ERRORS	<p>The <code>mkfifo()</code> function will fail if:</p> <table><tr><td><code>EACCES</code></td><td>A component of the path prefix denies search permission, or write permission is denied on the parent directory of the FIFO to be created.</td></tr><tr><td><code>EEXIST</code></td><td>The named file already exists.</td></tr><tr><td><code>ELOOP</code></td><td>A loop exists in symbolic links encountered during resolution of the <i>path</i> argument.</td></tr><tr><td><code>ENAMETOOLONG</code></td><td>The length of the <i>path</i> argument exceeds <code>{PATH_MAX}</code> or a pathname component is longer than <code>{NAME_MAX}</code>.</td></tr><tr><td><code>ENOENT</code></td><td>A component of the path prefix specified by <i>path</i> does not name an existing directory or <i>path</i> is an empty string.</td></tr><tr><td><code>ENOSPC</code></td><td>The directory that would contain the new file cannot be extended or the file system is out of file-allocation resources.</td></tr><tr><td><code>ENOTDIR</code></td><td>A component of the path prefix is not a directory.</td></tr><tr><td><code>EROFS</code></td><td>The named file resides on a read-only file system.</td></tr></table> <p>The <code>mkfifo()</code> function may fail if:</p>	<code>EACCES</code>	A component of the path prefix denies search permission, or write permission is denied on the parent directory of the FIFO to be created.	<code>EEXIST</code>	The named file already exists.	<code>ELOOP</code>	A loop exists in symbolic links encountered during resolution of the <i>path</i> argument.	<code>ENAMETOOLONG</code>	The length of the <i>path</i> argument exceeds <code>{PATH_MAX}</code> or a pathname component is longer than <code>{NAME_MAX}</code> .	<code>ENOENT</code>	A component of the path prefix specified by <i>path</i> does not name an existing directory or <i>path</i> is an empty string.	<code>ENOSPC</code>	The directory that would contain the new file cannot be extended or the file system is out of file-allocation resources.	<code>ENOTDIR</code>	A component of the path prefix is not a directory.	<code>EROFS</code>	The named file resides on a read-only file system.
<code>EACCES</code>	A component of the path prefix denies search permission, or write permission is denied on the parent directory of the FIFO to be created.																
<code>EEXIST</code>	The named file already exists.																
<code>ELOOP</code>	A loop exists in symbolic links encountered during resolution of the <i>path</i> argument.																
<code>ENAMETOOLONG</code>	The length of the <i>path</i> argument exceeds <code>{PATH_MAX}</code> or a pathname component is longer than <code>{NAME_MAX}</code> .																
<code>ENOENT</code>	A component of the path prefix specified by <i>path</i> does not name an existing directory or <i>path</i> is an empty string.																
<code>ENOSPC</code>	The directory that would contain the new file cannot be extended or the file system is out of file-allocation resources.																
<code>ENOTDIR</code>	A component of the path prefix is not a directory.																
<code>EROFS</code>	The named file resides on a read-only file system.																

ELOOP Too many symbolic links were encountered in resolving *path*.

ENAMETOOLONG The length of the *path* argument exceeds {PATH_MAX} or a pathname component is longer than {NAME_MAX}.

EXAMPLES **EXAMPLE 1** Create a FIFO File

The following example demonstrates how to create a FIFO file named `/home/cnd/mod_done` with read and write permissions for the owner and read permissions for the group and others.

```
#include sys/types.h>
#include sys/stat.h>
int status;
...
status = mkfifo("/home/cnd/mod_done", S_IWUSR | S_IRUSR |
              S_IRGRP | S_IROTH);
```

mkstemp(3C)

NAME	mkstemp – make a unique file name
SYNOPSIS	<pre>#include <stdlib.h> int mkstemp(char *<i>template</i>);</pre>
DESCRIPTION	The <code>mkstemp()</code> function replaces the contents of the string pointed to by <i>template</i> by a unique file name, and returns a file descriptor for the file open for reading and writing. The function thus prevents any possible race condition between testing whether the file exists and opening it for use. The string in <i>template</i> should look like a file name with six trailing 'X's; <code>mkstemp()</code> replaces each 'X' with a character from the portable file name character set. The characters are chosen such that the resulting name does not duplicate the name of an existing file.
RETURN VALUES	Upon successful completion, <code>mkstemp()</code> returns an open file descriptor. Otherwise <code>-1</code> is returned if no suitable file could be created.
ERRORS	No errors are defined.
USAGE	It is possible to run out of letters. <p>The <code>mkstemp()</code> function does not check to determine whether the file name part of <i>template</i> exceeds the maximum allowable file name length.</p> <p>The <code>tmpfile(3C)</code> function is preferred over this function.</p> <p>The <code>mkstemp()</code> function has a transitional interface for 64-bit file offsets. See <code>lf64(5)</code>.</p>
SEE ALSO	<code>getpid(2)</code> , <code>open(2)</code> , <code>tmpfile(3C)</code> , <code>tmpnam(3C)</code> , <code>lf64(5)</code> , <code>standards(5)</code>

- NAME** mktemp – make a unique file name
- SYNOPSIS** `#include <stdlib.h>`
`char *mktemp(char *template);`
- DESCRIPTION** The `mktemp()` function replaces the contents of the string pointed to by *template* with a unique file name, and returns *template*. The string in *template* should look like a file name with six trailing 'X's; `mktemp()` will replace the 'X's with a character string that can be used to create a unique file name. Only 26 unique file names per thread can be created for each unique *template*.
- RETURN VALUES** The `mktemp()` function will assign to *template* the empty string if it cannot create a unique name.
- ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
MT-Level	Safe

mktime(3C)

NAME	mktime – converts a tm structure to a calendar time
SYNOPSIS	<pre>#include <time.h> time_t mktime(struct tm *timeptr);</pre>
DESCRIPTION	<p>The mktime() function converts the time represented by the tm structure pointed to by timeptr into a calendar time (the number of seconds since 00:00:00 UTC, January 1, 1970).</p> <p>The tm structure contains the following members:</p> <pre>int tm_sec; /* seconds after the minute [0, 61] */ int tm_min; /* minutes after the hour [0, 59] */ int tm_hour; /* hour since midnight [0, 23] */ int tm_mday; /* day of the month [1, 31] */ int tm_mon; /* months since January [0, 11] */ int tm_year; /* years since 1900 */ int tm_wday; /* days since Sunday [0, 6] */ int tm_yday; /* days since January 1 [0, 365] */ int tm_isdst; /* flag for daylight savings time */</pre> <p>In addition to computing the calendar time, mktime() normalizes the supplied tm structure. The original values of the tm_wday and tm_yday components of the structure are ignored, and the original values of the other components are not restricted to the ranges indicated in the definition of the structure. On successful completion, the values of the tm_wday and tm_yday components are set appropriately, and the other components are set to represent the specified calendar time, but with their values forced to be within the appropriate ranges. The final value of tm_mday is not set until tm_mon and tm_year are determined.</p> <p>The tm_year member must be for year 1901 or later. Calendar times before 20:45:52 UTC, December 13, 1901 or after 03:14:07 UTC, January 19, 2038 cannot be represented. Portable applications should not try to create dates before 00:00:00 UTC, January 1, 1970 or after 00:00:00 UTC, January 1, 2038.</p> <p>The original values of the components may be either greater than or less than the specified range. For example, a tm_hour of -1 means 1 hour before midnight, tm_mday of 0 means the day preceding the current month, and tm_mon of -2 means 2 months before January of tm_year.</p> <p>If tm_isdst is positive, the original values are assumed to be in the alternate timezone. If it turns out that the alternate timezone is not valid for the computed calendar time, then the components are adjusted to the main timezone. Likewise, if tm_isdst is zero, the original values are assumed to be in the main timezone and are converted to the alternate timezone if the main timezone is not valid. If tm_isdst is negative, mktime() attempts to determine whether the alternate timezone is in effect for the specified time.</p> <p>Local timezone information is used as if mktime() had called tzset(). See ctime(3C).</p>

RETURN VALUES	If the calendar time can be represented in an object of type <code>time_t</code> , <code>mktime()</code> returns the specified calendar time without changing <code>errno</code> . If the calendar time cannot be represented, the function returns the value <code>(time_t)-1</code> and sets <code>errno</code> to indicate the error.
ERRORS	The <code>mktime()</code> function will fail if: <ul style="list-style-type: none"> <code>EOVERFLOW</code> The date represented by the input <code>tm</code> struct cannot be represented in a <code>time_t</code>. Note that the <code>errno</code> setting may change if future revisions to the standards specify a different value.
USAGE	The <code>mktime()</code> function is MT-Safe in multithreaded applications, as long as no user-defined function directly modifies one of the following variables: <code>timezone</code> , <code>altzone</code> , <code>daylight</code> , and <code>tzname</code> . See <code>ctime(3C)</code> . <p>Note that <code>-1</code> can be a valid return value for the time that is one second before the Epoch. The user should clear <code>errno</code> before calling <code>mktime()</code>. If <code>mktime()</code> then returns <code>-1</code>, the user should check <code>errno</code> to determine whether or not an error actually occurred.</p> <p>The <code>mktime()</code> function assumes Gregorian dates. Times before the adoption of the Gregorian calendar will not match historical records.</p>
EXAMPLES	EXAMPLE 1 Sample code using <code>mktime()</code> . <p>What day of the week is July 4, 2001?</p> <pre>#include <stdio.h> #include <time.h> static char *const wday[] = { "Sunday", "Monday", "Tuesday", "Wednesday", "Thursday", "Friday", "Saturday", "-unknown-" }; struct tm time_str; /* . . . */ time_str.tm_year = 2001 - 1900; time_str.tm_mon = 7 - 1; time_str.tm_mday = 4; time_str.tm_hour = 0; time_str.tm_min = 0; time_str.tm_sec = 1; time_str.tm_isdst = -1; if (mktime(&time_str) == -1) time_str.tm_wday = 7; printf("%s\n", wday[time_str.tm_wday]);</pre>
BUGS	The <code>zoneinfo</code> <code>timezone</code> data files do not transition past Tue Jan 19 03:14:07 2038 UTC. Therefore for 64-bit applications using <code>zoneinfo</code> timezones, calculations beyond this date may not use the correct offset from standard time, and could return incorrect values. This affects the 64-bit version of <code>mktime()</code> .

mktime(3C)

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
MT-Level	MT-Safe with exceptions

SEE ALSO `ctime(3C)`, `getenv(3C)`, `TIMEZONE(4)`, `attributes(5)`

NAME	mlock, munlock – lock or unlock pages in memory				
Default	<pre>#include <sys/mman.h> int mlock(caddr_t addr, size_t len); int munlock(caddr_t addr, size_t len);</pre>				
Standard conforming	<pre>#include <sys/mman.h> int mlock(const void * addr, size_t len); int munlock(const void * addr, size_t len);</pre>				
DESCRIPTION	<p>The <code>mlock()</code> function uses the mappings established for the address range <code>[addr, addr + len)</code> to identify pages to be locked in memory. If the page identified by a mapping changes, such as occurs when a copy of a writable <code>MAP_PRIVATE</code> page is made upon the first store, the lock will be transferred to the newly copied private page.</p> <p>The <code>munlock()</code> function removes locks established with <code>mlock()</code>.</p> <p>A given page may be locked multiple times by executing an <code>mlock()</code> through different mappings. That is, if two different processes lock the same page, then the page will remain locked until both processes remove their locks. However, within a given mapping, page locks do not nest – multiple <code>mlock()</code> operations on the same address in the same process will all be removed with a single <code>munlock()</code>. Of course, a page locked in one process and mapped in another (or visible through a different mapping in the locking process) is still locked in memory. This fact can be used to create applications that do nothing other than lock important data in memory, thereby avoiding page I/O faults on references from other processes in the system.</p> <p>If the mapping through which an <code>mlock()</code> has been performed is removed, an <code>munlock()</code> is implicitly performed. An <code>munlock()</code> is also performed implicitly when a page is deleted through file removal or truncation.</p> <p>Locks established with <code>mlock()</code> are not inherited by a child process after a <code>fork()</code> and are not nested.</p> <p>Attempts to <code>mlock()</code> more memory than a system-specific limit will fail.</p>				
RETURN VALUES	<p>Upon successful completion, the <code>mlock()</code> and <code>munlock()</code> functions return 0. Otherwise, no changes are made to any locks in the address space of the process, the functions return <code>-1</code> and set <code>errno</code> to indicate the error.</p>				
ERRORS	<p>The <code>mlock()</code> and <code>munlock()</code> functions will fail if:</p> <table border="0"> <tr> <td style="padding-right: 20px;">EINVAL</td> <td>The <code>addr</code> argument is not a multiple of the page size as returned by <code>sysconf(3C)</code>.</td> </tr> <tr> <td>ENOMEM</td> <td>Addresses in the range <code>[addr, addr + len)</code> are invalid for the address space of a process, or specify one or more pages which are not mapped.</td> </tr> </table>	EINVAL	The <code>addr</code> argument is not a multiple of the page size as returned by <code>sysconf(3C)</code> .	ENOMEM	Addresses in the range <code>[addr, addr + len)</code> are invalid for the address space of a process, or specify one or more pages which are not mapped.
EINVAL	The <code>addr</code> argument is not a multiple of the page size as returned by <code>sysconf(3C)</code> .				
ENOMEM	Addresses in the range <code>[addr, addr + len)</code> are invalid for the address space of a process, or specify one or more pages which are not mapped.				

mlock(3C)

ENOSYS The system does not support this memory locking interface.

EPERM The process's effective user ID is not superuser.

The `mlock()` function will fail if:

EAGAIN Some or all of the memory identified by the range `[addr, addr + len)` could not be locked because of insufficient system resources.

USAGE Because of the impact on system resources, the use of `mlock()` and `munlock()` is restricted to the superuser.

NAME	mlockall, munlockall – lock or unlock address space						
SYNOPSIS	<pre>#include <sys/mman.h> int mlockall(int <i>flags</i>); int munlockall(void);</pre>						
DESCRIPTION	<p>The <code>mlockall()</code> function locks in memory all pages mapped by an address space.</p> <p>The value of <i>flags</i> determines whether the pages to be locked are those currently mapped by the address space, those that will be mapped in the future, or both:</p> <pre> MCL_CURRENT Lock current mappings MCL_FUTURE Lock future mappings</pre> <p>If <code>MCL_FUTURE</code> is specified for <code>mlockall()</code>, mappings are locked as they are added to the address space (or replace existing mappings), provided sufficient memory is available. Locking in this manner is not persistent across the <code>exec</code> family of functions (see <code>exec(2)</code>).</p> <p>Mappings locked using <code>mlockall()</code> with any option may be explicitly unlocked with a <code>munlock()</code> call (see <code>mlock(3C)</code>).</p> <p>The <code>munlockall()</code> function removes address space locks and locks on mappings in the address space.</p> <p>All conditions and constraints on the use of locked memory that apply to <code>mlock(3C)</code> also apply to <code>mlockall()</code>.</p> <p>Locks established with <code>mlockall()</code> are not inherited by a child process after a <code>fork(2)</code> call, and are not nested.</p>						
RETURN VALUES	Upon successful completion, the <code>mlockall()</code> and <code>munlockall()</code> functions return 0. Otherwise, they return <code>-1</code> and set <code>errno</code> to indicate the error.						
ERRORS	<p>The <code>mlockall()</code> and <code>munlockall()</code> functions will fail if:</p> <table border="0"> <tr> <td style="vertical-align: top;"><code>EAGAIN</code></td> <td>Some or all of the memory in the address space could not be locked due to sufficient resources. This error condition applies to <code>mlockall()</code> only.</td> </tr> <tr> <td style="vertical-align: top;"><code>EINVAL</code></td> <td>The <i>flags</i> argument contains values other than <code>MCL_CURRENT</code> and <code>MCL_FUTURE</code>.</td> </tr> <tr> <td style="vertical-align: top;"><code>EPERM</code></td> <td>The process's effective user ID is not super-user.</td> </tr> </table>	<code>EAGAIN</code>	Some or all of the memory in the address space could not be locked due to sufficient resources. This error condition applies to <code>mlockall()</code> only.	<code>EINVAL</code>	The <i>flags</i> argument contains values other than <code>MCL_CURRENT</code> and <code>MCL_FUTURE</code> .	<code>EPERM</code>	The process's effective user ID is not super-user.
<code>EAGAIN</code>	Some or all of the memory in the address space could not be locked due to sufficient resources. This error condition applies to <code>mlockall()</code> only.						
<code>EINVAL</code>	The <i>flags</i> argument contains values other than <code>MCL_CURRENT</code> and <code>MCL_FUTURE</code> .						
<code>EPERM</code>	The process's effective user ID is not super-user.						
USAGE	The <code>mlockall()</code> and <code>munlockall()</code> functions require super-user privileges.

NAME	modf, modff – decompose floating-point number				
SYNOPSIS	<pre>#include <math.h> double modf(double <i>x</i>, double <i>*iptr</i>); float modff(float <i>x</i>, float <i>*iptr</i>);</pre>				
DESCRIPTION	The <code>modf()</code> and <code>modff()</code> functions break the argument <i>x</i> into integral and fractional parts, each of which has the same sign as the argument. The <code>modf()</code> function stores the integral part as a <code>double</code> in the object pointed to by <i>iptr</i> . The <code>modff()</code> function stores the integral part as a <code>float</code> in the object pointed to by <i>iptr</i> .				
RETURN VALUES	<p>Upon successful completion, <code>modf()</code> and <code>modff()</code> return the signed fractional part of <i>x</i>.</p> <p>If <i>x</i> is NaN, NaN is returned and <i>*iptr</i> is set to NaN.</p> <p>If the correct value would cause underflow to 0.0, <code>modf()</code> returns 0 and <code>errno</code> may be set to <code>ERANGE</code>.</p>				
ERRORS	<p>The <code>modf()</code> function may fail if:</p> <p><code>ERANGE</code> The result underflows.</p>				
USAGE	An application wishing to check for error situations should set <code>errno</code> to 0 before calling <code>modf()</code> . If <code>errno</code> is non-zero on return, or the return value is NaN, an error has occurred.

NAME	monitor – prepare process execution profile
SYNOPSIS	<pre>#include <mon.h> void monitor(int (*lowpc()), int (*highpc()), WORD *buffer, size_t bufsize, size_t nfunc);</pre>
DESCRIPTION	<p>The <code>monitor()</code> function is an interface to the <code>profil(2)</code> function and is called automatically with default parameters by any program created by the <code>cc(1B)</code> utility with the <code>-p</code> option specified. Except to establish further control over profiling activity, it is not necessary to explicitly call <code>monitor()</code>.</p> <p>When used, <code>monitor()</code> is called at least at the beginning and the end of a program. The first call to <code>monitor()</code> initiates the recording of two different kinds of execution-profile information: execution-time distribution and function call count. Execution-time distribution data is generated by <code>profil()</code> and the function call counts are generated by code supplied to the object file (or files) by <code>cc(1B) -p</code>. Both types of information are collected as a program executes. The last call to <code>monitor()</code> writes this collected data to the output file <code>mon.out</code>.</p> <p>The name of the file written by <code>monitor()</code> is controlled by the environment variable <code>PROFDIR</code>. If <code>PROFDIR</code> does not exist, the file <code>mon.out</code> is created in the current directory. If <code>PROFDIR</code> exists but has no value, <code>monitor()</code> does no profiling and creates no output file. If <code>PROFDIR</code> is <code>dirname</code>, and <code>monitor()</code> is called automatically by compilation with <code>cc -p</code>, the file created is <code>dirname/pid.progname</code> where <i>progname</i> is the name of the program.</p> <p>The <i>lowpc</i> and <i>highpc</i> arguments are the beginning and ending addresses of the region to be profiled.</p> <p>The <i>buffer</i> argument is the address of a user-supplied array of <code>WORD</code> (defined in the header <code><mon.h></code>). The <i>buffer</i> argument is used by <code>monitor()</code> to store the histogram generated by <code>profil()</code> and the call counts.</p> <p>The <i>bufsize</i> argument identifies the number of array elements in <i>buffer</i>.</p> <p>The <i>nfunc</i> argument is the number of call count cells that have been reserved in <i>buffer</i>. Additional call count cells will be allocated automatically as they are needed.</p> <p>The <i>bufsize</i> argument should be computed using the following formula:</p> <pre>size_of_buffer = sizeof(struct hdr) + nfunc * sizeof(struct cnt) + ((highpc-lowpc)/BARSIZE) * sizeof(WORD) + sizeof(WORD) - 1 ; bufsize = (size_of_buffer / sizeof(WORD));</pre> <p>where:</p> <ul style="list-style-type: none"> ■ <i>lowpc</i>, <i>highpc</i>, <i>nfunc</i> are the same as the arguments to <code>monitor()</code>;

monitor(3C)

- *BARSIZE* is the number of program bytes that correspond to each histogram bar, or cell, of the `profil()` buffer;
- the `hdr` and `cnt` structures and the type `WORD` are defined in the header `<mon.h>`.

The default call to `monitor()` is as follows:

```
monitor (&eprol, &etext, wbuf, wbufsz, 600);
```

where:

- `eprol` is the beginning of the user's program when linked with `cc -p` (see `end(3C)`);
- `etext` is the end of the user's program (see `end(3C)`);
- `wbuf` is an array of `WORD` with `wbufsz` elements;
- `wbufsz` is computed using the *bufsize* formula shown above with *BARSIZE* of 8;
- 600 is the number of call count cells that have been reserved in *buffer*.

These parameter settings establish the computation of an execution-time distribution histogram that uses `profil()` for the entire program, initially reserves room for 600 call count cells in *buffer*, and provides for enough histogram cells to generate significant distribution-measurement results. For more information on the effects of *bufsize* on execution-distribution measurements, see `profil(2)`.

EXAMPLES

EXAMPLE 1 Example to stop execution monitoring and write the results to a file.

To stop execution monitoring and write the results to a file, use the following:

```
monitor( (int (*)())0, (int (*)())0, (WORD *)0, 0, 0);
```

Use `prof` to examine the results.

USAGE

Additional calls to `monitor()` after `main()` has been called and before `exit()` has been called will add to the function-call count capacity, but such calls will also replace and restart the `profil()` histogram computation.

NAME	drand48, erand48, lrand48, nrand48, mrand48, jrand48, srand48, seed48, lcong48 – generate uniformly distributed pseudo-random numbers
SYNOPSIS	<pre>#include <stdlib.h> double drand48(void); double erand48(unsigned short <i>x_i[3]</i>); long lrand48(void); long nrand48(unsigned short <i>x_i[3]</i>); long mrnd48(void); long jrnd48(unsigned short <i>x_i[3]</i>); void srand48(long <i>seedval</i>); unsigned short *seed48(unsigned short <i>seed16v[3]</i>); void lcong48(unsigned short <i>param[7]</i>);</pre>
DESCRIPTION	<p>This family of functions generates pseudo-random numbers using the well-known linear congruential algorithm and 48-bit integer arithmetic.</p> <p>Functions <code>drand48()</code> and <code>erand48()</code> return non-negative double-precision floating-point values uniformly distributed over the interval [0.0, 1.0).</p> <p>Functions <code>lrand48()</code> and <code>nrand48()</code> return non-negative long integers uniformly distributed over the interval $[0, 2^{31}]$.</p> <p>Functions <code>mrnd48()</code> and <code>jrnd48()</code> return signed long integers uniformly distributed over the interval $[-2^{31}, 2^{31}]$.</p> <p>Functions <code>srand48()</code>, <code>seed48()</code>, and <code>lcong48()</code> are initialization entry points, one of which should be invoked before either <code>drand48()</code>, <code>lrand48()</code>, or <code>mrnd48()</code> is called. (Although it is not recommended practice, constant default initializer values will be supplied automatically if <code>drand48()</code>, <code>lrand48()</code>, or <code>mrnd48()</code> is called without a prior call to an initialization entry point.) Functions <code>erand48()</code>, <code>nrand48()</code>, and <code>jrnd48()</code> do not require an initialization entry point to be called first.</p> <p>All the routines work by generating a sequence of 48-bit integer values, X_i, according to the linear congruential formula</p> $X_{n+1} = (aX_n + c) \bmod m \quad n \geq 0.$ <p>The parameter $m = 2^{48}$; hence 48-bit integer arithmetic is performed. Unless <code>lcong48()</code> has been invoked, the multiplier value a and the addend value c are given by</p> $a = 5DEECE66D_{16} = 273673163155_8$

rand48(3C)

$c = B_{16} = 13_8$.

The value returned by any of the functions `drand48()`, `erand48()`, `lrand48()`, `nrand48()`, `rand48()`, or `jrand48()` is computed by first generating the next 48-bit X_i in the sequence. Then the appropriate number of bits, according to the type of data item to be returned, are copied from the high-order (leftmost) bits of X_i and transformed into the returned value.

The functions `drand48()`, `lrand48()`, and `rand48()` store the last 48-bit X_i generated in an internal buffer. X_i must be initialized prior to being invoked. The functions `erand48()`, `nrand48()`, and `jrand48()` require the calling program to provide storage for the successive X_i values in the array specified as an argument when the functions are invoked. These routines do not have to be initialized; the calling program must place the desired initial value of X_i into the array and pass it as an argument. By using different arguments, functions `erand48()`, `nrand48()`, and `jrand48()` allow separate modules of a large program to generate several *independent* streams of pseudo-random numbers, that is, the sequence of numbers in each stream will *not* depend upon how many times the routines have been called to generate numbers for the other streams.

The initializer function `srand48()` sets the high-order 32 bits of X_i to the 32 bits contained in its argument. The low-order 16 bits of X_i are set to the arbitrary value $330E_{16}$.

The initializer function `seed48()` sets the value of X_i to the 48-bit value specified in the argument array. In addition, the previous value of X_i is copied into a 48-bit internal buffer, used only by `seed48()`, and a pointer to this buffer is the value returned by `seed48()`. This returned pointer, which can just be ignored if not needed, is useful if a program is to be restarted from a given point at some future time — use the pointer to get at and store the last X_i value, and then use this value to reinitialize using `seed48()` when the program is restarted.

The initialization function `lcg48()` allows the user to specify the initial X_i , the multiplier value a , and the addend value c . Argument array elements `param[0-2]` specify X_i , `param[3-5]` specify the multiplier a , and `param[6]` specifies the 16-bit addend c . After `lcg48()` has been called, a subsequent call to either `srand48()` or `seed48()` will restore the “standard” multiplier and addend values, a and c , specified above.

NAME	msync – synchronize memory with physical storage
SYNOPSIS	<pre>#include <sys/mman.h> int msync(void *addr, size_t len, int flags);</pre>
DESCRIPTION	<p>The <code>msync()</code> function writes all modified copies of pages over the range <code>[addr, addr + len)</code> to the underlying hardware, or invalidates any copies so that further references to the pages will be obtained by the system from their permanent storage locations. The permanent storage for a modified <code>MAP_SHARED</code> mapping is the file the page is mapped to; the permanent storage for a modified <code>MAP_PRIVATE</code> mapping is its swap area.</p> <p>The <code>flags</code> argument is a bit pattern built from the following values:</p> <p><code>MS_ASYNC</code> perform asynchronous writes</p> <p><code>MS_SYNC</code> perform synchronous writes</p> <p><code>MS_INVALIDATE</code> invalidate mappings</p> <p>If <code>flags</code> is <code>MS_ASYNC</code> or <code>MS_SYNC</code>, the function synchronizes the file contents to match the current contents of the memory region.</p> <ul style="list-style-type: none"> ■ All write references to the memory region made prior to the call are visible by subsequent read operations on the file. ■ All writes to the same portion of the file prior to the call may or may not be visible by read references to the memory region. ■ Unmodified pages in the specified range are not written to the underlying hardware. <p>If <code>flags</code> is <code>MS_ASYNC</code>, the function may return immediately once all write operations are scheduled; if <code>flags</code> is <code>MS_SYNC</code>, the function does not return until all write operations are completed.</p> <p>If <code>flags</code> is <code>MS_INVALIDATE</code>, the function synchronizes the contents of the memory region to match the current file contents.</p> <ul style="list-style-type: none"> ■ All writes to the mapped portion of the file made prior to the call are visible by subsequent read references to the mapped memory region. ■ All write references prior to the call, by any process, to memory regions mapped to the same portion of the file using <code>MAP_SHARED</code>, are visible by read references to the region. <p>If <code>msync()</code> causes any write to the file, then the file's <code>st_ctime</code> and <code>st_mtime</code> fields are marked for update.</p>
RETURN VALUES	Upon successful completion, <code>msync()</code> returns 0; otherwise, it returns -1 and sets <code>errno</code> to indicate the error.
ERRORS	The <code>msync()</code> function will fail if:

msync(3C)

EBUSY	Some or all of the addresses in the range [<i>addr</i> , <i>addr + len</i>) are locked and MS_SYNC with the MS_INVALIDATE option is specified.
EAGAIN	Some or all pages in the range [<i>addr</i> , <i>addr + len</i>) are locked for I/O.
EINVAL	The <i>addr</i> argument is not a multiple of the page size as returned by <code>sysconf(3C)</code> . The <i>flags</i> argument is not some combination of MS_ASYNC and MS_INVALIDATE.
EIO	An I/O error occurred while reading from or writing to the file system.
ENOMEM	Addresses in the range [<i>addr</i> , <i>addr + len</i>) are outside the valid range for the address space of a process, or specify one or more pages that are not mapped.
EPERM	MS_INVALIDATE was specified and one or more of the pages is locked in memory.

USAGE The `msync()` function should be used by programs that require a memory object to be in a known state, for example in building transaction facilities.

Normal system activity can cause pages to be written to disk. Therefore, there are no guarantees that `msync()` is the only control over when pages are or are not written to disk.

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

NAME	mtmalloc, mallocctl – MT hot memory allocator
SYNOPSIS	<pre>#include <mtmalloc.h> cc -o a.out -pthread -lmtmalloc void *malloc(size_t size); void *calloc(size_t nelem, size_t elsize); void free(void *ptr); void *memalign(size_t alignment, size_t size); void *realloc(void *ptr, size_t size); void *valloc(size_t size); void mallocctl(int cmd, long value);</pre>
DESCRIPTION	<p>The <code>malloc()</code> and <code>free()</code> functions provide a simple general-purpose memory allocation package that is suitable for use in high performance multithreaded applications. The suggested use of this library is in multithreaded applications; it can be used for single threaded applications, but there is no advantage in doing so. This library cannot be dynamically loaded via <code>dlopen()</code> during runtime because there must be only one manager of the process heap.</p> <p>The <code>malloc()</code> function returns a pointer to a block of at least <i>size</i> bytes suitably aligned for any use.</p> <p>The argument to <code>free()</code> is a pointer to a block previously allocated by <code>malloc()</code>, <code>calloc()</code> or <code>realloc()</code>. After <code>free()</code> is performed this space is available for further allocation. If <i>ptr</i> is a null pointer, no action occurs.</p> <p>Undefined results will occur if the space assigned by <code>malloc()</code> is overrun or if a random number is handed to <code>free()</code>. A freed pointer that is passed to <code>free()</code> will send a SIGABRT signal to the calling process. This behavior is controlled by <code>mallocctl()</code>.</p> <p>The <code>calloc()</code> function allocates a zero-initialized space for an array of <i>nelem</i> elements of size <i>elsize</i>.</p> <p>The <code>memalign()</code> function allocates <i>size</i> bytes on a specified alignment boundary and returns a pointer to the allocated block. The value of the returned address is guaranteed to be an even multiple of <i>alignment</i>. Note that the value of <i>alignment</i> must be a power of two, and must be greater than or equal to the size of a word.</p> <p>The <code>realloc()</code> function changes the size of the block pointed to by <i>ptr</i> to <i>size</i> bytes and returns a pointer to the (possibly moved) block. The contents will be unchanged up to the lesser of the new and old sizes. If <i>ptr</i> is NULL, <code>realloc()</code> behaves like <code>malloc()</code> for the specified size. If <i>size</i> is 0 and <i>ptr</i> is not a null pointer, the object pointed to is freed.</p>

mtmalloc(3MALLOC)

The `valloc()` function has the same effect as `malloc()`, except that the allocated memory will be aligned to a multiple of the value returned by `sysconf(_SC_PAGESIZE)`.

After possible pointer coercion, each allocation routine returns a pointer to a space that is suitably aligned for storage of any type of object.

The `malloc()`, `realloc()`, `calloc()`, `memalign()`, and `valloc()` functions will fail if there is not enough available memory.

The `mallocctl()` function controls the behavior of the `malloc` library. The options fall into two general classes, debugging options and performance options.

MTDOUBLEFREE	Allows double free of a pointer. Setting <i>value</i> to 1 means yes and 0 means no. The default behavior of double free results in a core dump.
MTDEBUGPATTERN	Writes misaligned data into the buffer after <code>free()</code> . When the buffer is reallocated, the contents are verified to ensure that there was no access to the buffer after the free. If the buffer has been dirtied, a SIGABRT signal is delivered to the process. Setting <i>value</i> to 1 means yes and 0 means no. The default behavior is to <i>not</i> write misaligned data. The pattern used is <code>0xdeadbeef</code> . Use of this option results in a performance penalty.
MTINITBUFFER	Writes misaligned data into the newly allocated buffer. This option is useful for detecting some accesses before initialization. Setting <i>value</i> to 1 means yes and 0 means no. The default behavior is to <i>not</i> write misaligned data to the newly allocated buffer. The pattern used is <code>0xbaddcafe</code> . Use of this option results in a performance penalty.
MTCHUNKSIZE	This option changes the size of allocated memory when a pool has exhausted all available memory in the buffer. Increasing this value allocates more memory for the application. A substantial performance gain can occur because the library makes fewer calls to the OS for more memory. Acceptable number <i>values</i> are between 9 and 256; the default value is 9. This value is multiplied by 8192.

RETURN VALUES

If there is no available memory, `malloc()`, `realloc()`, `memalign()`, `valloc()`, and `calloc()` return a null pointer. When `realloc()` is called with *size* > 0 and returns `NULL`, the block pointed to by *ptr* is left intact. If *size*, *nelem*, or *elsize* is 0, either a null pointer or a unique pointer that can be passed to `free()` is returned.

If `malloc()`, `calloc()`, or `realloc()` returns unsuccessfully, `errno` will be set to indicate the error.

ERRORS The `malloc()`, `calloc()`, and `realloc()` functions will fail if:

- | | |
|--------|--|
| ENOMEM | The physical limits of the system are exceeded by <i>size</i> bytes of memory which cannot be allocated. |
| EAGAIN | There is not enough memory available to allocate <i>size</i> bytes of memory; but the application could try again later. |

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
MT-Level	Safe

SEE ALSO `brk(2)`, `getrlimit(2)`, `bsdmalloc(3MALLOC)`, `dlopen(3DL)`, `malloc(3C)`, `malloc(3MALLOC)`, `mapmalloc(3MALLOC)`, `signal(3HEAD)`, `watchmalloc(3MALLOC)`, `attributes(5)`

WARNINGS Undefined results will occur if the size requested for a block of memory exceeds the maximum size of a process's heap. This information may be obtained using `getrlimit()`.

NOTES Comparative Features of `malloc(3C)`, `bsdmalloc(3MALLOC)`, `malloc(3MALLOC)`, and `mtmalloc`.

- The `bsdmalloc(3MALLOC)` routines afford better performance, but are space-inefficient.
- The `malloc(3MALLOC)` routines are space-efficient, but have slower performance.
- The standard, fully SCD-compliant `malloc` routines are a trade-off between performance and space-efficiency.
- The `mtmalloc` routines provide fast, concurrent `malloc()` implementation that is space-inefficient.

The `free()` function does not set `errno`.

munlock(3C)

NAME	<code>mlock</code> , <code>munlock</code> – lock or unlock pages in memory				
Default	<pre>#include <sys/mman.h> int mlock(caddr_t <i>addr</i>, size_t <i>len</i>); int munlock(caddr_t <i>addr</i>, size_t <i>len</i>);</pre>				
Standard conforming	<pre>#include <sys/mman.h> int mlock(const void * <i>addr</i>, size_t <i>len</i>); int munlock(const void * <i>addr</i>, size_t <i>len</i>);</pre>				
DESCRIPTION	<p>The <code>mlock()</code> function uses the mappings established for the address range <code>[addr, addr + len)</code> to identify pages to be locked in memory. If the page identified by a mapping changes, such as occurs when a copy of a writable <code>MAP_PRIVATE</code> page is made upon the first store, the lock will be transferred to the newly copied private page.</p> <p>The <code>munlock()</code> function removes locks established with <code>mlock()</code>.</p> <p>A given page may be locked multiple times by executing an <code>mlock()</code> through different mappings. That is, if two different processes lock the same page, then the page will remain locked until both processes remove their locks. However, within a given mapping, page locks do not nest – multiple <code>mlock()</code> operations on the same address in the same process will all be removed with a single <code>munlock()</code>. Of course, a page locked in one process and mapped in another (or visible through a different mapping in the locking process) is still locked in memory. This fact can be used to create applications that do nothing other than lock important data in memory, thereby avoiding page I/O faults on references from other processes in the system.</p> <p>If the mapping through which an <code>mlock()</code> has been performed is removed, an <code>munlock()</code> is implicitly performed. An <code>munlock()</code> is also performed implicitly when a page is deleted through file removal or truncation.</p> <p>Locks established with <code>mlock()</code> are not inherited by a child process after a <code>fork()</code> and are not nested.</p> <p>Attempts to <code>mlock()</code> more memory than a system-specific limit will fail.</p>				
RETURN VALUES	Upon successful completion, the <code>mlock()</code> and <code>munlock()</code> functions return 0. Otherwise, no changes are made to any locks in the address space of the process, the functions return <code>-1</code> and set <code>errno</code> to indicate the error.				
ERRORS	The <code>mlock()</code> and <code>munlock()</code> functions will fail if: <table><tr><td><code>EINVAL</code></td><td>The <i>addr</i> argument is not a multiple of the page size as returned by <code>sysconf(3C)</code>.</td></tr><tr><td><code>ENOMEM</code></td><td>Addresses in the range <code>[addr, addr + len)</code> are invalid for the address space of a process, or specify one or more pages which are not mapped.</td></tr></table>	<code>EINVAL</code>	The <i>addr</i> argument is not a multiple of the page size as returned by <code>sysconf(3C)</code> .	<code>ENOMEM</code>	Addresses in the range <code>[addr, addr + len)</code> are invalid for the address space of a process, or specify one or more pages which are not mapped.
<code>EINVAL</code>	The <i>addr</i> argument is not a multiple of the page size as returned by <code>sysconf(3C)</code> .				
<code>ENOMEM</code>	Addresses in the range <code>[addr, addr + len)</code> are invalid for the address space of a process, or specify one or more pages which are not mapped.				

munlock(3C)

ENOSYS The system does not support this memory locking interface.

EPERM The process's effective user ID is not superuser.

The `mlock()` function will fail if:

EAGAIN Some or all of the memory identified by the range `[addr, addr + len)` could not be locked because of insufficient system resources.

USAGE Because of the impact on system resources, the use of `mlock()` and `munlock()` is restricted to the superuser.

munlockall(3C)

NAME	mlockall, munlockall – lock or unlock address space						
SYNOPSIS	<pre>#include <sys/mman.h> int mlockall(int flags); int munlockall(void);</pre>						
DESCRIPTION	<p>The <code>mlockall()</code> function locks in memory all pages mapped by an address space.</p> <p>The value of <i>flags</i> determines whether the pages to be locked are those currently mapped by the address space, those that will be mapped in the future, or both:</p> <pre> MCL_CURRENT Lock current mappings MCL_FUTURE Lock future mappings</pre> <p>If <code>MCL_FUTURE</code> is specified for <code>mlockall()</code>, mappings are locked as they are added to the address space (or replace existing mappings), provided sufficient memory is available. Locking in this manner is not persistent across the <code>exec</code> family of functions (see <code>exec(2)</code>).</p> <p>Mappings locked using <code>mlockall()</code> with any option may be explicitly unlocked with a <code>munlock()</code> call (see <code>mlock(3C)</code>).</p> <p>The <code>munlockall()</code> function removes address space locks and locks on mappings in the address space.</p> <p>All conditions and constraints on the use of locked memory that apply to <code>mlock(3C)</code> also apply to <code>mlockall()</code>.</p> <p>Locks established with <code>mlockall()</code> are not inherited by a child process after a <code>fork(2)</code> call, and are not nested.</p>						
RETURN VALUES	Upon successful completion, the <code>mlockall()</code> and <code>munlockall()</code> functions return 0. Otherwise, they return <code>-1</code> and set <code>errno</code> to indicate the error.						
ERRORS	The <code>mlockall()</code> and <code>munlockall()</code> functions will fail if:						
	<table><tr><td>EAGAIN</td><td>Some or all of the memory in the address space could not be locked due to sufficient resources. This error condition applies to <code>mlockall()</code> only.</td></tr><tr><td>EINVAL</td><td>The <i>flags</i> argument contains values other than <code>MCL_CURRENT</code> and <code>MCL_FUTURE</code>.</td></tr><tr><td>EPERM</td><td>The process's effective user ID is not super-user.</td></tr></table>	EAGAIN	Some or all of the memory in the address space could not be locked due to sufficient resources. This error condition applies to <code>mlockall()</code> only.	EINVAL	The <i>flags</i> argument contains values other than <code>MCL_CURRENT</code> and <code>MCL_FUTURE</code> .	EPERM	The process's effective user ID is not super-user.
EAGAIN	Some or all of the memory in the address space could not be locked due to sufficient resources. This error condition applies to <code>mlockall()</code> only.						
EINVAL	The <i>flags</i> argument contains values other than <code>MCL_CURRENT</code> and <code>MCL_FUTURE</code> .						
EPERM	The process's effective user ID is not super-user.						
USAGE	The <code>mlockall()</code> and <code>munlockall()</code> functions require super-user privileges.

ndbm(3C)

NAME	ndbm, dbm_clearerr, dbm_close, dbm_delete, dbm_error, dbm_fetch, dbm_firstkey, dbm_nextkey, dbm_open, dbm_store – database functions
SYNOPSIS	<pre>#include <ndbm.h> int dbm_clearerr(DBM *db); void dbm_close(DBM *db); int dbm_delete(DBM *db, datum key); int dbm_error(DBM *db); datum dbm_fetch(DBM *db, datum key); datum dbm_firstkey(DBM *db); datum dbm_nextkey(DBM *db); DBM *dbm_open(const char *file, int open_flags, mode_t file_mode); int dbm_store(DBM *db, datum key, datum content, int store_mode);</pre>
DESCRIPTION	<p>These functions create, access and modify a database. They maintain <i>key/content</i> pairs in a database. The functions will handle large databases (up to a billion blocks) and will access a keyed item in one or two file system accesses. This package replaces the earlier dbm(3UCB) library, which managed only a single database.</p> <p><i>keys</i> and <i>contents</i> are described by the datum typedef. A datum consists of at least two members, <i>dptr</i> and <i>dsize</i>. The <i>dptr</i> member points to an object that is <i>dsize</i> bytes in length. Arbitrary binary data, as well as ASCII character strings, may be stored in the object pointed to by <i>dptr</i>.</p> <p>The database is stored in two files. One file is a directory containing a bit map of keys and has <i>.dir</i> as its suffix. The second file contains all data and has <i>.pag</i> as its suffix.</p> <p>The <code>dbm_open()</code> function opens a database. The <i>file</i> argument to the function is the pathname of the database. The function opens two files named <i>file.dir</i> and <i>file.pag</i>. The <i>open_flags</i> argument has the same meaning as the <i>flags</i> argument of <code>open(2)</code> except that a database opened for write-only access opens the files for read and write access. The <i>file_mode</i> argument has the same meaning as the third argument of <code>open(2)</code>.</p> <p>The <code>dbm_close()</code> function closes a database. The argument <i>db</i> must be a pointer to a dbm structure that has been returned from a call to <code>dbm_open()</code>.</p> <p>The <code>dbm_fetch()</code> function reads a record from a database. The argument <i>db</i> is a pointer to a database structure that has been returned from a call to <code>dbm_open()</code>. The argument <i>key</i> is a datum that has been initialized by the application program to the value of the key that matches the key of the record the program is fetching.</p> <p>The <code>dbm_store()</code> function writes a record to a database. The argument <i>db</i> is a pointer to a database structure that has been returned from a call to <code>dbm_open()</code>. The argument <i>key</i> is a datum that has been initialized by the application program to the</p>

value of the key that identifies (for subsequent reading, writing or deleting) the record the program is writing. The argument *content* is a datum that has been initialized by the application program to the value of the record the program is writing. The argument *store_mode* controls whether `dbm_store()` replaces any pre-existing record that has the same key that is specified by the *key* argument. The application program must set *store_mode* to either `DBM_INSERT` or `DBM_REPLACE`. If the database contains a record that matches the *key* argument and *store_mode* is `DBM_REPLACE`, the existing record is replaced with the new record. If the database contains a record that matches the *key* argument and *store_mode* is `DBM_INSERT`, the existing record is not replaced with the new record. If the database does not contain a record that matches the *key* argument and *store_mode* is either `DBM_INSERT` or `DBM_REPLACE`, the new record is inserted in the database.

The `dbm_delete()` function deletes a record and its key from the database. The argument *db* is a pointer to a database structure that has been returned from a call to `dbm_open()`. The argument *key* is a datum that has been initialized by the application program to the value of the key that identifies the record the program is deleting.

The `dbm_firstkey()` function returns the first key in the database. The argument *db* is a pointer to a database structure that has been returned from a call to `dbm_open()`.

The `dbm_nextkey()` function returns the next key in the database. The argument *db* is a pointer to a database structure that has been returned from a call to `dbm_open()`. The `dbm_firstkey()` function must be called before calling `dbm_nextkey()`. Subsequent calls to `dbm_nextkey()` return the next key until all of the keys in the database have been returned.

The `dbm_error()` function returns the error condition of the database. The argument *db* is a pointer to a database structure that has been returned from a call to `dbm_open()`.

The `dbm_clearerr()` function clears the error condition of the database. The argument *db* is a pointer to a database structure that has been returned from a call to `dbm_open()`.

These database functions support key/content pairs of at least 1024 bytes.

RETURN VALUES

The `dbm_store()` and `dbm_delete()` functions return 0 when they succeed and a negative value when they fail.

The `dbm_store()` function returns 1 if it is called with a *flags* value of `DBM_INSERT` and the function finds an existing record with the same key.

The `dbm_error()` function returns 0 if the error condition is not set and returns a non-zero value if the error condition is set.

The return value of `dbm_clearerr()` is unspecified.

The `dbm_firstkey()` and `dbm_nextkey()` functions return a key datum. When the end of the database is reached, the `dptr` member of the key is a null pointer. If an error is detected, the `dptr` member of the key is a null pointer and the error condition of the database is set.

The `dbm_fetch()` function returns a content datum. If no record in the database matches the key or if an error condition has been detected in the database, the `dptr` member of the content is a null pointer.

The `dbm_open()` function returns a pointer to a database structure. If an error is detected during the operation, `dbm_open()` returns a `(DBM *)0`.

ERRORS No errors are defined.

USAGE The following code can be used to traverse the database:

```
for(key = dbm_firstkey(db); key.dptr != NULL; key = dbm_nextkey(db))
```

The `dbm_*` functions provided in this library should not be confused in any way with those of a general-purpose database management system. These functions do not provide for multiple search keys per entry, they do not protect against multi-user access (in other words they do not lock records or files), and they do not provide the many other useful database functions that are found in more robust database management systems. Creating and updating databases by use of these functions is relatively slow because of data copies that occur upon hash collisions. These functions are useful for applications requiring fast lookup of relatively static information that is to be indexed by a single key.

The `dptr` pointers returned by these functions may point into static storage that may be changed by subsequent calls.

The `dbm_delete()` function does not physically reclaim file space, although it does make it available for reuse.

After calling `dbm_store()` or `dbm_delete()` during a pass through the keys by `dbm_firstkey()` and `dbm_nextkey()`, the application should reset the database by calling `dbm_firstkey()` before again calling `dbm_nextkey()`.

EXAMPLES **EXAMPLE 1** Using the Database Functions

The following example stores and retrieves a phone number, using the name as the key. Note that this example does not include error checking.

```
#include <ndbm.h>
#include <stdio.h>
#include <fcntl.h>
#define NAME      "Bill"
#define PHONE_NO  "123-4567"
#define DB_NAME   "phones"
main()
{
    DBM *db;
    datum name = {NAME, sizeof (NAME)};
```

EXAMPLE 1 Using the Database Functions (Continued)

```

datum put_phone_no = {PHONE_NO, sizeof (PHONE_NO)};
datum get_phone_no;
/* Open the database and store the record */
db = dbm_open(DB_NAME, O_RDWR | O_CREAT, 0660);
(void) dbm_store(db, name, put_phone_no, DBM_INSERT);
/* Retrieve the record */
get_phone_no = dbm_fetch(db, name);
(void) printf("Name: %s, Phone Number: %s\n", name.dptr,
get_phone_no.dptr);
/* Close the database */
dbm_close(db);
return (0);
}

```

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
MT-Level	Unsafe

SEE ALSO `ar(1)`, `cat(1)`, `cp(1)`, `tar(1)`, `open(2)`, `dbm(3UCB)`, `netconfig(4)`, `attributes(5)`

NOTES The `.pag` file will contain holes so that its apparent size may be larger than its actual content. Older versions of the UNIX operating system may create real file blocks for these holes when touched. These files cannot be copied by normal means (`cp(1)`, `cat(1)`, `tar(1)`, `ar(1)`) without filling in the holes.

The sum of the sizes of a *key/content* pair must not exceed the internal block size (currently 1024 bytes). Moreover all *key/content* pairs that hash together must fit on a single block. `dbm_store()` will return an error in the event that a disk block fills with inseparable data.

The order of keys presented by `dbm_firstkey()` and `dbm_nextkey()` depends on a hashing function.

There are no interlocks and no reliable cache flushing; thus concurrent updating and reading is risky.

The database files (`file.dir` and `file.pag`) are binary and are architecture-specific (for example, they depend on the architecture's byte order.) These files are not guaranteed to be portable across architectures.

nextkey(3UCB)

NAME	dbm, dbmopen, dbmclose, fetch, store, delete, firstkey, nextkey – data base subroutines
SYNOPSIS	<pre>/usr/ucb/cc [flag ...] file ... -ldb #include <dbm.h> typedef struct { char *dptr; int dsize; } datum; int dbmopen (file) ; char *file; int dbmclose () ; datum fetch (key) ; datum key; int store (key, dat) ; datum key, dat; int delete (key) ; datum key; datum firstkey() datum nextkey (key) ; datum key;</pre>
DESCRIPTION	<p>The <code>dbm()</code> library has been superseded by <code>ndbm</code> (see <code>ndbm(3C)</code>).</p> <p>These functions maintain key/content pairs in a data base. The functions will handle very large (a billion blocks) databases and will access a keyed item in one or two file system accesses.</p> <p><i>key/dat</i> and their content are described by the <code>datum</code> typedef. A <code>datum</code> specifies a string of <i>dsize</i> bytes pointed to by <i>dptr</i>. Arbitrary binary data, as well as normal ASCII strings, are allowed. The data base is stored in two files. One file is a directory containing a bit map and has <code>.dir</code> as its suffix. The second file contains all data and has <code>.pag</code> as its suffix.</p> <p>Before a database can be accessed, it must be opened by <code>dbmopen()</code>. At the time of this call, the files <code>file.dir</code> and <code>file.pag</code> must exist. An empty database is created by creating zero-length <code>.dir</code> and <code>.pag</code> files.</p> <p>A database may be closed by calling <code>dbmclose()</code>. You must close a database before opening a new one.</p>

nextkey(3UCB)

Once open, the data stored under a key is accessed by `fetch()` and data is placed under a key by `store`. A key (and its associated contents) is deleted by `delete()`. A linear pass through all keys in a database may be made, in an (apparently) random order, by use of `firstkey()` and `nextkey()`. `firstkey()` will return the first key in the database. With any key `nextkey()` will return the next key in the database. This code will traverse the data base:

```
for (key = firstkey; key.dptr != NULL; key = nextkey(key))
```

RETURN VALUES

All functions that return an `int` indicate errors with negative values. A zero return indicates no error. Routines that return a `datum` indicate errors with a `NULL (0) dptr`.

SEE ALSO

`ar(1)`, `cat(1)`, `cp(1)`, `tar(1)`, `ndbm(3C)`

NOTES

Use of these interfaces should be restricted to only applications written on BSD platforms. Use of these interfaces with any of the system libraries or in multi-thread applications is unsupported.

The `.pag` file will contain holes so that its apparent size may be larger than its actual content. Older versions of the UNIX operating system may create real file blocks for these holes when touched. These files cannot be copied by normal means (`cp(1)`, `cat(1)`, `tar(1)`, `ar(1)`) without filling in the holes.

`dptr` pointers returned by these subroutines point into static storage that is changed by subsequent calls.

The sum of the sizes of a key/content pair must not exceed the internal block size (currently 1024 bytes). Moreover all key/content pairs that hash together must fit on a single block. `store` will return an error in the event that a disk block fills with inseparable data.

`delete()` does not physically reclaim file space, although it does make it available for reuse.

The order of keys presented by `firstkey()` and `nextkey()` depends on a hashing function, not on anything interesting.

There are no interlocks and no reliable cache flushing; thus concurrent updating and reading is risky.

The database files (`file.dir` and `file.pag`) are binary and are architecture-specific (for example, they depend on the architecture's byte order.) These files are not guaranteed to be portable across architectures.

nftw(3C)

NAME	ftw, nftw – walk a file tree																
SYNOPSIS	<pre>#include <ftw.h> int ftw(const char *path, int (*fn) (const char *, const struct stat *, int), int depth); int nftw(const char *path, int (*fn) (const char *, const struct stat *, int, struct FTW *), int depth, int flags);</pre>																
DESCRIPTION	<p>The <code>ftw()</code> function recursively descends the directory hierarchy rooted in <code>path</code>. For each object in the hierarchy, <code>ftw()</code> calls the user-defined function <code>fn</code>, passing it a pointer to a null-terminated character string containing the name of the object, a pointer to a <code>stat</code> structure (see <code>stat(2)</code>) containing information about the object, and an integer. Possible values of the integer, defined in the <code><ftw.h></code> header, are:</p> <table border="0"> <tr> <td style="padding-right: 20px;"><code>FTW_F</code></td> <td>The object is a file.</td> </tr> <tr> <td><code>FTW_D</code></td> <td>The object is a directory.</td> </tr> <tr> <td><code>FTW_DNR</code></td> <td>The object is a directory that cannot be read. Descendants of the directory are not processed.</td> </tr> <tr> <td><code>FTW_NS</code></td> <td>The <code>stat()</code> function failed on the object because of lack of appropriate permission or the object is a symbolic link that points to a non-existent file. The <code>stat</code> buffer passed to <code>fn</code> is undefined.</td> </tr> </table> <p>The <code>ftw()</code> function visits a directory before visiting any of its descendants.</p> <p>The tree traversal continues until the tree is exhausted, an invocation of <code>fn</code> returns a non-zero value, or some error is detected within <code>ftw()</code> (such as an I/O error). If the tree is exhausted, <code>ftw()</code> returns 0. If <code>fn</code> returns a non-zero value, <code>ftw()</code> stops its tree traversal and returns whatever value was returned by <code>fn</code>.</p> <p>The <code>nftw()</code> function is similar to <code>ftw()</code> except that it takes the additional argument <code>flags</code>, which is a bitwise-inclusive OR of zero or more of the following flags:</p> <table border="0"> <tr> <td style="padding-right: 20px;"><code>FTW_CHDIR</code></td> <td>If set, <code>nftw()</code> changes the current working directory to each directory as it reports files in that directory. If clear, <code>nftw()</code> does not change the current working directory.</td> </tr> <tr> <td><code>FTW_DEPTH</code></td> <td>If set, <code>nftw()</code> reports all files in a directory before reporting the directory itself. If clear, <code>nftw()</code> reports any directory before reporting the files in that directory.</td> </tr> <tr> <td><code>FTW_MOUNT</code></td> <td>If set, <code>nftw()</code> reports only files in the same file system as <code>path</code>. If clear, <code>nftw()</code> reports all files encountered during the walk.</td> </tr> <tr> <td><code>FTW_PHYS</code></td> <td>If set, <code>nftw()</code> performs a physical walk and does not follow symbolic links.</td> </tr> </table>	<code>FTW_F</code>	The object is a file.	<code>FTW_D</code>	The object is a directory.	<code>FTW_DNR</code>	The object is a directory that cannot be read. Descendants of the directory are not processed.	<code>FTW_NS</code>	The <code>stat()</code> function failed on the object because of lack of appropriate permission or the object is a symbolic link that points to a non-existent file. The <code>stat</code> buffer passed to <code>fn</code> is undefined.	<code>FTW_CHDIR</code>	If set, <code>nftw()</code> changes the current working directory to each directory as it reports files in that directory. If clear, <code>nftw()</code> does not change the current working directory.	<code>FTW_DEPTH</code>	If set, <code>nftw()</code> reports all files in a directory before reporting the directory itself. If clear, <code>nftw()</code> reports any directory before reporting the files in that directory.	<code>FTW_MOUNT</code>	If set, <code>nftw()</code> reports only files in the same file system as <code>path</code> . If clear, <code>nftw()</code> reports all files encountered during the walk.	<code>FTW_PHYS</code>	If set, <code>nftw()</code> performs a physical walk and does not follow symbolic links.
<code>FTW_F</code>	The object is a file.																
<code>FTW_D</code>	The object is a directory.																
<code>FTW_DNR</code>	The object is a directory that cannot be read. Descendants of the directory are not processed.																
<code>FTW_NS</code>	The <code>stat()</code> function failed on the object because of lack of appropriate permission or the object is a symbolic link that points to a non-existent file. The <code>stat</code> buffer passed to <code>fn</code> is undefined.																
<code>FTW_CHDIR</code>	If set, <code>nftw()</code> changes the current working directory to each directory as it reports files in that directory. If clear, <code>nftw()</code> does not change the current working directory.																
<code>FTW_DEPTH</code>	If set, <code>nftw()</code> reports all files in a directory before reporting the directory itself. If clear, <code>nftw()</code> reports any directory before reporting the files in that directory.																
<code>FTW_MOUNT</code>	If set, <code>nftw()</code> reports only files in the same file system as <code>path</code> . If clear, <code>nftw()</code> reports all files encountered during the walk.																
<code>FTW_PHYS</code>	If set, <code>nftw()</code> performs a physical walk and does not follow symbolic links.																

If `FTW_PHYS` is clear and `FTW_DEPTH` is set, `nftw()` follows links instead of reporting them, but does not report any directory that would be a descendant of itself. If `FTW_PHYS` is clear and `FTW_DEPTH` is clear, `nftw()` follows links instead of reporting them, but does not report the contents of any directory that would be a descendant of itself.

At each file it encounters, `nftw()` calls the user-supplied function `fn` with four arguments:

- The first argument is the pathname of the object.
- The second argument is a pointer to the `stat` buffer containing information on the object.
- The third argument is an integer giving additional information. Its value is one of the following:

<code>FTW_F</code>	The object is a file.
<code>FTW_D</code>	The object is a directory.
<code>FTW_DP</code>	The object is a directory and subdirectories have been visited. (This condition only occurs if the <code>FTW_DEPTH</code> flag is included in flags.)
<code>FTW_SL</code>	The object is a symbolic link. (This condition only occurs if the <code>FTW_PHYS</code> flag is included in flags.)
<code>FTW_SLN</code>	The object is a symbolic link that points to a non-existent file. (This condition only occurs if the <code>FTW_PHYS</code> flag is not included in flags.)
<code>FTW_DNR</code>	The object is a directory that cannot be read. The user-defined function <code>fn</code> will not be called for any of its descendants.
<code>FTW_NS</code>	The <code>stat()</code> function failed on the object because of lack of appropriate permission. The <code>stat</code> buffer passed to <code>fn</code> is undefined. Failure of <code>stat()</code> for any other reason is considered an error and <code>nftw()</code> returns <code>-1</code> .

- The fourth argument is a pointer to an `FTW` structure that contains the following members:

```
int    base;
int    level;
```

The `base` member is the offset of the object's filename in the pathname passed as the first argument to `fn()`. The value of `level` indicates the depth relative to the root of the walk, where the root level is 0.

Both `ftw()` and `nftw()` use one file descriptor for each level in the tree. The `depth` argument limits the number of file descriptors used. If `depth` is zero or negative, the effect is the same as if it were 1. It must not be greater than the number of file

nftw(3C)

descriptors currently available for use. The `ftw()` function runs faster if *depth* is at least as large as the number of levels in the tree. When `ftw()` and `nftw()` return, they close any file descriptors they have opened; they do not close any file descriptors that might have been opened by *fn*.

RETURN VALUES

If the tree is exhausted, `ftw()` and `nftw()` return 0. If the function pointed to by *fn* returns a non-zero value, `ftw()` and `nftw()` stop their tree traversal and return whatever value was returned by the function pointed to by *fn*. If `ftw()` and `nftw()` detect an error, they return `-1` and set `errno` to indicate the error.

If `ftw()` and `nftw()` encounter an error other than `EACCES` (see `FTW_DNR` and `FTW_NS` above), they return `-1` and set `errno` to indicate the error. The external variable `errno` can contain any error value that is possible when a directory is opened or when one of the `stat` functions is executed on a directory or file.

ERRORS

The `ftw()` and `nftw()` functions will fail if:

<code>ELOOP</code>	A loop exists in symbolic links encountered during resolution of the <i>path</i> argument
<code>ENAMETOOLONG</code>	The length of the path exceeds <code>{PATH_MAX}</code> , or a path name component is longer than <code>{NAME_MAX}</code> .
<code>ENOENT</code>	A component of <i>path</i> does not name an existing file or <i>path</i> is an empty string.
<code>ENOTDIR</code>	A component of <i>path</i> is not a directory.
<code>EOVERFLOW</code>	A field in the <code>stat</code> structure cannot be represented correctly in the current programming environment for one or more files found in the file hierarchy.

The `ftw()` function will fail if:

<code>EACCES</code>	Search permission is denied for any component of <i>path</i> or read permission is denied for <i>path</i> .
---------------------	---

The `nftw()` function will fail if:

<code>EACCES</code>	Search permission is denied for any component of <i>path</i> or read permission is denied for <i>path</i> , or <i>fn()</i> returns <code>-1</code> and does not reset <code>errno</code> .
---------------------	--

The `nftw()` and `ftw()` functions may fail if:

<code>ELOOP</code>	Too many symbolic links were encountered during resolution of the <i>path</i> argument.
<code>ENAMETOOLONG</code>	Pathname resolution of a symbolic link produced an intermediate result whose length exceeds <code>{PATH_MAX}</code> .

The `ftw()` function may fail if:

EINVAL The value of the *ndirs* argument is invalid.

The `nftw()` function may fail if:

EMFILE There are {OPEN_MAX} file descriptors currently open in the calling process.

ENFILE Too many files are currently open in the system.

If the function pointed to by *fn* encounters system errors, `errno` may be set accordingly.

EXAMPLES

EXAMPLE 1 Walk a directory structure using `ftw()`.

The following example walks the current directory structure, calling the `fn()` function for every directory entry, using at most 10 file descriptors:

```
#include <ftw.h>
...
if (ftw(".", fn, 10) != 0) {
    perror("ftw"); exit(2);
}
```

EXAMPLE 2 Walk a directory structure using `nftw()`.

The following example walks the `/tmp` directory and its subdirectories, calling the `nftw()` function for every directory entry, to a maximum of 5 levels deep.

```
#include <ftw.h>
...
int nftwfunc(const char *, const struct stat *, int, struct FTW *);
int nftwfunc(const char *filename, const struct stat *statptr,
             int fileflags, struct FTW *pftw)
{
    return 0;
}
...
char *startpath = "/tmp";
int depth = 5;
int flags = FTW_CHDIR | FTW_DEPTH | FTW_MOUNT;
int ret;
ret = nftw(startpath, nftwfunc, depth, flags);
```

USAGE

Because `ftw()` is recursive, it can terminate with a memory fault when applied to very deep file structures.

The `ftw()` function uses `malloc(3C)` to allocate dynamic storage during its operation. If `ftw()` is forcibly terminated, such as by `longjmp(3C)` being executed by *fn* or an interrupt routine, `ftw()` will not have a chance to free that storage, so it remains permanently allocated. A safe way to handle interrupts is to store the fact that an interrupt has occurred and arrange to have *fn* return a non-zero value at its next invocation.

nftw(3C)

The `ftw()` and `nftw()` functions have transitional interfaces for 64-bit file offsets. See `lf64(5)`.

The `ftw()` function is safe in multithreaded applications. The `nftw()` function is safe in multithreaded applications when the `FTW_CHDIR` flag is not set.

NAME	gettext, dgettext, dcgettext, ngettext, dngettext, dcngettext, textdomain, bindtextdomain, bind_textdomain_codeset – message handling functions
Solaris and GNU-compatible	<pre>#include <libintl.h> char *gettext(const char *msgid); char *dgettext(const char *domainname, const char *msgid); char *textdomain(const char *domainname); char *bindtextdomain(const char *domainname, const char *dirname); #include <libintl.h> #include <locale.h> char *dcgettext(const char *domainname, const char *msgid, int category);</pre>
GNU-compatible	<pre>#include <libintl.h> char *ngettext(const char *msgid1, const char *msgid2, unsigned long int n); char *dngettext(const char *domainname, const char *msgid1, const char *msgid2, unsigned long int n); char *bind_textdomain_codeset(const char *domainname, const char *codeset); #include <libintl.h> #include <locale.h> char *dcngettext(const char *domainname, const char *msgid1, const char *msgid2, unsigned long int n, int category);</pre>
DESCRIPTION	<p>The <code>gettext()</code>, <code>dgettext()</code>, and <code>dcgettext()</code> functions attempt to retrieve a target string based on the specified <code>msgid</code> argument within the context of a specific domain and the current locale. The length of strings returned by <code>gettext()</code>, <code>dgettext()</code>, and <code>dcgettext()</code> is undetermined until the function is called. The <code>msgid</code> argument is a null-terminated string.</p> <p>The <code>ngettext()</code>, <code>dngettext()</code>, and <code>dcngettext()</code> functions are equivalent to <code>gettext()</code>, <code>dgettext()</code>, and <code>dcgettext()</code>, respectively, except for the handling of plural forms. These functions work only with GNU-compatible message catalogues. The <code>ngettext()</code>, <code>dngettext()</code>, and <code>dcngettext()</code> functions search for the message string using the <code>msgid1</code> argument as the key and the <code>n</code> argument to determine the plural form. If no message catalogues are found, <code>msgid1</code> is returned if <code>n == 1</code>, otherwise <code>msgid2</code> is returned.</p> <p>The <code>NLSPATH</code> environment variable (see <code>environ(5)</code>) is searched first for the location of the <code>LC_MESSAGES</code> catalogue. The setting of the <code>LC_MESSAGES</code> category of the current locale determines the locale used by <code>gettext()</code> and <code>dgettext()</code> for string retrieval. The <code>category</code> argument determines the locale used by <code>dcgettext()</code>. If <code>NLSPATH</code> is not defined and the current locale is "C", <code>gettext()</code>, <code>dgettext()</code>, and</p>

ngettext(3C)

`dcgettext()` simply return the message string that was passed. In a locale other than "C", if `NLSPATH` is not defined or if a message catalogue is not found in any of the components specified by `NLSPATH`, the routines search for the message catalogue using the scheme described in the following paragraph.

The `LANGUAGE` environment variable is examined to determine the GNU-compatible message catalogues to be used. The value of `LANGUAGE` is a list of locale names separated by a colon (':') character. If `LANGUAGE` is defined, each locale name is tried in the specified order and if a GNU-compatible message catalogue is found, the message is returned. If a GNU-compatible message catalogue is found but failed to find a corresponding *msgid*, the *msgid* string is return. If `LANGUAGE` is not defined or if a Solaris message catalogue is found or no GNU-compatible message catalogue is found in processing `LANGUAGE`, the pathname used to locate the message catalogue is *dirname/locale/category/domainname.mo*, where *dirname* is the directory specified by `bindtextdomain()`, *locale* is a locale name, and *category* is either `LC_MESSAGES` if `gettext()`, `dgettext()`, `ngettext()`, or `dcgettext()` is called, or `LC_XXX` where the name is the same as the locale category name specified by the *category* argument to `dcgettext()` or `dcngettext()`.

For `gettext()` and `ngettext()`, the domain used is set by the last valid call to `textdomain()`. If a valid call to `textdomain()` has not been made, the default domain (called `messages`) is used.

For `dgettext()`, `dcgettext()`, `dcngettext()`, and `dcngettext()`, the domain used is specified by the *domainname* argument. The *domainname* argument is equivalent in syntax and meaning to the *domainname* argument to `textdomain()`, except that the selection of the domain is valid only for the duration of the `dgettext()`, `dcgettext()`, `dcngettext()`, or `dcngettext()` function call.

The `textdomain()` function sets or queries the name of the current domain of the active `LC_MESSAGES` locale category. The *domainname* argument is a null-terminated string that can contain only the characters allowed in legal filenames.

The *domainname* argument is the unique name of a domain on the system. If there are multiple versions of the same domain on one system, namespace collisions can be avoided by using `bindtextdomain()`. If `textdomain()` is not called, a default domain is selected. The setting of domain made by the last valid call to `textdomain()` remains valid across subsequent calls to `setlocale(3C)`, and `gettext()`.

The *domainname* argument is applied to the currently active `LC_MESSAGES` locale.

The current setting of the domain can be queried without affecting the current state of the domain by calling `textdomain()` with *domainname* set to the null pointer. Calling `textdomain()` with a *domainname* argument of a null string sets the domain to the default domain (`messages`).

The `bindtextdomain()` function binds the path predicate for a message domain *domainname* to the value contained in *dirname*. If *domainname* is a non-empty string and has not been bound previously, `bindtextdomain()` binds *domainname* with *dirname*.

If *domainname* is a non-empty string and has been bound previously, `bindtextdomain()` replaces the old binding with *dirname*. The *dirname* argument can be an absolute or relative pathname being resolved when `gettext()`, `dgettext()`, or `dcgettext()` are called. If *domainname* is a null pointer or an empty string, `bindtextdomain()` returns NULL. User defined domain names cannot begin with the string `SYS_`. Domain names beginning with this string are reserved for system use.

The `bind_textdomain_codeset()` function can be used to specify the output codeset for message catalogues for domain *domainname*. The *codeset* argument must be a valid codeset name that can be used for the `iconv_open(3C)` function, or a null pointer. If the *codeset* argument is the null pointer, `bind_textdomain_codeset()` returns the currently selected codeset for the domain with the name *domainname*. It returns a null pointer if a codeset has not yet been selected. The `bind_textdomain_codeset()` function can be used multiple times. If used multiple times with the same *domainname* argument, the later call overrides the settings made by the earlier one. The `bind_textdomain_codeset()` function returns a pointer to a string containing the name of the selected codeset. The string is allocated internally in the function and must not be changed by the user.

RETURN VALUES

The `gettext()`, `dgettext()`, and `dcgettext()` functions return the message string if the search succeeds. Otherwise they return the *msgid* string.

The `ngettext()`, `dngettext()`, and `dcngettext()` functions return the message string if the search succeeds. If the search fails, *msgid1* is returned if *n* == 1. Otherwise *msgid2* is returned.

The individual bytes of the string returned by `gettext()`, `dgettext()`, `dcgettext()`, `ngettext()`, `dngettext()`, or `dcngettext()` can contain any value other than NULL. If *msgid* is a null pointer, the return value is undefined. The string returned must not be modified by the program and can be invalidated by a subsequent call to `bind_textdomain_codeset()` or `setlocale(3C)`. If the *domainname* argument to `dgettext()`, `dcgettext()`, `dngettext()`, or `dcngettext()` is a null pointer, the the domain currently bound by `textdomain()` is used.

The normal return value from `textdomain()` is a pointer to a string containing the current setting of the domain. If *domainname* is a null pointer, `textdomain()` returns a pointer to the string containing the current domain. If `textdomain()` was not previously called and *domainname* is a null string, the name of the default domain is returned. The name of the default domain is `messages`. If `textdomain()` fails, a null pointer is returned.

The return value from `bindtextdomain()` is a null-terminated string containing *dirname* or the directory binding associated with *domainname* if *dirname* is NULL. If no binding is found, the default return value is `/usr/lib/locale`. If *domainname* is a null pointer or an empty string, `bindtextdomain()` takes no action and returns a null pointer. The string returned must not be modified by the caller. If `bindtextdomain()` fails, a null pointer is returned.

ngettext(3C)

USAGE These functions impose no limit on message length. However, a text *domainname* is limited to TEXTDOMAINMAX (256) bytes.

The `gettext()`, `dgettext()`, `dcgettext()`, `ngettext()`, `dngettext()`, `dcngettext()`, `textdomain()`, and `bindtextdomain()` functions can be used safely in multithreaded applications, as long as `setlocale(3C)` is not being called to change the locale.

The `gettext()`, `dgettext()`, `dcgettext()`, `textdomain()`, and `bindtextdomain()` functions work with both Solaris message catalogues and GNU-compatible message catalogues. The `ngettext()`, `dngettext()`, `dcngettext()`, and `bind_textdomain_codeset()` functions work only with GNU-compatible message catalogues. See `msgfmt(1)` for information about Solaris message catalogues and GNU-compatible message catalogues.

FILES `/usr/lib/locale`

default path predicate for message domain files

`/usr/lib/locale/locale/LC_MESSAGES/domainname.mo`

system default location for file containing messages for language *locale* and *domainname*

`/usr/lib/locale/locale/LC_XXX/domainname.mo`

system default location for file containing messages for language *locale* and *domainname* for `dcgettext()` calls where `LC_XXX` is `LC_CTYPE`, `LC_NUMERIC`, `LC_TIME`, `LC_COLLATE`, `LC_MONETARY`, or `LC_MESSAGES`

`dirname/locale/LC_MESSAGES/domainname.mo`

location for file containing messages for domain *domainname* and path predicate *dirname* after a successful call to `bindtextdomain()`

`dirname/locale/LC_XXX/domainname.mo`

location for files containing messages for domain *domainname*, language *locale*, and path predicate *dirname* after a successful call to `bindtextdomain()` for `dcgettext()` calls where `LC_XXX` is one of `LC_CTYPE`, `LC_NUMERIC`, `LC_TIME`, `LC_COLLATE`, `LC_MONETARY`, or `LC_MESSAGES`

NAME	nice – change priority of a process
SYNOPSIS	<pre> /usr/ucb/cc[flag ...] file ... #include<unistd.h> int nice (incr) ; int incr; </pre>
DESCRIPTION	<p>The scheduling priority of the process is augmented by <i>incr</i>. Positive priorities get less service than normal. Priority 10 is recommended to users who wish to execute long-running programs without undue impact on system performance.</p> <p>Negative increments are illegal, except when specified by the privileged user. The priority is limited to the range –20 (most urgent) to 20 (least). Requests for values above or below these limits result in the scheduling priority being set to the corresponding limit.</p> <p>The priority of a process is passed to a child process by <code>fork(2)</code>. For a privileged process to return to normal priority from an unknown state, <code>nice()</code> should be called successively with arguments –40 (goes to priority –20 because of truncation), 20 (to get to 0), then 0 (to maintain compatibility with previous versions of this call).</p>
RETURN VALUES	Upon successful completion, <code>nice()</code> returns 0. Otherwise, a value of –1 is returned and <code>errno</code> is set to indicate the error.
ERRORS	<p>The priority is not changed if:</p> <p><code>EPERM</code> The value of <i>incr</i> specified was negative, and the effective user ID is not the privileged user.</p>
SEE ALSO	<code>nice(1)</code> , <code>renice(1)</code> , <code>fork(2)</code> , <code>priocntl(2)</code> , <code>getpriority(3C)</code>
NOTES	Use of these interfaces should be restricted to only applications written on BSD platforms. Use of these interfaces with any of the system libraries or in multi-threaded applications is unsupported.

nlist(3UCB)

NAME	nlist – get entries from symbol table
SYNOPSIS	<pre>/usr/ucb/cc [flag ...] file ... #include <nlist.h> int nlist (filename, nl) ; char *filename ; struct nlist *nl ;</pre>
DESCRIPTION	<p>nlist() examines the symbol table from the executable image whose name is pointed to by <i>filename</i>, and selectively extracts a list of values and puts them in the array of nlist structures pointed to by <i>nl</i>. The name list pointed to by <i>nl</i> consists of an array of structures containing names, types and values. The n_name field of each such structure is taken to be a pointer to a character string representing a symbol name. The list is terminated by an entry with a NULL pointer (or a pointer to a NULL string) in the n_name field. For each entry in <i>nl</i>, if the named symbol is present in the executable image's symbol table, its value and type are placed in the n_value and n_type fields. If a symbol cannot be located, the corresponding n_type field of <i>nl</i> is set to zero.</p>
RETURN VALUES	Upon normal completion, nlist() returns the number of symbols that were not located in the symbol table. If an error occurs, nlist() returns -1 and sets all of the n_type fields in members of the array pointed to by <i>nl</i> to zero.
SEE ALSO	nlist(3ELF), a.out(4)
NOTES	<p>Use of these interfaces should be restricted to only applications written on BSD platforms. Use of these interfaces with any of the system libraries or in multi-thread applications is unsupported.</p> <p>Only the n_value field is compatibly set. Other fields in the nlist structure are filled with the ELF (Executable and Linking Format) values (see nlist(3ELF) and a.out(4)).</p>

NAME	nl_langinfo – language information						
SYNOPSIS	<pre>#include <langinfo.h> char *nl_langinfo(nl_item item);</pre>						
DESCRIPTION	<p>The <code>nl_langinfo()</code> function returns a pointer to a null-terminated string containing information relevant to a particular language or cultural area defined in the programs locale. The manifest constant names and values of <i>item</i> are defined by <code><langinfo.h></code>. For example:</p> <pre>nl_langinfo (ABDAY_1);</pre> <p>would return a pointer to the string “Dim” if the identified language was French and a French locale was correctly installed; or “Sun” if the identified language was English.</p>						
RETURN VALUES	<p>If <code>setlocale(3C)</code> has not been called successfully, or if data for a supported language is either not available, or if <i>item</i> is not defined therein, then <code>nl_langinfo()</code> returns a pointer to the corresponding string in the C locale. In all locales, <code>nl_langinfo()</code> returns a pointer to an empty string if <i>item</i> contains an invalid setting.</p>						
USAGE	<p>The <code>nl_langinfo()</code> function can be used safely in multithreaded applications, as long as <code>setlocale(3C)</code> is not being called to change the locale.</p>						
ATTRIBUTES	<p>See <code>attributes(5)</code> for descriptions of the following attributes:</p> <table border="1"> <thead> <tr> <th>ATTRIBUTE TYPE</th> <th>ATTRIBUTE VALUE</th> </tr> </thead> <tbody> <tr> <td>MT-Level</td> <td>MT-Safe with exceptions</td> </tr> <tr> <td>CSI</td> <td>Enabled</td> </tr> </tbody> </table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	MT-Level	MT-Safe with exceptions	CSI	Enabled
ATTRIBUTE TYPE	ATTRIBUTE VALUE						
MT-Level	MT-Safe with exceptions						
CSI	Enabled						
SEE ALSO	<p><code>setlocale(3C)</code>, <code>attributes(5)</code>, <code>langinfo(3HEAD)</code>, <code>nl_types(3HEAD)</code></p>						
WARNINGS	<p>The array pointed to by the return value should not be modified by the program. Subsequent calls to <code>nl_langinfo()</code> may overwrite the array.</p>						

nrnd48(3C)

NAME	drand48, erand48, lrand48, nrnd48, mrand48, jrand48, srand48, seed48, lcong48 – generate uniformly distributed pseudo-random numbers
SYNOPSIS	<pre>#include <stdlib.h> double drand48(void); double erand48(unsigned short <i>x_i[3]</i>); long lrnd48(void); long nrnd48(unsigned short <i>x_i[3]</i>); long mrnd48(void); long jrnd48(unsigned short <i>x_i[3]</i>); void srand48(long <i>seedval</i>); unsigned short *seed48(unsigned short <i>seed16v[3]</i>); void lcong48(unsigned short <i>param[7]</i>);</pre>
DESCRIPTION	<p>This family of functions generates pseudo-random numbers using the well-known linear congruential algorithm and 48-bit integer arithmetic.</p> <p>Functions <code>drand48()</code> and <code>erand48()</code> return non-negative double-precision floating-point values uniformly distributed over the interval [0.0, 1.0).</p> <p>Functions <code>lrnd48()</code> and <code>nrnd48()</code> return non-negative long integers uniformly distributed over the interval $[0, 2^{31}]$.</p> <p>Functions <code>mrnd48()</code> and <code>jrnd48()</code> return signed long integers uniformly distributed over the interval $[-2^{31}, 2^{31}]$.</p> <p>Functions <code>srand48()</code>, <code>seed48()</code>, and <code>lcong48()</code> are initialization entry points, one of which should be invoked before either <code>drand48()</code>, <code>lrnd48()</code>, or <code>mrnd48()</code> is called. (Although it is not recommended practice, constant default initializer values will be supplied automatically if <code>drand48()</code>, <code>lrnd48()</code>, or <code>mrnd48()</code> is called without a prior call to an initialization entry point.) Functions <code>erand48()</code>, <code>nrnd48()</code>, and <code>jrnd48()</code> do not require an initialization entry point to be called first.</p> <p>All the routines work by generating a sequence of 48-bit integer values, X_i, according to the linear congruential formula</p> $X_{n+1} = (aX_n + c) \bmod m \quad n \geq 0.$ <p>The parameter $m = 2^{48}$; hence 48-bit integer arithmetic is performed. Unless <code>lcong48()</code> has been invoked, the multiplier value a and the addend value c are given by</p> $a = 5DEECE66D_{16} = 273673163155_8$

$c = B_{16} = 13_8$.

The value returned by any of the functions `drand48()`, `erand48()`, `lrand48()`, `nrand48()`, `mrand48()`, or `jrand48()` is computed by first generating the next 48-bit X_i in the sequence. Then the appropriate number of bits, according to the type of data item to be returned, are copied from the high-order (leftmost) bits of X_i and transformed into the returned value.

The functions `drand48()`, `lrand48()`, and `mrand48()` store the last 48-bit X_i generated in an internal buffer. X_i must be initialized prior to being invoked. The functions `erand48()`, `nrand48()`, and `jrand48()` require the calling program to provide storage for the successive X_i values in the array specified as an argument when the functions are invoked. These routines do not have to be initialized; the calling program must place the desired initial value of X_i into the array and pass it as an argument. By using different arguments, functions `erand48()`, `nrand48()`, and `jrand48()` allow separate modules of a large program to generate several *independent* streams of pseudo-random numbers, that is, the sequence of numbers in each stream will *not* depend upon how many times the routines have been called to generate numbers for the other streams.

The initializer function `srand48()` sets the high-order 32 bits of X_i to the 32 bits contained in its argument. The low-order 16 bits of X_i are set to the arbitrary value $330E_{16}$.

The initializer function `seed48()` sets the value of X_i to the 48-bit value specified in the argument array. In addition, the previous value of X_i is copied into a 48-bit internal buffer, used only by `seed48()`, and a pointer to this buffer is the value returned by `seed48()`. This returned pointer, which can just be ignored if not needed, is useful if a program is to be restarted from a given point at some future time — use the pointer to get at and store the last X_i value, and then use this value to reinitialize using `seed48()` when the program is restarted.

The initialization function `lcg48()` allows the user to specify the initial X_i , the multiplier value a , and the addend value c . Argument array elements `param[0-2]` specify X_i , `param[3-5]` specify the multiplier a , and `param[6]` specifies the 16-bit addend c . After `lcg48()` has been called, a subsequent call to either `srand48()` or `seed48()` will restore the “standard” multiplier and addend values, a and c , specified above.

NAME	opendir, fdopendir – open directory																
SYNOPSIS	<pre>#include <sys/types.h> #include <dirent.h> DIR *opendir(const char *dirname); DIR *fdopendir(int fildes);</pre>																
DESCRIPTION	<p>The <code>opendir()</code> function opens a directory stream corresponding to the directory named by the <i>dirname</i> argument.</p> <p>The <code>fdopendir()</code> function opens a directory stream for the directory file descriptor <i>fildes</i>. The directory file descriptor should not be used or closed following a successful function call, as this might cause undefined results from future operations on the directory stream obtained from the call. Use <code>closedir(3C)</code> to close a directory stream.</p> <p>The directory stream is positioned at the first entry. If the type <code>DIR</code> is implemented using a file descriptor, applications will only be able to open up to a total of <code>{OPEN_MAX}</code> files and directories. A successful call to any of the <code>exec</code> functions will close any directory streams that are open in the calling process. See <code>exec(2)</code>.</p>																
RETURN VALUES	Upon successful completion, <code>opendir()</code> and <code>fdopendir()</code> return a pointer to an object of type <code>DIR</code> . Otherwise, a null pointer is returned and <code>errno</code> is set to indicate the error.																
ERRORS	<p>The <code>opendir()</code> function will fail if:</p> <table border="0"> <tr> <td style="vertical-align: top;"><code>EACCES</code></td> <td>Search permission is denied for the component of the path prefix of <i>dirname</i> or read permission is denied for <i>dirname</i>.</td> </tr> <tr> <td style="vertical-align: top;"><code>ELOOP</code></td> <td>Too many symbolic links were encountered in resolving <i>path</i>.</td> </tr> <tr> <td style="vertical-align: top;"><code>ENAMETOOLONG</code></td> <td>The length of the <i>dirname</i> argument exceeds <code>{PATH_MAX}</code>, or a path name component is longer than <code>{NAME_MAX}</code> while <code>{_POSIX_NO_TRUNC}</code> is in effect.</td> </tr> <tr> <td style="vertical-align: top;"><code>ENOENT</code></td> <td>A component of <i>dirname</i> does not name an existing directory or <i>dirname</i> is an empty string.</td> </tr> <tr> <td style="vertical-align: top;"><code>ENOTDIR</code></td> <td>A component of <i>dirname</i> is not a directory.</td> </tr> </table> <p>The <code>fdopendir()</code> function will fail if:</p> <table border="0"> <tr> <td style="vertical-align: top;"><code>ENOTDIR</code></td> <td>The file descriptor <i>fildes</i> does not reference a directory.</td> </tr> </table> <p>The <code>opendir()</code> function may fail if:</p> <table border="0"> <tr> <td style="vertical-align: top;"><code>EMFILE</code></td> <td>There are <code>{OPEN_MAX}</code> file descriptors currently open in the calling process.</td> </tr> <tr> <td style="vertical-align: top;"><code>ENAMETOOLONG</code></td> <td>Pathname resolution of a symbolic link produced an intermediate result whose length exceeds <code>PATH_MAX</code>.</td> </tr> </table>	<code>EACCES</code>	Search permission is denied for the component of the path prefix of <i>dirname</i> or read permission is denied for <i>dirname</i> .	<code>ELOOP</code>	Too many symbolic links were encountered in resolving <i>path</i> .	<code>ENAMETOOLONG</code>	The length of the <i>dirname</i> argument exceeds <code>{PATH_MAX}</code> , or a path name component is longer than <code>{NAME_MAX}</code> while <code>{_POSIX_NO_TRUNC}</code> is in effect.	<code>ENOENT</code>	A component of <i>dirname</i> does not name an existing directory or <i>dirname</i> is an empty string.	<code>ENOTDIR</code>	A component of <i>dirname</i> is not a directory.	<code>ENOTDIR</code>	The file descriptor <i>fildes</i> does not reference a directory.	<code>EMFILE</code>	There are <code>{OPEN_MAX}</code> file descriptors currently open in the calling process.	<code>ENAMETOOLONG</code>	Pathname resolution of a symbolic link produced an intermediate result whose length exceeds <code>PATH_MAX</code> .
<code>EACCES</code>	Search permission is denied for the component of the path prefix of <i>dirname</i> or read permission is denied for <i>dirname</i> .																
<code>ELOOP</code>	Too many symbolic links were encountered in resolving <i>path</i> .																
<code>ENAMETOOLONG</code>	The length of the <i>dirname</i> argument exceeds <code>{PATH_MAX}</code> , or a path name component is longer than <code>{NAME_MAX}</code> while <code>{_POSIX_NO_TRUNC}</code> is in effect.																
<code>ENOENT</code>	A component of <i>dirname</i> does not name an existing directory or <i>dirname</i> is an empty string.																
<code>ENOTDIR</code>	A component of <i>dirname</i> is not a directory.																
<code>ENOTDIR</code>	The file descriptor <i>fildes</i> does not reference a directory.																
<code>EMFILE</code>	There are <code>{OPEN_MAX}</code> file descriptors currently open in the calling process.																
<code>ENAMETOOLONG</code>	Pathname resolution of a symbolic link produced an intermediate result whose length exceeds <code>PATH_MAX</code> .																

opendir(3C)

ENFILE Too many files are currently open on the system.

USAGE The `opendir()` and `fdopendir()` functions should be used in conjunction with `readdir(3C)`, `closedir(3C)` and `rewinddir(3C)` to examine the contents of the directory (see the `EXAMPLES` section in `readdir(3C)`). This method is recommended for portability.

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

NAME	syslog, openlog, closelog, setlogmask – control system log																
SYNOPSIS	<pre>#include <syslog.h> void openlog(const char *ident, int logopt, int facility); void syslog(int priority, const char *message, .../* arguments */); void closelog(void); int setlogmask(int maskpri);</pre>																
DESCRIPTION	<p>The <code>syslog()</code> function sends a message to <code>syslogd(1M)</code>, which, depending on the configuration of <code>/etc/syslog.conf</code>, logs it in an appropriate system log, writes it to the system console, forwards it to a list of users, or forwards it to <code>syslogd</code> on another host over the network. The logged message includes a message header and a message body. The message header consists of a facility indicator, a severity level indicator, a timestamp, a tag string, and optionally the process ID.</p> <p>The message body is generated from the <code>message</code> and following arguments in the same manner as if these were arguments to <code>printf(3UCB)</code>, except that occurrences of <code>%m</code> in the format string pointed to by the <code>message</code> argument are replaced by the error message string associated with the current value of <code>errno</code>. A trailing <code>NEWLINE</code> character is added if needed.</p> <p>Values of the <code>priority</code> argument are formed by ORing together a <code>severity level</code> value and an optional <code>facility</code> value. If no facility value is specified, the current default facility value is used.</p> <p>Possible values of severity level include:</p> <table border="0"> <tr> <td style="padding-right: 20px;"><code>LOG_EMERG</code></td> <td>A panic condition. This is normally broadcast to all users.</td> </tr> <tr> <td><code>LOG_ALERT</code></td> <td>A condition that should be corrected immediately, such as a corrupted system database.</td> </tr> <tr> <td><code>LOG_CRIT</code></td> <td>Critical conditions, such as hard device errors.</td> </tr> <tr> <td><code>LOG_ERR</code></td> <td>Errors.</td> </tr> <tr> <td><code>LOG_WARNING</code></td> <td>Warning messages.</td> </tr> <tr> <td><code>LOG_NOTICE</code></td> <td>Conditions that are not error conditions, but that may require special handling.</td> </tr> <tr> <td><code>LOG_INFO</code></td> <td>Informational messages.</td> </tr> <tr> <td><code>LOG_DEBUG</code></td> <td>Messages that contain information normally of use only when debugging a program.</td> </tr> </table> <p>The facility indicates the application or system component generating the message. Possible facility values include:</p>	<code>LOG_EMERG</code>	A panic condition. This is normally broadcast to all users.	<code>LOG_ALERT</code>	A condition that should be corrected immediately, such as a corrupted system database.	<code>LOG_CRIT</code>	Critical conditions, such as hard device errors.	<code>LOG_ERR</code>	Errors.	<code>LOG_WARNING</code>	Warning messages.	<code>LOG_NOTICE</code>	Conditions that are not error conditions, but that may require special handling.	<code>LOG_INFO</code>	Informational messages.	<code>LOG_DEBUG</code>	Messages that contain information normally of use only when debugging a program.
<code>LOG_EMERG</code>	A panic condition. This is normally broadcast to all users.																
<code>LOG_ALERT</code>	A condition that should be corrected immediately, such as a corrupted system database.																
<code>LOG_CRIT</code>	Critical conditions, such as hard device errors.																
<code>LOG_ERR</code>	Errors.																
<code>LOG_WARNING</code>	Warning messages.																
<code>LOG_NOTICE</code>	Conditions that are not error conditions, but that may require special handling.																
<code>LOG_INFO</code>	Informational messages.																
<code>LOG_DEBUG</code>	Messages that contain information normally of use only when debugging a program.																

openlog(3C)

LOG_KERN	Messages generated by the kernel. These cannot be generated by any user processes.
LOG_USER	Messages generated by random user processes. This is the default facility identifier if none is specified.
LOG_MAIL	The mail system.
LOG_DAEMON	System daemons, such as <code>in.ftpd(1M)</code> .
LOG_AUTH	The authorization system: <code>login(1)</code> , <code>su(1M)</code> , <code>getty(1M)</code> .
LOG_LPR	The line printer spooling system: <code>lpr(1B)</code> , <code>lpc(1B)</code> .
LOG_NEWS	Reserved for the USENET network news system.
LOG_UUCP	Reserved for the UUCP system; it does not currently use <code>syslog</code> .
LOG_CRON	The <code>cron/at</code> facility; <code>crontab(1)</code> , <code>at(1)</code> , <code>cron(1M)</code> .
LOG_LOCAL0	Reserved for local use.
LOG_LOCAL1	Reserved for local use.
LOG_LOCAL2	Reserved for local use.
LOG_LOCAL3	Reserved for local use.
LOG_LOCAL4	Reserved for local use.
LOG_LOCAL5	Reserved for local use.
LOG_LOCAL6	Reserved for local use.
LOG_LOCAL7	Reserved for local use.

The `openlog()` function sets process attributes that affect subsequent calls to `syslog()`. The *ident* argument is a string that is prepended to every message. The *logopt* argument indicates logging options. Values for *logopt* are constructed by a bitwise-inclusive OR of zero or more of the following:

LOG_PID	Log the process ID with each message. This is useful for identifying specific daemon processes (for daemons that fork).
LOG_CONS	Write messages to the system console if they cannot be sent to <code>syslogd(1M)</code> . This option is safe to use in daemon processes that have no controlling terminal, since <code>syslog()</code> forks before opening the console.
LOG_NDELAY	Open the connection to <code>syslogd(1M)</code> immediately. Normally the open is delayed until the first message is

	logged. This is useful for programs that need to manage the order in which file descriptors are allocated.
LOG_ODELAY	Delay open until <code>syslog()</code> is called.
LOG_NOWAIT	Do not wait for child processes that have been forked to log messages onto the console. This option should be used by processes that enable notification of child termination using <code>SIGCHLD</code> , since <code>syslog()</code> may otherwise block waiting for a child whose exit status has already been collected.

The *facility* argument encodes a default facility to be assigned to all messages that do not have an explicit facility already encoded. The initial default facility is `LOG_USER`.

The `openlog()` and `syslog()` functions may allocate a file descriptor. It is not necessary to call `openlog()` prior to calling `syslog()`.

The `closelog()` function closes any open file descriptors allocated by previous calls to `openlog()` or `syslog()`.

The `setlogmask()` function sets the log priority mask for the current process to *maskpri* and returns the previous mask. If the *maskpri* argument is 0, the current log mask is not modified. Calls by the current process to `syslog()` with a priority not set in *maskpri* are rejected. The mask for an individual priority *pri* is calculated by the macro `LOG_MASK(pri)`; the mask for all priorities up to and including *toppri* is given by the macro `LOG_UPT(toppri)`. The default log mask allows all priorities to be logged.

Symbolic constants for use as values of the *logopt*, *facility*, *priority*, and *maskpri* arguments are defined in the `<syslog.h>` header.

RETURN VALUES

The `setlogmask()` function returns the previous log priority mask. The `closelog()`, `openlog()` and `syslog()` functions return no value.

ERRORS

No errors are defined.

EXAMPLES

EXAMPLE 1 Example of `LOG_ALERT` message.

This call logs a message at priority `LOG_ALERT`:

```
syslog(LOG_ALERT, "who: internal error 23");
```

The FTP daemon `ftpd` would make this call to `openlog()` to indicate that all messages it logs should have an identifying string of `ftpd`, should be treated by `syslogd(1M)` as other messages from system daemons are, should include the process ID of the process logging the message:

```
openlog("ftpd", LOG_PID, LOG_DAEMON);
```

openlog(3C)

EXAMPLE 1 Example of LOG_ALERT message. (Continued)

Then it would make the following call to `setlogmask()` to indicate that messages at priorities from LOG_EMERG through LOG_ERR should be logged, but that no messages at any other priority should be logged:

```
setlogmask(LOG_UPTO(LOG_ERR));
```

Then, to log a message at priority LOG_INFO, it would make the following call to `syslog`:

```
syslog(LOG_INFO, "Connection from host %d", CallingHost);
```

A locally-written utility could use the following call to `syslog()` to log a message at priority LOG_INFO to be treated by `syslogd(1M)` as other messages to the facility LOG_LOCAL2 are:

```
syslog(LOG_INFO|LOG_LOCAL2, "error: %m");
```

NAME	popen, pclose – initiate a pipe to or from a process						
SYNOPSIS	<pre>#include <stdio.h> FILE *popen(const char *command, const char *mode); int pclose(FILE *stream);</pre>						
DESCRIPTION	<p>The popen() function creates a pipe between the calling program and the command to be executed. The arguments to popen() are pointers to null-terminated strings. The <i>command</i> argument consists of a shell command line. The <i>mode</i> argument is an I/O mode, either <i>r</i> for reading or <i>w</i> for writing. The value returned is a stream pointer such that one can write to the standard input of the command, if the I/O mode is <i>w</i>, by writing to the file <i>stream</i> (see intro(3)); and one can read from the standard output of the command, if the I/O mode is <i>r</i>, by reading from the file <i>stream</i>. Because open files are shared, a type <i>r</i> command may be used as an input filter and a type <i>w</i> as an output filter.</p> <p>The environment of the executed command will be as if a child process were created within the popen() call using fork(2). If the application is standard-conforming (see standards(5)), the child is invoked with the call:</p> <pre>execl("/usr/xpg4/bin/ksh", "sh", "-c", command, (char *)0);</pre> <p>otherwise, the child is invoked with the call:</p> <pre>execl("/usr/bin/sh", "sh", "-c", command, (char *)0);</pre> <p>A stream opened by popen() should be closed by pclose(), which closes the pipe, and waits for the associated process to terminate and returns the termination status of the process running the command language interpreter. This is the value returned by waitpid(2). See wstat(3XFN) for more information on termination status.</p>						
RETURN VALUES	<p>The popen() function returns a null pointer if files or processes cannot be created.</p> <p>The pclose() function returns the termination status of the command. It returns -1 if <i>stream</i> is not associated with a popen() command and sets errno to indicate the error.</p>						
ERRORS	<p>The popen() function may fail if:</p> <table border="0" style="margin-left: 20px;"> <tr> <td style="padding-right: 20px;">EMFILE</td> <td>There are currently FOPEN_MAX or STREAM_MAX streams open in the calling process.</td> </tr> <tr> <td>EINVAL</td> <td>The <i>mode</i> argument is invalid.</td> </tr> </table> <p>The pclose() function will fail if:</p> <table border="0" style="margin-left: 20px;"> <tr> <td style="padding-right: 20px;">ECHILD</td> <td>The status of the child process could not be obtained, as described above.</td> </tr> </table>	EMFILE	There are currently FOPEN_MAX or STREAM_MAX streams open in the calling process.	EINVAL	The <i>mode</i> argument is invalid.	ECHILD	The status of the child process could not be obtained, as described above.
EMFILE	There are currently FOPEN_MAX or STREAM_MAX streams open in the calling process.						
EINVAL	The <i>mode</i> argument is invalid.						
ECHILD	The status of the child process could not be obtained, as described above.						

pclose(3C)

The `popen()` function may also set `errno` values as described by `fork(2)` or `pipe(2)`.

USAGE If the original and `popen()` processes concurrently read or write a common file, neither should use buffered I/O. Problems with an output filter may be forestalled by careful buffer flushing, for example, with `fflush()` (see `fclose(3C)`). A security hole exists through the `IFS` and `PATH` environment variables. Full pathnames should be used (or `PATH` reset) and `IFS` should be set to space and tab ("`\t`").

The signal handler for `SIGCHLD` should be set to default when using `popen()`. If the process has established a signal handler for `SIGCHLD`, it will be called when the command terminates. If the signal handler or another thread in the same process issues a `wait(2)` call, it will interfere with the return value of `pclose()`. If the process's signal handler for `SIGCHLD` has been set to ignore the signal, `pclose()` will fail and `errno` will be set to `ECHILD`.

