration changes are necessary to enable this behavior. If SSI and servlets are both enabled, the `<SERVLET>` tag is enabled.
The `<SERVLET>` tag syntax is slightly different from that of other SSI commands; it resembles the `<APPLET>` tag syntax:

```html
<servlet code="code">
  <param name="param1" value="v3">
  <param name="param2" value="v4">
  ...
</servlet>
```

The code parameter specifies the URI of the servlet, including the web application context root. This URI must match a url-pattern subelement of a servlet-mapping element in the J2EE deployment descriptor (`web.xml`).

## Time Formats

The following table describes the format strings for dates and times used by server-parsed HTML. The left column lists time format symbols, and the right column explains the meanings of the symbols.

<table>
<thead>
<tr>
<th>Symbol</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>%a</td>
<td>Abbreviated weekday name (3 chars)</td>
</tr>
<tr>
<td>%d</td>
<td>Day of month as decimal number (01-31)</td>
</tr>
<tr>
<td>%S</td>
<td>Second as decimal number (00-59)</td>
</tr>
<tr>
<td>%M</td>
<td>Minute as decimal number (00-59)</td>
</tr>
<tr>
<td>%H</td>
<td>Hour in 24-hour format (00-23)</td>
</tr>
<tr>
<td>%Y</td>
<td>Year with century, as decimal number, up to 2099</td>
</tr>
<tr>
<td>%b</td>
<td>Abbreviated month name (3 chars)</td>
</tr>
<tr>
<td>%h</td>
<td>Abbreviated month name (3 chars)</td>
</tr>
<tr>
<td>%T</td>
<td>Time &quot;HH:MM:SS&quot;</td>
</tr>
<tr>
<td>%X</td>
<td>Time &quot;HH:MM:SS&quot;</td>
</tr>
<tr>
<td>%A</td>
<td>Full weekday name</td>
</tr>
<tr>
<td>%B</td>
<td>Full month name</td>
</tr>
<tr>
<td>%C</td>
<td>&quot;%a %b %e %H:%M:%S %Y&quot;</td>
</tr>
<tr>
<td>%c</td>
<td>Date &amp; time &quot;%m/%d/%y %H:%M:%S&quot;</td>
</tr>
</tbody>
</table>
#### Time Formats

<table>
<thead>
<tr>
<th>Symbol</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>%D</td>
<td>Date &quot;%m/%d/%y&quot;</td>
</tr>
<tr>
<td>%e</td>
<td>Day of month as decimal number (1-31) without leading zeros</td>
</tr>
<tr>
<td>%I</td>
<td>Hour in 12-hour format (01-12)</td>
</tr>
<tr>
<td>%j</td>
<td>Day of year as decimal number (001-366)</td>
</tr>
<tr>
<td>%k</td>
<td>Hour in 24-hour format (0-23) without leading zeros</td>
</tr>
<tr>
<td>%l</td>
<td>Hour in 12-hour format (1-12) without leading zeros</td>

</tr>
<tr>
<td>%U</td>
<td>Week of year as decimal number, with Sunday as first day of week (00-51)</td>
</tr>
<tr>
<td>%w</td>
<td>Weekday as decimal number (0-6; Sunday is 0)</td>
</tr>
<tr>
<td>%W</td>
<td>Week of year as decimal number, with Monday as first day of week (00-51)</td>
</tr>
<tr>
<td>%x</td>
<td>Date &quot;%m/%d/%y&quot;</td>
</tr>
<tr>
<td>%y</td>
<td>Year without century, as decimal number (00-99)</td>
</tr>
<tr>
<td>%%</td>
<td>Percent sign</td>
</tr>
</tbody>
</table>
Common Gateway Interface (CGI) programs run on the server and generate a response to return to the requesting client. CGI programs can be written in various languages, including C, C++, Perl, and as shell scripts. CGI programs are invoked through URL invocation.

A myriad of information about writing CGI programs is available. A good starting point is “The Common Gateway Interface” at:

http://hoohoo.ncsa.uiuc.edu/cgi/overview.html

Sun ONE Application Server complies with the version 1.1 CGI specification.