EXAMPLES **EXAMPLE 1** `popen()` example

The following program will print on the standard output (see `stdio(3C)`) the names of files in the current directory with a `.c` suffix.

```
#include <stdio.h>
#include <stdlib.h>
main( )
{
    char *cmd = "/usr/bin/ls *.c";
    char buf[BUFSIZ];
    FILE *ptr;

    if ((ptr = popen(cmd, "r")) != NULL)
        while (fgets(buf, BUFSIZ, ptr) != NULL)
            (void) printf("%s", buf);
        (void) pclose(ptr);
    return 0;
}
```

EXAMPLE 2 `system()` replacement

The following code fragment can be used in a multithreaded process in place of the MT-Unsafe `system(3C)` function:

```
pclose(popen(cmd, "w"));
```

NAME	perror, errno – print system error messages				
SYNOPSIS	<pre>#include <stdio.h> void perror(const char *s); #include <errno.h> int errno;</pre>				
DESCRIPTION	<p>The <code>perror()</code> function produces a message on the standard error output (file descriptor 2) describing the last error encountered during a call to a system or library function. The argument string <code>s</code> is printed, followed by a colon and a blank, followed by the message and a NEWLINE character. If <code>s</code> is a null pointer or points to a null string, the colon is not printed. The argument string should include the name of the program that incurred the error. The error number is taken from the external variable <code>errno</code>, which is set when errors occur but not cleared when non-erroneous calls are made. See <code>intro(2)</code>.</p>				
USAGE	<p>If the application is linked with <code>-lintl</code>, then messages printed from this function are in the native language specified by the <code>LC_MESSAGES</code> locale category. See <code>setlocale(3C)</code>.</p>				
ATTRIBUTES	<p>See <code>attributes(5)</code> for descriptions of the following attributes:</p> <table border="1"> <thead> <tr> <th>ATTRIBUTE TYPE</th> <th>ATTRIBUTE VALUE</th> </tr> </thead> <tbody> <tr> <td>MT-Level</td> <td>MT-Safe</td> </tr> </tbody> </table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	MT-Level	MT-Safe

pfmt(3C)

NAME	pfmt – display error message in standard format
SYNOPSIS	<pre>#include <pfmt.h> int pfmt(FILE *stream, long flags, char *format, ... /* arg */);</pre>
DESCRIPTION	<p>The <code>pfmt()</code> retrieves a format string from a locale-specific message database (unless <code>MM_NOGET</code> is specified) and uses it for <code>printf(3C)</code> style formatting of <code>args</code>. The output is displayed on <code>stream</code>.</p> <p>The <code>pfmt()</code> function encapsulates the output in the standard error message format (unless <code>MM_NOSTD</code> is specified, in which case the output is similar to <code>printf()</code>).</p> <p>If the <code>printf()</code> format string is to be retrieved from a message database, the <code>format</code> argument must have the following structure:</p> <pre><catalog> : <msgnum> : <defmsg>.</pre> <p>If <code>MM_NOGET</code> is specified, only the <code>defmsg</code> field must be specified.</p> <p>The <code>catalog</code> field is used to indicate the message database that contains the localized version of the format string. This field must be limited to 14 characters selected from the set of all characters values, excluding <code>\0</code> (null) and the ASCII codes for <code>/</code> (slash) and <code>:</code> (colon).</p> <p>The <code>msgnum</code> field is a positive number that indicates the index of the string into the message database.</p> <p>If the catalog does not exist in the locale (specified by the last call to <code>setlocale(3C)</code> using the <code>LC_ALL</code> or <code>LC_MESSAGES</code> categories), or if the message number is out of bound, <code>pfmt()</code> will attempt to retrieve the message from the C locale. If this second retrieval fails, <code>pfmt()</code> uses the <code>defmsg</code> field of the <code>format</code> argument.</p> <p>If <code>catalog</code> is omitted, <code>pfmt()</code> will attempt to retrieve the string from the default catalog specified by the last call to <code>setcat(3C)</code>. In this case, the <code>format</code> argument has the following structure:</p> <pre>: <msgnum> : <defmsg>.</pre> <p>The <code>pfmt()</code> will output <code>Message not found!!\n</code> as format string if <code>catalog</code> is not a valid catalog name, if no catalog is specified (either explicitly or with <code>setcat()</code>), if <code>msgnum</code> is not a valid number, or if no message could be retrieved from the message databases and <code>defmsg</code> was omitted.</p> <p>The <code>flags</code> argument determine the type of output (such as whether the <code>format</code> should be interpreted as is or encapsulated in the standard message format), and the access to message catalogs to retrieve a localized version of <code>format</code>.</p> <p>The <code>flags</code> argument is composed of several groups, and can take the following values (one from each group):</p>

Output format control

MM_NOSTD	Do not use the standard message format, interpret <code>format</code> as <code>printf()</code> format. Only <i>catalog access control flags</i> should be specified if MM_NOSTD is used; all other flags will be ignored.
MM_STD	Output using the standard message format (default value 0).

Catalog access control

MM_NOGET	Do not retrieve a localized version of <code>format</code> . In this case, only the <i>defmsg</i> field of the <code>format</code> is specified.
MM_GET	Retrieve a localized version of <code>format</code> from the <i>catalog</i> , using <i>msgid</i> as the index and <i>defmsg</i> as the default message (default value 0).

Severity (standard message format only)

MM_HALT	Generate a localized version of HALT, but do not halt the machine.
MM_ERROR	Generate a localized version of ERROR (default value 0).
MM_WARNING	Generate a localized version of WARNING.
MM_INFO	Generate a localized version of INFO.

Additional severities can be defined. Add-on severities can be defined with number-string pairs with numeric values from the range [5-255], using `addsev(3C)`. The specified severity will be generated from the bitwise OR operation of the numeric value and other *flags*. If the severity is not defined, `pfmt()` uses the string `SEV=N`, where *N* is replaced by the integer severity value passed in *flags*.

Multiple severities passed in *flags* will not be detected as an error. Any combination of severities will be summed and the numeric value will cause the display of either a severity string (if defined) or the string `SEV=N` (if undefined).

Action

MM_ACTION	Specify an action message. Any severity value is superseded and replaced by a localized version of <code>TO FIX</code> .
-----------	--

**STANDARD
ERROR
MESSAGE
FORMAT**

The `pfmt()` function displays error messages in the following format:

label: *severity*: *text*

If no *label* was defined by a call to `setLabel(3C)`, the message is displayed in the format:

severity: *text*

If `pfmt()` is called twice to display an error message and a helpful *action* or recovery message, the output can look like:

pfmt(3C)

label: severity: textlabel: TO FIX: text

RETURN VALUES

Upon success, `pfmt()` returns the number of bytes transmitted. Upon failure, it returns a negative value:

-1 Write error to *stream*.

EXAMPLES

EXAMPLE 1 Example of `pfmt()` function.

Example 1:

```
setlabel("UX:test");  
pfmt(stderr, MM_ERROR, "test:2:Cannot open file: %s\n", strerror(errno));
```

displays the message:

```
UX:test: ERROR: Cannot open file: No such file or directory
```

Example 2:

```
setlabel("UX:test");  
setcat("test");  
pfmt(stderr, MM_ERROR, ":10:Syntax error\n");  
pfmt(stderr, MM_ACTION, "55:Usage ... \n");
```

displays the message

```
UX:test: ERROR: Syntax error  
UX:test: TO FIX: Usage ...
```

USAGE

Since it uses `gettext(3C)`, `pfmt()` should not be used.

NAME	plock – lock or unlock into memory process, text, or data								
SYNOPSIS	<pre>#include <sys/lock.h> int plock(int op);</pre>								
DESCRIPTION	<p>The plock() function allows the calling process to lock or unlock into memory its text segment (text lock), its data segment (data lock), or both its text and data segments (process lock). Locked segments are immune to all routine swapping. The effective user ID of the calling process must be super-user to use this call.</p> <p>The plock() function performs the function specified by <i>op</i>:</p> <table border="0"> <tr> <td>PROCLOCK</td> <td>Lock text and data segments into memory (process lock).</td> </tr> <tr> <td>TXTLOCK</td> <td>Lock text segment into memory (text lock).</td> </tr> <tr> <td>DATLOCK</td> <td>Lock data segment into memory (data lock).</td> </tr> <tr> <td>UNLOCK</td> <td>Remove locks.</td> </tr> </table>	PROCLOCK	Lock text and data segments into memory (process lock).	TXTLOCK	Lock text segment into memory (text lock).	DATLOCK	Lock data segment into memory (data lock).	UNLOCK	Remove locks.
PROCLOCK	Lock text and data segments into memory (process lock).								
TXTLOCK	Lock text segment into memory (text lock).								
DATLOCK	Lock data segment into memory (data lock).								
UNLOCK	Remove locks.								
RETURN VALUES	Upon successful completion, 0 is returned. Otherwise, -1 is returned and errno is set to indicate the error.								
ERRORS	<p>The plock() function fails and does not perform the requested operation if:</p> <table border="0"> <tr> <td>EAGAIN</td> <td>Not enough memory.</td> </tr> <tr> <td>EINVAL</td> <td>The <i>op</i> argument is equal to PROCLOCK and a process lock, a text lock, or a data lock already exists on the calling process; the <i>op</i> argument is equal to TXTLOCK and a text lock or a process lock already exists on the calling process; the <i>op</i> argument is equal to DATLOCK and a data lock or a process lock already exists on the calling process; or the <i>op</i> argument is equal to UNLOCK and no lock exists on the calling process.</td> </tr> <tr> <td>EPERM</td> <td>The effective user of the calling process is not super-user.</td> </tr> </table>	EAGAIN	Not enough memory.	EINVAL	The <i>op</i> argument is equal to PROCLOCK and a process lock, a text lock, or a data lock already exists on the calling process; the <i>op</i> argument is equal to TXTLOCK and a text lock or a process lock already exists on the calling process; the <i>op</i> argument is equal to DATLOCK and a data lock or a process lock already exists on the calling process; or the <i>op</i> argument is equal to UNLOCK and no lock exists on the calling process.	EPERM	The effective user of the calling process is not super-user.		
EAGAIN	Not enough memory.								
EINVAL	The <i>op</i> argument is equal to PROCLOCK and a process lock, a text lock, or a data lock already exists on the calling process; the <i>op</i> argument is equal to TXTLOCK and a text lock or a process lock already exists on the calling process; the <i>op</i> argument is equal to DATLOCK and a data lock or a process lock already exists on the calling process; or the <i>op</i> argument is equal to UNLOCK and no lock exists on the calling process.								
EPERM	The effective user of the calling process is not super-user.								
USAGE	The mlock(3C) and mlockall(3C) functions are the preferred interfaces for process locking.								
ATTRIBUTES	See attributes(5) for descriptions of the following attributes:

popen(3C)

NAME	popen, pclose – initiate a pipe to or from a process						
SYNOPSIS	<pre>#include <stdio.h> FILE *popen(const char *command, const char *mode); int pclose(FILE *stream);</pre>						
DESCRIPTION	<p>The popen() function creates a pipe between the calling program and the command to be executed. The arguments to popen() are pointers to null-terminated strings. The <i>command</i> argument consists of a shell command line. The <i>mode</i> argument is an I/O mode, either <i>r</i> for reading or <i>w</i> for writing. The value returned is a stream pointer such that one can write to the standard input of the command, if the I/O mode is <i>w</i>, by writing to the file <i>stream</i> (see intro(3)); and one can read from the standard output of the command, if the I/O mode is <i>r</i>, by reading from the file <i>stream</i>. Because open files are shared, a type <i>r</i> command may be used as an input filter and a type <i>w</i> as an output filter.</p> <p>The environment of the executed command will be as if a child process were created within the popen() call using fork(2). If the application is standard-conforming (see standards(5)), the child is invoked with the call:</p> <pre>execl("/usr/xpg4/bin/ksh", "sh", "-c", command, (char *)0);</pre> <p>otherwise, the child is invoked with the call:</p> <pre>execl("/usr/bin/sh", "sh", "-c", command, (char *)0);</pre> <p>A stream opened by popen() should be closed by pclose(), which closes the pipe, and waits for the associated process to terminate and returns the termination status of the process running the command language interpreter. This is the value returned by waitpid(2). See wstat(3XFN) for more information on termination status.</p>						
RETURN VALUES	<p>The popen() function returns a null pointer if files or processes cannot be created.</p> <p>The pclose() function returns the termination status of the command. It returns -1 if <i>stream</i> is not associated with a popen() command and sets errno to indicate the error.</p>						
ERRORS	<p>The popen() function may fail if:</p> <table><tr><td>EMFILE</td><td>There are currently FOPEN_MAX or STREAM_MAX streams open in the calling process.</td></tr><tr><td>EINVAL</td><td>The <i>mode</i> argument is invalid.</td></tr></table> <p>The pclose() function will fail if:</p> <table><tr><td>ECHILD</td><td>The status of the child process could not be obtained, as described above.</td></tr></table>	EMFILE	There are currently FOPEN_MAX or STREAM_MAX streams open in the calling process.	EINVAL	The <i>mode</i> argument is invalid.	ECHILD	The status of the child process could not be obtained, as described above.
EMFILE	There are currently FOPEN_MAX or STREAM_MAX streams open in the calling process.						
EINVAL	The <i>mode</i> argument is invalid.						
ECHILD	The status of the child process could not be obtained, as described above.						

The `popen()` function may also set `errno` values as described by `fork(2)` or `pipe(2)`.

USAGE If the original and `popen()` processes concurrently read or write a common file, neither should use buffered I/O. Problems with an output filter may be forestalled by careful buffer flushing, for example, with `fflush()` (see `fclose(3C)`). A security hole exists through the `IFS` and `PATH` environment variables. Full pathnames should be used (or `PATH` reset) and `IFS` should be set to space and tab ("`\t`").

The signal handler for `SIGCHLD` should be set to default when using `popen()`. If the process has established a signal handler for `SIGCHLD`, it will be called when the command terminates. If the signal handler or another thread in the same process issues a `wait(2)` call, it will interfere with the return value of `pclose()`. If the process's signal handler for `SIGCHLD` has been set to ignore the signal, `pclose()` will fail and `errno` will be set to `ECHILD`.

EXAMPLES **EXAMPLE 1** `popen()` example

The following program will print on the standard output (see `stdio(3C)`) the names of files in the current directory with a `.c` suffix.

```
#include <stdio.h>
#include <stdlib.h>
main( )
{
    char *cmd = "/usr/bin/ls *.c";
    char buf[BUFSIZ];
    FILE *ptr;

    if ((ptr = popen(cmd, "r")) != NULL)
        while (fgets(buf, BUFSIZ, ptr) != NULL)
            (void) printf("%s", buf);
        (void) pclose(ptr);
    return 0;
}
```

EXAMPLE 2 `system()` replacement

The following code fragment can be used in a multithreaded process in place of the MT-Unsafe `system(3C)` function:

```
pclose(popen(cmd, "w"));
```

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

printf(3C)

NAME	printf, fprintf, sprintf, snprintf – print formatted output
SYNOPSIS	<pre>#include <stdio.h> int printf(const char *format, /* args*/ ...); int fprintf(FILE *stream, const char *format, /* args*/ ...); int sprintf(char *s, const char *format, /* args*/ ...); int snprintf(char *s, size_t n, const char *format, /* args*/ ...);</pre>
DESCRIPTION	<p>The <code>printf()</code> function places output on the standard output stream <code>stdout</code>.</p> <p>The <code>fprintf()</code> function places output on on the named output stream <i>stream</i>.</p> <p>The <code>sprintf()</code> function places output, followed by the null byte (<code>\0</code>), in consecutive bytes starting at <i>s</i>; it is the user's responsibility to ensure that enough storage is available.</p> <p>The <code>snprintf()</code> function is identical to <code>sprintf()</code> with the addition of the argument <i>n</i>, which specifies the size of the buffer referred to by <i>s</i>. The buffer is always terminated with the null byte.</p> <p>Each of these functions converts, formats, and prints its arguments under control of the <i>format</i>. The <i>format</i> is a character string, beginning and ending in its initial shift state, if any. The <i>format</i> is composed of zero or more directives: <i>ordinary characters</i>, which are simply copied to the output stream and <i>conversion specifications</i>, each of which results in the fetching of zero or more arguments. The results are undefined if there are insufficient arguments for the <i>format</i>. If the <i>format</i> is exhausted while arguments remain, the excess arguments are evaluated but are otherwise ignored.</p> <p>Conversions can be applied to the <i>n</i>th argument after the <i>format</i> in the argument list, rather than to the next unused argument. In this case, the conversion character <code>%</code> (see below) is replaced by the sequence <code>%n\$</code>, where <i>n</i> is a decimal integer in the range <code>[1, NL_ARGMAX]</code>, giving the position of the argument in the argument list. This feature provides for the definition of format strings that select arguments in an order appropriate to specific languages (see the <code>EXAMPLES</code> section).</p> <p>In format strings containing the <code>%n\$</code> form of conversion specifications, numbered arguments in the argument list can be referenced from the format string as many times as required.</p> <p>In format strings containing the <code>%</code> form of conversion specifications, each argument in the argument list is used exactly once.</p> <p>All forms of the <code>printf()</code> functions allow for the insertion of a language-dependent radix character in the output string. The radix character is defined by the program's locale (category <code>LC_NUMERIC</code>). In the POSIX locale, or in a locale where the radix character is not defined, the radix character defaults to a period (<code>.</code>).</p>

Conversion Specifications

Each conversion specification is introduced by the % character or by the character sequence %n\$, after which the following appear in sequence:

- An optional field, consisting of a decimal digit string followed by a \$, specifying the next argument to be converted. If this field is not provided, the *args* following the last argument converted will be used.
- Zero or more *flags* (in any order), which modify the meaning of the conversion specification.
- An optional minimum *field width*. If the converted value has fewer bytes than the field width, it will be padded with spaces by default on the left; it will be padded on the right, if the left-adjustment flag (‐), described below, is given to the field width. The field width takes the form of an asterisk (*), described below, or a decimal integer.

If the conversion character is *s*, a standard-conforming application (see `standards(5)`) interprets the field width as the minimum number of bytes to be printed; an application that is not standard-conforming interprets the field width as the minimum number of columns of screen display. For an application that is not standard-conforming, %10*s* means if the converted value has a screen width of 7 columns, 3 spaces would be padded on the right.

If the format is %*ws*, then the field width should be interpreted as the minimum number of columns of screen display.

- An optional *precision* that gives the minimum number of digits to appear for the *d*, *i*, *o*, *u*, *x*, and *X* conversions (the field is padded with leading zeros); the number of digits to appear after the radix character for the *e*, *E*, and *f* conversions, the maximum number of significant digits for the *g* and *G* conversions; or the maximum number of bytes to be printed from a string in *s* and *S* conversions. The precision takes the form of a period (.) followed either by an asterisk (*), described below, or an optional decimal digit string, where a null digit string is treated as 0. If a precision appears with any other conversion character, the behavior is undefined.

If the conversion character is *s* or *S*, a standard-conforming application (see `standards(5)`) interprets the precision as the maximum number of bytes to be written; an application that is not standard-conforming interprets the precision as the maximum number of columns of screen display. For an application that is not standard-conforming, %.*5s* would print only the portion of the string that would display in 5 screen columns. Only complete characters are written.

For %*ws*, the precision should be interpreted as the maximum number of columns of screen display. The precision takes the form of a period (.) followed by a decimal digit string; a null digit string is treated as zero. Padding specified by the precision overrides the padding specified by the field width.

- An optional *h* specifies that a following *d*, *i*, *o*, *u*, *x*, or *X* conversion character applies to a type `short int` or type `unsigned short int` argument (the argument will be promoted according to the integral promotions, and its value converted to type `short int` or `unsigned short int` before printing); an optional *h* specifying that a following *n* conversion character applies to a pointer to a type `short int` argument; an optional *l* (ell) specifying that a following *d*, *i*, *o*, *u*, *x*, or *X* conversion character applies to a type `long int` or `unsigned long`

printf(3C)

int argument; an optional l (ell) specifying that a following n conversion character applies to a pointer to a type long int argument; an optional ll (ell ell) specifying that a following d, i, o, u, x, or X conversion character applies to a type long long or unsigned long long argument; an optional lll (ell ell ell) specifying that a following n conversion character applies to a pointer to a long long argument; or an optional L specifying that a following e, E, f, g, or G conversion character applies to a type long double argument. If an h, l, ll, or L appears with any other conversion character, the behavior is undefined.

- An optional l (ell) specifying that a following c conversion character applies to a wint_t argument; an optional l (ell) specifying that a following s conversion character applies to a pointer to a wchar_t argument.
- A *conversion character* (see below) that indicates the type of conversion to be applied.

A field width, or precision, or both may be indicated by an asterisk (*). In this case, an argument of type int supplies the field width or precision. Arguments specifying field width, or precision, or both must appear in that order before the argument, if any, to be converted. A negative field width is taken as a - flag followed by a positive field width. A negative precision is taken as if the precision were omitted. In format strings containing the %n\$ form of a conversion specification, a field width or precision may be indicated by the sequence *m\$, where m is a decimal integer in the range [1, NL_ARGMAX] giving the position in the argument list (after the format argument) of an integer argument containing the field width or precision, for example:

```
printf("%1$d:%2$.*3$d:%4$.*3$d\n", hour, min, precision, sec);
```

The *format* can contain either numbered argument specifications (that is, %n\$ and *m\$), or unnumbered argument specifications (that is, % and *), but normally not both. The only exception to this is that %% can be mixed with the %n\$ form. The results of mixing numbered and unnumbered argument specifications in a *format* string are undefined. When numbered argument specifications are used, specifying the Nth argument requires that all the leading arguments, from the first to the (N-1)th, are specified in the format string.

Flag Characters

The flag characters and their meanings are:

- ' The integer portion of the result of a decimal conversion (%i, %d, %u, %f, %g, or %G) will be formatted with thousands' grouping characters. For other conversions the behavior is undefined. The non-monetary grouping character is used.
- The result of the conversion will be left-justified within the field. The conversion will be right-justified if this flag is not specified.
- + The result of a signed conversion will always begin with a sign (+ or -). The conversion will begin with a sign only when a negative value is converted if this flag is not specified.

space	If the first character of a signed conversion is not a sign or if a signed conversion results in no characters, a space will be placed before the result. This means that if the <code>space</code> and <code>+</code> flags both appear, the space flag will be ignored.
#	The value is to be converted to an alternate form. For <code>c</code> , <code>d</code> , <code>i</code> , <code>s</code> , and <code>u</code> conversions, the flag has no effect. For an <code>o</code> conversion, it increases the precision (if necessary) to force the first digit of the result to be a zero. For <code>x</code> or <code>X</code> conversion, a non-zero result will have <code>0x</code> (or <code>0X</code>) prepended to it. For <code>e</code> , <code>E</code> , <code>f</code> , <code>g</code> , and <code>G</code> conversions, the result will always contain a radix character, even if no digits follow the radix character. Without this flag, the radix character appears in the result of these conversions only if a digit follows it. For <code>g</code> and <code>G</code> conversions, trailing zeros will not be removed from the result as they normally are.
0	For <code>d</code> , <code>i</code> , <code>o</code> , <code>u</code> , <code>x</code> , <code>X</code> , <code>e</code> , <code>E</code> , <code>f</code> , <code>g</code> , and <code>G</code> conversions, leading zeros (following any indication of sign or base) are used to pad to the field width; no space padding is performed. If the <code>0</code> and <code>-</code> flags both appear, the <code>0</code> flag will be ignored. For <code>d</code> , <code>i</code> , <code>o</code> , <code>u</code> , <code>x</code> , and <code>X</code> conversions, if a precision is specified, the <code>0</code> flag will be ignored. If the <code>0</code> and <code>'</code> flags both appear, the grouping characters are inserted before zero padding. For other conversions, the behavior is undefined.
Conversion Characters	Each conversion character results in fetching zero or more arguments. The results are undefined if there are insufficient arguments for the format. If the format is exhausted while arguments remain, the excess arguments are ignored. The conversion characters and their meanings are:
d,i	The <code>int</code> argument is converted to a signed decimal in the style <code>[-] dddd</code> . The precision specifies the minimum number of digits to appear; if the value being converted can be represented in fewer digits, it will be expanded with leading zeros. The default precision is 1. The result of converting 0 with an explicit precision of 0 is no characters.
o	The unsigned <code>int</code> argument is converted to unsigned octal format in the style <code>dddd</code> . The precision specifies the minimum number of digits to appear; if the value being converted can be represented in fewer digits, it will be expanded with leading zeros. The default precision is 1. The result of converting 0 with an explicit precision of 0 is no characters.
u	The unsigned <code>int</code> argument is converted to unsigned decimal format in the style <code>dddd</code> . The precision specifies the minimum number of digits to appear; if the value being converted can be represented in fewer digits, it will be expanded with leading zeros. The default precision is 1. The result of converting 0 with an explicit precision of 0 is no characters.
x	The unsigned <code>int</code> argument is converted to unsigned hexadecimal format in the style <code>dddd</code> ; the letters <code>abcdef</code> are used. The precision specifies the minimum number of digits to appear; if the value being

printf(3C)

	converted can be represented in fewer digits, it will be expanded with leading zeros. The default precision is 1. The result of converting 0 with an explicit precision of 0 is no characters.
X	Behaves the same as the x conversion character except that letters ABCDEF are used instead of abcdef.
f	The double argument is converted to decimal notation in the style <code>[-]ddd.ddd</code> , where the number of digits after the radix character (see <code>setlocale(3C)</code>) is equal to the precision specification. If the precision is missing it is taken as 6; if the precision is explicitly 0 and the # flag is not specified, no radix character appears. If a radix character appears, at least 1 digit appears before it. The value is rounded to the appropriate number of digits.
e,E	The double argument is converted to the style <code>[-]d.ddd\pmdd</code> , where there is one digit before the radix character (which is non-zero if the argument is non-zero) and the number of digits after it is equal to the precision. When the precision is missing it is taken as 6; if the precision is 0 and the # flag is not specified, no radix character appears. The E conversion character will produce a number with E instead of e introducing the exponent. The exponent always contains at least two digits. The value is rounded to the appropriate number of digits.
g,G	The double argument is printed in style f or e (or in style E in the case of a G conversion character), with the precision specifying the number of significant digits. If an explicit precision is 0, it is taken as 1. The style used depends on the value converted: style e (or E) will be used only if the exponent resulting from the conversion is less than -4 or greater than or equal to the precision. Trailing zeros are removed from the fractional part of the result. A radix character appears only if it is followed by a digit.
c	The int argument is converted to an unsigned char, and the resulting byte is printed. If an l (ell) qualifier is present, the wint_t argument is converted as if by an ls conversion specification with no precision and an argument that points to a two-element array of type wchar_t, the first element of which contains the wint_t argument to the ls conversion specification and the second element contains a null wide-character.
C	Same as lc.
wc	The int argument is converted to a wide character (wchar_t), and the resulting wide character is printed.
s	The argument must be a pointer to an array of char. Bytes from the array are written up to (but not including) any terminating null byte. If a precision is specified, a standard-conforming application (see <code>standards(5)</code>) will write only the number of bytes specified by precision; an application that is not standard-conforming will write only the portion

of the string that will display in the number of columns of screen display specified by precision. If the precision is not specified, it is taken to be infinite, so all bytes up to the first null byte are printed. An argument with a null value will yield undefined results.

If an `l` (ell) qualifier is present, the argument must be a pointer to an array of type `wchar_t`. Wide-characters from the array are converted to characters (each as if by a call to the `wcrtomb(3C)` function, with the conversion state described by an `mbstate_t` object initialized to zero before the first wide-character is converted) up to and including a terminating null wide-character. The resulting characters are written up to (but not including) the terminating null character (byte). If no precision is specified, the array must contain a null wide-character. If a precision is specified, no more than that many characters (bytes) are written (including shift sequences, if any), and the array must contain a null wide-character if, to equal the character sequence length given by the precision, the function would need to access a wide-character one past the end of the array. In no case is a partial character written.

`S` Same as `ls`.

`ws` The argument must be a pointer to an array of `wchar_t`. Bytes from the array are written up to (but not including) any terminating null character. If the precision is specified, only that portion of the wide-character array that will display in the number of columns of screen display specified by precision will be written. If the precision is not specified, it is taken to be infinite, so all wide characters up to the first null character are printed. An argument with a null value will yield undefined results.

`p` The argument must be a pointer to `void`. The value of the pointer is converted to a set of sequences of printable characters, which should be the same as the set of sequences that are matched by the `%p` conversion of the `scanf(3C)` function.

`n` The argument must be a pointer to an integer into which is written the number of bytes written to the output standard I/O stream so far by this call to one of the `printf()` functions. No argument is converted.

`%` Print a `%`; no argument is converted. The entire conversion specification must be `%%`.

If a conversion specification does not match one of the above forms, the behavior is undefined.

If a floating-point value is the internal representation for infinity, the output is `[±]Infinity`, where *Infinity* is either `Infinity` or `Inf`, depending on the desired output string length. Printing of the sign follows the rules described above.

If a floating-point value is the internal representation for “not-a-number,” the output is `[±]NaN`. Printing of the sign follows the rules described above.

printf(3C)

In no case does a non-existent or small field width cause truncation of a field; if the result of a conversion is wider than the field width, the field is simply expanded to contain the conversion result. Characters generated by `printf()` and `fprintf()` are printed as if the `putc(3C)` function had been called.

The `st_ctime` and `st_mtime` fields of the file will be marked for update between the call to a successful execution of `printf()` or `fprintf()` and the next successful completion of a call to `fflush(3C)` or `fclose(3C)` on the same stream or a call to `exit(3C)` or `abort(3C)`.

RETURN VALUES

The `printf()`, `fprintf()`, and `sprintf()` functions return the number of bytes transmitted (excluding the terminating null byte in the case of `sprintf()`).

The `snprintf()` function returns the number of characters formatted, that is, the number of characters that would have been written to the buffer if it were large enough. If the value of `n` is 0 on a call to `snprintf()`, an unspecified value less than 1 is returned.

Each function returns a negative value if an output error was encountered.

ERRORS

For the conditions under which `printf()` and `fprintf()` will fail and may fail, refer to `fputc(3C)` or `fputwc(3C)`.

In addition, all forms of `printf()` may fail if:

`EILSEQ` A wide-character code that does not correspond to a valid character has been detected.

`EINVAL` There are insufficient arguments.

In addition, `printf()` and `fprintf()` may fail if:

`ENOMEM` Insufficient storage space is available.

USAGE

If the application calling the `printf()` functions has any objects of type `wint_t` or `wchar_t`, it must also include the header `<wchar.h>` to have these objects defined.

The `sprintf()` and `snprintf()` functions are MT-Safe in multithreaded applications. The `printf()` and `fprintf()` functions can be used safely in multithreaded applications, as long as `setlocale(3C)` is not being called to change the locale.

Escape Character Sequences

It is common to use the following escape sequences built into the C language when entering format strings for the `printf()` functions, but these sequences are processed by the C compiler, not by the `printf()` function.

`\a` Alert. Ring the bell.

`\b` Backspace. Move the printing position to one character before the current position, unless the current position is the start of a line.

<code>\f</code>	Form feed. Move the printing position to the initial printing position of the next logical page.
<code>\n</code>	Newline. Move the printing position to the start of the next line.
<code>\r</code>	Carriage return. Move the printing position to the start of the current line.
<code>\t</code>	Horizontal tab. Move the printing position to the next implementation-defined horizontal tab position on the current line.
<code>\v</code>	Vertical tab. Move the printing position to the start of the next implementation-defined vertical tab position.

In addition, the C language supports character sequences of the form

`\octal-numberand`

`\hex-number` which translates into the character represented by the octal or hexadecimal number. For example, if ASCII representations are being used, the letter 'a' may be written as `'\141'` and 'Z' as `'\132'`. This syntax is most frequently used to represent the null character as `'\0'`. This is exactly equivalent to the numeric constant zero (0). Note that the octal number does not include the zero prefix as it would for a normal octal constant. To specify a hexadecimal number, omit the zero so that the prefix is an 'x' (uppercase 'X' is not allowed in this context). Support for hexadecimal sequences is an ANSI extension. See `standards(5)`.

EXAMPLES

EXAMPLE 1 To print the language-independent date and time format, the following statement could be used:

```
printf (format, weekday, month, day, hour, min);
```

For American usage, *format* could be a pointer to the string:

```
"%s, %s %d, %d:%.2d\n"
```

producing the message:

```
Sunday, July 3, 10:02
```

whereas for German usage, *format* could be a pointer to the string:

```
"%1$s, %3$d. %2$s, %4$d:%5$.2d\n"
```

producing the message:

```
Sonntag, 3. Juli, 10:02
```

EXAMPLE 2 To print a date and time in the form `Sunday, July 3, 10:02`, where *weekday* and *month* are pointers to null-terminated strings:

```
printf("%s, %s %i, %d:%.2d", weekday, month, day, hour, min);
```

printf(3C)

EXAMPLE 2 To print a date and time in the form `Sunday, July 3, 10:02`, where `weekday` and `month` are pointers to null-terminated strings: *(Continued)*

EXAMPLE 3 To print pi to 5 decimal places:

```
printf("pi = %.5f", 4 * atan(1.0));
```

Default

EXAMPLE 4 The following example applies only to applications which are not standard-conforming (see `standards(5)`). To print a list of names in columns which are 20 characters wide:

```
printf("%20s%20s%20s", lastname, firstname, middlename);
```

NAME	printf, fprintf, sprintf, vprintf, fprintf, vsprintf – formatted output conversion
SYNOPSIS	<pre> /usr/ucb/cc [flag ...] file ... #include <stdio.h> int printf(format, ...); const char *format; int fprintf(stream, format, va_list); FILE *stream; char *format; va_dcl; char *sprintf(s, format, va_list); char *s, *format; va_dcl; int vprintf(format, ap); char *format; va_list ap; int fprintf(stream, format, ap); FILE *stream; char *format; va_list ap; char *vsprintf(s, format, ap); char *s, *format; va_list ap; </pre>
DESCRIPTION	<p>printf() places output on the standard output stream <code>stdout</code>. fprintf() places output on the named output <code>stream</code>. sprintf() places “output,” followed by the NULL character (<code>\0</code>), in consecutive bytes starting at <code>*s</code>; it is the user’s responsibility to ensure that enough storage is available.</p> <p>vprintf(), fprintf(), and vsprintf() are the same as printf(), fprintf(), and sprintf() respectively, except that instead of being called with a variable number of arguments, they are called with an argument list as defined by <code>varargs(3HEAD)</code>.</p> <p>Each of these functions converts, formats, and prints its <code>args</code> under control of the <code>format</code>. The <code>format</code> is a character string which contains two types of objects: plain characters, which are simply copied to the output stream, and conversion specifications, each of which causes conversion and printing of zero or more <code>args</code>. The results are undefined if there are insufficient <code>args</code> for the format. If the format is exhausted while <code>args</code> remain, the excess <code>args</code> are simply ignored.</p> <p>Each conversion specification is introduced by the character <code>%</code>. After the <code>%</code>, the following appear in sequence:</p>

printf(3UCB)

- Zero or more *flags*, which modify the meaning of the conversion specification.
- An optional decimal digit string specifying a minimum *field width*. If the converted value has fewer characters than the field width, it will be padded on the left (or right, if the left-adjustment flag '-', described below, has been given) to the field width. The padding is with blanks unless the field width digit string starts with a zero, in which case the padding is with zeros.
- A *precision* that gives the minimum number of digits to appear for the d, i, o, u, x, or X conversions, the number of digits to appear after the decimal point for the e, E, and f conversions, the maximum number of significant digits for the g and G conversion, or the maximum number of characters to be printed from a string in s conversion. The precision takes the form of a period (.) followed by a decimal digit string; a NULL digit string is treated as zero. Padding specified by the precision overrides the padding specified by the field width.
- An optional l (ell) specifying that a following d, i, o, u, x, or X conversion character applies to a long integer *arg*. An l before any other conversion character is ignored.
- A character that indicates the type of conversion to be applied.

A field width or precision or both may be indicated by an asterisk (*) instead of a digit string. In this case, an integer *arg* supplies the field width or precision. The *arg* that is actually converted is not fetched until the conversion letter is seen, so the *args* specifying field width or precision must appear *before* the *arg* (if any) to be converted. A negative field width argument is taken as a '-' flag followed by a positive field width. If the precision argument is negative, it will be changed to zero.

The flag characters and their meanings are:

-	The result of the conversion will be left-justified within the field.
+	The result of a signed conversion will always begin with a sign (+ or -).
blank	If the first character of a signed conversion is not a sign, a blank will be prefixed to the result. This implies that if the blank and + flags both appear, the blank flag will be ignored.
#	This flag specifies that the value is to be converted to an "alternate form." For c, d, i, s, and u conversions, the flag has no effect. For o conversion, it increases the precision to force the first digit of the result to be a zero. For x or X conversion, a non-zero result will have 0x or 0X prefixed to it. For e, E, f, g, and G conversions, the result will always contain a decimal point, even if no digits follow the point (normally, a decimal point appears in the result of these conversions only if a digit follows it). For g and G conversions, trailing zeroes will <i>not</i> be removed from the result (which they normally are).

The conversion characters and their meanings are:

d,i,o,u,x,X	The integer <i>arg</i> is converted to signed decimal (d or i), unsigned octal (o), unsigned decimal (u), or unsigned hexadecimal notation (x and X), respectively; the letters abcdef are used for x conversion and the letters ABCDEF for X conversion. The precision specifies the minimum number of digits to appear; if the value being converted can be represented in fewer digits, it will be expanded with leading zeroes. (For compatibility with older versions, padding with leading zeroes may alternatively be specified by prepending a zero to the field width. This does not imply an octal value for the field width.) The default precision is 1. The result of converting a zero value with a precision of zero is a NULL string.
f	The float or double <i>arg</i> is converted to decimal notation in the style <code>[-]ddd.ddd</code> where the number of digits after the decimal point is equal to the precision specification. If the precision is missing, 6 digits are given; if the precision is explicitly 0, no digits and no decimal point are printed.
e,E	The float or double <i>arg</i> is converted in the style <code>[-]d.ddd_{e±ddd}</code> , where there is one digit before the decimal point and the number of digits after it is equal to the precision; when the precision is missing, 6 digits are produced; if the precision is zero, no decimal point appears. The E format code will produce a number with E instead of e introducing the exponent. The exponent always contains at least two digits.
g,G	The float or double <i>arg</i> is printed in style f or e (or in style E in the case of a G format code), with the precision specifying the number of significant digits. The style used depends on the value converted: style e or E will be used only if the exponent resulting from the conversion is less than -4 or greater than the precision. Trailing zeroes are removed from the result; a decimal point appears only if it is followed by a digit.
The e, E f, g, and G formats print IEEE indeterminate values (infinity or not-a-number) as "Infinity" or "NaN" respectively.	
c	The character <i>arg</i> is printed.
s	The <i>arg</i> is taken to be a string (character pointer) and characters from the string are printed until a NULL character (<code>\0</code>) is encountered or until the number of characters indicated by the precision specification is reached. If the precision is missing, it is taken to be infinite, so all characters up to the first NULL character are printed. A NULL value for <i>arg</i> will yield undefined results.
%	Print a %; no argument is converted.

printf(3UCB)

In no case does a non-existent or small field width cause truncation of a field; if the result of a conversion is wider than the field width, the field is simply expanded to contain the conversion result. Padding takes place only if the specified field width exceeds the actual width. Characters generated by `printf()` and `fprintf()` are printed as if `putc(3C)` had been called.

RETURN VALUES Upon success, `printf()` and `fprintf()` return the number of characters transmitted, excluding the null character. `vprintf()` and `vfprintf()` return the number of characters transmitted. `sprintf()` and `vsprintf()` always return `s`. If an output error is encountered, `printf()`, `fprintf()`, `vprintf()`, and `vfprintf()` return EOF.

EXAMPLES **EXAMPLE 1** Examples of the `printf` Command To Print a Date and Time

To print a date and time in the form "Sunday, July 3, 10:02," where *weekday* and *month* are pointers to NULL-terminated strings:

```
printf("%s, %s %i, %d:%.2d", weekday, month, day, hour, min);
```

EXAMPLE 2 Examples of the `printf` Command To Print to Five Decimal Places

To print to five decimal places:

```
printf("pi = %.5f", 4 * atan(1. 0));
```

SEE ALSO `econvert(3C)`, `putc(3C)`, `scanf(3C)`, `vprintf(3C)`, `varargs(3HEAD)`

NOTES Use of these interfaces should be restricted to only applications written on BSD platforms. Use of these interfaces with any of the system libraries or in multi-thread applications is unsupported.

Very wide fields (>128 characters) fail.

NAME	walkcontext, printstack – walk stack pointed to by ucontext
SYNOPSIS	<pre>#include <ucontext.h> int walkcontext(const ucontext_t *uptr, int (*operate_func)(uintptr_t, int, void *), void *usrarg); int printstack(int fd);</pre>
DESCRIPTION	<p>The <code>walkcontext()</code> function walks the call stack pointed to by <code>uptr</code>, which can be obtained by a call to <code>getcontext(2)</code> or from a signal handler installed with the <code>SA_SIGINFO</code> flag. The <code>walkcontext()</code> function calls the user-supplied function <code>operate_func</code> for each routine found on the call stack and each signal handler invoked. The user function is passed three arguments: the PC at which the call or signal occurred, the signal number that occurred at this PC (0 if no signal occurred), and the third argument passed to <code>walkcontext()</code>. If the user function returns a non-zero value, <code>walkcontext()</code> returns without completing the callstack walk.</p> <p>The <code>printstack()</code> function uses <code>walkcontext()</code> to print a symbolic stack trace to the specified file descriptor. This is useful for reporting errors from signal handlers. The <code>printstack()</code> function uses <code>dladdr1()</code> (see <code>dladdr(3DL)</code>) to obtain symbolic symbol names. As a result, only global symbols are reported as symbol names by <code>printstack()</code>.</p>
RETURN VALUES	Upon successful completion, <code>walkstack()</code> and <code>printstack()</code> return 0. If <code>walkstack()</code> cannot read the stack or the stack trace appears corrupted, both functions return -1.
ERRORS	No error values are defined.
USAGE	<p>The <code>walkcontext()</code> function is typically used to obtain information about the call stack for error reporting, performance analysis, or diagnostic purposes. Many library functions are not Async-Signal-Safe and should not be used from a signal handler. If <code>walkcontext()</code> is to be called from a signal handler, careful programming is required. In particular, <code>stdio(3C)</code> and <code>malloc(3C)</code> cannot be used.</p> <p>The <code>printstack()</code> function is Async-Signal-Safe and can be called from a signal handler. The output format from <code>printstack()</code> is unstable, as it varies with the scope of the routines.</p> <p>Tail-call optimizations on SPARC eliminate stack frames that would otherwise be present. For example, if the code is of the form</p> <pre>#include <stdio.h> main() { bar(); exit(0); } bar()</pre>

printstack(3C)

```
{
    int a;
    a = foo(fileno(stdout));
    return (a);
}

foo(int file)
{
    printstack(file);
}
```

compiling without optimization will yield a stack trace of the form

```
/tmp/q:foo+0x8
/tmp/q:bar+0x14
/tmp/q:main+0x4
/tmp/q:_start+0xb8
```

whereas with higher levels of optimization the output is

```
/tmp/q:main+0x10
/tmp/q:_start+0xb8
```

since both the call to `foo()` in `main` and the call to `bar()` in `foo()` are handled as tail calls that perform a return or restore in the delay slot. For further information, see *The SPARC Architecture Manual*.

NAME	pset_getloadavg – get system load averages for a processor set						
SYNOPSIS	<pre>#include <sys/pset.h> #include <sys/loadavg.h> int pset_getloadavg(psetid_t pset, double loadavg[], int nelem);</pre>						
DESCRIPTION	<p>The pset_getloadavg() function returns the number of processes assigned to the specified processor set that are in the system run queue, averaged over various periods of time. Up to <i>nelem</i> samples are retrieved and assigned to successive elements of <i>loadavg[]</i>. The system imposes a maximum of 3 samples, representing averages over the last 1, 5, and 15 minutes, respectively.</p> <p>The LOADAVG_1MIN, LOADAVG_5MIN, and LOADAVG_15MIN indices, defined in <sys/loadavg.h>, can be used to extract the data from the appropriate element of the <i>loadavg[]</i> array.</p> <p>If pset is PS_NONE, the load average for processes not assigned to a processor set is returned.</p> <p>If pset is PS_MYID, the load average for the processor set to which the caller is bound is returned. If the caller is not bound to a processor set, the result is the same as if PS_NONE was specified.</p>						
RETURN VALUES	Upon successful completion, the number of samples actually retrieved is returned. If the load average was unobtainable or the processor set does not exist, -1 is returned and errno is set to indicate the error.						
ERRORS	<p>The pset_getloadavg() function will fail if:</p> <p>EINVAL The number of elements specified is less than 0, or an invalid processor set ID was specified.</p>

psiginfo(3C)

NAME | psignal, psiginfo – system signal messages

SYNOPSIS | #include <siginfo.h>
| void **psignal**(int *sig*, const char **s*);
| void **psiginfo**(siginfo_t **pinfo*, char **s*);

DESCRIPTION | The psignal() and psiginfo() functions produce messages on the standard error output describing a signal. The *sig* argument is a signal that may have been passed as the first argument to a signal handler. The *pinfo* argument is a pointer to a siginfo structure that may have been passed as the second argument to an enhanced signal handler. See sigaction(2). The argument string *s* is printed first, followed by a colon and a blank, followed by the message and a NEWLINE character.

USAGE | If the application is linked with -lintl, then messages printed from these functions are in the native language specified by the LC_MESSAGES locale category. See setlocale(3C).

ATTRIBUTES | See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
MT-Level	Safe

SEE ALSO | sigaction(2), gettext(3C), perror(3C), setlocale(3C), attributes(5), siginfo(3HEAD), signal(3HEAD)

NAME	psignal, psignal – system signal messages				
SYNOPSIS	<pre>#include <siginfo.h> void psignal(int <i>sig</i>, const char *<i>s</i>); void psiginfo(siginfo_t *<i>pinfo</i>, char *<i>s</i>);</pre>				
DESCRIPTION	The <code>psignal()</code> and <code>psiginfo()</code> functions produce messages on the standard error output describing a signal. The <i>sig</i> argument is a signal that may have been passed as the first argument to a signal handler. The <i>pinfo</i> argument is a pointer to a <code>siginfo</code> structure that may have been passed as the second argument to an enhanced signal handler. See <code>sigaction(2)</code> . The argument string <i>s</i> is printed first, followed by a colon and a blank, followed by the message and a NEWLINE character.				
USAGE	If the application is linked with <code>-lintl</code> , then messages printed from these functions are in the native language specified by the <code>LC_MESSAGES</code> locale category. See <code>setlocale(3C)</code> .				
ATTRIBUTES	See <code>attributes(5)</code> for descriptions of the following attributes:

psignal(3UCB)

NAME	psignal, sys_siglist – system signal messages
SYNOPSIS	<pre>/usr/ucb/cc[<i>flag</i> ...] <i>file</i> ... void psignal(<i>sig</i>, <i>s</i>); unsigned <i>sig</i>; char *<i>s</i>; char *sys_siglist[];</pre>
DESCRIPTION	<p>psignal() produces a short message on the standard error file describing the indicated signal. First the argument string <i>s</i> is printed, then a colon, then the name of the signal and a NEWLINE. Most usefully, the argument string is the name of the program which incurred the signal. The signal number should be from among those found in <signal.h>.</p> <p>To simplify variant formatting of signal names, the vector of message strings <i>sys_siglist</i> is provided; the signal number can be used as an index in this table to get the signal name without the newline. The define <i>NSIG</i> defined in <signal.h> is the number of messages provided for in the table; it should be checked because new signals may be added to the system before they are added to the table.</p>
SEE ALSO	perror(3C), signal(3C)
NOTES	Use of these interfaces should be restricted to only applications written on BSD platforms. Use of these interfaces with any of the system libraries or in multi-thread applications is unsupported.

NAME	pthread_atfork – register fork handlers
SYNOPSIS	<pre>#include <sys/types.h> #include <unistd.h> int pthread_atfork(void (*prepare) (void), void (*parent) (void), void (*child) (void));</pre>
DESCRIPTION	<p>The <code>pthread_atfork()</code> function declares fork handlers to be called prior to and following <code>fork(2)</code>, within the thread that called <code>fork()</code>. The order of calls to <code>pthread_atfork()</code> is significant.</p> <p>Before <code>fork()</code> processing begins, the <i>prepare</i> fork handler is called. The <i>prepare</i> handler is not called if its address is <code>NULL</code>.</p> <p>The <i>parent</i> fork handler is called after <code>fork()</code> processing finishes in the parent process, and the <i>child</i> fork handler is called after <code>fork()</code> processing finishes in the child process. If the address of <i>parent</i> or <i>child</i> is <code>NULL</code>, then its handler is not called.</p> <p>The <i>prepare</i> fork handler is called in LIFO (last-in first-out) order, whereas the <i>parent</i> and <i>child</i> fork handlers are called in FIFO (first-in first-out) order. This calling order allows applications to preserve locking order.</p>
RETURN VALUES	Upon successful completion, <code>pthread_atfork()</code> returns 0. Otherwise, an error number is returned.
ERRORS	<p>The <code>pthread_atfork()</code> function will fail if:</p> <p><code>ENOMEM</code> Insufficient table space exists to record the fork handler addresses.</p>
USAGE	Solaris threads do not offer <code>pthread_atfork()</code> functionality, though a Solaris threads application can call this interface to ensure <code>fork1()</code> -safety, since the two thread APIs are interoperable. If the application is linked with <code>-lpthread</code> , <code>fork()</code> is defined to be the same as <code>fork1()</code> ; otherwise <code>fork()</code> and <code>fork1()</code> behave differently. The <code>pthread_atfork()</code> function affects only <code>fork1()</code> . See <code>fork(2)</code> .
EXAMPLES	<p>EXAMPLE 1 make a library safe with respect to <code>fork()</code></p> <p>All multithreaded applications that call <code>fork()</code> in a POSIX threads program and do more than simply call <code>exec(2)</code> in the child of the fork need to ensure that the child is protected from deadlock.</p> <p>Since the "fork-one" model results in duplicating only the thread that called <code>fork()</code>, it is possible that at the time of the call another thread in the parent owns a lock. This thread is not duplicated in the child, so no thread will unlock this lock in the child. Deadlock occurs if the single thread in the child needs this lock.</p> <p>The problem is more serious with locks in libraries. Since a library writer does not know if the application using the library calls <code>fork()</code>, the library must protect itself from such a deadlock scenario. If the application that links with this library calls</p>

pthread_atfork(3C)

EXAMPLE 1 make a library safe with respect to `fork()` (Continued)

`fork()` and does not call `exec()` in the child, and if it needs a library lock that may be held by some other thread in the parent that is inside the library at the time of the fork, the application deadlocks inside the library.

The following describes how to make a library safe with respect to `fork()` by using `pthread_atfork()`.

1. Identify all locks used by the library (for example $\{L1, \dots, Ln\}$). Identify also the locking order for these locks (for example $\{L1 \dots Ln\}$, as well.)
2. Add a call to `pthread_atfork(f1, f2, f3)` in the library's `.init` section. `f1`, `f2`, `f3` are defined as follows:

```
f1( )
{
    /* ordered in lock order */
    pthread_mutex_lock(L1);
    pthread_mutex_lock( . . . );
    pthread_mutex_lock(Ln);
}

f2( )
{
    pthread_mutex_unlock(L1);
    pthread_mutex_unlock( . . . );
    pthread_mutex_unlock(Ln);
}

f3( )
{
    pthread_mutex_unlock(L1);
    pthread_mutex_unlock( . . . );
    pthread_mutex_unlock(Ln);
}
```

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

NAME	ptsname – get name of the slave pseudo-terminal device
SYNOPSIS	<pre>#include <stdlib.h> char *ptsname(int fildes);</pre>
DESCRIPTION	The ptsname() function returns the name of the slave pseudo-terminal device associated with a master pseudo-terminal device. <i>fildes</i> is a file descriptor returned from a successful open of the master device. ptsname() returns a pointer to a string containing the null-terminated path name of the slave device of the form /dev/pts/N, where N is a non-negative integer.
RETURN VALUES	Upon successful completion, the function ptsname() returns a pointer to a string which is the name of the pseudo-terminal slave device. This value points to a static data area that is overwritten by each call to ptsname(). Upon failure, ptsname() returns NULL. This could occur if <i>fildes</i> is an invalid file descriptor or if the slave device name does not exist in the file system.
ATTRIBUTES	See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE

STREAMS Programming Guide

putc(3C)

NAME	<code>fputc</code> , <code>putc</code> , <code>putc_unlocked</code> , <code>putchar</code> , <code>putchar_unlocked</code> , <code>putw</code> – put a byte on a stream
SYNOPSIS	<pre>#include <stdio.h> int fputc(int <i>c</i>, FILE *<i>stream</i>); int putc(int <i>c</i>, FILE *<i>stream</i>); int putc_unlocked(int <i>c</i>, FILE *<i>stream</i>); int putchar(int <i>c</i>); int putchar_unlocked(int <i>c</i>); int putw(int <i>w</i>, FILE *<i>stream</i>);</pre>
DESCRIPTION	<p>The <code>fputc()</code> function writes the byte specified by <i>c</i> (converted to an unsigned char) to the output stream pointed to by <i>stream</i>, at the position indicated by the associated file-position indicator for the stream (if defined), and advances the indicator appropriately. If the file cannot support positioning requests, or if the stream was opened with append mode, the byte is appended to the output stream.</p> <p>The <code>st_ctime</code> and <code>st_mtime</code> fields of the file will be marked for update between the successful execution of <code>fputc()</code> and the next successful completion of a call to <code>fflush(3C)</code> or <code>fclose(3C)</code> on the same stream or a call to <code>exit(3C)</code> or <code>abort(3C)</code>.</p> <p>The <code>putc()</code> routine behaves like <code>fputc()</code>, except that it is implemented as a macro. It runs faster than <code>fputc()</code>, but it takes up more space per invocation and its name cannot be passed as an argument to a function call.</p> <p>The call <code>putchar(<i>c</i>)</code> is equivalent to <code>putc(<i>c</i>, <i>stdout</i>)</code>. The <code>putchar()</code> routine is implemented as a macro.</p> <p>The <code>putc_unlocked()</code> and <code>putchar_unlocked()</code> routines are variants of <code>putc()</code> and <code>putchar()</code>, respectively, that do not lock the stream. It is the caller's responsibility to acquire the stream lock before calling these routines and releasing the lock afterwards; see <code>flockfile(3C)</code> and <code>stdio(3C)</code>. These routines are implemented as macros.</p> <p>The <code>putw()</code> function writes the word (that is, type <code>int</code>) <i>w</i> to the output <i>stream</i> (at the position at which the file offset, if defined, is pointing). The size of a word is the size of a type <code>int</code> and varies from machine to machine. The <code>putw()</code> function neither assumes nor causes special alignment in the file.</p> <p>The <code>st_ctime</code> and <code>st_mtime</code> fields of the file will be marked for update between the successful execution of <code>putw()</code> and the next successful completion of a call to <code>fflush(3C)</code> or <code>fclose(3C)</code> on the same stream or a call to <code>exit(3C)</code> or <code>abort(3C)</code>.</p>
RETURN VALUES	Upon successful completion, <code>fputc()</code> , <code>putc()</code> , <code>putc_unlocked()</code> , <code>putchar()</code> , and <code>putchar_unlocked()</code> return the value that was written. Otherwise, these functions return EOF, the error indicator for the stream is set, and <code>errno</code> is set to indicate the error.

Upon successful completion, `putw()` returns 0. Otherwise, it returns a non-zero value, sets the error indicator for the associated *stream*, and sets `errno` to indicate the error.

An unsuccessful completion will occur, for example, if the file associated with *stream* is not open for writing or if the output file cannot grow.

ERRORS

The `fputc()`, `putc()`, `putc_unlocked()`, `putchar()`, `putchar_unlocked()`, and `putw()` functions will fail if either the *stream* is unbuffered or the *stream's* buffer needs to be flushed, and:

EAGAIN	The <code>O_NONBLOCK</code> flag is set for the file descriptor underlying <i>stream</i> and the process would be delayed in the write operation.
EBADF	The file descriptor underlying <i>stream</i> is not a valid file descriptor open for writing.
EFBIG	An attempt was made to write to a file that exceeds the maximum file size or the process' file size limit.
EFBIG	The file is a regular file and an attempt was made to write at or beyond the offset maximum.
EINTR	The write operation was terminated due to the receipt of a signal, and no data was transferred.
EIO	A physical I/O error has occurred, or the process is a member of a background process group attempting to write to its controlling terminal, <code>TOSTOP</code> is set, the process is neither ignoring nor blocking <code>SIGTTOU</code> and the process group of the process is orphaned. This error may also be returned under implementation-dependent conditions.
ENOSPC	There was no free space remaining on the device containing the file.
EPIPE	An attempt is made to write to a pipe or FIFO that is not open for reading by any process. A <code>SIGPIPE</code> signal will also be sent to the process.

The `fputc()`, `putc()`, `putc_unlocked()`, `putchar()`, `putchar_unlocked()`, and `putw()` functions may fail if:

ENOMEM	Insufficient storage space is available.
ENXIO	A request was made of a non-existent device, or the request was outside the capabilities of the device.

USAGE

Functions exist for the `putc()`, `putc_unlocked()`, `putchar()`, and `putchar_unlocked()` macros. To get the function form, the macro name must be undefined (for example, `#undef putc`).

putc(3C)

When the macro forms are used, `putc()` and `putc_unlocked()` evaluate the *stream* argument more than once. In particular, `putc(c, *f++)`; does not work sensibly. The `fputc()` function should be used instead when evaluating the *stream* argument has side effects.

Because of possible differences in word length and byte ordering, files written using `putw()` are implementation-dependent, and possibly cannot be read using `getw(3C)` by a different application or by the same application running in a different environment.

The `putw()` function is inherently byte stream oriented and is not tenable in the context of either multibyte character streams or wide-character streams. Application programmers are encouraged to use one of the character-based output functions instead.

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

putchar_unlocked(3C)

NAME	<code>fputc</code> , <code>putc</code> , <code>putc_unlocked</code> , <code>putchar</code> , <code>putchar_unlocked</code> , <code>putw</code> – put a byte on a stream
SYNOPSIS	<pre>#include <stdio.h> int fputc(int <i>c</i>, FILE *<i>stream</i>); int putc(int <i>c</i>, FILE *<i>stream</i>); int putc_unlocked(int <i>c</i>, FILE *<i>stream</i>); int putchar(int <i>c</i>); int putchar_unlocked(int <i>c</i>); int putw(int <i>w</i>, FILE *<i>stream</i>);</pre>
DESCRIPTION	<p>The <code>fputc()</code> function writes the byte specified by <i>c</i> (converted to an unsigned char) to the output stream pointed to by <i>stream</i>, at the position indicated by the associated file-position indicator for the stream (if defined), and advances the indicator appropriately. If the file cannot support positioning requests, or if the stream was opened with append mode, the byte is appended to the output stream.</p> <p>The <code>st_ctime</code> and <code>st_mtime</code> fields of the file will be marked for update between the successful execution of <code>fputc()</code> and the next successful completion of a call to <code>fflush(3C)</code> or <code>fclose(3C)</code> on the same stream or a call to <code>exit(3C)</code> or <code>abort(3C)</code>.</p> <p>The <code>putc()</code> routine behaves like <code>fputc()</code>, except that it is implemented as a macro. It runs faster than <code>fputc()</code>, but it takes up more space per invocation and its name cannot be passed as an argument to a function call.</p> <p>The call <code>putchar(<i>c</i>)</code> is equivalent to <code>putc(<i>c</i>, <i>stdout</i>)</code>. The <code>putchar()</code> routine is implemented as a macro.</p> <p>The <code>putc_unlocked()</code> and <code>putchar_unlocked()</code> routines are variants of <code>putc()</code> and <code>putchar()</code>, respectively, that do not lock the stream. It is the caller's responsibility to acquire the stream lock before calling these routines and releasing the lock afterwards; see <code>flockfile(3C)</code> and <code>stdio(3C)</code>. These routines are implemented as macros.</p> <p>The <code>putw()</code> function writes the word (that is, type <code>int</code>) <i>w</i> to the output <i>stream</i> (at the position at which the file offset, if defined, is pointing). The size of a word is the size of a type <code>int</code> and varies from machine to machine. The <code>putw()</code> function neither assumes nor causes special alignment in the file.</p> <p>The <code>st_ctime</code> and <code>st_mtime</code> fields of the file will be marked for update between the successful execution of <code>putw()</code> and the next successful completion of a call to <code>fflush(3C)</code> or <code>fclose(3C)</code> on the same stream or a call to <code>exit(3C)</code> or <code>abort(3C)</code>.</p>
RETURN VALUES	Upon successful completion, <code>fputc()</code> , <code>putc()</code> , <code>putc_unlocked()</code> , <code>putchar()</code> , and <code>putchar_unlocked()</code> return the value that was written. Otherwise, these functions return EOF, the error indicator for the stream is set, and <code>errno</code> is set to indicate the error.

Upon successful completion, `putw()` returns 0. Otherwise, it returns a non-zero value, sets the error indicator for the associated *stream*, and sets `errno` to indicate the error.

An unsuccessful completion will occur, for example, if the file associated with *stream* is not open for writing or if the output file cannot grow.

ERRORS

The `fputc()`, `putc()`, `putc_unlocked()`, `putchar()`, `putchar_unlocked()`, and `putw()` functions will fail if either the *stream* is unbuffered or the *stream's* buffer needs to be flushed, and:

- EAGAIN The `O_NONBLOCK` flag is set for the file descriptor underlying *stream* and the process would be delayed in the write operation.
- EBADF The file descriptor underlying *stream* is not a valid file descriptor open for writing.
- EFBIG An attempt was made to write to a file that exceeds the maximum file size or the process' file size limit.
- EFBIG The file is a regular file and an attempt was made to write at or beyond the offset maximum.
- EINTR The write operation was terminated due to the receipt of a signal, and no data was transferred.
- EIO A physical I/O error has occurred, or the process is a member of a background process group attempting to write to its controlling terminal, `TOSTOP` is set, the process is neither ignoring nor blocking `SIGTTOU` and the process group of the process is orphaned. This error may also be returned under implementation-dependent conditions.
- ENOSPC There was no free space remaining on the device containing the file.
- EPIPE An attempt is made to write to a pipe or FIFO that is not open for reading by any process. A `SIGPIPE` signal will also be sent to the process.

The `fputc()`, `putc()`, `putc_unlocked()`, `putchar()`, `putchar_unlocked()`, and `putw()` functions may fail if:

- ENOMEM Insufficient storage space is available.
- ENXIO A request was made of a non-existent device, or the request was outside the capabilities of the device.

USAGE

Functions exist for the `putc()`, `putc_unlocked()`, `putchar()`, and `putchar_unlocked()` macros. To get the function form, the macro name must be undefined (for example, `#undef putc`).

putchar_unlocked(3C)

When the macro forms are used, `putc()` and `putc_unlocked()` evaluate the *stream* argument more than once. In particular, `putc(c, *f++)`; does not work sensibly. The `fputc()` function should be used instead when evaluating the *stream* argument has side effects.

Because of possible differences in word length and byte ordering, files written using `putw()` are implementation-dependent, and possibly cannot be read using `getw(3C)` by a different application or by the same application running in a different environment.

The `putw()` function is inherently byte stream oriented and is not tenable in the context of either multibyte character streams or wide-character streams. Application programmers are encouraged to use one of the character-based output functions instead.

NOTES The `fputc()`, `putc()`, `putchar()`, and `putw()` routines are MT-Safe in multithreaded applications. The `putc_unlocked()` and `putchar_unlocked()` routines are unsafe in multithreaded applications.

putenv(3C)

NAME	putenv – change or add value to environment				
SYNOPSIS	<pre>#include <stdlib.h> int putenv(char *string);</pre>				
DESCRIPTION	<p>The <code>putenv()</code> function makes the value of the environment variable <i>name</i> equal to <i>value</i> by altering an existing variable or creating a new one. In either case, the string pointed to by <i>string</i> becomes part of the environment, so altering the string will change the environment.</p> <p>The <i>string</i> argument points to a string of the form <i>name=value</i>. The space used by <i>string</i> is no longer used once a new string-defining <i>name</i> is passed to <code>putenv()</code>.</p> <p>The <code>putenv()</code> function uses <code>malloc(3C)</code> to enlarge the environment.</p> <p>After <code>putenv()</code> is called, environment variables are not in alphabetical order.</p>				
RETURN VALUES	The <code>putenv()</code> functions returns a non-zero value if it was unable to obtain enough space using <code>malloc(3C)</code> for an expanded environment. Otherwise, 0 is returned.				
ERRORS	The <code>putenv()</code> function may fail if: ENOMEM Insufficient memory was available.				
USAGE	The <code>putenv()</code> function can be safely called from multithreaded programs. Caution must be exercised when using this function and <code>getenv(3C)</code> in multithreaded programs. These functions examine and modify the environment list, which is shared by all threads in a program. The system prevents the list from being accessed simultaneously by two different threads. It does not, however, prevent two threads from successively accessing the environment list using <code>putenv()</code> or <code>getenv()</code> .				
ATTRIBUTES	See <code>attributes(5)</code> for descriptions of the following attributes:				
	<table border="1"><thead><tr><th>ATTRIBUTE TYPE</th><th>ATTRIBUTE VALUE</th></tr></thead><tbody><tr><td>MT-Level</td><td>Safe</td></tr></tbody></table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	MT-Level	Safe
ATTRIBUTE TYPE	ATTRIBUTE VALUE				
MT-Level	Safe				
SEE ALSO	<code>exec(2)</code> , <code>getenv(3C)</code> , <code>malloc(3C)</code> , <code>attributes(5)</code> , <code>environ(5)</code>				
WARNINGS	The <i>string</i> argument should not be an automatic variable. It should be declared static if it is declared within a function because it cannot be automatically declared. A potential error is to call <code>putenv()</code> with a pointer to an automatic variable as the argument and to then exit the calling function while <i>string</i> is still part of the environment.				

NAME	getmntent, getmntany, getextmntent, hasmntopt, putmntent, resetmnttab – get mounted device information
SYNOPSIS	<pre>#include <stdio.h> #include <sys/mnttab.h> int getmntent(FILE *fp, struct mnttab *mp); int getmntany(FILE *fp, struct mnttab *mp, struct mnttab *mpref); int getextmntent(FILE *fp, struct extmnttab *mp, int len); char *hasmntopt(struct mnttab *mnt, char *opt); int putmntent(FILE *iop, struct mnttab *mp); void resetmnttab(FILE *fp);</pre>
getmntent() and getmntany()	<p>The <code>getmntent()</code> and <code>getmntany()</code> functions each fill in the structure pointed to by <code>mp</code> with the broken-out fields of a line in the <code>mnttab</code> file. Each line read from the file contains a <code>mnttab</code> structure, which is defined in the <code><sys/mnttab.h></code> header. The structure contains the following members, which correspond to the broken-out fields from a line in <code>/etc/mnttab</code> (see <code>mnttab(4)</code>).</p> <pre>char *mnt_special; /* name of mounted resource */ char *mnt_mountp; /* mount point */ char *mnt_fstype; /* type of file system mounted */ char *mnt_mntopts; /* options for this mount */ char *mnt_time; /* time file system mounted */</pre> <p>Each <code>getmntent()</code> call causes a new line to be read from the <code>mnttab</code> file. Successive calls can be used to search the entire list. The <code>getmntany()</code> function searches the file referenced by <code>fp</code> until a match is found between a line in the file and <code>mpref</code>. A match occurs if all non-null entries in <code>mpref</code> match the corresponding fields in the file. Note that these functions do not open, close, or rewind the file.</p>
getextmntent()	<p>The <code>getextmntent()</code> function is an extended version of the <code>getmntent()</code> function that returns, in addition to the information that <code>getmntent()</code> returns, the major and minor number of the mounted resource to which the line in <code>mnttab</code> corresponds. The <code>getextmntent()</code> function also fills in the <code>extmntent</code> structure defined in the <code><sys/mnttab.h></code> header. For <code>getextmntent()</code> to function properly, it must be notified when the <code>mnttab</code> file has been reopened or rewound since a previous <code>getextmntent()</code> call. This notification is accomplished by calling <code>resetmnttab()</code>. Otherwise, it behaves exactly as <code>getmntent()</code> described above.</p> <p>The data pointed to by the <code>mnttab</code> structure members are stored in a static area and must be copied to be saved between successive calls.</p>
hasmntopt()	<p>The <code>hasmntopt()</code> function scans the <code>mnt_mntopts</code> member of the <code>mnttab</code> structure <code>mnt</code> for a substring that matches <code>opt</code>. It returns the address of the substring if a match is found; otherwise it returns 0. Substrings are delimited by commas and the end of the <code>mnt_mntopts</code> string.</p>

putmntent(3C)

- `putmntent()` | The `putmntent()` function is obsolete and no longer has any effect. Entries appear in `mnttab` as a side effect of a `mount(2)` call. The function name is still defined for transition purposes.
- `resetmnttab()` | The `resetmnttab()` function notifies `getextmntent()` to reload from the kernel the device information that corresponds to the new snapshot of the `mnttab` information (see `mnttab(4)`). Subsequent `getextmntent()` calls then return correct `extmnttab` information. This function should be called whenever the `mnttab` file is either rewound or closed and reopened before any calls are made to `getextmntent()`.
- `getmntent()` and `getmntany()` | If the next entry is successfully read by `getmntent()` or a match is found with `getmntany()`, 0 is returned. If an EOF is encountered on reading, these functions return -1. If an error is encountered, a value greater than 0 is returned. The following error values are defined in `<sys/mnttab.h>`:
- `MNT_TOOLONG` | A line in the file exceeded the internal buffer size of `MNT_LINE_MAX`.
- `MNT_TOOMANY` | A line in the file contains too many fields.
- `MNT_TOOFEW` | A line in the file contains too few fields.
- `hasmntopt()` | Upon successful completion, `hasmntopt()` returns the address of the substring if a match is found. Otherwise, it returns 0.
- `putmntent()` | The `putmntent()` is obsolete and always returns -1.

NAME	putpwent – write password file entry				
SYNOPSIS	<pre>#include <pwd.h> int putpwent(const struct passwd *p, FILE *f);</pre>				
DESCRIPTION	The putpwent () function is the inverse of getpwent (). See getpwnam(3C). Given a pointer to a passwd structure created by getpwent (), getpwuid (), or getpwnam (), putpwent () writes a line on the stream <i>f</i> that matches the format of /etc/passwd.				
RETURN VALUES	The putpwent () function returns a non-zero value if an error was detected during its operation. Otherwise, it returns 0.				
USAGE	The putpwent () function is of limited utility, since most password files are maintained as Network Information Service (NIS) files that cannot be updated with this function. For this reason, the use of this function is discouraged. If used at all, it should be used with putspent(3C) to update the shadow file.				
ATTRIBUTES	See attributes(5) for descriptions of the following attributes:				
	<table border="1"> <thead> <tr> <th>ATTRIBUTE TYPE</th> <th>ATTRIBUTE VALUE</th> </tr> </thead> <tbody> <tr> <td>MT-Level</td> <td>Unsafe</td> </tr> </tbody> </table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	MT-Level	Unsafe
ATTRIBUTE TYPE	ATTRIBUTE VALUE

puts(3C)

NAME puts, fputs – put a string on a stream

SYNOPSIS `#include <stdio.h>`
`int puts(const char *s);`
`int fputs(const char *s, FILE *stream);`

DESCRIPTION The `puts()` function writes the string pointed to by `s`, followed by a `NEWLINE` character, to the standard output stream `stdout` (see `intro(3)`). The terminating null byte is not written.

The `fputs()` function writes the null-terminated string pointed to by `s` to the named output `stream`. The terminating null byte is not written.

The `st_ctime` and `st_mtime` fields of the file will be marked for update between the successful execution of `fputs()` and the next successful completion of a call to `fflush(3C)` or `fclose(3C)` on the same stream or a call to `exit(2)` or `abort(3C)`.

RETURN VALUES On successful completion, both functions return the number of bytes written; otherwise they return `EOF` and set `errno` to indicate the error.

ERRORS Refer to `fputc(3C)`.

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

NAME	putspent – write shadow password file entry				
SYNOPSIS	<pre>#include <shadow.h> int putspent(const struct spwd *p, FILE *fp);</pre>				
DESCRIPTION	<p>The <code>putspent()</code> function is the inverse of <code>getspent()</code>. See <code>getspnam(3C)</code>. Given a pointer to a <code>spwd</code> structure created by <code>getspent()</code> or <code>getspnam()</code>, <code>putspent()</code> writes a line on the stream <code>fp</code> that matches the format of <code>/etc/shadow</code>.</p> <p>The <code>spwd</code> structure contains the following members:</p> <pre>char *sp_namp; char *sp_pwdp; long sp_lstchg; long sp_min; long sp_max; long sp_warn; long sp_inact; long sp_expire; unsigned long sp_flag;</pre> <p>If the <code>sp_min</code>, <code>sp_max</code>, <code>sp_lstchg</code>, <code>sp_warn</code>, <code>sp_inact</code>, or <code>sp_expire</code> member of the <code>spwd</code> structure is <code>-1</code>, or if <code>sp_flag</code> is <code>0</code>, the corresponding <code>/etc/shadow</code> field is cleared.</p>				
RETURN VALUES	The <code>putspent()</code> function returns a non-zero value if an error was detected during its operation. Otherwise, it returns <code>0</code> .				
USAGE	Since this function is for internal use only, compatibility is not guaranteed. For this reason, its use is discouraged. If used at all, it should be used with <code>putpwent(3C)</code> to update the password file.

pututline(3C)

NAME	getutent, getutid, getutline, pututline, setutent, endutent, utmpname – user accounting database functions
SYNOPSIS	<pre>#include <utmp.h> struct utmp *getutent(void); struct utmp *getutid(const struct utmp *id); struct utmp *getutline(const struct utmp *line); struct utmp *pututline(const struct utmp *utmp); void setutent(void); void endutent(void); int utmpname(const char *file);</pre>
DESCRIPTION	<p>These functions provide access to the user accounting database, utmp. Entries in the database are described by the definitions and data structures in <utmp.h>.</p> <p>The utmp structure contains the following members:</p> <pre>char ut_user[8]; /* user login name */ char ut_id[4]; /* /sbin/inittab id (usually line #) */ char ut_line[12]; /* device name (console, lnxx) */ short ut_pid; /* process id */ short ut_type; /* type of entry */ struct exit_status ut_exit; /* exit status of a process */ /* marked as DEAD_PROCESS */ time_t ut_time; /* time entry was made */</pre> <p>The structure exit_status includes the following members:</p> <pre>short e_termination; /* termination status */ short e_exit; /* exit status */</pre>
getutent()	The getutent() function reads in the next entry from a utmp database. If the database is not already open, it opens it. If it reaches the end of the database, it fails.
getutid()	The getutid() function searches forward from the current point in the utmp database until it finds an entry with a ut_type matching id->ut_type if the type specified is RUN_LVL, BOOT_TIME, OLD_TIME, or NEW_TIME. If the type specified in id is INIT_PROCESS, LOGIN_PROCESS, USER_PROCESS, or DEAD_PROCESS, then getutid() will return a pointer to the first entry whose type is one of these four and whose ut_id member matches id->ut_id. If the end of database is reached without a match, it fails.
getutline()	The getutline() function searches forward from the current point in the utmp database until it finds an entry of the type LOGIN_PROCESS or ut_line string matching the line->ut_line string. If the end of database is reached without a match, it fails.

`pututline()` The `pututline()` function writes the supplied `utmp` structure into the `utmp` database. It uses `getutid()` to search forward for the proper place if it finds that it is not already at the proper place. It is expected that normally the user of `pututline()` will have searched for the proper entry using one of the these functions. If so, `pututline()` will not search. If `pututline()` does not find a matching slot for the new entry, it will add a new entry to the end of the database. It returns a pointer to the `utmp` structure. When called by a non-root user, `pututline()` invokes a `setuid()` root program to verify and write the entry, since the `utmp` database is normally writable only by root. In this event, the `ut_name` member must correspond to the actual user name associated with the process; the `ut_type` member must be either `USER_PROCESS` or `DEAD_PROCESS`; and the `ut_line` member must be a device special file and be writable by the user.

`setutent()` The `setutent()` function resets the input stream to the beginning. This reset should be done before each search for a new entry if it is desired that the entire database be examined.

`endutent()` The `endutent()` function closes the currently open database.

`utmpname()` The `utmpname()` function allows the user to change the name of the database file examined to another file. If the file does not exist, this will not be apparent until the first attempt to reference the file is made. The `utmpname()` function does not open the file but closes the old file if it is currently open and saves the new file name.

RETURN VALUES A null pointer is returned upon failure to read, whether for permissions or having reached the end of file, or upon failure to write. If the file name given is longer than 79 characters, `utmpname()` returns 0. Otherwise, it returns 1.

USAGE These functions use buffered standard I/O for input, but `pututline()` uses an unbuffered non-standard write to avoid race conditions between processes trying to modify the `utmp` and `wtmp` databases.

Applications should not access the `utmp` and `wtmp` databases directly, but should use these functions to ensure that these databases are maintained consistently. Using these functions, however, may cause applications to fail if user accounting data cannot be represented properly in the `utmp` structure (for example, on a system where PIDs can exceed 32767). Use the functions described on the `getutxent(3C)` manual page instead.

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
MT-Level	Unsafe

SEE ALSO `getutxent(3C)`, `ttyslot(3C)`, `utmpx(4)`, `attributes(5)`

pututline(3C)

NOTES | The most current entry is saved in a static structure. Multiple accesses require that it be copied before further accesses are made. On each call to either `getutid()` or `getutline()`, the function examines the static structure before performing more I/O. If the contents of the static structure match what it is searching for, it looks no further. For this reason, to use `getutline()` to search for multiple occurrences, it would be necessary to zero out the static area after each success, or `getutline()` would just return the same structure over and over again. There is one exception to the rule about emptying the structure before further reads are done. The implicit read done by `pututline()` (if it finds that it is not already at the correct place in the file) will not hurt the contents of the static structure returned by the `getutent()`, `getutid()` or `getutline()` functions, if the user has just modified those contents and passed the pointer back to `pututline()`.

NAME	getutxent, getutxid, getutxline, pututxline, setutxent, endutxent, utmpxname, getutmp, getutmpx, updwtmp, updwtmpx – user accounting database functions
SYNOPSIS	<pre>#include <utmpx.h> struct utmpx *getutxent (void); struct utmpx *getutxid (const struct utmpx *id); struct utmpx *getutxline (const struct utmpx *line); struct utmpx *pututxline (const struct utmpx *utmpx); void setutxent (void); void endutxent (void); int utmpxname (const char *file); void getutmp (struct utmpx *utmpx, struct utmp *utmp); void getutmpx (struct utmp *utmp, struct utmpx *utmpx); void updwtmp (char *wfile, struct utmp *utmp); void updwtmpx (char *wfile, struct utmpx *utmpx);</pre>
DESCRIPTION	<p>These functions provide access to the user accounting database, utmpx (see utmpx(4)). Entries in the database are described by the definitions and data structures in <utmpx.h>.</p> <p>The utmpx structure contains the following members:</p> <pre>char ut_user[32]; /* user login name */ char ut_id[4]; /* /etc/inittab id (usually line #) */ char ut_line[32]; /* device name (console, lnxx) */ pid_t ut_pid; /* process id */ short ut_type; /* type of entry */ struct exit_status ut_exit; /* exit status of a process */ /* marked as DEAD_PROCESS */ struct timeval ut_tv; /* time entry was made */ int ut_session; /* session ID, used for windowing */ short ut_syslen; /* significant length of ut_host */ /* including terminating null */ char ut_host[257]; /* host name, if remote */</pre> <p>The exit_status structure includes the following members:</p> <pre>short e_termination; /* termination status */ short e_exit; /* exit status */</pre> <p>getutxent () The getutxent () function reads in the next entry from a utmpx database. If the database is not already open, it opens it. If it reaches the end of the database, it fails.</p> <p>getutxid () The getutxid () function searches forward from the current point in the utmpx database until it finds an entry with a ut_type matching id->ut_type, if the type specified is RUN_LVL, BOOT_TIME, OLD_TIME, or NEW_TIME. If the type specified in</p>

pututxline(3C)

	<p><i>id</i> is INIT_PROCESS, LOGIN_PROCESS, USER_PROCESS, or DEAD_PROCESS, then <code>getutxid()</code> will return a pointer to the first entry whose type is one of these four and whose <code>ut_id</code> member matches <i>id</i>-><code>ut_id</code>. If the end of database is reached without a match, it fails.</p>
<code>getutxline()</code>	<p>The <code>getutxline()</code> function searches forward from the current point in the <code>utmpx</code> database until it finds an entry of the type LOGIN_PROCESS or USER_PROCESS which also has a <code>ut_line</code> string matching the <i>line</i>-><code>ut_line</code> string. If the end of the database is reached without a match, it fails.</p>
<code>pututxline()</code>	<p>The <code>pututxline()</code> function writes the supplied <code>utmpx</code> structure into the <code>utmpx</code> database. It uses <code>getutxid()</code> to search forward for the proper place if it finds that it is not already at the proper place. It is expected that normally the user of <code>pututxline()</code> will have searched for the proper entry using one of the <code>getutx()</code> routines. If so, <code>pututxline()</code> will not search. If <code>pututxline()</code> does not find a matching slot for the new entry, it will add a new entry to the end of the database. It returns a pointer to the <code>utmpx</code> structure. When called by a non-root user, <code>pututxline()</code> invokes a <code>setuid()</code> root program to verify and write the entry, since the <code>utmpx</code> database is normally writable only by root. In this event, the <code>ut_name</code> member must correspond to the actual user name associated with the process; the <code>ut_type</code> member must be either USER_PROCESS or DEAD_PROCESS; and the <code>ut_line</code> member must be a device special file and be writable by the user.</p>
<code>setutxent()</code>	<p>The <code>setutxent()</code> function resets the input stream to the beginning. This should be done before each search for a new entry if it is desired that the entire database be examined.</p>
<code>endutxent()</code>	<p>The <code>endutxent()</code> function closes the currently open database.</p>
<code>utmpxname()</code>	<p>The <code>utmpxname()</code> function allows the user to change the name of the database file examined from <code>/var/adm/utmpx</code> to any other file, most often <code>/var/adm/wtmpx</code>. If the file does not exist, this will not be apparent until the first attempt to reference the file is made. The <code>utmpxname()</code> function does not open the file, but closes the old file if it is currently open and saves the new file name. The new file name must end with the "x" character to allow the name of the corresponding <code>utmp</code> file to be easily obtainable.; otherwise, an error value of 0 is returned. The function returns 1 on success.</p>
<code>getutmp()</code>	<p>The <code>getutmp()</code> function copies the information stored in the members of the <code>utmpx</code> structure to the corresponding members of the <code>utmp</code> structure. If the information in any member of <code>utmpx</code> does not fit in the corresponding <code>utmp</code> member, the data is silently truncated. (See <code>getutent(3C)</code> for <code>utmp</code> structure)</p>
<code>getutmpx()</code>	<p>The <code>getutmpx()</code> function copies the information stored in the members of the <code>utmp</code> structure to the corresponding members of the <code>utmpx</code> structure. (See <code>getutent(3C)</code> for <code>utmp</code> structure)</p>
<code>updwtmp()</code>	<p>The <code>updwtmp()</code> function can be used in two ways.</p>

	<p>If <i>wfile</i> is <code>/var/adm/wtmp</code>, the <code>utmp</code> format record supplied by the caller is converted to a <code>utmpx</code> format record and the <code>/var/adm/wtmpx</code> file is updated (because the <code>/var/adm/wtmp</code> file no longer exists, operations on <code>wtmp</code> are converted to operations on <code>wtmpx</code> by the library functions).</p> <p>If <i>wfile</i> is a file other than <code>/var/adm/wtmp</code>, it is assumed to be an old file in <code>utmp</code> format and is updated directly with the <code>utmp</code> format record supplied by the caller.</p>
<code>updwtmpx()</code>	<p>The <code>updwtmpx()</code> function writes the contents of the <code>utmpx</code> structure pointed to by <i>utmpx</i> to the database.</p>
utmpx structure	<p>The values of the <code>e_termination</code> and <code>e_exit</code> members of the <code>ut_exit</code> structure are valid only for records of type <code>DEAD_PROCESS</code>. For <code>utmpx</code> entries created by <code>init(1M)</code>, these values are set according to the result of the <code>wait()</code> call that <code>init</code> performs on the process when the process exits. See the <code>wait(2)</code> manual page for the values <code>init</code> uses. Applications creating <code>utmpx</code> entries can set <code>ut_exit</code> values using the following code example:</p> <pre>u->ut_exit.e_termination = WTERMSIG(process->p_exit) u->ut_exit.e_exit = WEXITSTATUS(process->p_exit)</pre> <p>See <code>wstat(3XFN)</code> for descriptions of the <code>WTERMSIG</code> and <code>WEXITSTATUS</code> macros.</p> <p>The <code>ut_session</code> member is not acted upon by the operating system. It is used by applications interested in creating <code>utmpx</code> entries.</p> <p>For records of type <code>USER_PROCESS</code>, the <code>nonuser()</code> and <code>nonuserx()</code> macros use the value of the <code>ut_exit.e_exit</code> member to mark <code>utmpx</code> entries as real logins (as opposed to multiple <code>xterms</code> started by the same user on a window system). This allows the system utilities that display users to obtain an accurate indication of the number of actual users, while still permitting each <code>pty</code> to have a <code>utmpx</code> record (as most applications expect.). The <code>NONROOT_USER</code> macro defines the value that <code>login</code> places in the <code>ut_exit.e_exit</code> member.</p>
RETURN VALUES	<p>Upon successful completion, <code>getutxent()</code>, <code>getutxid()</code>, and <code>getutxline()</code> each return a pointer to a <code>utmpx</code> structure containing a copy of the requested entry in the user accounting database. Otherwise a null pointer is returned.</p> <p>The return value may point to a static area which is overwritten by a subsequent call to <code>getutxid()</code> or <code>getutxline()</code>.</p> <p>Upon successful completion, <code>pututxline()</code> returns a pointer to a <code>utmpx</code> structure containing a copy of the entry added to the user accounting database. Otherwise a null pointer is returned.</p> <p>The <code>endutxent()</code> and <code>setutxent()</code> functions return no value.</p> <p>A null pointer is returned upon failure to read, whether for permissions or having reached the end of file, or upon failure to write.</p>

pututxline(3C)

USAGE These functions use buffered standard I/O for input, but `pututxline()` uses an unbuffered write to avoid race conditions between processes trying to modify the `utmpx` and `wtmpx` files.

Applications should not access the `utmpx` and `wtmpx` databases directly, but should use these functions to ensure that these databases are maintained consistently.

FILES

<code>/var/adm/utmpx</code>	user access and accounting information
<code>/var/adm/wtmpx</code>	history of user access and accounting information

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
MT-Level	Unsafe

SEE ALSO `wait(2)`, `getutent(3C)`, `ttyslot(3C)`, `utmpx(4)`, `attributes(5)`, `wstat(3XFN)`

NOTES The most current entry is saved in a static structure. Multiple accesses require that it be copied before further accesses are made. On each call to either `getutxid()` or `getutxline()`, the routine examines the static structure before performing more I/O. If the contents of the static structure match what it is searching for, it looks no further. For this reason, to use `getutxline()` to search for multiple occurrences it would be necessary to zero out the static after each success, or `getutxline()` would just return the same structure over and over again. There is one exception to the rule about emptying the structure before further reads are done. The implicit read done by `pututxline()` (if it finds that it is not already at the correct place in the file) will not hurt the contents of the static structure returned by the `getutxent()`, `getutxid()`, or `getutxline()` routines, if the user has just modified those contents and passed the pointer back to `pututxline()`.

NAME	fputc, putc, putc_unlocked, putchar, putchar_unlocked, putw – put a byte on a stream
SYNOPSIS	<pre>#include <stdio.h> int fputc(int c, FILE *stream); int putc(int c, FILE *stream); int putc_unlocked(int c, FILE *stream); int putchar(int c); int putchar_unlocked(int c); int putw(int w, FILE *stream);</pre>
DESCRIPTION	<p>The <code>fputc()</code> function writes the byte specified by <code>c</code> (converted to an unsigned char) to the output stream pointed to by <code>stream</code>, at the position indicated by the associated file-position indicator for the stream (if defined), and advances the indicator appropriately. If the file cannot support positioning requests, or if the stream was opened with append mode, the byte is appended to the output stream.</p> <p>The <code>st_ctime</code> and <code>st_mtime</code> fields of the file will be marked for update between the successful execution of <code>fputc()</code> and the next successful completion of a call to <code>fflush(3C)</code> or <code>fclose(3C)</code> on the same stream or a call to <code>exit(3C)</code> or <code>abort(3C)</code>.</p> <p>The <code>putc()</code> routine behaves like <code>fputc()</code>, except that it is implemented as a macro. It runs faster than <code>fputc()</code>, but it takes up more space per invocation and its name cannot be passed as an argument to a function call.</p> <p>The call <code>putchar(c)</code> is equivalent to <code>putc(c, stdout)</code>. The <code>putchar()</code> routine is implemented as a macro.</p> <p>The <code>putc_unlocked()</code> and <code>putchar_unlocked()</code> routines are variants of <code>putc()</code> and <code>putchar()</code>, respectively, that do not lock the stream. It is the caller's responsibility to acquire the stream lock before calling these routines and releasing the lock afterwards; see <code>flockfile(3C)</code> and <code>stdio(3C)</code>. These routines are implemented as macros.</p> <p>The <code>putw()</code> function writes the word (that is, type <code>int</code>) <code>w</code> to the output <code>stream</code> (at the position at which the file offset, if defined, is pointing). The size of a word is the size of a type <code>int</code> and varies from machine to machine. The <code>putw()</code> function neither assumes nor causes special alignment in the file.</p> <p>The <code>st_ctime</code> and <code>st_mtime</code> fields of the file will be marked for update between the successful execution of <code>putw()</code> and the next successful completion of a call to <code>fflush(3C)</code> or <code>fclose(3C)</code> on the same stream or a call to <code>exit(3C)</code> or <code>abort(3C)</code>.</p>
RETURN VALUES	Upon successful completion, <code>fputc()</code> , <code>putc()</code> , <code>putc_unlocked()</code> , <code>putchar()</code> , and <code>putchar_unlocked()</code> return the value that was written. Otherwise, these functions return EOF, the error indicator for the stream is set, and <code>errno</code> is set to indicate the error.

putw(3C)

Upon successful completion, `putw()` returns 0. Otherwise, it returns a non-zero value, sets the error indicator for the associated *stream*, and sets `errno` to indicate the error.

An unsuccessful completion will occur, for example, if the file associated with *stream* is not open for writing or if the output file cannot grow.

ERRORS

The `fputc()`, `putc()`, `putc_unlocked()`, `putchar()`, `putchar_unlocked()`, and `putw()` functions will fail if either the *stream* is unbuffered or the *stream's* buffer needs to be flushed, and:

EAGAIN	The <code>O_NONBLOCK</code> flag is set for the file descriptor underlying <i>stream</i> and the process would be delayed in the write operation.
EBADF	The file descriptor underlying <i>stream</i> is not a valid file descriptor open for writing.
EFBIG	An attempt was made to write to a file that exceeds the maximum file size or the process' file size limit.
EFBIG	The file is a regular file and an attempt was made to write at or beyond the offset maximum.
EINTR	The write operation was terminated due to the receipt of a signal, and no data was transferred.
EIO	A physical I/O error has occurred, or the process is a member of a background process group attempting to write to its controlling terminal, <code>TOSTOP</code> is set, the process is neither ignoring nor blocking <code>SIGTTOU</code> and the process group of the process is orphaned. This error may also be returned under implementation-dependent conditions.
ENOSPC	There was no free space remaining on the device containing the file.
EPIPE	An attempt is made to write to a pipe or FIFO that is not open for reading by any process. A <code>SIGPIPE</code> signal will also be sent to the process.

The `fputc()`, `putc()`, `putc_unlocked()`, `putchar()`, `putchar_unlocked()`, and `putw()` functions may fail if:

ENOMEM	Insufficient storage space is available.
ENXIO	A request was made of a non-existent device, or the request was outside the capabilities of the device.

USAGE

Functions exist for the `putc()`, `putc_unlocked()`, `putchar()`, and `putchar_unlocked()` macros. To get the function form, the macro name must be undefined (for example, `#undef putc`).

When the macro forms are used, `putc()` and `putc_unlocked()` evaluate the *stream* argument more than once. In particular, `putc(c, *f++)`; does not work sensibly. The `fputc()` function should be used instead when evaluating the *stream* argument has side effects.

Because of possible differences in word length and byte ordering, files written using `putw()` are implementation-dependent, and possibly cannot be read using `getw(3C)` by a different application or by the same application running in a different environment.

The `putw()` function is inherently byte stream oriented and is not tenable in the context of either multibyte character streams or wide-character streams. Application programmers are encouraged to use one of the character-based output functions instead.

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
MT-Level	See NOTES below.

SEE ALSO `getrlimit(2)`, `ulimit(2)`, `write(2)`, `intro(3)`, `abort(3C)`, `exit(3C)`, `fclose(3C)`, `ferror(3C)`, `fflush(3C)`, `flockfile(3C)`, `fopen(3UCB)`, `printf(3C)`, `putc(3C)`, `puts(3C)`, `setbuf(3C)`, `stdio(3C)`, `attributes(5)`

NOTES The `fputc()`, `putc()`, `putchar()`, and `putw()` routines are MT-Safe in multithreaded applications. The `putc_unlocked()` and `putchar_unlocked()` routines are unsafe in multithreaded applications.

putwc(3C)

NAME	fputwc, putwc, putwchar – put wide-character code on a stream
SYNOPSIS	<pre>#include <stdio.h> #include <wchar.h> wint_t fputwc(wchar_t wc, FILE*stream); wint_t putwc(wchar_t wc, FILE*stream); #include <wchar.h> wint_t putwchar(wchar_t wc);</pre>
DESCRIPTION	<p>The <code>fputwc()</code> function writes the character corresponding to the wide-character code <code>wc</code> to the output stream pointed to by <code>stream</code>, at the position indicated by the associated file-position indicator for the stream (if defined), and advances the indicator appropriately. If the file cannot support positioning requests, or if the stream was opened with append mode, the character is appended to the output stream. If an error occurs while writing the character, the shift state of the output file is left in an undefined state.</p> <p>The <code>st_ctime</code> and <code>st_mtime</code> fields of the file will be marked for update between the successful execution of <code>fputwc()</code> and the next successful completion of a call to <code>fflush(3C)</code> or <code>fclose(3C)</code> on the same stream or a call to <code>exit(2)</code> or <code>abort(3C)</code>.</p> <p>The <code>putwc()</code> function is equivalent to <code>fputwc()</code>, except that it is implemented as a macro.</p> <p>The call <code>putwchar(wc)</code> is equivalent to <code>putwc(wc, stdout)</code>. The <code>putwchar()</code> routine is implemented as a macro.</p>
RETURN VALUES	Upon successful completion, <code>fputwc()</code> , <code>putwc()</code> , and <code>putwchar()</code> return <code>wc</code> . Otherwise, they return <code>WEOF</code> , the error indicator for the stream is set, and <code>errno</code> is set to indicate the error.
ERRORS	The <code>fputwc()</code> , <code>putwc()</code> , and <code>putwchar()</code> functions will fail if either the stream is unbuffered or data in the <code>stream</code> 's buffer needs to be written, and:
EAGAIN	The <code>O_NONBLOCK</code> flag is set for the file descriptor underlying <code>stream</code> and the process would be delayed in the write operation.
EBADF	The file descriptor underlying <code>stream</code> is not a valid file descriptor open for writing.
EFBIG	An attempt was made to write to a file that exceeds the maximum file size or the process's file size limit; or the file is a regular file and an attempt was made to write at or beyond the offset maximum associated with the corresponding stream.
EINTR	The write operation was terminated due to the receipt of a signal, and no data was transferred.
EIO	A physical I/O error has occurred, or the process is a member of a background process group attempting to write to its controlling

terminal, TOSTOP is set, the process is neither ignoring nor blocking SIGTTOU, and the process group of the process is orphaned.

ENOSPC There was no free space remaining on the device containing the file.

EPIPE An attempt is made to write to a pipe or FIFO that is not open for reading by any process. A SIGPIPE signal will also be sent to the process.

The `fputc()`, `putwc()`, and `putwchar()` functions may fail if:

ENOMEM Insufficient storage space is available.

ENXIO A request was made of a non-existent device, or the request was outside the capabilities of the device.

EILSEQ The wide-character code `wc` does not correspond to a valid character.

USAGE Functions exist for the `putwc()` and `putwchar()` macros. To get the function form, the macro name must be undefined (for example, `#undef putc`).

When the macro form is used, `putwc()` evaluates the *stream* argument more than once. In particular, `putwc(wc, *f++)` does not work sensibly. The `fputc()` function should be used instead when evaluating the *stream* argument has side effects.

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

putwchar(3C)

NAME	<code>fputc</code> , <code>putc</code> , <code>putwchar</code> – put wide-character code on a stream
SYNOPSIS	<pre>#include <stdio.h> #include <wchar.h> wint_t fputc(wchar_t <i>wc</i>, FILE*<i>stream</i>); wint_t putc(wchar_t <i>wc</i>, FILE*<i>stream</i>); #include <wchar.h> wint_t putwchar(wchar_t <i>wc</i>);</pre>
DESCRIPTION	<p>The <code>fputc()</code> function writes the character corresponding to the wide-character code <i>wc</i> to the output stream pointed to by <i>stream</i>, at the position indicated by the associated file-position indicator for the stream (if defined), and advances the indicator appropriately. If the file cannot support positioning requests, or if the stream was opened with append mode, the character is appended to the output stream. If an error occurs while writing the character, the shift state of the output file is left in an undefined state.</p> <p>The <code>st_ctime</code> and <code>st_mtime</code> fields of the file will be marked for update between the successful execution of <code>fputc()</code> and the next successful completion of a call to <code>fflush(3C)</code> or <code>fclose(3C)</code> on the same stream or a call to <code>exit(2)</code> or <code>abort(3C)</code>.</p> <p>The <code>putc()</code> function is equivalent to <code>fputc()</code>, except that it is implemented as a macro.</p> <p>The call <code>putwchar(<i>wc</i>)</code> is equivalent to <code>putc(<i>wc</i>, stdout)</code>. The <code>putwchar()</code> routine is implemented as a macro.</p>
RETURN VALUES	Upon successful completion, <code>fputc()</code> , <code>putc()</code> , and <code>putwchar()</code> return <i>wc</i> . Otherwise, they return <code>WEOF</code> , the error indicator for the stream is set, and <code>errno</code> is set to indicate the error.
ERRORS	The <code>fputc()</code> , <code>putc()</code> , and <code>putwchar()</code> functions will fail if either the stream is unbuffered or data in the <i>stream</i> 's buffer needs to be written, and:
EAGAIN	The <code>O_NONBLOCK</code> flag is set for the file descriptor underlying <i>stream</i> and the process would be delayed in the write operation.
EBADF	The file descriptor underlying <i>stream</i> is not a valid file descriptor open for writing.
EFBIG	An attempt was made to write to a file that exceeds the maximum file size or the process's file size limit; or the file is a regular file and an attempt was made to write at or beyond the offset maximum associated with the corresponding stream.
EINTR	The write operation was terminated due to the receipt of a signal, and no data was transferred.
EIO	A physical I/O error has occurred, or the process is a member of a background process group attempting to write to its controlling

terminal, TOSTOP is set, the process is neither ignoring nor blocking SIGTTOU, and the process group of the process is orphaned.

ENOSPC There was no free space remaining on the device containing the file.

EPIPE An attempt is made to write to a pipe or FIFO that is not open for reading by any process. A SIGPIPE signal will also be sent to the process.

The `fputc()`, `fputwc()`, and `putwchar()` functions may fail if:

ENOMEM Insufficient storage space is available.

ENXIO A request was made of a non-existent device, or the request was outside the capabilities of the device.

EILSEQ The wide-character code *wc* does not correspond to a valid character.

USAGE Functions exist for the `putwc()` and `putwchar()` macros. To get the function form, the macro name must be undefined (for example, `#undef putc`).

When the macro form is used, `putwc()` evaluates the *stream* argument more than once. In particular, `putwc(wc, *f++)` does not work sensibly. The `fputc()` function should be used instead when evaluating the *stream* argument has side effects.

putws(3C)

NAME putws – convert a string of Process Code characters to EUC characters

SYNOPSIS

```
#include <stdio.h>
#include <wchar.h>

int putws(wchar_t *s);
```

DESCRIPTION The putws() function converts the Process Code string (terminated by a (wchar_t) NULL) pointed to by s, to an Extended Unix Code (EUC) string followed by a NEWLINE character, and writes it to the standard output stream stdout. It does not write the terminal null character.

RETURN VALUES The putws() function returns the number of Process Code characters transformed and written. It returns EOF if it attempts to write to a file that has not been opened for writing.

ATTRIBUTES See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
MT-Level	MT-Safe

SEE ALSO ferror(3C), fopen(3C), fread(3C), getws(3C), printf(3C), putwc(3C), attributes(5)

NAME	econvert, fconvert, gconvert, seconvert, sfconvert, sgconvert, qeconvert, qfconvert, qgconvert – output conversion
SYNOPSIS	<pre>#include <floatingpoint.h> char *econvert(double value, int ndigit, int *decpt, int *sign, char *buf) ; char *fconvert(double value, int ndigit, int *decpt, int *sign, char *buf) ; char *gconvert(double value, int ndigit, int trailing, char *buf) ; char *seconvert(single *value, int ndigit, int *decpt, int *sign, char *buf) ; char *sfconvert(single *value, int ndigit, int *decpt, int *sign, char *buf) ; char *sgconvert(single *value, int ndigit, int trailing, char *buf) ; char *qeconvert(quadruple *value, int ndigit, int *decpt, int *sign, char *buf) ; char *qfconvert(quadruple *value, int ndigit, int *decpt, int *sign, char *buf) ; char *qgconvert(quadruple *value, int ndigit, int trailing, char *buf) ;</pre>
DESCRIPTION	<p>The <code>econvert()</code> function converts the <i>value</i> to a null-terminated string of <i>ndigit</i> ASCII digits in <i>buf</i> and returns a pointer to <i>buf</i>. <i>buf</i> should contain at least <i>ndigit</i>+1 characters. The position of the decimal point relative to the beginning of the string is stored indirectly through <i>decpt</i>. Thus <i>buf</i> == "314" and <i>*decpt</i> == 1 corresponds to the numerical value 3.14, while <i>buf</i> == "314" and <i>*decpt</i> == -1 corresponds to the numerical value .0314. If the sign of the result is negative, the word pointed to by <i>sign</i> is nonzero; otherwise it is zero. The least significant digit is rounded.</p> <p>The <code>fconvert()</code> function works much like <code>econvert()</code>, except that the correct digit has been rounded as if for <code>printf(%w.nf)</code> output with $n=ndigit$ digits to the right of the decimal point. <i>ndigit</i> can be negative to indicate rounding to the left of the decimal point. The return value is a pointer to <i>buf</i>. <i>buf</i> should contain at least $310+max(0,ndigit)$ characters to accommodate any double-precision <i>value</i>.</p> <p>The <code>gconvert()</code> function converts the <i>value</i> to a null-terminated ASCII string in <i>buf</i> and returns a pointer to <i>buf</i>. It produces <i>ndigit</i> significant digits in fixed-decimal format, like <code>printf(%w.nf)</code>, if possible, and otherwise in floating-decimal format, like <code>printf(%w.ne)</code>; in either case <i>buf</i> is ready for printing, with sign and exponent. The result corresponds to that obtained by</p> <pre>(void) printf(buf, ``%w.ng'', value) ;</pre> <p>If <i>trailing</i> = 0, trailing zeros and a trailing point are suppressed, as in <code>printf(%g)</code>. If <i>trailing</i> != 0, trailing zeros and a trailing point are retained, as in <code>printf(%#g)</code>.</p>

qeconvert(3C)

The `seconvert()`, `sfconvert()`, and `sgconvert()` functions are single-precision versions of these functions, and are more efficient than the corresponding double-precision versions. A pointer rather than the value itself is passed to avoid C's usual conversion of single-precision arguments to double.