Since the server starts up a process each time the CGI script or program runs, this is an expensive method of programming the server.

For security, CGI scripts depend on the server’s security configuration. For more information, see “Security for SHTML and CGI,” on page 81 and the Sun ONE Application Server Administrator’s Guide to Security.

This chapter includes the following topics:

- CGI and J2EE Web Applications
- Enabling CGI
- Creating Custom Execution Environments for CGI Programs (UNIX only)
- Adding CGI Programs to the Server
- Setting the Priority of a CGI Program
- Windows CGI Programs
- Shell CGI Programs for Windows
- The Query Handler
- Perl CGI Programs
• Global CGI Settings
• CGI Variables

CGI and J2EE Web Applications

In Sun ONE Application Server, CGI programs cannot interoperate with J2EE web applications. Specifically:
• Do not place CGI programs within web application context roots.
• Do not include the output of CGI programs in servlets or JSPs.
• Do not forward requests to CGI programs from servlets or JSPs.
• You cannot apply J2EE security-constraint and filter-mapping features to CGI programs.

Enabling CGI

Sun ONE Application Server provides these ways to identify CGI programs:
• Specifying CGI Directories. The server treats all files in CGI directories as CGI programs.
• Specifying CGI File Extensions. The server treats all files with the specified extensions as CGI programs.

Specifying CGI Directories

To specify directories that contain CGI programs (and only CGI programs):
1. Create the CGI directory on your computer. This directory doesn’t have to be a subdirectory of your document root directory. This is why you must specify a URL prefix in Step 7.
2. Open the HTTP Server component under your server instance in the Administration interface.
3. Go to the Virtual Servers page.
4. Click on the name of the virtual server for which you are specifying a CGI directory.
5. Click on the CGI tab.

6. Click on the CGI Directory option.

7. In the URL Prefix field, type the URL prefix to use for this directory. That is, the text you type appears as the directory for the CGI programs in URLs.

   For example, if you type cgi-bin as the URL prefix, then all URLs to these CGI programs have the following structure:

   http://yourserver.domain.com/cgi-bin/program-name

   **NOTE** The URL prefix you specify can be different from the real CGI directory you specify in the previous step.

8. In the CGI Directory text field, type the location of the directory as an absolute path.

9. Click on the OK button.

10. Go to the server instance page and select the Apply Changes button.

The server treats all files in these directories as CGI programs.

To remove an existing CGI directory, click that directory’s Remove button in the CGI Directory page. To change the URL prefix or CGI directory of an existing directory, click that directory’s Edit button.

Copy your CGI programs into the directories you’ve specified. Remember that any files in those directories are processed as CGI files, so don’t put HTML files in your CGI directory.

For each CGI directory, the file obj.conf contains a NameTrans directive that associates the name cgi with each request for a resource in that directory. These directives are automatically added to obj.conf when you specify CGI directories in the Administration interface, or you can manually add them to obj.conf if desired.

For example, the following instruction interprets all requests for resources in http://server-name/cgi-local as requests to invoke CGI programs in the directory C:/SunServer/docs/mycgi.

   NameTrans fn="pfx2dir" from="/cgi-local"
   dir="C:/SunServer/docs/mycgi" name="cgi"

The obj.conf file must contain the following named object:
Do not remove this object from `obj.conf`. If you do, the server will never recognize CGI directories, regardless of whether you specify them in the Administration interface or manually add more `NameTrans` directives to `obj.conf`.

### Specifying CGI File Extensions

To instruct the server to treat all files with certain extensions as CGI programs, regardless of which directory they reside in:

1. Open the HTTP Server component under your server instance in the Administration interface.
2. Go to the Virtual Servers page.
3. Click on the name of the virtual server for which you are specifying CGI file types.
4. Click on the CGI tab.
5. Click on the CGI File Type option.
6. From the Editing picker, choose the resource you want this change to apply to.
7. Click the Yes radio button under Activate CGI as a File Type.
8. Click on the OK button.
9. Go to the server instance page and select the Apply Changes button.

The default CGI extensions are `.cgi`, `.bat` and `.exe`.

To change which extensions indicate CGI programs, modify the following line in `mime.types` to specify the desired extensions. Be sure to restart the server after editing `mime.types`.

```
type=magnus-internal/cgi exts=cgi,exe,bat
```

When the server is enabled to treat all files with an appropriate extensions as CGI programs, the `obj.conf` file contains the following `Service` directive:

```
Service fn="send-cgi" type="magnus-internal/cgi"
```
Creating Custom Execution Environments for CGI Programs (UNIX only)

Before you can create a custom execution environment, you must install the suid Cgistub and run it as root:

1. Log in as the superuser.
   
   su

2. Create the private directory for Cgistub:
   
   cd  
   mkdir private

3. Copy Cgistub to the private directory:
   
   cd private
   cp install_dir/lib/Cgistub .

4. Set the owner of private to the server user:
   
   chown username .

5. Set the permissions on private:
   
   chmod 500 .

6. Set the owner of Cgistub to root:
   
   chown root Cgistub

7. Set the permissions on Cgistub:
   
   chmod 4711 Cgistub

8. You can give each reference to the send-cgi function in obj.conf a user parameter. For example:

   Service fn="send-cgi" user="username"

   You can use variable substitution. For example, in server.xml, give a virtual-server element the following property subelement:

   <property name="user" value="username"/>

   This lets you write the send-cgi function line in obj.conf as follows:

   Service fn="send-cgi" user="$user"
Creating Custom Execution Environments for CGI Programs (UNIX only)

For more information about send-cgi and obj.conf, see the Sun ONE Application Server Developer’s Guide to NSAPI. For more information about server.xml, see the Sun ONE Application Server Administrator’s Configuration File Reference.

9. Restart the server so these changes take effect.

NOTE Installing Cgistub in the instance_dir/private directory is recommended. If you install it anywhere else, you must specify the path to Cgistub in the init-cgi function in init.conf. For details, see the Sun ONE Application Server Developer’s Guide to NSAPI.

NOTE It may not be possible to install the suid Cgistub program on an NFS mount. If you wish to use an suid Cgistub, you must install your server instance to a local file system.

Cgistub enforces the following security restrictions:

- The user the CGI program executes as must have a uid of 100 or greater. This prevents anyone from using Cgistub to obtain root access.
- The CGI program must be owned by the user it is executed as and must not be writable by anyone other than its owner. This makes it difficult for anyone to covertly inject and then remotely execute programs.
- Cgistub creates its UNIX listen socket with 0700 permissions.

NOTE Socket permissions are not respected on a number of UNIX variants, including current versions of SunOS/Solaris. To prevent a malicious user from exploiting Cgistub, change the server’s temporary directory (using the init.conf TempDir directive) to a directory accessible only to the server user. For details, see the Sun ONE Application Server Administrator’s Configuration File Reference.
After you have installed Cgistub, you can create custom execution environments in the following ways:

- Specifying a Unique CGI Directory and UNIX User and Group for a Virtual Server
- Specifying a Chroot Directory for a Virtual Server

### Specifying a Unique CGI Directory and UNIX User and Group for a Virtual Server

To prevent a virtual server’s CGI programs from interfering with other users, these programs should be stored in a unique directory and execute with the permissions of a unique UNIX user and group.

First, create the UNIX user and group. The exact steps required to create a user and group vary by operating system. For help, consult your operating system’s documentation.

Next, follow these steps to create a `cgi-bin` directory for the virtual server:

1. Log in as the superuser.
   
   `su`

2. Change to the virtual server directory.
   
   `cd vs_dir`

3. Create the `cgi-bin` directory.
   
   `mkdir cgi-bin`

   `chown user:group cgi-bin`

   `chmod 755 cgi-bin`

You can set the virtual server’s CGI directory, user, and group in one of these ways:

- Use the `dir`, `user`, and `group` parameters of the `send-cgi` function in the `obj.conf` file. For more information, see the *Sun ONE Application Server Developer's Guide to NSAPI*.