The `qeconvert()`, `qfconvert()`, and `qgconvert()` functions are quadruple-precision versions of these functions. The `qfconvert()` function can overflow the `decimal_record` field `ds` if `value` is too large. In that case, `buf[0]` is set to zero.

The `ecvt()`, `fcvt()` and `gcvt()` functions are versions of `econvert()`, `fconvert()`, and `gconvert()`, respectively, that are documented on the `ecvt(3C)` manual page. They constitute the default implementation of these functions and conform to the X/Open CAE Specification, System Interfaces and Headers, Issue 4, Version 2.

USAGE IEEE Infinities and NaNs are treated similarly by these functions. "NaN" is returned for NaN, and "Inf" or "Infinity" for Infinity. The longer form is produced when `ndigit` \geq 8.

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

NAME	qsort – quick sort
SYNOPSIS	<pre>#include <stdlib.h> void qsort(void *base, size_t nel, size_t width, int (*compar)(const void *, const void *));</pre>
DESCRIPTION	<p>The <code>qsort()</code> function is an implementation of the quick-sort algorithm. It sorts a table of data in place. The contents of the table are sorted in ascending order according to the user-supplied comparison function.</p> <p>The <i>base</i> argument points to the element at the base of the table. The <i>nel</i> argument is the number of elements in the table. The <i>width</i> argument specifies the size of each element in bytes. The <i>compar</i> argument is the name of the comparison function, which is called with two arguments that point to the elements being compared.</p> <p>The function must return an integer less than, equal to, or greater than zero to indicate if the first argument is to be considered less than, equal to, or greater than the second argument.</p> <p>The contents of the table are sorted in ascending order according to the user supplied comparison function.</p>
EXAMPLES	<p>EXAMPLE 1 Program sorts.</p> <p>The following program sorts a simple array:</p> <pre>#include <stdlib.h> #include <stdio.h> static int intcompare(const void *p1, const void *p2) { int i = *((int *)p1); int j = *((int *)p2); if (i > j) return (1); if (i < j) return (-1); return (0); } int main() { int i; int a[10] = { 9, 8, 7, 6, 5, 4, 3, 2, 1, 0 }; size_t nelems = sizeof (a) / sizeof (int); qsort((void *)a, nelems, sizeof (int), intcompare); for (i = 0; i < nelems; i++) { (void) printf("%d ", a[i]); } }</pre>

qsort(3C)

EXAMPLE 1 Program sorts. *(Continued)*

```
(void) printf("\n");  
return (0);  
}
```

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
MT-Level	MT-Safe

SEE ALSO `sort(1)`, `bsearch(3C)`, `lsearch(3C)`, `string(3C)`, `attributes(5)`

NOTES The comparison function need not compare every byte, so arbitrary data may be contained in the elements in addition to the values being compared.

The relative order in the output of two items that compare as equal is unpredictable.

NAME	floating_to_decimal, single_to_decimal, double_to_decimal, extended_to_decimal, quadruple_to_decimal – convert floating-point value to decimal record
SYNOPSIS	<pre>#include <floatingpoint.h> void single_to_decimal(single *px, decimal_mode *pm, decimal_record *pd, fp_exception_field_type *ps); void double_to_decimal(double *px, decimal_mode *pm, decimal_record *pd, fp_exception_field_type *ps); void extended_to_decimal(extended *px, decimal_mode *pm, decimal_record *pd, fp_exception_field_type *ps); void quadruple_to_decimal(quadruple *px, decimal_mode *pm, decimal_record *pd, fp_exception_field_type *ps);</pre>
DESCRIPTION	<p>The <code>floating_to_decimal()</code> functions convert the floating-point value at <code>*px</code> into a decimal record at <code>*pd</code>, observing the modes specified in <code>*pm</code> and setting exceptions in <code>*ps</code>. If there are no IEEE exceptions, <code>*ps</code> will be zero.</p> <p>If <code>*px</code> is zero, infinity, or NaN, then only <code>pd->sign</code> and <code>pd->fpclass</code> are set. Otherwise <code>pd->exponent</code> and <code>pd->ds</code> are also set so that</p> <p>$(\text{sig}) * (\text{pd->ds}) * 10^{(\text{pd->exponent})}$ is a correctly rounded approximation to <code>*px</code>, where <code>sig</code> is +1 or -1, depending upon whether <code>pd->sign</code> is 0 or -1. <code>pd->ds</code> has at least one and no more than <code>DECIMAL_STRING_LENGTH-1</code> significant digits because one character is used to terminate the string with a NULL.</p> <p><code>pd->ds</code> is correctly rounded according to the IEEE rounding modes in <code>pm->rd</code>. <code>*ps</code> has <code>fp_inexact</code> set if the result was inexact, and has <code>fp_overflow</code> set if the string result does not fit in <code>pd->ds</code> because of the limitation <code>DECIMAL_STRING_LENGTH</code>.</p> <p>If <code>pm->df == floating_form</code>, then <code>pd->ds</code> always contains <code>pm->ndigits</code> significant digits. Thus if <code>*px == 12.34</code> and <code>pm->ndigits == 8</code>, then <code>pd->ds</code> will contain 12340000 and <code>pd->exponent</code> will contain -6.</p> <p>If <code>pm->df == fixed_form</code> and <code>pm->ndigits >= 0</code>, then <code>pd->ds</code> always contains <code>pm->ndigits</code> after the point and as many digits as necessary before the point. Since the latter is not known in advance, the total number of digits required is returned in <code>pd->ndigits</code>; if that number <code>>= DECIMAL_STRING_LENGTH</code>, then <code>ds</code> is undefined. <code>pd->exponent</code> always gets <code>-pm->ndigits</code>. Thus if <code>*px == 12.34</code> and <code>pm->ndigits == 1</code>, then <code>pd->ds</code> gets 123, <code>pd->exponent</code> gets -1, and <code>pd->ndigits</code> gets 3.</p> <p>If <code>pm->df == fixed_form</code> and <code>pm->ndigits < 0</code>, then <code>pd->ds</code> always contains <code>-pm->ndigits</code> trailing zeros; in other words, rounding occurs <code>-pm->ndigits</code> to the left of the decimal point, but the digits rounded away are retained as zeros. The total number of digits required is in <code>pd->ndigits</code>. <code>pd->exponent</code> always gets 0. Thus if <code>*px == 12.34</code> and <code>pm->ndigits == -1</code>, then <code>pd->ds</code> gets 10, <code>pd->exponent</code> gets 0, and <code>pd->ndigits</code> gets 2.</p> <p><code>pd->more</code> is not used.</p>

quadruple_to_decimal(3C)

econvert(3C), fconvert(3C), gconvert(3C), printf(3C), and sprintf(3C) all use `double_to_decimal()`.

rand(3C)

NAME	rand, srand, rand_r – simple random-number generator				
SYNOPSIS	<pre>#include <stdlib.h> int rand(void); void srand(unsigned int seed); int rand_r(unsigned int *seed);</pre>				
DESCRIPTION	<p>The <code>rand()</code> function uses a multiplicative congruential random-number generator with period 2^{32} that returns successive pseudo-random numbers in the range of 0 to <code>RAND_MAX</code> (defined in <code><stdlib.h></code>).</p> <p>The <code>srand()</code> function uses the argument <i>seed</i> as a seed for a new sequence of pseudo-random numbers to be returned by subsequent calls to <code>rand()</code>. If <code>srand()</code> is then called with the same <i>seed</i> value, the sequence of pseudo-random numbers will be repeated. If <code>rand()</code> is called before any calls to <code>srand()</code> have been made, the same sequence will be generated as when <code>srand()</code> is first called with a <i>seed</i> value of 1.</p> <p>The <code>rand_r()</code> function has the same functionality as <code>rand()</code> except that a pointer to a seed <i>seed</i> must be supplied by the caller. The seed to be supplied is not the same seed as in <code>srand()</code>.</p>				
USAGE	<p>The spectral properties of <code>rand()</code> are limited. The <code>drand48(3C)</code> function provides a better, more elaborate random-number generator.</p> <p>The <code>rand()</code> is unsafe in multithreaded applications. The <code>rand_r()</code> function is MT-Safe, and should be used instead. The <code>srand()</code> function is unsafe in multithreaded applications.</p> <p>When compiling multithreaded applications, the <code>_REENTRANT</code> flag must be defined on the compile line. This flag should only be used in multithreaded applications.</p>				
ATTRIBUTES	See <code>attributes(5)</code> for descriptions of the following attributes:				
	<table border="1"><thead><tr><th>ATTRIBUTE TYPE</th><th>ATTRIBUTE VALUE</th></tr></thead><tbody><tr><td>MT-Level</td><td>See <code>USAGE</code> above.</td></tr></tbody></table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	MT-Level	See <code>USAGE</code> above.

NAME	rand, srand – simple random number generator
SYNOPSIS	<pre><i>/usr/ucb/cc</i> [<i>flag ...</i>] <i>file ...</i> int rand() int srand(<i>seed</i>); unsigned <i>seed</i>;</pre>
DESCRIPTION	<p>rand() uses a multiplicative congruential random number generator with period 2^{32} to return successive pseudo-random numbers in the range from 0 to "$2^{31} - 1$."</p> <p>srand() can be called at any time to reset the random-number generator to a random starting point. The generator is initially seeded with a value of 1.</p>
SEE ALSO	drand48(3C), rand(3C), random(3C)
NOTES	<p>Use of these interfaces should be restricted to only applications written on BSD platforms. Use of these interfaces with any of the system libraries or in multi-thread applications is unsupported.</p> <p>The spectral properties of rand() leave a great deal to be desired. drand48(3C) and random(3C) provide much better, though more elaborate, random-number generators.</p> <p>The low bits of the numbers generated are not very random; use the middle bits. In particular the lowest bit alternates between 0 and 1.</p>

random(3C)

NAME	random, srandom, initstate, setstate – pseudorandom number functions
SYNOPSIS	<pre>#include <stdlib.h> long random(void); void srandom(unsigned int seed); char *initstate(unsigned int seed, char *state, size_t size); char *setstate(const char *state);</pre>
DESCRIPTION	<p>The <code>random()</code> function uses a nonlinear additive feedback random-number generator employing a default state array size of 31 long integers to return successive pseudo-random numbers in the range from 0 to $2^{31}-1$. The period of this random-number generator is approximately $16 \times (2^{31}-1)$. The size of the state array determines the period of the random-number generator. Increasing the state array size increases the period.</p> <p>The <code>srandom()</code> function initializes the current state array using the value of <i>seed</i>.</p> <p>The <code>random()</code> and <code>srandom()</code> functions have (almost) the same calling sequence and initialization properties as <code>rand()</code> and <code>srand()</code> (see <code>rand(3C)</code>). The difference is that <code>rand(3C)</code> produces a much less random sequence—in fact, the low dozen bits generated by <code>rand</code> go through a cyclic pattern. All the bits generated by <code>random()</code> are usable.</p> <p>The algorithm from <code>rand()</code> is used by <code>srandom()</code> to generate the 31 state integers. Because of this, different <code>srandom()</code> seeds often produce, within an offset, the same sequence of low order bits from <code>random()</code>. If low order bits are used directly, <code>random()</code> should be initialized with <code>setstate()</code> using high quality random values.</p> <p>Unlike <code>srand()</code>, <code>srandom()</code> does not return the old seed because the amount of state information used is much more than a single word. Two other routines are provided to deal with restarting/changing random number generators. With 256 bytes of state information, the period of the random-number generator is greater than 2^{69}, which should be sufficient for most purposes.</p> <p>Like <code>rand(3C)</code>, <code>random()</code> produces by default a sequence of numbers that can be duplicated by calling <code>srandom()</code> with 1 as the seed.</p> <p>The <code>initstate()</code> and <code>setstate()</code> functions handle restarting and changing random-number generators. The <code>initstate()</code> function allows a state array, pointed to by the <i>state</i> argument, to be initialized for future use. The <i>size</i> argument, which specifies the size in bytes of the state array, is used by <code>initstate()</code> to decide what type of random-number generator to use; the larger the state array, the more random the numbers. Values for the amount of state information are 8, 32, 64, 128, and 256 bytes. Other values greater than 8 bytes are rounded down to the nearest one of these values. For values smaller than 8, <code>random()</code> uses a simple linear congruential random number generator. The <i>seed</i> argument specifies a starting point for the random-number sequence and provides for restarting at the same point. The <code>initstate()</code> function returns a pointer to the previous state information array.</p>

If `initstate()` has not been called, then `random()` behaves as though `initstate()` had been called with `seed = 1` and `size = 128`.

If `initstate()` is called with `size < 8`, then `random()` uses a simple linear congruential random number generator.

Once a state has been initialized, `setstate()` allows switching between state arrays. The array defined by the `state` argument is used for further random-number generation until `initstate()` is called or `setstate()` is called again. The `setstate()` function returns a pointer to the previous state array.

RETURN VALUES

The `random()` function returns the generated pseudo-random number.

The `srandom()` function returns no value.

Upon successful completion, `initstate()` and `setstate()` return a pointer to the previous state array. Otherwise, a null pointer is returned.

ERRORS

No errors are defined.

USAGE

After initialization, a state array can be restarted at a different point in one of two ways:

- The `initstate()` function can be used, with the desired seed, state array, and size of the array.
- The `setstate()` function, with the desired state, can be used, followed by `srandom()` with the desired seed. The advantage of using both of these functions is that the size of the state array does not have to be saved once it is initialized.

EXAMPLES

EXAMPLE 1 Initialize an array.

The following example demonstrates the use of `initstate()` to initialize an array. It also demonstrates how to initialize an array and pass it to `setstate()`.

```
# include <stdlib.h>
static unsigned int state0[32];
static unsigned int state1[32] = {
    3,
    0x9a319039, 0x32d9c024, 0x9b663182, 0x5da1f342,
    0x7449e56b, 0xeb1dbb0, 0xab5c5918, 0x946554fd,
    0x8c2e680f, 0xeb3d799f, 0xb11ee0b7, 0x2d436b86,
    0xda672e2a, 0x1588ca88, 0xe369735d, 0x904f35f7,
    0xd7158fd6, 0x6fa6f051, 0x616e6b96, 0xac94efdc,
    0xde3b81e0, 0xdf0a6fb5, 0xf103bc02, 0x48f340fb,
    0x36413f93, 0xc622c298, 0xf5a42ab8, 0x8a88d77b,
    0xf5ad9d0e, 0x8999220b, 0x27fb47b9
};
main() {
    unsigned seed;
    int n;
    seed = 1;
    n = 128;
    (void)initstate(seed, (char *)state0, n);
    printf("random() = %d0\
```

random(3C)

EXAMPLE 1 Initialize an array. (Continued)

```
" , random());
    (void) setstate((char *)state1);
    printf("random() = %d\n", random());
}
```

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
MT-Level	See NOTES below.

SEE ALSO `drand48(3C)`, `rand(3C)`, `attributes(5)`

NOTES The `random()` and `srandom()` functions are unsafe in multithreaded applications.

Use of these functions in multithreaded applications is unsupported.

For `initstate()` and `setstate()`, the *state* argument must be aligned on an `int` boundary.

Newer and better performing random number generators such as `addrans()` and `lcrans()` are available with the SUNWsprow package.

NAME	rand, srand, rand_r – simple random-number generator				
SYNOPSIS	<pre>#include <stdlib.h> int rand(void); void srand(unsigned int seed); int rand_r(unsigned int *seed);</pre>

rctlblk_get_enforced_value(3C)

NAME	rctlblk_set_value, rctlblk_get_firing_time, rctlblk_get_global_action, rctlblk_get_global_flags, rctlblk_get_local_action, rctlblk_get_local_flags, rctlblk_get_privilege, rctlblk_get_recipient_pid, rctlblk_get_value, rctlblk_get_enforced_value, rctlblk_set_local_action, rctlblk_set_local_flags, rctlblk_set_privilege, rctlblk_size – manipulate resource control blocks
SYNOPSIS	<pre>#include <rctl.h> hrtime_t rctlblk_get_firing_time(rctlblk_t *rblk); int rctlblk_get_global_action(rctlblk_t *rblk); int rctlblk_get_global_flags(rctlblk_t *rblk); int rctlblk_get_local_action(rctlblk_t *rblk, int *signalp); int rctlblk_get_local_flags(rctlblk_t *rblk); rctl_priv_t rctlblk_get_privilege(rctlblk_t *rblk); id_t rctlblk_get_recipient_pid(rctlblk_t *rblk); rctl_qty_t rctlblk_get_value(rctlblk_t *rblk); rctl_qty_t rctlblk_get_enforced_value(rctlblk_t *rblk); void rctlblk_set_local_action(rctlblk_t *rblk, rctl_action_t action, int signal); void rctlblk_set_local_flags(rctlblk_t *rblk, int flags); void rctlblk_set_privilege(rctlblk_t *rblk, rctl_priv_t privilege); void rctlblk_set_value(rctlblk_t *rblk, rctl_qty_t value); size_t rctlblk_size(void);</pre>
DESCRIPTION	<p>The resource control block routines allow the establishment or retrieval of values from a resource control block used to transfer information using the <code>getrctl(2)</code> and <code>setrctl(2)</code> functions. Each of the routines accesses or sets the resource control block member corresponding to its name. Certain of these members are read-only and do not possess set routines.</p> <p>The firing time of a resource control block is 0 if the resource control action-value has not been exceeded for its lifetime on the process. Otherwise the firing time is the value of <code>gethrtime(3C)</code> at the moment the action on the resource control value was taken.</p> <p>The global actions and flags are the action and flags set by <code>rctladm(1M)</code>. These values cannot be set with <code>setrctl()</code>. Valid global actions are listed in the table below. Global flags are generally a published property of the control and are not modifiable.</p> <p>RCTL_GLOBAL_DENY_ALWAYS The action taken when a control value is exceeded on this control will always include denial of the resource.</p>

RCTL_GLOBAL_DENY_NEVER

The action taken when a control value is exceeded on this control will always exclude denial of the resource; the resource will always be granted, although other actions can also be taken.

RCTL_GLOBAL_CPU_TIME

The valid signals available as local actions include the SIGXCPU signal.

RCTL_GLOBAL_FILE_SIZE

The valid signals available as local actions include the SIGXFSZ signal.

RCTL_GLOBAL_INFINITE

This resource control supports the concept of an unlimited value; generally true only of accumulation-oriented resources, such as CPU time.

RCTL_GLOBAL_LOWERABLE

Non-privileged callers are able to lower the value of privileged resource control values on this control.

RCTL_GLOBAL_NOACTION

No global action will be taken when a resource control value is exceeded on this control.

RCTL_GLOBAL_NOBASIC

No values with the RCPRIV_BASIC privilege are permitted on this control.

RCTL_GLOBAL_NOLOCALACTION

No local actions are permitted on this control.

RCTL_GLOBAL_SYSLOG

A standard message will be logged by the `syslog()` facility when any resource control value on a sequence associated with this control is exceeded.

RCTL_GLOBAL_UNOBSERVABLE

The resource control (generally on a task- or project-related control) does not support observational control values. An RCPRIV_BASIC privileged control value placed by a process on the task or process will generate an action only if the value is exceeded by that process.

The local action and flags are those on the current resource control value represented by this resource control block. Valid actions and flags are listed in the table below. In the case of **RCTL_LOCAL_SIGNAL**, the second argument to `rctlblk_set_local_action()` contains the signal to be sent. Similarly, the signal to be sent is copied into the integer location specified by the second argument to `rctlblk_get_local_action()`. A restricted set of signals is made available for normal use by the resource control facility: SIGBART, SIGXRES, SIGHUP, SIGSTOP, SIGTERM, and SIGKILL. Other signals are permitted due to global properities of a specific control. Calls to `setrctl()` with illegal signals will fail.

RCTL_LOCAL_DENY

When this resource control value is encountered, the request for the resource will be denied. Set on all values if **RCTL_GLOBAL_DENY_ALWAYS** is set for this control; cleared on all values if **RCTL_GLOBAL_DENY_NEVER** is set for this control.

rctlblk_get_enforced_value(3C)

RCTL_LOCAL_MAXIMAL

This resource control value represents a request for the maximum amount of resource for this control. If RCTL_GLOBAL_INFINITE is set for this resource control, RCTL_LOCAL_MAXIMAL indicates an unlimited resource control value, one that will never be exceeded.

RCTL_LOCAL_NOACTION

No local action will be taken when this resource control value is exceeded.

RCTL_LOCAL_SIGNAL

The specified signal, sent by rctlblk_set_local_action(), will be sent to the process that placed this resource control value in the value sequence.

The rctlblk_get_recipient_pid() function returns the value of the process ID that placed the resource control value. This ID is set by the kernel by a caller invoking setrctl().

The rctlblk_get_privilege() function returns the privilege of the resource control block. Valid privileges are RCPRIV_BASIC, RCPRIV_PRIVILEGED, and RCPRIV_SYSTEM. System resource controls are read-only. Privileged resource controls require superuser privilege to write, unless the RCTL_GLOBAL_LOWERABLE global flag is set, in which case unprivileged applications can lower the value of a privileged control.

The rctlblk_get_value() and rctlblk_set_value() functions return or establish the enforced value associated with the resource control. In cases where the process, task, or project associated with the control possesses fewer capabilities than allowable by the current value, the value returned by rctlblk_get_enforced_value() will differ from that returned by rctlblk_get_value(). This capability difference arises with processes using an address space model smaller than the maximum address space model supported by the system.

The rctlblk_size() function returns the size of a resource control block for use in memory allocation. The rctlblk_t * type is an opaque pointer whose size is not connected with that of the resource control block itself. Use of rctlblk_size() is illustrated in the example below.

RETURN VALUES The various set routines have no return values. Incorrectly composed resource control blocks will generate errors when used with setrctl(2) or getrctl(2).

ERRORS No error values are returned. Incorrectly constructed resource control blocks will be rejected by the system calls.

EXAMPLES **EXAMPLE 1** Display the contents of a fetched resource control block.

The following example displays the contents of a fetched resource control block.

```
#include <rctl.h>
#include <stdio.h>
#include <stdlib.h>
```

These values cannot be set with <code>setrctl()</code>. Valid global actions are listed in the table below. Global flags are generally a published property of the control and are not modifiable.</p> <p>RCTL_GLOBAL_DENY_ALWAYS The action taken when a control value is exceeded on this control will always include denial of the resource.</p>

RCTL_GLOBAL_DENY_NEVER

The action taken when a control value is exceeded on this control will always exclude denial of the resource; the resource will always be granted, although other actions can also be taken.

RCTL_GLOBAL_CPU_TIME

The valid signals available as local actions include the SIGXCPU signal.

RCTL_GLOBAL_FILE_SIZE

The valid signals available as local actions include the SIGXFSZ signal.

RCTL_GLOBAL_INFINITE

This resource control supports the concept of an unlimited value; generally true only of accumulation-oriented resources, such as CPU time.

RCTL_GLOBAL_LOWERABLE

Non-privileged callers are able to lower the value of privileged resource control values on this control.

RCTL_GLOBAL_NOACTION

No global action will be taken when a resource control value is exceeded on this control.

RCTL_GLOBAL_NOBASIC

No values with the RCPRIV_BASIC privilege are permitted on this control.

RCTL_GLOBAL_NOLOCALACTION

No local actions are permitted on this control.

RCTL_GLOBAL_SYSLOG

A standard message will be logged by the `syslog()` facility when any resource control value on a sequence associated with this control is exceeded.

RCTL_GLOBAL_UNOBSERVABLE

The resource control (generally on a task- or project-related control) does not support observational control values. An RCPRIV_BASIC privileged control value placed by a process on the task or process will generate an action only if the value is exceeded by that process.

The local action and flags are those on the current resource control value represented by this resource control block. Valid actions and flags are listed in the table below. In the case of **RCTL_LOCAL_SIGNAL**, the second argument to `rctlblk_set_local_action()` contains the signal to be sent. Similarly, the signal to be sent is copied into the integer location specified by the second argument to `rctlblk_get_local_action()`. A restricted set of signals is made available for normal use by the resource control facility: SIGBART, SIGXRES, SIGHUP, SIGSTOP, SIGTERM, and SIGKILL. Other signals are permitted due to global properities of a specific control. Calls to `setrctl()` with illegal signals will fail.

RCTL_LOCAL_DENY

When this resource control value is encountered, the request for the resource will be denied. Set on all values if **RCTL_GLOBAL_DENY_ALWAYS** is set for this control; cleared on all values if **RCTL_GLOBAL_DENY_NEVER** is set for this control.

rctlblk_get_firing_time(3C)

RCTL_LOCAL_MAXIMAL

This resource control value represents a request for the maximum amount of resource for this control. If RCTL_GLOBAL_INFINITE is set for this resource control, RCTL_LOCAL_MAXIMAL indicates an unlimited resource control value, one that will never be exceeded.

RCTL_LOCAL_NOACTION

No local action will be taken when this resource control value is exceeded.

RCTL_LOCAL_SIGNAL

The specified signal, sent by `rctlblk_set_local_action()`, will be sent to the process that placed this resource control value in the value sequence.

The `rctlblk_get_recipient_pid()` function returns the value of the process ID that placed the resource control value. This ID is set by the kernel by a caller invoking `setrctl()`.

The `rctlblk_get_privilege()` function returns the privilege of the resource control block. Valid privileges are RCPRIV_BASIC, RCPRIV_PRIVILEGED, and RCPRIV_SYSTEM. System resource controls are read-only. Privileged resource controls require superuser privilege to write, unless the RCTL_GLOBAL_LOWERABLE global flag is set, in which case unprivileged applications can lower the value of a privileged control.

The `rctlblk_get_value()` and `rctlblk_set_value()` functions return or establish the enforced value associated with the resource control. In cases where the process, task, or project associated with the control possesses fewer capabilities than allowable by the current value, the value returned by `rctlblk_get_enforced_value()` will differ from that returned by `rctlblk_get_value()`. This capability difference arises with processes using an address space model smaller than the maximum address space model supported by the system.

The `rctlblk_size()` function returns the size of a resource control block for use in memory allocation. The `rctlblk_t *` type is an opaque pointer whose size is not connected with that of the resource control block itself. Use of `rctlblk_size()` is illustrated in the example below.

RETURN VALUES The various set routines have no return values. Incorrectly composed resource control blocks will generate errors when used with `setrctl(2)` or `getrctl(2)`.

ERRORS No error values are returned. Incorrectly constructed resource control blocks will be rejected by the system calls.

EXAMPLES **EXAMPLE 1** Display the contents of a fetched resource control block.

The following example displays the contents of a fetched resource control block.

```
#include <rctl.h>
#include <stdio.h>
#include <stdlib.h>
```

EXAMPLE 1 Display the contents of a fetched resource control block. (Continued)

```

rctlblk_t *rblk;
int rsignal;

SYNOPSIS	<pre>#include <rctl.h> hrtime_t rctlblk_get_firing_time(rctlblk_t *rblk); int rctlblk_get_global_action(rctlblk_t *rblk); int rctlblk_get_global_flags(rctlblk_t *rblk); int rctlblk_get_local_action(rctlblk_t *rblk, int *signalp); int rctlblk_get_local_flags(rctlblk_t *rblk); rctl_priv_t rctlblk_get_privilege(rctlblk_t *rblk); id_t rctlblk_get_recipient_pid(rctlblk_t *rblk); rctl_qty_t rctlblk_get_value(rctlblk_t *rblk); rctl_qty_t rctlblk_get_enforced_value(rctlblk_t *rblk); void rctlblk_set_local_action(rctlblk_t *rblk, rctl_action_t action, int signal); void rctlblk_set_local_flags(rctlblk_t *rblk, int flags); void rctlblk_set_privilege(rctlblk_t *rblk, rctl_priv_t privilege); void rctlblk_set_value(rctlblk_t *rblk, rctl_qty_t value); size_t rctlblk_size(void);</pre>
DESCRIPTION	<p>The resource control block routines allow the establishment or retrieval of values from a resource control block used to transfer information using the <code>getrctl(2)</code> and <code>setrctl(2)</code> functions. Each of the routines accesses or sets the resource control block member corresponding to its name. Certain of these members are read-only and do not possess set routines.</p> <p>The firing time of a resource control block is 0 if the resource control action-value has not been exceeded for its lifetime on the process. Otherwise the firing time is the value of <code>gethrtime(3C)</code> at the moment the action on the resource control value was taken.</p> <p>The global actions and flags are the action and flags set by <code>rctladm(1M)</code>. These values cannot be set with <code>setrctl()</code>. Valid global actions are listed in the table below. Global flags are generally a published property of the control and are not modifiable.</p> <p>RCTL_GLOBAL_DENY_ALWAYS The action taken when a control value is exceeded on this control will always include denial of the resource.</p>

RCTL_GLOBAL_DENY_NEVER

The action taken when a control value is exceeded on this control will always exclude denial of the resource; the resource will always be granted, although other actions can also be taken.

RCTL_GLOBAL_CPU_TIME

The valid signals available as local actions include the SIGXCPU signal.

RCTL_GLOBAL_FILE_SIZE

The valid signals available as local actions include the SIGXFSZ signal.

RCTL_GLOBAL_INFINITE

This resource control supports the concept of an unlimited value; generally true only of accumulation-oriented resources, such as CPU time.

RCTL_GLOBAL_LOWERABLE

Non-privileged callers are able to lower the value of privileged resource control values on this control.

RCTL_GLOBAL_NOACTION

No global action will be taken when a resource control value is exceeded on this control.

RCTL_GLOBAL_NOBASIC

No values with the RCPRIV_BASIC privilege are permitted on this control.

RCTL_GLOBAL_NOLOCALACTION

No local actions are permitted on this control.

RCTL_GLOBAL_SYSLOG

A standard message will be logged by the `syslog()` facility when any resource control value on a sequence associated with this control is exceeded.

RCTL_GLOBAL_UNOBSERVABLE

The resource control (generally on a task- or project-related control) does not support observational control values. An RCPRIV_BASIC privileged control value placed by a process on the task or process will generate an action only if the value is exceeded by that process.

The local action and flags are those on the current resource control value represented by this resource control block. Valid actions and flags are listed in the table below. In the case of **RCTL_LOCAL_SIGNAL**, the second argument to `rctlblk_set_local_action()` contains the signal to be sent. Similarly, the signal to be sent is copied into the integer location specified by the second argument to `rctlblk_get_local_action()`. A restricted set of signals is made available for normal use by the resource control facility: SIGBART, SIGXRES, SIGHUP, SIGSTOP, SIGTERM, and SIGKILL. Other signals are permitted due to global properites of a specific control. Calls to `setrctl()` with illegal signals will fail.

RCTL_LOCAL_DENY

When this resource control value is encountered, the request for the resource will be denied. Set on all values if **RCTL_GLOBAL_DENY_ALWAYS** is set for this control; cleared on all values if **RCTL_GLOBAL_DENY_NEVER** is set for this control.

rctlblk_get_global_action(3C)

RCTL_LOCAL_MAXIMAL

This resource control value represents a request for the maximum amount of resource for this control. If RCTL_GLOBAL_INFINITE is set for this resource control, RCTL_LOCAL_MAXIMAL indicates an unlimited resource control value, one that will never be exceeded.

RCTL_LOCAL_NOACTION

No local action will be taken when this resource control value is exceeded.

RCTL_LOCAL_SIGNAL

The specified signal, sent by `rctlblk_set_local_action()`, will be sent to the process that placed this resource control value in the value sequence.

The `rctlblk_get_recipient_pid()` function returns the value of the process ID that placed the resource control value. This ID is set by the kernel by a caller invoking `setrctl()`.

The `rctlblk_get_privilege()` function returns the privilege of the resource control block. Valid privileges are RCPRIV_BASIC, RCPRIV_PRIVILEGED, and RCPRIV_SYSTEM. System resource controls are read-only. Privileged resource controls require superuser privilege to write, unless the RCTL_GLOBAL_LOWERABLE global flag is set, in which case unprivileged applications can lower the value of a privileged control.

The `rctlblk_get_value()` and `rctlblk_set_value()` functions return or establish the enforced value associated with the resource control. In cases where the process, task, or project associated with the control possesses fewer capabilities than allowable by the current value, the value returned by `rctlblk_get_enforced_value()` will differ from that returned by `rctlblk_get_value()`. This capability difference arises with processes using an address space model smaller than the maximum address space model supported by the system.

The `rctlblk_size()` function returns the size of a resource control block for use in memory allocation. The `rctlblk_t *` type is an opaque pointer whose size is not connected with that of the resource control block itself. Use of `rctlblk_size()` is illustrated in the example below.

RETURN VALUES

The various set routines have no return values. Incorrectly composed resource control blocks will generate errors when used with `setrctl(2)` or `getrctl(2)`.

ERRORS

No error values are returned. Incorrectly constructed resource control blocks will be rejected by the system calls.

EXAMPLES

EXAMPLE 1 Display the contents of a fetched resource control block.

The following example displays the contents of a fetched resource control block.

```
#include <rctl.h>
#include <stdio.h>
#include <stdlib.h>
```

Global flags are generally a published property of the control and are not modifiable.</p> <p>RCTL_GLOBAL_DENY_ALWAYS The action taken when a control value is exceeded on this control will always include denial of the resource.</p>

RCTL_GLOBAL_DENY_NEVER

The action taken when a control value is exceeded on this control will always exclude denial of the resource; the resource will always be granted, although other actions can also be taken.

RCTL_GLOBAL_CPU_TIME

The valid signals available as local actions include the SIGXCPU signal.

RCTL_GLOBAL_FILE_SIZE

The valid signals available as local actions include the SIGXFSZ signal.

RCTL_GLOBAL_INFINITE

This resource control supports the concept of an unlimited value; generally true only of accumulation-oriented resources, such as CPU time.

RCTL_GLOBAL_LOWERABLE

Non-privileged callers are able to lower the value of privileged resource control values on this control.

RCTL_GLOBAL_NOACTION

No global action will be taken when a resource control value is exceeded on this control.

RCTL_GLOBAL_NOBASIC

No values with the RCPRIV_BASIC privilege are permitted on this control.

RCTL_GLOBAL_NOLOCALACTION

No local actions are permitted on this control.

RCTL_GLOBAL_SYSLOG

A standard message will be logged by the `syslog()` facility when any resource control value on a sequence associated with this control is exceeded.

RCTL_GLOBAL_UNOBSERVABLE

The resource control (generally on a task- or project-related control) does not support observational control values. An RCPRIV_BASIC privileged control value placed by a process on the task or process will generate an action only if the value is exceeded by that process.

The local action and flags are those on the current resource control value represented by this resource control block. Valid actions and flags are listed in the table below. In the case of **RCTL_LOCAL_SIGNAL**, the second argument to `rctlblk_set_local_action()` contains the signal to be sent. Similarly, the signal to be sent is copied into the integer location specified by the second argument to `rctlblk_get_local_action()`. A restricted set of signals is made available for normal use by the resource control facility: SIGBART, SIGXRES, SIGHUP, SIGSTOP, SIGTERM, and SIGKILL. Other signals are permitted due to global properities of a specific control. Calls to `setrctl()` with illegal signals will fail.

RCTL_LOCAL_DENY

When this resource control value is encountered, the request for the resource will be denied. Set on all values if **RCTL_GLOBAL_DENY_ALWAYS** is set for this control; cleared on all values if **RCTL_GLOBAL_DENY_NEVER** is set for this control.

rctlblk_get_global_flags(3C)

RCTL_LOCAL_MAXIMAL

This resource control value represents a request for the maximum amount of resource for this control. If RCTL_GLOBAL_INFINITE is set for this resource control, RCTL_LOCAL_MAXIMAL indicates an unlimited resource control value, one that will never be exceeded.

RCTL_LOCAL_NOACTION

No local action will be taken when this resource control value is exceeded.

RCTL_LOCAL_SIGNAL

The specified signal, sent by `rctlblk_set_local_action()`, will be sent to the process that placed this resource control value in the value sequence.

The `rctlblk_get_recipient_pid()` function returns the value of the process ID that placed the resource control value. This ID is set by the kernel by a caller invoking `setrctl()`.

The `rctlblk_get_privilege()` function returns the privilege of the resource control block. Valid privileges are RCPRIV_BASIC, RCPRIV_PRIVILEGED, and RCPRIV_SYSTEM. System resource controls are read-only. Privileged resource controls require superuser privilege to write, unless the RCTL_GLOBAL_LOWERABLE global flag is set, in which case unprivileged applications can lower the value of a privileged control.

The `rctlblk_get_value()` and `rctlblk_set_value()` functions return or establish the enforced value associated with the resource control. In cases where the process, task, or project associated with the control possesses fewer capabilities than allowable by the current value, the value returned by `rctlblk_get_enforced_value()` will differ from that returned by `rctlblk_get_value()`. This capability difference arises with processes using an address space model smaller than the maximum address space model supported by the system.

The `rctlblk_size()` function returns the size of a resource control block for use in memory allocation. The `rctlblk_t *` type is an opaque pointer whose size is not connected with that of the resource control block itself. Use of `rctlblk_size()` is illustrated in the example below.

RETURN VALUES The various set routines have no return values. Incorrectly composed resource control blocks will generate errors when used with `setrctl(2)` or `getrctl(2)`.

ERRORS No error values are returned. Incorrectly constructed resource control blocks will be rejected by the system calls.

EXAMPLES **EXAMPLE 1** Display the contents of a fetched resource control block.

The following example displays the contents of a fetched resource control block.

```
#include <rctl.h>
#include <stdio.h>
#include <stdlib.h>
```

DESCRIPTION	<p>The resource control block routines allow the establishment or retrieval of values from a resource control block used to transfer information using the <code>getrctl(2)</code> and <code>setrctl(2)</code> functions. Each of the routines accesses or sets the resource control block member corresponding to its name. Certain of these members are read-only and do not possess set routines.</p> <p>The firing time of a resource control block is 0 if the resource control action-value has not been exceeded for its lifetime on the process. Otherwise the firing time is the value of <code>gethrtime(3C)</code> at the moment the action on the resource control value was taken.</p> <p>The global actions and flags are the action and flags set by <code>rctladm(1M)</code>. These values cannot be set with <code>setrctl()</code>. Valid global actions are listed in the table below. Global flags are generally a published property of the control and are not modifiable.</p> <p>RCTL_GLOBAL_DENY_ALWAYS The action taken when a control value is exceeded on this control will always include denial of the resource.</p>

RCTL_GLOBAL_DENY_NEVER

The action taken when a control value is exceeded on this control will always exclude denial of the resource; the resource will always be granted, although other actions can also be taken.

RCTL_GLOBAL_CPU_TIME

The valid signals available as local actions include the SIGXCPU signal.

RCTL_GLOBAL_FILE_SIZE

The valid signals available as local actions include the SIGXFSZ signal.

RCTL_GLOBAL_INFINITE

This resource control supports the concept of an unlimited value; generally true only of accumulation-oriented resources, such as CPU time.

RCTL_GLOBAL_LOWERABLE

Non-privileged callers are able to lower the value of privileged resource control values on this control.

RCTL_GLOBAL_NOACTION

No global action will be taken when a resource control value is exceeded on this control.

RCTL_GLOBAL_NOBASIC

No values with the RCPRIV_BASIC privilege are permitted on this control.

RCTL_GLOBAL_NOLOCALACTION

No local actions are permitted on this control.

RCTL_GLOBAL_SYSLOG

A standard message will be logged by the `syslog()` facility when any resource control value on a sequence associated with this control is exceeded.

RCTL_GLOBAL_UNOBSERVABLE

The resource control (generally on a task- or project-related control) does not support observational control values. An RCPRIV_BASIC privileged control value placed by a process on the task or process will generate an action only if the value is exceeded by that process.

The local action and flags are those on the current resource control value represented by this resource control block. Valid actions and flags are listed in the table below. In the case of `RCTL_LOCAL_SIGNAL`, the second argument to `rctlblk_set_local_action()` contains the signal to be sent. Similarly, the signal to be sent is copied into the integer location specified by the second argument to `rctlblk_get_local_action()`. A restricted set of signals is made available for normal use by the resource control facility: SIGBART, SIGXRES, SIGHUP, SIGSTOP, SIGTERM, and SIGKILL. Other signals are permitted due to global properities of a specific control. Calls to `setrctl()` with illegal signals will fail.

RCTL_LOCAL_DENY

When this resource control value is encountered, the request for the resource will be denied. Set on all values if `RCTL_GLOBAL_DENY_ALWAYS` is set for this control; cleared on all values if `RCTL_GLOBAL_DENY_NEVER` is set for this control.

rctlblk_get_local_action(3C)

RCTL_LOCAL_MAXIMAL

This resource control value represents a request for the maximum amount of resource for this control. If RCTL_GLOBAL_INFINITE is set for this resource control, RCTL_LOCAL_MAXIMAL indicates an unlimited resource control value, one that will never be exceeded.

RCTL_LOCAL_NOACTION

No local action will be taken when this resource control value is exceeded.

RCTL_LOCAL_SIGNAL

The specified signal, sent by rctlblk_set_local_action(), will be sent to the process that placed this resource control value in the value sequence.

The rctlblk_get_recipient_pid() function returns the value of the process ID that placed the resource control value. This ID is set by the kernel by a caller invoking setrctl().

The rctlblk_get_privilege() function returns the privilege of the resource control block. Valid privileges are RCPRIV_BASIC, RCPRIV_PRIVILEGED, and RCPRIV_SYSTEM. System resource controls are read-only. Privileged resource controls require superuser privilege to write, unless the RCTL_GLOBAL_LOWERABLE global flag is set, in which case unprivileged applications can lower the value of a privileged control.

The rctlblk_get_value() and rctlblk_set_value() functions return or establish the enforced value associated with the resource control. In cases where the process, task, or project associated with the control possesses fewer capabilities than allowable by the current value, the value returned by rctlblk_get_enforced_value() will differ from that returned by rctlblk_get_value(). This capability difference arises with processes using an address space model smaller than the maximum address space model supported by the system.

The rctlblk_size() function returns the size of a resource control block for use in memory allocation. The rctlblk_t * type is an opaque pointer whose size is not connected with that of the resource control block itself. Use of rctlblk_size() is illustrated in the example below.

RETURN VALUES The various set routines have no return values. Incorrectly composed resource control blocks will generate errors when used with setrctl(2) or getrctl(2).

ERRORS No error values are returned. Incorrectly constructed resource control blocks will be rejected by the system calls.

EXAMPLES **EXAMPLE 1** Display the contents of a fetched resource control block.

The following example displays the contents of a fetched resource control block.

```
#include <rctl.h>
#include <stdio.h>
#include <stdlib.h>
```

EXAMPLE 1 Display the contents of a fetched resource control block. (Continued)

SYNOPSIS	<pre>#include <rctl.h> hrtime_t rctlblk_get_firing_time(rctlblk_t *rblk); int rctlblk_get_global_action(rctlblk_t *rblk); int rctlblk_get_global_flags(rctlblk_t *rblk); int rctlblk_get_local_action(rctlblk_t *rblk, int *signalp); int rctlblk_get_local_flags(rctlblk_t *rblk); rctl_priv_t rctlblk_get_privilege(rctlblk_t *rblk); id_t rctlblk_get_recipient_pid(rctlblk_t *rblk); rctl_qty_t rctlblk_get_value(rctlblk_t *rblk); rctl_qty_t rctlblk_get_enforced_value(rctlblk_t *rblk); void rctlblk_set_local_action(rctlblk_t *rblk, rctl_action_t action, int signal); void rctlblk_set_local_flags(rctlblk_t *rblk, int flags); void rctlblk_set_privilege(rctlblk_t *rblk, rctl_priv_t privilege); void rctlblk_set_value(rctlblk_t *rblk, rctl_qty_t value); size_t rctlblk_size(void);</pre>
DESCRIPTION	<p>The resource control block routines allow the establishment or retrieval of values from a resource control block used to transfer information using the <code>getrctl(2)</code> and <code>setrctl(2)</code> functions. Each of the routines accesses or sets the resource control block member corresponding to its name. Certain of these members are read-only and do not possess set routines.</p> <p>The firing time of a resource control block is 0 if the resource control action-value has not been exceeded for its lifetime on the process. Otherwise the firing time is the value of <code>gethrtime(3C)</code> at the moment the action on the resource control value was taken.</p> <p>The global actions and flags are the action and flags set by <code>rctladm(1M)</code>. These values cannot be set with <code>setrctl()</code>. Valid global actions are listed in the table below. Global flags are generally a published property of the control and are not modifiable.</p> <p>RCTL_GLOBAL_DENY_ALWAYS The action taken when a control value is exceeded on this control will always include denial of the resource.</p>

RCTL_GLOBAL_DENY_NEVER

The action taken when a control value is exceeded on this control will always exclude denial of the resource; the resource will always be granted, although other actions can also be taken.

RCTL_GLOBAL_CPU_TIME

The valid signals available as local actions include the SIGXCPU signal.

RCTL_GLOBAL_FILE_SIZE

The valid signals available as local actions include the SIGXFSZ signal.

RCTL_GLOBAL_INFINITE

This resource control supports the concept of an unlimited value; generally true only of accumulation-oriented resources, such as CPU time.

RCTL_GLOBAL_LOWERABLE

Non-privileged callers are able to lower the value of privileged resource control values on this control.

RCTL_GLOBAL_NOACTION

No global action will be taken when a resource control value is exceeded on this control.

RCTL_GLOBAL_NOBASIC

No values with the RCPRIV_BASIC privilege are permitted on this control.

RCTL_GLOBAL_NOLOCALACTION

No local actions are permitted on this control.

RCTL_GLOBAL_SYSLOG

A standard message will be logged by the `syslog()` facility when any resource control value on a sequence associated with this control is exceeded.

RCTL_GLOBAL_UNOBSERVABLE

The resource control (generally on a task- or project-related control) does not support observational control values. An RCPRIV_BASIC privileged control value placed by a process on the task or process will generate an action only if the value is exceeded by that process.

The local action and flags are those on the current resource control value represented by this resource control block. Valid actions and flags are listed in the table below. In the case of **RCTL_LOCAL_SIGNAL**, the second argument to `rctlblk_set_local_action()` contains the signal to be sent. Similarly, the signal to be sent is copied into the integer location specified by the second argument to `rctlblk_get_local_action()`. A restricted set of signals is made available for normal use by the resource control facility: SIGBART, SIGXRES, SIGHUP, SIGSTOP, SIGTERM, and SIGKILL. Other signals are permitted due to global properities of a specific control. Calls to `setrctl()` with illegal signals will fail.

RCTL_LOCAL_DENY

When this resource control value is encountered, the request for the resource will be denied. Set on all values if **RCTL_GLOBAL_DENY_ALWAYS** is set for this control; cleared on all values if **RCTL_GLOBAL_DENY_NEVER** is set for this control.

rctlblk_get_local_flags(3C)

RCTL_LOCAL_MAXIMAL

This resource control value represents a request for the maximum amount of resource for this control. If RCTL_GLOBAL_INFINITE is set for this resource control, RCTL_LOCAL_MAXIMAL indicates an unlimited resource control value, one that will never be exceeded.

RCTL_LOCAL_NOACTION

No local action will be taken when this resource control value is exceeded.

RCTL_LOCAL_SIGNAL

The specified signal, sent by rctlblk_set_local_action(), will be sent to the process that placed this resource control value in the value sequence.

The rctlblk_get_recipient_pid() function returns the value of the process ID that placed the resource control value. This ID is set by the kernel by a caller invoking setrctl().

The rctlblk_get_privilege() function returns the privilege of the resource control block. Valid privileges are RCPRIV_BASIC, RCPRIV_PRIVILEGED, and RCPRIV_SYSTEM. System resource controls are read-only. Privileged resource controls require superuser privilege to write, unless the RCTL_GLOBAL_LOWERABLE global flag is set, in which case unprivileged applications can lower the value of a privileged control.

The rctlblk_get_value() and rctlblk_set_value() functions return or establish the enforced value associated with the resource control. In cases where the process, task, or project associated with the control possesses fewer capabilities than allowable by the current value, the value returned by rctlblk_get_enforced_value() will differ from that returned by rctlblk_get_value(). This capability difference arises with processes using an address space model smaller than the maximum address space model supported by the system.

The rctlblk_size() function returns the size of a resource control block for use in memory allocation. The rctlblk_t * type is an opaque pointer whose size is not connected with that of the resource control block itself. Use of rctlblk_size() is illustrated in the example below.

RETURN VALUES

The various set routines have no return values. Incorrectly composed resource control blocks will generate errors when used with setrctl(2) or getrctl(2).

ERRORS

No error values are returned. Incorrectly constructed resource control blocks will be rejected by the system calls.

EXAMPLES

EXAMPLE 1 Display the contents of a fetched resource control block.

The following example displays the contents of a fetched resource control block.

```
#include <rctl.h>
#include <stdio.h>
#include <stdlib.h>
```

EXAMPLE 1 Display the contents of a fetched resource control block. (Continued)

```

rctlblk_t *rblk;
int rsignal;

Global flags are generally a published property of the control and are not modifiable.</p> <p>RCTL_GLOBAL_DENY_ALWAYS The action taken when a control value is exceeded on this control will always include denial of the resource.</p>

RCTL_GLOBAL_DENY_NEVER

The action taken when a control value is exceeded on this control will always exclude denial of the resource; the resource will always be granted, although other actions can also be taken.

RCTL_GLOBAL_CPU_TIME

The valid signals available as local actions include the SIGXCPU signal.

RCTL_GLOBAL_FILE_SIZE

The valid signals available as local actions include the SIGXFSZ signal.

RCTL_GLOBAL_INFINITE

This resource control supports the concept of an unlimited value; generally true only of accumulation-oriented resources, such as CPU time.

RCTL_GLOBAL_LOWERABLE

Non-privileged callers are able to lower the value of privileged resource control values on this control.

RCTL_GLOBAL_NOACTION

No global action will be taken when a resource control value is exceeded on this control.

RCTL_GLOBAL_NOBASIC

No values with the RCPRIV_BASIC privilege are permitted on this control.

RCTL_GLOBAL_NOLOCALACTION

No local actions are permitted on this control.

RCTL_GLOBAL_SYSLOG

A standard message will be logged by the `syslog()` facility when any resource control value on a sequence associated with this control is exceeded.

RCTL_GLOBAL_UNOBSERVABLE

The resource control (generally on a task- or project-related control) does not support observational control values. An RCPRIV_BASIC privileged control value placed by a process on the task or process will generate an action only if the value is exceeded by that process.

The local action and flags are those on the current resource control value represented by this resource control block. Valid actions and flags are listed in the table below. In the case of **RCTL_LOCAL_SIGNAL**, the second argument to `rctlblk_set_local_action()` contains the signal to be sent. Similarly, the signal to be sent is copied into the integer location specified by the second argument to `rctlblk_get_local_action()`. A restricted set of signals is made available for normal use by the resource control facility: SIGBART, SIGXRES, SIGHUP, SIGSTOP, SIGTERM, and SIGKILL. Other signals are permitted due to global properities of a specific control. Calls to `setrctl()` with illegal signals will fail.

RCTL_LOCAL_DENY

When this resource control value is encountered, the request for the resource will be denied. Set on all values if **RCTL_GLOBAL_DENY_ALWAYS** is set for this control; cleared on all values if **RCTL_GLOBAL_DENY_NEVER** is set for this control.

rctlblk_get_privilege(3C)

RCTL_LOCAL_MAXIMAL

This resource control value represents a request for the maximum amount of resource for this control. If RCTL_GLOBAL_INFINITE is set for this resource control, RCTL_LOCAL_MAXIMAL indicates an unlimited resource control value, one that will never be exceeded.

RCTL_LOCAL_NOACTION

No local action will be taken when this resource control value is exceeded.

RCTL_LOCAL_SIGNAL

The specified signal, sent by `rctlblk_set_local_action()`, will be sent to the process that placed this resource control value in the value sequence.

The `rctlblk_get_recipient_pid()` function returns the value of the process ID that placed the resource control value. This ID is set by the kernel by a caller invoking `setrctl()`.

The `rctlblk_get_privilege()` function returns the privilege of the resource control block. Valid privileges are RCPRIV_BASIC, RCPRIV_PRIVILEGED, and RCPRIV_SYSTEM. System resource controls are read-only. Privileged resource controls require superuser privilege to write, unless the RCTL_GLOBAL_LOWERABLE global flag is set, in which case unprivileged applications can lower the value of a privileged control.

The `rctlblk_get_value()` and `rctlblk_set_value()` functions return or establish the enforced value associated with the resource control. In cases where the process, task, or project associated with the control possesses fewer capabilities than allowable by the current value, the value returned by `rctlblk_get_enforced_value()` will differ from that returned by `rctlblk_get_value()`. This capability difference arises with processes using an address space model smaller than the maximum address space model supported by the system.

The `rctlblk_size()` function returns the size of a resource control block for use in memory allocation. The `rctlblk_t *` type is an opaque pointer whose size is not connected with that of the resource control block itself. Use of `rctlblk_size()` is illustrated in the example below.

RETURN VALUES The various set routines have no return values. Incorrectly composed resource control blocks will generate errors when used with `setrctl(2)` or `getrctl(2)`.

ERRORS No error values are returned. Incorrectly constructed resource control blocks will be rejected by the system calls.

EXAMPLES **EXAMPLE 1** Display the contents of a fetched resource control block.

The following example displays the contents of a fetched resource control block.

```
#include <rctl.h>
#include <stdio.h>
#include <stdlib.h>
```

DESCRIPTION	<p>The resource control block routines allow the establishment or retrieval of values from a resource control block used to transfer information using the <code>getrctl(2)</code> and <code>setrctl(2)</code> functions. Each of the routines accesses or sets the resource control block member corresponding to its name. Certain of these members are read-only and do not possess set routines.</p> <p>The firing time of a resource control block is 0 if the resource control action-value has not been exceeded for its lifetime on the process. Otherwise the firing time is the value of <code>gethrtime(3C)</code> at the moment the action on the resource control value was taken.</p> <p>The global actions and flags are the action and flags set by <code>rctladm(1M)</code>. These values cannot be set with <code>setrctl()</code>. Valid global actions are listed in the table below. Global flags are generally a published property of the control and are not modifiable.</p> <p>RCTL_GLOBAL_DENY_ALWAYS The action taken when a control value is exceeded on this control will always include denial of the resource.</p>

RCTL_GLOBAL_DENY_NEVER

The action taken when a control value is exceeded on this control will always exclude denial of the resource; the resource will always be granted, although other actions can also be taken.

RCTL_GLOBAL_CPU_TIME

The valid signals available as local actions include the SIGXCPU signal.

RCTL_GLOBAL_FILE_SIZE

The valid signals available as local actions include the SIGXFSZ signal.

RCTL_GLOBAL_INFINITE

This resource control supports the concept of an unlimited value; generally true only of accumulation-oriented resources, such as CPU time.

RCTL_GLOBAL_LOWERABLE

Non-privileged callers are able to lower the value of privileged resource control values on this control.

RCTL_GLOBAL_NOACTION

No global action will be taken when a resource control value is exceeded on this control.

RCTL_GLOBAL_NOBASIC

No values with the RCPRIV_BASIC privilege are permitted on this control.

RCTL_GLOBAL_NOLOCALACTION

No local actions are permitted on this control.

RCTL_GLOBAL_SYSLOG

A standard message will be logged by the `syslog()` facility when any resource control value on a sequence associated with this control is exceeded.

RCTL_GLOBAL_UNOBSERVABLE

The resource control (generally on a task- or project-related control) does not support observational control values. An RCPRIV_BASIC privileged control value placed by a process on the task or process will generate an action only if the value is exceeded by that process.

The local action and flags are those on the current resource control value represented by this resource control block. Valid actions and flags are listed in the table below. In the case of **RCTL_LOCAL_SIGNAL**, the second argument to `rctlblk_set_local_action()` contains the signal to be sent. Similarly, the signal to be sent is copied into the integer location specified by the second argument to `rctlblk_get_local_action()`. A restricted set of signals is made available for normal use by the resource control facility: SIGBART, SIGXRES, SIGHUP, SIGSTOP, SIGTERM, and SIGKILL. Other signals are permitted due to global properites of a specific control. Calls to `setrctl()` with illegal signals will fail.

RCTL_LOCAL_DENY

When this resource control value is encountered, the request for the resource will be denied. Set on all values if **RCTL_GLOBAL_DENY_ALWAYS** is set for this control; cleared on all values if **RCTL_GLOBAL_DENY_NEVER** is set for this control.

rctlblk_get_recipient_pid(3C)

RCTL_LOCAL_MAXIMAL

This resource control value represents a request for the maximum amount of resource for this control. If RCTL_GLOBAL_INFINITE is set for this resource control, RCTL_LOCAL_MAXIMAL indicates an unlimited resource control value, one that will never be exceeded.

RCTL_LOCAL_NOACTION

No local action will be taken when this resource control value is exceeded.

RCTL_LOCAL_SIGNAL

The specified signal, sent by `rctlblk_set_local_action()`, will be sent to the process that placed this resource control value in the value sequence.

The `rctlblk_get_recipient_pid()` function returns the value of the process ID that placed the resource control value. This ID is set by the kernel by a caller invoking `setrctl()`.

The `rctlblk_get_privilege()` function returns the privilege of the resource control block. Valid privileges are RCPRIV_BASIC, RCPRIV_PRIVILEGED, and RCPRIV_SYSTEM. System resource controls are read-only. Privileged resource controls require superuser privilege to write, unless the RCTL_GLOBAL_LOWERABLE global flag is set, in which case unprivileged applications can lower the value of a privileged control.

The `rctlblk_get_value()` and `rctlblk_set_value()` functions return or establish the enforced value associated with the resource control. In cases where the process, task, or project associated with the control possesses fewer capabilities than allowable by the current value, the value returned by `rctlblk_get_enforced_value()` will differ from that returned by `rctlblk_get_value()`. This capability difference arises with processes using an address space model smaller than the maximum address space model supported by the system.

The `rctlblk_size()` function returns the size of a resource control block for use in memory allocation. The `rctlblk_t *` type is an opaque pointer whose size is not connected with that of the resource control block itself. Use of `rctlblk_size()` is illustrated in the example below.

RETURN VALUES The various set routines have no return values. Incorrectly composed resource control blocks will generate errors when used with `setrctl(2)` or `getrctl(2)`.

ERRORS No error values are returned. Incorrectly constructed resource control blocks will be rejected by the system calls.

EXAMPLES **EXAMPLE 1** Display the contents of a fetched resource control block.

The following example displays the contents of a fetched resource control block.

```
#include <rctl.h>
#include <stdio.h>
#include <stdlib.h>
```

EXAMPLE 1 Display the contents of a fetched resource control block. (Continued)

rctlblk_get_value(3C)

NAME	rctlblk_set_value, rctlblk_get_firing_time, rctlblk_get_global_action, rctlblk_get_global_flags, rctlblk_get_local_action, rctlblk_get_local_flags, rctlblk_get_privilege, rctlblk_get_recipient_pid, rctlblk_get_value, rctlblk_get_enforced_value, rctlblk_set_local_action, rctlblk_set_local_flags, rctlblk_set_privilege, rctlblk_size – manipulate resource control blocks
SYNOPSIS	<pre>#include <rctl.h> hrtime_t rctlblk_get_firing_time(rctlblk_t *rblk); int rctlblk_get_global_action(rctlblk_t *rblk); int rctlblk_get_global_flags(rctlblk_t *rblk); int rctlblk_get_local_action(rctlblk_t *rblk, int *signalp); int rctlblk_get_local_flags(rctlblk_t *rblk); rctl_priv_t rctlblk_get_privilege(rctlblk_t *rblk); id_t rctlblk_get_recipient_pid(rctlblk_t *rblk); rctl_qty_t rctlblk_get_value(rctlblk_t *rblk); rctl_qty_t rctlblk_get_enforced_value(rctlblk_t *rblk); void rctlblk_set_local_action(rctlblk_t *rblk, rctl_action_t action, int signal); void rctlblk_set_local_flags(rctlblk_t *rblk, int flags); void rctlblk_set_privilege(rctlblk_t *rblk, rctl_priv_t privilege); void rctlblk_set_value(rctlblk_t *rblk, rctl_qty_t value); size_t rctlblk_size(void);</pre>
DESCRIPTION	<p>The resource control block routines allow the establishment or retrieval of values from a resource control block used to transfer information using the <code>getrctl(2)</code> and <code>setrctl(2)</code> functions. Each of the routines accesses or sets the resource control block member corresponding to its name. Certain of these members are read-only and do not possess set routines.</p> <p>The firing time of a resource control block is 0 if the resource control action-value has not been exceeded for its lifetime on the process. Otherwise the firing time is the value of <code>gethrtime(3C)</code> at the moment the action on the resource control value was taken.</p> <p>The global actions and flags are the action and flags set by <code>rctladm(1M)</code>. These values cannot be set with <code>setrctl()</code>. Valid global actions are listed in the table below. Global flags are generally a published property of the control and are not modifiable.</p> <p>RCTL_GLOBAL_DENY_ALWAYS The action taken when a control value is exceeded on this control will always include denial of the resource.</p>

RCTL_GLOBAL_DENY_NEVER

The action taken when a control value is exceeded on this control will always exclude denial of the resource; the resource will always be granted, although other actions can also be taken.

RCTL_GLOBAL_CPU_TIME

The valid signals available as local actions include the SIGXCPU signal.

RCTL_GLOBAL_FILE_SIZE

The valid signals available as local actions include the SIGXFSZ signal.

RCTL_GLOBAL_INFINITE

This resource control supports the concept of an unlimited value; generally true only of accumulation-oriented resources, such as CPU time.

RCTL_GLOBAL_LOWERABLE

Non-privileged callers are able to lower the value of privileged resource control values on this control.

RCTL_GLOBAL_NOACTION

No global action will be taken when a resource control value is exceeded on this control.

RCTL_GLOBAL_NOBASIC

No values with the RCPRIV_BASIC privilege are permitted on this control.

RCTL_GLOBAL_NOLOCALACTION

No local actions are permitted on this control.

RCTL_GLOBAL_SYSLOG

A standard message will be logged by the `syslog()` facility when any resource control value on a sequence associated with this control is exceeded.

RCTL_GLOBAL_UNOBSERVABLE

The resource control (generally on a task- or project-related control) does not support observational control values. An RCPRIV_BASIC privileged control value placed by a process on the task or process will generate an action only if the value is exceeded by that process.

The local action and flags are those on the current resource control value represented by this resource control block. Valid actions and flags are listed in the table below. In the case of **RCTL_LOCAL_SIGNAL**, the second argument to `rctlblk_set_local_action()` contains the signal to be sent. Similarly, the signal to be sent is copied into the integer location specified by the second argument to `rctlblk_get_local_action()`. A restricted set of signals is made available for normal use by the resource control facility: SIGBART, SIGXRES, SIGHUP, SIGSTOP, SIGTERM, and SIGKILL. Other signals are permitted due to global properities of a specific control. Calls to `setrctl()` with illegal signals will fail.

RCTL_LOCAL_DENY

When this resource control value is encountered, the request for the resource will be denied. Set on all values if **RCTL_GLOBAL_DENY_ALWAYS** is set for this control; cleared on all values if **RCTL_GLOBAL_DENY_NEVER** is set for this control.

rctlblk_get_value(3C)

RCTL_LOCAL_MAXIMAL

This resource control value represents a request for the maximum amount of resource for this control. If RCTL_GLOBAL_INFINITE is set for this resource control, RCTL_LOCAL_MAXIMAL indicates an unlimited resource control value, one that will never be exceeded.

RCTL_LOCAL_NOACTION

No local action will be taken when this resource control value is exceeded.

RCTL_LOCAL_SIGNAL

The specified signal, sent by `rctlblk_set_local_action()`, will be sent to the process that placed this resource control value in the value sequence.

The `rctlblk_get_recipient_pid()` function returns the value of the process ID that placed the resource control value. This ID is set by the kernel by a caller invoking `setrctl()`.

The `rctlblk_get_privilege()` function returns the privilege of the resource control block. Valid privileges are RCPRIV_BASIC, RCPRIV_PRIVILEGED, and RCPRIV_SYSTEM. System resource controls are read-only. Privileged resource controls require superuser privilege to write, unless the RCTL_GLOBAL_LOWERABLE global flag is set, in which case unprivileged applications can lower the value of a privileged control.

The `rctlblk_get_value()` and `rctlblk_set_value()` functions return or establish the enforced value associated with the resource control. In cases where the process, task, or project associated with the control possesses fewer capabilities than allowable by the current value, the value returned by `rctlblk_get_enforced_value()` will differ from that returned by `rctlblk_get_value()`. This capability difference arises with processes using an address space model smaller than the maximum address space model supported by the system.

The `rctlblk_size()` function returns the size of a resource control block for use in memory allocation. The `rctlblk_t *` type is an opaque pointer whose size is not connected with that of the resource control block itself. Use of `rctlblk_size()` is illustrated in the example below.

RETURN VALUES The various set routines have no return values. Incorrectly composed resource control blocks will generate errors when used with `setrctl(2)` or `getrctl(2)`.

ERRORS No error values are returned. Incorrectly constructed resource control blocks will be rejected by the system calls.

EXAMPLES **EXAMPLE 1** Display the contents of a fetched resource control block.

The following example displays the contents of a fetched resource control block.

```
#include <rctl.h>
#include <stdio.h>
#include <stdlib.h>
```

EXAMPLE 1 Display the contents of a fetched resource control block. (Continued)

```

rctlblk_t *rblk;
int rsignal;
int raction;

if ((rblk = malloc(rctlblk_size())) == NULL) {
    (void) perror("rblk malloc");
    exit(1);
}

if (getrctl("process.max-cpu-time", NULL, rblk, RCTL_FIRST) == -1) {
    (void) perror("getrctl");
    exit(1);
}

raction = rctlblk_get_local_action(rblk, &rsignal),

RCTL_GLOBAL_DENY_NEVER

The action taken when a control value is exceeded on this control will always exclude denial of the resource; the resource will always be granted, although other actions can also be taken.

RCTL_GLOBAL_CPU_TIME

The valid signals available as local actions include the SIGXCPU signal.

RCTL_GLOBAL_FILE_SIZE

The valid signals available as local actions include the SIGXFSZ signal.

RCTL_GLOBAL_INFINITE

This resource control supports the concept of an unlimited value; generally true only of accumulation-oriented resources, such as CPU time.

RCTL_GLOBAL_LOWERABLE

Non-privileged callers are able to lower the value of privileged resource control values on this control.

RCTL_GLOBAL_NOACTION

No global action will be taken when a resource control value is exceeded on this control.

RCTL_GLOBAL_NOBASIC

No values with the RCPRIV_BASIC privilege are permitted on this control.

RCTL_GLOBAL_NOLOCALACTION

No local actions are permitted on this control.

RCTL_GLOBAL_SYSLOG

A standard message will be logged by the `syslog()` facility when any resource control value on a sequence associated with this control is exceeded.

RCTL_GLOBAL_UNOBSERVABLE

The resource control (generally on a task- or project-related control) does not support observational control values. An RCPRIV_BASIC privileged control value placed by a process on the task or process will generate an action only if the value is exceeded by that process.

The local action and flags are those on the current resource control value represented by this resource control block. Valid actions and flags are listed in the table below. In the case of `RCTL_LOCAL_SIGNAL`, the second argument to `rctlblk_set_local_action()` contains the signal to be sent. Similarly, the signal to be sent is copied into the integer location specified by the second argument to `rctlblk_get_local_action()`. A restricted set of signals is made available for normal use by the resource control facility: SIGBART, SIGXRES, SIGHUP, SIGSTOP, SIGTERM, and SIGKILL. Other signals are permitted due to global properities of a specific control. Calls to `setrctl()` with illegal signals will fail.

RCTL_LOCAL_DENY

When this resource control value is encountered, the request for the resource will be denied. Set on all values if `RCTL_GLOBAL_DENY_ALWAYS` is set for this control; cleared on all values if `RCTL_GLOBAL_DENY_NEVER` is set for this control.

rctlblk_set_local_action(3C)

RCTL_LOCAL_MAXIMAL

This resource control value represents a request for the maximum amount of resource for this control. If RCTL_GLOBAL_INFINITE is set for this resource control, RCTL_LOCAL_MAXIMAL indicates an unlimited resource control value, one that will never be exceeded.

RCTL_LOCAL_NOACTION

No local action will be taken when this resource control value is exceeded.

RCTL_LOCAL_SIGNAL

The specified signal, sent by rctlblk_set_local_action(), will be sent to the process that placed this resource control value in the value sequence.

The rctlblk_get_recipient_pid() function returns the value of the process ID that placed the resource control value. This ID is set by the kernel by a caller invoking setrctl().

The rctlblk_get_privilege() function returns the privilege of the resource control block. Valid privileges are RCPRIV_BASIC, RCPRIV_PRIVILEGED, and RCPRIV_SYSTEM. System resource controls are read-only. Privileged resource controls require superuser privilege to write, unless the RCTL_GLOBAL_LOWERABLE global flag is set, in which case unprivileged applications can lower the value of a privileged control.

The rctlblk_get_value() and rctlblk_set_value() functions return or establish the enforced value associated with the resource control. In cases where the process, task, or project associated with the control possesses fewer capabilities than allowable by the current value, the value returned by rctlblk_get_enforced_value() will differ from that returned by rctlblk_get_value(). This capability difference arises with processes using an address space model smaller than the maximum address space model supported by the system.

The rctlblk_size() function returns the size of a resource control block for use in memory allocation. The rctlblk_t * type is an opaque pointer whose size is not connected with that of the resource control block itself. Use of rctlblk_size() is illustrated in the example below.

RETURN VALUES The various set routines have no return values. Incorrectly composed resource control blocks will generate errors when used with setrctl(2) or getrctl(2).

ERRORS No error values are returned. Incorrectly constructed resource control blocks will be rejected by the system calls.

EXAMPLES **EXAMPLE 1** Display the contents of a fetched resource control block.

The following example displays the contents of a fetched resource control block.

```
#include <rctl.h>
#include <stdio.h>
#include <stdlib.h>
```

Certain of these members are read-only and do not possess set routines.</p> <p>The firing time of a resource control block is 0 if the resource control action-value has not been exceeded for its lifetime on the process. Otherwise the firing time is the value of <code>gethrtime(3C)</code> at the moment the action on the resource control value was taken.</p> <p>The global actions and flags are the action and flags set by <code>rctladm(1M)</code>. These values cannot be set with <code>setrctl()</code>. Valid global actions are listed in the table below. Global flags are generally a published property of the control and are not modifiable.</p> <p>RCTL_GLOBAL_DENY_ALWAYS The action taken when a control value is exceeded on this control will always include denial of the resource.</p>

RCTL_GLOBAL_DENY_NEVER

The action taken when a control value is exceeded on this control will always exclude denial of the resource; the resource will always be granted, although other actions can also be taken.

RCTL_GLOBAL_CPU_TIME

The valid signals available as local actions include the SIGXCPU signal.

RCTL_GLOBAL_FILE_SIZE

The valid signals available as local actions include the SIGXFSZ signal.

RCTL_GLOBAL_INFINITE

This resource control supports the concept of an unlimited value; generally true only of accumulation-oriented resources, such as CPU time.

RCTL_GLOBAL_LOWERABLE

Non-privileged callers are able to lower the value of privileged resource control values on this control.

RCTL_GLOBAL_NOACTION

No global action will be taken when a resource control value is exceeded on this control.

RCTL_GLOBAL_NOBASIC

No values with the RCPRIV_BASIC privilege are permitted on this control.

RCTL_GLOBAL_NOLOCALACTION

No local actions are permitted on this control.

RCTL_GLOBAL_SYSLOG

A standard message will be logged by the `syslog()` facility when any resource control value on a sequence associated with this control is exceeded.

RCTL_GLOBAL_UNOBSERVABLE

The resource control (generally on a task- or project-related control) does not support observational control values. An RCPRIV_BASIC privileged control value placed by a process on the task or process will generate an action only if the value is exceeded by that process.

The local action and flags are those on the current resource control value represented by this resource control block. Valid actions and flags are listed in the table below. In the case of `RCTL_LOCAL_SIGNAL`, the second argument to `rctlblk_set_local_action()` contains the signal to be sent. Similarly, the signal to be sent is copied into the integer location specified by the second argument to `rctlblk_get_local_action()`. A restricted set of signals is made available for normal use by the resource control facility: SIGBART, SIGXRES, SIGHUP, SIGSTOP, SIGTERM, and SIGKILL. Other signals are permitted due to global properites of a specific control. Calls to `setrctl()` with illegal signals will fail.

RCTL_LOCAL_DENY

When this resource control value is encountered, the request for the resource will be denied. Set on all values if `RCTL_GLOBAL_DENY_ALWAYS` is set for this control; cleared on all values if `RCTL_GLOBAL_DENY_NEVER` is set for this control.

rctlblk_set_local_flags(3C)

RCTL_LOCAL_MAXIMAL

This resource control value represents a request for the maximum amount of resource for this control. If RCTL_GLOBAL_INFINITE is set for this resource control, RCTL_LOCAL_MAXIMAL indicates an unlimited resource control value, one that will never be exceeded.

RCTL_LOCAL_NOACTION

No local action will be taken when this resource control value is exceeded.

RCTL_LOCAL_SIGNAL

The specified signal, sent by rctlblk_set_local_action(), will be sent to the process that placed this resource control value in the value sequence.

The rctlblk_get_recipient_pid() function returns the value of the process ID that placed the resource control value. This ID is set by the kernel by a caller invoking setrctl().

The rctlblk_get_privilege() function returns the privilege of the resource control block. Valid privileges are RCPRIV_BASIC, RCPRIV_PRIVILEGED, and RCPRIV_SYSTEM. System resource controls are read-only. Privileged resource controls require superuser privilege to write, unless the RCTL_GLOBAL_LOWERABLE global flag is set, in which case unprivileged applications can lower the value of a privileged control.

The rctlblk_get_value() and rctlblk_set_value() functions return or establish the enforced value associated with the resource control. In cases where the process, task, or project associated with the control possesses fewer capabilities than allowable by the current value, the value returned by rctlblk_get_enforced_value() will differ from that returned by rctlblk_get_value(). This capability difference arises with processes using an address space model smaller than the maximum address space model supported by the system.

The rctlblk_size() function returns the size of a resource control block for use in memory allocation. The rctlblk_t * type is an opaque pointer whose size is not connected with that of the resource control block itself. Use of rctlblk_size() is illustrated in the example below.

RETURN VALUES The various set routines have no return values. Incorrectly composed resource control blocks will generate errors when used with setrctl(2) or getrctl(2).

ERRORS No error values are returned. Incorrectly constructed resource control blocks will be rejected by the system calls.

EXAMPLES **EXAMPLE 1** Display the contents of a fetched resource control block.

The following example displays the contents of a fetched resource control block.

```
#include <rctl.h>
#include <stdio.h>
#include <stdlib.h>
```

EXAMPLE 1 Display the contents of a fetched resource control block. (Continued)

```

rctlblk_set_privilege(3C)

NAME	rctlblk_set_value, rctlblk_get_firing_time, rctlblk_get_global_action, rctlblk_get_global_flags, rctlblk_get_local_action, rctlblk_get_local_flags, rctlblk_get_privilege, rctlblk_get_recipient_pid, rctlblk_get_value, rctlblk_get_enforced_value, rctlblk_set_local_action, rctlblk_set_local_flags, rctlblk_set_privilege, rctlblk_size – manipulate resource control blocks
SYNOPSIS	<pre>#include <rctl.h> hrtime_t rctlblk_get_firing_time(rctlblk_t *rblk); int rctlblk_get_global_action(rctlblk_t *rblk); int rctlblk_get_global_flags(rctlblk_t *rblk); int rctlblk_get_local_action(rctlblk_t *rblk, int *signalp); int rctlblk_get_local_flags(rctlblk_t *rblk); rctl_priv_t rctlblk_get_privilege(rctlblk_t *rblk); id_t rctlblk_get_recipient_pid(rctlblk_t *rblk); rctl_qty_t rctlblk_get_value(rctlblk_t *rblk); rctl_qty_t rctlblk_get_enforced_value(rctlblk_t *rblk); void rctlblk_set_local_action(rctlblk_t *rblk, rctl_action_t action, int signal); void rctlblk_set_local_flags(rctlblk_t *rblk, int flags); void rctlblk_set_privilege(rctlblk_t *rblk, rctl_priv_t privilege); void rctlblk_set_value(rctlblk_t *rblk, rctl_qty_t value); size_t rctlblk_size(void);</pre>
DESCRIPTION	<p>The resource control block routines allow the establishment or retrieval of values from a resource control block used to transfer information using the <code>getrctl(2)</code> and <code>setrctl(2)</code> functions. Each of the routines accesses or sets the resource control block member corresponding to its name. Certain of these members are read-only and do not possess set routines.</p> <p>The firing time of a resource control block is 0 if the resource control action-value has not been exceeded for its lifetime on the process. Otherwise the firing time is the value of <code>gethrtime(3C)</code> at the moment the action on the resource control value was taken.</p> <p>The global actions and flags are the action and flags set by <code>rctladm(1M)</code>. These values cannot be set with <code>setrctl()</code>. Valid global actions are listed in the table below. Global flags are generally a published property of the control and are not modifiable.</p> <p>RCTL_GLOBAL_DENY_ALWAYS The action taken when a control value is exceeded on this control will always include denial of the resource.</p>

RCTL_GLOBAL_DENY_NEVER

The action taken when a control value is exceeded on this control will always exclude denial of the resource; the resource will always be granted, although other actions can also be taken.

RCTL_GLOBAL_CPU_TIME

The valid signals available as local actions include the SIGXCPU signal.

RCTL_GLOBAL_FILE_SIZE

The valid signals available as local actions include the SIGXFSZ signal.

RCTL_GLOBAL_INFINITE

This resource control supports the concept of an unlimited value; generally true only of accumulation-oriented resources, such as CPU time.

RCTL_GLOBAL_LOWERABLE

Non-privileged callers are able to lower the value of privileged resource control values on this control.

RCTL_GLOBAL_NOACTION

No global action will be taken when a resource control value is exceeded on this control.

RCTL_GLOBAL_NOBASIC

No values with the RCPRIV_BASIC privilege are permitted on this control.

RCTL_GLOBAL_NOLOCALACTION

No local actions are permitted on this control.

RCTL_GLOBAL_SYSLOG

A standard message will be logged by the `syslog()` facility when any resource control value on a sequence associated with this control is exceeded.

RCTL_GLOBAL_UNOBSERVABLE

The resource control (generally on a task- or project-related control) does not support observational control values. An RCPRIV_BASIC privileged control value placed by a process on the task or process will generate an action only if the value is exceeded by that process.

The local action and flags are those on the current resource control value represented by this resource control block. Valid actions and flags are listed in the table below. In the case of **RCTL_LOCAL_SIGNAL**, the second argument to `rctlblk_set_local_action()` contains the signal to be sent. Similarly, the signal to be sent is copied into the integer location specified by the second argument to `rctlblk_get_local_action()`. A restricted set of signals is made available for normal use by the resource control facility: SIGBART, SIGXRES, SIGHUP, SIGSTOP, SIGTERM, and SIGKILL. Other signals are permitted due to global properites of a specific control. Calls to `setrctl()` with illegal signals will fail.

RCTL_LOCAL_DENY

When this resource control value is encountered, the request for the resource will be denied. Set on all values if **RCTL_GLOBAL_DENY_ALWAYS** is set for this control; cleared on all values if **RCTL_GLOBAL_DENY_NEVER** is set for this control.

rctlblk_set_privilege(3C)

RCTL_LOCAL_MAXIMAL

This resource control value represents a request for the maximum amount of resource for this control. If RCTL_GLOBAL_INFINITE is set for this resource control, RCTL_LOCAL_MAXIMAL indicates an unlimited resource control value, one that will never be exceeded.

RCTL_LOCAL_NOACTION

No local action will be taken when this resource control value is exceeded.

RCTL_LOCAL_SIGNAL

The specified signal, sent by `rctlblk_set_local_action()`, will be sent to the process that placed this resource control value in the value sequence.

The `rctlblk_get_recipient_pid()` function returns the value of the process ID that placed the resource control value. This ID is set by the kernel by a caller invoking `setrctl()`.

The `rctlblk_get_privilege()` function returns the privilege of the resource control block. Valid privileges are RCPRIV_BASIC, RCPRIV_PRIVILEGED, and RCPRIV_SYSTEM. System resource controls are read-only. Privileged resource controls require superuser privilege to write, unless the RCTL_GLOBAL_LOWERABLE global flag is set, in which case unprivileged applications can lower the value of a privileged control.

The `rctlblk_get_value()` and `rctlblk_set_value()` functions return or establish the enforced value associated with the resource control. In cases where the process, task, or project associated with the control possesses fewer capabilities than allowable by the current value, the value returned by `rctlblk_get_enforced_value()` will differ from that returned by `rctlblk_get_value()`. This capability difference arises with processes using an address space model smaller than the maximum address space model supported by the system.

The `rctlblk_size()` function returns the size of a resource control block for use in memory allocation. The `rctlblk_t *` type is an opaque pointer whose size is not connected with that of the resource control block itself. Use of `rctlblk_size()` is illustrated in the example below.

RETURN VALUES The various set routines have no return values. Incorrectly composed resource control blocks will generate errors when used with `setrctl(2)` or `getrctl(2)`.

ERRORS No error values are returned. Incorrectly constructed resource control blocks will be rejected by the system calls.

EXAMPLES **EXAMPLE 1** Display the contents of a fetched resource control block.

The following example displays the contents of a fetched resource control block.

```
#include <rctl.h>
#include <stdio.h>
#include <stdlib.h>
```

EXAMPLE 1 Display the contents of a fetched resource control block. (Continued)

```

rctlblk_t *rblk;
int rsignal;
int raction;

if ((rblk = malloc(rctlblk_size())) == NULL) {
    (void) perror("rblk malloc");
    exit(1);
}

if (getrctl("process.max-cpu-time", NULL, rblk, RCTL_FIRST) == -1) {
    (void) perror("getrctl");
    exit(1);
}

raction = rctlblk_get_local_action(rblk, &rsignal),
(void) printf("Resource control for %s\n",
    "process.max-cpu-time");

RCTL_GLOBAL_DENY_NEVER

The action taken when a control value is exceeded on this control will always exclude denial of the resource; the resource will always be granted, although other actions can also be taken.

RCTL_GLOBAL_CPU_TIME

The valid signals available as local actions include the SIGXCPU signal.

RCTL_GLOBAL_FILE_SIZE

The valid signals available as local actions include the SIGXFSZ signal.

RCTL_GLOBAL_INFINITE

This resource control supports the concept of an unlimited value; generally true only of accumulation-oriented resources, such as CPU time.

RCTL_GLOBAL_LOWERABLE

Non-privileged callers are able to lower the value of privileged resource control values on this control.

RCTL_GLOBAL_NOACTION

No global action will be taken when a resource control value is exceeded on this control.

RCTL_GLOBAL_NOBASIC

No values with the RCPRIV_BASIC privilege are permitted on this control.

RCTL_GLOBAL_NOLOCALACTION

No local actions are permitted on this control.

RCTL_GLOBAL_SYSLOG

A standard message will be logged by the `syslog()` facility when any resource control value on a sequence associated with this control is exceeded.

RCTL_GLOBAL_UNOBSERVABLE

The resource control (generally on a task- or project-related control) does not support observational control values. An RCPRIV_BASIC privileged control value placed by a process on the task or process will generate an action only if the value is exceeded by that process.

The local action and flags are those on the current resource control value represented by this resource control block. Valid actions and flags are listed in the table below. In the case of **RCTL_LOCAL_SIGNAL**, the second argument to `rctlblk_set_local_action()` contains the signal to be sent. Similarly, the signal to be sent is copied into the integer location specified by the second argument to `rctlblk_get_local_action()`. A restricted set of signals is made available for normal use by the resource control facility: SIGBART, SIGXRES, SIGHUP, SIGSTOP, SIGTERM, and SIGKILL. Other signals are permitted due to global properities of a specific control. Calls to `setrctl()` with illegal signals will fail.

RCTL_LOCAL_DENY

When this resource control value is encountered, the request for the resource will be denied. Set on all values if **RCTL_GLOBAL_DENY_ALWAYS** is set for this control; cleared on all values if **RCTL_GLOBAL_DENY_NEVER** is set for this control.

rctlblk_set_value(3C)

RCTL_LOCAL_MAXIMAL

This resource control value represents a request for the maximum amount of resource for this control. If RCTL_GLOBAL_INFINITE is set for this resource control, RCTL_LOCAL_MAXIMAL indicates an unlimited resource control value, one that will never be exceeded.

RCTL_LOCAL_NOACTION

No local action will be taken when this resource control value is exceeded.

RCTL_LOCAL_SIGNAL

The specified signal, sent by rctlblk_set_local_action(), will be sent to the process that placed this resource control value in the value sequence.

The rctlblk_get_recipient_pid() function returns the value of the process ID that placed the resource control value. This ID is set by the kernel by a caller invoking setrctl().

The rctlblk_get_privilege() function returns the privilege of the resource control block. Valid privileges are RCPRIV_BASIC, RCPRIV_PRIVILEGED, and RCPRIV_SYSTEM. System resource controls are read-only. Privileged resource controls require superuser privilege to write, unless the RCTL_GLOBAL_LOWERABLE global flag is set, in which case unprivileged applications can lower the value of a privileged control.

The rctlblk_get_value() and rctlblk_set_value() functions return or establish the enforced value associated with the resource control. In cases where the process, task, or project associated with the control possesses fewer capabilities than allowable by the current value, the value returned by rctlblk_get_enforced_value() will differ from that returned by rctlblk_get_value(). This capability difference arises with processes using an address space model smaller than the maximum address space model supported by the system.

The rctlblk_size() function returns the size of a resource control block for use in memory allocation. The rctlblk_t * type is an opaque pointer whose size is not connected with that of the resource control block itself. Use of rctlblk_size() is illustrated in the example below.

RETURN VALUES The various set routines have no return values. Incorrectly composed resource control blocks will generate errors when used with setrctl(2) or getrctl(2).

ERRORS No error values are returned. Incorrectly constructed resource control blocks will be rejected by the system calls.

EXAMPLES **EXAMPLE 1** Display the contents of a fetched resource control block.

The following example displays the contents of a fetched resource control block.

```
#include <rctl.h>

SYNOPSIS	<pre>#include <rctl.h> hrtime_t rctlblk_get_firing_time(rctlblk_t *rblk); int rctlblk_get_global_action(rctlblk_t *rblk); int rctlblk_get_global_flags(rctlblk_t *rblk); int rctlblk_get_local_action(rctlblk_t *rblk, int *signalp); int rctlblk_get_local_flags(rctlblk_t *rblk); rctl_priv_t rctlblk_get_privilege(rctlblk_t *rblk); id_t rctlblk_get_recipient_pid(rctlblk_t *rblk); rctl_qty_t rctlblk_get_value(rctlblk_t *rblk); rctl_qty_t rctlblk_get_enforced_value(rctlblk_t *rblk); void rctlblk_set_local_action(rctlblk_t *rblk, rctl_action_t action, int signal); void rctlblk_set_local_flags(rctlblk_t *rblk, int flags); void rctlblk_set_privilege(rctlblk_t *rblk, rctl_priv_t privilege); void rctlblk_set_value(rctlblk_t *rblk, rctl_qty_t value); size_t rctlblk_size(void);</pre>
DESCRIPTION	<p>The resource control block routines allow the establishment or retrieval of values from a resource control block used to transfer information using the <code>getrctl(2)</code> and <code>setrctl(2)</code> functions. Each of the routines accesses or sets the resource control block member corresponding to its name. Certain of these members are read-only and do not possess set routines.</p> <p>The firing time of a resource control block is 0 if the resource control action-value has not been exceeded for its lifetime on the process. Otherwise the firing time is the value of <code>gethrtime(3C)</code> at the moment the action on the resource control value was taken.</p> <p>The global actions and flags are the action and flags set by <code>rctladm(1M)</code>. These values cannot be set with <code>setrctl()</code>. Valid global actions are listed in the table below. Global flags are generally a published property of the control and are not modifiable.</p> <p>RCTL_GLOBAL_DENY_ALWAYS The action taken when a control value is exceeded on this control will always include denial of the resource.</p>

RCTL_GLOBAL_DENY_NEVER

The action taken when a control value is exceeded on this control will always exclude denial of the resource; the resource will always be granted, although other actions can also be taken.

RCTL_GLOBAL_CPU_TIME

The valid signals available as local actions include the SIGXCPU signal.

RCTL_GLOBAL_FILE_SIZE

The valid signals available as local actions include the SIGXFSZ signal.

RCTL_GLOBAL_INFINITE

This resource control supports the concept of an unlimited value; generally true only of accumulation-oriented resources, such as CPU time.

RCTL_GLOBAL_LOWERABLE

Non-privileged callers are able to lower the value of privileged resource control values on this control.

RCTL_GLOBAL_NOACTION

No global action will be taken when a resource control value is exceeded on this control.

RCTL_GLOBAL_NOBASIC

No values with the RCPRIV_BASIC privilege are permitted on this control.

RCTL_GLOBAL_NOLOCALACTION

No local actions are permitted on this control.

RCTL_GLOBAL_SYSLOG

A standard message will be logged by the `syslog()` facility when any resource control value on a sequence associated with this control is exceeded.

RCTL_GLOBAL_UNOBSERVABLE

The resource control (generally on a task- or project-related control) does not support observational control values. An RCPRIV_BASIC privileged control value placed by a process on the task or process will generate an action only if the value is exceeded by that process.

The local action and flags are those on the current resource control value represented by this resource control block. Valid actions and flags are listed in the table below. In the case of `RCTL_LOCAL_SIGNAL`, the second argument to `rctlblk_set_local_action()` contains the signal to be sent. Similarly, the signal to be sent is copied into the integer location specified by the second argument to `rctlblk_get_local_action()`. A restricted set of signals is made available for normal use by the resource control facility: `SIGBART`, `SIGXRES`, `SIGHUP`, `SIGSTOP`, `SIGTERM`, and `SIGKILL`. Other signals are permitted due to global properites of a specific control. Calls to `setrctl()` with illegal signals will fail.

RCTL_LOCAL_DENY

When this resource control value is encountered, the request for the resource will be denied. Set on all values if `RCTL_GLOBAL_DENY_ALWAYS` is set for this control; cleared on all values if `RCTL_GLOBAL_DENY_NEVER` is set for this control.

rctlblk_size(3C)

RCTL_LOCAL_MAXIMAL

This resource control value represents a request for the maximum amount of resource for this control. If RCTL_GLOBAL_INFINITE is set for this resource control, RCTL_LOCAL_MAXIMAL indicates an unlimited resource control value, one that will never be exceeded.

RCTL_LOCAL_NOACTION

No local action will be taken when this resource control value is exceeded.

RCTL_LOCAL_SIGNAL

The specified signal, sent by `rctlblk_set_local_action()`, will be sent to the process that placed this resource control value in the value sequence.

The `rctlblk_get_recipient_pid()` function returns the value of the process ID that placed the resource control value. This ID is set by the kernel by a caller invoking `setrctl()`.

The `rctlblk_get_privilege()` function returns the privilege of the resource control block. Valid privileges are RCPRIV_BASIC, RCPRIV_PRIVILEGED, and RCPRIV_SYSTEM. System resource controls are read-only. Privileged resource controls require superuser privilege to write, unless the RCTL_GLOBAL_LOWERABLE global flag is set, in which case unprivileged applications can lower the value of a privileged control.

The `rctlblk_get_value()` and `rctlblk_set_value()` functions return or establish the enforced value associated with the resource control. In cases where the process, task, or project associated with the control possesses fewer capabilities than allowable by the current value, the value returned by `rctlblk_get_enforced_value()` will differ from that returned by `rctlblk_get_value()`. This capability difference arises with processes using an address space model smaller than the maximum address space model supported by the system.

The `rctlblk_size()` function returns the size of a resource control block for use in memory allocation. The `rctlblk_t *` type is an opaque pointer whose size is not connected with that of the resource control block itself. Use of `rctlblk_size()` is illustrated in the example below.

RETURN VALUES The various set routines have no return values. Incorrectly composed resource control blocks will generate errors when used with `setrctl(2)` or `getrctl(2)`.

ERRORS No error values are returned. Incorrectly constructed resource control blocks will be rejected by the system calls.

EXAMPLES **EXAMPLE 1** Display the contents of a fetched resource control block.