- Enter this information using the Administration interface:
  
  a. Open the HTTP Server component under your server instance.
  
  b. Go to the Virtual Servers page.
c. Click on the name of the virtual server for which you are specifying CGI directories.

d. Click on the General tab.

e. Type values in the Directory, User, and Group fields.

f. Click on the Save button.

g. Go to the server instance page and select the Apply Changes button.

For more information, see the Sun ONE Application Server Administrator’s Guide.

Specifying a Chroot Directory for a Virtual Server

To further improve security, these CGI scripts should be prevented from accessing data above and outside of the virtual server directory.

First, set up the chroot environment. The exact steps required to set up the chroot environment vary by operating system. For help, consult your operating system’s documentation. The man pages for ftpd and chroot are often a good place to start.

These are the steps required for Solaris versions 2.6 through 8:

1. Log in as the superuser.
   ```
   su
   ```

2. Change to the chroot directory. This is typically the vs_dir directory mentioned in the previous section.
   ```
   cd chroot
   ```

3. Create tmp in the chroot directory:
   ```
   mkdir tmp
   chmod 1777 tmp
   ```

4. Create dev in the chroot directory:
   ```
   mkdir dev
   chmod 755 dev
   ```

5. List /dev/tcp, and note the major and minor numbers of the resulting output. In this example, the major number is 11 and the minor number is 42:
   ```
   ls -lL /dev/tcp
   crw-rw-rw-  1 root  sys  11, 42 Apr  9 1998 /dev/tcp
   ```
6. Create the tcp device using the major and minor numbers:

```
mknod dev/tcp c 11 42
chmod 666 dev/tcp
```

7. Repeat steps 5 and 6 for each of the following devices (each device will have a different major and minor combination):

```
/dev/udp
/dev/ip
/dev/kmem
/dev/kstat
/dev/ksyms
/dev/mem
/dev/null
/dev/stderr
/dev/stdin
/dev/stdout
/dev/ticotsord
/dev/zero
```

8. Set permissions on the devices in dev in the chroot directory:

```
chmod 666 dev/*
```

9. Create and populate lib and usr/lib in the chroot directory:

```
mkdir usr
mkdir usr/lib
ln -s /usr/lib
ln /usr/lib/* usr/lib
```

You can ignore the messages this command generates.

If the /usr/lib directory is on a different file system, replace the last command with the following:

```
cp -rf /usr/lib/* usr/lib
```

10. Create and populate bin and usr/bin in the chroot directory:

```
mkdir usr/bin
ln -s /usr/bin
ln /usr/bin/* usr/bin
```

You can ignore the messages this command generates.
If the /usr/bin directory is on a different file system, replace the last command with the following:

```
 cp -rf /usr/bin/* usr/bin
```

11. Create and populate etc in the chroot directory:

```
 mkdir etc
 ln /etc/passwd /etc/group /etc/netconfig etc
```

12. Test the chroot environment:

```
 chroot chroot bin/ls -l
```

The output should look something like this:

```
 total 14
 lrwxrwxrwx 1 root other 8 Jan 13 03:32 bin -> /usr/bin
drwxr-xr-x 2 user  group 512 Jan 13 03:42 cgi-bin
drwxr-xr-x 2 root other 512 Jan 13 03:28 dev
drwxr-xr-x 2 user  group 512 Jan 13 03:26 docs
drwxr-xr-x 2 root other 512 Jan 13 03:33 etc
 lrwxrwxrwx 1 root other 8 Jan 13 03:30 lib -> /usr/lib
drwxr-xr-x 4 root other 512 Jan 13 03:32 usr
```

You can set the virtual server’s chroot directory in one of these ways:

- Use the chroot parameter of the send-cgi function in the obj.conf file. For more information, see the Sun ONE Application Server Developer’s Guide to NSAPI.

- Enter this information using the Administration interface:
  
  a. Open the HTTP Server component under your server instance.
  b. Go to the Virtual Servers page.
  c. Click on the name of the virtual server for which you are specifying CGI directories.
  d. Click on the General tab.
  e. Type a value in the Chroot field.
  f. Click on the Save button.
  g. Go to the server instance page and select the Apply Changes button.

For more information, see the Sun ONE Application Server Administrator’s Guide.
Adding CGI Programs to the Server

To add CGI programs to the Sun ONE Application Server, simply do one of the following:

• Drop the program file in a CGI directory (if there are any).
• Give it a file name that the server recognizes as a CGI program and put it in any directory at or below the document root (if CGI file type recognition has been activated).

For UNIX, make sure the program file has execute permissions set.

Setting the Priority of a CGI Program

To set the priority of a CGI program:

1. Open the HTTP Server component under your server instance in the Administration interface.
2. Go to the Virtual Servers page.
3. Click on the name of the virtual server for which you are specifying CGI directories.
4. Click on the General tab.
5. Type a value in the Nice field. This increment determines the CGI program’s priority relative to the server. Typically, the server is run with a nice value of 0 and the nice increment would be between 0 (the CGI program runs at same priority as server) and 19 (the CGI program runs at much lower priority than server). While it is possible to increase the priority of the CGI program above that of the server by specifying a nice increment of −1, this is not recommended.
6. Click on the Save button.
7. Go to the server instance page and select the Apply Changes button.

For more information, see the Sun ONE Application Server Administrator’s Guide.
Windows CGI Programs

This section discusses how to install Windows CGI Programs. The following topics are included in this section:

- Overview of Windows CGI Programs
- Specifying a Windows CGI Directory
- Specifying Windows CGI as a File Type

Overview of Windows CGI Programs

Windows CGI programs are handled much as other CGI programs. You specify a directory that contains only Windows CGI programs, or you specify that all Windows CGI programs have the same file extension, or both.

Although Windows CGI programs behave like regular CGI programs, your server processes the actual programs slightly differently. Therefore, you need to specify different directories for Windows CGI programs. If you enable the Windows CGI file type, it uses the file extension .wcg.

Sun ONE Application Servers support the Windows CGI 1.3a informal specification, with the following differences:

- The following keywords have been added to the [CGI] section to support security methods:
  - HTTPS: its value is on or off, depending on whether the transaction is conducted through SSL.
  - HTTPS Keysize: when HTTPS is on, this value reports the number of bits in the session key used for encryption.
  - HTTPS Secret Keysize: when HTTPS is on, this value reports the number of bits used to generate the server’s private key.

- The keyword Document Root in the [CGI] section might not refer to the expected document root because the server does not have a single document root. The directory returned in this variable is the root directory for the Windows CGI program.

- The keyword Server Admin in the [CGI] section is not supported.

- The keyword Authentication Realm in the [CGI] section is not supported.

- Forms sent with multi-part/form-data encoding are not supported.
Specifying a Windows CGI Directory

To specify directories that contain WinCGI programs (and only WinCGI programs):

1. Create the Windows CGI directory on your computer. This directory doesn’t have to be a subdirectory of your document root directory. This is why you must specify a URL prefix in Step 7.

2. Open the HTTP Server component under your server instance in the Administration interface.

3. Go to the Virtual Servers page.

4. Click on the name of the virtual server for which you are specifying Windows CGI directories.

5. Click on the CGI tab.

6. Click on the WinCGI Directory option.

7. In the URL Prefix field, type the URL prefix to use for this directory. That is, the text you type appears as the directory for the CGI programs in URLs.
   
   For example, if you type `cgi-bin` as the URL prefix, then all URLs to these CGI programs have the following structure:
   
   `http://yourserver.domain.com/cgi-bin/program-name`

   **NOTE** The URL prefix you specify can be different from the real CGI directory you specify in the previous step.

8. In the WINCGI Directory text field, type the location of the directory as an absolute path.

9. To enable script tracing, select the Yes radio button.

10. Click on the OK button.

11. Go to the server instance page and select the Apply Changes button.

To remove an existing Windows CGI directory, click that directory’s Remove button in the WINCGI Directory page. To change the URL prefix or Windows CGI directory of an existing directory, click that directory’s Edit button.