The following example displays the contents of a fetched resource control block.

```
#include <rctl.h>
#include <stdio.h>
#include <stdlib.h>
```

EXAMPLE 1 Display the contents of a fetched resource control block. (Continued)

```

rctlblk_t *rblk;

rctl_walk(3C)

NAME	rctl_walk – visit registered rctls on current system
SYNOPSIS	<pre>#include <rctl.h> int rctl_walk(int (*callback) (const char *rctlname, void *walk_data), void *init_data);</pre>
DESCRIPTION	The rctl_walk() function provides a mechanism for the application author to examine all active resource controls (rctls) on the current system. The <i>callback</i> function provided by the application is given the name of an rctl at each invocation and can use the <i>walk_data</i> to record its own state. The callback function should return non-zero if it encounters an error condition or attempts to terminate the walk prematurely; otherwise the callback function should return 0.
RETURN VALUES	Upon successful completion, rctl_walk() returns 0. It returns -1 if the <i>callback</i> function returned a non-zero value or if the walk encountered an error, in which case <i>errno</i> is set to indicate the error.
ERRORS	The rctl_walk() function will fail if: ENOMEM There is insufficient memory available to set up the initial data for the walk. Other returned error values are presumably caused by the <i>callback</i> function.
EXAMPLES	<p>EXAMPLE 1 Count the number of rctls available on the system.</p> <p>The following example counts the number of resource controls on the system.</p> <pre>#include <sys/types.h> #include <rctl.h> #include <stdio.h> typedef struct wdata { uint_t count; } wdata_t; wdata_t total_count; int simple_callback(const char *name, void *pvt) { wdata_t *w = (wdata_t *)pvt; w->count++; return (0); } ... total_count.count = 0; errno = 0; if (rctl_walk(simple_callback, &total_count) == 0) (void) printf("count = %u\n", total_count.count);</pre>

readdir(3C)

NAME	readdir, readdir_r – read directory
SYNOPSIS	<pre>#include <sys/types.h> #include <dirent.h> struct dirent *readdir(DIR *dirp); struct dirent *readdir_r(DIR *dirp, struct dirent *entry);</pre>
POSIX	<pre>cc [flag ...] file ... -D_POSIX_PTHREAD_SEMANTICS [library ...] int readdir_r(DIR *dirp, struct dirent *entry, struct dirent **result);</pre>
DESCRIPTION	<p>The type <code>DIR</code>, which is defined in the header <code><dirent.h></code>, represents a <i>directory stream</i>, which is an ordered sequence of all the directory entries in a particular directory. Directory entries represent files; files may be removed from a directory or added to a directory asynchronously to the operation of <code>readdir()</code> and <code>readdir_r()</code>.</p>
<code>readdir()</code>	<p>The <code>readdir()</code> function returns a pointer to a structure representing the directory entry at the current position in the directory stream specified by the argument <code>dirp</code>, and positions the directory stream at the next entry. It returns a null pointer upon reaching the end of the directory stream. The structure <code>dirent</code> defined by the <code><dirent.h></code> header describes a directory entry.</p> <p>If entries for <code>.</code> (dot) or <code>..</code> (dot-dot) exist, one entry will be returned for dot and one entry will be returned for dot-dot; otherwise they will not be returned.</p> <p>The pointer returned by <code>readdir()</code> points to data which may be overwritten by another call to <code>readdir()</code> on the same directory stream. This data is not overwritten by another call to <code>readdir()</code> on a different directory stream.</p> <p>If a file is removed from or added to the directory after the most recent call to <code>opendir(3C)</code> or <code>rewinddir(3C)</code>, whether a subsequent call to <code>readdir()</code> returns an entry for that file is unspecified.</p> <p>The <code>readdir()</code> function may buffer several directory entries per actual read operation; <code>readdir()</code> marks for update the <code>st_atime</code> field of the directory each time the directory is actually read.</p> <p>After a call to <code>fork(2)</code>, either the parent or child (but not both) may continue processing the directory stream using <code>readdir()</code>, <code>rewinddir()</code> or <code>seekdir(3C)</code>. If both the parent and child processes use these functions, the result is undefined.</p> <p>If the entry names a symbolic link, the value of the <code>d_ino</code> member is unspecified.</p>
<code>readdir_r()</code>	<p>The <code>readdir_r()</code> function initializes the <code>dirent</code> structure referenced by <code>entry</code> to represent the directory entry at the current position in the directory stream referred to by <code>dirp</code>, and positions the directory stream at the next entry.</p>

The caller must allocate storage pointed to by *entry* to be large enough for a `dirent` structure with an array of `char d_name` member containing at least `NAME_MAX` (that is, `pathconf(_PC_NAME_MAX)`) plus one elements. `_PC_NAME_MAX` is defined in `<unistd.h>`.

The `readdir_r()` function will not return directory entries containing empty names. It is unspecified whether entries are returned for `.` (dot) or `..` (dot-dot).

If a file is removed from or added to the directory after the most recent call to `opendir()` or `rewinddir()`, whether a subsequent call to `readdir_r()` returns an entry for that file is unspecified.

The `readdir_r()` function may buffer several directory entries per actual read operation; the `readdir_r()` function marks for update the `st_atime` field of the directory each time the directory is actually read.

The POSIX version (see `standards(5)`) of the `readdir_r()` function initializes the structure referenced by *entry* and stores a pointer to this structure in *result*. On successful return, the pointer returned at **result* will be the same value as the argument *entry*. Upon reaching the end of the directory stream, this pointer will have the value `NULL`.

RETURN VALUES

Upon successful completion, `readdir()` and `readdir_r()` return a pointer to an object of type `struct dirent`. When an error is encountered, a null pointer is returned and `errno` is set to indicate the error. When the end of the directory is encountered, a null pointer is returned and `errno` is not changed. The POSIX `readdir_r()` returns 0 if successful or an error number to indicate failure.

ERRORS

The `readdir()` function will fail if:

<code>E_OVERFLOW</code>	One of the values in the structure to be returned cannot be represented correctly.
-------------------------	--

The `readdir()` and `readdir_r()` functions will fail if:

<code>EBADF</code>	The file descriptor determined by the <code>DIR</code> stream is no longer valid. This results if the <code>DIR</code> stream has been closed.
--------------------	--

<code>ENOENT</code>	The current file pointer for the directory is not located at a valid entry.
---------------------	---

The `readdir()` and `readdir_r()` functions may fail if:

<code>EBADF</code>	The <i>dirp</i> argument does not refer to an open directory stream.
--------------------	--

<code>ENOENT</code>	The current position of the directory stream is invalid.
---------------------	--

USAGE

The `readdir()` function should be used in conjunction with `opendir()`, `closedir()`, and `rewinddir()` to examine the contents of the directory. As `readdir()` returns a null pointer both at the end of the directory and on error, an application wishing to check for error situations should set `errno` to 0, then call `readdir()`, then check `errno` and if it is non-zero, assume an error has occurred.

readdir(3C)

Applications wishing to check for error situations should set `errno` to 0 before calling `readdir()`. If `errno` is set to non-zero on return, an error occurred.

The `readdir()` and `readdir_r()` functions have transitional interfaces for 64-bit file offsets. See `lf64(5)`.

EXAMPLES **EXAMPLE 1** Search the current directory for the entry *name*.

The following sample code will search the current directory for the entry *name*:

```
dirp = opendir(".");

while (dirp) {
    errno = 0;
    if ((dp = readdir(dirp)) != NULL) {
        if (strcmp(dp->d_name, name) == 0) {
            closedir(dirp);
            return FOUND;
        }
    } else {
        if (errno == 0) {
            closedir(dirp);
            return NOT_FOUND;
        }
        closedir(dirp);
        return READ_ERROR;
    }
}

return OPEN_ERROR;
```

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
MT-Level	See NOTES below.

NOTES When compiling multithreaded programs, see `Intro(3)`, *Notes On Multithreaded Applications*.

The `readdir()` function is unsafe in multithreaded applications. The `readdir_r()` function is safe, and should be used instead.

Solaris 2.4 and earlier releases provided a `readdir_r()` interface as specified in POSIX.1c Draft 6. The final POSIX.1c standard changed the interface as described above. Support for the Draft 6 interface is provided for compatibility only and may not be supported in future releases. New applications and libraries should use the POSIX standard interface.

readdir(3C)

For POSIX.1c-compliant applications, the `_POSIX_PTHREAD_SEMANTICS` and `_REENTRANT` flags are automatically turned on by defining the `_POSIX_C_SOURCE` flag with a value `>= 199506L`.

readdir(3UCB)

NAME	readdir – read a directory entry																						
SYNOPSIS	<pre><code>/usr/ucb/cc[flag ...] file ... #include <sys/types.h> #include <sys/dir.h> struct direct *readdir(dirp); DIR *dirp;</code></pre>																						
DESCRIPTION	<p>The <code>readdir()</code> function returns a pointer to a structure representing the directory entry at the current position in the directory stream to which <code>dirp</code> refers, and positions the directory stream at the next entry, except on read-only file systems. It returns a NULL pointer upon reaching the end of the directory stream, or upon detecting an invalid location in the directory. The <code>readdir()</code> function shall not return directory entries containing empty names. It is unspecified whether entries are returned for dot (<code>.</code>) or dot-dot (<code>..</code>). The pointer returned by <code>readdir()</code> points to data that may be overwritten by another call to <code>readdir()</code> on the same directory stream. This data shall not be overwritten by another call to <code>readdir()</code> on a different directory stream. The <code>readdir()</code> function may buffer several directory entries per actual read operation. The <code>readdir()</code> function marks for update the <code>st_atime</code> field of the directory each time the directory is actually read.</p>																						
RETURN VALUES	The <code>readdir()</code> function returns NULL on failure and sets <code>errno</code> to indicate the error.																						
ERRORS	<p>The <code>readdir()</code> function will fail if one or more of the following are true:</p> <table><tr><td>EAGAIN</td><td>Mandatory file/record locking was set, <code>O_NDELAY</code> or <code>O_NONBLOCK</code> was set, and there was a blocking record lock.</td></tr><tr><td>EAGAIN</td><td>Total amount of system memory available when reading using raw I/O is temporarily insufficient.</td></tr><tr><td>EAGAIN</td><td>No data is waiting to be read on a file associated with a tty device and <code>O_NONBLOCK</code> was set.</td></tr><tr><td>EAGAIN</td><td>No message is waiting to be read on a stream and <code>O_NDELAY</code> or <code>O_NONBLOCK</code> was set.</td></tr><tr><td>EBADF</td><td>The file descriptor determined by the DIR stream is no longer valid. EAGAIN	Total amount of system memory available when reading using raw I/O is temporarily insufficient.	EAGAIN	No data is waiting to be read on a file associated with a tty device and <code>O_NONBLOCK</code> was set.	EAGAIN	No message is waiting to be read on a stream and <code>O_NDELAY</code> or <code>O_NONBLOCK</code> was set.	EBADF	The file descriptor determined by the DIR stream is no longer valid. This results if the DIR stream has been closed.	EBADMSG	Message waiting to be read on a stream is not a data message.	EDEADLK	The <code>read()</code> was going to go to sleep and cause a deadlock to occur.	EFAULT	<code>buf</code> points to an illegal address.	EINTR	A signal was caught during the <code>read()</code> or <code>readv()</code> function.	EINVAL	Attempted to read from a stream linked to a multiplexor.	EIO	A physical I/O error has occurred, or the process is in a background process group and is attempting to read from its
EAGAIN	Mandatory file/record locking was set, <code>O_NDELAY</code> or <code>O_NONBLOCK</code> was set, and there was a blocking record lock.																						
EAGAIN	Total amount of system memory available when reading using raw I/O is temporarily insufficient.																						
EAGAIN	No data is waiting to be read on a file associated with a tty device and <code>O_NONBLOCK</code> was set.																						
EAGAIN	No message is waiting to be read on a stream and <code>O_NDELAY</code> or <code>O_NONBLOCK</code> was set.																						
EBADF	The file descriptor determined by the DIR stream is no longer valid. This results if the DIR stream has been closed.																						
EBADMSG	Message waiting to be read on a stream is not a data message.																						
EDEADLK	The <code>read()</code> was going to go to sleep and cause a deadlock to occur.																						
EFAULT	<code>buf</code> points to an illegal address.																						
EINTR	A signal was caught during the <code>read()</code> or <code>readv()</code> function.																						
EINVAL	Attempted to read from a stream linked to a multiplexor.																						
EIO	A physical I/O error has occurred, or the process is in a background process group and is attempting to read from its																						

controlling terminal, and either the process is ignoring or blocking the SIGTTIN signal or the process group of the process is orphaned.

ENOENT	The current file pointer for the directory is not located at a valid entry.
ENOLCK	The system record lock table was full, so the <code>read()</code> or <code>readv()</code> could not go to sleep until the blocking record lock was removed.
ENOLINK	<i>fildev</i> is on a remote machine and the link to that machine is no longer active.
ENXIO	The device associated with <i>fildev</i> is a block special or character special file and the value of the file pointer is out of range.
EOVERFLOW	The value of the <code>direct</code> structure member <code>d_ino</code> cannot be represented in an <code>ino_t</code> .

USAGE The `readdir()` function has a transitional interface for 64-bit file offsets. See `lf64(5)`.

SEE ALSO `getdents(2)`, `readdir(3C)`, `scandir(3UCB)`, `lf64(5)`

NOTES Use of these interfaces should be restricted to only applications written on BSD platforms. Use of these interfaces with any of the system libraries or in multi-thread applications is unsupported.

readdir_r(3C)

NAME	readdir, readdir_r – read directory
SYNOPSIS	<pre>#include <sys/types.h> #include <dirent.h> struct dirent *readdir(DIR *dirp); struct dirent *readdir_r(DIR *dirp, struct dirent *entry);</pre>
POSIX	<pre>cc [flag ...] file ... -D_POSIX_PTHREAD_SEMANTICS [library ...] int readdir_r(DIR *dirp, struct dirent *entry, struct dirent **result);</pre>
DESCRIPTION	<p>The type <code>DIR</code>, which is defined in the header <code><dirent.h></code>, represents a <i>directory stream</i>, which is an ordered sequence of all the directory entries in a particular directory. Directory entries represent files; files may be removed from a directory or added to a directory asynchronously to the operation of <code>readdir()</code> and <code>readdir_r()</code>.</p>
<code>readdir()</code>	<p>The <code>readdir()</code> function returns a pointer to a structure representing the directory entry at the current position in the directory stream specified by the argument <code>dirp</code>, and positions the directory stream at the next entry. It returns a null pointer upon reaching the end of the directory stream. The structure <code>dirent</code> defined by the <code><dirent.h></code> header describes a directory entry.</p> <p>If entries for <code>.</code> (dot) or <code>..</code> (dot-dot) exist, one entry will be returned for dot and one entry will be returned for dot-dot; otherwise they will not be returned.</p> <p>The pointer returned by <code>readdir()</code> points to data which may be overwritten by another call to <code>readdir()</code> on the same directory stream. This data is not overwritten by another call to <code>readdir()</code> on a different directory stream.</p> <p>If a file is removed from or added to the directory after the most recent call to <code>opendir(3C)</code> or <code>rewinddir(3C)</code>, whether a subsequent call to <code>readdir()</code> returns an entry for that file is unspecified.</p> <p>The <code>readdir()</code> function may buffer several directory entries per actual read operation; <code>readdir()</code> marks for update the <code>st_atime</code> field of the directory each time the directory is actually read.</p> <p>After a call to <code>fork(2)</code>, either the parent or child (but not both) may continue processing the directory stream using <code>readdir()</code>, <code>rewinddir()</code> or <code>seekdir(3C)</code>. If both the parent and child processes use these functions, the result is undefined.</p> <p>If the entry names a symbolic link, the value of the <code>d_ino</code> member is unspecified.</p>
<code>readdir_r()</code>	<p>The <code>readdir_r()</code> function initializes the <code>dirent</code> structure referenced by <code>entry</code> to represent the directory entry at the current position in the directory stream referred to by <code>dirp</code>, and positions the directory stream at the next entry.</p>

The caller must allocate storage pointed to by *entry* to be large enough for a `dirent` structure with an array of `char d_name` member containing at least `NAME_MAX` (that is, `pathconf(_PC_NAME_MAX)`) plus one elements. `_PC_NAME_MAX` is defined in `<unistd.h>`.

The `readdir_r()` function will not return directory entries containing empty names. It is unspecified whether entries are returned for `.` (dot) or `..` (dot-dot).

If a file is removed from or added to the directory after the most recent call to `opendir()` or `rewinddir()`, whether a subsequent call to `readdir_r()` returns an entry for that file is unspecified.

The `readdir_r()` function may buffer several directory entries per actual read operation; the `readdir_r()` function marks for update the `st_atime` field of the directory each time the directory is actually read.

The POSIX version (see `standards(5)`) of the `readdir_r()` function initializes the structure referenced by *entry* and stores a pointer to this structure in *result*. On successful return, the pointer returned at **result* will be the same value as the argument *entry*. Upon reaching the end of the directory stream, this pointer will have the value `NULL`.

RETURN VALUES

Upon successful completion, `readdir()` and `readdir_r()` return a pointer to an object of type `struct dirent`. When an error is encountered, a null pointer is returned and `errno` is set to indicate the error. When the end of the directory is encountered, a null pointer is returned and `errno` is not changed. The POSIX `readdir_r()` returns 0 if successful or an error number to indicate failure.

ERRORS

The `readdir()` function will fail if:

<code>EOVERFLOW</code>	One of the values in the structure to be returned cannot be represented correctly.
------------------------	--

The `readdir()` and `readdir_r()` functions will fail if:

<code>EBADF</code>	The file descriptor determined by the <code>DIR</code> stream is no longer valid. This results if the <code>DIR</code> stream has been closed.
--------------------	--

<code>ENOENT</code>	The current file pointer for the directory is not located at a valid entry.
---------------------	---

The `readdir()` and `readdir_r()` functions may fail if:

<code>EBADF</code>	The <i>dirp</i> argument does not refer to an open directory stream.
--------------------	--

<code>ENOENT</code>	The current position of the directory stream is invalid.
---------------------	--

readdir_r(3C)

USAGE The `readdir()` function should be used in conjunction with `opendir()`, `closedir()`, and `rewinddir()` to examine the contents of the directory. As `readdir()` returns a null pointer both at the end of the directory and on error, an application wishing to check for error situations should set `errno` to 0, then call `readdir()`, then check `errno` and if it is non-zero, assume an error has occurred.

Applications wishing to check for error situations should set `errno` to 0 before calling `readdir()`. If `errno` is set to non-zero on return, an error occurred.

The `readdir()` and `readdir_r()` functions have transitional interfaces for 64-bit file offsets. See `lf64(5)`.

EXAMPLES **EXAMPLE 1** Search the current directory for the entry *name*.

The following sample code will search the current directory for the entry *name*:

```
dirp = opendir(".");

while (dirp) {
    errno = 0;
    if ((dp = readdir(dirp)) != NULL) {
        if (strcmp(dp->d_name, name) == 0) {
            closedir(dirp);
            return FOUND;
        }
    } else {
        if (errno == 0) {
            closedir(dirp);
            return NOT_FOUND;
        }
        closedir(dirp);
        return READ_ERROR;
    }
}

return OPEN_ERROR;
```

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
MT-Level	See NOTES below.

NOTES When compiling multithreaded programs, see `Intro(3)`, *Notes On Multithreaded Applications*.

The `readdir()` function is unsafe in multithreaded applications. The `readdir_r()` function is safe, and should be used instead.

readdir_r(3C)

Solaris 2.4 and earlier releases provided a `readdir_r()` interface as specified in POSIX.1c Draft 6. The final POSIX.1c standard changed the interface as described above. Support for the Draft 6 interface is provided for compatibility only and may not be supported in future releases. New applications and libraries should use the POSIX standard interface.

For POSIX.1c-compliant applications, the `_POSIX_PTHREAD_SEMANTICS` and `_REENTRANT` flags are automatically turned on by defining the `_POSIX_C_SOURCE` flag with a value $\geq 199506L$.

SEE ALSO `fork(2)`, `lstat(2)`, `symlink(2)`, `Intro(3)`, `closedir(3C)`, `opendir(3C)`, `rewinddir(3C)`, `seekdir(3C)`, `attributes(5)`, `lf64(5)`, `standards(5)`

realloc(3C)

NAME	malloc, calloc, free, memalign, realloc, valloc, alloca – memory allocator
SYNOPSIS	<pre>#include <stdlib.h> void *malloc(size_t size); void *calloc(size_t nelem, size_t elsize); void free(void *ptr); void *memalign(size_t alignment, size_t size); void *realloc(void *ptr, size_t size); void *valloc(size_t size); #include <alloca.h> void *alloca(size_t size);</pre>
DESCRIPTION	<p>The <code>malloc()</code> and <code>free()</code> functions provide a simple, general-purpose memory allocation package. The <code>malloc()</code> function returns a pointer to a block of at least <i>size</i> bytes suitably aligned for any use. If the space assigned by <code>malloc()</code> is overrun, the results are undefined.</p> <p>The argument to <code>free()</code> is a pointer to a block previously allocated by <code>malloc()</code>, <code>calloc()</code>, or <code>realloc()</code>. After <code>free()</code> is executed, this space is made available for further allocation by the application, though not returned to the system. Memory is returned to the system only upon termination of the application. If <i>ptr</i> is a null pointer, no action occurs. If a random number is passed to <code>free()</code>, the results are undefined.</p> <p>The <code>calloc()</code> function allocates space for an array of <i>nelem</i> elements of size <i>elsize</i>. The space is initialized to zeros.</p> <p>The <code>memalign()</code> function allocates <i>size</i> bytes on a specified alignment boundary and returns a pointer to the allocated block. The value of the returned address is guaranteed to be an even multiple of <i>alignment</i>. The value of <i>alignment</i> must be a power of two and must be greater than or equal to the size of a word.</p> <p>The <code>realloc()</code> function changes the size of the block pointed to by <i>ptr</i> to <i>size</i> bytes and returns a pointer to the (possibly moved) block. The contents will be unchanged up to the lesser of the new and old sizes. If <i>ptr</i> is <code>NULL</code>, <code>realloc()</code> behaves like <code>malloc()</code> for the specified size. If <i>size</i> is 0 and <i>ptr</i> is not a null pointer, the space pointed to is made available for further allocation by the application, though not returned to the system. Memory is returned to the system only upon termination of the application.</p> <p>The <code>valloc()</code> function has the same effect as <code>malloc()</code>, except that the allocated memory will be aligned to a multiple of the value returned by <code>sysconf(_SC_PAGESIZE)</code>.</p>

- The `alloca()` function allocates *size* bytes of space in the stack frame of the caller, and returns a pointer to the allocated block. This temporary space is automatically freed when the caller returns. If the allocated block is beyond the current stack limit, the resulting behavior is undefined.
- RETURN VALUES** Upon successful completion, each of the allocation functions returns a pointer to space suitably aligned (after possible pointer coercion) for storage of any type of object.
- If there is no available memory, `malloc()`, `realloc()`, `memalign()`, `valloc()`, and `calloc()` return a null pointer. When `realloc()` is called with *size* > 0 and returns `NULL`, the block pointed to by *ptr* is left intact. If *size*, *nelem*, or *elsize* is 0, either a null pointer or a unique pointer that can be passed to `free()` is returned.
- If `malloc()`, `calloc()`, or `realloc()` returns unsuccessfully, `errno` will be set to indicate the error. The `free()` function does not set `errno`.
- ERRORS** The `malloc()`, `calloc()`, and `realloc()` functions will fail if:
- | | |
|---------------------|--|
| <code>ENOMEM</code> | The physical limits of the system are exceeded by <i>size</i> bytes of memory which cannot be allocated. |
| <code>EAGAIN</code> | There is not enough memory available to allocate <i>size</i> bytes of memory; but the application could try again later. |
- USAGE** Portable applications should avoid using `valloc()` but should instead use `malloc()` or `mmap(2)`. On systems with a large page size, the number of successful `valloc()` operations might be 0.
- Comparative features of `malloc(3C)`, `bsdmalloc(3MALLOC)`, and `malloc(3MALLOC)` are as follows:
- The `bsdmalloc(3MALLOC)` routines afford better performance, but are space-inefficient.
 - The `malloc(3MALLOC)` routines are space-efficient, but have slower performance.
 - The standard, fully SCD-compliant `malloc` routines are a trade-off between performance and space-efficiency.
- ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:
- | ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|---------------------|--|
| Interface Stability | <code>malloc()</code> , <code>calloc()</code> , <code>free()</code> , <code>realloc()</code> , <code>valloc()</code> are Standard; <code>memalign()</code> and <code>alloca()</code> are Stable. |
| MT-Level | Safe |
- SEE ALSO** `brk(2)`, `getrlimit(2)`, `bsdmalloc(3MALLOC)`, `malloc(3MALLOC)`, `mapmalloc(3MALLOC)`, `watchmalloc(3MALLOC)`, `attributes(5)`

realloc(3C)

WARNINGS | Undefined results will occur if the size requested for a block of memory exceeds the maximum size of a process's heap, which can be obtained with `getrlimit(2)`

The `alloca()` function is machine-, compiler-, and most of all, system-dependent. Its use is strongly discouraged.

NAME	malloc, free, realloc, calloc, malloc, mallinfo – memory allocator				
SYNOPSIS	<pre>cc [<i>flag ...</i>] <i>file ...</i> -lmalloc [<i>library ...</i>] #include <stdlib.h> void *malloc(size_t <i>size</i>); void free(void *<i>ptr</i>); void *realloc(void *<i>ptr</i>, size_t <i>size</i>); void *calloc(size_t <i>nelem</i>, size_t <i>elsize</i>); #include <malloc.h> int mallopt(int <i>cmd</i>, int <i>value</i>); struct mallinfo mallinfo(void);</pre>				
DESCRIPTION	<p>The malloc() and free() functions provide a simple general-purpose memory allocation package.</p> <p>The malloc() function returns a pointer to a block of at least <i>size</i> bytes suitably aligned for any use.</p> <p>The argument to free() is a pointer to a block previously allocated by malloc(). After free() is performed, this space is made available for further allocation, and its contents have been destroyed. See mallopt() below for a way to change this behavior. If <i>ptr</i> is a null pointer, no action occurs.</p> <p>Undefined results occur if the space assigned by malloc() is overrun or if some random number is handed to free().</p> <p>The realloc() function changes the size of the block pointed to by <i>ptr</i> to <i>size</i> bytes and returns a pointer to the (possibly moved) block. The contents are unchanged up to the lesser of the new and old sizes. If <i>ptr</i> is a null pointer, realloc() behaves like malloc() for the specified size. If <i>size</i> is 0 and <i>ptr</i> is not a null pointer, the object it points to is freed.</p> <p>The calloc() function allocates space for an array of <i>nelem</i> elements of size <i>elsize</i>. The space is initialized to zeros.</p> <p>The mallopt() function provides for control over the allocation algorithm. The available values for <i>cmd</i> are:</p> <table border="0" style="margin-left: 20px;"> <tr> <td style="padding-right: 20px;">M_MXFAST</td> <td>Set <i>maxfast</i> to <i>value</i>. The algorithm allocates all blocks below the size of <i>maxfast</i> in large groups and then does them out very quickly. The default value for <i>maxfast</i> is 24.</td> </tr> <tr> <td>M_NLBLKS</td> <td>Set <i>numlblks</i> to <i>value</i>. The above mentioned “large groups” each contain <i>numlblks</i> blocks. <i>numlblks</i> must be greater than 0. The default value for <i>numlblks</i> is 100.</td> </tr> </table>	M_MXFAST	Set <i>maxfast</i> to <i>value</i> . The algorithm allocates all blocks below the size of <i>maxfast</i> in large groups and then does them out very quickly. The default value for <i>maxfast</i> is 24.	M_NLBLKS	Set <i>numlblks</i> to <i>value</i> . The above mentioned “large groups” each contain <i>numlblks</i> blocks. <i>numlblks</i> must be greater than 0. The default value for <i>numlblks</i> is 100.
M_MXFAST	Set <i>maxfast</i> to <i>value</i> . The algorithm allocates all blocks below the size of <i>maxfast</i> in large groups and then does them out very quickly. The default value for <i>maxfast</i> is 24.				
M_NLBLKS	Set <i>numlblks</i> to <i>value</i> . The above mentioned “large groups” each contain <i>numlblks</i> blocks. <i>numlblks</i> must be greater than 0. The default value for <i>numlblks</i> is 100.				

realloc(3MALLOC)

M_GRAIN	Set <i>grain</i> to <i>value</i> . The sizes of all blocks smaller than <i>maxfast</i> are considered to be rounded up to the nearest multiple of <i>grain</i> . <i>grain</i> must be greater than 0. The default value of <i>grain</i> is the smallest number of bytes that will allow alignment of any data type. Value will be rounded up to a multiple of the default when <i>grain</i> is set.
M_KEEP	Preserve data in a freed block until the next <code>malloc()</code> , <code>realloc()</code> , or <code>calloc()</code> . This option is provided only for compatibility with the old version of <code>malloc()</code> , and it is not recommended.

These values are defined in the `<malloc.h>` header.

The `mallot()` function can be called repeatedly, but cannot be called after the first small block is allocated.

The `mallinfo()` function provides instrumentation describing space usage. It returns the `mallinfo` structure with the following members:

```
unsigned long arena;      /* total space in arena */
unsigned long ordblks;    /* number of ordinary blocks */
unsigned long smlbks;     /* number of small blocks */
unsigned long hblkhd;     /* space in holding block headers */
unsigned long hblks;     /* number of holding blocks */
unsigned long usmlbks;    /* space in small blocks in use */
unsigned long fsmblks;    /* space in free small blocks */
unsigned long uordblks;   /* space in ordinary blocks in use */
unsigned long fordblks;   /* space in free ordinary blocks */
unsigned long keepcost;   /* space penalty if keep option */
                        /* is used */
```

The `mallinfo` structure is defined in the `<malloc.h>` header.

Each of the allocation routines returns a pointer to space suitably aligned (after possible pointer coercion) for storage of any type of object.

RETURN VALUES

The `malloc()`, `realloc()`, and `calloc()` functions return a null pointer if there is not enough available memory. When `realloc()` returns `NULL`, the block pointed to by *ptr* is left intact. If `mallot()` is called after any allocation or if *cmd* or *value* are invalid, a non-zero value is returned. Otherwise, it returns 0.

ERRORS

If `malloc()`, `calloc()`, or `realloc()` returns unsuccessfully, `errno` is set to indicate the error:

ENOMEM	<i>size</i> bytes of memory exceeds the physical limits of your system, and cannot be allocated.
EAGAIN	There is not enough memory available at this point in time to allocate <i>size</i> bytes of memory; but the application could try again later.

realloc(3MALLOC)

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
MT-Level	Safe

SEE ALSO `brk(2)`, `bsdmalloc(3MALLOC)`, `libmtmalloc(3LIB)`, `malloc(3C)`, `mapmalloc(3MALLOC)`, `mtmalloc(3MALLOC)`, `watchmalloc(3MALLOC)`, `attributes(5)`

NOTES Note that unlike `malloc(3C)`, this package does not preserve the contents of a block when it is freed, unless the `M_KEEP` option of `mallopt()` is used.

Undocumented features of `malloc(3C)` have not been duplicated.

Function prototypes for `malloc()`, `realloc()`, `calloc()`, and `free()` are also defined in the `<malloc.h>` header for compatibility with old applications. New applications should include `<stdlib.h>` to access the prototypes for these functions. Comparative Features of these `malloc` routines, `bsdmalloc(3MALLOC)`, and `malloc(3C)`

- These `malloc` routines are space-efficient but have slower performance.
- The `bsdmalloc(3MALLOC)` routines afford better performance but are space-inefficient.
- The standard, fully SCD-compliant `malloc(3C)` routines are a trade-off between performance and space-efficiency.

The `free()` function does not set `errno`.

realpath(3C)

NAME	realpath – resolve pathname																		
SYNOPSIS	<pre>#include <stdlib.h> char *realpath(const char *file_name, char *resolved_name) ;</pre>																		
DESCRIPTION	<p>The <code>realpath()</code> function derives, from the pathname pointed to by <code>file_name</code>, an absolute pathname that names the same file, whose resolution does not involve ".", ". . .", or symbolic links. The generated pathname, using <code>PATH_MAX</code> bytes, is stored in the buffer pointed to by <code>resolved_name</code>.</p> <p>The <code>realpath()</code> function can handle both relative and absolute path names. For absolute path names and the relative names whose resolved name cannot be expressed relatively (for example, <code>. . / . . /reldir</code>), it returns the <i>resolved absolute</i> name. For the other relative path names, it returns the <i>resolved relative</i> name.</p>																		
RETURN VALUES	On successful completion, <code>realpath()</code> returns a pointer to the resolved name. Otherwise, <code>realpath()</code> returns a null pointer and sets <code>errno</code> to indicate the error, and the contents of the buffer pointed to by <code>resolved_name</code> are undefined.																		
ERRORS	<p>The <code>realpath()</code> function will fail if:</p> <table><tr><td>EACCES</td><td>Read or search permission was denied for a component of <code>file_name</code>.</td></tr><tr><td>EINVAL</td><td>Either the <code>file_name</code> or <code>resolved_name</code> argument is a null pointer.</td></tr><tr><td>EIO</td><td>An error occurred while reading from the file system.</td></tr><tr><td>ELOOP</td><td>Too many symbolic links were encountered in resolving <code>path</code>.</td></tr><tr><td>ENAMETOOLONG</td><td>The <code>file_name</code> argument is longer than <code>PATH_MAX</code> or a pathname component is longer than <code>NAME_MAX</code>.</td></tr><tr><td>ENOENT</td><td>A component of <code>file_name</code> does not name an existing file or <code>file_name</code> points to an empty string.</td></tr><tr><td>ENOTDIR</td><td>A component of the path prefix is not a directory.</td></tr></table> <p>The <code>realpath()</code> function may fail if:</p> <table><tr><td>ENAMETOOLONG</td><td>Pathname resolution of a symbolic link produced an intermediate result whose length exceeds <code>PATH_MAX</code>.</td></tr><tr><td>ENOMEM</td><td>Insufficient storage space is available.</td></tr></table>	EACCES	Read or search permission was denied for a component of <code>file_name</code> .	EINVAL	Either the <code>file_name</code> or <code>resolved_name</code> argument is a null pointer.	EIO	An error occurred while reading from the file system.	ELOOP	Too many symbolic links were encountered in resolving <code>path</code> .	ENAMETOOLONG	The <code>file_name</code> argument is longer than <code>PATH_MAX</code> or a pathname component is longer than <code>NAME_MAX</code> .	ENOENT	A component of <code>file_name</code> does not name an existing file or <code>file_name</code> points to an empty string.	ENOTDIR	A component of the path prefix is not a directory.	ENAMETOOLONG	Pathname resolution of a symbolic link produced an intermediate result whose length exceeds <code>PATH_MAX</code> .	ENOMEM	Insufficient storage space is available.
EACCES	Read or search permission was denied for a component of <code>file_name</code> .																		
EINVAL	Either the <code>file_name</code> or <code>resolved_name</code> argument is a null pointer.																		
EIO	An error occurred while reading from the file system.																		
ELOOP	Too many symbolic links were encountered in resolving <code>path</code> .																		
ENAMETOOLONG	The <code>file_name</code> argument is longer than <code>PATH_MAX</code> or a pathname component is longer than <code>NAME_MAX</code> .																		
ENOENT	A component of <code>file_name</code> does not name an existing file or <code>file_name</code> points to an empty string.																		
ENOTDIR	A component of the path prefix is not a directory.																		
ENAMETOOLONG	Pathname resolution of a symbolic link produced an intermediate result whose length exceeds <code>PATH_MAX</code> .																		
ENOMEM	Insufficient storage space is available.																		
USAGE	<p>The <code>realpath()</code> function operates on null-terminated strings.</p> <p>One should have execute permission on all the directories in the given and the resolved path.</p>																		

The `realpath()` function may fail to return to the current directory if an error occurs.

reboot(3C)

NAME	reboot – reboot system or halt processor								
SYNOPSIS	<pre>#include <sys/reboot.h> int reboot(int <i>howto</i>, char *<i>bootargs</i>);</pre>								
DESCRIPTION	<p>The <code>reboot()</code> function reboots the system. The <i>howto</i> argument specifies the behavior of the system while rebooting and is a mask constructed by a bitwise-inclusive-OR of flags from the following list:</p> <table><tr><td>RE_AUTOBOOT</td><td>The machine is rebooted from the root filesystem on the default boot device. This is the default behavior. See <code>boot(1M)</code> and <code>kernel(1M)</code>.</td></tr><tr><td>RB_HALT</td><td>The processor is simply halted; no reboot takes place. This option should be used with caution.</td></tr><tr><td>RB_ASKNAME</td><td>Interpreted by the bootstrap program and kernel, causing the user to be asked for pathnames during the bootstrap.</td></tr><tr><td>RB_DUMP</td><td>The system is forced to panic immediately without any further processing and a crash dump is written to the dump device (see <code>dumpadm(1M)</code>) before rebooting.</td></tr></table> <p>Any other <i>howto</i> argument causes the kernel file to boot.</p> <p>The interpretation of the <i>bootargs</i> argument is platform-dependent.</p>	RE_AUTOBOOT	The machine is rebooted from the root filesystem on the default boot device. This is the default behavior. See <code>boot(1M)</code> and <code>kernel(1M)</code> .	RB_HALT	The processor is simply halted; no reboot takes place. This option should be used with caution.	RB_ASKNAME	Interpreted by the bootstrap program and kernel, causing the user to be asked for pathnames during the bootstrap.	RB_DUMP	The system is forced to panic immediately without any further processing and a crash dump is written to the dump device (see <code>dumpadm(1M)</code>) before rebooting.
RE_AUTOBOOT	The machine is rebooted from the root filesystem on the default boot device. This is the default behavior. See <code>boot(1M)</code> and <code>kernel(1M)</code> .								
RB_HALT	The processor is simply halted; no reboot takes place. This option should be used with caution.								
RB_ASKNAME	Interpreted by the bootstrap program and kernel, causing the user to be asked for pathnames during the bootstrap.								
RB_DUMP	The system is forced to panic immediately without any further processing and a crash dump is written to the dump device (see <code>dumpadm(1M)</code>) before rebooting.								
RETURN VALUES	Upon successful completion, <code>reboot()</code> never returns. Otherwise, <code>-1</code> is returned and <code>errno</code> is set to indicate the error.								
ERRORS	The <code>reboot()</code> function will fail if: <table><tr><td>EPERM</td><td>The caller is not the super-user.</td></tr></table>	EPERM	The caller is not the super-user.						
EPERM	The caller is not the super-user.								
USAGE	Only the super-user may <code>reboot()</code> a machine.

NAME	re_comp, re_exec – compile and execute regular expressions
SYNOPSIS	<pre>#include <re_comp.h> char *re_comp(const char *string); int re_exec(const char *string);</pre>
DESCRIPTION	<p>The re_comp() function converts a regular expression string (RE) into an internal form suitable for pattern matching. The re_exec() function compares the string pointed to by the <i>string</i> argument with the last regular expression passed to re_comp().</p> <p>If re_comp() is called with a null pointer argument, the current regular expression remains unchanged.</p> <p>Strings passed to both re_comp() and re_exec() must be terminated by a null byte, and may include NEWLINE characters.</p> <p>The re_comp() and re_exec() functions support <i>simple regular expressions</i>, which are defined on the regexp(5) manual page. The regular expressions of the form <code>\{m\}</code>, <code>\{m,\}</code>, or <code>\{m,n\}</code> are not supported.</p>
RETURN VALUES	<p>The re_comp() function returns a null pointer when the string pointed to by the <i>string</i> argument is successfully converted. Otherwise, a pointer to one of the following error message strings is returned:</p> <pre>No previous regular expression Regular expression too long unmatched \ (missing] too many \ (\) pairs unmatched \)</pre> <p>Upon successful completion, re_exec() returns 1 if <i>string</i> matches the last compiled regular expression. Otherwise, re_exec() returns 0 if <i>string</i> fails to match the last compiled regular expression, and -1 if the compiled regular expression is invalid (indicating an internal error).</p>
ERRORS	No errors are defined.
USAGE	For portability to implementations conforming to X/Open standards prior to SUS, regcomp(3C) and regexexec(3C) are preferred to these functions. See standards(5).

ERRORS	No errors are defined.
USAGE	For portability to implementations conforming to X/Open standards prior to SUS, regcomp(3C) and regexec(3C) are preferred to these functions. See standards(5).
SEE ALSO	grep(1), regcmp(1), regcmp(3C), regcomp(3C), regexec(3C), regexpr(3GEN), regexp(5), standards(5)

NAME	regcmp, regex – compile and execute regular expression												
SYNOPSIS	<pre>#include <libgen.h> char *regcmp(const char *string1, /* char *string2 */ ..., int /* (char*) 0 */); char *regex(const char *re, const char *subject, /* char *ret0 */ ...); extern char *__loc1;</pre>												
DESCRIPTION	<p>The <code>regcmp()</code> function compiles a regular expression (consisting of the concatenated arguments) and returns a pointer to the compiled form. The <code>malloc(3C)</code> function is used to create space for the compiled form. It is the user's responsibility to free unneeded space so allocated. A <code>NULL</code> return from <code>regcmp()</code> indicates an incorrect argument. <code>regcmp(1)</code> has been written to generally preclude the need for this routine at execution time.</p> <p>The <code>regex()</code> function executes a compiled pattern against the subject string. Additional arguments are passed to receive values back. The <code>regex()</code> function returns <code>NULL</code> on failure or a pointer to the next unmatched character on success. A global character pointer <code>__loc1</code> points to where the match began. The <code>regcmp()</code> and <code>regex()</code> functions were mostly borrowed from the editor <code>ed(1)</code>; however, the syntax and semantics have been changed slightly. The following are the valid symbols and associated meanings.</p> <table border="0" style="width: 100%;"> <tr> <td style="vertical-align: top; padding-right: 10px;">[] * . ^</td> <td>This group of symbols retains its meaning as described on the <code>regex(5)</code> manual page.</td> </tr> <tr> <td style="vertical-align: top; padding-right: 10px;">\$</td> <td>Matches the end of the string; <code>\n</code> matches a newline.</td> </tr> <tr> <td style="vertical-align: top; padding-right: 10px;">–</td> <td>Within brackets the minus means <i>through</i>. For example, <code>[a–z]</code> is equivalent to <code>[abcd . . .xyz]</code>. The <code>–</code> can appear as itself only if used as the first or last character. For example, the character class expression <code>[]–]</code> matches the characters <code>]</code> and <code>–</code>.</td> </tr> <tr> <td style="vertical-align: top; padding-right: 10px;">+</td> <td>A regular expression followed by <code>+</code> means <i>one or more times</i>. For example, <code>[0–9]+</code> is equivalent to <code>[0–9][0–9]*</code>.</td> </tr> <tr> <td style="vertical-align: top; padding-right: 10px;">{m} {m,} {m,u}</td> <td>Integer values enclosed in <code>{ }</code> indicate the number of times the preceding regular expression is to be applied. The value <code>m</code> is the minimum number and <code>u</code> is a number, less than 256, which is the maximum. If only <code>m</code> is present (that is, <code>{m}</code>), it indicates the exact number of times the regular expression is to be applied. The value <code>{m, }</code> is analogous to <code>{m,infinity}</code>. The plus (<code>+</code>) and star (<code>*</code>) operations are equivalent to <code>{1, }</code> and <code>{0, }</code> respectively.</td> </tr> <tr> <td style="vertical-align: top; padding-right: 10px;">(. . .)\$n</td> <td>The value of the enclosed regular expression is to be returned. The value will be stored in the $(n+1)$th argument following the subject argument. At most, ten enclosed regular expressions are allowed. The <code>regex()</code> function makes its assignments unconditionally.</td> </tr> </table>	[] * . ^	This group of symbols retains its meaning as described on the <code>regex(5)</code> manual page.	\$	Matches the end of the string; <code>\n</code> matches a newline.	–	Within brackets the minus means <i>through</i> . For example, <code>[a–z]</code> is equivalent to <code>[abcd . . .xyz]</code> . The <code>–</code> can appear as itself only if used as the first or last character. For example, the character class expression <code>[]–]</code> matches the characters <code>]</code> and <code>–</code> .	+	A regular expression followed by <code>+</code> means <i>one or more times</i> . For example, <code>[0–9]+</code> is equivalent to <code>[0–9][0–9]*</code> .	{m} {m,} {m,u}	Integer values enclosed in <code>{ }</code> indicate the number of times the preceding regular expression is to be applied. The value <code>m</code> is the minimum number and <code>u</code> is a number, less than 256, which is the maximum. If only <code>m</code> is present (that is, <code>{m}</code>), it indicates the exact number of times the regular expression is to be applied. The value <code>{m, }</code> is analogous to <code>{m,infinity}</code> . The plus (<code>+</code>) and star (<code>*</code>) operations are equivalent to <code>{1, }</code> and <code>{0, }</code> respectively.	(. . .)\$n	The value of the enclosed regular expression is to be returned. The value will be stored in the $(n+1)$ th argument following the subject argument. At most, ten enclosed regular expressions are allowed. The <code>regex()</code> function makes its assignments unconditionally.
[] * . ^	This group of symbols retains its meaning as described on the <code>regex(5)</code> manual page.												
\$	Matches the end of the string; <code>\n</code> matches a newline.												
–	Within brackets the minus means <i>through</i> . For example, <code>[a–z]</code> is equivalent to <code>[abcd . . .xyz]</code> . The <code>–</code> can appear as itself only if used as the first or last character. For example, the character class expression <code>[]–]</code> matches the characters <code>]</code> and <code>–</code> .												
+	A regular expression followed by <code>+</code> means <i>one or more times</i> . For example, <code>[0–9]+</code> is equivalent to <code>[0–9][0–9]*</code> .												
{m} {m,} {m,u}	Integer values enclosed in <code>{ }</code> indicate the number of times the preceding regular expression is to be applied. The value <code>m</code> is the minimum number and <code>u</code> is a number, less than 256, which is the maximum. If only <code>m</code> is present (that is, <code>{m}</code>), it indicates the exact number of times the regular expression is to be applied. The value <code>{m, }</code> is analogous to <code>{m,infinity}</code> . The plus (<code>+</code>) and star (<code>*</code>) operations are equivalent to <code>{1, }</code> and <code>{0, }</code> respectively.												
(. . .)\$n	The value of the enclosed regular expression is to be returned. The value will be stored in the $(n+1)$ th argument following the subject argument. At most, ten enclosed regular expressions are allowed. The <code>regex()</code> function makes its assignments unconditionally.												

regcmp(3C)

(...) Parentheses are used for grouping. An operator, for example, *, +, { }, can work on a single character or a regular expression enclosed in parentheses. For example, (a*(cb+)*)\$0. By necessity, all the above defined symbols are special. They must, therefore, be escaped with a \ (backslash) to be used as themselves.

EXAMPLES **EXAMPLE 1** Example matching a leading newline in the subject string.

The following example matches a leading newline in the subject string pointed at by cursor.

```
char *cursor, *newcursor, *ptr;
. . .
newcursor = regex((ptr = regcmp("^\\n", (char *)0)), cursor);
free(ptr);
```

The following example matches through the string `Testing3` and returns the address of the character after the last matched character (the "4"). The string `Testing3` is copied to the character array `ret0`.

```
char ret0[9];
char *newcursor, *name;
. . .
name = regcmp("[A-Za-z][A-Za-z0-9]{0,7}")$0", (char *)0);
newcursor = regex(name, "012Testing345", ret0);
```

The following example applies a precompiled regular expression in `file.i` (see `regcmp(1)`) against `string`.

```
#include "file.i"
char *string, *newcursor;
. . .
newcursor = regex(name, string);
```

ATTRIBUTE TYPE	ATTRIBUTE VALUE
MT-Level	MT-Safe

SEE ALSO `ed(1)`, `regcmp(1)`, `malloc(3C)`, `attributes(5)`, `regex(5)`

NOTES The user program may run out of memory if `regcmp()` is called iteratively without freeing the vectors no longer required.

When compiling multithreaded applications, the `_REENTRANT` flag must be defined on the compile line. This flag should only be used in multithreaded applications.

NAME	regcomp, regex, regerror, regfree – regular expression matching
SYNOPSIS	<pre>#include <sys/types.h> #include <regex.h> int regcomp(regex_t *preg, const char *pattern, int cflags); int regex(const regex_t *preg, const char *string, size_t nmatch, regmatch_t pmatch[], int eflags); size_t regerror(int errcode, const regex_t *preg, char *errbuf, size_t errbuf_size); void regfree(regex_t *preg);</pre>
DESCRIPTION	<p>These functions interpret <i>basic</i> and <i>extended</i> regular expressions (described on the regex(5) manual page).</p> <p>The structure type <code>regex_t</code> contains at least the following member:</p> <pre>size_t re_nsub Number of parenthesised subexpressions.</pre> <p>The structure type <code>regmatch_t</code> contains at least the following members:</p> <pre>regoff_t rm_so Byte offset from start of <i>string</i> to start of substring. regoff_t rm_eo Byte offset from start of <i>string</i> of the first character after the end of substring.</pre> <p><code>regcomp()</code> The <code>regcomp()</code> function will compile the regular expression contained in the string pointed to by the <i>pattern</i> argument and place the results in the structure pointed to by <i>preg</i>. The <i>cflags</i> argument is the bitwise inclusive OR of zero or more of the following flags, which are defined in the header <code><regex.h></code>:</p> <pre>REG_EXTENDED Use Extended Regular Expressions. REG_ICASE Ignore case in match. REG_NOSUB Report only success/fail in <code>regex()</code>. REG_NEWLINE Change the handling of NEWLINE characters, as described in the text.</pre> <p>The default regular expression type for <i>pattern</i> is a Basic Regular Expression. The application can specify Extended Regular Expressions using the <code>REG_EXTENDED</code> <i>cflags</i> flag.</p> <p>If the <code>REG_NOSUB</code> flag was not set in <i>cflags</i>, then <code>regcomp()</code> will set <i>re_nsub</i> to the number of parenthesised subexpressions (delimited by <code>\(\)</code> in basic regular expressions or <code>()</code> in extended regular expressions) found in <i>pattern</i>.</p> <p><code>regex()</code> The <code>regex()</code> function compares the null-terminated string specified by <i>string</i> with the compiled regular expression <i>preg</i> initialized by a previous call to <code>regcomp()</code>. The <i>eflags</i> argument is the bitwise inclusive OR of zero or more of the following flags, which are defined in the header <code><regex.h></code>:</p>

regcomp(3C)

REG_NOTBOL	The first character of the string pointed to by <i>string</i> is not the beginning of the line. Therefore, the circumflex character (^), when taken as a special character, will not match the beginning of <i>string</i> .
REG_NOTEOL	The last character of the string pointed to by <i>string</i> is not the end of the line. Therefore, the dollar sign (\$), when taken as a special character, will not match the end of <i>string</i> .

If *nmatch* is zero or REG_NOSUB was set in the *cflags* argument to `regcomp()`, then `regexec()` will ignore the *pmatch* argument. Otherwise, the *pmatch* argument must point to an array with at least *nmatch* elements, and `regexec()` will fill in the elements of that array with offsets of the substrings of *string* that correspond to the parenthesised subexpressions of *pattern*: *pmatch*[*i*].*rm_so* will be the byte offset of the beginning and *pmatch*[*i*].*rm_eo* will be one greater than the byte offset of the end of substring *i*. (Subexpression *i* begins at the *i*th matched open parenthesis, counting from 1.) Offsets in *pmatch*[0] identify the substring that corresponds to the entire regular expression. Unused elements of *pmatch* up to *pmatch*[*nmatch*-1] will be filled with -1. If there are more than *nmatch* subexpressions in *pattern* (*pattern* itself counts as a subexpression), then `regexec()` will still do the match, but will record only the first *nmatch* substrings.

When matching a basic or extended regular expression, any given parenthesised subexpression of *pattern* might participate in the match of several different substrings of *string*, or it might not match any substring even though the pattern as a whole did match. The following rules are used to determine which substrings to report in *pmatch* when matching regular expressions:

1. If subexpression *i* in a regular expression is not contained within another subexpression, and it participated in the match several times, then the byte offsets in *pmatch*[*i*] will delimit the last such match.
2. If subexpression *i* is not contained within another subexpression, and it did not participate in an otherwise successful match, the byte offsets in *pmatch*[*i*] will be -1. A subexpression does not participate in the match when:
 - * or \{\} appears immediately after the subexpression in a basic regular expression, or *, ?, or { } appears immediately after the subexpression in an extended regular expression, and the subexpression did not match (matched zero times)
 - or
 - | is used in an extended regular expression to select this subexpression or another, and the other subexpression matched.
3. If subexpression *i* is contained within another subexpression *j*, and *i* is not contained within any other subexpression that is contained within *j*, and a match of subexpression *j* is reported in *pmatch*[*j*], then the match or

non-match of subexpression *i* reported in *pmatch* [*i*] will be as described in 1. and 2. above, but within the substring reported in *pmatch* [*j*] rather than the whole string.

4. If subexpression *i* is contained in subexpression *j*, and the byte offsets in *pmatch* [*j*] are -1 , then the pointers in *pmatch* [*i*] also will be -1 .
5. If subexpression *i* matched a zero-length string, then both byte offsets in *pmatch* [*i*] will be the byte offset of the character or NULL terminator immediately following the zero-length string.

If, when `regexec()` is called, the locale is different from when the regular expression was compiled, the result is undefined.

If `REG_NEWLINE` is not set in *cflags*, then a NEWLINE character in *pattern* or *string* will be treated as an ordinary character. If `REG_NEWLINE` is set, then newline will be treated as an ordinary character except as follows:

1. A NEWLINE character in *string* will not be matched by a period outside a bracket expression or by any form of a non-matching list.
2. A circumflex (^) in *pattern*, when used to specify expression anchoring will match the zero-length string immediately after a newline in *string*, regardless of the setting of `REG_NOTBOL`.
3. A dollar-sign (\$) in *pattern*, when used to specify expression anchoring, will match the zero-length string immediately before a newline in *string*, regardless of the setting of `REG_NOTEOL`.

`regfree()` The `regfree()` function frees any memory allocated by `regcomp()` associated with *preg*.

The following constants are defined as error return values:

<code>REG_NOMATCH</code>	The <code>regexec()</code> function failed to match.
<code>REG_BADPAT</code>	Invalid regular expression.
<code>REG_ECOLLATE</code>	Invalid collating element referenced.
<code>REG_ECTYPE</code>	Invalid character class type referenced.
<code>REG_EESCAPE</code>	Trailing <code>\</code> in pattern.
<code>REG_ESUBREG</code>	Number in <code>\digit</code> invalid or in error.
<code>REG_EBRACK</code>	[] imbalance.
<code>REG_ENOSYS</code>	The function is not supported.
<code>REG_EPAREN</code>	<code>\(\)</code> or <code>()</code> imbalance.
<code>REG_EBRACE</code>	<code>\{ \}</code> imbalance.

regcomp(3C)

	<p>REG_BADBR Content of <code>\{ \}</code> invalid: not a number, number too large, more than two numbers, first larger than second.</p> <p>REG_ERANGE Invalid endpoint in range expression.</p> <p>REG_ESPACE Out of memory.</p> <p>REG_BADRPT <code>?</code>, <code>*</code> or <code>+</code> not preceded by valid regular expression.</p>
regerror()	<p>The <code>regerror()</code> function provides a mapping from error codes returned by <code>regcomp()</code> and <code>regexexec()</code> to unspecified printable strings. It generates a string corresponding to the value of the <code>errcode</code> argument, which must be the last non-zero value returned by <code>regcomp()</code> or <code>regexexec()</code> with the given value of <code>preg</code>. If <code>errcode</code> is not such a value, an error message indicating that the error code is invalid is returned.</p> <p>If <code>preg</code> is a <code>NULL</code> pointer, but <code>errcode</code> is a value returned by a previous call to <code>regexexec()</code> or <code>regcomp()</code>, the <code>regerror()</code> still generates an error string corresponding to the value of <code>errcode</code>.</p> <p>If the <code>errbuf_size</code> argument is not zero, <code>regerror()</code> will place the generated string into the buffer of size <code>errbuf_size</code> bytes pointed to by <code>errbuf</code>. If the string (including the terminating <code>NULL</code>) cannot fit in the buffer, <code>regerror()</code> will truncate the string and null-terminate the result.</p> <p>If <code>errbuf_size</code> is zero, <code>regerror()</code> ignores the <code>errbuf</code> argument, and returns the size of the buffer needed to hold the generated string.</p> <p>If the <code>preg</code> argument to <code>regexexec()</code> or <code>regfree()</code> is not a compiled regular expression returned by <code>regcomp()</code>, the result is undefined. A <code>preg</code> is no longer treated as a compiled regular expression after it is given to <code>regfree()</code>.</p> <p>See <code>regex(5)</code> for BRE (Basic Regular Expression) Anchoring.</p>
RETURN VALUES	<p>On successful completion, the <code>regcomp()</code> function returns 0. Otherwise, it returns an integer value indicating an error as described in <code><regex.h></code>, and the content of <code>preg</code> is undefined.</p> <p>On successful completion, the <code>regexexec()</code> function returns 0. Otherwise it returns <code>REG_NOMATCH</code> to indicate no match, or <code>REG_ENOSYS</code> to indicate that the function is not supported.</p> <p>Upon successful completion, the <code>regerror()</code> function returns the number of bytes needed to hold the entire generated string. Otherwise, it returns 0 to indicate that the function is not implemented.</p> <p>The <code>regfree()</code> function returns no value.</p>
ERRORS	<p>No errors are defined.</p>
USAGE	<p>An application could use:</p>

```
regerror(code, preg, (char *)NULL, (size_t)0)
```

to find out how big a buffer is needed for the generated string, `malloc` a buffer to hold the string, and then call `regerror()` again to get the string (see `malloc(3C)`). Alternately, it could allocate a fixed, static buffer that is big enough to hold most strings, and then use `malloc()` to allocate a larger buffer if it finds that this is too small.

EXAMPLES

EXAMPLE 1 Example to match string against the extended regular expression in pattern.

```
#include <regex.h>
/*
 * Match string against the extended regular expression in
 * pattern, treating errors as no match.
 *
 * return 1 for match, 0 for no match
 */

int
match(const char *string, char *pattern)
{
    int status;
    regex_t re;
    if (regcomp(&re, pattern, REG_EXTENDED | REG_NOSUB) != 0) {
        return(0);      /* report error */
    }
    status = regexec(&re, string, (size_t)0, NULL, 0);
    regfree(&re);
    if (status != 0) {
        return(0);      /* report error */
    }
    return(1);
}
```

The following demonstrates how the `REG_NOTBOL` flag could be used with `regexec()` to find all substrings in a line that match a pattern supplied by a user. (For simplicity of the example, very little error checking is done.)

```
(void) regcomp (&re, pattern, 0);
/* this call to regexec() finds the first match on the line */
error = regexec (&re, &buffer[0], 1, &pm, 0);
while (error == 0) { /* while matches found */
    /* substring found between pm.rm_so and pm.rm_eo */
    /* This call to regexec() finds the next match */
    error = regexec (&re, buffer + pm.rm_eo, 1, &pm, REG_NOTBOL);
}
```

ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
MT-Level	MT-Safe with exceptions

regcomp(3C)

ATTRIBUTE TYPE	ATTRIBUTE VALUE
CSI	Enabled

SEE ALSO `fnmatch(3C)`, `glob(3C)`, `malloc(3C)`, `setlocale(3C)`, `attributes(5)`, `regex(5)`

NOTES The `regcomp()` function can be used safely in a multithreaded application as long as `setlocale(3C)` is not being called to change the locale.

NAME	regcomp, regexec, regerror, regfree – regular expression matching
SYNOPSIS	<pre>#include <sys/types.h> #include <regex.h> int regcomp(regex_t *preg, const char *pattern, int cflags); int regexec(const regex_t *preg, const char *string, size_t nmatch, regmatch_t pmatch[], int eflags); size_t regerror(int errcode, const regex_t *preg, char *errbuf, size_t errbuf_size); void regfree(regex_t *preg);</pre>
DESCRIPTION	<p>These functions interpret <i>basic</i> and <i>extended</i> regular expressions (described on the regex(5) manual page).</p> <p>The structure type <code>regex_t</code> contains at least the following member:</p> <pre>size_t re_nsub Number of parenthesised subexpressions.</pre> <p>The structure type <code>regmatch_t</code> contains at least the following members:</p> <pre>regoff_t rm_so Byte offset from start of <i>string</i> to start of substring. regoff_t rm_eo Byte offset from start of <i>string</i> of the first character after the end of substring.</pre> <p><code>regcomp()</code> The <code>regcomp()</code> function will compile the regular expression contained in the string pointed to by the <i>pattern</i> argument and place the results in the structure pointed to by <i>preg</i>. The <i>cflags</i> argument is the bitwise inclusive OR of zero or more of the following flags, which are defined in the header <code><regex.h></code>:</p> <pre>REG_EXTENDED Use Extended Regular Expressions. REG_ICASE Ignore case in match. REG_NOSUB Report only success/fail in <code>regexec()</code>. REG_NEWLINE Change the handling of NEWLINE characters, as described in the text.</pre> <p>The default regular expression type for <i>pattern</i> is a Basic Regular Expression. The application can specify Extended Regular Expressions using the <code>REG_EXTENDED</code> <i>cflags</i> flag.</p> <p>If the <code>REG_NOSUB</code> flag was not set in <i>cflags</i>, then <code>regcomp()</code> will set <i>re_nsub</i> to the number of parenthesised subexpressions (delimited by <code>\(\)</code> in basic regular expressions or <code>()</code> in extended regular expressions) found in <i>pattern</i>.</p> <p><code>regexec()</code> The <code>regexec()</code> function compares the null-terminated string specified by <i>string</i> with the compiled regular expression <i>preg</i> initialized by a previous call to <code>regcomp()</code>. The <i>eflags</i> argument is the bitwise inclusive OR of zero or more of the following flags, which are defined in the header <code><regex.h></code>:</p>

regerror(3C)

REG_NOTBOL	The first character of the string pointed to by <i>string</i> is not the beginning of the line. Therefore, the circumflex character (^), when taken as a special character, will not match the beginning of <i>string</i> .
REG_NOTEOL	The last character of the string pointed to by <i>string</i> is not the end of the line. Therefore, the dollar sign (\$), when taken as a special character, will not match the end of <i>string</i> .

If *nmatch* is zero or REG_NOSUB was set in the *cflags* argument to `regcomp()`, then `regexec()` will ignore the *pmatch* argument. Otherwise, the *pmatch* argument must point to an array with at least *nmatch* elements, and `regexec()` will fill in the elements of that array with offsets of the substrings of *string* that correspond to the parenthesised subexpressions of *pattern*: *pmatch*[*i*].*rm_so* will be the byte offset of the beginning and *pmatch*[*i*].*rm_eo* will be one greater than the byte offset of the end of substring *i*. (Subexpression *i* begins at the *i*th matched open parenthesis, counting from 1.) Offsets in *pmatch*[0] identify the substring that corresponds to the entire regular expression. Unused elements of *pmatch* up to *pmatch*[*nmatch*-1] will be filled with -1. If there are more than *nmatch* subexpressions in *pattern* (*pattern* itself counts as a subexpression), then `regexec()` will still do the match, but will record only the first *nmatch* substrings.

When matching a basic or extended regular expression, any given parenthesised subexpression of *pattern* might participate in the match of several different substrings of *string*, or it might not match any substring even though the pattern as a whole did match. The following rules are used to determine which substrings to report in *pmatch* when matching regular expressions:

1. If subexpression *i* in a regular expression is not contained within another subexpression, and it participated in the match several times, then the byte offsets in *pmatch*[*i*] will delimit the last such match.
2. If subexpression *i* is not contained within another subexpression, and it did not participate in an otherwise successful match, the byte offsets in *pmatch*[*i*] will be -1. A subexpression does not participate in the match when:
 - * or \{\} appears immediately after the subexpression in a basic regular expression, or *, ?, or { } appears immediately after the subexpression in an extended regular expression, and the subexpression did not match (matched zero times)
 - or
 - | is used in an extended regular expression to select this subexpression or another, and the other subexpression matched.
3. If subexpression *i* is contained within another subexpression *j*, and *i* is not contained within any other subexpression that is contained within *j*, and a match of subexpression *j* is reported in *pmatch*[*j*], then the match or

non-match of subexpression *i* reported in *pmatch* [*i*] will be as described in 1. and 2. above, but within the substring reported in *pmatch* [*j*] rather than the whole string.

4. If subexpression *i* is contained in subexpression *j*, and the byte offsets in *pmatch* [*j*] are -1 , then the pointers in *pmatch* [*i*] also will be -1 .
5. If subexpression *i* matched a zero-length string, then both byte offsets in *pmatch* [*i*] will be the byte offset of the character or NULL terminator immediately following the zero-length string.

If, when `regexec()` is called, the locale is different from when the regular expression was compiled, the result is undefined.

If `REG_NEWLINE` is not set in *cflags*, then a NEWLINE character in *pattern* or *string* will be treated as an ordinary character. If `REG_NEWLINE` is set, then newline will be treated as an ordinary character except as follows:

1. A NEWLINE character in *string* will not be matched by a period outside a bracket expression or by any form of a non-matching list.
2. A circumflex (^) in *pattern*, when used to specify expression anchoring will match the zero-length string immediately after a newline in *string*, regardless of the setting of `REG_NOTBOL`.
3. A dollar-sign (\$) in *pattern*, when used to specify expression anchoring, will match the zero-length string immediately before a newline in *string*, regardless of the setting of `REG_NOTEOL`.

`regfree()` The `regfree()` function frees any memory allocated by `regcomp()` associated with *preg*.

The following constants are defined as error return values:

<code>REG_NOMATCH</code>	The <code>regexec()</code> function failed to match.
<code>REG_BADPAT</code>	Invalid regular expression.
<code>REG_ECOLLATE</code>	Invalid collating element referenced.
<code>REG_ECTYPE</code>	Invalid character class type referenced.
<code>REG_EESCAPE</code>	Trailing <code>\</code> in pattern.
<code>REG_ESUBREG</code>	Number in <code>\digit</code> invalid or in error.
<code>REG_EBRACK</code>	[] imbalance.
<code>REG_ENOSYS</code>	The function is not supported.
<code>REG_EPAREN</code>	<code>\(\)</code> or <code>()</code> imbalance.
<code>REG_EBRACE</code>	<code>\{ \}</code> imbalance.

regerror(3C)

REG_BADBR	Content of <code>\{ \}</code> invalid: not a number, number too large, more than two numbers, first larger than second.
REG_ERANGE	Invalid endpoint in range expression.
REG_ESPACE	Out of memory.
REG_BADRPT	?, * or + not preceded by valid regular expression.

`regerror()` The `regerror()` function provides a mapping from error codes returned by `regcomp()` and `regexexec()` to unspecified printable strings. It generates a string corresponding to the value of the `errcode` argument, which must be the last non-zero value returned by `regcomp()` or `regexexec()` with the given value of `preg`. If `errcode` is not such a value, an error message indicating that the error code is invalid is returned.

If `preg` is a `NULL` pointer, but `errcode` is a value returned by a previous call to `regexexec()` or `regcomp()`, the `regerror()` still generates an error string corresponding to the value of `errcode`.

If the `errbuf_size` argument is not zero, `regerror()` will place the generated string into the buffer of size `errbuf_size` bytes pointed to by `errbuf`. If the string (including the terminating `NULL`) cannot fit in the buffer, `regerror()` will truncate the string and null-terminate the result.

If `errbuf_size` is zero, `regerror()` ignores the `errbuf` argument, and returns the size of the buffer needed to hold the generated string.

If the `preg` argument to `regexexec()` or `regfree()` is not a compiled regular expression returned by `regcomp()`, the result is undefined. A `preg` is no longer treated as a compiled regular expression after it is given to `regfree()`.

See `regex(5)` for BRE (Basic Regular Expression) Anchoring.

RETURN VALUES On successful completion, the `regcomp()` function returns 0. Otherwise, it returns an integer value indicating an error as described in `<regex.h>`, and the content of `preg` is undefined.

On successful completion, the `regexexec()` function returns 0. Otherwise it returns `REG_NOMATCH` to indicate no match, or `REG_ENOSYS` to indicate that the function is not supported.

Upon successful completion, the `regerror()` function returns the number of bytes needed to hold the entire generated string. Otherwise, it returns 0 to indicate that the function is not implemented.

The `regfree()` function returns no value.

ERRORS No errors are defined.

USAGE An application could use:

```
regerror(code, preg, (char *)NULL, (size_t)0)
```

to find out how big a buffer is needed for the generated string, `malloc` a buffer to hold the string, and then call `regerror()` again to get the string (see `malloc(3C)`). Alternately, it could allocate a fixed, static buffer that is big enough to hold most strings, and then use `malloc()` to allocate a larger buffer if it finds that this is too small.

EXAMPLES

EXAMPLE 1 Example to match string against the extended regular expression in pattern.

```
#include <regex.h>
/*
 * Match string against the extended regular expression in
 * pattern, treating errors as no match.
 *
 * return 1 for match, 0 for no match
 */

int
match(const char *string, char *pattern)
{
    int status;
    regex_t re;
    if (regcomp(&re, pattern, REG_EXTENDED | REG_NOSUB) != 0) {
        return(0);      /* report error */
    }
    status = regexec(&re, string, (size_t)0, NULL, 0);
    regfree(&re);
    if (status != 0) {
        return(0);      /* report error */
    }
    return(1);
}
```

The following demonstrates how the `REG_NOTBOL` flag could be used with `regexec()` to find all substrings in a line that match a pattern supplied by a user. (For simplicity of the example, very little error checking is done.)

```
(void) regcomp (&re, pattern, 0);
/* this call to regexec() finds the first match on the line */
error = regexec (&re, &buffer[0], 1, &pm, 0);
while (error == 0) { /* while matches found */
    /* substring found between pm.rm_so and pm.rm_eo */
    /* This call to regexec() finds the next match */
    error = regexec (&re, buffer + pm.rm_eo, 1, &pm, REG_NOTBOL);
}
```

CSI	Enabled

SEE ALSO `fnmatch(3C)`, `glob(3C)`, `malloc(3C)`, `setlocale(3C)`, `attributes(5)`, `regex(5)`

NOTES The `regcomp()` function can be used safely in a multithreaded application as long as `setlocale(3C)` is not being called to change the locale.

NAME	regcmp, regex – compile and execute regular expression												
SYNOPSIS	<pre>#include <libgen.h> char *regcmp(const char *string1, /* char *string2 */ ..., int /*(char*) 0*/); char *regex(const char *re, const char *subject, /* char *ret0 */ ...); extern char *__loc1;</pre>												
DESCRIPTION	<p>The <code>regcmp()</code> function compiles a regular expression (consisting of the concatenated arguments) and returns a pointer to the compiled form. The <code>malloc(3C)</code> function is used to create space for the compiled form. It is the user's responsibility to free unneeded space so allocated. A NULL return from <code>regcmp()</code> indicates an incorrect argument. <code>regcmp(1)</code> has been written to generally preclude the need for this routine at execution time.</p> <p>The <code>regex()</code> function executes a compiled pattern against the subject string. Additional arguments are passed to receive values back. The <code>regex()</code> function returns NULL on failure or a pointer to the next unmatched character on success. A global character pointer <code>__loc1</code> points to where the match began. The <code>regcmp()</code> and <code>regex()</code> functions were mostly borrowed from the editor <code>ed(1)</code>; however, the syntax and semantics have been changed slightly. The following are the valid symbols and associated meanings.</p> <table border="0" style="width: 100%;"> <tr> <td style="vertical-align: top; padding-right: 10px;">[] * . ^</td> <td>This group of symbols retains its meaning as described on the <code>regexp(5)</code> manual page.</td> </tr> <tr> <td style="vertical-align: top; padding-right: 10px;">\$</td> <td>Matches the end of the string; <code>\n</code> matches a newline.</td> </tr> <tr> <td style="vertical-align: top; padding-right: 10px;">-</td> <td>Within brackets the minus means <i>through</i>. For example, <code>[a-z]</code> is equivalent to <code>[abcd . . .xyz]</code>. The <code>-</code> can appear as itself only if used as the first or last character. For example, the character class expression <code>[]-</code> matches the characters <code>]</code> and <code>-</code>.</td> </tr> <tr> <td style="vertical-align: top; padding-right: 10px;">+</td> <td>A regular expression followed by <code>+</code> means <i>one or more times</i>. For example, <code>[0-9]+</code> is equivalent to <code>[0-9][0-9]*</code>.</td> </tr> <tr> <td style="vertical-align: top; padding-right: 10px;">{m} {m,} {m,u}</td> <td>Integer values enclosed in <code>{ }</code> indicate the number of times the preceding regular expression is to be applied. The value <code>m</code> is the minimum number and <code>u</code> is a number, less than 256, which is the maximum. If only <code>m</code> is present (that is, <code>{m}</code>), it indicates the exact number of times the regular expression is to be applied. The value <code>{m, }</code> is analogous to <code>{m, infinity}</code>. The plus (<code>+</code>) and star (<code>*</code>) operations are equivalent to <code>{1, }</code> and <code>{0, }</code> respectively.</td> </tr> <tr> <td style="vertical-align: top; padding-right: 10px;">(. . .) \$n</td> <td>The value of the enclosed regular expression is to be returned. The value will be stored in the <code>(n+1)</code>th argument following the subject argument. At most, ten enclosed regular expressions are allowed. The <code>regex()</code> function makes its assignments unconditionally.</td> </tr> </table>	[] * . ^	This group of symbols retains its meaning as described on the <code>regexp(5)</code> manual page.	\$	Matches the end of the string; <code>\n</code> matches a newline.	-	Within brackets the minus means <i>through</i> . For example, <code>[a-z]</code> is equivalent to <code>[abcd . . .xyz]</code> . The <code>-</code> can appear as itself only if used as the first or last character. For example, the character class expression <code>[]-</code> matches the characters <code>]</code> and <code>-</code> .	+	A regular expression followed by <code>+</code> means <i>one or more times</i> . For example, <code>[0-9]+</code> is equivalent to <code>[0-9][0-9]*</code> .	{m} {m,} {m,u}	Integer values enclosed in <code>{ }</code> indicate the number of times the preceding regular expression is to be applied. The value <code>m</code> is the minimum number and <code>u</code> is a number, less than 256, which is the maximum. If only <code>m</code> is present (that is, <code>{m}</code>), it indicates the exact number of times the regular expression is to be applied. The value <code>{m, }</code> is analogous to <code>{m, infinity}</code> . The plus (<code>+</code>) and star (<code>*</code>) operations are equivalent to <code>{1, }</code> and <code>{0, }</code> respectively.	(. . .) \$n	The value of the enclosed regular expression is to be returned. The value will be stored in the <code>(n+1)</code> th argument following the subject argument. At most, ten enclosed regular expressions are allowed. The <code>regex()</code> function makes its assignments unconditionally.
[] * . ^	This group of symbols retains its meaning as described on the <code>regexp(5)</code> manual page.												
\$	Matches the end of the string; <code>\n</code> matches a newline.												
-	Within brackets the minus means <i>through</i> . For example, <code>[a-z]</code> is equivalent to <code>[abcd . . .xyz]</code> . The <code>-</code> can appear as itself only if used as the first or last character. For example, the character class expression <code>[]-</code> matches the characters <code>]</code> and <code>-</code> .												
+	A regular expression followed by <code>+</code> means <i>one or more times</i> . For example, <code>[0-9]+</code> is equivalent to <code>[0-9][0-9]*</code> .												
{m} {m,} {m,u}	Integer values enclosed in <code>{ }</code> indicate the number of times the preceding regular expression is to be applied. The value <code>m</code> is the minimum number and <code>u</code> is a number, less than 256, which is the maximum. If only <code>m</code> is present (that is, <code>{m}</code>), it indicates the exact number of times the regular expression is to be applied. The value <code>{m, }</code> is analogous to <code>{m, infinity}</code> . The plus (<code>+</code>) and star (<code>*</code>) operations are equivalent to <code>{1, }</code> and <code>{0, }</code> respectively.												
(. . .) \$n	The value of the enclosed regular expression is to be returned. The value will be stored in the <code>(n+1)</code> th argument following the subject argument. At most, ten enclosed regular expressions are allowed. The <code>regex()</code> function makes its assignments unconditionally.												

regex(3C)

(...) Parentheses are used for grouping. An operator, for example, *, +, { }, can work on a single character or a regular expression enclosed in parentheses. For example, (a*(cb+)*)\$0. By necessity, all the above defined symbols are special. They must, therefore, be escaped with a \ (backslash) to be used as themselves.

EXAMPLES **EXAMPLE 1** Example matching a leading newline in the subject string.

The following example matches a leading newline in the subject string pointed at by cursor.

```
char *cursor, *newcursor, *ptr;
. . .
newcursor = regex((ptr = regcmp("^\n", (char *)0)), cursor);
free(ptr);
```

The following example matches through the string `Testing3` and returns the address of the character after the last matched character (the "4"). The string `Testing3` is copied to the character array `ret0`.

```
char ret0[9];
char *newcursor, *name;
. . .
name = regcmp("[A-Za-z][A-Za-z0-9]{0,7}")$0", (char *)0);
newcursor = regex(name, "012Testing345", ret0);
```

The following example applies a precompiled regular expression in `file.i` (see `regcmp(1)`) against `string`.

```
#include "file.i"
char *string, *newcursor;
. . .
newcursor = regex(name, string);
```

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
MT-Level	MT-Safe

SEE ALSO `ed(1)`, `regcmp(1)`, `malloc(3C)`, `attributes(5)`, `regexp(5)`

NOTES The user program may run out of memory if `regcmp()` is called iteratively without freeing the vectors no longer required.

When compiling multithreaded applications, the `_REENTRANT` flag must be defined on the compile line. This flag should only be used in multithreaded applications.

NAME	regcomp, regex, regerror, regfree – regular expression matching
SYNOPSIS	<pre>#include <sys/types.h> #include <regex.h> int regcomp(regex_t *preg, const char *pattern, int cflags); int regex(const regex_t *preg, const char *string, size_t nmatch, regmatch_t pmatch[], int eflags); size_t regerror(int errcode, const regex_t *preg, char *errbuf, size_t errbuf_size); void regfree(regex_t *preg);</pre>
DESCRIPTION	<p>These functions interpret <i>basic</i> and <i>extended</i> regular expressions (described on the regex(5) manual page).</p> <p>The structure type <code>regex_t</code> contains at least the following member:</p> <pre>size_t re_nsub Number of parenthesised subexpressions.</pre> <p>The structure type <code>regmatch_t</code> contains at least the following members:</p> <pre>regoff_t rm_so Byte offset from start of <i>string</i> to start of substring. regoff_t rm_eo Byte offset from start of <i>string</i> of the first character after the end of substring.</pre> <p><code>regcomp()</code> The <code>regcomp()</code> function will compile the regular expression contained in the string pointed to by the <i>pattern</i> argument and place the results in the structure pointed to by <i>preg</i>. The <i>cflags</i> argument is the bitwise inclusive OR of zero or more of the following flags, which are defined in the header <code><regex.h></code>:</p> <pre>REG_EXTENDED Use Extended Regular Expressions. REG_ICASE Ignore case in match. REG_NOSUB Report only success/fail in <code>regex()</code>. REG_NEWLINE Change the handling of NEWLINE characters, as described in the text.</pre> <p>The default regular expression type for <i>pattern</i> is a Basic Regular Expression. The application can specify Extended Regular Expressions using the <code>REG_EXTENDED</code> <i>cflags</i> flag.</p> <p>If the <code>REG_NOSUB</code> flag was not set in <i>cflags</i>, then <code>regcomp()</code> will set <i>re_nsub</i> to the number of parenthesised subexpressions (delimited by <code>\(\)</code> in basic regular expressions or <code>()</code> in extended regular expressions) found in <i>pattern</i>.</p> <p><code>regex()</code> The <code>regex()</code> function compares the null-terminated string specified by <i>string</i> with the compiled regular expression <i>preg</i> initialized by a previous call to <code>regcomp()</code>. The <i>eflags</i> argument is the bitwise inclusive OR of zero or more of the following flags, which are defined in the header <code><regex.h></code>:</p>

regex(3C)

REG_NOTBOL	The first character of the string pointed to by <i>string</i> is not the beginning of the line. Therefore, the circumflex character (^), when taken as a special character, will not match the beginning of <i>string</i> .
REG_NOTEOL	The last character of the string pointed to by <i>string</i> is not the end of the line. Therefore, the dollar sign (\$), when taken as a special character, will not match the end of <i>string</i> .

If *nmatch* is zero or REG_NOSUB was set in the *cflags* argument to `regcomp()`, then `regexexec()` will ignore the *pmatch* argument. Otherwise, the *pmatch* argument must point to an array with at least *nmatch* elements, and `regexexec()` will fill in the elements of that array with offsets of the substrings of *string* that correspond to the parenthesised subexpressions of *pattern*: *pmatch*[*i*].*rm_so* will be the byte offset of the beginning and *pmatch*[*i*].*rm_eo* will be one greater than the byte offset of the end of substring *i*. (Subexpression *i* begins at the *i*th matched open parenthesis, counting from 1.) Offsets in *pmatch*[0] identify the substring that corresponds to the entire regular expression. Unused elements of *pmatch* up to *pmatch*[*nmatch*-1] will be filled with -1. If there are more than *nmatch* subexpressions in *pattern* (*pattern* itself counts as a subexpression), then `regexexec()` will still do the match, but will record only the first *nmatch* substrings.

When matching a basic or extended regular expression, any given parenthesised subexpression of *pattern* might participate in the match of several different substrings of *string*, or it might not match any substring even though the pattern as a whole did match. The following rules are used to determine which substrings to report in *pmatch* when matching regular expressions:

1. If subexpression *i* in a regular expression is not contained within another subexpression, and it participated in the match several times, then the byte offsets in *pmatch*[*i*] will delimit the last such match.
2. If subexpression *i* is not contained within another subexpression, and it did not participate in an otherwise successful match, the byte offsets in *pmatch*[*i*] will be -1. A subexpression does not participate in the match when:
 - * or \{\} appears immediately after the subexpression in a basic regular expression, or *, ?, or { } appears immediately after the subexpression in an extended regular expression, and the subexpression did not match (matched zero times)
 - or
 - | is used in an extended regular expression to select this subexpression or another, and the other subexpression matched.
3. If subexpression *i* is contained within another subexpression *j*, and *i* is not contained within any other subexpression that is contained within *j*, and a match of subexpression *j* is reported in *pmatch*[*j*], then the match or

non-match of subexpression *i* reported in *pmatch* [*i*] will be as described in 1. and 2. above, but within the substring reported in *pmatch* [*j*] rather than the whole string.

4. If subexpression *i* is contained in subexpression *j*, and the byte offsets in *pmatch* [*j*] are -1, then the pointers in *pmatch* [*i*] also will be -1.
5. If subexpression *i* matched a zero-length string, then both byte offsets in *pmatch* [*i*] will be the byte offset of the character or NULL terminator immediately following the zero-length string.

If, when `regexec()` is called, the locale is different from when the regular expression was compiled, the result is undefined.

If `REG_NEWLINE` is not set in *cflags*, then a NEWLINE character in *pattern* or *string* will be treated as an ordinary character. If `REG_NEWLINE` is set, then newline will be treated as an ordinary character except as follows:

1. A NEWLINE character in *string* will not be matched by a period outside a bracket expression or by any form of a non-matching list.
2. A circumflex (^) in *pattern*, when used to specify expression anchoring will match the zero-length string immediately after a newline in *string*, regardless of the setting of `REG_NOTBOL`.
3. A dollar-sign (\$) in *pattern*, when used to specify expression anchoring, will match the zero-length string immediately before a newline in *string*, regardless of the setting of `REG_NOTEOL`.

`regfree()` The `regfree()` function frees any memory allocated by `regcomp()` associated with *preg*.

The following constants are defined as error return values:

<code>REG_NOMATCH</code>	The <code>regexec()</code> function failed to match.
<code>REG_BADPAT</code>	Invalid regular expression.
<code>REG_ECOLLATE</code>	Invalid collating element referenced.
<code>REG_ECTYPE</code>	Invalid character class type referenced.
<code>REG_EESCAPE</code>	Trailing <code>\</code> in pattern.
<code>REG_ESUBREG</code>	Number in <code>\digit</code> invalid or in error.
<code>REG_EBRACK</code>	[] imbalance.
<code>REG_ENOSYS</code>	The function is not supported.
<code>REG_EPAREN</code>	<code>\(\)</code> or <code>()</code> imbalance.
<code>REG_EBRACE</code>	<code>\{ \}</code> imbalance.

regex(3C)

	<p>REG_BADBR Content of <code>\{ \}</code> invalid: not a number, number too large, more than two numbers, first larger than second.</p> <p>REG_ERANGE Invalid endpoint in range expression.</p> <p>REG_ESPACE Out of memory.</p> <p>REG_BADRPT <code>?</code>, <code>*</code> or <code>+</code> not preceded by valid regular expression.</p>
<code>regerror()</code>	<p>The <code>regerror()</code> function provides a mapping from error codes returned by <code>regcomp()</code> and <code>regex()</code> to unspecified printable strings. It generates a string corresponding to the value of the <code>errcode</code> argument, which must be the last non-zero value returned by <code>regcomp()</code> or <code>regex()</code> with the given value of <code>preg</code>. If <code>errcode</code> is not such a value, an error message indicating that the error code is invalid is returned.</p> <p>If <code>preg</code> is a <code>NULL</code> pointer, but <code>errcode</code> is a value returned by a previous call to <code>regex()</code> or <code>regcomp()</code>, the <code>regerror()</code> still generates an error string corresponding to the value of <code>errcode</code>.</p> <p>If the <code>errbuf_size</code> argument is not zero, <code>regerror()</code> will place the generated string into the buffer of size <code>errbuf_size</code> bytes pointed to by <code>errbuf</code>. If the string (including the terminating <code>NULL</code>) cannot fit in the buffer, <code>regerror()</code> will truncate the string and null-terminate the result.</p> <p>If <code>errbuf_size</code> is zero, <code>regerror()</code> ignores the <code>errbuf</code> argument, and returns the size of the buffer needed to hold the generated string.</p> <p>If the <code>preg</code> argument to <code>regex()</code> or <code>regfree()</code> is not a compiled regular expression returned by <code>regcomp()</code>, the result is undefined. A <code>preg</code> is no longer treated as a compiled regular expression after it is given to <code>regfree()</code>.</p> <p>See <code>regex(5)</code> for BRE (Basic Regular Expression) Anchoring.</p>
RETURN VALUES	<p>On successful completion, the <code>regcomp()</code> function returns 0. Otherwise, it returns an integer value indicating an error as described in <code><regex.h></code>, and the content of <code>preg</code> is undefined.</p> <p>On successful completion, the <code>regex()</code> function returns 0. Otherwise it returns <code>REG_NOMATCH</code> to indicate no match, or <code>REG_ENOSYS</code> to indicate that the function is not supported.</p> <p>Upon successful completion, the <code>regerror()</code> function returns the number of bytes needed to hold the entire generated string. Otherwise, it returns 0 to indicate that the function is not implemented.</p> <p>The <code>regfree()</code> function returns no value.</p>
ERRORS	<p>No errors are defined.</p>
USAGE	<p>An application could use:</p>

```
regerror(code, preg, (char *)NULL, (size_t)0)
```

to find out how big a buffer is needed for the generated string, `malloc` a buffer to hold the string, and then call `regerror()` again to get the string (see `malloc(3C)`). Alternately, it could allocate a fixed, static buffer that is big enough to hold most strings, and then use `malloc()` to allocate a larger buffer if it finds that this is too small.

EXAMPLES

EXAMPLE 1 Example to match string against the extended regular expression in pattern.

```
#include <regex.h>
/*
 * Match string against the extended regular expression in
 * pattern, treating errors as no match.
 *
 * return 1 for match, 0 for no match
 */

int
match(const char *string, char *pattern)
{
    int status;
    regex_t re;
    if (regcomp(&re, pattern, REG_EXTENDED | REG_NOSUB) != 0) {
        return(0);      /* report error */
    }
    status = regexec(&re, string, (size_t)0, NULL, 0);
    regfree(&re);
    if (status != 0) {
        return(0);      /* report error */
    }
    return(1);
}
```

The following demonstrates how the `REG_NOTBOL` flag could be used with `regexec()` to find all substrings in a line that match a pattern supplied by a user. (For simplicity of the example, very little error checking is done.)

```
(void) regcomp (&re, pattern, 0);
/* this call to regexec() finds the first match on the line */
error = regexec (&re, &buffer[0], 1, &pm, 0);
while (error == 0) { /* while matches found */
    /* substring found between pm.rm_so and pm.rm_eo */
    /* This call to regexec() finds the next match */
    error = regexec (&re, buffer + pm.rm_eo, 1, &pm, REG_NOTBOL);
}
```

ATTRIBUTES

regexec(3C)

ATTRIBUTE TYPE	ATTRIBUTE VALUE
CSI	Enabled

SEE ALSO `fnmatch(3C)`, `glob(3C)`, `malloc(3C)`, `setlocale(3C)`, `attributes(5)`, `regex(5)`

NOTES The `regcomp()` function can be used safely in a multithreaded application as long as `setlocale(3C)` is not being called to change the locale.

NAME	regcomp, regexec, regerror, regfree – regular expression matching
SYNOPSIS	<pre>#include <sys/types.h> #include <regex.h> int regcomp(regex_t *preg, const char *pattern, int cflags); int regexec(const regex_t *preg, const char *string, size_t nmatch, regmatch_t pmatch[], int eflags); size_t regerror(int errcode, const regex_t *preg, char *errbuf, size_t errbuf_size); void regfree(regex_t *preg);</pre>
DESCRIPTION	<p>These functions interpret <i>basic</i> and <i>extended</i> regular expressions (described on the regex(5) manual page).</p> <p>The structure type <code>regex_t</code> contains at least the following member:</p> <pre>size_t re_nsub Number of parenthesised subexpressions.</pre> <p>The structure type <code>regmatch_t</code> contains at least the following members:</p> <pre>regoff_t rm_so Byte offset from start of <i>string</i> to start of substring. regoff_t rm_eo Byte offset from start of <i>string</i> of the first character after the end of substring.</pre> <p><code>regcomp()</code> The <code>regcomp()</code> function will compile the regular expression contained in the string pointed to by the <i>pattern</i> argument and place the results in the structure pointed to by <i>preg</i>. The <i>cflags</i> argument is the bitwise inclusive OR of zero or more of the following flags, which are defined in the header <code><regex.h></code>:</p> <pre>REG_EXTENDED Use Extended Regular Expressions. REG_ICASE Ignore case in match. REG_NOSUB Report only success/fail in <code>regexec()</code>. REG_NEWLINE Change the handling of NEWLINE characters, as described in the text.</pre> <p>The default regular expression type for <i>pattern</i> is a Basic Regular Expression. The application can specify Extended Regular Expressions using the <code>REG_EXTENDED</code> <i>cflags</i> flag.</p> <p>If the <code>REG_NOSUB</code> flag was not set in <i>cflags</i>, then <code>regcomp()</code> will set <i>re_nsub</i> to the number of parenthesised subexpressions (delimited by <code>\(\)</code> in basic regular expressions or <code>()</code> in extended regular expressions) found in <i>pattern</i>.</p> <p><code>regexec()</code> The <code>regexec()</code> function compares the null-terminated string specified by <i>string</i> with the compiled regular expression <i>preg</i> initialized by a previous call to <code>regcomp()</code>. The <i>eflags</i> argument is the bitwise inclusive OR of zero or more of the following flags, which are defined in the header <code><regex.h></code>:</p>

regfree(3C)

REG_NOTBOL	The first character of the string pointed to by <i>string</i> is not the beginning of the line. Therefore, the circumflex character (^), when taken as a special character, will not match the beginning of <i>string</i> .
REG_NOTEOL	The last character of the string pointed to by <i>string</i> is not the end of the line. Therefore, the dollar sign (\$), when taken as a special character, will not match the end of <i>string</i> .

If *nmatch* is zero or REG_NOSUB was set in the *cflags* argument to `regcomp()`, then `regexec()` will ignore the *pmatch* argument. Otherwise, the *pmatch* argument must point to an array with at least *nmatch* elements, and `regexec()` will fill in the elements of that array with offsets of the substrings of *string* that correspond to the parenthesised subexpressions of *pattern*: *pmatch*[*i*].*rm_so* will be the byte offset of the beginning and *pmatch*[*i*].*rm_eo* will be one greater than the byte offset of the end of substring *i*. (Subexpression *i* begins at the *i*th matched open parenthesis, counting from 1.) Offsets in *pmatch*[0] identify the substring that corresponds to the entire regular expression. Unused elements of *pmatch* up to *pmatch*[*nmatch*-1] will be filled with -1. If there are more than *nmatch* subexpressions in *pattern* (*pattern* itself counts as a subexpression), then `regexec()` will still do the match, but will record only the first *nmatch* substrings.

When matching a basic or extended regular expression, any given parenthesised subexpression of *pattern* might participate in the match of several different substrings of *string*, or it might not match any substring even though the pattern as a whole did match. The following rules are used to determine which substrings to report in *pmatch* when matching regular expressions:

1. If subexpression *i* in a regular expression is not contained within another subexpression, and it participated in the match several times, then the byte offsets in *pmatch*[*i*] will delimit the last such match.
2. If subexpression *i* is not contained within another subexpression, and it did not participate in an otherwise successful match, the byte offsets in *pmatch*[*i*] will be -1. A subexpression does not participate in the match when:
 - * or \{\} appears immediately after the subexpression in a basic regular expression, or *, ?, or { } appears immediately after the subexpression in an extended regular expression, and the subexpression did not match (matched zero times)
 - or
 - | is used in an extended regular expression to select this subexpression or another, and the other subexpression matched.
3. If subexpression *i* is contained within another subexpression *j*, and *i* is not contained within any other subexpression that is contained within *j*, and a match of subexpression *j* is reported in *pmatch*[*j*], then the match or

non-match of subexpression *i* reported in *pmatch* [*i*] will be as described in 1. and 2. above, but within the substring reported in *pmatch* [*j*] rather than the whole string.

4. If subexpression *i* is contained in subexpression *j*, and the byte offsets in *pmatch* [*j*] are -1 , then the pointers in *pmatch* [*i*] also will be -1 .
5. If subexpression *i* matched a zero-length string, then both byte offsets in *pmatch* [*i*] will be the byte offset of the character or NULL terminator immediately following the zero-length string.

If, when `regexec()` is called, the locale is different from when the regular expression was compiled, the result is undefined.

If `REG_NEWLINE` is not set in *cflags*, then a NEWLINE character in *pattern* or *string* will be treated as an ordinary character. If `REG_NEWLINE` is set, then newline will be treated as an ordinary character except as follows:

1. A NEWLINE character in *string* will not be matched by a period outside a bracket expression or by any form of a non-matching list.
2. A circumflex (^) in *pattern*, when used to specify expression anchoring will match the zero-length string immediately after a newline in *string*, regardless of the setting of `REG_NOTBOL`.
3. A dollar-sign (\$) in *pattern*, when used to specify expression anchoring, will match the zero-length string immediately before a newline in *string*, regardless of the setting of `REG_NOTEOL`.

`regfree()` The `regfree()` function frees any memory allocated by `regcomp()` associated with *preg*.

The following constants are defined as error return values:

<code>REG_NOMATCH</code>	The <code>regexec()</code> function failed to match.
<code>REG_BADPAT</code>	Invalid regular expression.
<code>REG_ECOLLATE</code>	Invalid collating element referenced.
<code>REG_ECTYPE</code>	Invalid character class type referenced.
<code>REG_EESCAPE</code>	Trailing <code>\</code> in pattern.
<code>REG_ESUBREG</code>	Number in <code>\digit</code> invalid or in error.
<code>REG_EBRACK</code>	[] imbalance.
<code>REG_ENOSYS</code>	The function is not supported.
<code>REG_EPAREN</code>	<code>\(\)</code> or <code>()</code> imbalance.
<code>REG_EBRACE</code>	<code>\{ \}</code> imbalance.

regfree(3C)

	REG_BADBR	Content of <code>\{ \}</code> invalid: not a number, number too large, more than two numbers, first larger than second.
	REG_ERANGE	Invalid endpoint in range expression.
	REG_ESPACE	Out of memory.
	REG_BADRPT	?, * or + not preceded by valid regular expression.
regerror()		<p>The <code>regerror()</code> function provides a mapping from error codes returned by <code>regcomp()</code> and <code>regexexec()</code> to unspecified printable strings. It generates a string corresponding to the value of the <code>errcode</code> argument, which must be the last non-zero value returned by <code>regcomp()</code> or <code>regexexec()</code> with the given value of <code>preg</code>. If <code>errcode</code> is not such a value, an error message indicating that the error code is invalid is returned.</p> <p>If <code>preg</code> is a <code>NULL</code> pointer, but <code>errcode</code> is a value returned by a previous call to <code>regexexec()</code> or <code>regcomp()</code>, the <code>regerror()</code> still generates an error string corresponding to the value of <code>errcode</code>.</p> <p>If the <code>errbuf_size</code> argument is not zero, <code>regerror()</code> will place the generated string into the buffer of size <code>errbuf_size</code> bytes pointed to by <code>errbuf</code>. If the string (including the terminating <code>NULL</code>) cannot fit in the buffer, <code>regerror()</code> will truncate the string and null-terminate the result.</p> <p>If <code>errbuf_size</code> is zero, <code>regerror()</code> ignores the <code>errbuf</code> argument, and returns the size of the buffer needed to hold the generated string.</p> <p>If the <code>preg</code> argument to <code>regexexec()</code> or <code>regfree()</code> is not a compiled regular expression returned by <code>regcomp()</code>, the result is undefined. A <code>preg</code> is no longer treated as a compiled regular expression after it is given to <code>regfree()</code>.</p> <p>See <code>regex(5)</code> for BRE (Basic Regular Expression) Anchoring.</p>
RETURN VALUES		<p>On successful completion, the <code>regcomp()</code> function returns 0. Otherwise, it returns an integer value indicating an error as described in <code><regex.h></code>, and the content of <code>preg</code> is undefined.</p> <p>On successful completion, the <code>regexexec()</code> function returns 0. Otherwise it returns <code>REG_NOMATCH</code> to indicate no match, or <code>REG_ENOSYS</code> to indicate that the function is not supported.</p> <p>Upon successful completion, the <code>regerror()</code> function returns the number of bytes needed to hold the entire generated string. Otherwise, it returns 0 to indicate that the function is not implemented.</p> <p>The <code>regfree()</code> function returns no value.</p>
ERRORS		No errors are defined.
USAGE		An application could use:

```
regerror(code, preg, (char *)NULL, (size_t)0)
```

to find out how big a buffer is needed for the generated string, `malloc` a buffer to hold the string, and then call `regerror()` again to get the string (see `malloc(3C)`). Alternately, it could allocate a fixed, static buffer that is big enough to hold most strings, and then use `malloc()` to allocate a larger buffer if it finds that this is too small.

EXAMPLES

EXAMPLE 1 Example to match string against the extended regular expression in pattern.

```
#include <regex.h>
/*
 * Match string against the extended regular expression in
 * pattern, treating errors as no match.
 *
 * return 1 for match, 0 for no match
 */

int
match(const char *string, char *pattern)
{
    int status;
    regex_t re;
    if (regcomp(&re, pattern, REG_EXTENDED | REG_NOSUB) != 0) {
        return(0);      /* report error */
    }
    status = regexec(&re, string, (size_t)0, NULL, 0);
    regfree(&re);
    if (status != 0) {
        return(0);      /* report error */
    }
    return(1);
}
```

The following demonstrates how the `REG_NOTBOL` flag could be used with `regexec()` to find all substrings in a line that match a pattern supplied by a user. (For simplicity of the example, very little error checking is done.)