Copy your Windows CGI programs into the directories you’ve specified. Remember that any file in those directories is processed as a Windows CGI file.
Specifying Windows CGI as a File Type

To specify a file extension for Windows CGI files, perform the following steps:

1. Open the HTTP Server component under your server instance in the Administration interface.

2. Go to the Virtual Servers page.

3. Click on the name of the virtual server for which you are specifying a Windows CGI file type.

4. Note the name of the MIME Types File for the virtual server.

5. Go to the MIME Type Files page.

6. Click on the name that matches the name you noted in Step 4.

7. Click on the MIME File... button.

8. Add a new MIME type with the following settings:
   - Category: type
   - Content-Type: magnus-internal/wincgi
   - File Suffix: Enter the file suffixes that you want the server to associate with Windows CGI. If you activated CGI, WinCGI, and shell CGI file types, you must specify a different suffix for each type of CGI. For example, you can't use the suffix .exe for both a CGI program and a shell CGI program. If you need to, you can edit the other MIME type fields on the page so that the suffixes are unique.

9. Click on the New Type button.

10. Go to the server instance page and select the Apply Changes button.

Shell CGI Programs for Windows

This section discusses how to install Shell CGI Programs for Windows. The following topics are included in this section:

- Overview of Shell CGI Programs for Windows
- Specifying a Shell CGI Directory (Windows)
- Specifying Shell CGI as a File Type (Windows)
Overview of Shell CGI Programs for Windows

Shell CGI is a server configuration that lets you run CGI applications using the file associations set in Windows.

For example, if the server gets a request for a shell CGI file called hello.pl, the server uses the Windows file associations to run the file using the program associated with the .pl extension. If the .pl extension is associated with the program C:\bin\perl.exe, the server attempts to execute the hello.pl file as follows:

    c:\bin\perl.exe hello.pl

The easiest way to configure shell CGI is to create a directory in your server’s document root that contains only shell CGI files. However, you can also configure the server to associate specific file extensions with shell CGI by editing MIME types from the Sun ONE Application Server.

NOTE For information on setting Windows file extensions, see your Windows documentation.

Specifying a Shell CGI Directory (Windows)

To specify directories that contain shell CGI programs (and only shell CGI programs):

1. Create the shell CGI directory on your computer. This directory doesn’t have to be a subdirectory of your document root directory. This is why you must specify a URL prefix in Step 7.

2. Open the HTTP Server component under your server instance in the Administration interface.

3. Go to the Virtual Servers page.

4. Click on the name of the virtual server for which you are specifying shell CGI directories.

5. Click on the CGI tab.

6. Click on the Shell CGI Directory option.
7. In the URL Prefix field, type the URL prefix to use for this directory. That is, the text you type appears as the directory for the CGI programs in URLs.

For example, if you type `cgi-bin` as the URL prefix, then all URLs to these CGI programs have the following structure:

http://yourserver.domain.com/cgi-bin/program-name

---

**NOTE** The URL prefix you specify can be different from the real CGI directory you specify in the previous step.

---

8. In the Shell CGI Directory text field, type the location of the directory as an absolute path.

9. Click on the OK button.

10. Go to the server instance page and select the Apply Changes button.

11. Make sure that any files in the shell CGI directory also have file associations set in Windows. The server returns an error if it attempts to run a file that has no file-extension association.

---

**CAUTION** The server must have read and execute permissions to the shell CGI directory. For Windows, the user account the server runs as (for example, `LocalSystem`) must have rights to read and execute programs in the shell CGI directory.

To remove an existing shell CGI directory, click that directory’s Remove button in the Shell CGI Directory page. To change the URL prefix or shell CGI directory of an existing directory, click that directory’s Edit button.

Copy your shell CGI programs into the directories you’ve specified. Remember that any file in those directories is processed as a shell CGI file.
Specifying Shell CGI as a File Type (Windows)

You can use the Sun ONE Application Server’s `mime.types` file to associate a file extension with the shell CGI feature. This is different from creating an association in Windows.