```
(void) regcomp (&re, pattern, 0);
/* this call to regexec() finds the first match on the line */
error = regexec (&re, &buffer[0], 1, &pm, 0);
while (error == 0) { /* while matches found */
    /* substring found between pm.rm_so and pm.rm_eo */
    /* This call to regexec() finds the next match */
    error = regexec (&re, buffer + pm.rm_eo, 1, &pm, REG_NOTBOL);
}
```

NOTES The `regcomp()` function can be used safely in a multithreaded application as long as `setlocale(3C)` is not being called to change the locale.

NAME	remove – remove file				
SYNOPSIS	<pre>#include <stdio.h> int remove(const char *path);</pre>				
DESCRIPTION	<p>The <code>remove()</code> function causes the file or empty directory whose name is the string pointed to by <i>path</i> to be no longer accessible by that name. A subsequent attempt to open that file using that name will fail, unless the file is created anew.</p> <p>For files, <code>remove()</code> is identical to <code>unlink()</code>. For directories, <code>remove()</code> is identical to <code>rmdir()</code>.</p> <p>See <code>rmdir(2)</code> and <code>unlink(2)</code> for a detailed list of failure conditions.</p>				
RETURN VALUES	Upon successful completion, <code>remove()</code> returns 0. Otherwise, it returns -1 and sets <code>errno</code> to indicate an error.				
ATTRIBUTES	See <code>attributes(5)</code> for descriptions of the following attributes:				
	<table border="1"> <thead> <tr> <th>ATTRIBUTE TYPE</th> <th>ATTRIBUTE VALUE</th> </tr> </thead> <tbody> <tr> <td>MT-Level</td> <td>MT-Safe</td> </tr> </tbody> </table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	MT-Level	MT-Safe

remque(3C)

NAME insque, remque – insert/remove element from a queue

SYNOPSIS

```
include <search.h>

void insque(struct qelem *elem, struct qelem *pred);
void remque(struct qelem *elem);
```

DESCRIPTION The insque() and remque() functions manipulate queues built from doubly linked lists. Each element in the queue must be in the following form:

```
struct qelem {
    struct qelem *q_forw;
    struct qelem *q_back;
    char        q_data[ ];
};
```

The insque() function inserts *elem* in a queue immediately after *pred*. The remque() function removes an entry *elem* from a queue.

ATTRIBUTES See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
MT-Level	Unsafe

SEE ALSO attributes(5)

NAME	getmntent, getmntany, getextmntent, hasmntopt, putmntent, resetmnttab – get mounted device information
SYNOPSIS	<pre>#include <stdio.h> #include <sys/mnttab.h> int getmntent(FILE *fp, struct mnttab *mp); int getmntany(FILE *fp, struct mnttab *mp, struct mnttab *mpref); int getextmntent(FILE *fp, struct extmnttab *mp, int len); char *hasmntopt(struct mnttab *mnt, char *opt); int putmntent(FILE *iop, struct mnttab *mp); void resetmnttab(FILE *fp);</pre>
getmntent() and getmntany()	<p>The <code>getmntent()</code> and <code>getmntany()</code> functions each fill in the structure pointed to by <code>mp</code> with the broken-out fields of a line in the <code>mnttab</code> file. Each line read from the file contains a <code>mnttab</code> structure, which is defined in the <code><sys/mnttab.h></code> header. The structure contains the following members, which correspond to the broken-out fields from a line in <code>/etc/mnttab</code> (see <code>mnttab(4)</code>).</p> <pre>char *mnt_special; /* name of mounted resource */ char *mnt_mountp; /* mount point */ char *mnt_fstype; /* type of file system mounted */ char *mnt_mntopts; /* options for this mount */ char *mnt_time; /* time file system mounted */</pre> <p>Each <code>getmntent()</code> call causes a new line to be read from the <code>mnttab</code> file. Successive calls can be used to search the entire list. The <code>getmntany()</code> function searches the file referenced by <code>fp</code> until a match is found between a line in the file and <code>mpref</code>. A match occurs if all non-null entries in <code>mpref</code> match the corresponding fields in the file. Note that these functions do not open, close, or rewind the file.</p>
getextmntent()	<p>The <code>getextmntent()</code> function is an extended version of the <code>getmntent()</code> function that returns, in addition to the information that <code>getmntent()</code> returns, the major and minor number of the mounted resource to which the line in <code>mnttab</code> corresponds. The <code>getextmntent()</code> function also fills in the <code>extmntent</code> structure defined in the <code><sys/mnttab.h></code> header. For <code>getextmntent()</code> to function properly, it must be notified when the <code>mnttab</code> file has been reopened or rewound since a previous <code>getextmntent()</code> call. This notification is accomplished by calling <code>resetmnttab()</code>. Otherwise, it behaves exactly as <code>getmntent()</code> described above.</p> <p>The data pointed to by the <code>mnttab</code> structure members are stored in a static area and must be copied to be saved between successive calls.</p>
hasmntopt()	<p>The <code>hasmntopt()</code> function scans the <code>mnt_mntopts</code> member of the <code>mnttab</code> structure <code>mnt</code> for a substring that matches <code>opt</code>. It returns the address of the substring if a match is found; otherwise it returns 0. Substrings are delimited by commas and the end of the <code>mnt_mntopts</code> string.</p>

resetmnttab(3C)

- `putmntent()` The `putmntent()` function is obsolete and no longer has any effect. Entries appear in `mnttab` as a side effect of a `mount(2)` call. The function name is still defined for transition purposes.
- `resetmnttab()` The `resetmnttab()` function notifies `getextmntent()` to reload from the kernel the device information that corresponds to the new snapshot of the `mnttab` information (see `mnttab(4)`). Subsequent `getextmntent()` calls then return correct `extmnttab` information. This function should be called whenever the `mnttab` file is either rewound or closed and reopened before any calls are made to `getextmntent()`.
- `getmntent()` and `getmntany()` If the next entry is successfully read by `getmntent()` or a match is found with `getmntany()`, 0 is returned. If an EOF is encountered on reading, these functions return -1. If an error is encountered, a value greater than 0 is returned. The following error values are defined in `<sys/mnttab.h>`:
- `MNT_TOOLONG` A line in the file exceeded the internal buffer size of `MNT_LINE_MAX`.
- `MNT_TOOMANY` A line in the file contains too many fields.
- `MNT_TOOFEW` A line in the file contains too few fields.
- `hasmntopt()` Upon successful completion, `hasmntopt()` returns the address of the substring if a match is found. Otherwise, it returns 0.
- `putmntent()` The `putmntent()` is obsolete and always returns -1.

NAME | rewind – reset file position indicator in a stream

SYNOPSIS | `#include <stdio.h>`
`void rewind(FILE *stream) ;`

DESCRIPTION | The call:
`rewind(stream)`
 is equivalent to:
`(void) fseek(stream, 0L, SEEK_SET)`
 except that `rewind()` also clears the error indicator.

RETURN VALUES | The `rewind()` function returns no value.

ERRORS | Refer to `fseek(3C)` with the exception of `EINVAL` which does not apply.

USAGE | Because `rewind()` does not return a value, an application wishing to detect errors should clear `errno`, then call `rewind()`, and if `errno` is non-zero, assume an error has occurred.

ATTRIBUTES | See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
MT-Level	MT-Safe

SEE ALSO | `fseek(3C)`, `attributes(5)`

rewinddir(3C)

NAME | rewinddir – reset position of directory stream to the beginning of a directory

SYNOPSIS | #include <sys/types.h>
| #include <dirent.h>
|
| void **rewinddir**(DIR *dirp) ;

DESCRIPTION | The `rewinddir()` function resets the position of the directory stream to which *dirp* refers to the beginning of the directory. It also causes the directory stream to refer to the current state of the corresponding directory, as a call to `opendir(3C)` would have done. If *dirp* does not refer to a directory stream, the effect is undefined.

| After a call to the `fork(2)` function, either the parent or child (but not both) may continue processing the directory stream using `readdir(3C)`, `rewinddir()` or `seekdir(3C)`. If both the parent and child processes use these functions, the result is undefined.

RETURN VALUES | The `rewinddir()` function does not return a value.

ERRORS | No errors are defined.

USAGE | The `rewinddir()` function should be used in conjunction with `opendir()`, `readdir()`, and `closedir(3C)` to examine the contents of the directory. This method is recommended for portability.

ATTRIBUTES | See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
MT-Level	Safe

NAME	index, rindex – string operations
SYNOPSIS	<pre>#include <strings.h> char *index(const char *s, int c); char *rindex(const char *s, int c);</pre>
DESCRIPTION	<p>The <code>index()</code> and <code>rindex()</code> functions operate on null-terminated strings.</p> <p>The <code>index()</code> function returns a pointer to the first occurrence of character <code>c</code> in string <code>s</code>.</p> <p>The <code>rindex()</code> function returns a pointer to the last occurrence of character <code>c</code> in string <code>s</code>.</p> <p>Both <code>index()</code> and <code>rindex()</code> return a null pointer if <code>c</code> does not occur in the string. The null character terminating a string is considered to be part of the string.</p>
USAGE	<p>On most modern computer systems, you can <i>not</i> use a null pointer to indicate a null string. A null pointer is an error and results in an abort of the program. If you wish to indicate a null string, you must use a pointer that points to an explicit null string. On some machines and with some implementations of the C programming language, a null pointer, if dereferenced, would yield a null string. Though often used, this practice is not always portable. Programmers using a null pointer to represent an empty string should be aware of this portability issue. Even on machines where dereferencing a null pointer does not cause an abort of the program, it does not necessarily yield a null string.</p>
SEE ALSO	<code>bstring(3C)</code> , <code>malloc(3C)</code> , <code>string(3C)</code>

scandir(3UCB)

NAME	scandir, alphasort – scan a directory
SYNOPSIS	<pre>/usr/ucb/cc [flag...] file... #include <sys/types.h> #include <sys/dir.h> int scandir(<i>dirname</i>, <i>namelist</i>, <i>select</i>, <i>dcomp</i>); char *<i>dirname</i>; struct direct *(*<i>namelist</i>[]) ; int (*<i>select</i>.), (*<i>dcomp</i>) (); int alphasort(<i>d1</i>, <i>d2</i>); struct direct **<i>d1</i>, **<i>d2</i>;</pre>
DESCRIPTION	<p>The <code>scandir()</code> function reads the directory <i>dirname</i> and builds an array of pointers to directory entries using <code>malloc(3C)</code>. The second parameter is a pointer to an array of structure pointers. The third parameter is a pointer to a routine which is called with a pointer to a directory entry and should return a non zero value if the directory entry should be included in the array. If this pointer is <code>NULL</code>, then all the directory entries will be included. The last argument is a pointer to a routine which is passed to <code>qsort(3C)</code>, which sorts the completed array. If this pointer is <code>NULL</code>, the array is not sorted.</p> <p>The <code>alphasort()</code> function sorts the array alphabetically.</p>
RETURN VALUES	<p>The <code>scandir()</code> function returns the number of entries in the array and a pointer to the array through the parameter <i>namelist</i>. The <code>scandir()</code> function returns <code>-1</code> if the directory cannot be opened for reading or if <code>malloc(3C)</code> cannot allocate enough memory to hold all the data structures.</p> <p>The <code>alphasort()</code> function returns an integer greater than, equal to, or less than 0 if the directory entry name pointed to by <i>d1</i> is greater than, equal to, or less than the directory entry name pointed to by <i>d2</i>.</p>
USAGE	The <code>scandir()</code> and <code>alphasort()</code> functions have transitional interfaces for 64-bit file offsets. See <code>lf64(5)</code> .
SEE ALSO	<code>getdents(2)</code> , <code>malloc(3C)</code> , <code>qsort(3C)</code> , <code>readdir(3UCB)</code> , <code>readdir(3C)</code> , <code>lf64(5)</code>
NOTES	Use of these functions should be restricted to applications written on BSD platforms. Use of these functions with any of the system libraries or in multithreaded applications is unsupported.

NAME	scanf, fscanf, sscanf, vscanf, vfscanf, vsscanf – convert formatted input
SYNOPSIS	<pre> #include <stdio.h> int scanf(const char *format, ...); int fscanf(FILE*stream, const char *format, ...); int sscanf(const char *s, const char *format, ...); #include <stdarg.h> #include <stdio.h> int vscanf(const char *format, va_list arg); int vfscanf(FILE *stream, const char *format, va_list arg); int vsscanf(const char *s, const char *format, va_list arg); </pre>
DESCRIPTION	<p>The <code>scanf()</code> function reads from the standard input stream <code>stdin</code>.</p> <p>The <code>fscanf()</code> function reads from the named input <code>stream</code>.</p> <p>The <code>sscanf()</code> function reads from the string <code>s</code>.</p> <p>The <code>vscanf()</code>, <code>vfscanf()</code>, and <code>vsscanf()</code> functions are equivalent to the <code>scanf()</code>, <code>fscanf()</code>, and <code>sscanf()</code> functions, respectively, except that instead of being called with a variable number of arguments, they are called with an argument list as defined by the <code><stdarg.h></code> header (see <code>stdarg(3HEAD)</code>). These functions do not invoke the <code>va_end()</code> macro. Applications using these functions should call <code>va_end(ap)</code> afterwards to clean up.</p> <p>Each function reads bytes, interprets them according to a format, and stores the results in its arguments. Each expects, as arguments, a control string <i>format</i> described below, and a set of <i>pointer</i> arguments indicating where the converted input should be stored. The result is undefined if there are insufficient arguments for the format. If the format is exhausted while arguments remain, the excess arguments are evaluated but are otherwise ignored.</p> <p>Conversions can be applied to the <i>n</i>th argument after the <i>format</i> in the argument list, rather than to the next unused argument. In this case, the conversion character <code>%</code> (see below) is replaced by the sequence <code>%n\$</code>, where <i>n</i> is a decimal integer in the range <code>[1, NL_ARGMAX]</code>. This feature provides for the definition of format strings that select arguments in an order appropriate to specific languages. In format strings containing the <code>%n\$</code> form of conversion specifications, it is unspecified whether numbered arguments in the argument list can be referenced from the format string more than once.</p> <p>The <i>format</i> can contain either form of a conversion specification, that is, <code>%</code> or <code>%n\$</code>, but the two forms cannot normally be mixed within a single <i>format</i> string. The only exception to this is that <code>%%</code> or <code>%*</code> can be mixed with the <code>%n\$</code> form.</p>

The `scanf()` function in all its forms allows for detection of a language-dependent radix character in the input string. The radix character is defined in the program's locale (category `LC_NUMERIC`). In the POSIX locale, or in a locale where the radix character is not defined, the radix character defaults to a period (`.`).

The format is a character string, beginning and ending in its initial shift state, if any, composed of zero or more directives. Each directive is composed of one of the following:

- one or more *white-space characters* (space, tab, newline, vertical-tab or form-feed characters);
- an *ordinary character* (neither `%` nor a white-space character); or
- a *conversion specification*.

Conversion Specifications

Each conversion specification is introduced by the character `%` or the character sequence `%n$`, after which the following appear in sequence:

- An optional assignment-suppressing character `*`.
- An optional non-zero decimal integer that specifies the maximum field width.
- An optional size modifier `h`, `l` (ell), `ll` (ell ell), or `L` indicating the size of the receiving object. The conversion characters `d`, `i`, and `n` must be preceded by `h` if the corresponding argument is a pointer to `short int` rather than a pointer to `int`, by `l` (ell) if it is a pointer to `long int`, or by `ll` (ell ell) if it is a pointer to `long long int`. Similarly, the conversion characters `o`, `u`, and `x` must be preceded by `h` if the corresponding argument is a pointer to `unsigned short int` rather than a pointer to `unsigned int`, by `l` (ell) if it is a pointer to `unsigned long int`, or by `ll` (ell ell) if it is a pointer to `unsigned long long int`. The conversion characters `e`, `f`, and `g` must be preceded by `l` (ell) if the corresponding argument is a pointer to `double` rather than a pointer to `float`, or by `L` if it is a pointer to `long double`. Finally, the conversion characters `c`, `s`, and `[` must be preceded by `l` (ell) if the corresponding argument is a pointer to `wchar_t` rather than a pointer to a character type. If an `h`, `l` (ell), `ll` (ell ell), or `L` appears with any other conversion character, the behavior is undefined.
- A conversion character that specifies the type of conversion to be applied. The valid conversion characters are described below.

The `scanf()` functions execute each directive of the format in turn. If a directive fails, as detailed below, the function returns. Failures are described as input failures (due to the unavailability of input bytes) or matching failures (due to inappropriate input).

A directive composed of one or more white-space characters is executed by reading input until no more valid input can be read, or up to the first byte which is not a white-space character which remains unread.

A directive that is an ordinary character is executed as follows. The next byte is read from the input and compared with the byte that comprises the directive; if the comparison shows that they are not equivalent, the directive fails, and the differing and subsequent bytes remain unread.

A directive that is a conversion specification defines a set of matching input sequences, as described below for each conversion character. A conversion specification is executed in the following steps:

Input white-space characters (as specified by `isspace(3C)`) are skipped, unless the conversion specification includes a `[\, c, C, or n` conversion character.

An item is read from the input, unless the conversion specification includes an `n` conversion character. An input item is defined as the longest sequence of input bytes (up to any specified maximum field width, which may be measured in characters or bytes dependent on the conversion character) which is an initial subsequence of a matching sequence. The first byte, if any, after the input item remains unread. If the length of the input item is 0, the execution of the conversion specification fails; this condition is a matching failure, unless end-of-file, an encoding error, or a read error prevented input from the stream, in which case it is an input failure.

Except in the case of a `%` conversion character, the input item (or, in the case of a `%n` conversion specification, the count of input bytes) is converted to a type appropriate to the conversion character. If the input item is not a matching sequence, the execution of the conversion specification fails; this condition is a matching failure. Unless assignment suppression was indicated by a `*`, the result of the conversion is placed in the object pointed to by the first argument following the *format* argument that has not already received a conversion result if the conversion specification is introduced by `%`, or in the *n*th argument if introduced by the character sequence `%n$`. If this object does not have an appropriate type, or if the result of the conversion cannot be represented in the space provided, the behavior is undefined.

Conversion Characters

The following conversion characters are valid:

- `d` Matches an optionally signed decimal integer, whose format is the same as expected for the subject sequence of `strtol(3C)` with the value 10 for the *base* argument. In the absence of a size modifier, the corresponding argument must be a pointer to `int`.
- `i` Matches an optionally signed integer, whose format is the same as expected for the subject sequence of `strtol()` with 0 for the *base* argument. In the absence of a size modifier, the corresponding argument must be a pointer to `int`.
- `o` Matches an optionally signed octal integer, whose format is the same as expected for the subject sequence of `strtoul(3C)` with the value 8 for the *base* argument. In the absence of a size modifier, the corresponding argument must be a pointer to `unsigned int`.
- `u` Matches an optionally signed decimal integer, whose format is the same as expected for the subject sequence of `strtoul()` with the value 10 for the *base* argument. In the absence of a size modifier, the corresponding argument must be a pointer to `unsigned int`.
- `x` Matches an optionally signed hexadecimal integer, whose format is the same as expected for the subject sequence of `strtoul()` with the value 16

scanf(3C)

	<p>for the <i>base</i> argument. In the absence of a size modifier, the corresponding argument must be a pointer to <code>unsigned int</code>.</p>
e,f,g	<p>Matches an optionally signed floating-point number, whose format is the same as expected for the subject sequence of <code>strtod(3C)</code>. In the absence of a size modifier, the corresponding argument must be a pointer to <code>float</code>.</p> <p>If the <code>printf(3C)</code> family of functions generates character string representations for infinity and NaN (a 7858 symbolic entity encoded in floating-point format) to support the ANSI/IEEE Std 754: 1985 standard, the <code>scanf()</code> family of functions will recognize them as input.</p>
s	<p>Matches a sequence of bytes that are not white-space characters. The corresponding argument must be a pointer to the initial byte of an array of <code>char</code>, <code>signed char</code>, or <code>unsigned char</code> large enough to accept the sequence and a terminating null character code, which will be added automatically.</p> <p>If an <code>l</code> (ell) qualifier is present, the input is a sequence of characters that begins in the initial shift state. Each character is converted to a wide-character as if by a call to the <code>mbrtowc(3C)</code> function, with the conversion state described by an <code>mbstate_t</code> object initialized to zero before the first character is converted. The corresponding argument must be a pointer to an array of <code>wchar_t</code> large enough to accept the sequence and the terminating null wide-character, which will be added automatically.</p>
[<p>Matches a non-empty sequence of characters from a set of expected characters (the <i>scanset</i>). The normal skip over white-space characters is suppressed in this case. The corresponding argument must be a pointer to the initial byte of an array of <code>char</code>, <code>signed char</code>, or <code>unsigned char</code> large enough to accept the sequence and a terminating null byte, which will be added automatically.</p> <p>If an <code>l</code> (ell) qualifier is present, the input is a sequence of characters that begins in the initial shift state. Each character in the sequence is converted to a wide-character as if by a call to the <code>mbrtowc()</code> function, with the conversion state described by an <code>mbstate_t</code> object initialized to zero before the first character is converted. The corresponding argument must be a pointer to an array of <code>wchar_t</code> large enough to accept the sequence and the terminating null wide-character, which will be added automatically.</p> <p>The conversion specification includes all subsequent characters in the <i>format</i> string up to and including the matching right square bracket (<code>]</code>). The characters between the square brackets (the <i>scanlist</i>) comprise the scanset, unless the character after the left square bracket is a circumflex (<code>^</code>), in which case the scanset contains all characters that do not appear in the scanlist between the circumflex and the right square bracket. If the</p>

conversion specification begins with [] or [^], the right square bracket is included in the scanlist and the next right square bracket is the matching right square bracket that ends the conversion specification; otherwise the first right square bracket is the one that ends the conversion specification. If a - is in the scanlist and is not the first character, nor the second where the first character is a ^, nor the last character, it indicates a range of characters to be matched.

c Matches a sequence of characters of the number specified by the field width (1 if no field width is present in the conversion specification). The corresponding argument must be a pointer to the initial byte of an array of `char`, `signed char`, or `unsigned char` large enough to accept the sequence. No null byte is added. The normal skip over white-space characters is suppressed in this case.

If an `l` (ell) qualifier is present, the input is a sequence of characters that begins in the initial shift state. Each character in the sequence is converted to a wide-character as if by a call to the `mbrtowc()` function, with the conversion state described by an `mbstate_t` object initialized to zero before the first character is converted. The corresponding argument must be a pointer to an array of `wchar_t` large enough to accept the resulting sequence of wide-characters. No null wide-character is added.

p Matches the set of sequences that is the same as the set of sequences that is produced by the `%p` conversion of the corresponding `printf(3C)` functions. The corresponding argument must be a pointer to a pointer to `void`. If the input item is a value converted earlier during the same program execution, the pointer that results will compare equal to that value; otherwise the behavior of the `%p` conversion is undefined.

n No input is consumed. The corresponding argument must be a pointer to the integer into which is to be written the number of bytes read from the input so far by this call to the `scanf()` functions. Execution of a `%n` conversion specification does not increment the assignment count returned at the completion of execution of the function.

C Same as `lc`.

S Same as `ls`.

% Matches a single `%`; no conversion or assignment occurs. The complete conversion specification must be `%%`.

If a conversion specification is invalid, the behavior is undefined.

The conversion characters `E`, `G`, and `X` are also valid and behave the same as, respectively, `e`, `g`, and `x`.

If end-of-file is encountered during input, conversion is terminated. If end-of-file occurs before any bytes matching the current conversion specification (except for `%n`) have been read (other than leading white-space characters, where permitted),

scanf(3C)

execution of the current conversion specification terminates with an input failure. Otherwise, unless execution of the current conversion specification is terminated with a matching failure, execution of the following conversion specification (if any) is terminated with an input failure.

Reaching the end of the string in `sscanf()` is equivalent to encountering end-of-file for `fscanf()`.

If conversion terminates on a conflicting input, the offending input is left unread in the input. Any trailing white space (including newline characters) is left unread unless matched by a conversion specification. The success of literal matches and suppressed assignments is only directly determinable via the `%n` conversion specification.

The `fscanf()` and `scanf()` functions may mark the `st_atime` field of the file associated with *stream* for update. The `st_atime` field will be marked for update by the first successful execution of `fgetc(3C)`, `fgets(3C)`, `fread(3C)`, `fscanf()`, `getc(3C)`, `getchar(3C)`, `gets(3C)`, or `scanf()` using *stream* that returns data not supplied by a prior call to `ungetc(3C)`.

RETURN VALUES

Upon successful completion, these functions return the number of successfully matched and assigned input items; this number can be 0 in the event of an early matching failure. If the input ends before the first matching failure or conversion, EOF is returned. If a read error occurs the error indicator for the stream is set, EOF is returned, and `errno` is set to indicate the error.

ERRORS

For the conditions under which the `scanf()` functions will fail and may fail, refer to `fgetc(3C)` or `fgetwc(3C)`.

In addition, `fscanf()` may fail if:

`EILSEQ` Input byte sequence does not form a valid character.
`EINVAL` There are insufficient arguments.

USAGE

If the application calling the `scanf()` functions has any objects of type `wint_t` or `wchar_t`, it must also include the header `<wchar.h>` to have these objects defined.

EXAMPLES

EXAMPLE 1 The call:

```
int i, n; float x; char name[50];
n = scanf("%d%f%s", &i, &x, name)
```

with the input line:

```
25 54.32E-1 Hamster
```

will assign to *n* the value 3, to *i* the value 25, to *x* the value 5.432, and *name* will contain the string Hamster.

EXAMPLE 2 The call:

```
int i; float x; char name[50];
(void) scanf("%2d%f%*d %[0123456789]", &i, &x, name);
```

with input:

```
56789 0123 56a72
```

will assign 56 to *i*, 789.0 to *x*, skip 0123, and place the string 56\0 in *name*. The next call to `getchar(3C)` will return the character a.

seconvert(3C)

NAME	<code>econvert</code> , <code>fconvert</code> , <code>gconvert</code> , <code>seconvert</code> , <code>sconvert</code> , <code>sgconvert</code> , <code>qeconvert</code> , <code>qfconvert</code> , <code>qgconvert</code> – output conversion
SYNOPSIS	<pre>#include <floatingpoint.h> char *econvert(double value, int ndigit, int *decpt, int *sign, char *buf) ; char *fconvert(double value, int ndigit, int *decpt, int *sign, char *buf) ; char *gconvert(double value, int ndigit, int trailing, char *buf) ; char *seconvert(single *value, int ndigit, int *decpt, int *sign, char *buf) ; char *sconvert(single *value, int ndigit, int *decpt, int *sign, char *buf) ; char *sgconvert(single *value, int ndigit, int trailing, char *buf) ; char *qeconvert(quadruple *value, int ndigit, int *decpt, int *sign, char *buf) ; char *qfconvert(quadruple *value, int ndigit, int *decpt, int *sign, char *buf) ; char *qgconvert(quadruple *value, int ndigit, int trailing, char *buf) ;</pre>
DESCRIPTION	<p>The <code>econvert()</code> function converts the <i>value</i> to a null-terminated string of <i>ndigit</i> ASCII digits in <i>buf</i> and returns a pointer to <i>buf</i>. <i>buf</i> should contain at least <i>ndigit</i>+1 characters. The position of the decimal point relative to the beginning of the string is stored indirectly through <i>decpt</i>. Thus <i>buf</i> == "314" and <i>*decpt</i> == 1 corresponds to the numerical value 3.14, while <i>buf</i> == "314" and <i>*decpt</i> == -1 corresponds to the numerical value .0314. If the sign of the result is negative, the word pointed to by <i>sign</i> is nonzero; otherwise it is zero. The least significant digit is rounded.</p> <p>The <code>fconvert()</code> function works much like <code>econvert()</code>, except that the correct digit has been rounded as if for <code>sprintf(%w.nf)</code> output with <i>n</i>=<i>ndigit</i> digits to the right of the decimal point. <i>ndigit</i> can be negative to indicate rounding to the left of the decimal point. The return value is a pointer to <i>buf</i>. <i>buf</i> should contain at least <code>310+max(0,ndigit)</code> characters to accomodate any double-precision <i>value</i>.</p> <p>The <code>gconvert()</code> function converts the <i>value</i> to a null-terminated ASCII string in <i>buf</i> and returns a pointer to <i>buf</i>. It produces <i>ndigit</i> significant digits in fixed-decimal format, like <code>sprintf(%w.nf)</code>, if possible, and otherwise in floating-decimal format, like <code>sprintf(%w.ne)</code>; in either case <i>buf</i> is ready for printing, with sign and exponent. The result corresponds to that obtained by</p> <pre>(void) sprintf(buf, ``%w.ng'', value) ;</pre> <p>If <i>trailing</i> = 0, trailing zeros and a trailing point are suppressed, as in <code>sprintf(%g)</code>. If <i>trailing</i> != 0, trailing zeros and a trailing point are retained, as in <code>sprintf(%#g)</code>.</p>

The `seconvert()`, `sfconvert()`, and `sgconvert()` functions are single-precision versions of these functions, and are more efficient than the corresponding double-precision versions. A pointer rather than the value itself is passed to avoid C's usual conversion of single-precision arguments to double.

The `geconvert()`, `qfconvert()`, and `ggconvert()` functions are quadruple-precision versions of these functions. The `qfconvert()` function can overflow the `decimal_record` field `ds` if `value` is too large. In that case, `buf[0]` is set to zero.

The `ecvt()`, `fcvt()` and `gcvt()` functions are versions of `econvert()`, `fconvert()`, and `gconvert()`, respectively, that are documented on the `ecvt(3C)` manual page. They constitute the default implementation of these functions and conform to the X/Open CAE Specification, System Interfaces and Headers, Issue 4, Version 2.

USAGE IEEE Infinities and NaNs are treated similarly by these functions. "NaN" is returned for NaN, and "Inf" or "Infinity" for Infinity. The longer form is produced when `ndigit` \geq 8.

seed48(3C)

NAME	drand48, erand48, lrand48, nrand48, mrand48, jrand48, srand48, seed48, lcong48 – generate uniformly distributed pseudo-random numbers
SYNOPSIS	<pre>#include <stdlib.h> double drand48(void); double erand48(unsigned short <i>x_i[3]</i>); long lrnd48(void); long nrand48(unsigned short <i>x_i[3]</i>); long mrnd48(void); long jrnd48(unsigned short <i>x_i[3]</i>); void srand48(long <i>seedval</i>); unsigned short *seed48(unsigned short <i>seed16v[3]</i>); void lcong48(unsigned short <i>param[7]</i>);</pre>
DESCRIPTION	<p>This family of functions generates pseudo-random numbers using the well-known linear congruential algorithm and 48-bit integer arithmetic.</p> <p>Functions <code>drand48()</code> and <code>erand48()</code> return non-negative double-precision floating-point values uniformly distributed over the interval [0.0, 1.0).</p> <p>Functions <code>lrnd48()</code> and <code>nrand48()</code> return non-negative long integers uniformly distributed over the interval $[0, 2^{31}]$.</p> <p>Functions <code>mrnd48()</code> and <code>jrnd48()</code> return signed long integers uniformly distributed over the interval $[-2^{31}, 2^{31}]$.</p> <p>Functions <code>srand48()</code>, <code>seed48()</code>, and <code>lcong48()</code> are initialization entry points, one of which should be invoked before either <code>drand48()</code>, <code>lrnd48()</code>, or <code>mrnd48()</code> is called. (Although it is not recommended practice, constant default initializer values will be supplied automatically if <code>drand48()</code>, <code>lrnd48()</code>, or <code>mrnd48()</code> is called without a prior call to an initialization entry point.) Functions <code>erand48()</code>, <code>nrand48()</code>, and <code>jrnd48()</code> do not require an initialization entry point to be called first.</p> <p>All the routines work by generating a sequence of 48-bit integer values, X_i, according to the linear congruential formula</p> $X_{n+1} = (aX_n + c) \bmod m \quad n \geq 0.$ <p>The parameter $m = 2^{48}$; hence 48-bit integer arithmetic is performed. Unless <code>lcong48()</code> has been invoked, the multiplier value a and the addend value c are given by</p> $a = 5DEECE66D_{16} = 273673163155_8$

$c = B_{16} = 13_8$.

The value returned by any of the functions `drand48()`, `erand48()`, `lrand48()`, `nrand48()`, `rand48()`, or `rand48()` is computed by first generating the next 48-bit X_i in the sequence. Then the appropriate number of bits, according to the type of data item to be returned, are copied from the high-order (leftmost) bits of X_i and transformed into the returned value.

The functions `drand48()`, `lrand48()`, and `rand48()` store the last 48-bit X_i generated in an internal buffer. X_i must be initialized prior to being invoked. The functions `erand48()`, `nrand48()`, and `rand48()` require the calling program to provide storage for the successive X_i values in the array specified as an argument when the functions are invoked. These routines do not have to be initialized; the calling program must place the desired initial value of X_i into the array and pass it as an argument. By using different arguments, functions `erand48()`, `nrand48()`, and `rand48()` allow separate modules of a large program to generate several *independent* streams of pseudo-random numbers, that is, the sequence of numbers in each stream will *not* depend upon how many times the routines have been called to generate numbers for the other streams.

The initializer function `srand48()` sets the high-order 32 bits of X_i to the 32 bits contained in its argument. The low-order 16 bits of X_i are set to the arbitrary value $330E_{16}$.

The initializer function `seed48()` sets the value of X_i to the 48-bit value specified in the argument array. In addition, the previous value of X_i is copied into a 48-bit internal buffer, used only by `seed48()`, and a pointer to this buffer is the value returned by `seed48()`. This returned pointer, which can just be ignored if not needed, is useful if a program is to be restarted from a given point at some future time — use the pointer to get at and store the last X_i value, and then use this value to reinitialize using `seed48()` when the program is restarted.

The initialization function `lcg48()` allows the user to specify the initial X_i the multiplier value a , and the addend value c . Argument array elements `param[0-2]` specify X_i , `param[3-5]` specify the multiplier a , and `param[6]` specifies the 16-bit addend c . After `lcg48()` has been called, a subsequent call to either `srand48()` or `seed48()` will restore the “standard” multiplier and addend values, a and c , specified above.

seekdir(3C)

NAME	seekdir – set position of directory stream				
SYNOPSIS	<pre>#include <sys/types.h> #include <dirent.h> void seekdir(DIR *dirp, long int loc);</pre>				
DESCRIPTION	<p>The <code>seekdir()</code> function sets the position of the next <code>readdir(3C)</code> operation on the directory stream specified by <code>dirp</code> to the position specified by <code>loc</code>. The value of <code>loc</code> should have been returned from an earlier call to <code>telldir(3C)</code>. The new position reverts to the one associated with the directory stream when <code>telldir()</code> was performed.</p> <p>If the value of <code>loc</code> was not obtained from an earlier call to <code>telldir()</code> or if a call to <code>rewinddir(3C)</code> occurred between the call to <code>telldir()</code> and the call to <code>seekdir()</code>, the results of subsequent calls to <code>readdir()</code> are unspecified.</p>				
RETURN VALUES	The <code>seekdir()</code> function returns no value.				
ERRORS	No errors are defined.				
ATTRIBUTES	See <code>attributes(5)</code> for descriptions of the following attributes:

NAME	select, FD_SET, FD_CLR, FD_ISSET, FD_ZERO – synchronous I/O multiplexing
SYNOPSIS	<pre>#include <sys/time.h> int select(int <i>nfds</i>, fd_set *<i>readfds</i>, fd_set *<i>writefds</i>, fd_set *<i>errorfds</i>, struct timeval *<i>timeout</i>); void FD_SET(int <i>fd</i>, fd_set *<i>fdset</i>); void FD_CLR(int <i>fd</i>, fd_set *<i>fdset</i>); int FD_ISSET(int <i>fd</i>, fd_set *<i>fdset</i>); void FD_ZERO(fd_set *<i>fdset</i>);</pre>
DESCRIPTION	<p>The <code>select()</code> function indicates which of the specified file descriptors is ready for reading, ready for writing, or has an error condition pending. If the specified condition is false for all of the specified file descriptors, <code>select()</code> blocks, up to the specified timeout interval, until the specified condition is true for at least one of the specified file descriptors.</p> <p>The <code>select()</code> function supports regular files, terminal and pseudo-terminal devices, STREAMS-based files, FIFOs and pipes. The behavior of <code>select()</code> on file descriptors that refer to other types of file is unspecified.</p> <p>The <i>nfds</i> argument specifies the range of file descriptors to be tested. The <code>select()</code> function tests file descriptors in the range of 0 to <i>nfds</i>-1.</p> <p>If the <i>readfds</i> argument is not a null pointer, it points to an object of type <code>fd_set</code> that on input specifies the file descriptors to be checked for being ready to read, and on output indicates which file descriptors are ready to read.</p> <p>If the <i>writefds</i> argument is not a null pointer, it points to an object of type <code>fd_set</code> that on input specifies the file descriptors to be checked for being ready to write, and on output indicates which file descriptors are ready to write.</p> <p>If the <i>errorfds</i> argument is not a null pointer, it points to an object of type <code>fd_set</code> that on input specifies the file descriptors to be checked for error conditions pending, and on output indicates which file descriptors have error conditions pending.</p> <p>On successful completion, the objects pointed to by the <i>readfds</i>, <i>writefds</i>, and <i>errorfds</i> arguments are modified to indicate which file descriptors are ready for reading, ready for writing, or have an error condition pending, respectively. For each file descriptor less than <i>nfds</i>, the corresponding bit will be set on successful completion if it was set on input and the associated condition is true for that file descriptor.</p> <p>If the <i>timeout</i> argument is not a null pointer, it points to an object of type <code>struct timeval</code> that specifies a maximum interval to wait for the selection to complete. If the <i>timeout</i> argument points to an object of type <code>struct timeval</code> whose members are 0, <code>select()</code> does not block. If the <i>timeout</i> argument is a null pointer, <code>select()</code> blocks</p>

select(3C)

until an event causes one of the masks to be returned with a valid (non-zero) value. If the time limit expires before any event occurs that would cause one of the masks to be set to a non-zero value, `select()` completes successfully and returns 0.

If the `readfs`, `writefs`, and `errorfds` arguments are all null pointers and the `timeout` argument is not a null pointer, `select()` blocks for the time specified, or until interrupted by a signal. If the `readfs`, `writefs`, and `errorfds` arguments are all null pointers and the `timeout` argument is a null pointer, `select()` blocks until interrupted by a signal.

File descriptors associated with regular files always select true for ready to read, ready to write, and error conditions.

On failure, the objects pointed to by the `readfs`, `writefs`, and `errorfds` arguments are not modified. If the timeout interval expires without the specified condition being true for any of the specified file descriptors, the objects pointed to by the `readfs`, `writefs`, and `errorfds` arguments have all bits set to 0.

A file descriptor for a socket that is listening for connections will indicate that it is ready for reading, when connections are available. A file descriptor for a socket that is connecting asynchronously will indicate that it is ready for writing, when a connection has been established.

Selecting true for reading on a socket descriptor upon which a `listen(3SOCKET)` call has been performed indicates that a subsequent `accept(3SOCKET)` call on that descriptor will not block.

File descriptor masks of type `fd_set` can be initialized and tested with the macros `FD_CLR()`, `FD_ISSET()`, `FD_SET()`, and `FD_ZERO()`.

<code>FD_CLR(<i>fd</i>, &<i>fdset</i>)</code>	Clears the bit for the file descriptor <i>fd</i> in the file descriptor set <i>fdset</i> .
<code>FD_ISSET(<i>fd</i>, &<i>fdset</i>)</code>	Returns a non-zero value if the bit for the file descriptor <i>fd</i> is set in the file descriptor set pointed to by <i>fdset</i> , and 0 otherwise.
<code>FD_SET(<i>fd</i>, &<i>fdset</i>)</code>	Sets the bit for the file descriptor <i>fd</i> in the file descriptor set <i>fdset</i> .
<code>FD_ZERO(&<i>fdset</i>)</code>	Initializes the file descriptor set <i>fdset</i> to have zero bits for all file descriptors.

The behavior of these macros is undefined if the *fd* argument is less than 0 or greater than or equal to `FD_SETSIZE`.

RETURN VALUES

The `FD_CLR()`, `FD_SET()`, and `FD_ZERO()` macros return no value. The `FD_ISSET()` macro returns a non-zero value if the bit for the file descriptor *fd* is set in the file descriptor set pointed to by *fdset*, and 0 otherwise.

On successful completion, `select()` returns the total number of bits set in the bit masks. Otherwise, `-1` is returned, and `errno` is set to indicate the error.

ERRORS

The `select()` function will fail if:

EBADF	One or more of the file descriptor sets specified a file descriptor that is not a valid open file descriptor.
EINTR	The <code>select()</code> function was interrupted before any of the selected events occurred and before the timeout interval expired. If <code>SA_RESTART</code> has been set for the interrupting signal, it is implementation-dependent whether <code>select()</code> restarts or returns with <code>EINTR</code> .
EINVAL	An invalid timeout interval was specified.
EINVAL	The <code>nfds</code> argument is less than 0 or greater than <code>FD_SETSIZE</code> .
EINVAL	One of the specified file descriptors refers to a <code>STREAM</code> or multiplexer that is linked (directly or indirectly) downstream from a multiplexer.
EINVAL	A component of the pointed-to time limit is outside the acceptable range: <code>t_sec</code> must be between 0 and 10^8 , inclusive. <code>t_usec</code> must be greater than or equal to 0, and less than 10^6 .

USAGE

The `poll(2)` function is preferred over this function. It must be used when the number of file descriptors exceeds `FD_SETSIZE`.

The use of a timeout does not affect any pending timers set up by `alarm(2)`, `ualarm(3C)` or `setitimer(2)`.

On successful completion, the object pointed to by the `timeout` argument may be modified.

ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
MT-Level	MT-Safe

SEE ALSO

`alarm(2)`, `fcntl(2)`, `poll(2)`, `read(2)`, `setitimer(2)`, `write(2)`, `accept(3SOCKET)`, `listen(3SOCKET)`, `ualarm(3C)`, `attributes(5)`

NOTES

The default value for `FD_SETSIZE` (currently 1024) is larger than the default limit on the number of open files. To accommodate 32-bit applications that wish to use a larger number of open files with `select()`, it is possible to increase this size at compile time

select(3C)

by providing a larger definition of `FD_SETSIZE` before the inclusion of any system-supplied header. The maximum supported size for `FD_SETSIZE` is 65536. The default value is already 65536 for 64-bit applications.

NAME	setbuf, setvbuf – assign buffering to a stream						
SYNOPSIS	<pre>#include <stdio.h> void setbuf(FILE *stream, char *buf); int setvbuf(FILE *stream, char *buf, int type, size_t size);</pre>						
DESCRIPTION	<p>The <code>setbuf()</code> function may be used after the stream pointed to by <code>stream</code> (see <code>intro(3)</code>) is opened but before it is read or written. It causes the array pointed to by <code>buf</code> to be used instead of an automatically allocated buffer. If <code>buf</code> is the null pointer, input/output will be completely unbuffered. The constant <code>BUFSIZ</code>, defined in the <code><stdio.h></code> header, indicates the size of the array pointed to by <code>buf</code>.</p> <p>The <code>setvbuf()</code> function may be used after a stream is opened but before it is read or written. The <code>type</code> argument determines how <code>stream</code> will be buffered. Legal values for <code>type</code> (defined in <code><stdio.h></code>) are:</p> <table border="0"> <tr> <td style="padding-right: 20px;"><code>_IOFBF</code></td> <td>Input/output to be fully buffered.</td> </tr> <tr> <td><code>_IOLBF</code></td> <td>Output to be line buffered; the buffer will be flushed when a <code>NEWLINE</code> is written, the buffer is full, or input is requested.</td> </tr> <tr> <td><code>_IONBF</code></td> <td>Input/output to be completely unbuffered.</td> </tr> </table> <p>If <code>buf</code> is not the null pointer, the array it points to will be used for buffering, instead of an automatically allocated buffer. The <code>size</code> argument specifies the size of the buffer to be used. If input/output is unbuffered, <code>buf</code> and <code>size</code> are ignored.</p> <p>For a further discussion of buffering, see <code>stdio(3C)</code>.</p>	<code>_IOFBF</code>	Input/output to be fully buffered.	<code>_IOLBF</code>	Output to be line buffered; the buffer will be flushed when a <code>NEWLINE</code> is written, the buffer is full, or input is requested.	<code>_IONBF</code>	Input/output to be completely unbuffered.
<code>_IOFBF</code>	Input/output to be fully buffered.						
<code>_IOLBF</code>	Output to be line buffered; the buffer will be flushed when a <code>NEWLINE</code> is written, the buffer is full, or input is requested.						
<code>_IONBF</code>	Input/output to be completely unbuffered.						
RETURN VALUES	If an illegal value for <code>type</code> is provided, <code>setvbuf()</code> returns a non-zero value. Otherwise, it returns 0.						
USAGE	<p>A common source of error is allocating buffer space as an “automatic” variable in a code block, and then failing to close the stream in the same block.</p> <p>When using <code>setbuf()</code>, <code>buf</code> should always be sized using <code>BUFSIZ</code>. If the array pointed to by <code>buf</code> is larger than <code>BUFSIZ</code>, a portion of <code>buf</code> will not be used. If <code>buf</code> is smaller than <code>BUFSIZ</code>, other memory may be unexpectedly overwritten.</p> <p>Parts of <code>buf</code> will be used for internal bookkeeping of the stream and, therefore, <code>buf</code> will contain less than <code>size</code> bytes when full. It is recommended that <code>stdio(3C)</code> be used to handle buffer allocation when using <code>setvbuf()</code>.</p>

NAME	setbuffer, setlinebuf – assign buffering to a stream
SYNOPSIS	<pre>#include <stdio.h> void setbuffer(FILE *iop, char *abuf, size_t asize); int setlinebuf(FILE *iop);</pre>
DESCRIPTION	<p>The <code>setbuffer()</code> and <code>setlinebuf()</code> functions assign buffering to a stream. The three types of buffering available are unbuffered, block buffered, and line buffered. When an output stream is unbuffered, information appears on the destination file or terminal as soon as written; when it is block buffered, many characters are saved and written as a block; when it is line buffered, characters are saved until either a NEWLINE is encountered or input is read from <code>stdin</code>. The <code>fflush(3C)</code> function may be used to force the block out early. Normally all files are block buffered. A buffer is obtained from <code>malloc(3C)</code> upon the first <code>getc(3C)</code> or <code>putc(3C)</code> performed on the file. If the standard stream <code>stdout</code> refers to a terminal, it is line buffered. The standard stream <code>stderr</code> is unbuffered by default.</p> <p>The <code>setbuffer()</code> function can be used after a stream <code>iop</code> has been opened but before it is read or written. It uses the character array <code>abuf</code> whose size is determined by the <code>asize</code> argument instead of an automatically allocated buffer. If <code>abuf</code> is the null pointer, input/output will be completely unbuffered. A manifest constant <code>BUFSIZ</code>, defined in the <code><stdio.h></code> header, tells how large an array is needed:</p> <pre>char buf[BUFSIZ];</pre> <p>The <code>setlinebuf()</code> function is used to change the buffering on a stream from block buffered or unbuffered to line buffered. Unlike <code>setbuffer()</code>, it can be used at any time that the stream <code>iop</code> is active.</p> <p>A stream can be changed from unbuffered or line buffered to block buffered by using <code>freopen(3C)</code>. A stream can be changed from block buffered or line buffered to unbuffered by using <code>freopen(3C)</code> followed by <code>setbuf(3C)</code> with a buffer argument of <code>NULL</code>.</p>
RETURN VALUES	The <code>setlinebuf()</code> function returns no useful value.
SEE ALSO	<code>malloc(3C)</code> , <code>fclose(3C)</code> , <code>fopen(3C)</code> , <code>fread(3C)</code> , <code>getc(3C)</code> , <code>printf(3C)</code> , <code>putc(3C)</code> , <code>puts(3C)</code> , <code>setbuf(3C)</code> , <code>setvbuf(3C)</code>
NOTES	A common source of error is allocating buffer space as an “automatic” variable in a code block, and then failing to close the stream in the same block.

setcat(3C)

NAME setcat – define default catalog

SYNOPSIS

```
#include <pfmt.h>
char *setcat(const char *catalog);
```

DESCRIPTION The `setcat()` function defines the default message catalog to be used by subsequent calls to `gettext(3C)`, `lfmt(3C)`, or `pfmt(3C)` that do not explicitly specify a message catalog.

The *catalog* argument must be limited to 14 characters. These characters must be selected from a set of all characters values, excluding `\0` (null) and the ASCII codes for `/` (slash) and `:` (colon).

The `setcat()` function assumes that the catalog exists. No checking is done on the argument.

A null pointer passed as an argument will result in the return of a pointer to the current default message catalog name. A pointer to an empty string passed as an argument will cancel the default catalog.

If no default catalog is specified, or if *catalog* is an invalid catalog name, subsequent calls to `gettext(3C)`, `lfmt(3C)`, or `pfmt(3C)` that do not explicitly specify a catalog name will use `Message not found!!\n` as default string.

RETURN VALUES Upon successful completion, `setcat()` returns a pointer to the catalog name. Otherwise, it returns a null pointer.

EXAMPLES **EXAMPLE 1** Example of `setcat()` function.

```
setcat("test");
gettext(":10", "hello world\n")
```

NAME	getgrnam, getgrnam_r, getgrent, getgrent_r, getgrgid, getgrgid_r, setgrent, endgrent, fgetgrent, fgetgrent_r – group database entry functions
SYNOPSIS	<pre>#include <grp.h> struct group *getgrnam(const char *name); struct group *getgrnam_r(const char *name, struct group *grp, char *buffer, int bufsize); struct group *getgrent(void); struct group *getgrent_r(struct group *grp, char *buffer, int bufsize); struct group *getgrgid(gid_t gid); struct group *getgrgid_r(gid_t gid, struct group *grp, char *buffer, int bufsize); void setgrent(void); void endgrent(void); struct group *fgetgrent(FILE *f); struct group *fgetgrent_r(FILE *f, struct group *grp, char *buffer, int bufsize);</pre>
POSIX	<pre>cc [flag...] file... -D_POSIX_PTHREAD_SEMANTICS [library...] int getgrnam_r(const char *name, struct group *grp, char *buffer, size_t bufsize, struct group **result); int getgrgid_r(gid_t gid, struct group *grp, char *buffer, size_t bufsize, struct group **result);</pre>
DESCRIPTION	<p>These functions are used to obtain entries describing user groups. Entries can come from any of the sources for group specified in the <code>/etc/nsswitch.conf</code> file (see <code>nsswitch.conf(4)</code>).</p> <p>The <code>getgrnam()</code> function searches the group database for an entry with the group name specified by the character string parameter <i>name</i>.</p> <p>The <code>getgrgid()</code> function searches the group database for an entry with the (numeric) group id specified by <i>gid</i>.</p> <p>The <code>setgrent()</code>, <code>getgrent()</code>, and <code>endgrent()</code> functions are used to enumerate group entries from the database.</p> <p>The <code>setgrent()</code> function effectively rewinds the group database to allow repeated searches. It sets (or resets) the enumeration to the beginning of the set of group entries. This function should be called before the first call to <code>getgrent()</code>.</p>

setgrent(3C)

The `getgrent()` function returns a pointer to a structure containing the broken-out fields of an entry in the group database. When first called, `getgrent()` returns a pointer to a `group` structure containing the next group structure in the group database. Successive calls may be used to search the entire database.

The `endgrent()` function may be called to close the group database and deallocate resources when processing is complete. It is permissible, though possibly less efficient, for the process to call more group functions after calling `endgrent()`.

The `fgetgrent()` function, unlike the other functions above, does not use `nsswitch.conf`. It reads and parses the next line from the stream `f`, which is assumed to have the format of the group file (see `group(4)`).

Reentrant Interfaces

The `getgrnam()`, `getgrgid()`, `getgrent()`, and `fgetgrent()` functions use static storage that is reused in each call, making them unsafe for multithreaded applications.

The parallel functions `getgrnam_r()`, `getgrgid_r()`, `getgrent_r()`, and `fgetgrent_r()` provide reentrant interfaces for these operations.

Each reentrant interface performs the same operation as its non-reentrant counterpart, named by removing the `_r` suffix. The reentrant interfaces, however, use buffers supplied by the caller to store returned results, and are safe for use in both single-threaded and multithreaded applications.

Each reentrant interface takes the same arguments as its non-reentrant counterpart, as well as the following additional parameters. The `grp` argument must be a pointer to a `struct group` structure allocated by the caller. On successful completion, the function returns the group entry in this structure. Storage referenced by the group structure is allocated from the memory provided with the `buffer` argument, which is `bufsize` characters in size. The maximum size needed for this buffer can be determined with the `_SC_GETGR_R_SIZE_MAX` `sysconf(3C)` parameter. The POSIX versions place a pointer to the modified `grp` structure in the `result` parameter, instead of returning a pointer to this structure.

For enumeration in multithreaded applications, the position within the enumeration is a process-wide property shared by all threads. `setgrent()` may be used in a multithreaded application but resets the enumeration position for all threads. If multiple threads interleave calls to `getgrent_r()`, the threads will enumerate disjoint subsets of the group database. Like their non-reentrant counterparts, `getgrnam_r()` and `getgrgid_r()` leave the enumeration position in an indeterminate state.

RETURN VALUES

Group entries are represented by the `struct group` structure defined in `<grp.h>`:

```
struct group {
    char *gr_name;           /* the name of the group */
    char *gr_passwd;        /* the encrypted group password */
    gid_t gr_gid;          /* the numerical group ID */
    char **gr_mem;         /* vector of pointers to member names */
};
```

The `getgrnam()`, `getgrnam_r()`, `getgrgid()`, and `getgrgid_r()` functions each return a pointer to a `struct group` if they successfully locate the requested entry; otherwise they return `NULL`. The POSIX functions `getgrnam_r()` and `getgrgid_r()` return 0 upon success or the error number in case of failure.

The `getgrent()`, `getgrent_r()`, `fgetgrent()`, and `fgetgrent_r()` functions each return a pointer to a `struct group` if they successfully enumerate an entry; otherwise they return `NULL`, indicating the end of the enumeration.

The `getgrnam()`, `getgrgid()`, `getgrent()`, and `fgetgrent()` functions use static storage, so returned data must be copied before a subsequent call to any of these functions if the data is to be saved.

When the pointer returned by the reentrant functions `getgrnam_r()`, `getgrgid_r()`, `getgrent_r()`, and `fgetgrent_r()` is non-null, it is always equal to the `grp` pointer that was supplied by the caller.

ERRORS The `getgrnam()`, `getgrgid()`, `getgrent()`, `fgetgrent()`, and `fgetgrent_r()` functions may fail if:

<code>EINTR</code>	A signal was caught during the operation.
<code>EIO</code>	An I/O error has occurred.
<code>EMFILE</code>	There are <code>OPEN_MAX</code> file descriptors currently open in the calling process.
<code>ENFILE</code>	The maximum allowable number of files is currently open in the system.
<code>ERANGE</code>	The group file contains a line that exceeds 512 bytes.

The `getgrnam_r()`, `getgrgid_r()`, and `getgrent_r()` functions may fail if:

<code>ERANGE</code>	Insufficient storage was supplied by <i>buffer</i> and <i>bufsize</i> to contain the data to be referenced by the resulting <code>group</code> structure.
---------------------	---

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
MT-Level	See "Reentrant Interfaces" in <code>DESCRIPTION</code> .

SEE ALSO `Intro(3)`, `getpwnam(3C)`, `group(4)`, `nsswitch.conf(4)`, `passwd(4)`, `attributes(5)`, `standards(5)`

NOTES When compiling multithreaded programs, see `Intro(3)`, *Notes On Multithreaded Applications*.

setgrent(3C)

Programs that use the interfaces described in this manual page cannot be linked statically since the implementations of these functions employ dynamic loading and linking of shared objects at run time.

Use of the enumeration interfaces `getgrent()` and `getgrent_r()` is discouraged; enumeration is supported for the group file, NIS, and NIS+, but in general is not efficient and may not be supported for all database sources. The semantics of enumeration are discussed further in `nsswitch.conf(4)`.

Previous releases allowed the use of "+" and "-" entries in `/etc/group` to selectively include and exclude entries from NIS. The primary usage of these entries is superseded by the name service switch, so the "+/-" form *may not be supported in future releases*.

If required, the "+/-" functionality can still be obtained for NIS by specifying `compat` as the source for `group`.

If the "+/-" functionality is required in conjunction with NIS+, specify both `compat` as the source for `group` and `nisplus` as the source for the pseudo-database `group_compat`. See `group(4)`, and `nsswitch.conf(4)` for details.

Solaris 2.4 and earlier releases provided definitions of the `getgrnam_r()` and `getgrgid_r()` functions as specified in POSIX.1c Draft 6. The final POSIX.1c standard changed the interface for these functions. Support for the Draft 6 interface is provided for compatibility only and may not be supported in future releases. New applications and libraries should use the POSIX standard interface.

For POSIX.1c-compliant applications, the `_POSIX_PTHREAD_SEMANTICS` and `_REENTRANT` flags are automatically turned on by defining the `_POSIX_C_SOURCE` flag with a value $\geq 199506L$.

NAME	gethostname, sethostname – get or set name of current host				
SYNOPSIS	<pre>#include <unistd.h> int gethostname(char *name, int namelen); int sethostname(char *name, int namelen);</pre>				
DESCRIPTION	<p>The <code>gethostname()</code> function returns the standard host name for the current processor, as previously set by <code>sethostname()</code>. The <i>namelen</i> argument specifies the size of the array pointed to by <i>name</i>. The returned name is null-terminated unless insufficient space is provided.</p> <p>The <code>sethostname()</code> function sets the name of the host machine to be <i>name</i>, which has length <i>namelen</i>. This call is restricted to the superuser and is normally used only when the system is bootstrapped.</p> <p>Host names are limited to <code>MAXHOSTNAMELEN</code> characters, currently 256, defined in the <code><netdb.h></code> header.</p>				
RETURN VALUES	Upon successful completion, <code>gethostname()</code> and <code>sethostname()</code> return 0. Otherwise, they return <code>-1</code> and set <code>errno</code> to indicate the error.				
ERRORS	<p>The <code>gethostname()</code> and <code>sethostname()</code> functions will fail if:</p> <p><code>EFAULT</code> The <i>name</i> or <i>namelen</i> argument gave an invalid address.</p> <p>The <code>sethostname()</code> function will fail if:</p> <p><code>EPERM</code> The caller was not the superuser.</p>

`_setjmp(3C)`

NAME	<code>_longjmp, _setjmp</code> – non-local goto
SYNOPSIS	<pre>#include <setjmp.h> void _longjmp(jmp_buf env, int val); int _setjmp(jmp_buf env);</pre>
DESCRIPTION	<p>The <code>_longjmp()</code> and <code>_setjmp()</code> functions are identical to <code>longjmp(3C)</code> and <code>setjmp(3C)</code>, respectively, with the additional restriction that <code>_longjmp()</code> and <code>_setjmp()</code> do not manipulate the signal mask.</p> <p>If <code>_longjmp()</code> is called even though <code>env</code> was never initialized by a call to <code>_setjmp()</code>, or when the last such call was in a function that has since returned, the results are undefined.</p>
RETURN VALUES	Refer to <code>longjmp(3C)</code> and <code>setjmp(3C)</code> .
ERRORS	No errors are defined.
USAGE	<p>If <code>_longjmp()</code> is executed and the environment in which <code>_setjmp()</code> was executed no longer exists, errors can occur. The conditions under which the environment of the <code>_setjmp()</code> no longer exists include exiting the function that contains the <code>_setjmp()</code> call, and exiting an inner block with temporary storage. This condition might not be detectable, in which case the <code>_longjmp()</code> occurs and, if the environment no longer exists, the contents of the temporary storage of an inner block are unpredictable. This condition might also cause unexpected process termination. If the function has returned, the results are undefined.</p> <p>Passing <code>longjmp()</code> a pointer to a buffer not created by <code>setjmp()</code>, passing <code>_longjmp()</code> a pointer to a buffer not created by <code>_setjmp()</code>, passing <code>siglongjmp(3C)</code> a pointer to a buffer not created by <code>sigsetjmp(3C)</code> or passing any of these three functions a buffer that has been modified by the user can cause all the problems listed above, and more.</p> <p>The <code>_longjmp()</code> and <code>_setjmp()</code> functions are included to support programs written to historical system interfaces. New applications should use <code>siglongjmp(3C)</code> and <code>sigsetjmp(3C)</code> respectively.</p>
SEE ALSO	<code>longjmp(3C)</code> , <code>setjmp(3C)</code> , <code>siglongjmp(3C)</code> , <code>sigsetjmp(3C)</code>

NAME	setjmp, sigsetjmp, longjmp, siglongjmp – non-local goto
SYNOPSIS	<pre>#include <setjmp.h> int setjmp(jmp_buf <i>env</i>); int sigsetjmp(sigjmp_buf <i>env</i>, int <i>savemask</i>); void longjmp(jmp_buf <i>env</i>, int <i>val</i>); void siglongjmp(sigjmp_buf <i>env</i>, int <i>val</i>);</pre>
DESCRIPTION	<p>These functions are useful for dealing with errors and interrupts encountered in a low-level subroutine of a program.</p> <p>The <code>setjmp()</code> function saves its stack environment in <i>env</i> for later use by <code>longjmp()</code>.</p> <p>The <code>sigsetjmp()</code> function saves the calling process's registers and stack environment (see <code>sigaltstack(2)</code>) in <i>env</i> for later use by <code>siglongjmp()</code>. If <i>savemask</i> is non-zero, the calling process's signal mask (see <code>sigprocmask(2)</code>) and scheduling parameters (see <code>prctl(2)</code>) are also saved.</p> <p>The <code>longjmp()</code> function restores the environment saved by the last call of <code>setjmp()</code> with the corresponding <i>env</i> argument. After <code>longjmp()</code> completes, program execution continues as if the corresponding call to <code>setjmp()</code> had just returned the value <i>val</i>. The caller of <code>setjmp()</code> must not have returned in the interim. The <code>longjmp()</code> function cannot cause <code>setjmp()</code> to return the value 0. If <code>longjmp()</code> is invoked with a second argument of 0, <code>setjmp()</code> will return 1. At the time of the second return from <code>setjmp()</code>, all external and static variables have values as of the time <code>longjmp()</code> is called (see <code>EXAMPLES</code>).</p> <p>The <code>siglongjmp()</code> function restores the environment saved by the last call of <code>sigsetjmp()</code> with the corresponding <i>env</i> argument. After <code>siglongjmp()</code> completes, program execution continues as if the corresponding call to <code>sigsetjmp()</code> had just returned the value <i>val</i>. The <code>siglongjmp()</code> function cannot cause <code>sigsetjmp()</code> to return the value 0. If <code>siglongjmp()</code> is invoked with a second argument of 0, <code>sigsetjmp()</code> will return 1. At the time of the second return from <code>sigsetjmp()</code>, all external and static variables have values as of the time <code>siglongjmp()</code> was called.</p> <p>If a signal-catching function interrupts <code>sleep(3C)</code> and calls <code>siglongjmp()</code> to restore an environment saved prior to the <code>sleep()</code> call, the action associated with <code>SIGALRM</code> and time it is scheduled to be generated are unspecified. It is also unspecified whether the <code>SIGALRM</code> signal is blocked, unless the process's signal mask is restored as part of the environment.</p> <p>The <code>siglongjmp()</code> function restores the saved signal mask if and only if the <i>env</i> argument was initialized by a call to the <code>sigsetjmp()</code> function with a non-zero <i>savemask</i> argument.</p>

setjmp(3C)

The values of register and automatic variables are undefined. Register or automatic variables whose value must be relied upon must be declared as volatile.

RETURN VALUES

If the return is from a direct invocation, `setjmp()` and `sigsetjmp()` return 0. If the return is from a call to `longjmp()`, `setjmp()` returns a non-zero value. If the return is from a call to `siglongjmp()`, `sigsetjmp()` returns a non-zero value.

After `longjmp()` is completed, program execution continues as if the corresponding invocation of `setjmp()` had just returned the value specified by *val*. The `longjmp()` function cannot cause `setjmp()` to return 0; if *val* is 0, `setjmp()` returns 1.

After `siglongjmp()` is completed, program execution continues as if the corresponding invocation of `sigsetjmp()` had just returned the value specified by *val*. The `siglongjmp()` function cannot cause `sigsetjmp()` to return 0; if *val* is 0, `sigsetjmp()` returns 1.

EXAMPLES

EXAMPLE 1 Example of `setjmp()` and `longjmp()` functions.

The following example uses both `setjmp()` and `longjmp()` to return the flow of control to the appropriate instruction block:

```
#include <stdio.h>
#include <setjmp.h>
#include <signal.h>
#include <unistd.h>
jmp_buf env; static void signal_handler();

main() {
    int returned_from_longjump, processing = 1;
    unsigned int time_interval = 4;
    if ((returned_from_longjump = setjmp(env)) != 0)
        switch (returned_from_longjump) {
            case SIGINT:
                printf("longjumped from interrupt %d\n",SIGINT);
                break;
            case SIGALRM:
                printf("longjumped from alarm %d\n",SIGALRM);
                break;
        }
    (void) signal(SIGINT, signal_handler);
    (void) signal(SIGALRM, signal_handler);
    alarm(time_interval);
    while (processing) {
        printf(" waiting for you to INTERRUPT (cntrl-C) ...\n");
        sleep(1);
    }
    /* end while forever loop */
}

static void signal_handler(sig)
int sig; {
    switch (sig) {
        case SIGINT:    ... /* process for interrupt */
                        longjmp(env,sig);
                        /* break never reached */
        case SIGALRM:  ... /* process for alarm */
    }
}
```

EXAMPLE 1 Example of `setjmp()` and `longjmp()` functions. (Continued)

```

                                longjmp(env, sig);
                                /* break never reached */
                                exit(sig);
    default:
    }
}

```

When this example is compiled and executed, and the user sends an interrupt signal, the output will be:

```
longjumped from interrupt
```

Additionally, every 4 seconds the alarm will expire, signalling this process, and the output will be:

```
longjumped from alarm
```

WARNINGS If `longjmp()` or `siglongjmp()` are called even though `env` was never primed by a call to `setjmp()` or `sigsetjmp()`, or when the last such call was in a function that has since returned, the results are undefined.

`_setjmp(3UCB)`

NAME	<code>setjmp, longjmp, _setjmp, _longjmp</code> – non-local goto
SYNOPSIS	<pre><code>/usr/ucb/cc [flag ...] file ... #include <setjmp.h> int setjmp (env) ; jmp_buf env ; void longjmp (env, val) ; jmp_buf env ; int val ; int _setjmp (env) ; jmp_buf env ; void _longjmp (env, val) ; jmp_buf env ; int val ;</code></pre>
DESCRIPTION	<p>The <code>setjmp()</code> and <code>longjmp()</code> functions are useful for dealing with errors and interrupts encountered in a low-level subroutine of a program.</p> <p>The <code>setjmp()</code> function saves its stack environment in <code>env</code> for later use by <code>longjmp()</code>. A normal call to <code>setjmp()</code> returns zero. <code>setjmp()</code> also saves the register environment. If a <code>longjmp()</code> call will be made, the routine which called <code>setjmp()</code> should not return until after the <code>longjmp()</code> has returned control (see below).</p> <p>The <code>longjmp()</code> function restores the environment saved by the last call of <code>setjmp()</code>, and then returns in such a way that execution continues as if the call of <code>setjmp()</code> had just returned the value <code>val</code> to the function that invoked <code>setjmp()</code>; however, if <code>val</code> were zero, execution would continue as if the call of <code>setjmp()</code> had returned one. This ensures that a “return” from <code>setjmp()</code> caused by a call to <code>longjmp()</code> can be distinguished from a regular return from <code>setjmp()</code>. The calling function must not itself have returned in the interim, otherwise <code>longjmp()</code> will be returning control to a possibly non-existent environment. All memory-bound data have values as of the time <code>longjmp()</code> was called. The CPU and floating-point data registers are restored to the values they had at the time that <code>setjmp()</code> was called. But, because the <code>register</code> storage class is only a hint to the C compiler, variables declared as <code>register</code> variables may not necessarily be assigned to machine registers, so their values are unpredictable after a <code>longjmp()</code>. This is especially a problem for programmers trying to write machine-independent C routines.</p> <p>The <code>setjmp()</code> and <code>longjmp()</code> functions save and restore the signal mask while <code>_setjmp()</code> and <code>_longjmp()</code> manipulate only the C stack and registers.</p> <p>None of these functions save or restore any floating-point status or control registers.</p>

EXAMPLES | **EXAMPLE 1** Examples of setjmp() and longjmp().

The following example uses both setjmp() and longjmp() to return the flow of control to the appropriate instruction block:

```
#include <stdio.h>
#include <setjmp.h>
#include <signal.h>
#include <unistd.h>
jmp_buf env; static void signal_handler();
main() {
    int returned_from_longjump, processing = 1;
    unsigned int time_interval = 4;
    if ((returned_from_longjump = setjmp(env)) != 0)
        switch (returned_from_longjump) {
            case SIGINT:
                printf("longjumped from interrupt %d\n",SIGINT);
                break;
            case SIGALRM:
                printf("longjumped from alarm %d\n",SIGALRM);
                break;
        }
    (void) signal(SIGINT, signal_handler);
    (void) signal(SIGALRM, signal_handler);
    alarm(time_interval);
    while (processing) {
        printf(" waiting for you to INTERRUPT (cntrl-C) ...\n");
        sleep(1);
    } /* end while forever loop */
}

static void signal_handler(sig)
int sig; {
    switch (sig) {
        case SIGINT:
            ... /* process for interrupt */
            longjmp(env,sig);
            /* break never reached */
        case SIGALRM:
            ... /* process for alarm */
            longjmp(env,sig);
            /* break never reached */
        default:
            exit(sig);
    }
}
```

When this example is compiled and executed, and the user sends an interrupt signal, the output will be:

longjumped from interrupt

Additionally, every 4 seconds the alarm will expire, signalling this process, and the output will be:

longjumped from alarm

setjmp(3UCB)

EXAMPLES **EXAMPLE 1** Examples of `setjmp()` and `longjmp()`.

The following example uses both `setjmp()` and `longjmp()` to return the flow of control to the appropriate instruction block:

```
#include <stdio.h>
#include <setjmp.h>
#include <signal.h>
#include <unistd.h>
jmp_buf env; static void signal_handler();
main() {
    int returned_from_longjump, processing = 1;
    unsigned int time_interval = 4;
    if ((returned_from_longjump = setjmp(env)) != 0)
        switch (returned_from_longjump) {
            case SIGINT:
                printf("longjumped from interrupt %d\n",SIGINT);
                break;
            case SIGALRM:
                printf("longjumped from alarm %d\n",SIGALRM);
                break;
        }
    (void) signal(SIGINT, signal_handler);
    (void) signal(SIGALRM, signal_handler);
    alarm(time_interval);
    while (processing) {
        printf(" waiting for you to INTERRUPT (cntrl-C) ...\n");
        sleep(1);
    } /* end while forever loop */
}

static void signal_handler(sig)
int sig; {
    switch (sig) {
        case SIGINT:
            ... /* process for interrupt */
            longjmp(env,sig);
            /* break never reached */
        case SIGALRM:
            ... /* process for alarm */
            longjmp(env,sig);
            /* break never reached */
        default:
            exit(sig);
    }
}
```

When this example is compiled and executed, and the user sends an interrupt signal, the output will be:

```
longjumped from interrupt
```

Additionally, every 4 seconds the alarm will expire, signalling this process, and the output will be:

```
longjumped from alarm
```

- NOTES** Use of these interfaces should be restricted to only applications written on BSD platforms. Use of these interfaces with any of the system libraries or in multi-thread applications is unsupported.
- BUGS** The `setjmp()` function does not save the current notion of whether the process is executing on the signal stack. The result is that a `longjmp()` to some place on the signal stack leaves the signal stack state incorrect.
- On some systems `setjmp()` also saves the register environment. Therefore, all data that are bound to registers are restored to the values they had at the time that `setjmp()` was called. All memory-bound data have values as of the time `longjmp()` was called. However, because the `register` storage class is only a hint to the C compiler, variables declared as `register` variables may not necessarily be assigned to machine registers, so their values are unpredictable after a `longjmp()`. When using compiler options that specify automatic register allocation (see `cc(1B)`), the compiler will not attempt to assign variables to registers in routines that call `setjmp()`.
- The `longjmp()` function never causes `setjmp()` to return 0, so programmers should not depend on `longjmp()` being able to cause `setjmp()` to return 0.

setkey(3C)

NAME	setkey – set encoding key				
SYNOPSIS	<pre>#include <stdlib.h> void setkey(const char *key);</pre>				
DESCRIPTION	The <code>setkey()</code> function provides (rather primitive) access to the hashing algorithm employed by the <code>crypt(3C)</code> function. The argument of <code>setkey()</code> is an array of length 64 bytes containing only the bytes with numerical value of 0 and 1. If this string is divided into groups of 8, the low-order bit in each group is ignored; this gives a 56-bit key which is used by the algorithm. This is the key that will be used with the algorithm to encode a string <i>block</i> passed to <code>encrypt(3C)</code> .				
RETURN VALUES	No values are returned.				
ERRORS	The <code>setkey()</code> function will fail if: ENOSYS The functionality is not supported on this implementation.				
USAGE	<p>In some environments, decoding may not be implemented. This is related to U.S. Government restrictions on encryption and decryption routines: the DES decryption algorithm cannot be exported outside the U.S.A. Historical practice has been to ship a different version of the encryption library without the decryption feature in the routines supplied. Thus the exported version of <code>encrypt()</code> does encoding but not decoding.</p> <p>Because <code>setkey()</code> does not return a value, applications wishing to check for errors should set <code>errno</code> to 0, call <code>setkey()</code>, then test <code>errno</code> and, if it is non-zero, assume an error has occurred.</p>

NAME	setlabel – define the label for <code>pfmt()</code> and <code>lfmt()</code>				
SYNOPSIS	<pre>#include <pfmt.h> int setlabel(const char *label);</pre>				
DESCRIPTION	<p>The <code>setlabel()</code> function defines the label for messages produced in standard format by subsequent calls to <code>lfmt(3C)</code> and <code>pfmt(3C)</code>.</p> <p>The <i>label</i> argument is a character string no more than 25 characters in length.</p> <p>No label is defined before <code>setlabel()</code> is called. The label should be set once at the beginning of a utility and remain constant. A null pointer or an empty string passed as argument will reset the definition of the label.</p>				
RETURN VALUE	Upon successful completion, <code>setlabel()</code> returns 0; otherwise, it returns a non-zero value.				
EXAMPLES	<p>The following code (without previous call to <code>setlabel()</code>):</p> <pre>pfmt(stderr, MM_ERROR, "test:2:Cannot open file\n"); setlabel("UX:test"); pfmt(stderr, MM_ERROR, "test:2:Cannot open file\n");</pre> <p>will produce the following output:</p> <pre>ERROR: Cannot open file UX:test: ERROR: Cannot open file</pre>				
ATTRIBUTES	See <code>attributes(5)</code> for descriptions of the following attributes:				
	<table border="1" style="width: 100%; border-collapse: collapse;"> <thead> <tr> <th style="text-align: center;">ATTRIBUTE TYPE</th> <th style="text-align: center;">ATTRIBUTE VALUE</th> </tr> </thead> <tbody> <tr> <td>MT-Level</td> <td>MT-Safe</td> </tr> </tbody> </table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	MT-Level	MT-Safe
ATTRIBUTE TYPE	ATTRIBUTE VALUE				
MT-Level	MT-Safe				
SEE ALSO	<code>getopt(3C)</code> , <code>lfmt(3C)</code> , <code>pfmt(3C)</code> , <code>attributes(5)</code>				

setlinebuf(3C)

NAME	setbuffer, setlinebuf – assign buffering to a stream
SYNOPSIS	<pre>#include <stdio.h> void setbuffer(FILE *iop, char *abuf, size_t asize); int setlinebuf(FILE *iop);</pre>
DESCRIPTION	<p>The <code>setbuffer()</code> and <code>setlinebuf()</code> functions assign buffering to a stream. The three types of buffering available are unbuffered, block buffered, and line buffered. When an output stream is unbuffered, information appears on the destination file or terminal as soon as written; when it is block buffered, many characters are saved and written as a block; when it is line buffered, characters are saved until either a NEWLINE is encountered or input is read from <code>stdin</code>. The <code>fflush(3C)</code> function may be used to force the block out early. Normally all files are block buffered. A buffer is obtained from <code>malloc(3C)</code> upon the first <code>getc(3C)</code> or <code>putc(3C)</code> performed on the file. If the standard stream <code>stdout</code> refers to a terminal, it is line buffered. The standard stream <code>stderr</code> is unbuffered by default.</p> <p>The <code>setbuffer()</code> function can be used after a stream <code>iop</code> has been opened but before it is read or written. It uses the character array <code>abuf</code> whose size is determined by the <code>asize</code> argument instead of an automatically allocated buffer. If <code>abuf</code> is the null pointer, input/output will be completely unbuffered. A manifest constant <code>BUFSIZ</code>, defined in the <code><stdio.h></code> header, tells how large an array is needed:</p> <pre>char buf[BUFSIZ];</pre> <p>The <code>setlinebuf()</code> function is used to change the buffering on a stream from block buffered or unbuffered to line buffered. Unlike <code>setbuffer()</code>, it can be used at any time that the stream <code>iop</code> is active.</p> <p>A stream can be changed from unbuffered or line buffered to block buffered by using <code>freopen(3C)</code>. A stream can be changed from block buffered or line buffered to unbuffered by using <code>freopen(3C)</code> followed by <code>setbuf(3C)</code> with a buffer argument of <code>NULL</code>.</p>
RETURN VALUES	The <code>setlinebuf()</code> function returns no useful value.
SEE ALSO	<code>malloc(3C)</code> , <code>fclose(3C)</code> , <code>fopen(3C)</code> , <code>fread(3C)</code> , <code>getc(3C)</code> , <code>printf(3C)</code> , <code>putc(3C)</code> , <code>puts(3C)</code> , <code>setbuf(3C)</code> , <code>setvbuf(3C)</code>
NOTES	A common source of error is allocating buffer space as an “automatic” variable in a code block, and then failing to close the stream in the same block.

NAME	setlocale – modify and query a program’s locale												
SYNOPSIS	<pre>#include <locale.h> char *setlocale(int <i>category</i>, const char *<i>locale</i>);</pre>												
DESCRIPTION	<p>The <code>setlocale()</code> function selects the appropriate piece of the program’s locale as specified by the <i>category</i> and <i>locale</i> arguments. The <i>category</i> argument may have the following values: <code>LC_CTYPE</code>, <code>LC_NUMERIC</code>, <code>LC_TIME</code>, <code>LC_COLLATE</code>, <code>LC_MONETARY</code>, <code>LC_MESSAGES</code>, and <code>LC_ALL</code>. These names are defined in the <code><locale.h></code> header. The <code>LC_ALL</code> variable names all of a program’s locale categories.</p> <p>The <code>LC_CTYPE</code> variable affects the behavior of character handling functions such as <code>isdigit(3C)</code> and <code>tolower(3C)</code>, and multibyte character functions such as <code>mbtowc(3C)</code> and <code>wctomb(3C)</code>.</p> <p>The <code>LC_NUMERIC</code> variable affects the decimal point character and thousands separator character for the formatted input/output functions and string conversion functions.</p> <p>The <code>LC_TIME</code> variable affects the date and time format as delivered by <code>ascftime(3C)</code>, <code>cftime(3C)</code>, <code>getdate(3C)</code>, <code>strftime(3C)</code> and <code>strptime(3C)</code>.</p> <p>The <code>LC_COLLATE</code> variable affects the sort order produced by collating functions such as <code>strcoll(3C)</code> and <code>strxfrm(3C)</code>.</p> <p>The <code>LC_MONETARY</code> variable affects the monetary formatted information returned by <code>localeconv(3C)</code>.</p> <p>The <code>LC_MESSAGES</code> variable affects the behavior of messaging functions such as <code>dgettext(3C)</code>, <code>gettext(3C)</code>, and <code>gettext(3C)</code>.</p> <p>A value of "C" for <i>locale</i> specifies the traditional UNIX system behavior. At program startup, the equivalent of</p> <pre>setlocale(LC_ALL, "C")</pre> <p>is executed. This has the effect of initializing each category to the locale described by the environment "C".</p> <p>A value of "" for <i>locale</i> specifies that the locale should be taken from environment variables. The order in which the environment variables are checked for the various categories is given below:</p> <table border="1" data-bbox="461 1566 1430 1703"> <thead> <tr> <th>Category</th> <th>1st Env Var</th> <th>2nd Env Var</th> <th>3rd Env Var</th> </tr> </thead> <tbody> <tr> <td>LC_CTYPE:</td> <td>LC_ALL</td> <td>LC_CTYPE</td> <td>LANG</td> </tr> <tr> <td>LC_COLLATE:</td> <td>LC_ALL</td> <td>LC_COLLATE</td> <td>LANG</td> </tr> </tbody> </table>	Category	1st Env Var	2nd Env Var	3rd Env Var	LC_CTYPE:	LC_ALL	LC_CTYPE	LANG	LC_COLLATE:	LC_ALL	LC_COLLATE	LANG
Category	1st Env Var	2nd Env Var	3rd Env Var										
LC_CTYPE:	LC_ALL	LC_CTYPE	LANG										
LC_COLLATE:	LC_ALL	LC_COLLATE	LANG										

setlocale(3C)

Category	1st Env Var	2nd Env Var	3rd Env Var
LC_CTIME:	LC_ALL	LC_CTIME	LANG
LC_NUMERIC:	LC_ALL	LC_NUMERIC	LANG
LC_MONETARY:	LC_ALL	LC_MONETARY	LANG
LC_MESSAGES:	LC_ALL	LC_MESSAGES	LANG

If a pointer to a string is given for *locale*, `setlocale()` attempts to set the locale for the given category to *locale*. If `setlocale()` succeeds, *locale* is returned. If `setlocale()` fails, a null pointer is returned and the program's locale is not changed.

For category `LC_ALL`, the behavior is slightly different. If a pointer to a string is given for *locale* and `LC_ALL` is given for *category*, `setlocale()` attempts to set the locale for all the categories to *locale*. The *locale* may be a simple locale, consisting of a single locale, or a composite locale. If the locales for all the categories are the same after all the attempted locale changes, `setlocale()` will return a pointer to the common simple locale. If there is a mixture of locales among the categories, `setlocale()` will return a composite locale.

RETURN VALUES

Upon successful completion, `setlocale()` returns the string associated with the specified category for the new locale. Otherwise, `setlocale()` returns a null pointer and the program's locale is not changed.

A null pointer for *locale* causes `setlocale()` to return a pointer to the string associated with the *category* for the program's current locale. The program's locale is not changed.

The string returned by `setlocale()` is such that a subsequent call with that string and its associated *category* will restore that part of the program's locale. The string returned must not be modified by the program, but may be overwritten by a subsequent call to `setlocale()`.

ERRORS

No errors are defined.

FILES

`/usr/lib/locale/locale` locale database directory for *locale*

ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
MT-Level	MT-Safe with exceptions
CSI	Enabled

SEE ALSO locale(1), ctype(3C), getdate(3C) gettext(3C), gettxt(3C), isdigit(3C), localeconv(3C), mbtowc(3C), strcoll(3C), strftime(3C), strptime(3C) strxfrm(3C) tolower(3C), wctomb(3C), libc(3LIB), attributes(5), environ(5), locale(5)

NOTES To change locale in a multithreaded application, `setlocale()` should be called prior to using any locale-sensitive routine. Using `setlocale()` to query the current locale is safe and can be used anywhere in a multithreaded application.

It is the user's responsibility to ensure that mixed locale categories are compatible. For example, setting `LC_CTYPE=C` and `LC_TIME=ja` (where `ja` indicates Japanese) will not work, because Japanese time cannot be represented in the "C" locale's ASCII codeset.

Internationalization functions by `setlocale()` are supported only when the dynamic linking version of `libc` has been linked with the application. If the static linking version of `libc` has been linked with the application, `setlocale()` can handle only C and POSIX locales.

setlogmask(3C)

NAME	syslog, openlog, closelog, setlogmask – control system log																
SYNOPSIS	<pre>#include <syslog.h> void openlog(const char *ident, int logopt, int facility); void syslog(int priority, const char *message, .../* arguments */); void closelog(void); int setlogmask(int maskpri);</pre>																
DESCRIPTION	<p>The <code>syslog()</code> function sends a message to <code>syslogd(1M)</code>, which, depending on the configuration of <code>/etc/syslog.conf</code>, logs it in an appropriate system log, writes it to the system console, forwards it to a list of users, or forwards it to <code>syslogd</code> on another host over the network. The logged message includes a message header and a message body. The message header consists of a facility indicator, a severity level indicator, a timestamp, a tag string, and optionally the process ID.</p> <p>The message body is generated from the <i>message</i> and following arguments in the same manner as if these were arguments to <code>printf(3UCB)</code>, except that occurrences of <code>%m</code> in the format string pointed to by the <i>message</i> argument are replaced by the error message string associated with the current value of <code>errno</code>. A trailing NEWLINE character is added if needed.</p> <p>Values of the <i>priority</i> argument are formed by ORing together a <i>severity level</i> value and an optional <i>facility</i> value. If no facility value is specified, the current default facility value is used.</p> <p>Possible values of severity level include:</p> <table><tr><td>LOG_EMERG</td><td>A panic condition. This is normally broadcast to all users.</td></tr><tr><td>LOG_ALERT</td><td>A condition that should be corrected immediately, such as a corrupted system database.</td></tr><tr><td>LOG_CRIT</td><td>Critical conditions, such as hard device errors.</td></tr><tr><td>LOG_ERR</td><td>Errors.</td></tr><tr><td>LOG_WARNING</td><td>Warning messages.</td></tr><tr><td>LOG_NOTICE</td><td>Conditions that are not error conditions, but that may require special handling.</td></tr><tr><td>LOG_INFO</td><td>Informational messages.</td></tr><tr><td>LOG_DEBUG</td><td>Messages that contain information normally of use only when debugging a program.</td></tr></table> <p>The facility indicates the application or system component generating the message. Possible facility values include:</p>	LOG_EMERG	A panic condition. This is normally broadcast to all users.	LOG_ALERT	A condition that should be corrected immediately, such as a corrupted system database.	LOG_CRIT	Critical conditions, such as hard device errors.	LOG_ERR	Errors.	LOG_WARNING	Warning messages.	LOG_NOTICE	Conditions that are not error conditions, but that may require special handling.	LOG_INFO	Informational messages.	LOG_DEBUG	Messages that contain information normally of use only when debugging a program.
LOG_EMERG	A panic condition. This is normally broadcast to all users.																
LOG_ALERT	A condition that should be corrected immediately, such as a corrupted system database.																
LOG_CRIT	Critical conditions, such as hard device errors.																
LOG_ERR	Errors.																
LOG_WARNING	Warning messages.																
LOG_NOTICE	Conditions that are not error conditions, but that may require special handling.																
LOG_INFO	Informational messages.																
LOG_DEBUG	Messages that contain information normally of use only when debugging a program.																

LOG_KERN	Messages generated by the kernel. These cannot be generated by any user processes.
LOG_USER	Messages generated by random user processes. This is the default facility identifier if none is specified.
LOG_MAIL	The mail system.
LOG_DAEMON	System daemons, such as <code>in.ftpd(1M)</code> .
LOG_AUTH	The authorization system: <code>login(1)</code> , <code>su(1M)</code> , <code>getty(1M)</code> .
LOG_LPR	The line printer spooling system: <code>lpr(1B)</code> , <code>lpc(1B)</code> .
LOG_NEWS	Reserved for the USENET network news system.
LOG_UUCP	Reserved for the UUCP system; it does not currently use <code>syslog</code> .
LOG_CRON	The <code>cron/at</code> facility; <code>crontab(1)</code> , <code>at(1)</code> , <code>cron(1M)</code> .
LOG_LOCAL0	Reserved for local use.
LOG_LOCAL1	Reserved for local use.
LOG_LOCAL2	Reserved for local use.
LOG_LOCAL3	Reserved for local use.
LOG_LOCAL4	Reserved for local use.
LOG_LOCAL5	Reserved for local use.
LOG_LOCAL6	Reserved for local use.
LOG_LOCAL7	Reserved for local use.

The `openlog()` function sets process attributes that affect subsequent calls to `syslog()`. The *ident* argument is a string that is prepended to every message. The *logopt* argument indicates logging options. Values for *logopt* are constructed by a bitwise-inclusive OR of zero or more of the following:

LOG_PID	Log the process ID with each message. This is useful for identifying specific daemon processes (for daemons that fork).
LOG_CONS	Write messages to the system console if they cannot be sent to <code>syslogd(1M)</code> . This option is safe to use in daemon processes that have no controlling terminal, since <code>syslog()</code> forks before opening the console.
LOG_NDELAY	Open the connection to <code>syslogd(1M)</code> immediately. Normally the open is delayed until the first message is

setlogmask(3C)

	logged. This is useful for programs that need to manage the order in which file descriptors are allocated.
LOG_ODELAY	Delay open until <code>syslog()</code> is called.
LOG_NOWAIT	Do not wait for child processes that have been forked to log messages onto the console. This option should be used by processes that enable notification of child termination using <code>SIGCHLD</code> , since <code>syslog()</code> may otherwise block waiting for a child whose exit status has already been collected.

The *facility* argument encodes a default facility to be assigned to all messages that do not have an explicit facility already encoded. The initial default facility is `LOG_USER`.

The `openlog()` and `syslog()` functions may allocate a file descriptor. It is not necessary to call `openlog()` prior to calling `syslog()`.

The `closelog()` function closes any open file descriptors allocated by previous calls to `openlog()` or `syslog()`.

The `setlogmask()` function sets the log priority mask for the current process to *maskpri* and returns the previous mask. If the *maskpri* argument is 0, the current log mask is not modified. Calls by the current process to `syslog()` with a priority not set in *maskpri* are rejected. The mask for an individual priority *pri* is calculated by the macro `LOG_MASK(pri)`; the mask for all priorities up to and including *toppri* is given by the macro `LOG_UPT(toppri)`. The default log mask allows all priorities to be logged.

Symbolic constants for use as values of the *logopt*, *facility*, *priority*, and *maskpri* arguments are defined in the `<syslog.h>` header.

RETURN VALUES

The `setlogmask()` function returns the previous log priority mask. The `closelog()`, `openlog()` and `syslog()` functions return no value.

ERRORS

No errors are defined.

EXAMPLES

EXAMPLE 1 Example of `LOG_ALERT` message.

This call logs a message at priority `LOG_ALERT`:

```
syslog(LOG_ALERT, "who: internal error 23");
```

The FTP daemon `ftpd` would make this call to `openlog()` to indicate that all messages it logs should have an identifying string of `ftpd`, should be treated by `syslogd(1M)` as other messages from system daemons are, should include the process ID of the process logging the message:

```
openlog("ftpd", LOG_PID, LOG_DAEMON);
```

EXAMPLE 1 Example of LOG_ALERT message. (Continued)

Then it would make the following call to `setlogmask()` to indicate that messages at priorities from LOG_EMERG through LOG_ERR should be logged, but that no messages at any other priority should be logged:

```
setlogmask(LOG_UPTO(LOG_ERR));
```

Then, to log a message at priority LOG_INFO, it would make the following call to `syslog`:

```
syslog(LOG_INFO, "Connection from host %d", CallingHost);
```

A locally-written utility could use the following call to `syslog()` to log a message at priority LOG_INFO to be treated by `syslogd(1M)` as other messages to the facility LOG_LOCAL2 are:

```
syslog(LOG_INFO|LOG_LOCAL2, "error: %m");
```

setnetgrent(3C)

NAME	getnetgrent, getnetgrent_r, setnetgrent, endnetgrent, innetgr – get network group entry
SYNOPSIS	<pre>#include <netdb.h> int getnetgrent(char **<i>machinep</i>, char **<i>userp</i>, char **<i>domainp</i>); int getnetgrent_r(char **<i>machinep</i>, char **<i>userp</i>, char **<i>domainp</i>, char *<i>buffer</i>, int<i>buflen</i>); int setnetgrent(const char *<i>netgroup</i>); int endnetgrent(void); int innetgr(const char *<i>netgroup</i>, const char *<i>machine</i>, const char *<i>user</i>, const char *<i>domain</i>);</pre>
DESCRIPTION	<p>These functions are used to test membership in and enumerate members of “netgroup” network groups defined in a system database. Netgroups are sets of (machine,user,domain) triples (see netgroup(4)).</p> <p>These functions consult the source specified for netgroup in the /etc/nsswitch.conf file (see nsswitch.conf(4)).</p> <p>The function innetgr() returns 1 if there is a netgroup <i>netgroup</i> that contains the specified <i>machine</i>, <i>user</i>, <i>domain</i> triple as a member; otherwise it returns 0. Any of the supplied pointers <i>machine</i>, <i>user</i>, and <i>domain</i> may be NULL, signifying a “wild card” that matches all values in that position of the triple.</p> <p>The innetgr() function is safe for use in single-threaded and multithreaded applications.</p> <p>The functions setnetgrent(), getnetgrent(), and endnetgrent() are used to enumerate the members of a given network group.</p> <p>The function setnetgrent() establishes the network group specified in the parameter <i>netgroup</i> as the current group whose members are to be enumerated.</p> <p>Successive calls to the function getnetgrent() will enumerate the members of the group established by calling setnetgrent(); each call returns 1 if it succeeds in obtaining another member of the network group, or 0 if there are no further members of the group.</p> <p>When calling either getnetgrent() or getnetgrent_r(), addresses of the three character pointers are used as arguments, for example:</p> <pre>char *<i>mp</i>, *<i>up</i>, *<i>dp</i>; getnetgrent(&<i>mp</i>, &<i>up</i>, &<i>dp</i>);</pre>

Upon successful return from `getnetgrent()`, the pointer `mp` points to a string containing the name of the machine part of the member triple, `up` points to a string containing the user name and `dp` points to a string containing the domain name. If the pointer returned for `mp`, `up`, or `dp` is `NULL`, it signifies that the element of the netgroup contains wild card specifier in that position of the triple.

The pointers returned by `getnetgrent()` point into a buffer allocated by `setnetgrent()` that is reused by each call. This space is released when an `endnetgrent()` call is made, and should not be released by the caller. This implementation is not safe for use in multi-threaded applications.

The function `getnetgrent_r()` is similar to `getnetgrent()` function, but it uses a buffer supplied by the caller for the space needed to store the results. The parameter `buffer` should be a pointer to a buffer allocated by the caller and the length of this buffer should be specified by the parameter `buflen`. The buffer must be large enough to hold the data associated with the triple. The `getnetgrent_r()` function is safe for use both in single-threaded and multi-threaded applications.

The function `endnetgrent()` frees the space allocated by the previous `setnetgrent()` call. The equivalent of an `endnetgrent()` implicitly performed whenever a `setnetgrent()` call is made to a new network group.

Note that while `setnetgrent()` and `endnetgrent()` are safe for use in multi-threaded applications, the effect of each is process-wide. Calling `setnetgrent()` resets the enumeration position for all threads. If multiple threads interleave calls to `getnetgrent_r()` each will enumerate a disjoint subset of the netgroup. Thus the effective use of these functions in multi-threaded applications may require coordination by the caller.

ERRORS The function `getnetgrent_r()` will return 0 and set `errno` to `ERANGE` if the length of the buffer supplied by caller is not large enough to store the result. See `Intro(2)` for the proper usage and interpretation of `errno` in multi-threaded applications.

The functions `setnetgrent()` and `endnetgrent()` return 0 upon success.

FILES `/etc/nsswitch.conf`

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
MT-Level	See <code>DESCRIPTION</code> section.

SEE ALSO `Intro(2)`, `Intro(3)`, `netgroup(4)`, `nsswitch.conf(4)`, `attributes(5)`

WARNINGS The function `getnetgrent_r()` is included in this release on an uncommitted basis only, and is subject to change or removal in future minor releases.

setnetgrent(3C)

NOTES Only the Network Information Services, NIS and NIS+, are supported as sources for the `netgroup` database.

Programs that use the interfaces described in this manual page cannot be linked statically since the implementations of these functions employ dynamic loading and linking of shared objects at run time.

When compiling multi-threaded applications, see `Intro(3)`, *Notes On Multithread Applications*, for information about the use of the `_REENTRANT` flag.

NAME	getpriority, setpriority – get or set process scheduling priority				
SYNOPSIS	<pre>#include <sys/resource.h> int getpriority(int <i>which</i>, id_t <i>who</i>); int setpriority(int <i>which</i>, id_t <i>who</i>, int <i>priority</i>);</pre>				
DESCRIPTION	<p>The <code>getpriority()</code> function obtains the current scheduling priority of a process, process group, or user. The <code>setpriority()</code> function sets the scheduling priority of a process, process group, or user.</p> <p>Target processes are specified by the values of the <i>which</i> and <i>who</i> arguments. The <i>which</i> argument may be one of the following values: <code>PRIO_PROCESS</code>, <code>PRIO_PGRP</code>, <code>PRIO_USER</code>, <code>PRIO_GROUP</code>, <code>PRIO_SESSION</code>, <code>PRIO_LWP</code>, <code>PRIO_LWP</code>, or <code>PRIO_PROJECT</code>, indicating that the <i>who</i> argument is to be interpreted as a process ID, a process group ID, a user ID, a group ID, a session ID, an lwp ID, a task ID, or a project ID, respectively. A 0 value for the <i>who</i> argument specifies the current process, process group, or user. A 0 value for the <i>who</i> argument is treated as valid group ID, session ID, lwp ID, task ID, or project ID. A <code>P_MYID</code> value for the <i>who</i> argument can be used to specify the current group, session, lwp, task, or project, respectively.</p> <p>If more than one process is specified, <code>getpriority()</code> returns the highest priority (lowest numerical value) pertaining to any of the specified processes, and <code>setpriority()</code> sets the priorities of all of the specified processes to the specified value.</p> <p>The default <i>priority</i> is 0; negative priorities cause more favorable scheduling. While the range of valid priority values is <code>[-20, 20]</code>, implementations may enforce more restrictive limits. If the value specified to <code>setpriority()</code> is less than the system's lowest supported priority value, the system's lowest supported value is used. If it is greater than the system's highest supported value, the system's highest supported value is used.</p> <p>Only a process with appropriate privileges can raise its priority (that is, assign a lower numerical priority value).</p>				
RETURN VALUES	<p>Upon successful completion, <code>getpriority()</code> returns an integer in the range from <code>-20</code> to <code>20</code>. Otherwise, <code>-1</code> is returned and <code>errno</code> is set to indicate the error.</p> <p>Upon successful completion, <code>setpriority()</code> returns <code>0</code>. Otherwise, <code>-1</code> is returned and <code>errno</code> is set to indicate the error.</p>				
ERRORS	<p>The <code>getpriority()</code> and <code>setpriority()</code> functions will fail if:</p> <table border="0"> <tr> <td style="padding-right: 20px;"><code>ESRCH</code></td> <td>No process could be located using the <i>which</i> and <i>who</i> argument values specified.</td> </tr> <tr> <td><code>EINVAL</code></td> <td>The value of the <i>which</i> argument was not recognized, or the value of the <i>who</i> argument is not a valid process ID, process group ID, user ID, group ID, session ID, lwp ID, task ID, or project ID.</td> </tr> </table>	<code>ESRCH</code>	No process could be located using the <i>which</i> and <i>who</i> argument values specified.	<code>EINVAL</code>	The value of the <i>which</i> argument was not recognized, or the value of the <i>who</i> argument is not a valid process ID, process group ID, user ID, group ID, session ID, lwp ID, task ID, or project ID.
<code>ESRCH</code>	No process could be located using the <i>which</i> and <i>who</i> argument values specified.				
<code>EINVAL</code>	The value of the <i>which</i> argument was not recognized, or the value of the <i>who</i> argument is not a valid process ID, process group ID, user ID, group ID, session ID, lwp ID, task ID, or project ID.				

setpriority(3C)

In addition, `setpriority()` may fail if:

- EPERM** A process was located, but neither the real nor effective user ID of the executing process is the privileged user or match the effective user ID of the process whose priority is being changed.
- EACCES** A request was made to change the priority to a lower numeric value (that is, to a higher priority) and the current process does not have appropriate privileges.

USAGE The effect of changing the scheduling priority can vary depending on the process-scheduling algorithm in effect.

Because `getpriority()` can return `-1` on successful completion, it is necessary to set `errno` to `0` prior to a call to `getpriority()`. If `getpriority()` returns `-1`, then `errno` can be checked to see if an error occurred or if the value is a legitimate priority.

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

NAME	getpwnam, getpwnam_r, getpwent, getpwent_r, getpwuid, getpwuid_r, setpwent, endpwent, fgetpwent, fgetpwent_r – get password entry
SYNOPSIS	<pre>#include <pwd.h> struct passwd *getpwnam(const char *name); struct passwd *getpwnam_r(const char *name, struct passwd *pwd, char *buffer, int buflen); struct passwd *getpwent(void); struct passwd *getpwent_r(struct passwd *pwd, char *buffer, int buflen); struct passwd *getpwuid(uid_t uid); struct passwd *getpwuid_r(uid_t uid, struct passwd *pwd, char *buffer, int buflen); void setpwent(void); void endpwent(void); struct passwd *fgetpwent(FILE *f); struct passwd *fgetpwent_r(FILE *f, struct passwd *pwd, char *buffer, int buflen);</pre>
POSIX	<pre>cc [flag...] file... -D_POSIX_PTHREAD_SEMANTICS [library...] int getpwnam_r(const char *name, struct passwd *pwd, char *buffer, size_t bufsize, struct passwd **result); int getpwuid_r(uid_t uid, struct passwd *pwd, char *buffer, size_t bufsize, struct passwd **result);</pre>
DESCRIPTION	<p>These functions are used to obtain password entries. Entries can come from any of the sources for <code>passwd</code> specified in the <code>/etc/nsswitch.conf</code> file (see <code>nsswitch.conf(4)</code>).</p> <p>The <code>getpwnam()</code> function searches for a password entry with the login name specified by the character string parameter <i>name</i>.</p> <p>The <code>getpwuid()</code> function searches for a password entry with the (numeric) user ID specified by the parameter <i>uid</i>.</p> <p>The <code>setpwent()</code>, <code>getpwent()</code>, and <code>endpwent()</code> functions are used to enumerate password entries from the database. <code>setpwent()</code> sets (or resets) the enumeration to the beginning of the set of password entries. This function should be called before the first call to <code>getpwent()</code>. Calls to <code>getpwnam()</code> and <code>getpwuid()</code> leave the enumeration position in an indeterminate state. Successive calls to <code>getpwent()</code> return either successive entries or <code>NULL</code>, indicating the end of the enumeration.</p>

setpwent(3C)

The `endpwent()` function may be called to indicate that the caller expects to do no further password retrieval operations; the system may then close the password file, deallocate resources it was using, and so forth. It is still allowed, but possibly less efficient, for the process to call more password functions after calling `endpwent()`.

The `fgetpwent()` function, unlike the other functions above, does not use `nsswitch.conf`; it reads and parses the next line from the stream *f*, which is assumed to have the format of the `passwd` file. See `passwd(4)`.

Reentrant Interfaces

The functions `getpwnam()`, `getpwuid()`, `getpwent()`, and `fgetpwent()` use static storage that is reused in each call, making these routines unsafe for use in multithreaded applications.

The parallel functions `getpwnam_r()`, `getpwuid_r()`, `getpwent_r()`, and `fgetpwent_r()` provide reentrant interfaces for these operations.

Each reentrant interface performs the same operation as its non-reentrant counterpart, named by removing the “_r” suffix. The reentrant interfaces, however, use buffers supplied by the caller to store returned results, and are safe for use in both single-threaded and multithreaded applications.

Each reentrant interface takes the same parameters as its non-reentrant counterpart, as well as the following additional parameters. The parameter `pwd` must be a pointer to a `struct passwd` structure allocated by the caller. On successful completion, the function returns the password entry in this structure. The parameter *buffer* is a pointer to a buffer supplied by the caller, used as storage space for the password data. All of the pointers within the returned `struct passwd` `pwd` point to data stored within this buffer; see RETURN VALUES. The buffer must be large enough to hold all the data associated with the password entry. The parameter *buflen* (or *bufsize* for the POSIX versions; see `standards(5)`) should give the size in bytes of *buffer*. The POSIX versions place a pointer to the modified `pwd` structure in the *result* parameter, instead of returning a pointer to this structure.

For enumeration in multithreaded applications, the position within the enumeration is a process-wide property shared by all threads. The `setpwent()` function may be used in a multithreaded application but resets the enumeration position for all threads. If multiple threads interleave calls to `getpwent_r()`, the threads will enumerate disjoint subsets of the password database.

Like their non-reentrant counterparts, `getpwnam_r()` and `getpwuid_r()` leave the enumeration position in an indeterminate state.

RETURN VALUES

Password entries are represented by the `struct passwd` structure defined in `<pwd.h>`:

```
struct passwd {
    char *pw_name;           /* user's login name */
    char *pw_passwd;        /* no longer used */
    uid_t pw_uid;           /* user's uid */
    gid_t pw_gid;           /* user's gid */
    char *pw_age;           /* not used */
}
```

```

char *pw_comment; /* not used */
char *pw_gecos; /* typically user's full name */
char *pw_dir; /* user's home dir */
char *pw_shell; /* user's login shell */
};

```

The `pw_passwd` member should not be used as the encrypted password for the user; use `getspnam()` or `getspnam_r()` instead. See `getspnam(3C)`.

The `getpwnam()`, `getpwnam_r()`, `getpwuid()`, and `getpwuid_r()` functions each return a pointer to a `struct passwd` if they successfully locate the requested entry; otherwise they return `NULL`. Upon successful completion (including the case when the requested entry is not found), the POSIX functions `getpwnam_r()` and `getpwuid_r()` return 0. Otherwise, an error number is returned to indicate the error.

The `getpwent()`, `getpwent_r()`, `fgetpwent()`, and `fgetpwent_r()` functions each return a pointer to a `struct passwd` if they successfully enumerate an entry; otherwise they return `NULL`, indicating the end of the enumeration.

The `getpwnam()`, `getpwuid()`, `getpwent()`, and `fgetpwent()` functions use static storage, so returned data must be copied before a subsequent call to any of these functions if the data is to be saved.

When the pointer returned by the reentrant functions `getpwnam_r()`, `getpwuid_r()`, `getpwent_r()`, and `fgetpwent_r()` is non-null, it is always equal to the `pwd` pointer that was supplied by the caller.

ERRORS The reentrant functions `getpwnam_r()`, `getpwuid_r()`, `getpwent_r()`, and `fgetpwent_r()` will return `NULL` and set `errno` to `ERANGE` (or in the case of POSIX functions `getpwnam_r()` and `getpwuid_r()` return the `ERANGE` error) if the length of the buffer supplied by caller is not large enough to store the result. See `Intro(2)` for the proper usage and interpretation of `errno` in multithreaded applications.

USAGE Applications that use the interfaces described on this manual page cannot be linked statically, since the implementations of these functions employ dynamic loading and linking of shared objects at run time.

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE

NOTES When compiling multithreaded programs, see `Intro(3)`, *Notes On Multithreaded Applications*.

setpwent(3C)

Use of the enumeration interfaces `getpwent()` and `getpwent_r()` is discouraged; enumeration is supported for the `passwd` file, NIS, and NIS+, but in general is not efficient and may not be supported for all database sources. The semantics of enumeration are discussed further in `nsswitch.conf(4)`.

Previous releases allowed the use of '+' and '-' entries in `/etc/passwd` to selectively include and exclude NIS entries. The primary usage of these '+/-' entries is superseded by the name service switch, so the '+/-' form may not be supported in future releases.

If required, the '+/-' functionality can still be obtained for NIS by specifying `compat` as the source for `passwd`.

If the '+/-' functionality is required in conjunction with NIS+, specify both `compat` as the source for `passwd` and `nisplus` as the source for the pseudo-database `passwd_compat`. See `passwd(4)`, `shadow(4)`, and `nsswitch.conf(4)` for details.

If the '+/-' is used, both `/etc/shadow` and `/etc/passwd` should have the same '+' and '-' entries to ensure consistency between the password and shadow databases.

If a password entry from any of the sources contains an empty `uid` or `gid` field, that entry will be ignored by the files, NIS, and NIS+ name service switch backends. This will cause the user to appear unknown to the system.

If a password entry contains an empty `gecos`, `home directory`, or `shell` field, `getpwnam()` and `getpwnam_r()` return a pointer to a null string in the respective field of the `passwd` structure.

If the shell field is empty, `login(1)` automatically assigns the default shell. See `login(1)`.

Solaris 2.4 and earlier releases provided definitions of the `getpwnam_r()` and `getpwuid_r()` functions as specified in POSIX.1c Draft 6. The final POSIX.1c standard changed the interface for these functions. Support for the Draft 6 interface is provided for compatibility only and may not be supported in future releases. New applications and libraries should use the POSIX standard interface.

For POSIX.1c-compliant applications, the `_POSIX_PTHREAD_SEMANTICS` and `_REENTRANT` flags are automatically turned on by defining the `_POSIX_C_SOURCE` flag with a value `>= 199506L`.

NAME	getspnam, getspnam_r, getspent, getspent_r, setspent, endspent, fgetspent, fgetspent_r – get password entry
SYNOPSIS	<pre>#include <shadow.h> struct spwd *getspnam(const char *name); struct spwd *getspnam_r(const char *name, struct spwd *result, char *buffer, int buflen); struct spwd *getspent(void); struct spwd *getspent_r(struct spwd *result, char *buffer, int buflen); void setspent(void); void endspent(void); struct spwd *fgetspent(FILE *fp); struct spwd *fgetspent_r(FILE *fp, struct spwd *result, char *buffer, int buflen);</pre>
DESCRIPTION	<p>These functions are used to obtain shadow password entries. An entry may come from any of the sources for shadow specified in the <code>/etc/nsswitch.conf</code> file (see <code>nsswitch.conf(4)</code>).</p> <p>The <code>getspnam()</code> function searches for a shadow password entry with the login name specified by the character string argument <i>name</i>.</p> <p>The <code>setspent()</code>, <code>getspent()</code>, and <code>endspent()</code> functions are used to enumerate shadow password entries from the database.</p> <p>The <code>setspent()</code> function sets (or resets) the enumeration to the beginning of the set of shadow password entries. This function should be called before the first call to <code>getspent()</code>. Calls to <code>getspnam()</code> leave the enumeration position in an indeterminate state.</p> <p>Successive calls to <code>getspent()</code> return either successive entries or NULL, indicating the end of the enumeration.</p> <p>The <code>endspent()</code> function may be called to indicate that the caller expects to do no further shadow password retrieval operations; the system may then close the shadow password file, deallocate resources it was using, and so forth. It is still allowed, but possibly less efficient, for the process to call more shadow password functions after calling <code>endspent()</code>.</p> <p>The <code>fgetspent()</code> function, unlike the other functions above, does not use <code>nsswitch.conf</code>; it reads and parses the next line from the stream <i>fp</i>, which is assumed to have the format of the shadow file (see <code>shadow(4)</code>).</p>
Reentrant Interfaces	The <code>getspnam()</code> , <code>getspent()</code> , and <code>fgetspent()</code> functions use static storage that is re-used in each call, making these routines unsafe for use in multithreaded applications.

setspent(3C)

The `getspnam_r()`, `getspent_r()`, and `fgetspent_r()` functions provide reentrant interfaces for these operations.

Each reentrant interface performs the same operation as its non-reentrant counterpart, named by removing the `_r` suffix. The reentrant interfaces, however, use buffers supplied by the caller to store returned results, and are safe for use in both single-threaded and multithreaded applications.

Each reentrant interface takes the same argument as its non-reentrant counterpart, as well as the following additional arguments. The *result* argument must be a pointer to a `struct spwd` structure allocated by the caller. On successful completion, the function returns the shadow password entry in this structure. The *buffer* argument must be a pointer to a buffer supplied by the caller. This buffer is used as storage space for the shadow password data. All of the pointers within the returned `struct spwd result` point to data stored within this buffer (see RETURN VALUES). The buffer must be large enough to hold all of the data associated with the shadow password entry. The *buflen* argument should give the size in bytes of the buffer indicated by *buffer*.

For enumeration in multithreaded applications, the position within the enumeration is a process-wide property shared by all threads. The `setspent()` function may be used in a multithreaded application but resets the enumeration position for all threads. If multiple threads interleave calls to `getspent_r()`, the threads will enumerate disjoint subsets of the shadow password database.

Like its non-reentrant counterpart, `getspnam_r()` leaves the enumeration position in an indeterminate state.

RETURN VALUES

Password entries are represented by the `struct spwd` structure defined in `<shadow.h>`:

```
struct spwd{
    char          *sp_namp;      /* login name */
    char          *sp_pwdp;     /* encrypted passwd */
    long          sp_lstchg;     /* date of last change */
    long          sp_min;       /* min days to passwd change */
    long          sp_max;       /* max days to passwd change*/
    long          sp_warn;      /* warning period */
    long          sp_inact;     /* max days inactive */
    long          sp_expire;    /* account expiry date */
    unsigned long sp_flag;     /* not used */
};
```

See `shadow(4)` for more information on the interpretation of this data.

The `getspnam()` and `getspnam_r()` functions each return a pointer to a `struct spwd` if they successfully locate the requested entry; otherwise they return `NULL`.

The `getspent()`, `getspent_r()`, `fgetspent()`, and `fgetspent_r()` functions each return a pointer to a `struct spwd` if they successfully enumerate an entry; otherwise they return `NULL`, indicating the end of the enumeration.

The `getspnam()`, `getspent()`, and `fgetspent()` functions use static storage, so returned data must be copied before a subsequent call to any of these functions if the data is to be saved.

When the pointer returned by the reentrant functions `getspnam_r()`, `getspent_r()`, and `fgetspent_r()` is non-null, it is always equal to the *result* pointer that was supplied by the caller.

ERRORS The reentrant functions `getspnam_r()`, `getspent_r()`, and `fgetspent_r()` will return NULL and set `errno` to `ERANGE` if the length of the buffer supplied by caller is not large enough to store the result. See `intro(2)` for the proper usage and interpretation of `errno` in multithreaded applications.

USAGE Applications that use the interfaces described on this manual page cannot be linked statically, since the implementations of these functions employ dynamic loading and linking of shared objects at run time.

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
MT-Level	See "Reentrant Interfaces" in <code>DESCRIPTION</code> .

SEE ALSO `nispasswd(1)`, `passwd(1)`, `yppasswd(1)`, `intro(3)` `getlogin(3C)`, `getpwnam(3C)`, `nsswitch.conf(4)`, `passwd(4)`, `shadow(4)`, `attributes(5)`

WARNINGS The reentrant interfaces `getspnam_r()`, `getspent_r()`, and `fgetspent_r()` are included in this release on an uncommitted basis only, and are subject to change or removal in future minor releases.

NOTES When compiling multithreaded applications, see `intro(3)`, *Notes On Multithreaded Applications*, for information about the use of the `_REENTRANT` flag.

Use of the enumeration interfaces `getspent()` and `getspent_r()` is not recommended; enumeration is supported for the shadow file, NIS, and NIS+, but in general is not efficient and may not be supported for all database sources. The semantics of enumeration are discussed further in `nsswitch.conf(4)`.

Access to shadow password information may be restricted in a manner depending on the database source being used. Access to the `/etc/shadow` file is generally restricted to processes running as the super-user (root). Other database sources may impose stronger or less stringent restrictions.

When NIS is used as the database source, the information for the shadow password entries is obtained from the "passwd.byname" map. This map stores only the information for the `sp_namp` and `sp_pwdp` fields of the `struct spwd` structure. Shadow password entries obtained from NIS will contain the value -1 in the remainder of the fields.

setspent(3C)

When NIS+ is used as the database source, and the caller lacks the permission needed to retrieve the encrypted password from the NIS+ "passwd.org_dir" table, the NIS+ service returns the string "*NP*" instead of the actual encrypted password string. The functions described on this page will then return the string "*NP*" to the caller as the value of the member `sp_pwdp` in the returned shadow password structure.

NAME	random, srandom, initstate, setstate – pseudorandom number functions
SYNOPSIS	<pre>#include <stdlib.h> long random(void); void srandom(unsigned int seed); char *initstate(unsigned int seed, char *state, size_t size); char *setstate(const char *state);</pre>
DESCRIPTION	<p>The <code>random()</code> function uses a nonlinear additive feedback random-number generator employing a default state array size of 31 long integers to return successive pseudo-random numbers in the range from 0 to $2^{31}-1$. The period of this random-number generator is approximately $16 \times (2^{31}-1)$. The size of the state array determines the period of the random-number generator. Increasing the state array size increases the period.</p> <p>The <code>srandom()</code> function initializes the current state array using the value of <i>seed</i>.</p> <p>The <code>random()</code> and <code>srandom()</code> functions have (almost) the same calling sequence and initialization properties as <code>rand()</code> and <code>srand()</code> (see <code>rand(3C)</code>). The difference is that <code>rand(3C)</code> produces a much less random sequence—in fact, the low dozen bits generated by <code>rand</code> go through a cyclic pattern. All the bits generated by <code>random()</code> are usable.</p> <p>The algorithm from <code>rand()</code> is used by <code>srandom()</code> to generate the 31 state integers. Because of this, different <code>srandom()</code> seeds often produce, within an offset, the same sequence of low order bits from <code>random()</code>. If low order bits are used directly, <code>random()</code> should be initialized with <code>setstate()</code> using high quality random values.</p> <p>Unlike <code>srand()</code>, <code>srandom()</code> does not return the old seed because the amount of state information used is much more than a single word. Two other routines are provided to deal with restarting/changing random number generators. With 256 bytes of state information, the period of the random-number generator is greater than 2^{69}, which should be sufficient for most purposes.</p> <p>Like <code>rand(3C)</code>, <code>random()</code> produces by default a sequence of numbers that can be duplicated by calling <code>srandom()</code> with 1 as the seed.</p> <p>The <code>initstate()</code> and <code>setstate()</code> functions handle restarting and changing random-number generators. The <code>initstate()</code> function allows a state array, pointed to by the <i>state</i> argument, to be initialized for future use. The <i>size</i> argument, which specifies the size in bytes of the state array, is used by <code>initstate()</code> to decide what type of random-number generator to use; the larger the state array, the more random the numbers. Values for the amount of state information are 8, 32, 64, 128, and 256 bytes. Other values greater than 8 bytes are rounded down to the nearest one of these values. For values smaller than 8, <code>random()</code> uses a simple linear congruential random number generator. The <i>seed</i> argument specifies a starting point for the random-number sequence and provides for restarting at the same point. The <code>initstate()</code> function returns a pointer to the previous state information array.</p>

setstate(3C)

If `initstate()` has not been called, then `random()` behaves as though `initstate()` had been called with `seed = 1` and `size = 128`.

If `initstate()` is called with `size < 8`, then `random()` uses a simple linear congruential random number generator.

Once a state has been initialized, `setstate()` allows switching between state arrays. The array defined by the `state` argument is used for further random-number generation until `initstate()` is called or `setstate()` is called again. The `setstate()` function returns a pointer to the previous state array.

RETURN VALUES

The `random()` function returns the generated pseudo-random number.

The `srandom()` function returns no value.

Upon successful completion, `initstate()` and `setstate()` return a pointer to the previous state array. Otherwise, a null pointer is returned.

ERRORS

No errors are defined.

USAGE

After initialization, a state array can be restarted at a different point in one of two ways:

- The `initstate()` function can be used, with the desired seed, state array, and size of the array.
- The `setstate()` function, with the desired state, can be used, followed by `srandom()` with the desired seed. The advantage of using both of these functions is that the size of the state array does not have to be saved once it is initialized.

EXAMPLES

EXAMPLE 1 Initialize an array.

The following example demonstrates the use of `initstate()` to initialize an array. It also demonstrates how to initialize an array and pass it to `setstate()`.

```
# include <stdlib.h>
static unsigned int state0[32];
static unsigned int state1[32] = {
    3,
    0x9a319039, 0x32d9c024, 0x9b663182, 0x5da1f342,
    0x7449e56b, 0xbef1dbb0, 0xab5c5918, 0x946554fd,
    0x8c2e680f, 0xeb3d799f, 0xb11ee0b7, 0x2d436b86,
    0xda672e2a, 0x1588ca88, 0xe369735d, 0x904f35f7,
    0xd7158fd6, 0x6fa6f051, 0x616e6b96, 0xac94efdc,
    0xde3b81e0, 0xdf0a6fb5, 0xf103bc02, 0x48f340fb,
    0x36413f93, 0xc622c298, 0xf5a42ab8, 0x8a88d77b,
    0xf5ad9d0e, 0x8999220b, 0x27fb47b9
};
main() {
    unsigned seed;
    int n;
    seed = 1;
    n = 128;
    (void)initstate(seed, (char *)state0, n);
    printf("random() = %d0\
```

EXAMPLE 1 Initialize an array. (Continued)

```

", random());
    (void)setstate((char *)state1);
    printf("random() = %d\n",
", random());
}

```

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
MT-Level	See NOTES below.

SEE ALSO `drand48(3C)`, `rand(3C)`, `attributes(5)`

NOTES The `random()` and `srandom()` functions are unsafe in multithreaded applications.

Use of these functions in multithreaded applications is unsupported.

For `initstate()` and `setstate()`, the *state* argument must be aligned on an `int` boundary.

Newer and better performing random number generators such as `addrands()` and `lcrans()` are available with the SUNWspro package.

settimeofday(3C)

NAME	gettimeofday, settimeofday – get or set the date and time						
SYNOPSIS	<pre>#include <sys/time.h> int gettimeofday(struct timeval *tp, void *); int settimeofday(struct timeval *tp, void *);</pre>						
DESCRIPTION	<p>The <code>gettimeofday()</code> function gets and the <code>settimeofday()</code> function sets the system's notion of the current time. The current time is expressed in elapsed seconds and microseconds since 00:00 Universal Coordinated Time, January 1, 1970. The resolution of the system clock is hardware dependent; the time may be updated continuously or in clock ticks.</p> <p>The <i>tp</i> argument points to a <code>timeval</code> structure, which includes the following members:</p> <pre>long tv_sec; /* seconds since Jan. 1, 1970 */ long tv_usec; /* and microseconds */</pre> <p>If <i>tp</i> is a null pointer, the current time information is not returned or set.</p> <p>The TZ environment variable holds time zone information. See <code>TIMEZONE(4)</code>.</p> <p>The second argument to <code>gettimeofday()</code> and <code>settimeofday()</code> is ignored.</p> <p>Only the super-user may set the time of day.</p>						
RETURN VALUES	Upon successful completion, 0 is returned. Otherwise, -1 is returned and <code>errno</code> is set to indicate the error.						
ERRORS	<p>The <code>gettimeofday()</code> function will fail if:</p> <table><tr><td>EINVAL</td><td>The structure pointed to by <i>tp</i> specifies an invalid time.</td></tr><tr><td>EPERM</td><td>A user other than the privileged user attempted to set the time or time zone.</td></tr></table> <p>Additionally, the <code>gettimeofday()</code> function will fail for 32-bit interfaces if:</p> <table><tr><td>EOVERFLOW</td><td>The system time has progressed beyond 2038, thus the size of the <code>tv_sec</code> member of the <code>timeval</code> structure pointed to by <i>tp</i> is insufficient to hold the current time in seconds.</td></tr></table>	EINVAL	The structure pointed to by <i>tp</i> specifies an invalid time.	EPERM	A user other than the privileged user attempted to set the time or time zone.	EOVERFLOW	The system time has progressed beyond 2038, thus the size of the <code>tv_sec</code> member of the <code>timeval</code> structure pointed to by <i>tp</i> is insufficient to hold the current time in seconds.
EINVAL	The structure pointed to by <i>tp</i> specifies an invalid time.						
EPERM	A user other than the privileged user attempted to set the time or time zone.						
EOVERFLOW	The system time has progressed beyond 2038, thus the size of the <code>tv_sec</code> member of the <code>timeval</code> structure pointed to by <i>tp</i> is insufficient to hold the current time in seconds.						
USAGE	If the <code>tv_usec</code> member of <i>tp</i> is > 500000, <code>settimeofday()</code> rounds the seconds upward. If the time needs to be set with better than one second accuracy, call <code>settimeofday()</code> for the seconds and then <code>adjtime(2)</code> for finer accuracy.						
ATTRIBUTES	See <code>attributes(5)</code> for descriptions of the following attributes:						

settimeofday(3C)

ATTRIBUTE TYPE	ATTRIBUTE VALUE
MT-Level	MT-Safe

SEE ALSO adjtime(2), ctime(3C), TIMEZONE(4), attributes(5)

settimeofday(3UCB)

NAME	gettimeofday, settimeofday – get or set the date and time
SYNOPSIS	<pre><code>/usr/ucb/cc[flag ...] file ... #include <sys/time.h> int gettimeofday(tp, tzp); struct timeval *tzp; struct timezone *tzp; int settimeofday(tp, tzp); struct timeval *tzp; struct timezone *tzp;</code></pre>
DESCRIPTION	<p>The system's notion of the current Greenwich time is obtained with the <code>gettimeofday()</code> call, and set with the <code>settimeofday()</code> call. The current time is expressed in elapsed seconds and microseconds since 00:00 GMT, January 1, 1970 (zero hour). The resolution of the system clock is hardware dependent; the time may be updated continuously, or in clock ticks.</p> <pre><code>long tv_sec; /* seconds since Jan. 1, 1970 */ long tv_usec; /* and microseconds */</code></pre> <p><i>tp</i> points to a <code>timeval</code> structure, which includes the following members:</p> <p>If <i>tp</i> is a NULL pointer, the current time information is not returned or set.</p> <p><i>tzp</i> is an obsolete pointer formerly used to get and set timezone information. <i>tzp</i> is now ignored. Timezone information is now handled using the TZ environment variable; see <code>TIMEZONE(4)</code>.</p> <p>Only the privileged user may set the time of day.</p>
RETURN VALUES	A -1 return value indicates an error occurred; in this case an error code is stored in the global variable <code>errno</code> .
ERRORS	The following error codes may be set in <code>errno</code> : EINVAL <i>tp</i> specifies an invalid time. EPERM A user other than the privileged user attempted to set the time.
SEE ALSO	<code>adjtime(2)</code> , <code>ctime(3C)</code> , <code>gettimeofday(3C)</code> , <code>TIMEZONE(4)</code>
NOTES	Use of these interfaces should be restricted to only applications written on BSD platforms. Use of these interfaces with any of the system libraries or in multi-thread applications is unsupported. <i>tzp</i> is ignored in SunOS 5.X releases. <code>tv_usec</code> is always 0.

NAME	getusershell, setusershell, endusershell – get legal user shells																								
SYNOPSIS	<pre>char *getusershell() void setusershell() void endusershell()</pre>																								
DESCRIPTION	<p>The <code>getusershell()</code> function returns a pointer to a legal user shell as defined by the system manager in the file <code>/etc/shells</code>. If <code>/etc/shells</code> does not exist, the following locations of the standard system shells are used in its place:</p> <table border="0"> <tr><td><code>/bin/bash</code></td><td><code>/bin/csh</code></td></tr> <tr><td><code>/bin/jsh</code></td><td><code>/bin/ksh</code></td></tr> <tr><td><code>/bin/pfcsh</code></td><td><code>/bin/pfksh</code></td></tr> <tr><td><code>/bin/pfsh</code></td><td><code>/bin/sh</code></td></tr> <tr><td><code>/bin/tcsh</code></td><td><code>/bin/zsh</code></td></tr> <tr><td><code>/sbin/jsh</code></td><td><code>/sbin/sh</code></td></tr> <tr><td><code>/usr/bin/bash</code></td><td><code>/usr/bin/csh</code></td></tr> <tr><td><code>/usr/bin/jsh</code></td><td><code>/usr/bin/ksh</code></td></tr> <tr><td><code>/usr/bin/pfcsh</code></td><td><code>/usr/bin/pfksh</code></td></tr> <tr><td><code>/usr/bin/pfsh</code></td><td><code>/usr/bin/sh</code></td></tr> <tr><td><code>/usr/bin/tcsh</code></td><td><code>/usr/bin/zsh</code></td></tr> <tr><td><code>/usr/xpg4/bin/sh</code></td><td></td></tr> </table> <p>The <code>getusershell()</code> function opens the file <code>/etc/shells</code>, if it exists, and returns the next entry in the list of shells.</p> <p>The <code>setusershell()</code> function rewinds the file or the list.</p> <p>The <code>endusershell()</code> function closes the file, frees any memory used by <code>getusershell()</code> and <code>setusershell()</code>, and rewinds the file <code>/etc/shells</code>.</p>	<code>/bin/bash</code>	<code>/bin/csh</code>	<code>/bin/jsh</code>	<code>/bin/ksh</code>	<code>/bin/pfcsh</code>	<code>/bin/pfksh</code>	<code>/bin/pfsh</code>	<code>/bin/sh</code>	<code>/bin/tcsh</code>	<code>/bin/zsh</code>	<code>/sbin/jsh</code>	<code>/sbin/sh</code>	<code>/usr/bin/bash</code>	<code>/usr/bin/csh</code>	<code>/usr/bin/jsh</code>	<code>/usr/bin/ksh</code>	<code>/usr/bin/pfcsh</code>	<code>/usr/bin/pfksh</code>	<code>/usr/bin/pfsh</code>	<code>/usr/bin/sh</code>	<code>/usr/bin/tcsh</code>	<code>/usr/bin/zsh</code>	<code>/usr/xpg4/bin/sh</code>	
<code>/bin/bash</code>	<code>/bin/csh</code>																								
<code>/bin/jsh</code>	<code>/bin/ksh</code>																								
<code>/bin/pfcsh</code>	<code>/bin/pfksh</code>																								
<code>/bin/pfsh</code>	<code>/bin/sh</code>																								
<code>/bin/tcsh</code>	<code>/bin/zsh</code>																								
<code>/sbin/jsh</code>	<code>/sbin/sh</code>																								
<code>/usr/bin/bash</code>	<code>/usr/bin/csh</code>																								
<code>/usr/bin/jsh</code>	<code>/usr/bin/ksh</code>																								
<code>/usr/bin/pfcsh</code>	<code>/usr/bin/pfksh</code>																								
<code>/usr/bin/pfsh</code>	<code>/usr/bin/sh</code>																								
<code>/usr/bin/tcsh</code>	<code>/usr/bin/zsh</code>																								
<code>/usr/xpg4/bin/sh</code>																									
RETURN VALUES	The <code>getusershell()</code> function returns a null pointer on EOF.																								
BUGS	All information is contained in memory that may be freed with a call to <code>endusershell()</code> , so it must be copied if it is to be saved.																								

setutent(3C)

NAME	getutent, getutid, getutline, pututline, setutent, endutent, utmpname – user accounting database functions
SYNOPSIS	<pre>#include <utmp.h> struct utmp *getutent(void); struct utmp *getutid(const struct utmp *id); struct utmp *getutline(const struct utmp *line); struct utmp *pututline(const struct utmp *utmp); void setutent(void); void endutent(void); int utmpname(const char *file);</pre>
DESCRIPTION	<p>These functions provide access to the user accounting database, utmp. Entries in the database are described by the definitions and data structures in <utmp.h>.</p> <p>The utmp structure contains the following members:</p> <pre>char ut_user[8]; /* user login name */ char ut_id[4]; /* /sbin/inittab id (usually line #) */ char ut_line[12]; /* device name (console, lnxx) */ short ut_pid; /* process id */ short ut_type; /* type of entry */ struct exit_status ut_exit; /* exit status of a process */ /* marked as DEAD_PROCESS */ time_t ut_time; /* time entry was made */</pre> <p>The structure exit_status includes the following members:</p> <pre>short e_termination; /* termination status */ short e_exit; /* exit status */</pre> <p>getutent() The getutent() function reads in the next entry from a utmp database. If the database is not already open, it opens it. If it reaches the end of the database, it fails.</p> <p>getutid() The getutid() function searches forward from the current point in the utmp database until it finds an entry with a ut_type matching id->ut_type if the type specified is RUN_LVL, BOOT_TIME, OLD_TIME, or NEW_TIME. If the type specified in id is INIT_PROCESS, LOGIN_PROCESS, USER_PROCESS, or DEAD_PROCESS, then getutid() will return a pointer to the first entry whose type is one of these four and whose ut_id member matches id->ut_id. If the end of database is reached without a match, it fails.</p> <p>getutline() The getutline() function searches forward from the current point in the utmp database until it finds an entry of the type LOGIN_PROCESS or ut_line string matching the line->ut_line string. If the end of database is reached without a match, it fails.</p>

- `pututline()` The `pututline()` function writes the supplied `utmp` structure into the `utmp` database. It uses `getutid()` to search forward for the proper place if it finds that it is not already at the proper place. It is expected that normally the user of `pututline()` will have searched for the proper entry using one of the these functions. If so, `pututline()` will not search. If `pututline()` does not find a matching slot for the new entry, it will add a new entry to the end of the database. It returns a pointer to the `utmp` structure. When called by a non-root user, `pututline()` invokes a `setuid()` root program to verify and write the entry, since the `utmp` database is normally writable only by root. In this event, the `ut_name` member must correspond to the actual user name associated with the process; the `ut_type` member must be either `USER_PROCESS` or `DEAD_PROCESS`; and the `ut_line` member must be a device special file and be writable by the user.
- `setutent()` The `setutent()` function resets the input stream to the beginning. This reset should be done before each search for a new entry if it is desired that the entire database be examined.
- `endutent()` The `endutent()` function closes the currently open database.
- `utmpname()` The `utmpname()` function allows the user to change the name of the database file examined to another file. If the file does not exist, this will not be apparent until the first attempt to reference the file is made. The `utmpname()` function does not open the file but closes the old file if it is currently open and saves the new file name.

RETURN VALUES A null pointer is returned upon failure to read, whether for permissions or having reached the end of file, or upon failure to write. If the file name given is longer than 79 characters, `utmpname()` returns 0. Otherwise, it returns 1.

USAGE These functions use buffered standard I/O for input, but `pututline()` uses an unbuffered non-standard write to avoid race conditions between processes trying to modify the `utmp` and `wtmp` databases.

Applications should not access the `utmp` and `wtmp` databases directly, but should use these functions to ensure that these databases are maintained consistently. Using these functions, however, may cause applications to fail if user accounting data cannot be represented properly in the `utmp` structure (for example, on a system where PIDs can exceed 32767). Use the functions described on the `getutxent(3C)` manual page instead.

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

setutent(3C)

NOTES | The most current entry is saved in a static structure. Multiple accesses require that it be copied before further accesses are made. On each call to either `getutid()` or `getutline()`, the function examines the static structure before performing more I/O. If the contents of the static structure match what it is searching for, it looks no further. For this reason, to use `getutline()` to search for multiple occurrences, it would be necessary to zero out the static area after each success, or `getutline()` would just return the same structure over and over again. There is one exception to the rule about emptying the structure before further reads are done. The implicit read done by `pututline()` (if it finds that it is not already at the correct place in the file) will not hurt the contents of the static structure returned by the `getutent()`, `getutid()` or `getutline()` functions, if the user has just modified those contents and passed the pointer back to `pututline()`.

NAME	getutxent, getutxid, getutxline, pututxline, setutxent, endutxent, utmpxname, getutmp, getutmpx, updwtmp, updwtmpx – user accounting database functions
SYNOPSIS	<pre>#include <utmpx.h> struct utmpx *getutxent (void); struct utmpx *getutxid (const struct utmpx *id); struct utmpx *getutxline (const struct utmpx *line); struct utmpx *pututxline (const struct utmpx *utmpx); void setutxent (void); void endutxent (void); int utmpxname (const char *file); void getutmp (struct utmpx *utmpx, struct utmp *utmp); void getutmpx (struct utmp *utmp, struct utmpx *utmpx); void updwtmp (char *wfile, struct utmp *utmp); void updwtmpx (char *wfile, struct utmpx *utmpx);</pre>
DESCRIPTION	<p>These functions provide access to the user accounting database, utmpx (see utmpx(4)). Entries in the database are described by the definitions and data structures in <utmpx.h>.</p> <p>The utmpx structure contains the following members:</p> <pre>char ut_user[32]; /* user login name */ char ut_id[4]; /* /etc/inittab id (usually line #) */ char ut_line[32]; /* device name (console, lnxx) */ pid_t ut_pid; /* process id */ short ut_type; /* type of entry */ struct exit_status ut_exit; /* exit status of a process */ /* marked as DEAD_PROCESS */ struct timeval ut_tv; /* time entry was made */ int ut_session; /* session ID, used for windowing */ short ut_syslen; /* significant length of ut_host */ /* including terminating null */ char ut_host[257]; /* host name, if remote */</pre> <p>The exit_status structure includes the following members:</p> <pre>short e_termination; /* termination status */ short e_exit; /* exit status */</pre> <p>getutxent () The getutxent () function reads in the next entry from a utmpx database. If the database is not already open, it opens it. If it reaches the end of the database, it fails.</p> <p>getutxid () The getutxid () function searches forward from the current point in the utmpx database until it finds an entry with a ut_type matching id->ut_type, if the type specified is RUN_LVL, BOOT_TIME, OLD_TIME, or NEW_TIME. If the type specified in</p>

setutxent(3C)

	<p><i>id</i> is INIT_PROCESS, LOGIN_PROCESS, USER_PROCESS, or DEAD_PROCESS, then <code>getutxid()</code> will return a pointer to the first entry whose type is one of these four and whose <code>ut_id</code> member matches <i>id</i>-><code>ut_id</code>. If the end of database is reached without a match, it fails.</p>
<code>getutxline()</code>	<p>The <code>getutxline()</code> function searches forward from the current point in the <code>utmpx</code> database until it finds an entry of the type LOGIN_PROCESS or USER_PROCESS which also has a <code>ut_line</code> string matching the <i>line</i>-><code>ut_line</code> string. If the end of the database is reached without a match, it fails.</p>
<code>pututxline()</code>	<p>The <code>pututxline()</code> function writes the supplied <code>utmpx</code> structure into the <code>utmpx</code> database. It uses <code>getutxid()</code> to search forward for the proper place if it finds that it is not already at the proper place. It is expected that normally the user of <code>pututxline()</code> will have searched for the proper entry using one of the <code>getutx()</code> routines. If so, <code>pututxline()</code> will not search. If <code>pututxline()</code> does not find a matching slot for the new entry, it will add a new entry to the end of the database. It returns a pointer to the <code>utmpx</code> structure. When called by a non-root user, <code>pututxline()</code> invokes a <code>setuid()</code> root program to verify and write the entry, since the <code>utmpx</code> database is normally writable only by root. In this event, the <code>ut_name</code> member must correspond to the actual user name associated with the process; the <code>ut_type</code> member must be either USER_PROCESS or DEAD_PROCESS; and the <code>ut_line</code> member must be a device special file and be writable by the user.</p>
<code>setutxent()</code>	<p>The <code>setutxent()</code> function resets the input stream to the beginning. This should be done before each search for a new entry if it is desired that the entire database be examined.</p>
<code>endutxent()</code>	<p>The <code>endutxent()</code> function closes the currently open database.</p>
<code>utmpxname()</code>	<p>The <code>utmpxname()</code> function allows the user to change the name of the database file examined from <code>/var/adm/utmpx</code> to any other file, most often <code>/var/adm/wtmpx</code>. If the file does not exist, this will not be apparent until the first attempt to reference the file is made. The <code>utmpxname()</code> function does not open the file, but closes the old file if it is currently open and saves the new file name. The new file name must end with the "x" character to allow the name of the corresponding <code>utmp</code> file to be easily obtainable.; otherwise, an error value of 0 is returned. The function returns 1 on success.</p>
<code>getutmp()</code>	<p>The <code>getutmp()</code> function copies the information stored in the members of the <code>utmpx</code> structure to the corresponding members of the <code>utmp</code> structure. If the information in any member of <code>utmpx</code> does not fit in the corresponding <code>utmp</code> member, the data is silently truncated. (See <code>getutent(3C)</code> for <code>utmp</code> structure)</p>
<code>getutmpx()</code>	<p>The <code>getutmpx()</code> function copies the information stored in the members of the <code>utmp</code> structure to the corresponding members of the <code>utmpx</code> structure. (See <code>getutent(3C)</code> for <code>utmp</code> structure)</p>
<code>updwtmp()</code>	<p>The <code>updwtmp()</code> function can be used in two ways.</p>

If *wfile* is `/var/adm/wtmp`, the `utmp` format record supplied by the caller is converted to a `utmpx` format record and the `/var/adm/wtmpx` file is updated (because the `/var/adm/wtmp` file no longer exists, operations on `wtmp` are converted to operations on `wtmpx` by the library functions).

If *wfile* is a file other than `/var/adm/wtmp`, it is assumed to be an old file in `utmp` format and is updated directly with the `utmp` format record supplied by the caller.

`updwtmpx()` The `updwtmpx()` function writes the contents of the `utmpx` structure pointed to by *utmpx* to the database.

utmpx structure The values of the `e_termination` and `e_exit` members of the `ut_exit` structure are valid only for records of type `DEAD_PROCESS`. For `utmpx` entries created by `init(1M)`, these values are set according to the result of the `wait()` call that `init` performs on the process when the process exits. See the `wait(2)` manual page for the values `init` uses. Applications creating `utmpx` entries can set `ut_exit` values using the following code example:

```
u->ut_exit.e_termination = WTERMSIG(process->p_exit)
u->ut_exit.e_exit = WEXITSTATUS(process->p_exit)
```

See `wstat(3XFN)` for descriptions of the `WTERMSIG` and `WEXITSTATUS` macros.

The `ut_session` member is not acted upon by the operating system. It is used by applications interested in creating `utmpx` entries.

For records of type `USER_PROCESS`, the `nonuser()` and `nonuserx()` macros use the value of the `ut_exit.e_exit` member to mark `utmpx` entries as real logins (as opposed to multiple `xterms` started by the same user on a window system). This allows the system utilities that display users to obtain an accurate indication of the number of actual users, while still permitting each `pty` to have a `utmpx` record (as most applications expect.). The `NONROOT_USER` macro defines the value that `login` places in the `ut_exit.e_exit` member.

RETURN VALUES Upon successful completion, `getutxent()`, `getutxid()`, and `getutxline()` each return a pointer to a `utmpx` structure containing a copy of the requested entry in the user accounting database. Otherwise a null pointer is returned.

The return value may point to a static area which is overwritten by a subsequent call to `getutxid()` or `getutxline()`.

Upon successful completion, `pututxline()` returns a pointer to a `utmpx` structure containing a copy of the entry added to the user accounting database. Otherwise a null pointer is returned.

The `endutxent()` and `setutxent()` functions return no value.

A null pointer is returned upon failure to read, whether for permissions or having reached the end of file, or upon failure to write.

setutxent(3C)

USAGE These functions use buffered standard I/O for input, but `pututxline()` uses an unbuffered write to avoid race conditions between processes trying to modify the `utmpx` and `wtmpx` files.

Applications should not access the `utmpx` and `wtmpx` databases directly, but should use these functions to ensure that these databases are maintained consistently.

NOTES The most current entry is saved in a static structure. Multiple accesses require that it be copied before further accesses are made. On each call to either `getutxid()` or `getutxline()`, the routine examines the static structure before performing more I/O. If the contents of the static structure match what it is searching for, it looks no further. For this reason, to use `getutxline()` to search for multiple occurrences it would be necessary to zero out the static after each success, or `getutxline()` would just return the same structure over and over again. There is one exception to the rule about emptying the structure before further reads are done. The implicit read done by `pututxline()` (if it finds that it is not already at the correct place in the file) will not hurt the contents of the static structure returned by the `getutxent()`, `getutxid()`, or `getutxline()` routines, if the user has just modified those contents and passed the pointer back to `pututxline()`.

NAME	setbuf, setvbuf – assign buffering to a stream						
SYNOPSIS	<pre>#include <stdio.h> void setbuf(FILE *stream, char *buf); int setvbuf(FILE *stream, char *buf, int type, size_t size);</pre>						
DESCRIPTION	<p>The <code>setbuf()</code> function may be used after the stream pointed to by <code>stream</code> (see <code>intro(3)</code>) is opened but before it is read or written. It causes the array pointed to by <code>buf</code> to be used instead of an automatically allocated buffer. If <code>buf</code> is the null pointer, input/output will be completely unbuffered. The constant <code>BUFSIZ</code>, defined in the <code><stdio.h></code> header, indicates the size of the array pointed to by <code>buf</code>.</p> <p>The <code>setvbuf()</code> function may be used after a stream is opened but before it is read or written. The <code>type</code> argument determines how <code>stream</code> will be buffered. Legal values for <code>type</code> (defined in <code><stdio.h></code>) are:</p> <table border="0"> <tr> <td><code>_IOFBF</code></td> <td>Input/output to be fully buffered.</td> </tr> <tr> <td><code>_IOLBF</code></td> <td>Output to be line buffered; the buffer will be flushed when a <code>NEWLINE</code> is written, the buffer is full, or input is requested.</td> </tr> <tr> <td><code>_IONBF</code></td> <td>Input/output to be completely unbuffered.</td> </tr> </table> <p>If <code>buf</code> is not the null pointer, the array it points to will be used for buffering, instead of an automatically allocated buffer. The <code>size</code> argument specifies the size of the buffer to be used. If input/output is unbuffered, <code>buf</code> and <code>size</code> are ignored.</p> <p>For a further discussion of buffering, see <code>stdio(3C)</code>.</p>	<code>_IOFBF</code>	Input/output to be fully buffered.	<code>_IOLBF</code>	Output to be line buffered; the buffer will be flushed when a <code>NEWLINE</code> is written, the buffer is full, or input is requested.	<code>_IONBF</code>	Input/output to be completely unbuffered.
<code>_IOFBF</code>	Input/output to be fully buffered.						
<code>_IOLBF</code>	Output to be line buffered; the buffer will be flushed when a <code>NEWLINE</code> is written, the buffer is full, or input is requested.						
<code>_IONBF</code>	Input/output to be completely unbuffered.						
RETURN VALUES	If an illegal value for <code>type</code> is provided, <code>setvbuf()</code> returns a non-zero value. Otherwise, it returns 0.						
USAGE	<p>A common source of error is allocating buffer space as an “automatic” variable in a code block, and then failing to close the stream in the same block.</p> <p>When using <code>setbuf()</code>, <code>buf</code> should always be sized using <code>BUFSIZ</code>. If the array pointed to by <code>buf</code> is larger than <code>BUFSIZ</code>, a portion of <code>buf</code> will not be used. If <code>buf</code> is smaller than <code>BUFSIZ</code>, other memory may be unexpectedly overwritten.</p> <p>Parts of <code>buf</code> will be used for internal bookkeeping of the stream and, therefore, <code>buf</code> will contain less than <code>size</code> bytes when full. It is recommended that <code>stdio(3C)</code> be used to handle buffer allocation when using <code>setvbuf()</code>.</p>						
ATTRIBUTES	See <code>attributes(5)</code> for descriptions of the following attributes:

setvbuf(3C)

SEE ALSO fopen(3C), getc(3C), malloc(3C), putc(3C), stdio(3C), attributes(5)

NAME	econvert, fconvert, gconvert, seconvert, sconvert, sgconvert, qeconvert, qfconvert, qgconvert – output conversion
SYNOPSIS	<pre>#include <floatingpoint.h> char *econvert(double value, int ndigit, int *decpt, int *sign, char *buf) ; char *fconvert(double value, int ndigit, int *decpt, int *sign, char *buf) ; char *gconvert(double value, int ndigit, int trailing, char *buf) ; char *seconvert(single *value, int ndigit, int *decpt, int *sign, char *buf) ; char *sconvert(single *value, int ndigit, int *decpt, int *sign, char *buf) ; char *sgconvert(single *value, int ndigit, int trailing, char *buf) ; char *qeconvert(quadruple *value, int ndigit, int *decpt, int *sign, char *buf) ; char *qfconvert(quadruple *value, int ndigit, int *decpt, int *sign, char *buf) ; char *qgconvert(quadruple *value, int ndigit, int trailing, char *buf) ;</pre>
DESCRIPTION	<p>The <code>econvert()</code> function converts the <i>value</i> to a null-terminated string of <i>ndigit</i> ASCII digits in <i>buf</i> and returns a pointer to <i>buf</i>. <i>buf</i> should contain at least <i>ndigit</i>+1 characters. The position of the decimal point relative to the beginning of the string is stored indirectly through <i>decpt</i>. Thus <i>buf</i> == "314" and <i>*decpt</i> == 1 corresponds to the numerical value 3.14, while <i>buf</i> == "314" and <i>*decpt</i> == -1 corresponds to the numerical value .0314. If the sign of the result is negative, the word pointed to by <i>sign</i> is nonzero; otherwise it is zero. The least significant digit is rounded.</p> <p>The <code>fconvert()</code> function works much like <code>econvert()</code>, except that the correct digit has been rounded as if for <code>printf("%w.nf")</code> output with $n=ndigit$ digits to the right of the decimal point. <i>ndigit</i> can be negative to indicate rounding to the left of the decimal point. The return value is a pointer to <i>buf</i>. <i>buf</i> should contain at least $310+max(0,ndigit)$ characters to accommodate any double-precision <i>value</i>.</p> <p>The <code>gconvert()</code> function converts the <i>value</i> to a null-terminated ASCII string in <i>buf</i> and returns a pointer to <i>buf</i>. It produces <i>ndigit</i> significant digits in fixed-decimal format, like <code>printf("%w.nf")</code>, if possible, and otherwise in floating-decimal format, like <code>printf("%w.ne")</code>; in either case <i>buf</i> is ready for printing, with sign and exponent. The result corresponds to that obtained by</p> <pre>(void) printf(buf, ``%w.ng'', value) ;</pre> <p>If <i>trailing</i> = 0, trailing zeros and a trailing point are suppressed, as in <code>printf("%g")</code>. If <i>trailing</i> != 0, trailing zeros and a trailing point are retained, as in <code>printf("%#g")</code>.</p>

sfconvert(3C)

The `seconvert()`, `sfconvert()`, and `sgconvert()` functions are single-precision versions of these functions, and are more efficient than the corresponding double-precision versions. A pointer rather than the value itself is passed to avoid C's usual conversion of single-precision arguments to double.

The `qeconvert()`, `qfconvert()`, and `qgconvert()` functions are quadruple-precision versions of these functions. The `qfconvert()` function can overflow the `decimal_record` field `ds` if `value` is too large. In that case, `buf[0]` is set to zero.

The `ecvt()`, `fcvt()` and `gcvt()` functions are versions of `econvert()`, `fconvert()`, and `gconvert()`, respectively, that are documented on the `ecvt(3C)` manual page. They constitute the default implementation of these functions and conform to the X/Open CAE Specification, System Interfaces and Headers, Issue 4, Version 2.

USAGE IEEE Infinities and NaNs are treated similarly by these functions. "NaN" is returned for NaN, and "Inf" or "Infinity" for Infinity. The longer form is produced when `ndigit` \geq 8.

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

NAME	str2sig, sig2str – translation between signal name and signal number
SYNOPSIS	<pre>#include <signal.h> int str2sig(const char *str, int *signum); int sig2str(int signum, char *str);</pre>
DESCRIPTION	<p>The <code>str2sig()</code> function translates the signal name <i>str</i> to a signal number, and stores that result in the location referenced by <i>signum</i>. The name in <i>str</i> can be either the symbol for that signal, without the "SIG" prefix, or a decimal number. All the signal symbols defined in <code><sys/signal.h></code> are recognized. This means that both "CLD" and "CHLD" are recognized and return the same signal number, as do both "POLL" and "IO". For access to the signals in the range SIGRTMIN to SIGRTMAX, the first four signals match the strings "RTMIN", "RTMIN+1", "RTMIN+2", and "RTMIN+3" and the last four match the strings "RTMAX-3", "RTMAX-2", "RTMAX-1", and "RTMAX".</p> <p>The <code>sig2str()</code> function translates the signal number <i>signum</i> to the symbol for that signal, without the "SIG" prefix, and stores that symbol at the location specified by <i>str</i>. The storage referenced by <i>str</i> should be large enough to hold the symbol and a terminating null byte. The symbol SIG2STR_MAX defined by <code><signal.h></code> gives the maximum size in bytes required.</p>
RETURN VALUES	<p>The <code>str2sig()</code> function returns 0 if it recognizes the signal name specified in <i>str</i>; otherwise, it returns -1.</p> <p>The <code>sig2str()</code> function returns 0 if the value <i>signum</i> corresponds to a valid signal number; otherwise, it returns -1.</p>
EXAMPLES	<p>EXAMPLE 1 A sample program using the <code>str2sig()</code> function.</p> <pre>int i; char buf[SIG2STR_MAX]; /*storage for symbol */ str2sig("KILL",&i); /*stores 9 in i */ str2sig("9", &i); /* stores 9 in i */ sig2str(SIGKILL,buf); /* stores "KILL" in buf */ sig2str(9,buf); /* stores "KILL" in buf */</pre>
SEE ALSO	kill(1), strsignal(3C)

sigaddset(3C)

NAME	sigsetops, sigemptyset, sigfillset, sigaddset, sigdelset, sigismember – manipulate sets of signals
SYNOPSIS	<pre>#include <signal.h> int sigemptyset(sigset_t *set); int sigfillset(sigset_t *set); int sigaddset(sigset_t *set, int signo); int sigdelset(sigset_t *set, int signo); int sigismember(sigset_t *set, int signo);</pre>
DESCRIPTION	<p>These functions manipulate <code>sigset_t</code> data types, representing the set of signals supported by the implementation.</p> <p>The <code>sigemptyset()</code> function initializes the set pointed to by <code>set</code> to exclude all signals defined by the system.</p> <p>The <code>sigfillset()</code> function initializes the set pointed to by <code>set</code> to include all signals defined by the system.</p> <p>The <code>sigaddset()</code> function adds the individual signal specified by the value of <code>signo</code> to the set pointed to by <code>set</code>.</p> <p>The <code>sigdelset()</code> function deletes the individual signal specified by the value of <code>signo</code> from the set pointed to by <code>set</code>.</p> <p>The <code>sigismember()</code> function checks whether the signal specified by the value of <code>signo</code> is a member of the set pointed to by <code>set</code>.</p> <p>Any object of type <code>sigset_t</code> must be initialized by applying either <code>sigemptyset()</code> or <code>sigfillset()</code> before applying any other operation.</p>
RETURN VALUES	<p>Upon successful completion, the <code>sigismember()</code> function returns 1 if the specified signal is a member of the specified set, or 0 if it is not.</p> <p>Upon successful completion, the other functions return 0. Otherwise -1 is returned and <code>errno</code> is set to indicate the error.</p>
ERRORS	<p>The <code>sigaddset()</code>, <code>sigdelset()</code>, and <code>sigismember()</code> functions will fail if:</p> <p><code>EINVAL</code> The value of the <code>signo</code> argument is not a valid signal number.</p> <p>The <code>sigfillset()</code> function will fail if:</p> <p><code>EFAULT</code> The <code>set</code> argument specifies an invalid address.</p>

sigblock(3UCB)

NAME	sigblock, sigmask, sigpause, sigsetmask – block signals
SYNOPSIS	<pre>/usr/ucb/cc [flag ...] file ... #include <signal.h> int sigblock (mask) ; intmask; int sigmask (signal); int signal ; int sigpause (int mask) ; int mask ; int sigsetmask (mask) ; int mask ;</pre>
DESCRIPTION	<p>sigblock, sigmask, sigpause, sigsetmask – block signals</p> <p>sigblock () adds the signals specified in <i>mask</i> to the set of signals currently being blocked from delivery. Signals are blocked if the appropriate bit in <i>mask</i> is a 1; the macro sigmask is provided to construct the mask for a given <i>signal</i>. sigblock () returns the previous mask. The previous mask may be restored using sigsetmask () .</p> <p>sigpause () assigns <i>mask</i> to the set of masked signals and then waits for a signal to arrive; on return the set of masked signals is restored. <i>mask</i> is usually 0 to indicate that no signals are now to be blocked. sigpause () always terminates by being interrupted, returning -1 and setting errno to EINTR.</p> <p>sigsetmask () sets the current signal mask (those signals that are blocked from delivery). Signals are blocked if the corresponding bit in <i>mask</i> is a 1; the macro sigmask is provided to construct the mask for a given <i>signal</i>.</p> <p>In normal usage, a signal is blocked using sigblock () . To begin a critical section, variables modified on the occurrence of the signal are examined to determine that there is no work to be done, and the process pauses awaiting work by using sigpause () with the mask returned by sigblock () .</p> <p>It is not possible to block SIGKILL, SIGSTOP, or SIGCONT, this restriction is silently imposed by the system.</p>
RETURN VALUES	sigblock () and sigsetmask () return the previous set of masked signals. sigpause () returns -1 and sets errno to EINTR.
SEE ALSO	kill(2), sigaction(2), signal(3UCB), sigvec(3UCB)
NOTES	Use of these interfaces should be restricted to only applications written on BSD platforms. Use of these interfaces with any of the system libraries or in multi-thread applications is unsupported.

NAME	sigfpe – signal handling for specific SIGFPE codes
SYNOPSIS	<pre>#include <floatingpoint.h> #include <siginfo.h> sigfpe_handler_type sigfpe(sigfpe_code_type <i>code</i>, sigfpe_handler_type <i>hdl</i>);</pre>
DESCRIPTION	<p>This function allows signal handling to be specified for particular SIGFPE codes. A call to <code>sigfpe()</code> defines a new handler <i>hdl</i> for a particular SIGFPE <i>code</i> and returns the old handler as the value of the function <code>sigfpe()</code>. Normally handlers are specified as pointers to functions; the special cases SIGFPE_IGNORE, SIGFPE_ABORT, and SIGFPE_DEFAULT allow ignoring, dumping core using <code>abort(3C)</code>, or default handling respectively. Default handling is to dump core using <code>abort(3C)</code>.</p> <p><i>code</i> is usually one of the five IEEE 754-related SIGFPE codes:</p> <pre>FPE_FLTRES fp_inexact - floating-point inexact result FPE_FLTDIV fp_division - floating-point division by zero FPE_FLTUND fp_underflow - floating-point underflow FPE_FLTOVF fp_overflow - floating-point overflow FPE_FLTINV fp_invalid - floating-point invalid operation</pre> <p>Three steps are required to intercept an IEEE 754-related SIGFPE code with <code>sigfpe()</code>:</p> <ol style="list-style-type: none"> 1. Set up a handler with <code>sigfpe()</code>. 2. Enable the relevant IEEE 754 trapping capability in the hardware, perhaps by using assembly-language instructions. 3. Perform a floating-point operation that generates the intended IEEE 754 exception. <p><code>sigfpe()</code> never changes floating-point hardware mode bits affecting IEEE 754 trapping. No IEEE 754-related SIGFPE signals will be generated unless those hardware mode bits are enabled.</p> <p>SIGFPE signals can be handled using <code>sigfpe()</code>, <code>sigaction(2)</code> or <code>signal(3C)</code>. In a particular program, to avoid confusion, use only one of these interfaces to handle SIGFPE signals.</p>
EXAMPLES	<p>EXAMPLE 1 Example Of A User-Specified Signal Handler</p> <p>A user-specified signal handler might look like this:</p> <pre>#include <floatingpoint.h> #include <siginfo.h> #include <ucontext.h> /* * The sample_handler prints out a message then commits suicide. */ void sample_handler(int sig, siginfo_t *sip, ucontext_t *uap) { char *label; switch (sip->si_code) {</pre>

sigfpe(3C)

EXAMPLE 1 Example Of A User-Specified Signal Handler (Continued)

```

    case FPE_FLTINV: label = "invalid operand"; break;
    case FPE_FLTRES: label = "inexact"; break;
    case FPE_FLTDIV: label = "division-by-zero"; break;
    case FPE_FLTUND: label = "underflow"; break;
    case FPE_FLTOVF: label = "overflow"; break;
    default: label = "???"; break;
}
fprintf(stderr, "FP exception %s (0x%x) occurred at address %p.\n",
        label, sip->si_code, (void *) sip->si_addr);
abort();
}

```

and it might be set up like this:

```

#include <floatingpoint.h>
#include <siginfo.h>
#include <ucontext.h>
extern void sample_handler(int, siginfo_t *, ucontext_t *);
main(void) {
    sigfpe_handler_type hdl, old_handler1, old_handler2;
    /*
     * save current fp_overflow and fp_invalid handlers; set the new
     * fp_overflow handler to sample_handler( ) and set the new
     * fp_invalid handler to SIGFPE_ABORT (abort on invalid)
     */
    hdl = (sigfpe_handler_type) sample_handler;
    old_handler1 = sigfpe(FPE_FLTOVF, hdl);
    old_handler2 = sigfpe(FPE_FLTINV, SIGFPE_ABORT);
    . . .
    /*
     * restore old fp_overflow and fp_invalid handlers
     */
    sigfpe(FPE_FLTOVF, old_handler1);
    sigfpe(FPE_FLTINV, old_handler2);
}

```

DIAGNOSTICS sigfpe() returns BADSIG if *code* is not zero or a defined SIGFPE code.

NAME	signal, sigset, sighold, sigrelse, sigignore, sigpause – simplified signal management for application processes
SYNOPSIS	<pre>#include <signal.h> void (*signal (int sig, void (*disp) (int))) (int); void (*sigset (int sig, void (*disp) (int))) (int); int sighold (int sig); int sigrelse (int sig); int sigignore (int sig); int sigpause (int sig);</pre>
DESCRIPTION	<p>These functions provide simplified signal management for application processes. See signal(3HEAD) for an explanation of general signal concepts.</p> <p>The signal () and sigset () functions modify signal dispositions. The sig argument specifies the signal, which may be any signal except SIGKILL and SIGSTOP. The disp argument specifies the signal's disposition, which may be SIG_DFL, SIG_IGN, or the address of a signal handler. If signal () is used, disp is the address of a signal handler, and sig is not SIGILL, SIGTRAP, or SIGPWR, the system first sets the signal's disposition to SIG_DFL before executing the signal handler. If sigset () is used and disp is the address of a signal handler, the system adds sig to the calling process's signal mask before executing the signal handler; when the signal handler returns, the system restores the calling process's signal mask to its state prior to the delivery of the signal. In addition, if sigset () is used and disp is equal to SIG_HOLD, sig is added to the calling process's signal mask and the signal's disposition remains unchanged.</p> <p>The sighold () function adds sig to the calling process's signal mask.</p> <p>The sigrelse () function removes sig from the calling process's signal mask.</p> <p>The sigignore () function sets the disposition of sig to SIG_IGN.</p> <p>The sigpause () function removes sig from the calling process's signal mask and suspends the calling process until a signal is received.</p>
RETURN VALUES	<p>Upon successful completion, signal () returns the signal's previous disposition. Otherwise, it returns SIG_ERR and sets errno to indicate the error.</p> <p>Upon successful completion, sigset () returns SIG_HOLD if the signal had been blocked or the signal's previous disposition if it had not been blocked. Otherwise, it returns SIG_ERR and sets errno to indicate the error.</p> <p>Upon successful completion, sighold (), sigrelse (), sigignore (), and sigpause (), return 0. Otherwise, they return -1 and set errno to indicate the error.</p>
ERRORS	<p>These functions fail if:</p> <p>EINTR A signal was caught during the execution sigpause ().</p>

sighold(3C)

EINVAL The value of the *sig* argument is not a valid signal or is equal to SIGKILL or SIGSTOP.

USAGE The `sighold()` function used in conjunction with `sigrelse()` or `sigpause()` may be used to establish critical regions of code that require the delivery of a signal to be temporarily deferred.

If `signal()` or `sigset()` is used to set SIGCHLD's disposition to a signal handler, SIGCHLD will not be sent when the calling process's children are stopped or continued.

If any of the above functions are used to set SIGCHLD's disposition to SIG_IGN, the calling process's child processes will not create zombie processes when they terminate (see `exit(2)`). If the calling process subsequently waits for its children, it blocks until all of its children terminate; it then returns `-1` with `errno` set to ECHILD (see `wait(2)` and `waitid(2)`).

The system guarantees that if more than one instance of the same signal is generated to a process, at least one signal will be received. It does not guarantee the reception of every generated signal.

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

NAME	signal, sigset, sighold, sigrelse, sigignore, sigpause – simplified signal management for application processes
SYNOPSIS	<pre>#include <signal.h> void (*signal (int sig, void (*disp) (int))) (int); void (*sigset (int sig, void (*disp) (int))) (int); int sighold (int sig); int sigrelse (int sig); int sigignore (int sig); int sigpause (int sig);</pre>
DESCRIPTION	<p>These functions provide simplified signal management for application processes. See signal(3HEAD) for an explanation of general signal concepts.</p> <p>The signal() and sigset() functions modify signal dispositions. The sig argument specifies the signal, which may be any signal except SIGKILL and SIGSTOP. The disp argument specifies the signal's disposition, which may be SIG_DFL, SIG_IGN, or the address of a signal handler. If signal() is used, disp is the address of a signal handler, and sig is not SIGILL, SIGTRAP, or SIGPWR, the system first sets the signal's disposition to SIG_DFL before executing the signal handler. If sigset() is used and disp is the address of a signal handler, the system adds sig to the calling process's signal mask before executing the signal handler; when the signal handler returns, the system restores the calling process's signal mask to its state prior to the delivery of the signal. In addition, if sigset() is used and disp is equal to SIG_HOLD, sig is added to the calling process's signal mask and the signal's disposition remains unchanged.</p> <p>The sighold() function adds sig to the calling process's signal mask.</p> <p>The sigrelse() function removes sig from the calling process's signal mask.</p> <p>The sigignore() function sets the disposition of sig to SIG_IGN.</p> <p>The sigpause() function removes sig from the calling process's signal mask and suspends the calling process until a signal is received.</p>
RETURN VALUES	<p>Upon successful completion, signal() returns the signal's previous disposition. Otherwise, it returns SIG_ERR and sets errno to indicate the error.</p> <p>Upon successful completion, sigset() returns SIG_HOLD if the signal had been blocked or the signal's previous disposition if it had not been blocked. Otherwise, it returns SIG_ERR and sets errno to indicate the error.</p> <p>Upon successful completion, sighold(), sigrelse(), sigignore(), and sigpause(), return 0. Otherwise, they return -1 and set errno to indicate the error.</p>
ERRORS	<p>These functions fail if:</p> <p>EINTR A signal was caught during the execution sigpause().</p>

sigignore(3C)

EINVAL The value of the *sig* argument is not a valid signal or is equal to SIGKILL or SIGSTOP.

USAGE The `sighold()` function used in conjunction with `sigrelse()` or `sigpause()` may be used to establish critical regions of code that require the delivery of a signal to be temporarily deferred.

If `signal()` or `sigset()` is used to set SIGCHLD's disposition to a signal handler, SIGCHLD will not be sent when the calling process's children are stopped or continued.

If any of the above functions are used to set SIGCHLD's disposition to SIG_IGN, the calling process's child processes will not create zombie processes when they terminate (see `exit(2)`). If the calling process subsequently waits for its children, it blocks until all of its children terminate; it then returns `-1` with `errno` set to ECHILD (see `wait(2)` and `waitid(2)`).

The system guarantees that if more than one instance of the same signal is generated to a process, at least one signal will be received. It does not guarantee the reception of every generated signal.

NAME	siginterrupt – allow signals to interrupt functions
SYNOPSIS	<pre> /usr/ucb/cc [flag ...] file ... int siginterrupt(sig, flag); int sig, flag; </pre>
DESCRIPTION	<p>siginterrupt () is used to change the function restart behavior when a function is interrupted by the specified signal. If the flag is false (0), then functions will be restarted if they are interrupted by the specified signal and no data has been transferred yet. System call restart is the default behavior when the signal(3C) routine is used.</p> <p>If the flag is true, (1), then restarting of functions is disabled. If a function is interrupted by the specified signal and no data has been transferred, the function will return -1 with errno set to EINTR. Interrupted functions that have started transferring data will return the amount of data actually transferred.</p> <p>Issuing a siginterrupt () call during the execution of a signal handler will cause the new action to take place on the next signal to be caught.</p>
NOTES	<p>Use of these interfaces should be restricted to only applications written on BSD platforms. Use of these interfaces with any of the system libraries or in multi-threaded applications is unsupported.</p> <p>This library routine uses an extension of the sigvec(3UCB) function that is not available in 4.2 BSD, hence it should not be used if backward compatibility is needed.</p>
RETURN VALUES	A 0 value indicates that the call succeeded. A -1 value indicates that the call failed and errno is set to indicate the error.
ERRORS	<p>siginterrupt () may return the following error:</p> <p>EINVAL <i>sig</i> is not a valid signal.</p>
SEE ALSO	sigblock(3UCB), sigvec(3UCB), signal(3C)

sigismember(3C)

NAME	sigsetops, sigemptyset, sigfillset, sigaddset, sigdelset, sigismember – manipulate sets of signals
SYNOPSIS	<pre>#include <signal.h> int sigemptyset(sigset_t *set); int sigfillset(sigset_t *set); int sigaddset(sigset_t *set, int signo); int sigdelset(sigset_t *set, int signo); int sigismember(sigset_t *set, int signo);</pre>
DESCRIPTION	<p>These functions manipulate <code>sigset_t</code> data types, representing the set of signals supported by the implementation.</p> <p>The <code>sigemptyset()</code> function initializes the set pointed to by <code>set</code> to exclude all signals defined by the system.</p> <p>The <code>sigfillset()</code> function initializes the set pointed to by <code>set</code> to include all signals defined by the system.</p> <p>The <code>sigaddset()</code> function adds the individual signal specified by the value of <code>signo</code> to the set pointed to by <code>set</code>.</p> <p>The <code>sigdelset()</code> function deletes the individual signal specified by the value of <code>signo</code> from the set pointed to by <code>set</code>.</p> <p>The <code>sigismember()</code> function checks whether the signal specified by the value of <code>signo</code> is a member of the set pointed to by <code>set</code>.</p> <p>Any object of type <code>sigset_t</code> must be initialized by applying either <code>sigemptyset()</code> or <code>sigfillset()</code> before applying any other operation.</p>
RETURN VALUES	<p>Upon successful completion, the <code>sigismember()</code> function returns 1 if the specified signal is a member of the specified set, or 0 if it is not.</p> <p>Upon successful completion, the other functions return 0. Otherwise -1 is returned and <code>errno</code> is set to indicate the error.</p>
ERRORS	<p>The <code>sigaddset()</code>, <code>sigdelset()</code>, and <code>sigismember()</code> functions will fail if:</p> <p><code>EINVAL</code> The value of the <code>signo</code> argument is not a valid signal number.</p> <p>The <code>sigfillset()</code> function will fail if:</p> <p><code>EFAULT</code> The <code>set</code> argument specifies an invalid address.</p>

siglongjmp(3C)

NAME	setjmp, sigsetjmp, longjmp, siglongjmp – non-local goto
SYNOPSIS	<pre>#include <setjmp.h> int setjmp(jmp_buf <i>env</i>); int sigsetjmp(sigjmp_buf <i>env</i>, int <i>savemask</i>); void longjmp(jmp_buf <i>env</i>, int <i>val</i>); void siglongjmp(sigjmp_buf <i>env</i>, int <i>val</i>);</pre>
DESCRIPTION	<p>These functions are useful for dealing with errors and interrupts encountered in a low-level subroutine of a program.</p> <p>The <code>setjmp()</code> function saves its stack environment in <i>env</i> for later use by <code>longjmp()</code>.</p> <p>The <code>sigsetjmp()</code> function saves the calling process's registers and stack environment (see <code>sigaltstack(2)</code>) in <i>env</i> for later use by <code>siglongjmp()</code>. If <i>savemask</i> is non-zero, the calling process's signal mask (see <code>sigprocmask(2)</code>) and scheduling parameters (see <code>priocntl(2)</code>) are also saved.</p> <p>The <code>longjmp()</code> function restores the environment saved by the last call of <code>setjmp()</code> with the corresponding <i>env</i> argument. After <code>longjmp()</code> completes, program execution continues as if the corresponding call to <code>setjmp()</code> had just returned the value <i>val</i>. The caller of <code>setjmp()</code> must not have returned in the interim. The <code>longjmp()</code> function cannot cause <code>setjmp()</code> to return the value 0. If <code>longjmp()</code> is invoked with a second argument of 0, <code>setjmp()</code> will return 1. At the time of the second return from <code>setjmp()</code>, all external and static variables have values as of the time <code>longjmp()</code> is called (see <code>EXAMPLES</code>).</p> <p>The <code>siglongjmp()</code> function restores the environment saved by the last call of <code>sigsetjmp()</code> with the corresponding <i>env</i> argument. After <code>siglongjmp()</code> completes, program execution continues as if the corresponding call to <code>sigsetjmp()</code> had just returned the value <i>val</i>. The <code>siglongjmp()</code> function cannot cause <code>sigsetjmp()</code> to return the value 0. If <code>siglongjmp()</code> is invoked with a second argument of 0, <code>sigsetjmp()</code> will return 1. At the time of the second return from <code>sigsetjmp()</code>, all external and static variables have values as of the time <code>siglongjmp()</code> was called.</p> <p>If a signal-catching function interrupts <code>sleep(3C)</code> and calls <code>siglongjmp()</code> to restore an environment saved prior to the <code>sleep()</code> call, the action associated with <code>SIGALRM</code> and time it is scheduled to be generated are unspecified. It is also unspecified whether the <code>SIGALRM</code> signal is blocked, unless the process's signal mask is restored as part of the environment.</p> <p>The <code>siglongjmp()</code> function restores the saved signal mask if and only if the <i>env</i> argument was initialized by a call to the <code>sigsetjmp()</code> function with a non-zero <i>savemask</i> argument.</p>

The values of register and automatic variables are undefined. Register or automatic variables whose value must be relied upon must be declared as volatile.

RETURN VALUES

If the return is from a direct invocation, `setjmp()` and `sigsetjmp()` return 0. If the return is from a call to `longjmp()`, `setjmp()` returns a non-zero value. If the return is from a call to `siglongjmp()`, `sigsetjmp()` returns a non-zero value.

After `longjmp()` is completed, program execution continues as if the corresponding invocation of `setjmp()` had just returned the value specified by *val*. The `longjmp()` function cannot cause `setjmp()` to return 0; if *val* is 0, `setjmp()` returns 1.

After `siglongjmp()` is completed, program execution continues as if the corresponding invocation of `sigsetjmp()` had just returned the value specified by *val*. The `siglongjmp()` function cannot cause `sigsetjmp()` to return 0; if *val* is 0, `sigsetjmp()` returns 1.

EXAMPLES

EXAMPLE 1 Example of `setjmp()` and `longjmp()` functions.

The following example uses both `setjmp()` and `longjmp()` to return the flow of control to the appropriate instruction block:

```
#include <stdio.h>
#include <setjmp.h>
#include <signal.h>
#include <unistd.h>
jmp_buf env; static void signal_handler();

main() {
    int returned_from_longjump, processing = 1;
    unsigned int time_interval = 4;
    if ((returned_from_longjump = setjmp(env)) != 0)
        switch (returned_from_longjump) {
            case SIGINT:
                printf("longjumped from interrupt %d\n",SIGINT);
                break;
            case SIGALRM:
                printf("longjumped from alarm %d\n",SIGALRM);
                break;
        }
    (void) signal(SIGINT, signal_handler);
    (void) signal(SIGALRM, signal_handler);
    alarm(time_interval);
    while (processing) {
        printf(" waiting for you to INTERRUPT (cntrl-C) ...\n");
        sleep(1);
    }
    /* end while forever loop */
}

static void signal_handler(sig)
int sig; {
    switch (sig) {
        case SIGINT:    ... /* process for interrupt */
                       longjmp(env,sig);
                       /* break never reached */
        case SIGALRM:  ... /* process for alarm */
    }
}
```

siglongjmp(3C)

EXAMPLE 1 Example of `setjmp()` and `longjmp()` functions. (Continued)

```
                                longjmp(env, sig);
                                /* break never reached */
    default:                    exit(sig);
    }
}
```

When this example is compiled and executed, and the user sends an interrupt signal, the output will be:

```
longjumped from interrupt
```

Additionally, every 4 seconds the alarm will expire, signalling this process, and the output will be:

```
longjumped from alarm
```

WARNINGS If `longjmp()` or `siglongjmp()` are called even though `env` was never primed by a call to `setjmp()` or `sigsetjmp()`, or when the last such call was in a function that has since returned, the results are undefined.

NAME	sigblock, sigmask, sigpause, sigsetmask – block signals
SYNOPSIS	<pre> /usr/ucb/cc [flag ...] file ... #include <signal.h> int sigblock (mask) ; int mask; int sigmask (signal) ; int signal; int sigpause (int mask) ; int mask; int sigsetmask (mask) ; int mask; </pre>
DESCRIPTION	<p>sigblock, sigmask, sigpause, sigsetmask – block signals</p> <p>sigblock() adds the signals specified in <i>mask</i> to the set of signals currently being blocked from delivery. Signals are blocked if the appropriate bit in <i>mask</i> is a 1; the macro sigmask is provided to construct the mask for a given <i>signal</i>. sigblock() returns the previous mask. The previous mask may be restored using sigsetmask().</p> <p>sigpause() assigns <i>mask</i> to the set of masked signals and then waits for a signal to arrive; on return the set of masked signals is restored. <i>mask</i> is usually 0 to indicate that no signals are now to be blocked. sigpause() always terminates by being interrupted, returning -1 and setting errno to EINTR.</p> <p>sigsetmask() sets the current signal mask (those signals that are blocked from delivery). Signals are blocked if the corresponding bit in <i>mask</i> is a 1; the macro sigmask is provided to construct the mask for a given <i>signal</i>.</p> <p>In normal usage, a signal is blocked using sigblock(). To begin a critical section, variables modified on the occurrence of the signal are examined to determine that there is no work to be done, and the process pauses awaiting work by using sigpause() with the mask returned by sigblock().</p> <p>It is not possible to block SIGKILL, SIGSTOP, or SIGCONT, this restriction is silently imposed by the system.</p>
RETURN VALUES	sigblock() and sigsetmask() return the previous set of masked signals. sigpause() returns -1 and sets errno to EINTR.
SEE ALSO	kill(2), sigaction(2), signal(3UCB), sigvec(3UCB)
NOTES	Use of these interfaces should be restricted to only applications written on BSD platforms. Use of these interfaces with any of the system libraries or in multi-thread applications is unsupported.

signal(3C)

NAME	signal, sigset, sighold, sigrelse, sigignore, sigpause – simplified signal management for application processes
SYNOPSIS	<pre>#include <signal.h> void (*signal (int sig, void (*disp) (int))) (int); void (*sigset (int sig, void (*disp) (int))) (int); int sighold (int sig); int sigrelse (int sig); int sigignore (int sig); int sigpause (int sig);</pre>
DESCRIPTION	<p>These functions provide simplified signal management for application processes. See signal(3HEAD) for an explanation of general signal concepts.</p> <p>The signal () and sigset () functions modify signal dispositions. The sig argument specifies the signal, which may be any signal except SIGKILL and SIGSTOP. The disp argument specifies the signal's disposition, which may be SIG_DFL, SIG_IGN, or the address of a signal handler. If signal () is used, disp is the address of a signal handler, and sig is not SIGILL, SIGTRAP, or SIGPWR, the system first sets the signal's disposition to SIG_DFL before executing the signal handler. If sigset () is used and disp is the address of a signal handler, the system adds sig to the calling process's signal mask before executing the signal handler; when the signal handler returns, the system restores the calling process's signal mask to its state prior to the delivery of the signal. In addition, if sigset () is used and disp is equal to SIG_HOLD, sig is added to the calling process's signal mask and the signal's disposition remains unchanged.</p> <p>The sighold () function adds sig to the calling process's signal mask.</p> <p>The sigrelse () function removes sig from the calling process's signal mask.</p> <p>The sigignore () function sets the disposition of sig to SIG_IGN.</p> <p>The sigpause () function removes sig from the calling process's signal mask and suspends the calling process until a signal is received.</p>
RETURN VALUES	<p>Upon successful completion, signal () returns the signal's previous disposition. Otherwise, it returns SIG_ERR and sets errno to indicate the error.</p> <p>Upon successful completion, sigset () returns SIG_HOLD if the signal had been blocked or the signal's previous disposition if it had not been blocked. Otherwise, it returns SIG_ERR and sets errno to indicate the error.</p> <p>Upon successful completion, sighold (), sigrelse (), sigignore (), and sigpause (), return 0. Otherwise, they return -1 and set errno to indicate the error.</p>
ERRORS	<p>These functions fail if:</p> <p>EINTR A signal was caught during the execution sigpause ().</p>

EINVAL The value of the *sig* argument is not a valid signal or is equal to SIGKILL or SIGSTOP.

USAGE The `sighold()` function used in conjunction with `sigrelse()` or `sigpause()` may be used to establish critical regions of code that require the delivery of a signal to be temporarily deferred.

If `signal()` or `sigset()` is used to set SIGCHLD's disposition to a signal handler, SIGCHLD will not be sent when the calling process's children are stopped or continued.

If any of the above functions are used to set SIGCHLD's disposition to SIG_IGN, the calling process's child processes will not create zombie processes when they terminate (see `exit(2)`). If the calling process subsequently waits for its children, it blocks until all of its children terminate; it then returns `-1` with `errno` set to ECHILD (see `wait(2)` and `waitid(2)`).

The system guarantees that if more than one instance of the same signal is generated to a process, at least one signal will be received. It does not guarantee the reception of every generated signal.

signal(3UCB)

NAME	signal – simplified software signal facilities
SYNOPSIS	<pre>/usr/ucb/cc [flag ...] file ... #include <signal.h> void (*signal(sig, func)) (); int sig; void (*func) ();</pre>
DESCRIPTION	<p>signal() is a simplified interface to the more general sigvec(3UCB) facility. Programs that use signal() in preference to sigvec() are more likely to be portable to all systems.</p> <p>A signal is generated by some abnormal event, initiated by a user at a terminal (quit, interrupt, stop), by a program error (bus error, etc.), by request of another program (kill), or when a process is stopped because it wishes to access its control terminal while in the background (see termio(7I)). Signals are optionally generated when a process resumes after being stopped, when the status of child processes changes, or when input is ready at the control terminal. Most signals cause termination of the receiving process if no action is taken; some signals instead cause the process receiving them to be stopped, or are simply discarded if the process has not requested otherwise. Except for the SIGKILL and SIGSTOP signals, the signal() call allows signals either to be ignored or to interrupt to a specified location. See sigvec(3UCB) for a complete list of the signals.</p> <p>If <i>func</i> is SIG_DFL, the default action for signal <i>sig</i> is reinstated; this default is termination (with a core image for starred signals) except for signals marked with • or a dagger. Signals marked with • are discarded if the action is SIG_DFL; signals marked with a dagger cause the process to stop. If <i>func</i> is SIG_IGN the signal is subsequently ignored and pending instances of the signal are discarded. Otherwise, when the signal occurs further occurrences of the signal are automatically blocked and <i>func</i> is called.</p> <p>A return from the function unblocks the handled signal and continues the process at the point it was interrupted.</p> <p>If a caught signal occurs during certain functions, terminating the call prematurely, the call is automatically restarted. In particular this can occur during a read(2) or write(2) on a slow device (such as a terminal; but not a file) and during a wait(2).</p> <p>The value of signal() is the previous (or initial) value of <i>func</i> for the particular signal.</p> <p>After a fork(2) or vfork(2) the child inherits all signals. An exec(2) resets all caught signals to the default action; ignored signals remain ignored.</p>
RETURN VALUES	The previous action is returned on a successful call. Otherwise, -1 is returned and errno is set to indicate the error.
ERRORS	signal() will fail and no action will take place if the following occurs:

EINVAL *sig* is not a valid signal number, or is SIGKILL or SIGSTOP.

SEE ALSO kill(1), exec(2), fcntl(2), fork(2), getitimer(2), getrlimit(2), kill(2), ptrace(2), read(2), sigaction(2), wait(2), write(2), abort(3C), setjmp(3UCB), sigblock(3UCB), sigstack(3UCB), sigvec(3UCB), wait(3UCB), setjmp(3C), signal(3C), signal(3HEAD), termio(7I)

NOTES Use of these interfaces should be restricted to only applications written on BSD platforms. Use of these interfaces with any of the system libraries or in multi-threaded applications is unsupported.

The handler routine, *func*, can be declared:

```
void handler( signum) int signum; Here signum is the signal number. See sigvec(3UCB) for more details.
```

sigpause(3C)

NAME	signal, sigset, sighold, sigrelse, sigignore, sigpause – simplified signal management for application processes
SYNOPSIS	<pre>#include <signal.h> void (*signal (int sig, void (*disp) (int))) (int); void (*sigset (int sig, void (*disp) (int))) (int); int sighold (int sig); int sigrelse (int sig); int sigignore (int sig); int sigpause (int sig);</pre>
DESCRIPTION	<p>These functions provide simplified signal management for application processes. See signal(3HEAD) for an explanation of general signal concepts.</p> <p>The signal() and sigset() functions modify signal dispositions. The sig argument specifies the signal, which may be any signal except SIGKILL and SIGSTOP. The disp argument specifies the signal's disposition, which may be SIG_DFL, SIG_IGN, or the address of a signal handler. If signal() is used, disp is the address of a signal handler, and sig is not SIGILL, SIGTRAP, or SIGPWR, the system first sets the signal's disposition to SIG_DFL before executing the signal handler. If sigset() is used and disp is the address of a signal handler, the system adds sig to the calling process's signal mask before executing the signal handler; when the signal handler returns, the system restores the calling process's signal mask to its state prior to the delivery of the signal. In addition, if sigset() is used and disp is equal to SIG_HOLD, sig is added to the calling process's signal mask and the signal's disposition remains unchanged.</p> <p>The sighold() function adds sig to the calling process's signal mask.</p> <p>The sigrelse() function removes sig from the calling process's signal mask.</p> <p>The sigignore() function sets the disposition of sig to SIG_IGN.</p> <p>The sigpause() function removes sig from the calling process's signal mask and suspends the calling process until a signal is received.</p>
RETURN VALUES	<p>Upon successful completion, signal() returns the signal's previous disposition. Otherwise, it returns SIG_ERR and sets errno to indicate the error.</p> <p>Upon successful completion, sigset() returns SIG_HOLD if the signal had been blocked or the signal's previous disposition if it had not been blocked. Otherwise, it returns SIG_ERR and sets errno to indicate the error.</p> <p>Upon successful completion, sighold(), sigrelse(), sigignore(), and sigpause(), return 0. Otherwise, they return -1 and set errno to indicate the error.</p>
ERRORS	These functions fail if:

EINTR A signal was caught during the execution `sigpause()`.

EINVAL The value of the `sig` argument is not a valid signal or is equal to `SIGKILL` or `SIGSTOP`.

USAGE The `sighold()` function used in conjunction with `sigrelse()` or `sigpause()` may be used to establish critical regions of code that require the delivery of a signal to be temporarily deferred.

If `signal()` or `sigset()` is used to set `SIGCHLD`'s disposition to a signal handler, `SIGCHLD` will not be sent when the calling process's children are stopped or continued.

If any of the above functions are used to set `SIGCHLD`'s disposition to `SIG_IGN`, the calling process's child processes will not create zombie processes when they terminate (see `exit(2)`). If the calling process subsequently waits for its children, it blocks until all of its children terminate; it then returns `-1` with `errno` set to `ECHILD` (see `wait(2)` and `waitid(2)`).

The system guarantees that if more than one instance of the same signal is generated to a process, at least one signal will be received. It does not guarantee the reception of every generated signal.

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
MT-Level	MT-Safe

sigpause(3UCB)

NAME	sigblock, sigmask, sigpause, sigsetmask – block signals
SYNOPSIS	<pre><code>/usr/ucb/cc [flag ...] file ... #include <signal.h> int sigblock (mask) ; intmask; int sigmask (signal) ; int signal ; int sigpause (int mask) ; int mask ; int sigsetmask (mask) ; int mask ;</code></pre>
DESCRIPTION	<p>sigblock, sigmask, sigpause, sigsetmask – block signals</p> <p>sigblock () adds the signals specified in <i>mask</i> to the set of signals currently being blocked from delivery. Signals are blocked if the appropriate bit in <i>mask</i> is a 1; the macro sigmask is provided to construct the mask for a given <i>signal</i>. sigblock () returns the previous mask. The previous mask may be restored using sigsetmask ().</p> <p>sigpause () assigns <i>mask</i> to the set of masked signals and then waits for a signal to arrive; on return the set of masked signals is restored. <i>mask</i> is usually 0 to indicate that no signals are now to be blocked. sigpause () always terminates by being interrupted, returning -1 and setting errno to EINTR.</p> <p>sigsetmask () sets the current signal mask (those signals that are blocked from delivery). Signals are blocked if the corresponding bit in <i>mask</i> is a 1; the macro sigmask is provided to construct the mask for a given <i>signal</i>.</p> <p>In normal usage, a signal is blocked using sigblock (). To begin a critical section, variables modified on the occurrence of the signal are examined to determine that there is no work to be done, and the process pauses awaiting work by using sigpause () with the mask returned by sigblock ().</p> <p>It is not possible to block SIGKILL, SIGSTOP, or SIGCONT, this restriction is silently imposed by the system.</p>
RETURN VALUES	sigblock () and sigsetmask () return the previous set of masked signals. sigpause () returns -1 and sets errno to EINTR.
SEE ALSO	kill(2), sigaction(2), signal(3UCB), sigvec(3UCB)
NOTES	Use of these interfaces should be restricted to only applications written on BSD platforms. Use of these interfaces with any of the system libraries or in multi-thread applications is unsupported.

NAME	signal, sigset, sighold, sigrelse, sigignore, sigpause – simplified signal management for application processes
SYNOPSIS	<pre>#include <signal.h> void (*signal (int sig, void (*disp) (int))) (int); void (*sigset (int sig, void (*disp) (int))) (int); int sighold (int sig); int sigrelse (int sig); int sigignore (int sig); int sigpause (int sig);</pre>
DESCRIPTION	<p>These functions provide simplified signal management for application processes. See signal(3HEAD) for an explanation of general signal concepts.</p> <p>The signal () and sigset () functions modify signal dispositions. The sig argument specifies the signal, which may be any signal except SIGKILL and SIGSTOP. The disp argument specifies the signal's disposition, which may be SIG_DFL, SIG_IGN, or the address of a signal handler. If signal () is used, disp is the address of a signal handler, and sig is not SIGILL, SIGTRAP, or SIGPWR, the system first sets the signal's disposition to SIG_DFL before executing the signal handler. If sigset () is used and disp is the address of a signal handler, the system adds sig to the calling process's signal mask before executing the signal handler; when the signal handler returns, the system restores the calling process's signal mask to its state prior to the delivery of the signal. In addition, if sigset () is used and disp is equal to SIG_HOLD, sig is added to the calling process's signal mask and the signal's disposition remains unchanged.</p> <p>The sighold () function adds sig to the calling process's signal mask.</p> <p>The sigrelse () function removes sig from the calling process's signal mask.</p> <p>The sigignore () function sets the disposition of sig to SIG_IGN.</p> <p>The sigpause () function removes sig from the calling process's signal mask and suspends the calling process until a signal is received.</p>
RETURN VALUES	<p>Upon successful completion, signal () returns the signal's previous disposition. Otherwise, it returns SIG_ERR and sets errno to indicate the error.</p> <p>Upon successful completion, sigset () returns SIG_HOLD if the signal had been blocked or the signal's previous disposition if it had not been blocked. Otherwise, it returns SIG_ERR and sets errno to indicate the error.</p> <p>Upon successful completion, sighold (), sigrelse (), sigignore (), and sigpause (), return 0. Otherwise, they return -1 and set errno to indicate the error.</p>
ERRORS	<p>These functions fail if:</p> <p>EINTR A signal was caught during the execution sigpause ().</p>

sigrelse(3C)

EINVAL The value of the *sig* argument is not a valid signal or is equal to SIGKILL or SIGSTOP.

USAGE The `sighold()` function used in conjunction with `sigrelse()` or `sigpause()` may be used to establish critical regions of code that require the delivery of a signal to be temporarily deferred.

If `signal()` or `sigset()` is used to set SIGCHLD's disposition to a signal handler, SIGCHLD will not be sent when the calling process's children are stopped or continued.

If any of the above functions are used to set SIGCHLD's disposition to SIG_IGN, the calling process's child processes will not create zombie processes when they terminate (see `exit(2)`). If the calling process subsequently waits for its children, it blocks until all of its children terminate; it then returns `-1` with `errno` set to ECHILD (see `wait(2)` and `waitid(2)`).

The system guarantees that if more than one instance of the same signal is generated to a process, at least one signal will be received. It does not guarantee the reception of every generated signal.

NAME	setjmp, sigsetjmp, longjmp, siglongjmp – non-local goto
SYNOPSIS	<pre>#include <setjmp.h> int setjmp(jmp_buf <i>env</i>); int sigsetjmp(sigjmp_buf <i>env</i>, int <i>savemask</i>); void longjmp(jmp_buf <i>env</i>, int <i>val</i>); void siglongjmp(sigjmp_buf <i>env</i>, int <i>val</i>);</pre>
DESCRIPTION	<p>These functions are useful for dealing with errors and interrupts encountered in a low-level subroutine of a program.</p> <p>The <code>setjmp()</code> function saves its stack environment in <i>env</i> for later use by <code>longjmp()</code>.</p> <p>The <code>sigsetjmp()</code> function saves the calling process's registers and stack environment (see <code>sigaltstack(2)</code>) in <i>env</i> for later use by <code>siglongjmp()</code>. If <i>savemask</i> is non-zero, the calling process's signal mask (see <code>sigprocmask(2)</code>) and scheduling parameters (see <code>prctl(2)</code>) are also saved.</p> <p>The <code>longjmp()</code> function restores the environment saved by the last call of <code>setjmp()</code> with the corresponding <i>env</i> argument. After <code>longjmp()</code> completes, program execution continues as if the corresponding call to <code>setjmp()</code> had just returned the value <i>val</i>. The caller of <code>setjmp()</code> must not have returned in the interim. The <code>longjmp()</code> function cannot cause <code>setjmp()</code> to return the value 0. If <code>longjmp()</code> is invoked with a second argument of 0, <code>setjmp()</code> will return 1. At the time of the second return from <code>setjmp()</code>, all external and static variables have values as of the time <code>longjmp()</code> is called (see <code>EXAMPLES</code>).</p> <p>The <code>siglongjmp()</code> function restores the environment saved by the last call of <code>sigsetjmp()</code> with the corresponding <i>env</i> argument. After <code>siglongjmp()</code> completes, program execution continues as if the corresponding call to <code>sigsetjmp()</code> had just returned the value <i>val</i>. The <code>siglongjmp()</code> function cannot cause <code>sigsetjmp()</code> to return the value 0. If <code>siglongjmp()</code> is invoked with a second argument of 0, <code>sigsetjmp()</code> will return 1. At the time of the second return from <code>sigsetjmp()</code>, all external and static variables have values as of the time <code>siglongjmp()</code> was called.</p> <p>If a signal-catching function interrupts <code>sleep(3C)</code> and calls <code>siglongjmp()</code> to restore an environment saved prior to the <code>sleep()</code> call, the action associated with <code>SIGALRM</code> and time it is scheduled to be generated are unspecified. It is also unspecified whether the <code>SIGALRM</code> signal is blocked, unless the process's signal mask is restored as part of the environment.</p> <p>The <code>siglongjmp()</code> function restores the saved signal mask if and only if the <i>env</i> argument was initialized by a call to the <code>sigsetjmp()</code> function with a non-zero <i>savemask</i> argument.</p>

sigsetjmp(3C)

The values of register and automatic variables are undefined. Register or automatic variables whose value must be relied upon must be declared as volatile.

RETURN VALUES If the return is from a direct invocation, `setjmp()` and `sigsetjmp()` return 0. If the return is from a call to `longjmp()`, `setjmp()` returns a non-zero value. If the return is from a call to `siglongjmp()`, `sigsetjmp()` returns a non-zero value.

After `longjmp()` is completed, program execution continues as if the corresponding invocation of `setjmp()` had just returned the value specified by *val*. The `longjmp()` function cannot cause `setjmp()` to return 0; if *val* is 0, `setjmp()` returns 1.

After `siglongjmp()` is completed, program execution continues as if the corresponding invocation of `sigsetjmp()` had just returned the value specified by *val*. The `siglongjmp()` function cannot cause `sigsetjmp()` to return 0; if *val* is 0, `sigsetjmp()` returns 1.

EXAMPLES **EXAMPLE 1** Example of `setjmp()` and `longjmp()` functions.

The following example uses both `setjmp()` and `longjmp()` to return the flow of control to the appropriate instruction block:

```
#include <stdio.h>
#include <setjmp.h>
#include <signal.h>
#include <unistd.h>
jmp_buf env; static void signal_handler();

main() {
    int returned_from_longjump, processing = 1;
    unsigned int time_interval = 4;
    if ((returned_from_longjump = setjmp(env)) != 0)
        switch (returned_from_longjump) {
            case SIGINT:
                printf("longjumped from interrupt %d\n",SIGINT);
                break;
            case SIGALRM:
                printf("longjumped from alarm %d\n",SIGALRM);
                break;
        }
    (void) signal(SIGINT, signal_handler);
    (void) signal(SIGALRM, signal_handler);
    alarm(time_interval);
    while (processing) {
        printf(" waiting for you to INTERRUPT (cntrl-C) ...\n");
        sleep(1);
    }
    /* end while forever loop */
}

static void signal_handler(sig)
int sig; {
    switch (sig) {
        case SIGINT:    ... /* process for interrupt */
                        longjmp(env,sig);
                        /* break never reached */
        case SIGALRM:  ... /* process for alarm */
    }
}
```

EXAMPLE 1 Example of `setjmp()` and `longjmp()` functions. (Continued)

```

                                longjmp(env, sig);
                                /* break never reached */
                                exit(sig);
    default:
    }
}

```

When this example is compiled and executed, and the user sends an interrupt signal, the output will be:

```
longjumped from interrupt
```

Additionally, every 4 seconds the alarm will expire, signalling this process, and the output will be:

```
longjumped from alarm
```

WARNINGS If `longjmp()` or `siglongjmp()` are called even though `env` was never primed by a call to `setjmp()` or `sigsetjmp()`, or when the last such call was in a function that has since returned, the results are undefined.

sigsetmask(3UCB)

NAME	sigblock, sigmask, sigpause, sigsetmask – block signals
SYNOPSIS	<pre>/usr/ucb/cc [flag ...] file ... #include <signal.h> int sigblock (mask) ; intmask; int sigmask (signum) ; int signum; int sigpause (int mask) ; int mask; int sigsetmask (mask) ; int mask;</pre>
DESCRIPTION	<p>sigblock, sigmask, sigpause, sigsetmask – block signals</p> <p>sigblock () adds the signals specified in <i>mask</i> to the set of signals currently being blocked from delivery. Signals are blocked if the appropriate bit in <i>mask</i> is a 1; the macro sigmask is provided to construct the mask for a given <i>signum</i>. sigblock () returns the previous mask. The previous mask may be restored using sigsetmask ().</p> <p>sigpause () assigns <i>mask</i> to the set of masked signals and then waits for a signal to arrive; on return the set of masked signals is restored. <i>mask</i> is usually 0 to indicate that no signals are now to be blocked. sigpause () always terminates by being interrupted, returning -1 and setting errno to EINTR.</p> <p>sigsetmask () sets the current signal mask (those signals that are blocked from delivery). Signals are blocked if the corresponding bit in <i>mask</i> is a 1; the macro sigmask is provided to construct the mask for a given <i>signum</i>.</p> <p>In normal usage, a signal is blocked using sigblock (). To begin a critical section, variables modified on the occurrence of the signal are examined to determine that there is no work to be done, and the process pauses awaiting work by using sigpause () with the mask returned by sigblock ().</p> <p>It is not possible to block SIGKILL, SIGSTOP, or SIGCONT, this restriction is silently imposed by the system.</p>
RETURN VALUES	sigblock () and sigsetmask () return the previous set of masked signals. sigpause () returns -1 and sets errno to EINTR.
SEE ALSO	kill(2), sigaction(2), signal(3UCB), sigvec(3UCB)
NOTES	Use of these interfaces should be restricted to only applications written on BSD platforms. Use of these interfaces with any of the system libraries or in multi-thread applications is unsupported.

NAME	sigsetops, sigemptyset, sigfillset, sigaddset, sigdelset, sigismember – manipulate sets of signals
SYNOPSIS	<pre>#include <signal.h> int sigemptyset(sigset_t *set); int sigfillset(sigset_t *set); int sigaddset(sigset_t *set, int signo); int sigdelset(sigset_t *set, int signo); int sigismember(sigset_t *set, int signo);</pre>
DESCRIPTION	<p>These functions manipulate <code>sigset_t</code> data types, representing the set of signals supported by the implementation.</p> <p>The <code>sigemptyset()</code> function initializes the set pointed to by <code>set</code> to exclude all signals defined by the system.</p> <p>The <code>sigfillset()</code> function initializes the set pointed to by <code>set</code> to include all signals defined by the system.</p> <p>The <code>sigaddset()</code> function adds the individual signal specified by the value of <code>signo</code> to the set pointed to by <code>set</code>.</p> <p>The <code>sigdelset()</code> function deletes the individual signal specified by the value of <code>signo</code> from the set pointed to by <code>set</code>.</p> <p>The <code>sigismember()</code> function checks whether the signal specified by the value of <code>signo</code> is a member of the set pointed to by <code>set</code>.</p> <p>Any object of type <code>sigset_t</code> must be initialized by applying either <code>sigemptyset()</code> or <code>sigfillset()</code> before applying any other operation.</p>
RETURN VALUES	<p>Upon successful completion, the <code>sigismember()</code> function returns 1 if the specified signal is a member of the specified set, or 0 if it is not.</p> <p>Upon successful completion, the other functions return 0. Otherwise -1 is returned and <code>errno</code> is set to indicate the error.</p>
ERRORS	<p>The <code>sigaddset()</code>, <code>sigdelset()</code>, and <code>sigismember()</code> functions will fail if:</p> <p><code>EINVAL</code> The value of the <code>signo</code> argument is not a valid signal number.</p> <p>The <code>sigfillset()</code> function will fail if:</p> <p><code>EFAULT</code> The <code>set</code> argument specifies an invalid address.</p>

NAME	sigstack – set and/or get alternate signal stack context
SYNOPSIS	<pre>#include <signal.h> int sigstack(struct sigstack *ss, struct sigstack *oss);</pre>
DESCRIPTION	<p>The <code>sigstack()</code> function allows the calling process to indicate to the system an area of its address space to be used for processing signals received by the process.</p> <p>If the <code>ss</code> argument is not a null pointer, it must point to a <code>sigstack</code> structure. The length of the application-supplied stack must be at least <code>SIGSTKSZ</code> bytes. If the alternate signal stack overflows, the resulting behavior is undefined. (See <code>USAGE</code> below.)</p> <ul style="list-style-type: none"> ■ The value of the <code>ss_onstack</code> member indicates whether the process wants the system to use an alternate signal stack when delivering signals. ■ The value of the <code>ss_sp</code> member indicates the desired location of the alternate signal stack area in the process' address space. ■ If the <code>ss</code> argument is a null pointer, the current alternate signal stack context is not changed. <p>If the <code>oss</code> argument is not a null pointer, it points to a <code>sigstack</code> structure in which the current alternate signal stack context is placed. The value stored in the <code>ss_onstack</code> member of <code>oss</code> will be non-zero if the process is currently executing on the alternate signal stack. If the <code>oss</code> argument is a null pointer, the current alternate signal stack context is not returned.</p> <p>When a signal's action indicates its handler should execute on the alternate signal stack (specified by calling <code>sigaction(2)</code>), <code>sigstack()</code> checks to see if the process is currently executing on that stack. If the process is not currently executing on the alternate signal stack, the system arranges a switch to the alternate signal stack for the duration of the signal handler's execution.</p> <p>After a successful call to one of the <code>exec</code> functions, there are no alternate signal stacks in the new process image.</p>
RETURN VALUES	Upon successful completion, <code>sigstack()</code> returns 0. Otherwise, it returns -1 and sets <code>errno</code> to indicate the error.
ERRORS	<p>The <code>sigstack()</code> function will fail if:</p> <p><code>EPERM</code> An attempt was made to modify an active stack.</p>
USAGE	<p>A portable application, when being written or rewritten, should use <code>sigaltstack(2)</code> instead of <code>sigstack()</code>.</p> <p>The direction of stack growth is not indicated in the historical definition of <code>struct sigstack</code>. The only way to portably establish a stack pointer is for the application to determine stack growth direction, or to allocate a block of storage and set the stack</p>

sigstack(3C)

pointer to the middle. `sigstack()` may assume that the size of the signal stack is `SIGSTKSZ` as found in `<signal.h>`. An application that would like to specify a signal stack size other than `SIGSTKSZ` should use `sigaltstack(2)`.

Applications should not use `longjmp(3C)` to leave a signal handler that is running on a stack established with `sigstack()`. Doing so may disable future use of the signal stack. For abnormal exit from a signal handler, `siglongjmp(3C)`, `setcontext(2)`, or `swapcontext(3C)` may be used. These functions fully support switching from one stack to another.

The `sigstack()` function requires the application to have knowledge of the underlying system's stack architecture. For this reason, `sigaltstack(2)` is recommended over this function.

SEE ALSO `fork(2)`, `_longjmp(3C)`, `longjmp(3C)`, `setjmp(3C)`, `sigaltstack(2)`, `siglongjmp(3C)`, `sigsetjmp(3C)`

NAME	sigstack – set and/or get signal stack context
SYNOPSIS	<pre> /usr/ucb/cc [flag ...] file ... #include <signal.h> int sigstack(nss, oss); struct sigstack *nss, *oss; </pre>
DESCRIPTION	<p>The <code>sigstack()</code> function allows users to define an alternate stack, called the “signal stack”, on which signals are to be processed. When a signal’s action indicates its handler should execute on the signal stack (specified with a <code>sigvec(3UCB)</code> call), the system checks to see if the process is currently executing on that stack. If the process is not currently executing on the signal stack, the system arranges a switch to the signal stack for the duration of the signal handler’s execution.</p> <p>A signal stack is specified by a <code>sigstack()</code> structure, which includes the following members:</p> <pre> char *ss_sp; /* signal stack pointer */ int ss_onstack; /* current status */ </pre> <p>The <code>ss_sp</code> member is the initial value to be assigned to the stack pointer when the system switches the process to the signal stack. Note that, on machines where the stack grows downwards in memory, this is <i>not</i> the address of the beginning of the signal stack area. The <code>ss_onstack</code> member is zero or non-zero depending on whether the process is currently executing on the signal stack or not.</p> <p>If <code>nss</code> is not a null pointer, <code>sigstack()</code> sets the signal stack state to the value in the <code>sigstack()</code> structure pointed to by <code>nss</code>. If <code>nss</code> is a null pointer, the signal stack state will be unchanged. If <code>oss</code> is not a null pointer, the current signal stack state is stored in the <code>sigstack()</code> structure pointed to by <code>oss</code>.</p>
RETURN VALUES	Upon successful completion, 0 is returned. Otherwise, -1 is returned and <code>errno</code> is set to indicate the error.
ERRORS	<p>The <code>sigstack()</code> function will fail and the signal stack context will remain unchanged if one of the following occurs.</p> <p>EFAULT Either <code>nss</code> or <code>oss</code> points to memory that is not a valid part of the process address space.</p>
SEE ALSO	<code>sigaltstack(2)</code> , <code>sigvec(3UCB)</code> , <code>signal(3C)</code>
WARNINGS	Signal stacks are not “grown” automatically, as is done for the normal stack. If the stack overflows unpredictable results may occur.
NOTES	Use of these interfaces should be restricted to only applications written on BSD platforms. Use of these interfaces with any of the system libraries or in multi-threaded applications is unsupported.

sigvec(3UCB)

NAME	sigvec – software signal facilities
SYNOPSIS	<pre>/usr/ucb/cc[flag ...] file... #include <signal.h> int sigvec (ssig, *nvec, *ovec); int sig; struct sigvec *nvec struct sigvec *ovec struct sigvec *nvec, *ovec;</pre>
DESCRIPTION	<p>The system defines a set of signals that may be delivered to a process. Signal delivery resembles the occurrence of a hardware interrupt: the signal is blocked from further occurrence, the current process context is saved, and a new one is built. A process may specify a <i>handler</i> to which a signal is delivered, or specify that a signal is to be <i>blocked</i> or <i>ignored</i>. A process may also specify that a default action is to be taken by the system when a signal occurs. Normally, signal handlers execute on the current stack of the process. This may be changed, on a per-handler basis, so that signals are taken on a special <i>signal stack</i>.</p> <p>All signals have the same <i>priority</i>. Signal routines execute with the signal that caused their invocation to be <i>blocked</i>, but other signals may yet occur. A global <i>signal mask</i> defines the set of signals currently blocked from delivery to a process. The signal mask for a process is initialized from that of its parent (normally 0). It may be changed with a <code>sigblock()</code> or <code>sigsetmask()</code> call, or when a signal is delivered to the process.</p> <p>A process may also specify a set of <i>flags</i> for a signal that affect the delivery of that signal.</p> <p>When a signal condition arises for a process, the signal is added to a set of signals pending for the process. If the signal is not currently <i>blocked</i> by the process then it is delivered to the process. When a signal is delivered, the current state of the process is saved, a new signal mask is calculated (as described below), and the signal handler is invoked. The call to the handler is arranged so that if the signal handling routine returns normally the process will resume execution in the context from before the signal's delivery. If the process wishes to resume in a different context, then it must arrange to restore the previous context itself.</p> <p>When a signal is delivered to a process a new signal mask is installed for the duration of the process' signal handler (or until a <code>sigblock()</code> or <code>sigsetmask()</code> call is made). This mask is formed by taking the current signal mask, adding the signal to be delivered, and ORing in the signal mask associated with the handler to be invoked.</p> <p>The action to be taken when the signal is delivered is specified by a <code>sigvec()</code> structure, which includes the following members:</p> <pre>void (*sv_handler)(); /* signal handler */ int sv_mask; /* signal mask to apply */ int sv_flags; /* see signal options */</pre>

```
#define SV_ONSTACK      /* take signal on signal stack */
#define SV_INTERRUPT    /* do not restart system on signal return */
#define SV_RESETHAND    /* reset handler to SIG_DFL when signal taken*/
```

If the `SV_ONSTACK` bit is set in the flags for that signal, the system will deliver the signal to the process on the signal stack specified with `sigstack(3UCB)` rather than delivering the signal on the current stack.

If `nvec` is not a NULL pointer, `sigvec()` assigns the handler specified by `sv_handler()`, the mask specified by `sv_mask()`, and the flags specified by `sv_flags()` to the specified signal. If `nvec` is a NULL pointer, `sigvec()` does not change the handler, mask, or flags for the specified signal.

The mask specified in `nvec` is not allowed to block `SIGKILL`, `SIGSTOP`, or `SIGCONT`. The system enforces this restriction silently.

If `ovec` is not a NULL pointer, the handler, mask, and flags in effect for the signal before the call to `sigvec()` are returned to the user. A call to `sigvec()` with `nvec` a NULL pointer and `ovec` not a NULL pointer can be used to determine the handling information currently in effect for a signal without changing that information.

The following is a list of all signals with names as in the include file `<signal.h>`:

<code>SIGHUP</code>	hangup
<code>SIGINT</code>	interrupt
<code>SIGQUIT*</code>	quit
<code>SIGILL*</code>	illegal instruction
<code>SIGTRAP*</code>	trace trap
<code>SIGABRT*</code>	abort (generated by <code>abort(3C)</code> routine)
<code>SIGEMT*</code>	emulator trap
<code>SIGFPE*</code>	arithmetic exception
<code>SIGKILL</code>	kill (cannot be caught, blocked, or ignored)
<code>SIGBUS*</code>	bus error
<code>SIGSEGV*</code>	segmentation violation
<code>SIGSYS*</code>	bad argument to function
<code>SIGPIPE</code>	write on a pipe or other socket with no one to read it
<code>SIGALRM</code>	alarm clock
<code>SIGTERM</code>	software termination signal
<code>SIGURG*</code>	urgent condition present on socket
<code>SIGSTOP**</code>	stop (cannot be caught, blocked, or ignored)

sigvec(3UCB)

SIGTSTP**	stop signal generated from keyboard
SIGCONT*	continue after stop (cannot be blocked)
SIGCHLD*	child status has changed
SIGTTIN**	background read attempted from control terminal
SIGTTOU**	background write attempted to control terminal
SIGIO*	I/O is possible on a descriptor (see <code>fcntl(2)</code>)
SIGXCPU	cpu time limit exceeded (see <code>getrlimit(2)</code>)
SIGXFSZ	file size limit exceeded (see <code>getrlimit(2)</code>)
SIGVTALRM	virtual time alarm; see <code>setitimer()</code> on <code>getitimer(2)</code>
SIGPROF	profiling timer alarm; see <code>setitimer()</code> on <code>getitimer(2)</code>
SIGWINCH*	window changed (see <code>termio(7I)</code>)
SIGLOST	resource lost (see <code>lockd(1M)</code>)
SIGUSR1	user-defined signal 1
SIGUSR2	user-defined signal 2

The starred signals in the list above cause a core image if not caught or ignored.

Once a signal handler is installed, it remains installed until another `sigvec()` call is made, or an `execve(2)` is performed, unless the `SV_RESETHAND` bit is set in the flags for that signal. In that case, the value of the handler for the caught signal will be set to `SIG_DFL` before entering the signal-catching function, unless the signal is `SIGILL`, `SIGPWR`, or `SIGTRAP`. Also, if this bit is set, the bit for that signal in the signal mask will not be set; unless the signal mask associated with that signal blocks that signal, further occurrences of that signal will not be blocked. The `SV_RESETHAND` flag is not available in 4.2BSD, hence it should not be used if backward compatibility is needed.

The default action for a signal may be reinstated by setting the signal's handler to `SIG_DFL`; this default is termination except for signals marked with * or **. Signals marked with * are discarded if the action is `SIG_DFL`; signals marked with ** cause the process to stop. If the process is terminated, a "core image" will be made in the current working directory of the receiving process if the signal is one for which an asterisk appears in the above list (see `core(4)`).

If the handler for that signal is `SIG_IGN`, the signal is subsequently ignored, and pending instances of the signal are discarded.

If a caught signal occurs during certain functions, the call is normally restarted. The call can be forced to terminate prematurely with an `EINTR` error return by setting the `SV_INTERRUPT` bit in the flags for that signal. The `SV_INTERRUPT` flag is not

available in 4.2BSD, hence it should not be used if backward compatibility is needed. The affected functions are `read(2)` or `write(2)` on a slow device (such as a terminal or pipe or other socket, but not a file) and during a `wait(2)`.

After a `fork(2)` or `vfork(2)` the child inherits all signals, the signal mask, the signal stack, and the restart/interrupt and reset-signal-handler flags.

The `execve(2)` call resets all caught signals to default action and resets all signals to be caught on the user stack. Ignored signals remain ignored; the signal mask remains the same; signals that interrupt functions continue to do so.

The accuracy of *addr* is machine dependent. For example, certain machines may supply an address that is on the same page as the address that caused the fault. If an appropriate *addr* cannot be computed it will be set to `SIG_NOADDR`.

RETURN VALUES A 0 value indicates that the call succeeded. A -1 return value indicates that an error occurred and `errno` is set to indicate the reason.

ERRORS `sigvec()` will fail and no new signal handler will be installed if one of the following occurs:

EFAULT Either *nvec* or *ovec* is not a NULL pointer and points to memory that is not a valid part of the process address space.

EINVAL *sig* is not a valid signal number, or, `SIGKILL`, or `SIGSTOP`.

SEE ALSO `intro(2)`, `exec(2)`, `fcntl(2)`, `fork(2)`, `getitimer(2)`, `getrlimit(2)`, `ioctl(2)`, `kill(2)`, `ptrace(2)`, `read(2)`, `umask(2)`, `vfork(2)`, `wait(2)`, `write(2)`, `setjmp(3C)`, `sigblock(3UCB)`, `sigstack(3UCB)`, `signal(3UCB)`, `wait(3UCB)`, `signal(3C)`, `core(4)`, `streamio(7I)`, `termio(7I)`

NOTES Use of these interfaces should be restricted to only applications written on BSD platforms. Use of these interfaces with any of the system libraries or in multi-thread applications is unsupported.

`SIGPOLL` is a synonym for `SIGIO`. A `SIGIO` will be issued when a file descriptor corresponding to a `STREAMS` (see `intro(2)`) file has a "selectable" event pending. Unless that descriptor has been put into asynchronous mode (see `fcntl(2)`), a process may specifically request that this signal be sent using the `I_SETSIG` `ioctl(2)` call (see `streamio(7I)`). Otherwise, the process will never receive `SIGPOLLs0`.

The handler routine can be declared:

```
void handler(int sig, int code, struct sigcontext *scp, char *addr);
```

Here *sig* is the signal number; *code* is a parameter of certain signals that provides additional detail; *scp* is a pointer to the `sigcontext` structure (defined in `signal.h`), used to restore the context from before the signal; and *addr* is additional address information.

sigvec(3UCB)

The signals `SIGKILL`, `SIGSTOP`, and `SIGCONT` cannot be ignored.

single_to_decimal(3C)

NAME	floating_to_decimal, single_to_decimal, double_to_decimal, extended_to_decimal, quadruple_to_decimal – convert floating-point value to decimal record
SYNOPSIS	<pre>#include <floatingpoint.h> void single_to_decimal(single *px, decimal_mode *pm, decimal_record *pd, fp_exception_field_type *ps); void double_to_decimal(double *px, decimal_mode *pm, decimal_record *pd, fp_exception_field_type *ps); void extended_to_decimal(extended *px, decimal_mode *pm, decimal_record *pd, fp_exception_field_type *ps); void quadruple_to_decimal(quadruple *px, decimal_mode *pm, decimal_record *pd, fp_exception_field_type *ps);</pre>
DESCRIPTION	<p>The <code>floating_to_decimal()</code> functions convert the floating-point value at <code>*px</code> into a decimal record at <code>*pd</code>, observing the modes specified in <code>*pm</code> and setting exceptions in <code>*ps</code>. If there are no IEEE exceptions, <code>*ps</code> will be zero.</p> <p>If <code>*px</code> is zero, infinity, or NaN, then only <code>pd->sign</code> and <code>pd->fpclass</code> are set. Otherwise <code>pd->exponent</code> and <code>pd->ds</code> are also set so that</p> <p>$(\text{sig}) * (\text{pd}->\text{ds}) * 10^{(\text{pd}->\text{exponent})}$ is a correctly rounded approximation to <code>*px</code>, where <code>sig</code> is +1 or -1, depending upon whether <code>pd->sign</code> is 0 or -1. <code>pd->ds</code> has at least one and no more than <code>DECIMAL_STRING_LENGTH-1</code> significant digits because one character is used to terminate the string with a NULL.</p> <p><code>pd->ds</code> is correctly rounded according to the IEEE rounding modes in <code>pm->rd</code>. <code>*ps</code> has <code>fp_inexact</code> set if the result was inexact, and has <code>fp_overflow</code> set if the string result does not fit in <code>pd->ds</code> because of the limitation <code>DECIMAL_STRING_LENGTH</code>.</p> <p>If <code>pm->df == floating_form</code>, then <code>pd->ds</code> always contains <code>pm->ndigits</code> significant digits. Thus if <code>*px == 12.34</code> and <code>pm->ndigits == 8</code>, then <code>pd->ds</code> will contain 12340000 and <code>pd->exponent</code> will contain -6.</p> <p>If <code>pm->df == fixed_form</code> and <code>pm->ndigits >= 0</code>, then <code>pd->ds</code> always contains <code>pm->ndigits</code> after the point and as many digits as necessary before the point. Since the latter is not known in advance, the total number of digits required is returned in <code>pd->ndigits</code>; if that number <code>>= DECIMAL_STRING_LENGTH</code>, then <code>ds</code> is undefined. <code>pd->exponent</code> always gets <code>-pm->ndigits</code>. Thus if <code>*px == 12.34</code> and <code>pm->ndigits == 1</code>, then <code>pd->ds</code> gets 123, <code>pd->exponent</code> gets -1, and <code>pd->ndigits</code> gets 3.</p> <p>If <code>pm->df == fixed_form</code> and <code>pm->ndigits < 0</code>, then <code>pd->ds</code> always contains <code>-pm->ndigits</code> trailing zeros; in other words, rounding occurs <code>-pm->ndigits</code> to the left of the decimal point, but the digits rounded away are retained as zeros. The total number of digits required is in <code>pd->ndigits</code>. <code>pd->exponent</code> always gets 0. Thus if <code>*px == 12.34</code> and <code>pm->ndigits == -1</code>, then <code>pd->ds</code> gets 10, <code>pd->exponent</code> gets 0, and <code>pd->ndigits</code> gets 2.</p> <p><code>pd->more</code> is not used.</p>

single_to_decimal(3C)

econvert(3C), fconvert(3C), gconvert(3C), printf(3C), and sprintf(3C) all use double_to_decimal().

ATTRIBUTES See attributes(5) for descriptions of the following attributes:

NAME	sleep – suspend execution for an interval of time				
SYNOPSIS	<pre>#include <unistd.h> unsigned int sleep(unsigned int <i>seconds</i>);</pre>				
DESCRIPTION	<p>The current process is suspended from execution for the number of <i>seconds</i> specified by the argument. The actual suspension time may be less than that requested because any caught signal will terminate the <code>sleep()</code> following execution of that signal's catching routine. Also, the suspension time may be longer than requested by an arbitrary amount because of the scheduling of other activity in the system. The value returned by <code>sleep()</code> will be the "unslept" amount (the requested time minus the time actually slept) in case the caller had an alarm set to go off earlier than the end of the requested <code>sleep()</code> time, or premature arousal because of another caught signal.</p> <p>In a single-threaded program (one not linked with <code>-lthread</code> or <code>-lpthread</code>), the routine is implemented by setting an alarm signal and pausing until it (or some other signal) occurs. The previous state of the alarm signal is saved and restored. The calling program may have set up an alarm signal before calling <code>sleep()</code>. If the <code>sleep()</code> time exceeds the time until such alarm signal, the process sleeps only until the alarm signal would have occurred. The caller's alarm catch routine is executed just before the <code>sleep()</code> routine returns. But if the <code>sleep()</code> time is less than the time till such alarm, the prior alarm time is reset to go off at the same time it would have without the intervening <code>sleep()</code>.</p> <p>In a multithreaded program (one linked with <code>-lthread</code> or <code>-lpthread</code>), the routine is implemented with a call to the <code>nanosleep(3RT)</code> function and does not modify the state of the alarm signal.</p>

	<table border="1"> <thead> <tr> <th style="text-align: center;">ATTRIBUTE TYPE</th> <th style="text-align: center;">ATTRIBUTE VALUE</th> </tr> </thead> <tbody> <tr> <td>MT-Level</td> <td>Safe</td> </tr> </tbody> </table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	MT-Level	Safe
ATTRIBUTE TYPE	ATTRIBUTE VALUE				
MT-Level	Safe				
SEE ALSO	<code>alarm(2)</code> , <code>pause(2)</code> , <code>signal(3C)</code> , <code>attributes(5)</code>				
NOTES	<p>In a single-threaded program, the <code>SIGALRM</code> signal should not be blocked or ignored during a call to <code>sleep()</code>. This restriction does not apply to a multithreaded program.</p> <p>In a multithreaded program, only the invoking thread is suspended from execution.</p>				

sleep(3UCB)

NAME	sleep – suspend execution for interval				
SYNOPSIS	<pre>/usr/ucb/cc [flag ...] file ... int sleep(seconds); unsigned seconds;</pre>				
DESCRIPTION	<p><code>sleep()</code> suspends the current process from execution for the number of seconds specified by the argument. The actual suspension time may be up to 1 second less than that requested, because scheduled wakeups occur at fixed 1-second intervals, and may be an arbitrary amount longer because of other activity in the system.</p> <p><code>sleep()</code> is implemented by setting an interval timer and pausing until it expires. The previous state of this timer is saved and restored. If the sleep time exceeds the time to the expiration of the previous value of the timer, the process sleeps only until the timer would have expired, and the signal which occurs with the expiration of the timer is sent one second later.</p>				
ATTRIBUTES	See <code>attributes(5)</code> for descriptions of the following attributes:				
	<table border="1"><thead><tr><th>ATTRIBUTE TYPE</th><th>ATTRIBUTE VALUE</th></tr></thead><tbody><tr><td>MT-Level</td><td>Async-Signal-Safe</td></tr></tbody></table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	MT-Level	Async-Signal-Safe
ATTRIBUTE TYPE	ATTRIBUTE VALUE				
MT-Level	Async-Signal-Safe				
SEE ALSO	<code>alarm(2)</code> , <code>getitimer(2)</code> , <code>longjmp(3C)</code> , <code>siglongjmp(3C)</code> , <code>sleep(3C)</code> , <code>usleep(3C)</code> , <code>attributes(5)</code>				
NOTES	<p>Use of these interfaces should be restricted to only applications written on BSD platforms. Use of these interfaces with any of the system libraries or in multi-thread applications is unsupported.</p> <p>SIGALRM should <i>not</i> be blocked or ignored during a call to <code>sleep()</code>. Only a prior call to <code>alarm(2)</code> should generate SIGALRM for the calling process during a call to <code>sleep()</code>. A signal-catching function should <i>not</i> interrupt a call to <code>sleep()</code> to call <code>siglongjmp(3C)</code> or <code>longjmp(3C)</code> to restore an environment saved prior to the <code>sleep()</code> call.</p>				
WARNINGS	<code>sleep()</code> is slightly incompatible with <code>alarm(2)</code> . Programs that do not execute for at least one second of clock time between successive calls to <code>sleep()</code> indefinitely delay the alarm signal. Use <code>sleep(3C)</code> . Each <code>sleep(3C)</code> call postpones the alarm signal that would have been sent during the requested sleep period to occur one second later.				

NAME	printf, fprintf, sprintf, snprintf – print formatted output
SYNOPSIS	<pre>#include <stdio.h> int printf(const char *format, /* args*/ ...); int fprintf(FILE *stream, const char *format, /* args*/ ...); int sprintf(char *s, const char *format, /* args*/ ...); int snprintf(char *s, size_t n, const char *format, /* args*/ ...);</pre>
DESCRIPTION	<p>The <code>printf()</code> function places output on the standard output stream <code>stdout</code>.</p> <p>The <code>fprintf()</code> function places output on on the named output stream <i>stream</i>.</p> <p>The <code>sprintf()</code> function places output, followed by the null byte (<code>\0</code>), in consecutive bytes starting at <i>s</i>; it is the user's responsibility to ensure that enough storage is available.</p> <p>The <code>snprintf()</code> function is identical to <code>sprintf()</code> with the addition of the argument <i>n</i>, which specifies the size of the buffer referred to by <i>s</i>. The buffer is always terminated with the null byte.</p> <p>Each of these functions converts, formats, and prints its arguments under control of the <i>format</i>. The <i>format</i> is a character string, beginning and ending in its initial shift state, if any. The <i>format</i> is composed of zero or more directives: <i>ordinary characters</i>, which are simply copied to the output stream and <i>conversion specifications</i>, each of which results in the fetching of zero or more arguments. The results are undefined if there are insufficient arguments for the <i>format</i>. If the <i>format</i> is exhausted while arguments remain, the excess arguments are evaluated but are otherwise ignored.</p> <p>Conversions can be applied to the <i>n</i>th argument after the <i>format</i> in the argument list, rather than to the next unused argument. In this case, the conversion character <code>%</code> (see below) is replaced by the sequence <code>%n\$</code>, where <i>n</i> is a decimal integer in the range <code>[1, NL_ARGMAX]</code>, giving the position of the argument in the argument list. This feature provides for the definition of format strings that select arguments in an order appropriate to specific languages (see the <code>EXAMPLES</code> section).</p> <p>In format strings containing the <code>%n\$</code> form of conversion specifications, numbered arguments in the argument list can be referenced from the format string as many times as required.</p> <p>In format strings containing the <code>%</code> form of conversion specifications, each argument in the argument list is used exactly once.</p> <p>All forms of the <code>printf()</code> functions allow for the insertion of a language-dependent radix character in the output string. The radix character is defined by the program's locale (category <code>LC_NUMERIC</code>). In the POSIX locale, or in a locale where the radix character is not defined, the radix character defaults to a period (<code>.</code>).</p>

snprintf(3C)

Conversion Specifications

Each conversion specification is introduced by the % character or by the character sequence %n\$, after which the following appear in sequence:

- An optional field, consisting of a decimal digit string followed by a \$, specifying the next argument to be converted. If this field is not provided, the *args* following the last argument converted will be used.
- Zero or more *flags* (in any order), which modify the meaning of the conversion specification.
- An optional minimum *field width*. If the converted value has fewer bytes than the field width, it will be padded with spaces by default on the left; it will be padded on the right, if the left-adjustment flag (‐), described below, is given to the field width. The field width takes the form of an asterisk (*), described below, or a decimal integer.

If the conversion character is *s*, a standard-conforming application (see `standards(5)`) interprets the field width as the minimum number of bytes to be printed; an application that is not standard-conforming interprets the field width as the minimum number of columns of screen display. For an application that is not standard-conforming, %10*s* means if the converted value has a screen width of 7 columns, 3 spaces would be padded on the right.

If the format is %*ws*, then the field width should be interpreted as the minimum number of columns of screen display.

- An optional *precision* that gives the minimum number of digits to appear for the *d*, *i*, *o*, *u*, *x*, and *X* conversions (the field is padded with leading zeros); the number of digits to appear after the radix character for the *e*, *E*, and *f* conversions, the maximum number of significant digits for the *g* and *G* conversions; or the maximum number of bytes to be printed from a string in *s* and *S* conversions. The precision takes the form of a period (.) followed either by an asterisk (*), described below, or an optional decimal digit string, where a null digit string is treated as 0. If a precision appears with any other conversion character, the behavior is undefined.

If the conversion character is *s* or *S*, a standard-conforming application (see `standards(5)`) interprets the precision as the maximum number of bytes to be written; an application that is not standard-conforming interprets the precision as the maximum number of columns of screen display. For an application that is not standard-conforming, % .5*s* would print only the portion of the string that would display in 5 screen columns. Only complete characters are written.

For %*ws*, the precision should be interpreted as the maximum number of columns of screen display. The precision takes the form of a period (.) followed by a decimal digit string; a null digit string is treated as zero. Padding specified by the precision overrides the padding specified by the field width.

- An optional *h* specifies that a following *d*, *i*, *o*, *u*, *x*, or *X* conversion character applies to a type `short int` or type `unsigned short int` argument (the argument will be promoted according to the integral promotions, and its value converted to type `short int` or `unsigned short int` before printing); an optional *h* specifying that a following *n* conversion character applies to a pointer to a type `short int` argument; an optional *l* (ell) specifying that a following *d*, *i*, *o*, *u*, *x*, or *X* conversion character applies to a type `long int` or `unsigned long`

int argument; an optional l (ell) specifying that a following n conversion character applies to a pointer to a type long int argument; an optional ll (ell ell) specifying that a following d, i, o, u, x, or X conversion character applies to a type long long or unsigned long long argument; an optional ll (ell ell) specifying that a following n conversion character applies to a pointer to a long long argument; or an optional L specifying that a following e, E, f, g, or G conversion character applies to a type long double argument. If an h, l, ll, or L appears with any other conversion character, the behavior is undefined.

- An optional l (ell) specifying that a following c conversion character applies to a wint_t argument; an optional l (ell) specifying that a following s conversion character applies to a pointer to a wchar_t argument.
- A *conversion character* (see below) that indicates the type of conversion to be applied.

A field width, or precision, or both may be indicated by an asterisk (*). In this case, an argument of type int supplies the field width or precision. Arguments specifying field width, or precision, or both must appear in that order before the argument, if any, to be converted. A negative field width is taken as a – flag followed by a positive field width. A negative precision is taken as if the precision were omitted. In format strings containing the %n\$ form of a conversion specification, a field width or precision may be indicated by the sequence *m\$, where m is a decimal integer in the range [1, NL_ARGMAX] giving the position in the argument list (after the format argument) of an integer argument containing the field width or precision, for example:

```
printf("%1$d:%2$.*3$d:%4$.*3$d\n", hour, min, precision, sec);
```

The *format* can contain either numbered argument specifications (that is, %n\$ and *m\$), or unnumbered argument specifications (that is, % and *), but normally not both. The only exception to this is that %% can be mixed with the %n\$ form. The results of mixing numbered and unnumbered argument specifications in a *format* string are undefined. When numbered argument specifications are used, specifying the Nth argument requires that all the leading arguments, from the first to the (N–1)th, are specified in the format string.

Flag Characters

The flag characters and their meanings are:

- ' The integer portion of the result of a decimal conversion (%i, %d, %u, %f, %g, or %G) will be formatted with thousands' grouping characters. For other conversions the behavior is undefined. The non-monetary grouping character is used.
- The result of the conversion will be left-justified within the field. The conversion will be right-justified if this flag is not specified.
- + The result of a signed conversion will always begin with a sign (+ or –). The conversion will begin with a sign only when a negative value is converted if this flag is not specified.

snprintf(3C)

space	If the first character of a signed conversion is not a sign or if a signed conversion results in no characters, a space will be placed before the result. This means that if the <code>space</code> and <code>+</code> flags both appear, the space flag will be ignored.								
#	The value is to be converted to an alternate form. For <code>c</code> , <code>d</code> , <code>i</code> , <code>s</code> , and <code>u</code> conversions, the flag has no effect. For an <code>o</code> conversion, it increases the precision (if necessary) to force the first digit of the result to be a zero. For <code>x</code> or <code>X</code> conversion, a non-zero result will have <code>0x</code> (or <code>0X</code>) prepended to it. For <code>e</code> , <code>E</code> , <code>f</code> , <code>g</code> , and <code>G</code> conversions, the result will always contain a radix character, even if no digits follow the radix character. Without this flag, the radix character appears in the result of these conversions only if a digit follows it. For <code>g</code> and <code>G</code> conversions, trailing zeros will not be removed from the result as they normally are.								
0	For <code>d</code> , <code>i</code> , <code>o</code> , <code>u</code> , <code>x</code> , <code>X</code> , <code>e</code> , <code>E</code> , <code>f</code> , <code>g</code> , and <code>G</code> conversions, leading zeros (following any indication of sign or base) are used to pad to the field width; no space padding is performed. If the <code>0</code> and <code>-</code> flags both appear, the <code>0</code> flag will be ignored. For <code>d</code> , <code>i</code> , <code>o</code> , <code>u</code> , <code>x</code> , and <code>X</code> conversions, if a precision is specified, the <code>0</code> flag will be ignored. If the <code>0</code> and <code>'</code> flags both appear, the grouping characters are inserted before zero padding. For other conversions, the behavior is undefined.								
Conversion Characters	<p>Each conversion character results in fetching zero or more arguments. The results are undefined if there are insufficient arguments for the format. If the format is exhausted while arguments remain, the excess arguments are ignored.</p> <p>The conversion characters and their meanings are:</p> <table><tr><td><code>d,i</code></td><td>The <code>int</code> argument is converted to a signed decimal in the style <code>[-] dddd</code>. The precision specifies the minimum number of digits to appear; if the value being converted can be represented in fewer digits, it will be expanded with leading zeros. The default precision is 1. The result of converting 0 with an explicit precision of 0 is no characters.</td></tr><tr><td><code>o</code></td><td>The unsigned <code>int</code> argument is converted to unsigned octal format in the style <code>dddd</code>. The precision specifies the minimum number of digits to appear; if the value being converted can be represented in fewer digits, it will be expanded with leading zeros. The default precision is 1. The result of converting 0 with an explicit precision of 0 is no characters.</td></tr><tr><td><code>u</code></td><td>The unsigned <code>int</code> argument is converted to unsigned decimal format in the style <code>dddd</code>. The result of converting 0 with an explicit precision of 0 is no characters.</td></tr><tr><td><code>x</code></td><td>The unsigned <code>int</code> argument is converted to unsigned hexadecimal format in the style <code>dddd</code>; the letters <code>abcdef</code> are used. The precision specifies the minimum number of digits to appear; if the value being</td></tr></table>	<code>d,i</code>	The <code>int</code> argument is converted to a signed decimal in the style <code>[-] dddd</code> . The precision specifies the minimum number of digits to appear; if the value being converted can be represented in fewer digits, it will be expanded with leading zeros. The default precision is 1. The result of converting 0 with an explicit precision of 0 is no characters.	<code>o</code>	The unsigned <code>int</code> argument is converted to unsigned octal format in the style <code>dddd</code> . The precision specifies the minimum number of digits to appear; if the value being converted can be represented in fewer digits, it will be expanded with leading zeros. The default precision is 1. The result of converting 0 with an explicit precision of 0 is no characters.	<code>u</code>	The unsigned <code>int</code> argument is converted to unsigned decimal format in the style <code>dddd</code> . The precision specifies the minimum number of digits to appear; if the value being converted can be represented in fewer digits, it will be expanded with leading zeros. The default precision is 1. The result of converting 0 with an explicit precision of 0 is no characters.	<code>x</code>	The unsigned <code>int</code> argument is converted to unsigned hexadecimal format in the style <code>dddd</code> ; the letters <code>abcdef</code> are used. The precision specifies the minimum number of digits to appear; if the value being
<code>d,i</code>	The <code>int</code> argument is converted to a signed decimal in the style <code>[-] dddd</code> . The precision specifies the minimum number of digits to appear; if the value being converted can be represented in fewer digits, it will be expanded with leading zeros. The default precision is 1. The result of converting 0 with an explicit precision of 0 is no characters.								
<code>o</code>	The unsigned <code>int</code> argument is converted to unsigned octal format in the style <code>dddd</code> . The precision specifies the minimum number of digits to appear; if the value being converted can be represented in fewer digits, it will be expanded with leading zeros. The default precision is 1. The result of converting 0 with an explicit precision of 0 is no characters.								
<code>u</code>	The unsigned <code>int</code> argument is converted to unsigned decimal format in the style <code>dddd</code> . The precision specifies the minimum number of digits to appear; if the value being converted can be represented in fewer digits, it will be expanded with leading zeros. The default precision is 1. The result of converting 0 with an explicit precision of 0 is no characters.								
<code>x</code>	The unsigned <code>int</code> argument is converted to unsigned hexadecimal format in the style <code>dddd</code> ; the letters <code>abcdef</code> are used. The precision specifies the minimum number of digits to appear; if the value being								

	converted can be represented in fewer digits, it will be expanded with leading zeros. The default precision is 1. The result of converting 0 with an explicit precision of 0 is no characters.
X	Behaves the same as the x conversion character except that letters ABCDEF are used instead of abcdef.
f	The <code>double</code> argument is converted to decimal notation in the style <code>[-]ddd.ddd</code> , where the number of digits after the radix character (see <code>setlocale(3C)</code>) is equal to the precision specification. If the precision is missing it is taken as 6; if the precision is explicitly 0 and the # flag is not specified, no radix character appears. If a radix character appears, at least 1 digit appears before it. The value is rounded to the appropriate number of digits.
e,E	The <code>double</code> argument is converted to the style <code>[-]d.ddd\pmdd</code> , where there is one digit before the radix character (which is non-zero if the argument is non-zero) and the number of digits after it is equal to the precision. When the precision is missing it is taken as 6; if the precision is 0 and the # flag is not specified, no radix character appears. The E conversion character will produce a number with E instead of e introducing the exponent. The exponent always contains at least two digits. The value is rounded to the appropriate number of digits.
g,G	The <code>double</code> argument is printed in style f or e (or in style E in the case of a G conversion character), with the precision specifying the number of significant digits. If an explicit precision is 0, it is taken as 1. The style used depends on the value converted: style e (or E) will be used only if the exponent resulting from the conversion is less than -4 or greater than or equal to the precision. Trailing zeros are removed from the fractional part of the result. A radix character appears only if it is followed by a digit.
c	The <code>int</code> argument is converted to an unsigned <code>char</code> , and the resulting byte is printed. If an l (ell) qualifier is present, the <code>wint_t</code> argument is converted as if by an <code>ls</code> conversion specification with no precision and an argument that points to a two-element array of type <code>wchar_t</code> , the first element of which contains the <code>wint_t</code> argument to the <code>ls</code> conversion specification and the second element contains a null wide-character.
C	Same as <code>lc</code> .
wc	The <code>int</code> argument is converted to a wide character (<code>wchar_t</code>), and the resulting wide character is printed.
s	The argument must be a pointer to an array of <code>char</code> . Bytes from the array are written up to (but not including) any terminating null byte. If a precision is specified, a standard-conforming application (see <code>standards(5)</code>) will write only the number of bytes specified by precision; an application that is not standard-conforming will write only the portion

snprintf(3C)

of the string that will display in the number of columns of screen display specified by precision. If the precision is not specified, it is taken to be infinite, so all bytes up to the first null byte are printed. An argument with a null value will yield undefined results.

If an `l` (ell) qualifier is present, the argument must be a pointer to an array of type `wchar_t`. Wide-characters from the array are converted to characters (each as if by a call to the `wcrtomb(3C)` function, with the conversion state described by an `mbstate_t` object initialized to zero before the first wide-character is converted) up to and including a terminating null wide-character. The resulting characters are written up to (but not including) the terminating null character (byte). If no precision is specified, the array must contain a null wide-character. If a precision is specified, no more than that many characters (bytes) are written (including shift sequences, if any), and the array must contain a null wide-character if, to equal the character sequence length given by the precision, the function would need to access a wide-character one past the end of the array. In no case is a partial character written.

`s` Same as `ls`.

`ws` The argument must be a pointer to an array of `wchar_t`. Bytes from the array are written up to (but not including) any terminating null character. If the precision is specified, only that portion of the wide-character array that will display in the number of columns of screen display specified by precision will be written. If the precision is not specified, it is taken to be infinite, so all wide characters up to the first null character are printed. An argument with a null value will yield undefined results.

`p` The argument must be a pointer to `void`. The value of the pointer is converted to a set of sequences of printable characters, which should be the same as the set of sequences that are matched by the `%p` conversion of the `scanf(3C)` function.

`n` The argument must be a pointer to an integer into which is written the number of bytes written to the output standard I/O stream so far by this call to one of the `printf()` functions. No argument is converted.

`%` Print a `%`; no argument is converted. The entire conversion specification must be `%%`.

If a conversion specification does not match one of the above forms, the behavior is undefined.

If a floating-point value is the internal representation for infinity, the output is `[±]Infinity`, where *Infinity* is either `Infinity` or `Inf`, depending on the desired output string length. Printing of the sign follows the rules described above.

If a floating-point value is the internal representation for “not-a-number,” the output is `[±]NaN`. Printing of the sign follows the rules described above.

	<p>In no case does a non-existent or small field width cause truncation of a field; if the result of a conversion is wider than the field width, the field is simply expanded to contain the conversion result. Characters generated by <code>printf()</code> and <code>fprintf()</code> are printed as if the <code>putc(3C)</code> function had been called.</p> <p>The <code>st_ctime</code> and <code>st_mtime</code> fields of the file will be marked for update between the call to a successful execution of <code>printf()</code> or <code>fprintf()</code> and the next successful completion of a call to <code>fflush(3C)</code> or <code>fclose(3C)</code> on the same stream or a call to <code>exit(3C)</code> or <code>abort(3C)</code>.</p>						
RETURN VALUES	<p>The <code>printf()</code>, <code>fprintf()</code>, and <code>sprintf()</code> functions return the number of bytes transmitted (excluding the terminating null byte in the case of <code>sprintf()</code>).</p> <p>The <code>snprintf()</code> function returns the number of characters formatted, that is, the number of characters that would have been written to the buffer if it were large enough. If the value of <code>n</code> is 0 on a call to <code>snprintf()</code>, an unspecified value less than 1 is returned.</p> <p>Each function returns a negative value if an output error was encountered.</p>						
ERRORS	<p>For the conditions under which <code>printf()</code> and <code>fprintf()</code> will fail and may fail, refer to <code>fputc(3C)</code> or <code>fputwc(3C)</code>.</p> <p>In addition, all forms of <code>printf()</code> may fail if:</p> <table border="0"> <tr> <td style="padding-right: 20px;"><code>EILSEQ</code></td> <td>A wide-character code that does not correspond to a valid character has been detected.</td> </tr> <tr> <td><code>EINVAL</code></td> <td>There are insufficient arguments.</td> </tr> </table> <p>In addition, <code>printf()</code> and <code>fprintf()</code> may fail if:</p> <table border="0"> <tr> <td style="padding-right: 20px;"><code>ENOMEM</code></td> <td>Insufficient storage space is available.</td> </tr> </table>	<code>EILSEQ</code>	A wide-character code that does not correspond to a valid character has been detected.	<code>EINVAL</code>	There are insufficient arguments.	<code>ENOMEM</code>	Insufficient storage space is available.
<code>EILSEQ</code>	A wide-character code that does not correspond to a valid character has been detected.						
<code>EINVAL</code>	There are insufficient arguments.						
<code>ENOMEM</code>	Insufficient storage space is available.						
USAGE	<p>If the application calling the <code>printf()</code> functions has any objects of type <code>wint_t</code> or <code>wchar_t</code>, it must also include the header <code><wchar.h></code> to have these objects defined.</p> <p>The <code>sprintf()</code> and <code>snprintf()</code> functions are MT-Safe in multithreaded applications. The <code>printf()</code> and <code>fprintf()</code> functions can be used safely in multithreaded applications, as long as <code>setlocale(3C)</code> is not being called to change the locale.</p>						
Escape Character Sequences	<p>It is common to use the following escape sequences built into the C language when entering format strings for the <code>printf()</code> functions, but these sequences are processed by the C compiler, not by the <code>printf()</code> function.</p> <table border="0"> <tr> <td style="padding-right: 20px;"><code>\a</code></td> <td>Alert. Ring the bell.</td> </tr> <tr> <td><code>\b</code></td> <td>Backspace. Move the printing position to one character before the current position, unless the current position is the start of a line.</td> </tr> </table>	<code>\a</code>	Alert. Ring the bell.	<code>\b</code>	Backspace. Move the printing position to one character before the current position, unless the current position is the start of a line.		
<code>\a</code>	Alert. Ring the bell.						
<code>\b</code>	Backspace. Move the printing position to one character before the current position, unless the current position is the start of a line.						

snprintf(3C)

<code>\f</code>	Form feed. Move the printing position to the initial printing position of the next logical page.
<code>\n</code>	Newline. Move the printing position to the start of the next line.
<code>\r</code>	Carriage return. Move the printing position to the start of the current line.
<code>\t</code>	Horizontal tab. Move the printing position to the next implementation-defined horizontal tab position on the current line.
<code>\v</code>	Vertical tab. Move the printing position to the start of the next implementation-defined vertical tab position.

In addition, the C language supports character sequences of the form

`\octal-numberand`

`\hex-number` which translates into the character represented by the octal or hexadecimal number. For example, if ASCII representations are being used, the letter 'a' may be written as `'\141'` and 'Z' as `'\132'`. This syntax is most frequently used to represent the null character as `'\0'`. This is exactly equivalent to the numeric constant zero (0). Note that the octal number does not include the zero prefix as it would for a normal octal constant. To specify a hexadecimal number, omit the zero so that the prefix is an 'x' (uppercase 'X' is not allowed in this context). Support for hexadecimal sequences is an ANSI extension. See `standards(5)`.

EXAMPLES

EXAMPLE 1 To print the language-independent date and time format, the following statement could be used:

```
printf (format, weekday, month, day, hour, min);
```

For American usage, *format* could be a pointer to the string:

```
"%s, %s %d, %d:%.2d\n"
```

producing the message:

```
Sunday, July 3, 10:02
```

whereas for German usage, *format* could be a pointer to the string:

```
"%1$s, %3$d. %2$s, %4$d:%5$.2d\n"
```

producing the message:

```
Sonntag, 3. Juli, 10:02
```

EXAMPLE 2 To print a date and time in the form `Sunday, July 3, 10:02`, where *weekday* and *month* are pointers to null-terminated strings:

```
printf("%s, %s %i, %d:%.2d", weekday, month, day, hour, min);
```

EXAMPLE 2 To print a date and time in the form *Sunday, July 3, 10:02*, where *weekday* and *month* are pointers to null-terminated strings: *(Continued)*

EXAMPLE 3 To print pi to 5 decimal places:

```
printf("pi = %.5f", 4 * atan(1.0));
```

Default

EXAMPLE 4 The following example applies only to applications which are not standard-conforming (see `standards(5)`). To print a list of names in columns which are 20 characters wide:

```
printf("%20s%20s%20s", lastname, firstname, middlename);
```

sprintf(3C)

NAME	<code>printf</code> , <code>fprintf</code> , <code>sprintf</code> , <code>snprintf</code> – print formatted output
SYNOPSIS	<pre>#include <stdio.h> int printf(const char *format, /* args*/ ...); int fprintf(FILE *stream, const char *format, /* args*/ ...); int sprintf(char *s, const char *format, /* args*/ ...); int snprintf(char *s, size_t n, const char *format, /* args*/ ...);</pre>
DESCRIPTION	<p>The <code>printf()</code> function places output on the standard output stream <code>stdout</code>.</p> <p>The <code>fprintf()</code> function places output on on the named output stream <i>stream</i>.</p> <p>The <code>sprintf()</code> function places output, followed by the null byte (<code>\0</code>), in consecutive bytes starting at <i>s</i>; it is the user's responsibility to ensure that enough storage is available.</p> <p>The <code>snprintf()</code> function is identical to <code>sprintf()</code> with the addition of the argument <i>n</i>, which specifies the size of the buffer referred to by <i>s</i>. The buffer is always terminated with the null byte.</p> <p>Each of these functions converts, formats, and prints its arguments under control of the <i>format</i>. The <i>format</i> is a character string, beginning and ending in its initial shift state, if any. The <i>format</i> is composed of zero or more directives: <i>ordinary characters</i>, which are simply copied to the output stream and <i>conversion specifications</i>, each of which results in the fetching of zero or more arguments. The results are undefined if there are insufficient arguments for the <i>format</i>. If the <i>format</i> is exhausted while arguments remain, the excess arguments are evaluated but are otherwise ignored.</p> <p>Conversions can be applied to the <i>n</i>th argument after the <i>format</i> in the argument list, rather than to the next unused argument. In this case, the conversion character <code>%</code> (see below) is replaced by the sequence <code>%n\$</code>, where <i>n</i> is a decimal integer in the range <code>[1, NL_ARGMAX]</code>, giving the position of the argument in the argument list. This feature provides for the definition of format strings that select arguments in an order appropriate to specific languages (see the <code>EXAMPLES</code> section).</p> <p>In format strings containing the <code>%n\$</code> form of conversion specifications, numbered arguments in the argument list can be referenced from the format string as many times as required.</p> <p>In format strings containing the <code>%</code> form of conversion specifications, each argument in the argument list is used exactly once.</p> <p>All forms of the <code>printf()</code> functions allow for the insertion of a language-dependent radix character in the output string. The radix character is defined by the program's locale (category <code>LC_NUMERIC</code>). In the POSIX locale, or in a locale where the radix character is not defined, the radix character defaults to a period (<code>.</code>).</p>

Conversion Specifications

Each conversion specification is introduced by the % character or by the character sequence %n\$, after which the following appear in sequence:

- An optional field, consisting of a decimal digit string followed by a \$, specifying the next argument to be converted. If this field is not provided, the *args* following the last argument converted will be used.
- Zero or more *flags* (in any order), which modify the meaning of the conversion specification.
- An optional minimum *field width*. If the converted value has fewer bytes than the field width, it will be padded with spaces by default on the left; it will be padded on the right, if the left-adjustment flag (‐), described below, is given to the field width. The field width takes the form of an asterisk (*), described below, or a decimal integer.

If the conversion character is *s*, a standard-conforming application (see `standards(5)`) interprets the field width as the minimum number of bytes to be printed; an application that is not standard-conforming interprets the field width as the minimum number of columns of screen display. For an application that is not standard-conforming, %10*s* means if the converted value has a screen width of 7 columns, 3 spaces would be padded on the right.

If the format is %*ws*, then the field width should be interpreted as the minimum number of columns of screen display.

- An optional *precision* that gives the minimum number of digits to appear for the *d*, *i*, *o*, *u*, *x*, and *X* conversions (the field is padded with leading zeros); the number of digits to appear after the radix character for the *e*, *E*, and *f* conversions, the maximum number of significant digits for the *g* and *G* conversions; or the maximum number of bytes to be printed from a string in *s* and *S* conversions. The precision takes the form of a period (.) followed either by an asterisk (*), described below, or an optional decimal digit string, where a null digit string is treated as 0. If a precision appears with any other conversion character, the behavior is undefined.

If the conversion character is *s* or *S*, a standard-conforming application (see `standards(5)`) interprets the precision as the maximum number of bytes to be written; an application that is not standard-conforming interprets the precision as the maximum number of columns of screen display. For an application that is not standard-conforming, % .5*s* would print only the portion of the string that would display in 5 screen columns. Only complete characters are written.

For %*ws*, the precision should be interpreted as the maximum number of columns of screen display. The precision takes the form of a period (.) followed by a decimal digit string; a null digit string is treated as zero. Padding specified by the precision overrides the padding specified by the field width.

- An optional *h* specifies that a following *d*, *i*, *o*, *u*, *x*, or *X* conversion character applies to a type `short int` or type `unsigned short int` argument (the argument will be promoted according to the integral promotions, and its value converted to type `short int` or `unsigned short int` before printing); an optional *h* specifying that a following *n* conversion character applies to a pointer to a type `short int` argument; an optional *l* (ell) specifying that a following *d*, *i*, *o*, *u*, *x*, or *X* conversion character applies to a type `long int` or `unsigned long`

sprintf(3C)

int argument; an optional l (ell) specifying that a following n conversion character applies to a pointer to a type long int argument; an optional ll (ell ell) specifying that a following d, i, o, u, x, or X conversion character applies to a type long long or unsigned long long argument; an optional ll (ell ell) specifying that a following n conversion character applies to a pointer to a long long argument; or an optional L specifying that a following e, E, f, g, or G conversion character applies to a type long double argument. If an h, l, ll, or L appears with any other conversion character, the behavior is undefined.

- An optional l (ell) specifying that a following c conversion character applies to a wint_t argument; an optional l (ell) specifying that a following s conversion character applies to a pointer to a wchar_t argument.
- A *conversion character* (see below) that indicates the type of conversion to be applied.

A field width, or precision, or both may be indicated by an asterisk (*). In this case, an argument of type int supplies the field width or precision. Arguments specifying field width, or precision, or both must appear in that order before the argument, if any, to be converted. A negative field width is taken as a - flag followed by a positive field width. A negative precision is taken as if the precision were omitted. In format strings containing the %n\$ form of a conversion specification, a field width or precision may be indicated by the sequence *m\$, where m is a decimal integer in the range [1, NL_ARGMAX] giving the position in the argument list (after the format argument) of an integer argument containing the field width or precision, for example:

```
printf("%1$d:%2$.*3$d:%4$.*3$d\n", hour, min, precision, sec);
```

The *format* can contain either numbered argument specifications (that is, %n\$ and *m\$), or unnumbered argument specifications (that is, % and *), but normally not both. The only exception to this is that %% can be mixed with the %n\$ form. The results of mixing numbered and unnumbered argument specifications in a *format* string are undefined. When numbered argument specifications are used, specifying the Nth argument requires that all the leading arguments, from the first to the (N-1)th, are specified in the format string.

Flag Characters

The flag characters and their meanings are:

- ' The integer portion of the result of a decimal conversion (%i, %d, %u, %f, %g, or %G) will be formatted with thousands' grouping characters. For other conversions the behavior is undefined. The non-monetary grouping character is used.
- The result of the conversion will be left-justified within the field. The conversion will be right-justified if this flag is not specified.
- + The result of a signed conversion will always begin with a sign (+ or -). The conversion will begin with a sign only when a negative value is converted if this flag is not specified.

space	If the first character of a signed conversion is not a sign or if a signed conversion results in no characters, a space will be placed before the result. This means that if the <code>space</code> and <code>+</code> flags both appear, the space flag will be ignored.
#	The value is to be converted to an alternate form. For <code>c</code> , <code>d</code> , <code>i</code> , <code>s</code> , and <code>u</code> conversions, the flag has no effect. For an <code>o</code> conversion, it increases the precision (if necessary) to force the first digit of the result to be a zero. For <code>x</code> or <code>X</code> conversion, a non-zero result will have <code>0x</code> (or <code>0X</code>) prepended to it. For <code>e</code> , <code>E</code> , <code>f</code> , <code>g</code> , and <code>G</code> conversions, the result will always contain a radix character, even if no digits follow the radix character. Without this flag, the radix character appears in the result of these conversions only if a digit follows it. For <code>g</code> and <code>G</code> conversions, trailing zeros will not be removed from the result as they normally are.
0	For <code>d</code> , <code>i</code> , <code>o</code> , <code>u</code> , <code>x</code> , <code>X</code> , <code>e</code> , <code>E</code> , <code>f</code> , <code>g</code> , and <code>G</code> conversions, leading zeros (following any indication of sign or base) are used to pad to the field width; no space padding is performed. If the <code>0</code> and <code>-</code> flags both appear, the <code>0</code> flag will be ignored. For <code>d</code> , <code>i</code> , <code>o</code> , <code>u</code> , <code>x</code> , and <code>X</code> conversions, if a precision is specified, the <code>0</code> flag will be ignored. If the <code>0</code> and <code>'</code> flags both appear, the grouping characters are inserted before zero padding. For other conversions, the behavior is undefined.
Conversion Characters	Each conversion character results in fetching zero or more arguments. The results are undefined if there are insufficient arguments for the format. If the format is exhausted while arguments remain, the excess arguments are ignored. The conversion characters and their meanings are:
d,i	The <code>int</code> argument is converted to a signed decimal in the style <code>[-] dddd</code> . The precision specifies the minimum number of digits to appear; if the value being converted can be represented in fewer digits, it will be expanded with leading zeros. The default precision is 1. The result of converting 0 with an explicit precision of 0 is no characters.
o	The unsigned <code>int</code> argument is converted to unsigned octal format in the style <code>dddd</code> . The precision specifies the minimum number of digits to appear; if the value being converted can be represented in fewer digits, it will be expanded with leading zeros. The default precision is 1. The result of converting 0 with an explicit precision of 0 is no characters.
u	The unsigned <code>int</code> argument is converted to unsigned decimal format in the style <code>dddd</code> . The precision specifies the minimum number of digits to appear; if the value being converted can be represented in fewer digits, it will be expanded with leading zeros. The default precision is 1. The result of converting 0 with an explicit precision of 0 is no characters.
x	The unsigned <code>int</code> argument is converted to unsigned hexadecimal format in the style <code>dddd</code> ; the letters <code>abcdef</code> are used. The precision specifies the minimum number of digits to appear; if the value being

sprintf(3C)

	converted can be represented in fewer digits, it will be expanded with leading zeros. The default precision is 1. The result of converting 0 with an explicit precision of 0 is no characters.
X	Behaves the same as the x conversion character except that letters ABCDEF are used instead of abcdef.
f	The double argument is converted to decimal notation in the style [-]ddd.ddd, where the number of digits after the radix character (see setlocale(3C)) is equal to the precision specification. If the precision is missing it is taken as 6; if the precision is explicitly 0 and the # flag is not specified, no radix character appears. If a radix character appears, at least 1 digit appears before it. The value is rounded to the appropriate number of digits.
e,E	The double argument is converted to the style [-]d.ddd \pm dd, where there is one digit before the radix character (which is non-zero if the argument is non-zero) and the number of digits after it is equal to the precision. When the precision is missing it is taken as 6; if the precision is 0 and the # flag is not specified, no radix character appears. The E conversion character will produce a number with E instead of e introducing the exponent. The exponent always contains at least two digits. The value is rounded to the appropriate number of digits.
g,G	The double argument is printed in style f or e (or in style E in the case of a G conversion character), with the precision specifying the number of significant digits. If an explicit precision is 0, it is taken as 1. The style used depends on the value converted: style e (or E) will be used only if the exponent resulting from the conversion is less than -4 or greater than or equal to the precision. Trailing zeros are removed from the fractional part of the result. A radix character appears only if it is followed by a digit.
c	The int argument is converted to an unsigned char, and the resulting byte is printed. If an l (ell) qualifier is present, the wint_t argument is converted as if by an ls conversion specification with no precision and an argument that points to a two-element array of type wchar_t, the first element of which contains the wint_t argument to the ls conversion specification and the second element contains a null wide-character.
C	Same as lc.
wc	The int argument is converted to a wide character (wchar_t), and the resulting wide character is printed.
s	The argument must be a pointer to an array of char. Bytes from the array are written up to (but not including) any terminating null byte. If a precision is specified, a standard-conforming application (see standards(5)) will write only the number of bytes specified by precision; an application that is not standard-conforming will write only the portion

of the string that will display in the number of columns of screen display specified by precision. If the precision is not specified, it is taken to be infinite, so all bytes up to the first null byte are printed. An argument with a null value will yield undefined results.

If an `l` (ell) qualifier is present, the argument must be a pointer to an array of type `wchar_t`. Wide-characters from the array are converted to characters (each as if by a call to the `wcrtomb(3C)` function, with the conversion state described by an `mbstate_t` object initialized to zero before the first wide-character is converted) up to and including a terminating null wide-character. The resulting characters are written up to (but not including) the terminating null character (byte). If no precision is specified, the array must contain a null wide-character. If a precision is specified, no more than that many characters (bytes) are written (including shift sequences, if any), and the array must contain a null wide-character if, to equal the character sequence length given by the precision, the function would need to access a wide-character one past the end of the array. In no case is a partial character written.

`S` Same as `ls`.

`ws` The argument must be a pointer to an array of `wchar_t`. Bytes from the array are written up to (but not including) any terminating null character. If the precision is specified, only that portion of the wide-character array that will display in the number of columns of screen display specified by precision will be written. If the precision is not specified, it is taken to be infinite, so all wide characters up to the first null character are printed. An argument with a null value will yield undefined results.

`p` The argument must be a pointer to `void`. The value of the pointer is converted to a set of sequences of printable characters, which should be the same as the set of sequences that are matched by the `%p` conversion of the `scanf(3C)` function.

`n` The argument must be a pointer to an integer into which is written the number of bytes written to the output standard I/O stream so far by this call to one of the `printf()` functions. No argument is converted.

`%` Print a `%`; no argument is converted. The entire conversion specification must be `%%`.

If a conversion specification does not match one of the above forms, the behavior is undefined.

If a floating-point value is the internal representation for infinity, the output is `[±]Infinity`, where *Infinity* is either `Infinity` or `Inf`, depending on the desired output string length. Printing of the sign follows the rules described above.

If a floating-point value is the internal representation for “not-a-number,” the output is `[±]NaN`. Printing of the sign follows the rules described above.

sprintf(3C)

	<p>In no case does a non-existent or small field width cause truncation of a field; if the result of a conversion is wider than the field width, the field is simply expanded to contain the conversion result. Characters generated by <code>printf()</code> and <code>fprintf()</code> are printed as if the <code>putc(3C)</code> function had been called.</p> <p>The <code>st_ctime</code> and <code>st_mtime</code> fields of the file will be marked for update between the call to a successful execution of <code>printf()</code> or <code>fprintf()</code> and the next successful completion of a call to <code>fflush(3C)</code> or <code>fclose(3C)</code> on the same stream or a call to <code>exit(3C)</code> or <code>abort(3C)</code>.</p>						
RETURN VALUES	<p>The <code>printf()</code>, <code>fprintf()</code>, and <code>sprintf()</code> functions return the number of bytes transmitted (excluding the terminating null byte in the case of <code>sprintf()</code>).</p> <p>The <code>snprintf()</code> function returns the number of characters formatted, that is, the number of characters that would have been written to the buffer if it were large enough. If the value of <code>n</code> is 0 on a call to <code>snprintf()</code>, an unspecified value less than 1 is returned.</p> <p>Each function returns a negative value if an output error was encountered.</p>						
ERRORS	<p>For the conditions under which <code>printf()</code> and <code>fprintf()</code> will fail and may fail, refer to <code>fputc(3C)</code> or <code>fputwc(3C)</code>.</p> <p>In addition, all forms of <code>printf()</code> may fail if:</p> <table><tr><td><code>EILSEQ</code></td><td>A wide-character code that does not correspond to a valid character has been detected.</td></tr><tr><td><code>EINVAL</code></td><td>There are insufficient arguments.</td></tr></table> <p>In addition, <code>printf()</code> and <code>fprintf()</code> may fail if:</p> <table><tr><td><code>ENOMEM</code></td><td>Insufficient storage space is available.</td></tr></table>	<code>EILSEQ</code>	A wide-character code that does not correspond to a valid character has been detected.	<code>EINVAL</code>	There are insufficient arguments.	<code>ENOMEM</code>	Insufficient storage space is available.
<code>EILSEQ</code>	A wide-character code that does not correspond to a valid character has been detected.						
<code>EINVAL</code>	There are insufficient arguments.						
<code>ENOMEM</code>	Insufficient storage space is available.						
USAGE	<p>If the application calling the <code>printf()</code> functions has any objects of type <code>wint_t</code> or <code>wchar_t</code>, it must also include the header <code><wchar.h></code> to have these objects defined.</p> <p>The <code>sprintf()</code> and <code>snprintf()</code> functions are MT-Safe in multithreaded applications. The <code>printf()</code> and <code>fprintf()</code> functions can be used safely in multithreaded applications, as long as <code>setlocale(3C)</code> is not being called to change the locale.</p>						
Escape Character Sequences	<p>It is common to use the following escape sequences built into the C language when entering format strings for the <code>printf()</code> functions, but these sequences are processed by the C compiler, not by the <code>printf()</code> function.</p> <table><tr><td><code>\a</code></td><td>Alert. Ring the bell.</td></tr><tr><td><code>\b</code></td><td>Backspace. Move the printing position to one character before the current position, unless the current position is the start of a line.</td></tr></table>	<code>\a</code>	Alert. Ring the bell.	<code>\b</code>	Backspace. Move the printing position to one character before the current position, unless the current position is the start of a line.		
<code>\a</code>	Alert. Ring the bell.						
<code>\b</code>	Backspace. Move the printing position to one character before the current position, unless the current position is the start of a line.						

<code>\f</code>	Form feed. Move the printing position to the initial printing position of the next logical page.
<code>\n</code>	Newline. Move the printing position to the start of the next line.
<code>\r</code>	Carriage return. Move the printing position to the start of the current line.
<code>\t</code>	Horizontal tab. Move the printing position to the next implementation-defined horizontal tab position on the current line.
<code>\v</code>	Vertical tab. Move the printing position to the start of the next implementation-defined vertical tab position.

In addition, the C language supports character sequences of the form

`\octal-numberand`

`\hex-number` which translates into the character represented by the octal or hexadecimal number. For example, if ASCII representations are being used, the letter 'a' may be written as `'\141'` and 'Z' as `'\132'`. This syntax is most frequently used to represent the null character as `'\0'`. This is exactly equivalent to the numeric constant zero (0). Note that the octal number does not include the zero prefix as it would for a normal octal constant. To specify a hexadecimal number, omit the zero so that the prefix is an 'x' (uppercase 'X' is not allowed in this context). Support for hexadecimal sequences is an ANSI extension. See `standards(5)`.

EXAMPLES

EXAMPLE 1 To print the language-independent date and time format, the following statement could be used:

```
printf (format, weekday, month, day, hour, min);
```

For American usage, *format* could be a pointer to the string:

```
"%s, %s %d, %d:%.2d\n"
```

producing the message:

```
Sunday, July 3, 10:02
```

whereas for German usage, *format* could be a pointer to the string:

```
"%1$s, %3$d. %2$s, %4$d:%5$.2d\n"
```

producing the message:

```
Sonntag, 3. Juli, 10:02
```

EXAMPLE 2 To print a date and time in the form `Sunday, July 3, 10:02`, where *weekday* and *month* are pointers to null-terminated strings:

```
printf("%s, %s %i, %d:%.2d", weekday, month, day, hour, min);
```

sprintf(3C)

EXAMPLE 2 To print a date and time in the form `Sunday, July 3, 10:02`, where `weekday` and `month` are pointers to null-terminated strings: *(Continued)*

EXAMPLE 3 To print pi to 5 decimal places:

```
printf("pi = %.5f", 4 * atan(1.0));
```

Default

EXAMPLE 4 The following example applies only to applications which are not standard-conforming (see `standards(5)`). To print a list of names in columns which are 20 characters wide:

```
printf("%20s%20s%20s", lastname, firstname, middlename);
```

ATTRIBUTES

NAME	printf, fprintf, sprintf, vprintf, fprintf, vsprintf – formatted output conversion
SYNOPSIS	<pre> /usr/ucb/cc [flag ...] file ... #include <stdio.h> int printf(format, ...); const char *format; int fprintf(stream, format, va_list); FILE *stream; char *format; va_dcl; char *sprintf(s, format, va_list); char *s, *format; va_dcl; int vprintf(format, ap); char *format; va_list ap; int fprintf(stream, format, ap); FILE *stream; char *format; va_list ap; char *vsprintf(s, format, ap); char *s, *format; va_list ap; </pre>
DESCRIPTION	<p>printf() places output on the standard output stream <code>stdout</code>. fprintf() places output on the named output <code>stream</code>. sprintf() places “output,” followed by the NULL character (<code>\0</code>), in consecutive bytes starting at <code>*s</code>; it is the user’s responsibility to ensure that enough storage is available.</p> <p>vprintf(), fprintf(), and vsprintf() are the same as printf(), fprintf(), and sprintf() respectively, except that instead of being called with a variable number of arguments, they are called with an argument list as defined by <code>varargs(3HEAD)</code>.</p> <p>Each of these functions converts, formats, and prints its <code>args</code> under control of the <code>format</code>. The <code>format</code> is a character string which contains two types of objects: plain characters, which are simply copied to the output stream, and conversion specifications, each of which causes conversion and printing of zero or more <code>args</code>. The results are undefined if there are insufficient <code>args</code> for the format. If the format is exhausted while <code>args</code> remain, the excess <code>args</code> are simply ignored.</p> <p>Each conversion specification is introduced by the character <code>%</code>. After the <code>%</code>, the following appear in sequence:</p>

sprintf(3UCB)

- Zero or more *flags*, which modify the meaning of the conversion specification.
- An optional decimal digit string specifying a minimum *field width*. If the converted value has fewer characters than the field width, it will be padded on the left (or right, if the left-adjustment flag *'-'*, described below, has been given) to the field width. The padding is with blanks unless the field width digit string starts with a zero, in which case the padding is with zeros.
- A *precision* that gives the minimum number of digits to appear for the *d*, *i*, *o*, *u*, *x*, or *X* conversions, the number of digits to appear after the decimal point for the *e*, *E*, and *f* conversions, the maximum number of significant digits for the *g* and *G* conversion, or the maximum number of characters to be printed from a string in *s* conversion. The precision takes the form of a period (.) followed by a decimal digit string; a `NULL` digit string is treated as zero. Padding specified by the precision overrides the padding specified by the field width.
- An optional `l` (ell) specifying that a following *d*, *i*, *o*, *u*, *x*, or *X* conversion character applies to a long integer *arg*. An `l` before any other conversion character is ignored.
- A character that indicates the type of conversion to be applied.

A field width or precision or both may be indicated by an asterisk (*) instead of a digit string. In this case, an integer *arg* supplies the field width or precision. The *arg* that is actually converted is not fetched until the conversion letter is seen, so the *args* specifying field width or precision must appear *before* the *arg* (if any) to be converted. A negative field width argument is taken as a *'-'* flag followed by a positive field width. If the precision argument is negative, it will be changed to zero.

The flag characters and their meanings are:

-	The result of the conversion will be left-justified within the field.
+	The result of a signed conversion will always begin with a sign (+ or -).
blank	If the first character of a signed conversion is not a sign, a blank will be prefixed to the result. This implies that if the blank and + flags both appear, the blank flag will be ignored.
#	This flag specifies that the value is to be converted to an "alternate form." For <i>c</i> , <i>d</i> , <i>i</i> , <i>s</i> , and <i>u</i> conversions, the flag has no effect. For <i>o</i> conversion, it increases the precision to force the first digit of the result to be a zero. For <i>x</i> or <i>X</i> conversion, a non-zero result will have <code>0x</code> or <code>0X</code> prefixed to it. For <i>e</i> , <i>E</i> , <i>f</i> , <i>g</i> , and <i>G</i> conversions, the result will always contain a decimal point, even if no digits follow the point (normally, a decimal point appears in the result of these conversions only if a digit follows it). For <i>g</i> and <i>G</i> conversions, trailing zeroes will <i>not</i> be removed from the result (which they normally are).

The conversion characters and their meanings are:

d,i,o,u,x,X	The integer <i>arg</i> is converted to signed decimal (d or i), unsigned octal (o), unsigned decimal (u), or unsigned hexadecimal notation (x and X), respectively; the letters abcdef are used for x conversion and the letters ABCDEF for X conversion. The precision specifies the minimum number of digits to appear; if the value being converted can be represented in fewer digits, it will be expanded with leading zeroes. (For compatibility with older versions, padding with leading zeroes may alternatively be specified by prepending a zero to the field width. This does not imply an octal value for the field width.) The default precision is 1. The result of converting a zero value with a precision of zero is a NULL string.
f	The float or double <i>arg</i> is converted to decimal notation in the style <code>[-]ddd.ddd</code> where the number of digits after the decimal point is equal to the precision specification. If the precision is missing, 6 digits are given; if the precision is explicitly 0, no digits and no decimal point are printed.
e,E	The float or double <i>arg</i> is converted in the style <code>[-]d.ddd_{e±ddd}</code> , where there is one digit before the decimal point and the number of digits after it is equal to the precision; when the precision is missing, 6 digits are produced; if the precision is zero, no decimal point appears. The E format code will produce a number with E instead of e introducing the exponent. The exponent always contains at least two digits.
g,G	The float or double <i>arg</i> is printed in style f or e (or in style E in the case of a G format code), with the precision specifying the number of significant digits. The style used depends on the value converted: style e or E will be used only if the exponent resulting from the conversion is less than -4 or greater than the precision. Trailing zeroes are removed from the result; a decimal point appears only if it is followed by a digit.
The e, E f, g, and G formats print IEEE indeterminate values (infinity or not-a-number) as "Infinity" or "NaN" respectively.	
c	The character <i>arg</i> is printed.
s	The <i>arg</i> is taken to be a string (character pointer) and characters from the string are printed until a NULL character (<code>\0</code>) is encountered or until the number of characters indicated by the precision specification is reached. If the precision is missing, it is taken to be infinite, so all characters up to the first NULL character are printed. A NULL value for <i>arg</i> will yield undefined results.
%	Print a %; no argument is converted.

sprintf(3UCB)

In no case does a non-existent or small field width cause truncation of a field; if the result of a conversion is wider than the field width, the field is simply expanded to contain the conversion result. Padding takes place only if the specified field width exceeds the actual width. Characters generated by `printf()` and `fprintf()` are printed as if `putc(3C)` had been called.

RETURN VALUES Upon success, `printf()` and `fprintf()` return the number of characters transmitted, excluding the null character. `vprintf()` and `vfprintf()` return the number of characters transmitted. `sprintf()` and `vsprintf()` always return `s`. If an output error is encountered, `printf()`, `fprintf()`, `vprintf()`, and `vfprintf()` return EOF.

EXAMPLES **EXAMPLE 1** Examples of the `printf` Command To Print a Date and Time

To print a date and time in the form "Sunday, July 3, 10:02," where *weekday* and *month* are pointers to NULL-terminated strings:

```
printf("%s, %s %i, %d:%.2d", weekday, month, day, hour, min);
```

EXAMPLE 2 Examples of the `printf` Command To Print to Five Decimal Places

To print to five decimal places:

```
printf("pi = %.5f", 4 * atan(1. 0));
```

SEE ALSO `econvert(3C)`, `putc(3C)`, `scanf(3C)`, `vprintf(3C)`, `varargs(3HEAD)`

NOTES Use of these interfaces should be restricted to only applications written on BSD platforms. Use of these interfaces with any of the system libraries or in multi-thread applications is unsupported.

Very wide fields (>128 characters) fail.

NAME	rand, srand, rand_r – simple random-number generator				
SYNOPSIS	<pre>#include <stdlib.h> int rand(void); void srand(unsigned int seed); int rand_r(unsigned int *seed);</pre>				
DESCRIPTION	<p>The rand() function uses a multiplicative congruential random-number generator with period 2^{32} that returns successive pseudo-random numbers in the range of 0 to RAND_MAX (defined in <stdlib.h>).</p> <p>The srand() function uses the argument <i>seed</i> as a seed for a new sequence of pseudo-random numbers to be returned by subsequent calls to rand(). If srand() is then called with the same <i>seed</i> value, the sequence of pseudo-random numbers will be repeated. If rand() is called before any calls to srand() have been made, the same sequence will be generated as when srand() is first called with a <i>seed</i> value of 1.</p> <p>The rand_r() function has the same functionality as rand() except that a pointer to a seed <i>seed</i> must be supplied by the caller. The seed to be supplied is not the same seed as in srand().</p>				
USAGE	<p>The spectral properties of rand() are limited. The drand48(3C) function provides a better, more elaborate random-number generator.</p> <p>The rand() is unsafe in multithreaded applications. The rand_r() function is MT-Safe, and should be used instead. The srand() function is unsafe in multithreaded applications.</p> <p>When compiling multithreaded applications, the <code>_REENTRANT</code> flag must be defined on the compile line. This flag should only be used in multithreaded applications.</p>

srand(3UCB)

NAME	rand, srand – simple random number generator
SYNOPSIS	<pre>/usr/ucb/cc[flag ...] file ... int rand() int srand(seed); unsigned seed;</pre>
DESCRIPTION	<p>rand() uses a multiplicative congruential random number generator with period 2^{32} to return successive pseudo-random numbers in the range from 0 to "$2^{31} - 1$."</p> <p>srand() can be called at any time to reset the random-number generator to a random starting point. The generator is initially seeded with a value of 1.</p>
SEE ALSO	drand48(3C), rand(3C), random(3C)
NOTES	<p>Use of these interfaces should be restricted to only applications written on BSD platforms. Use of these interfaces with any of the system libraries or in multi-thread applications is unsupported.</p> <p>The spectral properties of rand() leave a great deal to be desired. drand48(3C) and random(3C) provide much better, though more elaborate, random-number generators.</p> <p>The low bits of the numbers generated are not very random; use the middle bits. In particular the lowest bit alternates between 0 and 1.</p>

NAME	drand48, erand48, lrand48, nrand48, mrand48, jrand48, srand48, seed48, lcong48 – generate uniformly distributed pseudo-random numbers
SYNOPSIS	<pre>#include <stdlib.h> double drand48(void); double erand48(unsigned short <i>x_i[3]</i>); long lrand48(void); long nrand48(unsigned short <i>x_i[3]</i>); long mrnd48(void); long jrnd48(unsigned short <i>x_i[3]</i>); void srand48(long <i>seedval</i>); unsigned short *seed48(unsigned short <i>seed16v[3]</i>); void lcong48(unsigned short <i>param[7]</i>);</pre>
DESCRIPTION	<p>This family of functions generates pseudo-random numbers using the well-known linear congruential algorithm and 48-bit integer arithmetic.</p> <p>Functions <code>drand48()</code> and <code>erand48()</code> return non-negative double-precision floating-point values uniformly distributed over the interval [0.0, 1.0).</p> <p>Functions <code>lrand48()</code> and <code>nrand48()</code> return non-negative long integers uniformly distributed over the interval $[0, 2^{31}]$.</p> <p>Functions <code>mrnd48()</code> and <code>jrnd48()</code> return signed long integers uniformly distributed over the interval $[-2^{31}, 2^{31}]$.</p> <p>Functions <code>srand48()</code>, <code>seed48()</code>, and <code>lcong48()</code> are initialization entry points, one of which should be invoked before either <code>drand48()</code>, <code>lrand48()</code>, or <code>mrnd48()</code> is called. (Although it is not recommended practice, constant default initializer values will be supplied automatically if <code>drand48()</code>, <code>lrand48()</code>, or <code>mrnd48()</code> is called without a prior call to an initialization entry point.) Functions <code>erand48()</code>, <code>nrand48()</code>, and <code>jrnd48()</code> do not require an initialization entry point to be called first.</p> <p>All the routines work by generating a sequence of 48-bit integer values, X_i, according to the linear congruential formula</p> $X_{n+1} = (aX_n + c) \bmod m \quad n \geq 0.$ <p>The parameter $m = 2^{48}$; hence 48-bit integer arithmetic is performed. Unless <code>lcong48()</code> has been invoked, the multiplier value a and the addend value c are given by</p> $a = 5DEECE66D_{16} = 273673163155_8$

srand48(3C)

$c = B_{16} = 13_8$.

The value returned by any of the functions `drand48()`, `erand48()`, `lrand48()`, `nrand48()`, `mrnd48()`, or `jrand48()` is computed by first generating the next 48-bit X_i in the sequence. Then the appropriate number of bits, according to the type of data item to be returned, are copied from the high-order (leftmost) bits of X_i and transformed into the returned value.

The functions `drand48()`, `lrand48()`, and `mrnd48()` store the last 48-bit X_i generated in an internal buffer. X_i must be initialized prior to being invoked. The functions `erand48()`, `nrand48()`, and `jrand48()` require the calling program to provide storage for the successive X_i values in the array specified as an argument when the functions are invoked. These routines do not have to be initialized; the calling program must place the desired initial value of X_i into the array and pass it as an argument. By using different arguments, functions `erand48()`, `nrand48()`, and `jrand48()` allow separate modules of a large program to generate several *independent* streams of pseudo-random numbers, that is, the sequence of numbers in each stream will *not* depend upon how many times the routines have been called to generate numbers for the other streams.

The initializer function `srand48()` sets the high-order 32 bits of X_i to the 32 bits contained in its argument. The low-order 16 bits of X_i are set to the arbitrary value $330E_{16}$.

The initializer function `seed48()` sets the value of X_i to the 48-bit value specified in the argument array. In addition, the previous value of X_i is copied into a 48-bit internal buffer, used only by `seed48()`, and a pointer to this buffer is the value returned by `seed48()`. This returned pointer, which can just be ignored if not needed, is useful if a program is to be restarted from a given point at some future time — use the pointer to get at and store the last X_i value, and then use this value to reinitialize using `seed48()` when the program is restarted.

The initialization function `lcng48()` allows the user to specify the initial X_i , the multiplier value a , and the addend value c . Argument array elements `param[0-2]` specify X_i , `param[3-5]` specify the multiplier a , and `param[6]` specifies the 16-bit addend c . After `lcng48()` has been called, a subsequent call to either `srand48()` or `seed48()` will restore the “standard” multiplier and addend values, a and c , specified above.

NAME	random, srandom, initstate, setstate – pseudorandom number functions
SYNOPSIS	<pre>#include <stdlib.h> long random(void); void srandom(unsigned int seed); char *initstate(unsigned int seed, char *state, size_t size); char *setstate(const char *state);</pre>
DESCRIPTION	<p>The <code>random()</code> function uses a nonlinear additive feedback random-number generator employing a default state array size of 31 long integers to return successive pseudo-random numbers in the range from 0 to $2^{31}-1$. The period of this random-number generator is approximately $16 \times (2^{31}-1)$. The size of the state array determines the period of the random-number generator. Increasing the state array size increases the period.</p> <p>The <code>srandom()</code> function initializes the current state array using the value of <i>seed</i>.</p> <p>The <code>random()</code> and <code>srandom()</code> functions have (almost) the same calling sequence and initialization properties as <code>rand()</code> and <code>srand()</code> (see <code>rand(3C)</code>). The difference is that <code>rand(3C)</code> produces a much less random sequence—in fact, the low dozen bits generated by <code>rand</code> go through a cyclic pattern. All the bits generated by <code>random()</code> are usable.</p> <p>The algorithm from <code>rand()</code> is used by <code>srandom()</code> to generate the 31 state integers. Because of this, different <code>srandom()</code> seeds often produce, within an offset, the same sequence of low order bits from <code>random()</code>. If low order bits are used directly, <code>random()</code> should be initialized with <code>setstate()</code> using high quality random values.</p> <p>Unlike <code>srand()</code>, <code>srandom()</code> does not return the old seed because the amount of state information used is much more than a single word. Two other routines are provided to deal with restarting/changing random number generators. With 256 bytes of state information, the period of the random-number generator is greater than 2^{69}, which should be sufficient for most purposes.</p> <p>Like <code>rand(3C)</code>, <code>random()</code> produces by default a sequence of numbers that can be duplicated by calling <code>srandom()</code> with 1 as the seed.</p> <p>The <code>initstate()</code> and <code>setstate()</code> functions handle restarting and changing random-number generators. The <code>initstate()</code> function allows a state array, pointed to by the <i>state</i> argument, to be initialized for future use. The <i>size</i> argument, which specifies the size in bytes of the state array, is used by <code>initstate()</code> to decide what type of random-number generator to use; the larger the state array, the more random the numbers. Values for the amount of state information are 8, 32, 64, 128, and 256 bytes. Other values greater than 8 bytes are rounded down to the nearest one of these values. For values smaller than 8, <code>random()</code> uses a simple linear congruential random number generator. The <i>seed</i> argument specifies a starting point for the random-number sequence and provides for restarting at the same point. The <code>initstate()</code> function returns a pointer to the previous state information array.</p>

srandom(3C)

If `initstate()` has not been called, then `random()` behaves as though `initstate()` had been called with `seed = 1` and `size = 128`.

If `initstate()` is called with `size < 8`, then `random()` uses a simple linear congruential random number generator.

Once a state has been initialized, `setstate()` allows switching between state arrays. The array defined by the `state` argument is used for further random-number generation until `initstate()` is called or `setstate()` is called again. The `setstate()` function returns a pointer to the previous state array.

RETURN VALUES

The `random()` function returns the generated pseudo-random number.

The `srandom()` function returns no value.

Upon successful completion, `initstate()` and `setstate()` return a pointer to the previous state array. Otherwise, a null pointer is returned.

ERRORS

No errors are defined.

USAGE

After initialization, a state array can be restarted at a different point in one of two ways:

- The `initstate()` function can be used, with the desired seed, state array, and size of the array.
- The `setstate()` function, with the desired state, can be used, followed by `srandom()` with the desired seed. The advantage of using both of these functions is that the size of the state array does not have to be saved once it is initialized.

EXAMPLES

EXAMPLE 1 Initialize an array.

The following example demonstrates the use of `initstate()` to initialize an array. It also demonstrates how to initialize an array and pass it to `setstate()`.

```
# include <stdlib.h>
static unsigned int state0[32];
static unsigned int state1[32] = {
    3,
    0x9a319039, 0x32d9c024, 0x9b663182, 0x5da1f342,
    0x7449e56b, 0xbdb1dbb0, 0xab5c5918, 0x946554fd,
    0x8c2e680f, 0xeb3d799f, 0xb11ee0b7, 0x2d436b86,
    0xda672e2a, 0x1588ca88, 0xe369735d, 0x904f35f7,
    0xd7158fd6, 0x6fa6f051, 0x616e6b96, 0xac94efdc,
    0xde3b81e0, 0xdf0a6fb5, 0xf103bc02, 0x48f340fb,
    0x36413f93, 0xc622c298, 0xf5a42ab8, 0x8a88d77b,
    0xf5ad9d0e, 0x8999220b, 0x27fb47b9
};
main() {
    unsigned seed;
    int n;
    seed = 1;
    n = 128;
    (void)initstate(seed, (char *)state0, n);
    printf("random() = %d0\
```

EXAMPLE 1 Initialize an array. (Continued)

```

", random());
    (void) setstate((char *)state1);
    printf("random() = %d\n",
", random());
}

```

ATTRIBUTES See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
MT-Level	See NOTES below.

SEE ALSO [drand48\(3C\)](#), [rand\(3C\)](#), [attributes\(5\)](#)

NOTES The `random()` and `srandom()` functions are unsafe in multithreaded applications.

Use of these functions in multithreaded applications is unsupported.

For `initstate()` and `setstate()`, the *state* argument must be aligned on an `int` boundary.

Newer and better performing random number generators such as `addrands()` and `lcrans()` are available with the SUNWspro package.

sscanf(3C)

NAME	scanf, fscanf, sscanf, vscanf, vfscanf, vsscanf – convert formatted input
SYNOPSIS	<pre>#include <stdio.h> int scanf(const char *format, ...); int fscanf(FILE*stream, const char *format, ...); int sscanf(const char *s, const char *format, ...); #include <stdarg.h> #include <stdio.h> int vscanf(const char *format, va_list arg); int vfscanf(FILE *stream, const char *format, va_list arg); int vsscanf(const char *s, const char *format, va_list arg);</pre>
DESCRIPTION	<p>The <code>scanf()</code> function reads from the standard input stream <code>stdin</code>.</p> <p>The <code>fscanf()</code> function reads from the named input <i>stream</i>.</p> <p>The <code>sscanf()</code> function reads from the string <i>s</i>.</p> <p>The <code>vscanf()</code>, <code>vfscanf()</code>, and <code>vsscanf()</code> functions are equivalent to the <code>scanf()</code>, <code>fscanf()</code>, and <code>sscanf()</code> functions, respectively, except that instead of being called with a variable number of arguments, they are called with an argument list as defined by the <code><stdarg.h></code> header (see <code>stdarg(3HEAD)</code>). These functions do not invoke the <code>va_end()</code> macro. Applications using these functions should call <code>va_end(ap)</code> afterwards to clean up.</p> <p>Each function reads bytes, interprets them according to a format, and stores the results in its arguments. Each expects, as arguments, a control string <i>format</i> described below, and a set of <i>pointer</i> arguments indicating where the converted input should be stored. The result is undefined if there are insufficient arguments for the format. If the format is exhausted while arguments remain, the excess arguments are evaluated but are otherwise ignored.</p> <p>Conversions can be applied to the <i>n</i>th argument after the <i>format</i> in the argument list, rather than to the next unused argument. In this case, the conversion character <code>%</code> (see below) is replaced by the sequence <code>%n\$</code>, where <i>n</i> is a decimal integer in the range <code>[1, NL_ARGMAX]</code>. This feature provides for the definition of format strings that select arguments in an order appropriate to specific languages. In format strings containing the <code>%n\$</code> form of conversion specifications, it is unspecified whether numbered arguments in the argument list can be referenced from the format string more than once.</p> <p>The <i>format</i> can contain either form of a conversion specification, that is, <code>%</code> or <code>%n\$</code>, but the two forms cannot normally be mixed within a single <i>format</i> string. The only exception to this is that <code>%%</code> or <code>%*</code> can be mixed with the <code>%n\$</code> form.</p>

The `scanf()` function in all its forms allows for detection of a language-dependent radix character in the input string. The radix character is defined in the program's locale (category `LC_NUMERIC`). In the POSIX locale, or in a locale where the radix character is not defined, the radix character defaults to a period (`.`).

The format is a character string, beginning and ending in its initial shift state, if any, composed of zero or more directives. Each directive is composed of one of the following:

- one or more *white-space characters* (space, tab, newline, vertical-tab or form-feed characters);
- an *ordinary character* (neither `%` nor a white-space character); or
- a *conversion specification*.

Conversion Specifications

Each conversion specification is introduced by the character `%` or the character sequence `%n$`, after which the following appear in sequence:

- An optional assignment-suppressing character `*`.
- An optional non-zero decimal integer that specifies the maximum field width.
- An optional size modifier `h`, `l` (ell), `ll` (ell ell), or `L` indicating the size of the receiving object. The conversion characters `d`, `i`, and `n` must be preceded by `h` if the corresponding argument is a pointer to `short int` rather than a pointer to `int`, by `l` (ell) if it is a pointer to `long int`, or by `ll` (ell ell) if it is a pointer to `long long int`. Similarly, the conversion characters `o`, `u`, and `x` must be preceded by `h` if the corresponding argument is a pointer to `unsigned short int` rather than a pointer to `unsigned int`, by `l` (ell) if it is a pointer to `unsigned long int`, or by `ll` (ell ell) if it is a pointer to `unsigned long long int`. The conversion characters `e`, `f`, and `g` must be preceded by `l` (ell) if the corresponding argument is a pointer to `double` rather than a pointer to `float`, or by `L` if it is a pointer to `long double`. Finally, the conversion characters `c`, `s`, and `[` must be preceded by `l` (ell) if the corresponding argument is a pointer to `wchar_t` rather than a pointer to a character type. If an `h`, `l` (ell), `ll` (ell ell), or `L` appears with any other conversion character, the behavior is undefined.
- A conversion character that specifies the type of conversion to be applied. The valid conversion characters are described below.

The `scanf()` functions execute each directive of the format in turn. If a directive fails, as detailed below, the function returns. Failures are described as input failures (due to the unavailability of input bytes) or matching failures (due to inappropriate input).

A directive composed of one or more white-space characters is executed by reading input until no more valid input can be read, or up to the first byte which is not a white-space character which remains unread.

A directive that is an ordinary character is executed as follows. The next byte is read from the input and compared with the byte that comprises the directive; if the comparison shows that they are not equivalent, the directive fails, and the differing and subsequent bytes remain unread.

sscanf(3C)

A directive that is a conversion specification defines a set of matching input sequences, as described below for each conversion character. A conversion specification is executed in the following steps:

Input white-space characters (as specified by `isspace(3C)`) are skipped, unless the conversion specification includes a `[\, c, C, or n` conversion character.

An item is read from the input, unless the conversion specification includes an `n` conversion character. An input item is defined as the longest sequence of input bytes (up to any specified maximum field width, which may be measured in characters or bytes dependent on the conversion character) which is an initial subsequence of a matching sequence. The first byte, if any, after the input item remains unread. If the length of the input item is 0, the execution of the conversion specification fails; this condition is a matching failure, unless end-of-file, an encoding error, or a read error prevented input from the stream, in which case it is an input failure.

Except in the case of a `%` conversion character, the input item (or, in the case of a `%n` conversion specification, the count of input bytes) is converted to a type appropriate to the conversion character. If the input item is not a matching sequence, the execution of the conversion specification fails; this condition is a matching failure. Unless assignment suppression was indicated by a `*`, the result of the conversion is placed in the object pointed to by the first argument following the *format* argument that has not already received a conversion result if the conversion specification is introduced by `%`, or in the *n*th argument if introduced by the character sequence `%n$`. If this object does not have an appropriate type, or if the result of the conversion cannot be represented in the space provided, the behavior is undefined.

Conversion Characters

The following conversion characters are valid:

- `d` Matches an optionally signed decimal integer, whose format is the same as expected for the subject sequence of `strtol(3C)` with the value 10 for the *base* argument. In the absence of a size modifier, the corresponding argument must be a pointer to `int`.
- `i` Matches an optionally signed integer, whose format is the same as expected for the subject sequence of `strtol()` with 0 for the *base* argument. In the absence of a size modifier, the corresponding argument must be a pointer to `int`.
- `o` Matches an optionally signed octal integer, whose format is the same as expected for the subject sequence of `strtoul(3C)` with the value 8 for the *base* argument. In the absence of a size modifier, the corresponding argument must be a pointer to `unsigned int`.
- `u` Matches an optionally signed decimal integer, whose format is the same as expected for the subject sequence of `strtoul()` with the value 10 for the *base* argument. In the absence of a size modifier, the corresponding argument must be a pointer to `unsigned int`.
- `x` Matches an optionally signed hexadecimal integer, whose format is the same as expected for the subject sequence of `strtoul()` with the value 16

for the *base* argument. In the absence of a size modifier, the corresponding argument must be a pointer to `unsigned int`.

e,f,g Matches an optionally signed floating-point number, whose format is the same as expected for the subject sequence of `strtod(3C)`. In the absence of a size modifier, the corresponding argument must be a pointer to `float`.

If the `printf(3C)` family of functions generates character string representations for infinity and NaN (a 7858 symbolic entity encoded in floating-point format) to support the ANSI/IEEE Std 754: 1985 standard, the `scanf()` family of functions will recognize them as input.

s Matches a sequence of bytes that are not white-space characters. The corresponding argument must be a pointer to the initial byte of an array of `char`, `signed char`, or `unsigned char` large enough to accept the sequence and a terminating null character code, which will be added automatically.

If an `l` (*ell*) qualifier is present, the input is a sequence of characters that begins in the initial shift state. Each character is converted to a wide-character as if by a call to the `mbrtowc(3C)` function, with the conversion state described by an `mbstate_t` object initialized to zero before the first character is converted. The corresponding argument must be a pointer to an array of `wchar_t` large enough to accept the sequence and the terminating null wide-character, which will be added automatically.

[Matches a non-empty sequence of characters from a set of expected characters (the *scanset*). The normal skip over white-space characters is suppressed in this case. The corresponding argument must be a pointer to the initial byte of an array of `char`, `signed char`, or `unsigned char` large enough to accept the sequence and a terminating null byte, which will be added automatically.

If an `l` (*ell*) qualifier is present, the input is a sequence of characters that begins in the initial shift state. Each character in the sequence is converted to a wide-character as if by a call to the `mbrtowc()` function, with the conversion state described by an `mbstate_t` object initialized to zero before the first character is converted. The corresponding argument must be a pointer to an array of `wchar_t` large enough to accept the sequence and the terminating null wide-character, which will be added automatically.

The conversion specification includes all subsequent characters in the *format* string up to and including the matching right square bracket (`]`). The characters between the square brackets (the *scanlist*) comprise the *scanset*, unless the character after the left square bracket is a circumflex (`^`), in which case the *scanset* contains all characters that do not appear in the *scanlist* between the circumflex and the right square bracket. If the

sscanf(3C)

	conversion specification begins with [] or [^], the right square bracket is included in the scanlist and the next right square bracket is the matching right square bracket that ends the conversion specification; otherwise the first right square bracket is the one that ends the conversion specification. If a - is in the scanlist and is not the first character, nor the second where the first character is a ^, nor the last character, it indicates a range of characters to be matched.
c	Matches a sequence of characters of the number specified by the field width (1 if no field width is present in the conversion specification). The corresponding argument must be a pointer to the initial byte of an array of char, signed char, or unsigned char large enough to accept the sequence. No null byte is added. The normal skip over white-space characters is suppressed in this case. If an l (ell) qualifier is present, the input is a sequence of characters that begins in the initial shift state. Each character in the sequence is converted to a wide-character as if by a call to the <code>mbrtowc()</code> function, with the conversion state described by an <code>mbstate_t</code> object initialized to zero before the first character is converted. The corresponding argument must be a pointer to an array of <code>wchar_t</code> large enough to accept the resulting sequence of wide-characters. No null wide-character is added.
p	Matches the set of sequences that is the same as the set of sequences that is produced by the %p conversion of the corresponding <code>printf(3C)</code> functions. The corresponding argument must be a pointer to a pointer to void. If the input item is a value converted earlier during the same program execution, the pointer that results will compare equal to that value; otherwise the behavior of the %p conversion is undefined.
n	No input is consumed. The corresponding argument must be a pointer to the integer into which is to be written the number of bytes read from the input so far by this call to the <code>scanf()</code> functions. Execution of a %n conversion specification does not increment the assignment count returned at the completion of execution of the function.
C	Same as lc.
S	Same as ls.
%	Matches a single %; no conversion or assignment occurs. The complete conversion specification must be %%.

If a conversion specification is invalid, the behavior is undefined.

The conversion characters E, G, and X are also valid and behave the same as, respectively, e, g, and x.

If end-of-file is encountered during input, conversion is terminated. If end-of-file occurs before any bytes matching the current conversion specification (except for %n) have been read (other than leading white-space characters, where permitted),

execution of the current conversion specification terminates with an input failure. Otherwise, unless execution of the current conversion specification is terminated with a matching failure, execution of the following conversion specification (if any) is terminated with an input failure.

Reaching the end of the string in `sscanf()` is equivalent to encountering end-of-file for `fscanf()`.

If conversion terminates on a conflicting input, the offending input is left unread in the input. Any trailing white space (including newline characters) is left unread unless matched by a conversion specification. The success of literal matches and suppressed assignments is only directly determinable via the `%n` conversion specification.

The `fscanf()` and `scanf()` functions may mark the `st_atime` field of the file associated with *stream* for update. The `st_atime` field will be marked for update by the first successful execution of `fgetc(3C)`, `fgets(3C)`, `fread(3C)`, `fscanf()`, `getc(3C)`, `getchar(3C)`, `gets(3C)`, or `scanf()` using *stream* that returns data not supplied by a prior call to `ungetc(3C)`.

RETURN VALUES

Upon successful completion, these functions return the number of successfully matched and assigned input items; this number can be 0 in the event of an early matching failure. If the input ends before the first matching failure or conversion, EOF is returned. If a read error occurs the error indicator for the stream is set, EOF is returned, and `errno` is set to indicate the error.

ERRORS

For the conditions under which the `scanf()` functions will fail and may fail, refer to `fgetc(3C)` or `fgetwc(3C)`.

In addition, `fscanf()` may fail if:

`EILSEQ` Input byte sequence does not form a valid character.
`EINVAL` There are insufficient arguments.

USAGE

If the application calling the `scanf()` functions has any objects of type `wint_t` or `wchar_t`, it must also include the header `<wchar.h>` to have these objects defined.

EXAMPLES

EXAMPLE 1 The call:

```
int i, n; float x; char name[50];
n = scanf("%d%f%s", &i, &x, name)
```

with the input line:

```
25 54.32E-1 Hamster
```

will assign to *n* the value 3, to *i* the value 25, to *x* the value 5.432, and *name* will contain the string Hamster.

sscanf(3C)

EXAMPLE 2 The call:

```
int i; float x; char name[50];
(void) scanf("%2d%f%d %[0123456789]", &i, &x, name);
```

with input:

```
56789 0123 56a72
```

will assign 56 to *i*, 789.0 to *x*, skip 0123, and place the string 56\0 in *name*. The next call to `getchar(3C)` will return the character a.

NAME | `ssignal, gsignal` – software signals

SYNOPSIS | `#include <signal.h>`
`void(*ssignal (int sig, int (*action) (int))) (int);`
`int gsignal (int sig);`

DESCRIPTION | The `ssignal()` and `gsignal()` functions implement a software facility similar to `signal(3C)`. This facility is made available to users for their own purposes.

ssignal() | Software signals made available to users are associated with integers in the inclusive range 1 through 17. A call to `ssignal()` associates a procedure, *action*, with the software signal *sig*; the software signal, *sig*, is raised by a call to `gsignal()`. Raising a software signal causes the action established for that signal to be taken.

The first argument to `ssignal()` is a number identifying the type of signal for which an action is to be established. The second argument defines the action; it is either the name of a (user-defined) *action function* or one of the manifest constants `SIG_DFL` (default) or `SIG_IGN` (ignore). The `ssignal()` function returns the action previously established for that signal type; if no action has been established or the signal number is illegal, `ssignal()` returns `SIG_DFL`.

gsignal() | The `gsignal()` raises the signal identified by its argument, *sig*.

If an action function has been established for *sig*, then that action is reset to `SIG_DFL` and the action function is entered with argument *sig*. The `gsignal()` function returns the value returned to it by the action function.

If the action for *sig* is `SIG_IGN`, `gsignal()` returns the value 1 and takes no other action.

If the action for *sig* is `SIG_DFL`, `gsignal()` returns the value 0 and takes no other action.

If *sig* has an illegal value or no action was ever specified for *sig*, `gsignal()` returns the value 0 and takes no other action.

stack_getbounds(3C)

NAME | stack_getbounds – retrieve stack boundaries

SYNOPSIS | #include <ucontext.h>
| int **stack_getbounds**(stack_t *sp);

DESCRIPTION | The `stack_getbounds()` function retrieves the stack boundaries that the calling thread is currently operating on. If the thread is currently operating on the alternate signal stack, this function will retrieve the bounds of that stack.

| If successful, `stack_getbounds()` sets the `ss_sp` member of the `stack_t` structure pointed to by `sp` to the base of the stack region and the `ss_size` member to its size (maximum extent) in bytes. The `ss_flags` member is set to `SS_ONSTACK` if the calling thread is executing on its alternate signal stack, and zero otherwise.

RETURN VALUES | Upon successful completion, `stack_getbounds()` returns 0. Otherwise, -1 is returned and `errno` is set to indicate the error.

ERRORS | The `stack_getbounds()` function will fail if:
| EFAULT The `sp` argument does not refer to a valid address.

ATTRIBUTES | See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Interface Stability	Evolving
MT-Level	Async-Signal-Safe

SEE ALSO | `getustack(2)`, `sigaction(2)`, `sigaltstack(2)`, `stack_setbounds(3C)`, `attributes(5)`

NAME | `_stack_grow` – express an intention to extend the stack

SYNOPSIS | `#include <ucontext.h>`
`void * _stack_grow(void *addr);`

DESCRIPTION | The `_stack_grow()` function indicates to the system that the stack is about to be extended to the address specified by *addr*. If extending the stack to this address would violate the stack boundaries as retrieved by `stack_getbounds(3C)`, a `SIGSEGV` is raised.

If the disposition of `SIGSEGV` is `SIG_DFL`, the process is terminated and a core dump is generated. If the application has installed its own `SIGSEGV` handler to run on the alternate signal stack, the signal information passed to the handler will be such that a call to `stack_violation(3C)` with these parameters returns 1.

The *addr* argument is a biased stack pointer value. See the Solaris 64-bit Developer’s Guide.

This function has no effect if the specified address, *addr*, is within the bounds of the current stack.

RETURN VALUES | If the `_stack_grow()` function succeeds and does not detect a stack violation, it returns *addr*.

ERRORS | No errors are defined.

USAGE | The `_stack_grow()` function does not actually adjust the stack pointer register. The caller is responsible for manipulating the stack pointer register once `_stack_grow()` returns.

The `_stack_grow()` function is typically invoked by code created by the compilation environment prior to executing code that modifies the stack pointer. It can also be used by hand-written assembly routines to allocate stack-based storage safely.

stack_inbounds(3C)

NAME	stack_inbounds – determine if address is within stack boundaries						
SYNOPSIS	<pre>#include <ucontext.h> int stack_inbounds(void *addr);</pre>						
DESCRIPTION	The <code>stack_inbounds()</code> function returns a boolean value indicating whether the address specified by <i>addr</i> is within the boundaries of the stack of the calling thread. The address is compared to the stack boundary information returned by a call to <code>stack_getbounds(3C)</code> .						
RETURN VALUES	The <code>stack_inbounds()</code> function returns 0 to indicate that <i>addr</i> is not within the current stack bounds, or a non-zero value to indicate that <i>addr</i> is within the stack bounds.						
ERRORS	No errors are defined.						
ATTRIBUTES	See <code>attributes(5)</code> for descriptions of the following attributes:

SEE ALSO	<code>stack_getbounds(3C)</code> , <code>attributes(5)</code>						

NAME	stack_setbounds – update stack boundaries						
SYNOPSIS	<pre>#include <ucontext.h> int stack_setbounds(const stack_t *sp);</pre>						
DESCRIPTION	The <code>stack_setbounds()</code> function updates the current base and bounds of the stack for the current thread to the bounds specified by the <code>stack_t</code> structure pointed to by <code>sp</code> . The <code>ss_sp</code> member refers to the virtual address of the base of the stack memory. The <code>ss_size</code> member refers to the size of the stack in bytes. The <code>ss_flags</code> member must be set to 0.						
RETURN VALUES	Upon successful completion, <code>stack_setbounds()</code> returns 0. Otherwise, -1 is returned and <code>errno</code> is set to indicate the error.						
ERRORS	The <code>stack_setbounds()</code> function will fail if: <table border="0" style="margin-left: 2em;"> <tr> <td style="vertical-align: top;">EFAULT</td> <td>The <code>sp</code> argument does not refer to a valid address or the <code>ss_sp</code> member of the <code>stack_t</code> structure pointed to by <code>sp</code> points to an illegal address.</td> </tr> <tr> <td style="vertical-align: top;">EINVAL</td> <td>The <code>ss_sp</code> member of the <code>stack_t</code> structure pointed to by <code>sp</code> is not properly aligned, the <code>ss_size</code> member is too small or is not properly aligned, or the <code>ss_flags</code> member is non-zero.</td> </tr> </table>	EFAULT	The <code>sp</code> argument does not refer to a valid address or the <code>ss_sp</code> member of the <code>stack_t</code> structure pointed to by <code>sp</code> points to an illegal address.	EINVAL	The <code>ss_sp</code> member of the <code>stack_t</code> structure pointed to by <code>sp</code> is not properly aligned, the <code>ss_size</code> member is too small or is not properly aligned, or the <code>ss_flags</code> member is non-zero.		
EFAULT	The <code>sp</code> argument does not refer to a valid address or the <code>ss_sp</code> member of the <code>stack_t</code> structure pointed to by <code>sp</code> points to an illegal address.						
EINVAL	The <code>ss_sp</code> member of the <code>stack_t</code> structure pointed to by <code>sp</code> is not properly aligned, the <code>ss_size</code> member is too small or is not properly aligned, or the <code>ss_flags</code> member is non-zero.						
USAGE	The <code>stack_setbounds()</code> function is intended for use by applications that are managing their own alternate stacks.						
ATTRIBUTES	See <code>attributes(5)</code> for descriptions of the following attributes: <table border="1" style="margin-left: 2em; width: 100%;"> <thead> <tr> <th style="text-align: center;">ATTRIBUTE TYPE</th> <th style="text-align: center;">ATTRIBUTE VALUE</th> </tr> </thead> <tbody> <tr> <td>Interface Stability</td> <td>Evolving</td> </tr> <tr> <td>MT-Level</td> <td>Async-Signal-Safe</td> </tr> </tbody> </table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	Interface Stability	Evolving	MT-Level	Async-Signal-Safe

stack_violation(3C)

NAME	stack_violation – determine stack boundary violation event
SYNOPSIS	<pre>#include <ucontext.h> int stack_violation(int sig, const siginfo_t *sip, const ucontext_t *ucp);</pre>
DESCRIPTION	The <code>stack_violation()</code> function returns a boolean value indicating whether the signal, <i>sig</i> , and accompanying signal information, <i>sip</i> , and saved context, <i>ucp</i> , represent a stack boundary violation event or a stack overflow.
RETURN VALUES	The <code>stack_violation()</code> function returns 0 if the signal does not represent a stack boundary violation event and 1 if the signal does represent a stack boundary violation event.
ERRORS	No errors are defined.
EXAMPLES	<p>EXAMPLE 1 Set up a signal handler to run on an alternate stack.</p> <p>The following example sets up a signal handler for SIGSEGV to run on an alternate signal stack. For each signal it handles, the handler emits a message to indicate if the signal was produced due to a stack boundary violation.</p> <pre>#include <stdlib.h> #include <unistd.h> #include <ucontext.h> #include <signal.h> static void handler(int sig, siginfo_t *sip, void *p) { ucontext_t *ucp = p; const char *str; if (stack_violation(sig, sip, ucp)) str = "stack violation.\n"; else str = "no stack violation.\n"; (void) write(STDERR_FILENO, str, strlen(str)); exit(1); } int main(int argc, char **argv) { struct sigaction sa; stack_t altstack; altstack.ss_size = SIGSTKSZ; altstack.ss_sp = malloc(SIGSTKSZ); altstack.ss_flags = 0; (void) sigaltstack(&altstack, NULL);</pre>

EXAMPLE 1 Set up a signal handler to run on an alternate stack. (Continued)

```

sa.sa_sigaction = handler;
(void) sigfillset(&sa.sa_mask);
sa.sa_flags = SA_ONSTACK | SA_SIGINFO;
(void) sigaction(SIGSEGV, &sa, NULL);