To associate a file extension with the shell CGI feature in the server, for example, you can create an association for files with the `.pl` extension. When the server gets a request for a file with that extension, the server knows to treat the file as a shell CGI file by calling the executable associated in Windows with that file extension.

To associate a file extension as a shell CGI file, perform the following steps:

1. Open the HTTP Server component under your server instance in the Administration interface.
2. Go to the Virtual Servers page.
3. Click on the name of the virtual server for which you are specifying a Windows CGI file type.
4. Note the name of the MIME Types File for the virtual server.
5. Go to the MIME Type Files page.
6. Click on the name that matches the name you noted in Step 4.
7. Click on the MIME File... button.
8. Add a new MIME type with the following settings:
   - **Category:** type
   - **Content-Type:** magnus-internal/shellcgi
   - **File Suffix:** Enter the file suffixes that you want the server to associate with Windows CGI. If you activated CGI, WinCGI, and shell CGI file types, you must specify a different suffix for each type of CGI. For example, you can’t use the suffix `.exe` for both a CGI program and a shell CGI program. If you need to, you can edit the other MIME type fields on the page so that the suffixes are unique.
9. Click on the New Type button.
10. Go to the server instance page and select the Apply Changes button.
The Query Handler

NOTE  The use of Query Handlers is outdated. Although Sun ONE Application Server and Netscape Navigator clients still support it, it is rarely used. It is much more common for people to use forms in their HTML pages to submit queries.

You can specify a default query handler CGI program. A query handler processes text sent to it via the ISINDEX tag in an HTML file.

ISINDEX is similar to a form text field in that it creates a text field in the HTML page that can accept typed input. Unlike the information in a form text field, however, the information in the ISINDEX box is immediately submitted when the user presses Return. When you specify your default query handler, you tell your server to which program to direct the input. For an in-depth discussion of the ISINDEX tag, see an HTML reference manual.

To set a query handler, perform the following steps:

1. Open the HTTP Server component under your server instance in the Administration interface.
2. Go to the Virtual Servers page.
3. Click on the name of the virtual server for which you are specifying a query handler.
4. Click on the CGI tab.
5. Click on the Query Handler option.
6. Use the Editing Picker to select the resource you want to set with a default query handler.
   If you choose a directory, the query handler you specify runs only when the server receives a URL for that directory or any file in that directory.
7. In the Default Query Handler field, enter the full path for the CGI program you want to use as the default for the resource you chose.
8. Click on the OK button.
9. Go to the server instance page and select the Apply Changes button.
Perl CGI Programs

You cannot run CGIs using Perl 5.6.x with the -w flag. Instead, include the following code in the file:

```
use warnings;
```

Global CGI Settings

To change global CGI settings:

1. Open the HTTP Server component under your server instance in the Administration interface.
2. Go to the HTTP Server page.
3. Click on the Advanced tab.
4. Click on the CGI option.
5. You can change the following settings:
   - MinCGIStubs - Sets the number of CGIStub processes that are started by default. This value must be lower than MaxCGIStubs. The default is 2.
   - CGIExpirationTimeout - Specifies the maximum time in seconds that CGI processes are allowed to run before being killed. The default is 0, which means processes are allowed to run indefinitely.
   - CGIStubIdleTimeout - Kills any CGIStub processes that have been idle for this number of seconds. The default is 30.
   - MaxCGIStubs - Sets the maximum number of CGIStub processes the server can execute concurrently. The default is 10.
6. Click on the OK button.
7. Go to the server instance page and select the Apply Changes button.

For more information about these global CGI settings, see the description of the init.conf file in the Sun ONE Application Server Administrator’s Configuration File Reference.
CGI Variables

In addition to the standard CGI variables, you can use the Sun ONE Application Server CGI variables in CGI programs to access information about the client certificate if the server is running in secure mode. The CLIENT_CERT and REVOCATION variables are available only when client certificate based authentication is enabled.

The following table lists the Sun ONE Application Server CGI variables. The left column lists the variables, and the right column lists descriptions of those variables.

<table>
<thead>
<tr>
<th>Variable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SERVER_URL</td>
<td>The URL of the server that the client requested</td>
</tr>
<tr>
<td>HTTP_xxx</td>
<td>An incoming HTTP request header, where xxx is the name of the header</td>
</tr>
<tr>
<td>HTTPS</td>
<td>ON if the server is in secure mode and OFF otherwise</td>
</tr>
<tr>
<td>HTTPS_KEYSIZE</td>
<td>The keysize of the SSL handshake (available if the server is in secure mode)</td>
</tr>
<tr>
<td>HTTPS_SECRETKEYSIZE</td>
<td>The keysize of the secret part of the SSL handshake (available if the server is in secure mode)</td>
</tr>
<tr>
<td>HTTPS_SESSIONID</td>
<td>The session ID for the connection (available if the server is in secure mode)</td>
</tr>
<tr>
<td>CLIENT_CERT</td>
<td>The certificate that the client provided (binary DER format)</td>
</tr>
<tr>
<td>CLIENT_CERT_SUBJECT_DN</td>
<td>The Distinguished Name of the subject of the client certificate</td>
</tr>
<tr>
<td>CLIENT_CERT_SUBJECT_OU</td>
<td>The Organization Unit of the subject of the client certificate</td>
</tr>
<tr>
<td>CLIENT_CERT_SUBJECT_O</td>
<td>The Organization of the subject of the client certificate</td>
</tr>
<tr>
<td>CLIENT_CERT_SUBJECT_C</td>
<td>The Country of the subject of the client certificate</td>
</tr>
<tr>
<td>CLIENT_CERT_SUBJECT_L</td>
<td>The Location of the subject of the client certificate</td>
</tr>
<tr>
<td>CLIENT_CERT_SUBJECT_ST</td>
<td>The State of the subject of the client certificate</td>
</tr>
<tr>
<td>CLIENT_CERT_SUBJECT_E</td>
<td>The E-mail of the subject of the client certificate</td>
</tr>
<tr>
<td>Variable</td>
<td>Description</td>
</tr>
<tr>
<td>----------------------------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>CLIENT_CERT_SUBJECT_UID</td>
<td>The UID part of the CN of the subject of the client certificate</td>
</tr>
<tr>
<td>CLIENT_CERT_ISSUER_DN</td>
<td>The Distinguished Name of the issuer of the client certificate</td>
</tr>
<tr>
<td>CLIENT_CERT_ISSUER_OU</td>
<td>The Organization Unit of the issuer of the client certificate</td>
</tr>
<tr>
<td>CLIENT_CERT_ISSUER_O</td>
<td>The Organization of the issuer of the client certificate</td>
</tr>
<tr>
<td>CLIENT_CERT_ISSUER_C</td>
<td>The Country of the issuer of the client certificate</td>
</tr>
<tr>
<td>CLIENT_CERT_ISSUER_L</td>
<td>The Location of the issuer of the client certificate</td>
</tr>
<tr>
<td>CLIENT_CERT_ISSUER_ST</td>
<td>The State of the issuer of the client certificate</td>
</tr>
<tr>
<td>CLIENT_CERT_ISSUER_E</td>
<td>The E-mail of the issuer of the client certificate</td>
</tr>
<tr>
<td>CLIENT_CERT_ISSUER_UID</td>
<td>The UID part of the CN of the issuer of the client certificate</td>
</tr>
<tr>
<td>CLIENT_CERT_VALIDITY_START</td>
<td>The start date of the certificate</td>
</tr>
<tr>
<td>CLIENT_CERT_VALIDITY_EXPIRES</td>
<td>The expiration date of the certificate</td>
</tr>
<tr>
<td>CLIENT_CERT_EXTENSION_(xxx)</td>
<td>The certificate extension, where (xxx) is the name of the extension</td>
</tr>
<tr>
<td>REVOCACTION_METHOD</td>
<td>The name of the certificate revocation method if it exists</td>
</tr>
<tr>
<td>REVOCACTION_STATUS</td>
<td>The status of certificate revocation if it exists</td>
</tr>
</tbody>
</table>