/*
 * The application is now set up to use stack_violation(3C).
 */

return (0);
}

```

USAGE An application typically uses `stack_violation()` in a signal handler that has been installed for `SIGSEGV` using `sigaction(2)` with the `SA_SIGINFO` flag set and is configured to run on an alternate signal stack.

stdio(3C)

NAME	stdio – standard buffered input/output package																		
SYNOPSIS	<pre>#include <stdio.h> extern FILE *stdin; extern FILE *stdout; extern FILE *stderr;</pre>																		
DESCRIPTION	<p>The functions described in the entries of section 3S of this manual constitute an efficient, user-level I/O buffering scheme. The in-line macros <code>getc()</code> and <code>putc()</code> handle characters quickly. The macros <code>getchar(3C)</code> and <code>putchar(3C)</code>, and the higher-level routines <code>fgetc(3C)</code>, <code>fgets(3C)</code>, <code>fprintf(3C)</code>, <code>fputc(3C)</code>, <code>fputs(3C)</code>, <code>fread(3C)</code>, <code>fscanf(3C)</code>, <code>fwrite(3C)</code>, <code>gets(3C)</code>, <code>getw(3C)</code>, <code>printf(3C)</code>, <code>puts(3C)</code>, <code>putw(3C)</code>, and <code>scanf(3C)</code> all use or act as if they use <code>getc()</code> and <code>putc()</code>; they can be freely intermixed.</p> <p>A file with associated buffering is called a <i>stream</i> (see <code>intro(3)</code>) and is declared to be a pointer to a defined type <code>FILE</code>. The <code>fopen(3C)</code> function creates certain descriptive data for a stream and returns a pointer to designate the stream in all further transactions. Normally, there are three open streams with constant pointers declared in the <code><stdio.h></code> header and associated with the standard open files:</p> <table><tr><td><code>stdin</code></td><td>standard input file</td></tr><tr><td><code>stdout</code></td><td>standard output file</td></tr><tr><td><code>stderr</code></td><td>standard error file</td></tr></table> <p>The following symbolic values in <code><unistd.h></code> define the file descriptors that will be associated with the C-language <code>stdin</code>, <code>stdout</code> and <code>stderr</code> when the application is started:</p> <table><tr><td><code>STDIN_FILENO</code></td><td>Standard input value</td><td>0</td><td><code>stdin</code></td></tr><tr><td><code>STDOUT_FILENO</code></td><td>Standard output value</td><td>1</td><td><code>stdout</code></td></tr><tr><td><code>STDERR_FILENO</code></td><td>Standard error value</td><td>2</td><td><code>stderr</code></td></tr></table> <p>The constant <code>NULL</code> designates a null pointer.</p> <p>The integer-constant <code>EOF</code> is returned upon end-of-file or error by most integer functions that deal with streams (see the individual descriptions for details).</p> <p>The integer constant <code>BUFSIZ</code> specifies the size of the buffers used by the particular implementation.</p> <p>The integer constant <code>FILENAME_MAX</code> specifies the number of bytes needed to hold the longest pathname of a file allowed by the implementation. If the system does not impose a maximum limit, this value is the recommended size for a buffer intended to hold a file's pathname.</p>	<code>stdin</code>	standard input file	<code>stdout</code>	standard output file	<code>stderr</code>	standard error file	<code>STDIN_FILENO</code>	Standard input value	0	<code>stdin</code>	<code>STDOUT_FILENO</code>	Standard output value	1	<code>stdout</code>	<code>STDERR_FILENO</code>	Standard error value	2	<code>stderr</code>
<code>stdin</code>	standard input file																		
<code>stdout</code>	standard output file																		
<code>stderr</code>	standard error file																		
<code>STDIN_FILENO</code>	Standard input value	0	<code>stdin</code>																
<code>STDOUT_FILENO</code>	Standard output value	1	<code>stdout</code>																
<code>STDERR_FILENO</code>	Standard error value	2	<code>stderr</code>																

The integer constant `FOPEN_MAX` specifies the minimum number of files that the implementation guarantees can be open simultaneously. Note that no more than 255 files may be opened using `fopen()`, and only file descriptors 0 through 255 can be used in a stream.

The functions and constants mentioned in the entries of section 3S of this manual are declared in that header and need no further declaration. The constants and the following “functions” are implemented as macros (redeclaration of these names is perilous): `getc()`, `getchar()`, `putc()`, `putchar()`, `ferror(3C)`, `feof(3C)`, `clearerr(3C)`, and `fileno(3C)`. There are also function versions of `getc()`, `getchar()`, `putc()`, `putchar()`, `ferror()`, `feof()`, `clearerr()`, and `fileno()`.

Output streams, with the exception of the standard error stream `stderr`, are by default buffered if the output refers to a file and line-buffered if the output refers to a terminal. The standard error output stream `stderr` is by default unbuffered, but use of `freopen()` (see `fopen(3C)`) will cause it to become buffered or line-buffered. When an output stream is unbuffered, information is queued for writing on the destination file or terminal as soon as written; when it is buffered, many characters are saved up and written as a block. When it is line-buffered, each line of output is queued for writing on the destination terminal as soon as the line is completed (that is, as soon as a new-line character is written or terminal input is requested). The `setbuf()` or `setvbuf()` functions (both described on the `setbuf(3C)` manual page) may be used to change the stream’s buffering strategy.

Interactions of Other FILE-Type C Functions

A single open file description can be accessed both through streams and through file descriptors. Either a file descriptor or a stream will be called a *handle* on the open file description to which it refers; an open file description may have several handles.

Handles can be created or destroyed by user action without affecting the underlying open file description. Some of the ways to create them include `fcntl(2)`, `dup(2)`, `fdopen(3C)`, `fileno(3C)` and `fork(2)` (which duplicates existing ones into new processes). They can be destroyed by at least `fclose(3C)` and `close(2)`, and by the `exec` functions (see `exec(2)`), which close some file descriptors and destroy streams.

A file descriptor that is never used in an operation and could affect the file offset (for example `read(2)`, `write(2)`, or `lseek(2)`) is not considered a handle in this discussion, but could give rise to one (as a consequence of `fdopen()`, `dup()`, or `fork()`, for example). This exception does include the file descriptor underlying a stream, whether created with `fopen()` or `fdopen()`, as long as it is not used directly by the application to affect the file offset. (The `read()` and `write()` functions implicitly affect the file offset; `lseek()` explicitly affects it.)

If two or more handles are used, and any one of them is a stream, their actions shall be coordinated as described below. If this is not done, the result is undefined.

A handle that is a stream is considered to be closed when either an `fclose()` or `freopen(3C)` is executed on it (the result of `freopen()` is a new stream for this discussion, which cannot be a handle on the same open file description as its previous

value) or when the process owning that stream terminates the `exit(2)` or `abort(3C)`. A file descriptor is closed by `close()`, `_exit()` (see `exit(2)`), or by one of the `exec` functions when `FD_CLOEXEC` is set on that file descriptor.

For a handle to become the active handle, the actions below must be performed between the last other user of the first handle (the current active handle) and the first other user of the second handle (the future active handle). The second handle then becomes the active handle. All activity by the application affecting the file offset on the first handle shall be suspended until it again becomes the active handle. (If a stream function has as an underlying function that affects the file offset, the stream function will be considered to affect the file offset. The underlying functions are described below.)

The handles need not be in the same process for these rules to apply. Note that after a `fork()`, two handles exist where one existed before. The application shall assure that, if both handles will ever be accessed, that they will both be in a state where the other could become the active handle first. The application shall prepare for a `fork()` exactly as if it were a change of active handle. (If the only action performed by one of the processes is one of the `exec` functions or `_exit()`, the handle is never accessed in that process.)

1. For the first handle, the first applicable condition below shall apply. After the actions required below are taken, the handle may be closed if it is still open.
 - a. If it is a file descriptor, no action is required.
 - b. If the only further action to be performed on any handle to this open file description is to close it, no action need be taken.
 - c. If it is a stream that is unbuffered, no action need be taken.
 - d. If it is a stream that is line-buffered and the last character written to the stream was a newline (that is, as if a `putc('\n')` was the most recent operation on that stream), no action need be taken.
 - e. If it is a stream that is open for writing or append (but not also open for reading), either an `fflush(3C)` shall occur or the stream shall be closed.
 - f. If the stream is open for reading and it is at the end of the file (`feof(3C)` is true), no action need be taken.
 - g. If the stream is open with a mode that allows reading and the underlying open file description refers to a device that is capable of seeking, either an `fflush()` shall occur or the stream shall be closed.
 - h. Otherwise, the result is undefined.
2. For the second handle: if any previous active handle has called a function that explicitly changed the file offset, except as required above for the first handle, the application shall perform an `lseek()` or an `fseek(3C)` (as appropriate to the type of the handle) to an appropriate location.
3. If the active handle ceases to be accessible before the requirements on the first handle above have been met, the state of the open file description becomes undefined. This might occur, for example, during a `fork()` or an `_exit()`.

4. The `exec` functions shall be considered to make inaccessible all streams that are open at the time they are called, independent of what streams or file descriptors may be available to the new process image.
5. Implementation shall assure that an application, even one consisting of several processes, shall yield correct results (no data is lost or duplicated when writing, all data is written in order, except as requested by seeks) when the rules above are followed, regardless of the sequence of handles used. If the rules above are not followed, the result is unspecified. When these rules are followed, it is implementation defined whether, and under what conditions, all input is seen exactly once.

Use of stdio in Multithreaded Applications

All the `stdio` functions are safe unless they have the `_unlocked` suffix. Each `FILE` pointer has its own lock to guarantee that only one thread can access it. In the case that output needs to be synchronized, the lock for the `FILE` pointer can be acquired before performing a series of `stdio` operations. For example:

```
FILE iop;
flockfile(iop);
fprintf(iop, "hello ");
fprintf(iop, "world");
fputc(iop, 'a');
funlockfile(iop);
```

will print everything out together, blocking other threads that might want to write to the same file between calls to `fprintf()`.

An unlocked interface is available in case performance is an issue. For example:

```
flockfile(iop);
while (!feof(iop)) {
    *c++ = getc_unlocked(iop);
}
funlockfile(iop);
```

RETURN VALUES

Invalid stream pointers usually cause grave disorder, possibly including program termination. Individual function descriptions describe the possible error conditions.

store(3UCB)

NAME	dbm, dbmopen, dbmclose, fetch, store, delete, firstkey, nextkey – data base subroutines
SYNOPSIS	<pre>/usr/ucb/cc [flag ...] file ... -ldbms #include <dbm.h> typedef struct { char *dptr; int dsize; } datum; int dbmopen (file); char *file; int dbmclose (); datum fetch (key); datum key; int store (key, dat); datum key, dat; int delete (key); datum key; datum firstkey() datum nextkey (key); datum key;</pre>
DESCRIPTION	<p>The dbm() library has been superseded by ndbm (see ndbm(3C)).</p> <p>These functions maintain key/content pairs in a data base. The functions will handle very large (a billion blocks) databases and will access a keyed item in one or two file system accesses.</p> <p><i>key/dat</i> and their content are described by the datum typedef. A datum specifies a string of <i>dsize</i> bytes pointed to by <i>dptr</i>. Arbitrary binary data, as well as normal ASCII strings, are allowed. The data base is stored in two files. One file is a directory containing a bit map and has <i>.dir</i> as its suffix. The second file contains all data and has <i>.pag</i> as its suffix.</p> <p>Before a database can be accessed, it must be opened by dbmopen(). At the time of this call, the files <i>file.dir</i> and <i>file.pag</i> must exist. An empty database is created by creating zero-length <i>.dir</i> and <i>.pag</i> files.</p> <p>A database may be closed by calling dbmclose(). You must close a database before opening a new one.</p>

store(3UCB)

Once open, the data stored under a key is accessed by `fetch()` and data is placed under a key by `store`. A key (and its associated contents) is deleted by `delete()`. A linear pass through all keys in a database may be made, in an (apparently) random order, by use of `firstkey()` and `nextkey()`. `firstkey()` will return the first key in the database. With any key `nextkey()` will return the next key in the database. This code will traverse the data base:

```
for (key = firstkey; key.dptr != NULL; key = nextkey(key))
```

RETURN VALUES

All functions that return an `int` indicate errors with negative values. A zero return indicates no error. Routines that return a datum indicate errors with a `NULL (0) dptr`.

SEE ALSO

`ar(1)`, `cat(1)`, `cp(1)`, `tar(1)`, `ndbm(3C)`

NOTES

Use of these interfaces should be restricted to only applications written on BSD platforms. Use of these interfaces with any of the system libraries or in multi-thread applications is unsupported.

The `.pag` file will contain holes so that its apparent size may be larger than its actual content. Older versions of the UNIX operating system may create real file blocks for these holes when touched. These files cannot be copied by normal means (`cp(1)`, `cat(1)`, `tar(1)`, `ar(1)`) without filling in the holes.

`dptr` pointers returned by these subroutines point into static storage that is changed by subsequent calls.

The sum of the sizes of a key/content pair must not exceed the internal block size (currently 1024 bytes). Moreover all key/content pairs that hash together must fit on a single block. `store` will return an error in the event that a disk block fills with inseparable data.

`delete()` does not physically reclaim file space, although it does make it available for reuse.

The order of keys presented by `firstkey()` and `nextkey()` depends on a hashing function, not on anything interesting.

There are no interlocks and no reliable cache flushing; thus concurrent updating and reading is risky.

The database files (`file.dir` and `file.pag`) are binary and are architecture-specific (for example, they depend on the architecture's byte order.) These files are not guaranteed to be portable across architectures.

str2sig(3C)

NAME	str2sig, sig2str – translation between signal name and signal number
SYNOPSIS	<pre>#include <signal.h> int str2sig(const char *str, int *signum); int sig2str(int signum, char *str);</pre>
DESCRIPTION	<p>The <code>str2sig()</code> function translates the signal name <i>str</i> to a signal number, and stores that result in the location referenced by <i>signum</i>. The name in <i>str</i> can be either the symbol for that signal, without the "SIG" prefix, or a decimal number. All the signal symbols defined in <code><sys/signal.h></code> are recognized. This means that both "CLD" and "CHLD" are recognized and return the same signal number, as do both "POLL" and "IO". For access to the signals in the range SIGRTMIN to SIGRTMAX, the first four signals match the strings "RTMIN", "RTMIN+1", "RTMIN+2", and "RTMIN+3" and the last four match the strings "RTMAX-3", "RTMAX-2", "RTMAX-1", and "RTMAX".</p> <p>The <code>sig2str()</code> function translates the signal number <i>signum</i> to the symbol for that signal, without the "SIG" prefix, and stores that symbol at the location specified by <i>str</i>. The storage referenced by <i>str</i> should be large enough to hold the symbol and a terminating null byte. The symbol SIG2STR_MAX defined by <code><signal.h></code> gives the maximum size in bytes required.</p>
RETURN VALUES	<p>The <code>str2sig()</code> function returns 0 if it recognizes the signal name specified in <i>str</i>; otherwise, it returns -1.</p> <p>The <code>sig2str()</code> function returns 0 if the value <i>signum</i> corresponds to a valid signal number; otherwise, it returns -1.</p>
EXAMPLES	<p>EXAMPLE 1 A sample program using the <code>str2sig()</code> function.</p> <pre>int i; char buf[SIG2STR_MAX]; /*storage for symbol */ str2sig("KILL",&i); /*stores 9 in i */ str2sig("9", &i); /* stores 9 in i */ sig2str(SIGKILL,buf); /* stores "KILL" in buf */ sig2str(9,buf); /* stores "KILL" in buf */</pre>

SYNOPSIS	<pre> #include <strings.h> int strcasecmp(const char *s1, const char *s2); int strncasecmp(const char *s1, const char *s2, size_t n); #include <string.h> char *strcat(char *s1, const char *s2); char *strncat(char *s1, const char *s2, size_t n); size_t strlcat(char *dst, const char *src, size_t dstsize); char *strchr(const char *s, int c); char *strrchr(const char *s, int c); int strcmp(const char *s1, const char *s2); int strncmp(const char *s1, const char *s2, size_t n); char *strcpy(char *s1, const char *s2); char *strncpy(char *s1, const char *s2, size_t n); size_t strlcpy(char *dst, const char *src, size_t dstsize); size_t strcspn(const char *s1, const char *s2); size_t strspn(const char *s1, const char *s2); char *strdup(const char *s1); size_t strlen(const char *s); char *strpbrk(const char *s1, const char *s2); char *strstr(const char *s1, const char *s2); char *strtok(char *s1, const char *s2); char *strtok_r(char *s1, const char *s2, char **lasts); </pre>
ISO C++	<pre> #include <string.h> const char *strchr(const char *s, int c); const char *strpbrk(const char *s1, const char *s2); const char *strrchr(const char *s, int c); const char *strstr(const char *s1, const char *s2); #include <cstring> char *std::strchr(char *s, int c); </pre>

strcasecmp(3C)

	<pre>char *std::strpbrk(char *s1, const char *s2); char *std::strrchr(char *s, int c); char *std::strstr(char *s1, const char *s2);</pre>
DESCRIPTION	<p>The arguments <i>s</i>, <i>s1</i>, and <i>s2</i> point to strings (arrays of characters terminated by a null character). The <code>strcat()</code>, <code>strncat()</code>, <code>strlcat()</code>, <code>strcpy()</code>, <code>strncpy()</code>, <code>strncpy()</code>, <code>strtok()</code>, and <code>strtok_r()</code> functions all alter their first argument. These functions do not check for overflow of the array pointed to by the first argument.</p>
<code>strcasecmp()</code> , <code>strncasecmp()</code>	<p>The <code>strcasecmp()</code> and <code>strncasecmp()</code> functions are case-insensitive versions of <code>strcmp()</code> and <code>strncmp()</code> respectively, described below. They assume the ASCII character set and ignore differences in case when comparing lower and upper case characters.</p>
<code>strcat()</code> , <code>strncat()</code> , <code>strlcat()</code>	<p>The <code>strcat()</code> function appends a copy of string <i>s2</i>, including the terminating null character, to the end of string <i>s1</i>. The <code>strncat()</code> function appends at most <i>n</i> characters. Each returns a pointer to the null-terminated result. The initial character of <i>s2</i> overrides the null character at the end of <i>s1</i>.</p> <p>The <code>strlcat()</code> function appends at most $(dstsize - strlen(dst) - 1)$ characters of <i>src</i> to <i>dst</i> (<i>dstsize</i> being the size of the string buffer <i>dst</i>). If the string pointed to by <i>dst</i> contains a null-terminated string that fits into <i>dstsize</i> bytes when <code>strlcat()</code> is called, the string pointed to by <i>dst</i> will be a null-terminated string that fits in <i>dstsize</i> bytes (including the terminating null character) when it completes, and the initial character of <i>src</i> will override the null character at the end of <i>dst</i>. If the string pointed to by <i>dst</i> is longer than <i>dstsize</i> bytes when <code>strlcat()</code> is called, the string pointed to by <i>dst</i> will not be changed. The function returns the sum the of lengths of the two strings $strlen(dst) + strlen(src)$. Buffer overflow can be checked as follows:</p> <pre>if (strlcat(dst, src, dstsize) >= dstsize) return -1;</pre>
<code>strchr()</code> , <code>strrchr()</code>	<p>The <code>strchr()</code> function returns a pointer to the first occurrence of <i>c</i> (converted to a char) in string <i>s</i>, or a null pointer if <i>c</i> does not occur in the string. The <code>strrchr()</code> function returns a pointer to the last occurrence of <i>c</i>. The null character terminating a string is considered to be part of the string.</p>
<code>strcmp()</code> , <code>strncmp()</code>	<p>The <code>strcmp()</code> function compares two strings byte-by-byte, according to the ordering of your machine's character set. The function returns an integer greater than, equal to, or less than 0, if the string pointed to by <i>s1</i> is greater than, equal to, or less than the string pointed to by <i>s2</i> respectively. The sign of a non-zero return value is determined by the sign of the difference between the values of the first pair of bytes that differ in the strings being compared. The <code>strncmp()</code> function makes the same comparison but looks at a maximum of <i>n</i> bytes. Bytes following a null byte are not compared.</p>

<code>strcpy()</code> , <code>strncpy()</code> , <code>strncpy()</code> , <code>strncpy()</code>	<p>The <code>strcpy()</code> function copies string <code>s2</code> to <code>s1</code>, including the terminating null character, stopping after the null character has been copied. The <code>strncpy()</code> function copies exactly <code>n</code> bytes, truncating <code>s2</code> or adding null characters to <code>s1</code> if necessary. The result will not be null-terminated if the length of <code>s2</code> is <code>n</code> or more. Each function returns <code>s1</code>.</p> <p>The <code>strncpy()</code> function copies at most <code>dsize-1</code> characters (<code>dsize</code> being the size of the string buffer <code>dst</code>) from <code>src</code> to <code>dst</code>, truncating <code>src</code> if necessary. The result is always null-terminated. The function returns <code>strlen(src)</code>. Buffer overflow can be checked as follows:</p> <pre>if (strncpy(dst, src, dsize) >= dsize) return -1;</pre>
<code>strcspn()</code> , <code>strcspn()</code>	<p>The <code>strcspn()</code> function returns the length of the initial segment of string <code>s1</code> that consists entirely of characters not from string <code>s2</code>. The <code>strspn()</code> function returns the length of the initial segment of string <code>s1</code> that consists entirely of characters from string <code>s2</code>.</p>
<code>strdup()</code>	<p>The <code>strdup()</code> function returns a pointer to a new string that is a duplicate of the string pointed to by <code>s1</code>. The returned pointer can be passed to <code>free()</code>. The space for the new string is obtained using <code>malloc(3C)</code>. If the new string cannot be created, a null pointer is returned and <code>errno</code> may be set to <code>ENOMEM</code> to indicate that the storage space available is insufficient.</p>
<code>strlen()</code>	<p>The <code>strlen()</code> function returns the number of bytes in <code>s</code>, not including the terminating null character.</p>
<code>strpbrk()</code>	<p>The <code>strpbrk()</code> function returns a pointer to the first occurrence in string <code>s1</code> of any character from string <code>s2</code>, or a null pointer if no character from <code>s2</code> exists in <code>s1</code>.</p>
<code>strstr()</code>	<p>The <code>strstr()</code> function locates the first occurrence of the string <code>s2</code> (excluding the terminating null character) in string <code>s1</code> and returns a pointer to the located string, or a null pointer if the string is not found. If <code>s2</code> points to a string with zero length (that is, the string ""), the function returns <code>s1</code>.</p>
<code>strtok()</code>	<p>The <code>strtok()</code> function can be used to break the string pointed to by <code>s1</code> into a sequence of tokens, each of which is delimited by one or more characters from the string pointed to by <code>s2</code>. The <code>strtok()</code> function considers the string <code>s1</code> to consist of a sequence of zero or more text tokens separated by spans of one or more characters from the separator string <code>s2</code>. The first call (with pointer <code>s1</code> specified) returns a pointer to the first character of the first token, and will have written a null character into <code>s1</code> immediately following the returned token. The function keeps track of its position in the string between separate calls, so that subsequent calls (which must be made with the first argument being a null pointer) will work through the string <code>s1</code> immediately following that token. In this way subsequent calls will work through the string <code>s1</code> until no tokens remain. The separator string <code>s2</code> may be different from call to call. When no token remains in <code>s1</code>, a null pointer is returned.</p>

strcasemp(3C)

`strtok_r()` The `strtok_r()` function has the same functionality as `strtok()` except that a pointer to a string placeholder *lasts* must be supplied by the caller. The *lasts* pointer is to keep track of the next substring in which to search for the next token.

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
MT-Level	See NOTES below.

SEE ALSO `malloc(3C)`, `setlocale(3C)`, `strxfrm(3C)`, `attributes(5)`

NOTES When compiling multithreaded applications, the `_REENTRANT` flag must be defined on the compile line. This flag should only be used in multithreaded applications.

All of these functions assume the default locale "C." For some locales, `strxfrm()` should be applied to the strings before they are passed to the functions.

The `strcasemp()`, `strcat()`, `strchr()`, `strcmp()`, `strcpy()`, `strcspn()`, `strdup()`, `strlen()`, `strncasemp()`, `strncat()`, `strncmp()`, `strncpy()`, `strpbrk()`, `strrchr()`, `strspn()`, and `strstr()` functions are MT-Safe in multithreaded applications.

The `strtok()` function is Unsafe in multithreaded applications. The `strtok_r()` function should be used instead.

strchr(3C)

	<pre>char *std::strpbrk(char *s1, const char *s2); char *std::strrchr(char *s, int c); char *std::strstr(char *s1, const char *s2);</pre>
DESCRIPTION	<p>The arguments <i>s</i>, <i>s1</i>, and <i>s2</i> point to strings (arrays of characters terminated by a null character). The <code>strcat()</code>, <code>strncat()</code>, <code>strlcat()</code>, <code>strcpy()</code>, <code>strncpy()</code>, <code>strncpy()</code>, <code>strtok()</code>, and <code>strtok_r()</code> functions all alter their first argument. These functions do not check for overflow of the array pointed to by the first argument.</p>
<code>strcasecmp()</code> , <code>strncasecmp()</code>	<p>The <code>strcasecmp()</code> and <code>strncasecmp()</code> functions are case-insensitive versions of <code>strcmp()</code> and <code>strncmp()</code> respectively, described below. They assume the ASCII character set and ignore differences in case when comparing lower and upper case characters.</p>
<code>strcat()</code> , <code>strncat()</code> , <code>strlcat()</code>	<p>The <code>strcat()</code> function appends a copy of string <i>s2</i>, including the terminating null character, to the end of string <i>s1</i>. The <code>strncat()</code> function appends at most <i>n</i> characters. Each returns a pointer to the null-terminated result. The initial character of <i>s2</i> overrides the null character at the end of <i>s1</i>.</p> <p>The <code>strlcat()</code> function appends at most (<i>dstsize</i>-<code>strlen(dst)</code>-1) characters of <i>src</i> to <i>dst</i> (<i>dstsize</i> being the size of the string buffer <i>dst</i>). If the string pointed to by <i>dst</i> contains a null-terminated string that fits into <i>dstsize</i> bytes when <code>strlcat()</code> is called, the string pointed to by <i>dst</i> will be a null-terminated string that fits in <i>dstsize</i> bytes (including the terminating null character) when it completes, and the initial character of <i>src</i> will override the null character at the end of <i>dst</i>. If the string pointed to by <i>dst</i> is longer than <i>dstsize</i> bytes when <code>strlcat()</code> is called, the string pointed to by <i>dst</i> will not be changed. The function returns the sum the of lengths of the two strings <code>strlen(dst)+strlen(src)</code>. Buffer overflow can be checked as follows:</p> <pre>if (strlcat(dst, src, dstsize) >= dstsize) return -1;</pre>
<code>strchr()</code> , <code>strrchr()</code>	<p>The <code>strchr()</code> function returns a pointer to the first occurrence of <i>c</i> (converted to a char) in string <i>s</i>, or a null pointer if <i>c</i> does not occur in the string. The <code>strrchr()</code> function returns a pointer to the last occurrence of <i>c</i>. The null character terminating a string is considered to be part of the string.</p>
<code>strcmp()</code> , <code>strncmp()</code>	<p>The <code>strcmp()</code> function compares two strings byte-by-byte, according to the ordering of your machine's character set. The function returns an integer greater than, equal to, or less than 0, if the string pointed to by <i>s1</i> is greater than, equal to, or less than the string pointed to by <i>s2</i> respectively. The sign of a non-zero return value is determined by the sign of the difference between the values of the first pair of bytes that differ in the strings being compared. The <code>strncmp()</code> function makes the same comparison but looks at a maximum of <i>n</i> bytes. Bytes following a null byte are not compared.</p>

strcpy(), strncpy(), strncpy()	<p>The <code>strcpy()</code> function copies string <code>s2</code> to <code>s1</code>, including the terminating null character, stopping after the null character has been copied. The <code>strncpy()</code> function copies exactly <code>n</code> bytes, truncating <code>s2</code> or adding null characters to <code>s1</code> if necessary. The result will not be null-terminated if the length of <code>s2</code> is <code>n</code> or more. Each function returns <code>s1</code>.</p> <p>The <code>strncpy()</code> function copies at most <code>dsize-1</code> characters (<code>dsize</code> being the size of the string buffer <code>dst</code>) from <code>src</code> to <code>dst</code>, truncating <code>src</code> if necessary. The result is always null-terminated. The function returns <code>strlen(src)</code>. Buffer overflow can be checked as follows:</p> <pre>if (strncpy(dst, src, dsize) >= dsize) return -1;</pre>
strcspn(), strspn()	<p>The <code>strcspn()</code> function returns the length of the initial segment of string <code>s1</code> that consists entirely of characters not from string <code>s2</code>. The <code>strspn()</code> function returns the length of the initial segment of string <code>s1</code> that consists entirely of characters from string <code>s2</code>.</p>
strdup()	<p>The <code>strdup()</code> function returns a pointer to a new string that is a duplicate of the string pointed to by <code>s1</code>. The returned pointer can be passed to <code>free()</code>. The space for the new string is obtained using <code>malloc(3C)</code>. If the new string cannot be created, a null pointer is returned and <code>errno</code> may be set to <code>ENOMEM</code> to indicate that the storage space available is insufficient.</p>
strlen()	<p>The <code>strlen()</code> function returns the number of bytes in <code>s</code>, not including the terminating null character.</p>
strpbrk()	<p>The <code>strpbrk()</code> function returns a pointer to the first occurrence in string <code>s1</code> of any character from string <code>s2</code>, or a null pointer if no character from <code>s2</code> exists in <code>s1</code>.</p>
strstr()	<p>The <code>strstr()</code> function locates the first occurrence of the string <code>s2</code> (excluding the terminating null character) in string <code>s1</code> and returns a pointer to the located string, or a null pointer if the string is not found. If <code>s2</code> points to a string with zero length (that is, the string ""), the function returns <code>s1</code>.</p>
strtok()	<p>The <code>strtok()</code> function can be used to break the string pointed to by <code>s1</code> into a sequence of tokens, each of which is delimited by one or more characters from the string pointed to by <code>s2</code>. The <code>strtok()</code> function considers the string <code>s1</code> to consist of a sequence of zero or more text tokens separated by spans of one or more characters from the separator string <code>s2</code>. The first call (with pointer <code>s1</code> specified) returns a pointer to the first character of the first token, and will have written a null character into <code>s1</code> immediately following the returned token. The function keeps track of its position in the string between separate calls, so that subsequent calls (which must be made with the first argument being a null pointer) will work through the string <code>s1</code> immediately following that token. In this way subsequent calls will work through the string <code>s1</code> until no tokens remain. The separator string <code>s2</code> may be different from call to call. When no token remains in <code>s1</code>, a null pointer is returned.</p>

strchr(3C)

`strtok_r()` The `strtok_r()` function has the same functionality as `strtok()` except that a pointer to a string placeholder *lasts* must be supplied by the caller. The *lasts* pointer is to keep track of the next substring in which to search for the next token.

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
MT-Level	See NOTES below.

SEE ALSO `malloc(3C)`, `setlocale(3C)`, `strxfrm(3C)`, `attributes(5)`

NOTES When compiling multithreaded applications, the `_REENTRANT` flag must be defined on the compile line. This flag should only be used in multithreaded applications.

All of these functions assume the default locale "C." For some locales, `strxfrm()` should be applied to the strings before they are passed to the functions.

The `strcasemp()`, `strcat()`, `strchr()`, `strcmp()`, `strcpy()`, `strcspn()`, `strdup()`, `strlen()`, `strncasemp()`, `strncat()`, `strncmp()`, `strncpy()`, `strpbrk()`, `strrchr()`, `strspn()`, and `strstr()` functions are MT-Safe in multithreaded applications.

The `strtok()` function is Unsafe in multithreaded applications. The `strtok_r()` function should be used instead.

ISO C++	<pre> #include <string.h> const char *strchr(const char *s, int c); const char *strpbrk(const char *s1, const char *s2); const char *strrchr(const char *s, int c); const char *strstr(const char *s1, const char *s2); #include <cstring> char *std::strchr(char *s, int c); </pre>

strcmp(3C)

	<pre>char *std::strpbrk(char *s1, const char *s2); char *std::strrchr(char *s, int c); char *std::strstr(char *s1, const char *s2);</pre>
DESCRIPTION	<p>The arguments <i>s</i>, <i>s1</i>, and <i>s2</i> point to strings (arrays of characters terminated by a null character). The <code>strcat()</code>, <code>strncat()</code>, <code>strlcat()</code>, <code>strcpy()</code>, <code>strncpy()</code>, <code>strncpy()</code>, <code>strtok()</code>, and <code>strtok_r()</code> functions all alter their first argument. These functions do not check for overflow of the array pointed to by the first argument.</p>
<code>strcasecmp()</code> , <code>strncasecmp()</code>	<p>The <code>strcasecmp()</code> and <code>strncasecmp()</code> functions are case-insensitive versions of <code>strcmp()</code> and <code>strncmp()</code> respectively, described below. They assume the ASCII character set and ignore differences in case when comparing lower and upper case characters.</p>
<code>strcat()</code> , <code>strncat()</code> , <code>strlcat()</code>	<p>The <code>strcat()</code> function appends a copy of string <i>s2</i>, including the terminating null character, to the end of string <i>s1</i>. The <code>strncat()</code> function appends at most <i>n</i> characters. Each returns a pointer to the null-terminated result. The initial character of <i>s2</i> overrides the null character at the end of <i>s1</i>.</p> <p>The <code>strlcat()</code> function appends at most $(dstsize - strlen(dst) - 1)$ characters of <i>src</i> to <i>dst</i> (<i>dstsize</i> being the size of the string buffer <i>dst</i>). If the string pointed to by <i>dst</i> contains a null-terminated string that fits into <i>dstsize</i> bytes when <code>strlcat()</code> is called, the string pointed to by <i>dst</i> will be a null-terminated string that fits in <i>dstsize</i> bytes (including the terminating null character) when it completes, and the initial character of <i>src</i> will override the null character at the end of <i>dst</i>. If the string pointed to by <i>dst</i> is longer than <i>dstsize</i> bytes when <code>strlcat()</code> is called, the string pointed to by <i>dst</i> will not be changed. The function returns the sum the of lengths of the two strings $strlen(dst) + strlen(src)$. Buffer overflow can be checked as follows:</p> <pre>if (strlcat(dst, src, dstsize) >= dstsize) return -1;</pre>
<code>strchr()</code> , <code>strrchr()</code>	<p>The <code>strchr()</code> function returns a pointer to the first occurrence of <i>c</i> (converted to a char) in string <i>s</i>, or a null pointer if <i>c</i> does not occur in the string. The <code>strrchr()</code> function returns a pointer to the last occurrence of <i>c</i>. The null character terminating a string is considered to be part of the string.</p>
<code>strcmp()</code> , <code>strncmp()</code>	<p>The <code>strcmp()</code> function compares two strings byte-by-byte, according to the ordering of your machine's character set. The function returns an integer greater than, equal to, or less than 0, if the string pointed to by <i>s1</i> is greater than, equal to, or less than the string pointed to by <i>s2</i> respectively. The sign of a non-zero return value is determined by the sign of the difference between the values of the first pair of bytes that differ in the strings being compared. The <code>strncmp()</code> function makes the same comparison but looks at a maximum of <i>n</i> bytes. Bytes following a null byte are not compared.</p>

<code>strcpy()</code> , <code>strncpy()</code> , <code>strncpy()</code>	<p>The <code>strcpy()</code> function copies string <code>s2</code> to <code>s1</code>, including the terminating null character, stopping after the null character has been copied. The <code>strncpy()</code> function copies exactly <code>n</code> bytes, truncating <code>s2</code> or adding null characters to <code>s1</code> if necessary. The result will not be null-terminated if the length of <code>s2</code> is <code>n</code> or more. Each function returns <code>s1</code>.</p> <p>The <code>strncpy()</code> function copies at most <code>dsize-1</code> characters (<code>dsize</code> being the size of the string buffer <code>dst</code>) from <code>src</code> to <code>dst</code>, truncating <code>src</code> if necessary. The result is always null-terminated. The function returns <code>strlen(src)</code>. Buffer overflow can be checked as follows:</p> <pre>if (strncpy(dst, src, dsize) >= dsize) return -1;</pre>
<code>strcspn()</code> , <code>strspn()</code>	<p>The <code>strcspn()</code> function returns the length of the initial segment of string <code>s1</code> that consists entirely of characters not from string <code>s2</code>. The <code>strspn()</code> function returns the length of the initial segment of string <code>s1</code> that consists entirely of characters from string <code>s2</code>.</p>
<code>strdup()</code>	<p>The <code>strdup()</code> function returns a pointer to a new string that is a duplicate of the string pointed to by <code>s1</code>. The returned pointer can be passed to <code>free()</code>. The space for the new string is obtained using <code>malloc(3C)</code>. If the new string cannot be created, a null pointer is returned and <code>errno</code> may be set to <code>ENOMEM</code> to indicate that the storage space available is insufficient.</p>
<code>strlen()</code>	<p>The <code>strlen()</code> function returns the number of bytes in <code>s</code>, not including the terminating null character.</p>
<code>strpbrk()</code>	<p>The <code>strpbrk()</code> function returns a pointer to the first occurrence in string <code>s1</code> of any character from string <code>s2</code>, or a null pointer if no character from <code>s2</code> exists in <code>s1</code>.</p>
<code>strstr()</code>	<p>The <code>strstr()</code> function locates the first occurrence of the string <code>s2</code> (excluding the terminating null character) in string <code>s1</code> and returns a pointer to the located string, or a null pointer if the string is not found. If <code>s2</code> points to a string with zero length (that is, the string ""), the function returns <code>s1</code>.</p>
<code>strtok()</code>	<p>The <code>strtok()</code> function can be used to break the string pointed to by <code>s1</code> into a sequence of tokens, each of which is delimited by one or more characters from the string pointed to by <code>s2</code>. The <code>strtok()</code> function considers the string <code>s1</code> to consist of a sequence of zero or more text tokens separated by spans of one or more characters from the separator string <code>s2</code>. The first call (with pointer <code>s1</code> specified) returns a pointer to the first character of the first token, and will have written a null character into <code>s1</code> immediately following the returned token. The function keeps track of its position in the string between separate calls, so that subsequent calls (which must be made with the first argument being a null pointer) will work through the string <code>s1</code> immediately following that token. In this way subsequent calls will work through the string <code>s1</code> until no tokens remain. The separator string <code>s2</code> may be different from call to call. When no token remains in <code>s1</code>, a null pointer is returned.</p>

strcmp(3C)

`strtok_r()` The `strtok_r()` function has the same functionality as `strtok()` except that a pointer to a string placeholder *lasts* must be supplied by the caller. The *lasts* pointer is to keep track of the next substring in which to search for the next token.

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

NOTES When compiling multithreaded applications, the `_REENTRANT` flag must be defined on the compile line. This flag should only be used in multithreaded applications.

All of these functions assume the default locale "C." For some locales, `strxfrm()` should be applied to the strings before they are passed to the functions.

The `strcasemp()`, `strcat()`, `strchr()`, `strcmp()`, `strcpy()`, `strcspn()`, `strdup()`, `strlen()`, `strncasemp()`, `strncat()`, `strncmp()`, `strncpy()`, `strpbrk()`, `strrchr()`, `strspn()`, and `strstr()` functions are MT-Safe in multithreaded applications.

The `strtok()` function is Unsafe in multithreaded applications. The `strtok_r()` function should be used instead.

NAME	strcoll – string collation						
SYNOPSIS	<pre>#include <string.h> int strcoll(const char *s1, const char *s2);</pre>						
DESCRIPTION	Both <code>strcoll()</code> and <code>strxfrm(3C)</code> provide for locale-specific string sorting. <code>strcoll()</code> is intended for applications in which the number of comparisons per string is small. When strings are to be compared a number of times, <code>strxfrm(3C)</code> is a more appropriate function because the transformation process occurs only once.						
RETURN VALUES	<p>Upon successful completion, <code>strcoll()</code> returns an integer greater than, equal to, or less than zero in direct correlation to whether string <code>s1</code> is greater than, equal to, or less than the string <code>s2</code>. The comparison is based on strings interpreted as appropriate to the program's locale for category <code>LC_COLLATE</code> (see <code>setlocale(3C)</code>).</p> <p>On error, <code>strcoll()</code> may set <code>errno</code>, but no return value is reserved to indicate an error.</p>						
ERRORS	<p>The <code>strcoll()</code> function may fail if:</p> <p><code>EINVAL</code> The <code>s1</code> or <code>s2</code> arguments contain characters outside the domain of the collating sequence.</p>						
FILES	<pre>/usr/lib/locale/locale/locale.so.* LC_COLLATE database for locale</pre>						
ATTRIBUTES	See <code>attributes(5)</code> for descriptions of the following attributes:						
	<table border="1"> <thead> <tr> <th style="text-align: center;">ATTRIBUTE TYPE</th> <th style="text-align: center;">ATTRIBUTE VALUE</th> </tr> </thead> <tbody> <tr> <td>MT-Level</td> <td>MT-Safe with exceptions</td> </tr> <tr> <td>CSI</td> <td>Enabled</td> </tr> </tbody> </table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	MT-Level	MT-Safe with exceptions	CSI	Enabled
ATTRIBUTE TYPE	ATTRIBUTE VALUE						
MT-Level	MT-Safe with exceptions						
CSI	Enabled						
SEE ALSO	<code>localedef(1)</code> , <code>setlocale(3C)</code> , <code>string(3C)</code> , <code>strxfrm(3C)</code> , <code>wsxfrm(3C)</code> , <code>attributes(5)</code> , <code>environ(5)</code>						
NOTES	The <code>strcoll()</code> function can be used safely in multithreaded applications, as long as <code>setlocale(3C)</code> is not being called to change the locale.						

strcpy(3C)

NAME	string, strcasecmp, strncasecmp, strcat, strncat, strlcat, strchr, strrchr, strcmp, strncmp, strcpy, strncpy, strlcpy, strcspn, strspn, strdup, strlen, strpbrk, strstr, strtok, strtok_r – string operations
SYNOPSIS	<pre>#include <strings.h> int strcasecmp(const char *s1, const char *s2); int strncasecmp(const char *s1, const char *s2, size_t n); #include <string.h> char *strcat(char *s1, const char *s2); char *strncat(char *s1, const char *s2, size_t n); size_t strlcat(char *dst, const char *src, size_t dstsize); char *strchr(const char *s, int c); char *strrchr(const char *s, int c); int strcmp(const char *s1, const char *s2); int strncmp(const char *s1, const char *s2, size_t n); char *strcpy(char *s1, const char *s2); char *strncpy(char *s1, const char *s2, size_t n); size_t strlcpy(char *dst, const char *src, size_t dstsize); size_t strcspn(const char *s1, const char *s2); size_t strspn(const char *s1, const char *s2); char *strdup(const char *s1); size_t strlen(const char *s); char *strpbrk(const char *s1, const char *s2); char *strstr(const char *s1, const char *s2); char *strtok(char *s1, const char *s2); char *strtok_r(char *s1, const char *s2, char **lasts);</pre>

```

char *std::strpbrk(char *s1, const char *s2);
char *std::strrchr(char *s, int c);
char *std::strstr(char *s1, const char *s2);

```

DESCRIPTION

The arguments *s*, *s1*, and *s2* point to strings (arrays of characters terminated by a null character). The `strcat()`, `strncat()`, `strlcat()`, `strcpy()`, `strncpy()`, `strncpy()`, `strtok()`, and `strtok_r()` functions all alter their first argument. These functions do not check for overflow of the array pointed to by the first argument.

```

strcasecmp(),
strncasecmp()

```

The `strcasecmp()` and `strncasecmp()` functions are case-insensitive versions of `strcmp()` and `strncmp()` respectively, described below. They assume the ASCII character set and ignore differences in case when comparing lower and upper case characters.

```

strcat(),
strncat(),
strlcat()

```

The `strcat()` function appends a copy of string *s2*, including the terminating null character, to the end of string *s1*. The `strncat()` function appends at most *n* characters. Each returns a pointer to the null-terminated result. The initial character of *s2* overrides the null character at the end of *s1*.

The `strlcat()` function appends at most $(dstsize - strlen(dst) - 1)$ characters of *src* to *dst* (*dstsize* being the size of the string buffer *dst*). If the string pointed to by *dst* contains a null-terminated string that fits into *dstsize* bytes when `strlcat()` is called, the string pointed to by *dst* will be a null-terminated string that fits in *dstsize* bytes (including the terminating null character) when it completes, and the initial character of *src* will override the null character at the end of *dst*. If the string pointed to by *dst* is longer than *dstsize* bytes when `strlcat()` is called, the string pointed to by *dst* will not be changed. The function returns the sum of lengths of the two strings $strlen(dst) + strlen(src)$. Buffer overflow can be checked as follows:

```

if (strlcat(dst, src, dstsize) >= dstsize)
    return -1;

```

```

strchr(),
strrchr()

```

The `strchr()` function returns a pointer to the first occurrence of *c* (converted to a char) in string *s*, or a null pointer if *c* does not occur in the string. The `strrchr()` function returns a pointer to the last occurrence of *c*. The null character terminating a string is considered to be part of the string.

```

strcmp(),
strncmp()

```

The `strcmp()` function compares two strings byte-by-byte, according to the ordering of your machine's character set. The function returns an integer greater than, equal to, or less than 0, if the string pointed to by *s1* is greater than, equal to, or less than the string pointed to by *s2* respectively. The sign of a non-zero return value is determined by the sign of the difference between the values of the first pair of bytes that differ in the strings being compared. The `strncmp()` function makes the same comparison but looks at a maximum of *n* bytes. Bytes following a null byte are not compared.

strcpy(3C)

<code>strcpy()</code> , <code>strncpy()</code> , <code>strncpy()</code>	<p>The <code>strcpy()</code> function copies string <i>s2</i> to <i>s1</i>, including the terminating null character, stopping after the null character has been copied. The <code>strncpy()</code> function copies exactly <i>n</i> bytes, truncating <i>s2</i> or adding null characters to <i>s1</i> if necessary. The result will not be null-terminated if the length of <i>s2</i> is <i>n</i> or more. Each function returns <i>s1</i>.</p> <p>The <code>strncpy()</code> function copies at most <i>dsize-1</i> characters (<i>dsize</i> being the size of the string buffer <i>dst</i>) from <i>src</i> to <i>dst</i>, truncating <i>src</i> if necessary. The result is always null-terminated. The function returns <code>strlen(src)</code>. Buffer overflow can be checked as follows:</p> <pre>if (strncpy(dst, src, dsize) >= dsize) return -1;</pre>
<code>strcspn()</code> , <code>strcspn()</code>	<p>The <code>strcspn()</code> function returns the length of the initial segment of string <i>s1</i> that consists entirely of characters not from string <i>s2</i>. The <code>strcspn()</code> function returns the length of the initial segment of string <i>s1</i> that consists entirely of characters from string <i>s2</i>.</p>
<code>strdup()</code>	<p>The <code>strdup()</code> function returns a pointer to a new string that is a duplicate of the string pointed to by <i>s1</i>. The returned pointer can be passed to <code>free()</code>. The space for the new string is obtained using <code>malloc(3C)</code>. If the new string cannot be created, a null pointer is returned and <code>errno</code> may be set to <code>ENOMEM</code> to indicate that the storage space available is insufficient.</p>
<code>strlen()</code>	<p>The <code>strlen()</code> function returns the number of bytes in <i>s</i>, not including the terminating null character.</p>
<code>strpbrk()</code>	<p>The <code>strpbrk()</code> function returns a pointer to the first occurrence in string <i>s1</i> of any character from string <i>s2</i>, or a null pointer if no character from <i>s2</i> exists in <i>s1</i>.</p>
<code>strstr()</code>	<p>The <code>strstr()</code> function locates the first occurrence of the string <i>s2</i> (excluding the terminating null character) in string <i>s1</i> and returns a pointer to the located string, or a null pointer if the string is not found. If <i>s2</i> points to a string with zero length (that is, the string ""), the function returns <i>s1</i>.</p>
<code>strtok()</code>	<p>The <code>strtok()</code> function can be used to break the string pointed to by <i>s1</i> into a sequence of tokens, each of which is delimited by one or more characters from the string pointed to by <i>s2</i>. The <code>strtok()</code> function considers the string <i>s1</i> to consist of a sequence of zero or more text tokens separated by spans of one or more characters from the separator string <i>s2</i>. The first call (with pointer <i>s1</i> specified) returns a pointer to the first character of the first token, and will have written a null character into <i>s1</i> immediately following the returned token. The function keeps track of its position in the string between separate calls, so that subsequent calls (which must be made with the first argument being a null pointer) will work through the string <i>s1</i> immediately following that token. In this way subsequent calls will work through the string <i>s1</i> until no tokens remain. The separator string <i>s2</i> may be different from call to call. When no token remains in <i>s1</i>, a null pointer is returned.</p>

`strtok_r()` The `strtok_r()` function has the same functionality as `strtok()` except that a pointer to a string placeholder *lasts* must be supplied by the caller. The *lasts* pointer is to keep track of the next substring in which to search for the next token.

```

DESCRIPTION

The arguments *s*, *s1*, and *s2* point to strings (arrays of characters terminated by a null character). The `strcat()`, `strncat()`, `strlcat()`, `strcpy()`, `strncpy()`, `strncpy()`, `strtok()`, and `strtok_r()` functions all alter their first argument. These functions do not check for overflow of the array pointed to by the first argument.

```

strcasecmp(),
strncasecmp()

```

The `strcasecmp()` and `strncasecmp()` functions are case-insensitive versions of `strcmp()` and `strncmp()` respectively, described below. They assume the ASCII character set and ignore differences in case when comparing lower and upper case characters.

```

strcat(),
strncat(),
strlcat()

```

The `strcat()` function appends a copy of string *s2*, including the terminating null character, to the end of string *s1*. The `strncat()` function appends at most *n* characters. Each returns a pointer to the null-terminated result. The initial character of *s2* overrides the null character at the end of *s1*.

The `strlcat()` function appends at most $(dstsize - strlen(dst) - 1)$ characters of *src* to *dst* (*dstsize* being the size of the string buffer *dst*). If the string pointed to by *dst* contains a null-terminated string that fits into *dstsize* bytes when `strlcat()` is called, the string pointed to by *dst* will be a null-terminated string that fits in *dstsize* bytes (including the terminating null character) when it completes, and the initial character of *src* will override the null character at the end of *dst*. If the string pointed to by *dst* is longer than *dstsize* bytes when `strlcat()` is called, the string pointed to by *dst* will not be changed. The function returns the sum of lengths of the two strings $strlen(dst) + strlen(src)$. Buffer overflow can be checked as follows:

```

if (strlcat(dst, src, dstsize) >= dstsize)
    return -1;

```

```

strchr(),
strrchr()

```

The `strchr()` function returns a pointer to the first occurrence of *c* (converted to a char) in string *s*, or a null pointer if *c* does not occur in the string. The `strrchr()` function returns a pointer to the last occurrence of *c*. The null character terminating a string is considered to be part of the string.

```

strcmp(),
strncmp()

```

The `strcmp()` function compares two strings byte-by-byte, according to the ordering of your machine's character set. The function returns an integer greater than, equal to, or less than 0, if the string pointed to by *s1* is greater than, equal to, or less than the string pointed to by *s2* respectively. The sign of a non-zero return value is determined by the sign of the difference between the values of the first pair of bytes that differ in the strings being compared. The `strncmp()` function makes the same comparison but looks at a maximum of *n* bytes. Bytes following a null byte are not compared.

strcspn(3C)

<code>strcpy()</code> , <code>strncpy()</code> , <code>strncpy()</code>	<p>The <code>strcpy()</code> function copies string <i>s2</i> to <i>s1</i>, including the terminating null character, stopping after the null character has been copied. The <code>strncpy()</code> function copies exactly <i>n</i> bytes, truncating <i>s2</i> or adding null characters to <i>s1</i> if necessary. The result will not be null-terminated if the length of <i>s2</i> is <i>n</i> or more. Each function returns <i>s1</i>.</p> <p>The <code>strncpy()</code> function copies at most <i>dsize-1</i> characters (<i>dsize</i> being the size of the string buffer <i>dst</i>) from <i>src</i> to <i>dst</i>, truncating <i>src</i> if necessary. The result is always null-terminated. The function returns <code>strlen(src)</code>. Buffer overflow can be checked as follows:</p> <pre>if (strncpy(dst, src, dsize) >= dsize) return -1;</pre>
<code>strcspn()</code> , <code>strspn()</code>	<p>The <code>strcspn()</code> function returns the length of the initial segment of string <i>s1</i> that consists entirely of characters not from string <i>s2</i>. The <code>strspn()</code> function returns the length of the initial segment of string <i>s1</i> that consists entirely of characters from string <i>s2</i>.</p>
<code>strdup()</code>	<p>The <code>strdup()</code> function returns a pointer to a new string that is a duplicate of the string pointed to by <i>s1</i>. The returned pointer can be passed to <code>free()</code>. The space for the new string is obtained using <code>malloc(3C)</code>. If the new string cannot be created, a null pointer is returned and <code>errno</code> may be set to <code>ENOMEM</code> to indicate that the storage space available is insufficient.</p>
<code>strlen()</code>	<p>The <code>strlen()</code> function returns the number of bytes in <i>s</i>, not including the terminating null character.</p>
<code>strpbrk()</code>	<p>The <code>strpbrk()</code> function returns a pointer to the first occurrence in string <i>s1</i> of any character from string <i>s2</i>, or a null pointer if no character from <i>s2</i> exists in <i>s1</i>.</p>
<code>strstr()</code>	<p>The <code>strstr()</code> function locates the first occurrence of the string <i>s2</i> (excluding the terminating null character) in string <i>s1</i> and returns a pointer to the located string, or a null pointer if the string is not found. If <i>s2</i> points to a string with zero length (that is, the string ""), the function returns <i>s1</i>.</p>
<code>strtok()</code>	<p>The <code>strtok()</code> function can be used to break the string pointed to by <i>s1</i> into a sequence of tokens, each of which is delimited by one or more characters from the string pointed to by <i>s2</i>. The <code>strtok()</code> function considers the string <i>s1</i> to consist of a sequence of zero or more text tokens separated by spans of one or more characters from the separator string <i>s2</i>. The first call (with pointer <i>s1</i> specified) returns a pointer to the first character of the first token, and will have written a null character into <i>s1</i> immediately following the returned token. The function keeps track of its position in the string between separate calls, so that subsequent calls (which must be made with the first argument being a null pointer) will work through the string <i>s1</i> immediately following that token. In this way subsequent calls will work through the string <i>s1</i> until no tokens remain. The separator string <i>s2</i> may be different from call to call. When no token remains in <i>s1</i>, a null pointer is returned.</p>

strcspn(3C)

`strtok_r()` The `strtok_r()` function has the same functionality as `strtok()` except that a pointer to a string placeholder *lasts* must be supplied by the caller. The *lasts* pointer is to keep track of the next substring in which to search for the next token.

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
MT-Level	See NOTES below.

SEE ALSO `malloc(3C)`, `setlocale(3C)`, `strxfrm(3C)`, `attributes(5)`

NOTES When compiling multithreaded applications, the `_REENTRANT` flag must be defined on the compile line. This flag should only be used in multithreaded applications.

All of these functions assume the default locale "C." For some locales, `strxfrm()` should be applied to the strings before they are passed to the functions.

The `strcasemp()`, `strcat()`, `strchr()`, `strcmp()`, `strcpy()`, `strcspn()`, `strdup()`, `strlen()`, `strncasemp()`, `strncat()`, `strncmp()`, `strncpy()`, `strpbrk()`, `strrchr()`, `strspn()`, and `strstr()` functions are MT-Safe in multithreaded applications.

The `strtok()` function is Unsafe in multithreaded applications. The `strtok_r()` function should be used instead.

ISO C++	<pre>#include <string.h> const char *strchr(const char *s, int c); const char *strpbrk(const char *s1, const char *s2); const char *strrchr(const char *s, int c); const char *strstr(const char *s1, const char *s2); #include <cstring> char *std::strchr(char *s, int c);</pre>

```
char *std::strpbrk(char *s1, const char *s2);
char *std::strrchr(char *s, int c);
char *std::strstr(char *s1, const char *s2);
```

DESCRIPTION

The arguments *s*, *s1*, and *s2* point to strings (arrays of characters terminated by a null character). The `strcat()`, `strncat()`, `strlcat()`, `strcpy()`, `strncpy()`, `strncpy()`, `strtok()`, and `strtok_r()` functions all alter their first argument. These functions do not check for overflow of the array pointed to by the first argument.

```
strcasemp(),
strncasemp()
```

The `strcasemp()` and `strncasemp()` functions are case-insensitive versions of `strcmp()` and `strncmp()` respectively, described below. They assume the ASCII character set and ignore differences in case when comparing lower and upper case characters.

```
strcat(),
strncat(),
strlcat()
```

The `strcat()` function appends a copy of string *s2*, including the terminating null character, to the end of string *s1*. The `strncat()` function appends at most *n* characters. Each returns a pointer to the null-terminated result. The initial character of *s2* overrides the null character at the end of *s1*.

The `strlcat()` function appends at most $(dstsize - strlen(dst) - 1)$ characters of *src* to *dst* (*dstsize* being the size of the string buffer *dst*). If the string pointed to by *dst* contains a null-terminated string that fits into *dstsize* bytes when `strlcat()` is called, the string pointed to by *dst* will be a null-terminated string that fits in *dstsize* bytes (including the terminating null character) when it completes, and the initial character of *src* will override the null character at the end of *dst*. If the string pointed to by *dst* is longer than *dstsize* bytes when `strlcat()` is called, the string pointed to by *dst* will not be changed. The function returns the sum of lengths of the two strings $strlen(dst) + strlen(src)$. Buffer overflow can be checked as follows:

```
if (strlcat(dst, src, dstsize) >= dstsize)
    return -1;
```

```
strchr(),
strrchr()
```

The `strchr()` function returns a pointer to the first occurrence of *c* (converted to a char) in string *s*, or a null pointer if *c* does not occur in the string. The `strrchr()` function returns a pointer to the last occurrence of *c*. The null character terminating a string is considered to be part of the string.

```
strcmp(),
strncmp()
```

The `strcmp()` function compares two strings byte-by-byte, according to the ordering of your machine's character set. The function returns an integer greater than, equal to, or less than 0, if the string pointed to by *s1* is greater than, equal to, or less than the string pointed to by *s2* respectively. The sign of a non-zero return value is determined by the sign of the difference between the values of the first pair of bytes that differ in the strings being compared. The `strncmp()` function makes the same comparison but looks at a maximum of *n* bytes. Bytes following a null byte are not compared.

strdup(3C)

<code>strcpy()</code> , <code>strncpy()</code> , <code>strncpy()</code>	<p>The <code>strcpy()</code> function copies string <i>s2</i> to <i>s1</i>, including the terminating null character, stopping after the null character has been copied. The <code>strncpy()</code> function copies exactly <i>n</i> bytes, truncating <i>s2</i> or adding null characters to <i>s1</i> if necessary. The result will not be null-terminated if the length of <i>s2</i> is <i>n</i> or more. Each function returns <i>s1</i>.</p> <p>The <code>strncpy()</code> function copies at most <i>dsize-1</i> characters (<i>dsize</i> being the size of the string buffer <i>dst</i>) from <i>src</i> to <i>dst</i>, truncating <i>src</i> if necessary. The result is always null-terminated. The function returns <code>strlen(src)</code>. Buffer overflow can be checked as follows:</p> <pre>if (strncpy(dst, src, dsize) >= dsize) return -1;</pre>
<code>strcspn()</code> , <code>strspn()</code>	<p>The <code>strcspn()</code> function returns the length of the initial segment of string <i>s1</i> that consists entirely of characters not from string <i>s2</i>. The <code>strspn()</code> function returns the length of the initial segment of string <i>s1</i> that consists entirely of characters from string <i>s2</i>.</p>
<code>strdup()</code>	<p>The <code>strdup()</code> function returns a pointer to a new string that is a duplicate of the string pointed to by <i>s1</i>. The returned pointer can be passed to <code>free()</code>. The space for the new string is obtained using <code>malloc(3C)</code>. If the new string cannot be created, a null pointer is returned and <code>errno</code> may be set to <code>ENOMEM</code> to indicate that the storage space available is insufficient.</p>
<code>strlen()</code>	<p>The <code>strlen()</code> function returns the number of bytes in <i>s</i>, not including the terminating null character.</p>
<code>strpbrk()</code>	<p>The <code>strpbrk()</code> function returns a pointer to the first occurrence in string <i>s1</i> of any character from string <i>s2</i>, or a null pointer if no character from <i>s2</i> exists in <i>s1</i>.</p>
<code>strstr()</code>	<p>The <code>strstr()</code> function locates the first occurrence of the string <i>s2</i> (excluding the terminating null character) in string <i>s1</i> and returns a pointer to the located string, or a null pointer if the string is not found. If <i>s2</i> points to a string with zero length (that is, the string ""), the function returns <i>s1</i>.</p>
<code>strtok()</code>	<p>The <code>strtok()</code> function can be used to break the string pointed to by <i>s1</i> into a sequence of tokens, each of which is delimited by one or more characters from the string pointed to by <i>s2</i>. The <code>strtok()</code> function considers the string <i>s1</i> to consist of a sequence of zero or more text tokens separated by spans of one or more characters from the separator string <i>s2</i>. The first call (with pointer <i>s1</i> specified) returns a pointer to the first character of the first token, and will have written a null character into <i>s1</i> immediately following the returned token. The function keeps track of its position in the string between separate calls, so that subsequent calls (which must be made with the first argument being a null pointer) will work through the string <i>s1</i> immediately following that token. In this way subsequent calls will work through the string <i>s1</i> until no tokens remain. The separator string <i>s2</i> may be different from call to call. When no token remains in <i>s1</i>, a null pointer is returned.</p>

strdup(3C)

`strtok_r()` The `strtok_r()` function has the same functionality as `strtok()` except that a pointer to a string placeholder *lasts* must be supplied by the caller. The *lasts* pointer is to keep track of the next substring in which to search for the next token.

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
MT-Level	See NOTES below.

NOTES When compiling multithreaded applications, the `_REENTRANT` flag must be defined on the compile line. This flag should only be used in multithreaded applications.

All of these functions assume the default locale "C." For some locales, `strxfrm()` should be applied to the strings before they are passed to the functions.

The `strcasemp()`, `strcat()`, `strchr()`, `strcmp()`, `strcpy()`, `strcspn()`, `strdup()`, `strlen()`, `strncasemp()`, `strncat()`, `strncmp()`, `strncpy()`, `strpbrk()`, `strrchr()`, `strspn()`, and `strstr()` functions are MT-Safe in multithreaded applications.

The `strtok()` function is Unsafe in multithreaded applications. The `strtok_r()` function should be used instead.

strerror(3C)

- NAME** | strerror – get error message string
- SYNOPSIS** | #include <string.h>
| char ***strerror**(int *errnum*);
- DESCRIPTION** | The `strerror()` function maps the error number in *errnum* to an error message string, and returns a pointer to that string. It uses the same set of error messages as `perror(3C)`. The returned string should not be overwritten.
- RETURN VALUES** | The `strerror()` function returns the string “Unknown error” if *errnum* is out of range.
- ATTRIBUTES** | See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Interface Stability	Standard
MT-Level	Safe

SEE ALSO | `gettext(3C)`, `perror(3C)`, `setlocale(3C)`, `attributes(5)`

NOTES | If the application is linked with `-lintl`, then messages returned from this function are in the native language specified by the `LC_MESSAGES` locale category; see `setlocale(3C)`.

NAME	strfmon – convert monetary value to string
SYNOPSIS	<pre>#include <monetary.h> ssize_t strfmon(char *s, size_t <i>maxsize</i>, const char *<i>format</i>, ...);</pre>
DESCRIPTION	<p>The <code>strfmon()</code> function places characters into the array pointed to by <code>s</code> as controlled by the string pointed to by <code>format</code>. No more than <code>maxsize</code> bytes are placed into the array.</p> <p>The format is a character string that contains two types of objects: plain characters, which are simply copied to the output stream, and conversion specifications, each of which results in the fetching of zero or more arguments which are converted and formatted. The results are undefined if there are insufficient arguments for the format. If the format is exhausted while arguments remain, the excess arguments are simply ignored.</p> <p>A conversion specification consists of the following sequence:</p> <ul style="list-style-type: none"> ■ a % character ■ optional flags ■ optional field width ■ optional left precision ■ optional right precision ■ a required conversion character that determines the conversion to be performed.
Flags	<p>One or more of the following optional flags can be specified to control the conversion:</p> <p><code>=f</code> An <code>=</code> followed by a single character <code>f</code> which is used as the numeric fill character. The fill character must be representable in a single byte in order to work with precision and width counts. The default numeric fill character is the space character. This flag does not affect field width filling which always uses the space character. This flag is ignored unless a left precision (see below) is specified.</p> <p><code>^</code> Do not format the currency amount with grouping characters. The default is to insert the grouping characters if defined for the current locale.</p> <p><code>+ or (</code> Specify the style of representing positive and negative currency amounts. Only one of <code>'+'</code> or <code>'('</code> may be specified. If <code>'+'</code> is specified, the locale's equivalent of <code>+</code> and <code>'-'</code> are used (for example, in the U.S.A.: the empty string if positive and <code>'-'</code> if negative). If <code>'('</code> is specified, negative amounts are enclosed within parentheses. If neither flag is specified, the <code>'+'</code> style is used.</p> <p><code>!</code> Suppress the currency symbol from the output conversion.</p> <p><code>-</code> Specify the alignment. If this flag is present all fields are left-justified (padded to the right) rather than right-justified.</p>
Field Width	<p><code>w</code> A decimal digit string <code>w</code> specifying a minimum field width in bytes in which the result of the conversion is right-justified (or left-justified if the flag <code>'-'</code> is specified). The default is zero.</p>

strfmon(3C)

Left Precision	<i>#n</i>	<p>A '#' followed by a decimal digit string <i>n</i> specifying a maximum number of digits expected to be formatted to the left of the radix character. This option can be used to keep the formatted output from multiple calls to the <code>strfmon()</code> aligned in the same columns. It can also be used to fill unused positions with a special character as in <code>\$***123.45</code>. This option causes an amount to be formatted as if it has the number of digits specified by <i>n</i>. If more than <i>n</i> digit positions are required, this conversion specification is ignored. Digit positions in excess of those actually required are filled with the numeric fill character (see the <code>=f</code> flag above).</p> <p>If grouping has not been suppressed with the '^' flag, and it is defined for the current locale, grouping separators are inserted before the fill characters (if any) are added. Grouping separators are not applied to fill characters even if the fill character is a digit.</p> <p>To ensure alignment, any characters appearing before or after the number in the formatted output such as currency or sign symbols are padded as necessary with space characters to make their positive and negative formats an equal length.</p>
Right Precision	<i>.p</i>	<p>A period followed by a decimal digit string <i>p</i> specifying the number of digits after the radix character. If the value of the right precision <i>p</i> is zero, no radix character appears. If a right precision is not included, a default specified by the current locale is used. The amount being formatted is rounded to the specified number of digits prior to formatting.</p>
Conversion Characters		<p>The conversion characters and their meanings are:</p> <p><i>i</i> The <code>double</code> argument is formatted according to the locale's international currency format (for example, in the U.S.A.: USD 1,234.56).</p> <p><i>n</i> The <code>double</code> argument is formatted according to the locale's national currency format (for example, in the U.S.A.: \$1,234.56).</p> <p><i>%</i> Convert to a %; no argument is converted. The entire conversion specification must be <code>%%</code>.</p>
Locale Information		<p>The <code>LC_MONETARY</code> category of the program's locale affects the behavior of this function including the monetary radix character (which may be different from the numeric radix character affected by the <code>LC_NUMERIC</code> category), the grouping separator, the currency symbols and formats. The international currency symbol should be in conformance with the ISO 4217: 1987 standard.</p>
RETURN VALUES		<p>If the total number of resulting bytes (including the terminating null byte) is not more than <i>maxsize</i>, <code>strfmon()</code> returns the number of bytes placed into the array pointed to by <i>s</i>, not including the terminating null byte. Otherwise, <code>-1</code> is returned, the contents of the array are indeterminate, and <code>errno</code> is set to indicate the error.</p>
ERRORS		<p>The <code>strfmon()</code> function will fail if:</p> <p><code>ENOSYS</code> The function is not supported.</p>

E2BIG Conversion stopped due to lack of space in the buffer.

EXAMPLES

EXAMPLE 1 A sample output of `strfmon()`.

Given a locale for the U.S.A. and the values 123.45, -123.45, and 3456.781:

Conversion	Output	Comments
Specification		
%n	\$123.45 -\$123.45 \$3,456.78	default formatting
%11n	\$123.45 -\$123.45 \$3,456.78	right align within an 11 character field
%#5n	\$123.45 -\$123.45 \$3,456.78	aligned columns for values up to 99,999
%=#5n	\$\$\$123.45 -\$\$\$\$123.45 \$*3,456.78	specify a fill character
%=0#5n	\$000123.45 -\$000123.45 \$03,456.78	fill characters do not use grouping even if the fill character is a digit
%^#5n	\$123.45 -\$123.45 \$3456.78	disable the grouping separator
%^#5.0n	\$123 -\$123 \$3457	round off to whole units
%^#5.4n	\$123.4500 -\$123.4500 \$3456.7810	increase the precision

strfmon(3C)

EXAMPLE 1 A sample output of `strfmon()`. (Continued)

Conversion Specification	Output	Comments
%(#5n	123.45	use an alternative
	(\$123.45)	pos/neg style
	\$3,456.78	
%!(#5n	123.45	disable the currency
	(123.45)	symbol
	3,456.78	

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
MT-Level	MT-Safe with exceptions
CSI	Enabled

NOTES This function can be used safely in multithreaded applications, as long as `setlocale(3C)` is not called to change the locale.

NAME	strptime, cftime, ascftime – convert date and time to string																						
SYNOPSIS	<pre>#include <time.h> size_t strptime(char *s, size_t <i>maxsize</i>, const char *<i>format</i>, const struct tm *<i>timeptr</i>); int cftime(char *s, char *<i>format</i>, const time_t *<i>clock</i>); int ascftime(char *s, const char *<i>format</i>, const struct tm *<i>timeptr</i>);</pre>																						
DESCRIPTION	<p>The <code>strptime()</code>, <code>ascftime()</code>, and <code>cftime()</code> functions place bytes into the array pointed to by <code>s</code> as controlled by the string pointed to by <code>format</code>. The <code>format</code> string consists of zero or more conversion specifications and ordinary characters. A conversion specification consists of a '%' (percent) character and one or two terminating conversion characters that determine the conversion specification's behavior. All ordinary characters (including the terminating null byte) are copied unchanged into the array pointed to by <code>s</code>. If copying takes place between objects that overlap, the behavior is undefined. For <code>strptime()</code>, no more than <code>maxsize</code> bytes are placed into the array.</p> <p>If <code>format</code> is <code>(char *)0</code>, then the locale's default format is used. For <code>strptime()</code> the default format is the same as <code>%c</code>; for <code>cftime()</code> and <code>ascftime()</code> the default format is the same as <code>%C</code>. <code>cftime()</code> and <code>ascftime()</code> first try to use the value of the environment variable <code>CFTIME</code>, and if that is undefined or empty, the default format is used.</p> <p>Each conversion specification is replaced by appropriate characters as described in the following list. The appropriate characters are determined by the <code>LC_TIME</code> category of the program's locale and by the values contained in the structure pointed to by <code>timeptr</code> for <code>strptime()</code> and <code>ascftime()</code>, and by the time represented by <code>clock</code> for <code>cftime()</code>.</p> <table border="0"> <tr> <td style="padding-right: 20px;">%%</td> <td>Same as %.</td> </tr> <tr> <td>%a</td> <td>Locale's abbreviated weekday name.</td> </tr> <tr> <td>%A</td> <td>Locale's full weekday name.</td> </tr> <tr> <td>%b</td> <td>Locale's abbreviated month name.</td> </tr> <tr> <td>%B</td> <td>Locale's full month name.</td> </tr> <tr> <td>%c</td> <td>Locale's appropriate date and time representation.</td> </tr> <tr> <td>Default %C</td> <td>Locale's date and time representation as produced by <code>date(1)</code>.</td> </tr> <tr> <td>Standard conforming %C</td> <td>Century number (the year divided by 100 and truncated to an integer as a decimal number [1,99]); single digits are preceded by 0; see <code>standards(5)</code>.</td> </tr> <tr> <td>%d</td> <td>Day of month [1,31]; single digits are preceded by 0.</td> </tr> <tr> <td>%D</td> <td>Date as <code>%m/%d/%y</code>.</td> </tr> <tr> <td>%e</td> <td>Day of month [1,31]; single digits are preceded by a space.</td> </tr> </table>	%%	Same as %.	%a	Locale's abbreviated weekday name.	%A	Locale's full weekday name.	%b	Locale's abbreviated month name.	%B	Locale's full month name.	%c	Locale's appropriate date and time representation.	Default %C	Locale's date and time representation as produced by <code>date(1)</code> .	Standard conforming %C	Century number (the year divided by 100 and truncated to an integer as a decimal number [1,99]); single digits are preceded by 0; see <code>standards(5)</code> .	%d	Day of month [1,31]; single digits are preceded by 0.	%D	Date as <code>%m/%d/%y</code> .	%e	Day of month [1,31]; single digits are preceded by a space.

%a	Locale's abbreviated weekday name.																						
%A	Locale's full weekday name.																						
%b	Locale's abbreviated month name.																						
%B	Locale's full month name.																						
%c	Locale's appropriate date and time representation.																						
Default %C	Locale's date and time representation as produced by <code>date(1)</code> .																						
Standard conforming %C	Century number (the year divided by 100 and truncated to an integer as a decimal number [1,99]); single digits are preceded by 0; see <code>standards(5)</code> .																						
%d	Day of month [1,31]; single digits are preceded by 0.																						
%D	Date as <code>%m/%d/%y</code> .																						
%e	Day of month [1,31]; single digits are preceded by a space.																						

strftime(3C)

%g	Week-based year within century [00,99].
%G	Week-based year, including the century [0000,9999].
%h	Locale's abbreviated month name.
%H	Hour (24-hour clock) [0,23]; single digits are preceded by 0.
%I	Hour (12-hour clock) [1,12]; single digits are preceded by 0.
%j	Day number of year [1,366]; single digits are preceded by 0.
%k	Hour (24-hour clock) [0,23]; single digits are preceded by a blank.
%l	Hour (12-hour clock) [1,12]; single digits are preceded by a blank.
%m	Month number [1,12]; single digits are preceded by 0.
%M	Minute [00,59]; leading 0 is permitted but not required.
%n	Insert a NEWLINE.
%p	Locale's equivalent of either a.m. or p.m.
%r	Appropriate time representation in 12-hour clock format with %p.
%R	Time as %H:%M.
%S	Seconds [00,61]; the range of values is [00,61] rather than [00,59] to allow for the occasional leap second and even more occasional double leap second.
%t	Insert a TAB.
%T	Time as %H:%M:%S.
%u	Weekday as a decimal number [1,7], with 1 representing Monday. See NOTES below.
%U	Week number of year as a decimal number [00,53], with Sunday as the first day of week 1.
%V	The ISO 8601 week number as a decimal number [01,53]. In the ISO 8601 week-based system, weeks begin on a Monday and week 1 of the year is the week that includes both January 4th and the first Thursday of the year. If the first Monday of January is the 2nd, 3rd, or 4th, the preceding days are part of the last week of the preceding year. See NOTES below.
%w	Weekday as a decimal number [0,6], with 0 representing Sunday.
%W	Week number of year as a decimal number [00,53], with Monday as the first day of week 1.
%x	Locale's appropriate date representation.
%X	Locale's appropriate time representation.
%y	Year within century [00,99].

%Y	Year, including the century (for example 1993).
%Z	Time zone name or abbreviation, or no bytes if no time zone information exists.

If a conversion specification does not correspond to any of the above or to any of the modified conversion specifications listed below, the behavior is undefined and 0 is returned.

The difference between %U and %W (and also between modified conversion specifications %OU and %OW) lies in which day is counted as the first of the week. Week number 1 is the first week in January starting with a Sunday for %U or a Monday for %W. Week number 0 contains those days before the first Sunday or Monday in January for %U and %W, respectively.

Modified Conversion Specifications

Some conversion specifications can be modified by the E and O modifiers to indicate that an alternate format or specification should be used rather than the one normally used by the unmodified conversion specification. If the alternate format or specification does not exist in the current locale, the behavior will be as if the unmodified specification were used.

%Ec	Locale's alternate appropriate date and time representation.
%EC	Name of the base year (period) in the locale's alternate representation.
%Eg	Offset from %EC of the week-based year in the locale's alternative representation.
%EG	Full alternative representation of the week-based year.
%Ex	Locale's alternate date representation.
%EX	Locale's alternate time representation.
%Ey	Offset from %EC (year only) in the locale's alternate representation.
%EY	Full alternate year representation.
%Od	Day of the month using the locale's alternate numeric symbols.
%Oe	Same as %Od.
%Og	Week-based year (offset from %C) in the locale's alternate representation and using the locale's alternate numeric symbols.
%OH	Hour (24-hour clock) using the locale's alternate numeric symbols.
%OI	Hour (12-hour clock) using the locale's alternate numeric symbols.
%Om	Month using the locale's alternate numeric symbols.
%OM	Minutes using the locale's alternate numeric symbols.
%OS	Seconds using the locale's alternate numeric symbols.
%Ou	Weekday as a number in the locale's alternate numeric symbols.

strptime(3C)

%OU	Week number of the year (Sunday as the first day of the week) using the locale's alternate numeric symbols.
%Ow	Number of the weekday (Sunday=0) using the locale's alternate numeric symbols.
%OW	Week number of the year (Monday as the first day of the week) using the locale's alternate numeric symbols.
%Oy	Year (offset from %C) in the locale's alternate representation and using the locale's alternate numeric symbols.

Selecting the Output Language

By default, the output of `strptime()`, `cftime()`, and `ascftime()` appear in U.S. English. The user can request that the output of `strptime()`, `cftime()`, or `ascftime()` be in a specific language by setting the `LC_TIME` category using `setlocale()`.

Time Zone

Local time zone information is used as though `tzset(3C)` were called.

RETURN VALUES

The `strptime()`, `cftime()`, and `ascftime()` functions return the number of characters placed into the array pointed to by `s`, not including the terminating null character. If the total number of resulting characters including the terminating null character is more than `maxsize`, `strptime()` returns 0 and the contents of the array are indeterminate.

EXAMPLES

EXAMPLE 1 An example of the `strptime()` function.

The following example illustrates the use of `strptime()` for the POSIX locale. It shows what the string in `str` would look like if the structure pointed to by `tmptr` contains the values corresponding to Thursday, August 28, 1986 at 12:44:36.

```
strptime (str, strsize, "%A %b %d %j", tmptr)
```

This results in `str` containing "Thursday Aug 28 240".

strftime(3C)

NOTES The conversion specification for %V was changed in the Solaris 7 release. This change was based on the public review draft of the ISO C9x standard at that time. Previously, the specification stated that if the week containing 1 January had fewer than four days in the new year, it became week 53 of the previous year. The ISO C9x standard committee subsequently recognized that that specification had been incorrect.

The conversion specifications for %g, %G, %Eg, %EG, and %Og were added in the Solaris 7 release. This change was based on the public review draft of the ISO C9x standard at that time. These specifications are evolving. If the ISO C9x standard is finalized with a different conclusion, these specifications will change to conform to the ISO C9x standard decision.

The conversion specification for %u was changed in the Solaris 8 release. This change was based on the XPG4 specification.

If using the %Z specifier and `zoneinfo` timezones and if the input date is outside the range 20:45:52 UTC, December 13, 1901 to 03:14:07 UTC, January 19, 2038, the timezone name may not be correct.

string(3C)

NAME	string, strcasecmp, strncasecmp, strcat, strncat, strlcat, strchr, strrchr, strcmp, strncmp, strcpy, strncpy, strlcpy, strcspn, strspn, strdup, strlen, strpbrk, strstr, strtok, strtok_r – string operations
SYNOPSIS	<pre>#include <strings.h> int strcasecmp(const char *s1, const char *s2); int strncasecmp(const char *s1, const char *s2, size_t n); #include <string.h> char *strcat(char *s1, const char *s2); char *strncat(char *s1, const char *s2, size_t n); size_t strlcat(char *dst, const char *src, size_t dstsize); char *strchr(const char *s, int c); char *strrchr(const char *s, int c); int strcmp(const char *s1, const char *s2); int strncmp(const char *s1, const char *s2, size_t n); char *strcpy(char *s1, const char *s2); char *strncpy(char *s1, const char *s2, size_t n); size_t strlcpy(char *dst, const char *src, size_t dstsize); size_t strcspn(const char *s1, const char *s2); size_t strspn(const char *s1, const char *s2); char *strdup(const char *s1); size_t strlen(const char *s); char *strpbrk(const char *s1, const char *s2); char *strstr(const char *s1, const char *s2); char *strtok(char *s1, const char *s2); char *strtok_r(char *s1, const char *s2, char **lasts);</pre>
ISO C++	<pre>#include <string.h> const char *strchr(const char *s, int c); const char *strpbrk(const char *s1, const char *s2); const char *strrchr(const char *s, int c); const char *strstr(const char *s1, const char *s2); #include <cstring> char *std::strchr(char *s, int c);</pre>

	<pre>char *std::strpbrk(char *s1, const char *s2); char *std::strrchr(char *s, int c); char *std::strstr(char *s1, const char *s2);</pre>
DESCRIPTION	<p>The arguments <i>s</i>, <i>s1</i>, and <i>s2</i> point to strings (arrays of characters terminated by a null character). The <code>strcat()</code>, <code>strncat()</code>, <code>strlcat()</code>, <code>strcpy()</code>, <code>strncpy()</code>, <code>strncpy()</code>, <code>strtok()</code>, and <code>strtok_r()</code> functions all alter their first argument. These functions do not check for overflow of the array pointed to by the first argument.</p>
<code>strcasecmp()</code> , <code>strncasecmp()</code>	<p>The <code>strcasecmp()</code> and <code>strncasecmp()</code> functions are case-insensitive versions of <code>strcmp()</code> and <code>strncmp()</code> respectively, described below. They assume the ASCII character set and ignore differences in case when comparing lower and upper case characters.</p>
<code>strcat()</code> , <code>strncat()</code> , <code>strlcat()</code>	<p>The <code>strcat()</code> function appends a copy of string <i>s2</i>, including the terminating null character, to the end of string <i>s1</i>. The <code>strncat()</code> function appends at most <i>n</i> characters. Each returns a pointer to the null-terminated result. The initial character of <i>s2</i> overrides the null character at the end of <i>s1</i>.</p> <p>The <code>strlcat()</code> function appends at most $(dstsize - strlen(dst) - 1)$ characters of <i>src</i> to <i>dst</i> (<i>dstsize</i> being the size of the string buffer <i>dst</i>). If the string pointed to by <i>dst</i> contains a null-terminated string that fits into <i>dstsize</i> bytes when <code>strlcat()</code> is called, the string pointed to by <i>dst</i> will be a null-terminated string that fits in <i>dstsize</i> bytes (including the terminating null character) when it completes, and the initial character of <i>src</i> will override the null character at the end of <i>dst</i>. If the string pointed to by <i>dst</i> is longer than <i>dstsize</i> bytes when <code>strlcat()</code> is called, the string pointed to by <i>dst</i> will not be changed. The function returns the sum of lengths of the two strings $strlen(dst) + strlen(src)$. Buffer overflow can be checked as follows:</p> <pre>if (strlcat(dst, src, dstsize) >= dstsize) return -1;</pre>
<code>strchr()</code> , <code>strrchr()</code>	<p>The <code>strchr()</code> function returns a pointer to the first occurrence of <i>c</i> (converted to a char) in string <i>s</i>, or a null pointer if <i>c</i> does not occur in the string. The <code>strrchr()</code> function returns a pointer to the last occurrence of <i>c</i>. The null character terminating a string is considered to be part of the string.</p>
<code>strcmp()</code> , <code>strncmp()</code>	<p>The <code>strcmp()</code> function compares two strings byte-by-byte, according to the ordering of your machine's character set. The function returns an integer greater than, equal to, or less than 0, if the string pointed to by <i>s1</i> is greater than, equal to, or less than the string pointed to by <i>s2</i> respectively. The sign of a non-zero return value is determined by the sign of the difference between the values of the first pair of bytes that differ in the strings being compared. The <code>strncmp()</code> function makes the same comparison but looks at a maximum of <i>n</i> bytes. Bytes following a null byte are not compared.</p>

string(3C)

<code>strcpy()</code> , <code>strncpy()</code> , <code>strncpy()</code>	<p>The <code>strcpy()</code> function copies string <i>s2</i> to <i>s1</i>, including the terminating null character, stopping after the null character has been copied. The <code>strncpy()</code> function copies exactly <i>n</i> bytes, truncating <i>s2</i> or adding null characters to <i>s1</i> if necessary. The result will not be null-terminated if the length of <i>s2</i> is <i>n</i> or more. Each function returns <i>s1</i>.</p> <p>The <code>strncpy()</code> function copies at most <i>dsize-1</i> characters (<i>dsize</i> being the size of the string buffer <i>dst</i>) from <i>src</i> to <i>dst</i>, truncating <i>src</i> if necessary. The result is always null-terminated. The function returns <code>strlen(src)</code>. Buffer overflow can be checked as follows:</p> <pre>if (strncpy(dst, src, dsize) >= dsize) return -1;</pre>
<code>strcspn()</code> , <code>strcspn()</code>	<p>The <code>strcspn()</code> function returns the length of the initial segment of string <i>s1</i> that consists entirely of characters not from string <i>s2</i>. The <code>strcspn()</code> function returns the length of the initial segment of string <i>s1</i> that consists entirely of characters from string <i>s2</i>.</p>
<code>strdup()</code>	<p>The <code>strdup()</code> function returns a pointer to a new string that is a duplicate of the string pointed to by <i>s1</i>. The returned pointer can be passed to <code>free()</code>. The space for the new string is obtained using <code>malloc(3C)</code>. If the new string cannot be created, a null pointer is returned and <code>errno</code> may be set to <code>ENOMEM</code> to indicate that the storage space available is insufficient.</p>
<code>strlen()</code>	<p>The <code>strlen()</code> function returns the number of bytes in <i>s</i>, not including the terminating null character.</p>
<code>strpbrk()</code>	<p>The <code>strpbrk()</code> function returns a pointer to the first occurrence in string <i>s1</i> of any character from string <i>s2</i>, or a null pointer if no character from <i>s2</i> exists in <i>s1</i>.</p>
<code>strstr()</code>	<p>The <code>strstr()</code> function locates the first occurrence of the string <i>s2</i> (excluding the terminating null character) in string <i>s1</i> and returns a pointer to the located string, or a null pointer if the string is not found. If <i>s2</i> points to a string with zero length (that is, the string ""), the function returns <i>s1</i>.</p>
<code>strtok()</code>	<p>The <code>strtok()</code> function can be used to break the string pointed to by <i>s1</i> into a sequence of tokens, each of which is delimited by one or more characters from the string pointed to by <i>s2</i>. The <code>strtok()</code> function considers the string <i>s1</i> to consist of a sequence of zero or more text tokens separated by spans of one or more characters from the separator string <i>s2</i>. The first call (with pointer <i>s1</i> specified) returns a pointer to the first character of the first token, and will have written a null character into <i>s1</i> immediately following the returned token. The function keeps track of its position in the string between separate calls, so that subsequent calls (which must be made with the first argument being a null pointer) will work through the string <i>s1</i> immediately following that token. In this way subsequent calls will work through the string <i>s1</i> until no tokens remain. The separator string <i>s2</i> may be different from call to call. When no token remains in <i>s1</i>, a null pointer is returned.</p>

string(3C)

`strtok_r()` The `strtok_r()` function has the same functionality as `strtok()` except that a pointer to a string placeholder *lasts* must be supplied by the caller. The *lasts* pointer is to keep track of the next substring in which to search for the next token.

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
MT-Level	See NOTES below.

SEE ALSO `malloc(3C)`, `setlocale(3C)`, `strxfrm(3C)`, `attributes(5)`

NOTES When compiling multithreaded applications, the `_REENTRANT` flag must be defined on the compile line. This flag should only be used in multithreaded applications.

All of these functions assume the default locale "C." For some locales, `strxfrm()` should be applied to the strings before they are passed to the functions.

The `strcasemp()`, `strcat()`, `strchr()`, `strcmp()`, `strcpy()`, `strcspn()`, `strdup()`, `strlen()`, `strncasemp()`, `strncat()`, `strncmp()`, `strncpy()`, `strpbrk()`, `strrchr()`, `strspn()`, and `strstr()` functions are MT-Safe in multithreaded applications.

The `strtok()` function is Unsafe in multithreaded applications. The `strtok_r()` function should be used instead.

string_to_decimal(3C)

NAME	string_to_decimal, file_to_decimal, func_to_decimal – parse characters into decimal record																
SYNOPSIS	<pre>#include <floatingpoint.h> void string_to_decimal(char **pc, int nmax, int fortran_conventions, decimal_record *pd, enum decimal_string_form *pform, char **pechar); void func_to_decimal(char **pc, int nmax, int fortran_conventions, decimal_record *pd, enum decimal_string_form *pform, char **pechar, int (*pget)(void), int *pnread, int (*punget)(int c)); #include <stdio.h> void file_to_decimal(char **pc, int nmax, int fortran_conventions, decimal_record *pd, enum decimal_string_form *pform, char **pechar, FILE *pf, int *pnread);</pre>																
DESCRIPTION	<p>The char_to_decimal functions parse a numeric token from at most <i>nmax</i> characters in a string <i>**pc</i> or file <i>*pf</i> or function (<i>*pget</i>)() into a decimal record <i>*pd</i>, classifying the form of the string in <i>*pform</i> and <i>*pechar</i>. The accepted syntax is intended to be sufficiently flexible to accommodate many languages: <i>whitespace value</i> or <i>whitespace sign value</i>, where <i>whitespace</i> is any number of characters defined by <i>isspace</i> in <i><ctype.h></i>, <i>sign</i> is either of [+–], and <i>value</i> can be <i>number</i>, <i>nan</i>, or <i>inf</i>. <i>inf</i> can be INF (<i>inf_form</i>) or INFINITY (<i>infinity_form</i>) without regard to case. <i>nan</i> can be NAN (<i>nan_form</i>) or NAN(<i>nstring</i>) (<i>nanstring_form</i>) without regard to case; <i>nstring</i> is any string of characters not containing ' ' or NULL; <i>nstring</i> is copied to <i>pd</i>→<i>ds</i> and, currently, not used subsequently. <i>number</i> consists of <i>significand</i> or <i>significand efield</i> where <i>significand</i> must contain one or more digits and may contain one point; possible forms are</p> <table><tr><td><i>digits</i></td><td>(<i>int_form</i>)</td></tr><tr><td><i>digits.</i></td><td>(<i>intdot_form</i>)</td></tr><tr><td><i>.digits</i></td><td>(<i>dotfrac_form</i>)</td></tr><tr><td><i>digits.digits</i></td><td>(<i>intdotfrac_form</i>)</td></tr></table> <p><i>efield</i> consists of <i>echar digits</i> or <i>echar sign digits</i>, where <i>echar</i> is one of [Ee], and <i>digits</i> contains one or more digits.</p> <p>When <i>fortran_conventions</i> is nonzero, additional input forms are accepted according to various Fortran conventions:</p> <table><tr><td>0</td><td>no Fortran conventions</td></tr><tr><td>1</td><td>Fortran list-directed input conventions</td></tr><tr><td>2</td><td>Fortran formatted input conventions, ignore blanks (BN)</td></tr><tr><td>3</td><td>Fortran formatted input conventions, blanks are zeros (BZ)</td></tr></table> <p>When <i>fortran_conventions</i> is nonzero, <i>echar</i> may also be one of [DdQq], and <i>efield</i> may also have the form</p>	<i>digits</i>	(<i>int_form</i>)	<i>digits.</i>	(<i>intdot_form</i>)	<i>.digits</i>	(<i>dotfrac_form</i>)	<i>digits.digits</i>	(<i>intdotfrac_form</i>)	0	no Fortran conventions	1	Fortran list-directed input conventions	2	Fortran formatted input conventions, ignore blanks (BN)	3	Fortran formatted input conventions, blanks are zeros (BZ)
<i>digits</i>	(<i>int_form</i>)																
<i>digits.</i>	(<i>intdot_form</i>)																
<i>.digits</i>	(<i>dotfrac_form</i>)																
<i>digits.digits</i>	(<i>intdotfrac_form</i>)																
0	no Fortran conventions																
1	Fortran list-directed input conventions																
2	Fortran formatted input conventions, ignore blanks (BN)																
3	Fortran formatted input conventions, blanks are zeros (BZ)																

sign digits.

When *fortran_conventions* ≥ 2 , blanks may appear in the *digits* strings for the integer, fraction, and exponent fields and may appear between *echar* and the exponent sign and after the infinity and NaN forms. If *fortran_conventions* $= 2$, the blanks are ignored. When *fortran_conventions* $= 3$, the blanks that appear in *digits* strings are interpreted as zeros, and other blanks are ignored.

When *fortran_conventions* is zero, the current locale's decimal point character is used as the decimal point; when *fortran_conventions* is nonzero, the period is used as the decimal point.

The form of the accepted decimal string is placed in *pform*. If an *efield* is recognized, *pechar* is set to point to the *echar*.

On input, *pc* points to the beginning of a character string buffer of length $\geq nmax$. On output, *pc* points to a character in that buffer, one past the last accepted character. `string_to_decimal()` gets its characters from the buffer; `file_to_decimal()` gets its characters from *pf* and records them in the buffer, and places a null after the last character read. `func_to_decimal()` gets its characters from an int function (*pget*()).

The scan continues until no more characters could possibly fit the acceptable syntax or until *nmax* characters have been scanned. If the *nmax* limit is not reached then at least one extra character will usually be scanned that is not part of the accepted syntax. `file_to_decimal()` and `func_to_decimal()` set *pnread* to the number of characters read from the file; if greater than *nmax*, some characters were lost. If no characters were lost, `file_to_decimal()` and `func_to_decimal()` attempt to push back, with `ungetc(3C)` or (*punget*()), as many as possible of the excess characters read, adjusting *pnread* accordingly. If all `unget` calls are successful, then *pc* will be NULL. No push back will be attempted if (*punget*()) is NULL.

Typical declarations for *pget*() and *punget*() are:

```
int xget(void)
{ . . . }
int (*pget)(void) = xget;
int xunget(int c)
{ . . . }
int (*punget)(int) = xunget;
```

If no valid number was detected, *pd* \rightarrow *fpclass* is set to *fp_signaling*, *pc* is unchanged, and *pform* is set to *invalid_form*.

`atof(3C)` and `strtod(3C)` use `string_to_decimal()`. `scanf(3C)` uses `file_to_decimal()`.

string_to_decimal(3C)

NAME	string, strcasecmp, strncasecmp, strcat, strncat, strlcat, strchr, strrchr, strcmp, strncmp, strcpy, strncpy, strlcpy, strcspn, strspn, strdup, strlen, strpbrk, strstr, strtok, strtok_r – string operations
SYNOPSIS	<pre> #include <strings.h> int strcasecmp(const char *s1, const char *s2); int strncasecmp(const char *s1, const char *s2, size_t n); #include <string.h> char *strcat(char *s1, const char *s2); char *strncat(char *s1, const char *s2, size_t n); size_t strlcat(char *dst, const char *src, size_t dstsize); char *strchr(const char *s, int c); char *strrchr(const char *s, int c); int strcmp(const char *s1, const char *s2); int strncmp(const char *s1, const char *s2, size_t n); char *strcpy(char *s1, const char *s2); char *strncpy(char *s1, const char *s2, size_t n); size_t strlcpy(char *dst, const char *src, size_t dstsize); size_t strcspn(const char *s1, const char *s2); size_t strspn(const char *s1, const char *s2); char *strdup(const char *s1); size_t strlen(const char *s); char *strpbrk(const char *s1, const char *s2); char *strstr(const char *s1, const char *s2); char *strtok(char *s1, const char *s2); char *strtok_r(char *s1, const char *s2, char **lasts); </pre>
ISO C++	<pre> #include <string.h> const char *strchr(const char *s, int c); const char *strpbrk(const char *s1, const char *s2); const char *strrchr(const char *s, int c); const char *strstr(const char *s1, const char *s2); #include <cstring> char *std::strchr(char *s, int c); </pre>

strlcat(3C)

	<pre>char *std::strpbrk(char *s1, const char *s2); char *std::strrchr(char *s, int c); char *std::strstr(char *s1, const char *s2);</pre>
DESCRIPTION	<p>The arguments <i>s</i>, <i>s1</i>, and <i>s2</i> point to strings (arrays of characters terminated by a null character). The <code>strcat()</code>, <code>strncat()</code>, <code>strlcat()</code>, <code>strcpy()</code>, <code>strncpy()</code>, <code>strncpy()</code>, <code>strtok()</code>, and <code>strtok_r()</code> functions all alter their first argument. These functions do not check for overflow of the array pointed to by the first argument.</p>
<code>strcasecmp()</code> , <code>strncasecmp()</code>	<p>The <code>strcasecmp()</code> and <code>strncasecmp()</code> functions are case-insensitive versions of <code>strcmp()</code> and <code>strncmp()</code> respectively, described below. They assume the ASCII character set and ignore differences in case when comparing lower and upper case characters.</p>
<code>strcat()</code> , <code>strncat()</code> , <code>strlcat()</code>	<p>The <code>strcat()</code> function appends a copy of string <i>s2</i>, including the terminating null character, to the end of string <i>s1</i>. The <code>strncat()</code> function appends at most <i>n</i> characters. Each returns a pointer to the null-terminated result. The initial character of <i>s2</i> overrides the null character at the end of <i>s1</i>.</p> <p>The <code>strlcat()</code> function appends at most (<i>dstsize</i>-<code>strlen(dst)</code>-1) characters of <i>src</i> to <i>dst</i> (<i>dstsize</i> being the size of the string buffer <i>dst</i>). If the string pointed to by <i>dst</i> contains a null-terminated string that fits into <i>dstsize</i> bytes when <code>strlcat()</code> is called, the string pointed to by <i>dst</i> will be a null-terminated string that fits in <i>dstsize</i> bytes (including the terminating null character) when it completes, and the initial character of <i>src</i> will override the null character at the end of <i>dst</i>. If the string pointed to by <i>dst</i> is longer than <i>dstsize</i> bytes when <code>strlcat()</code> is called, the string pointed to by <i>dst</i> will not be changed. The function returns the sum the of lengths of the two strings <code>strlen(dst)+strlen(src)</code>. Buffer overflow can be checked as follows:</p> <pre>if (strlcat(dst, src, dstsize) >= dstsize) return -1;</pre>
<code>strchr()</code> , <code>strrchr()</code>	<p>The <code>strchr()</code> function returns a pointer to the first occurrence of <i>c</i> (converted to a char) in string <i>s</i>, or a null pointer if <i>c</i> does not occur in the string. The <code>strrchr()</code> function returns a pointer to the last occurrence of <i>c</i>. The null character terminating a string is considered to be part of the string.</p>
<code>strcmp()</code> , <code>strncmp()</code>	<p>The <code>strcmp()</code> function compares two strings byte-by-byte, according to the ordering of your machine's character set. The function returns an integer greater than, equal to, or less than 0, if the string pointed to by <i>s1</i> is greater than, equal to, or less than the string pointed to by <i>s2</i> respectively. The sign of a non-zero return value is determined by the sign of the difference between the values of the first pair of bytes that differ in the strings being compared. The <code>strncmp()</code> function makes the same comparison but looks at a maximum of <i>n</i> bytes. Bytes following a null byte are not compared.</p>

strcpy(), strncpy(), strlcpy()	<p>The <code>strcpy()</code> function copies string <code>s2</code> to <code>s1</code>, including the terminating null character, stopping after the null character has been copied. The <code>strncpy()</code> function copies exactly <code>n</code> bytes, truncating <code>s2</code> or adding null characters to <code>s1</code> if necessary. The result will not be null-terminated if the length of <code>s2</code> is <code>n</code> or more. Each function returns <code>s1</code>.</p> <p>The <code>strlcpy()</code> function copies at most <code>dsize-1</code> characters (<code>dsize</code> being the size of the string buffer <code>dst</code>) from <code>src</code> to <code>dst</code>, truncating <code>src</code> if necessary. The result is always null-terminated. The function returns <code>strlen(src)</code>. Buffer overflow can be checked as follows:</p> <pre>if (strlcpy(dst, src, dsize) >= dsize) return -1;</pre>
strcspn(), strspn()	<p>The <code>strcspn()</code> function returns the length of the initial segment of string <code>s1</code> that consists entirely of characters not from string <code>s2</code>. The <code>strspn()</code> function returns the length of the initial segment of string <code>s1</code> that consists entirely of characters from string <code>s2</code>.</p>
strdup()	<p>The <code>strdup()</code> function returns a pointer to a new string that is a duplicate of the string pointed to by <code>s1</code>. The returned pointer can be passed to <code>free()</code>. The space for the new string is obtained using <code>malloc(3C)</code>. If the new string cannot be created, a null pointer is returned and <code>errno</code> may be set to <code>ENOMEM</code> to indicate that the storage space available is insufficient.</p>
strlen()	<p>The <code>strlen()</code> function returns the number of bytes in <code>s</code>, not including the terminating null character.</p>
strpbrk()	<p>The <code>strpbrk()</code> function returns a pointer to the first occurrence in string <code>s1</code> of any character from string <code>s2</code>, or a null pointer if no character from <code>s2</code> exists in <code>s1</code>.</p>
strstr()	<p>The <code>strstr()</code> function locates the first occurrence of the string <code>s2</code> (excluding the terminating null character) in string <code>s1</code> and returns a pointer to the located string, or a null pointer if the string is not found. If <code>s2</code> points to a string with zero length (that is, the string ""), the function returns <code>s1</code>.</p>
strtok()	<p>The <code>strtok()</code> function can be used to break the string pointed to by <code>s1</code> into a sequence of tokens, each of which is delimited by one or more characters from the string pointed to by <code>s2</code>. The <code>strtok()</code> function considers the string <code>s1</code> to consist of a sequence of zero or more text tokens separated by spans of one or more characters from the separator string <code>s2</code>. The first call (with pointer <code>s1</code> specified) returns a pointer to the first character of the first token, and will have written a null character into <code>s1</code> immediately following the returned token. The function keeps track of its position in the string between separate calls, so that subsequent calls (which must be made with the first argument being a null pointer) will work through the string <code>s1</code> immediately following that token. In this way subsequent calls will work through the string <code>s1</code> until no tokens remain. The separator string <code>s2</code> may be different from call to call. When no token remains in <code>s1</code>, a null pointer is returned.</p>

strlcat(3C)

`strtok_r()` The `strtok_r()` function has the same functionality as `strtok()` except that a pointer to a string placeholder *lasts* must be supplied by the caller. The *lasts* pointer is to keep track of the next substring in which to search for the next token.

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
MT-Level	See NOTES below.

SEE ALSO `malloc(3C)`, `setlocale(3C)`, `strxfrm(3C)`, `attributes(5)`

NOTES When compiling multithreaded applications, the `_REENTRANT` flag must be defined on the compile line. This flag should only be used in multithreaded applications.

All of these functions assume the default locale "C." For some locales, `strxfrm()` should be applied to the strings before they are passed to the functions.

The `strcascmp()`, `strcat()`, `strchr()`, `strcmp()`, `strcpy()`, `strcspn()`, `strdup()`, `strlen()`, `strncascmp()`, `strncat()`, `strncmp()`, `strncpy()`, `strpbrk()`, `strrchr()`, `strspn()`, and `strstr()` functions are MT-Safe in multithreaded applications.

The `strtok()` function is Unsafe in multithreaded applications. The `strtok_r()` function should be used instead.

ISO C++	<pre> #include <string.h> const char *strchr(const char *s, int c); const char *strpbrk(const char *s1, const char *s2); const char *strrchr(const char *s, int c); const char *strstr(const char *s1, const char *s2); #include <cstring> char *std::strchr(char *s, int c); </pre>

strncpy(3C)

	<pre>char *std::strpbrk(char *s1, const char *s2); char *std::strrchr(char *s, int c); char *std::strstr(char *s1, const char *s2);</pre>
DESCRIPTION	<p>The arguments <i>s</i>, <i>s1</i>, and <i>s2</i> point to strings (arrays of characters terminated by a null character). The <code>strcat()</code>, <code>strncat()</code>, <code>strlcat()</code>, <code>strcpy()</code>, <code>strncpy()</code>, <code>strlcpy()</code>, <code>strtok()</code>, and <code>strtok_r()</code> functions all alter their first argument. These functions do not check for overflow of the array pointed to by the first argument.</p>
<code>strcasemp()</code> , <code>strncasemp()</code>	<p>The <code>strcasemp()</code> and <code>strncasemp()</code> functions are case-insensitive versions of <code>strcmp()</code> and <code>strncmp()</code> respectively, described below. They assume the ASCII character set and ignore differences in case when comparing lower and upper case characters.</p>
<code>strcat()</code> , <code>strncat()</code> , <code>strlcat()</code>	<p>The <code>strcat()</code> function appends a copy of string <i>s2</i>, including the terminating null character, to the end of string <i>s1</i>. The <code>strncat()</code> function appends at most <i>n</i> characters. Each returns a pointer to the null-terminated result. The initial character of <i>s2</i> overrides the null character at the end of <i>s1</i>.</p> <p>The <code>strlcat()</code> function appends at most $(dstsize - strlen(dst) - 1)$ characters of <i>src</i> to <i>dst</i> (<i>dstsize</i> being the size of the string buffer <i>dst</i>). If the string pointed to by <i>dst</i> contains a null-terminated string that fits into <i>dstsize</i> bytes when <code>strlcat()</code> is called, the string pointed to by <i>dst</i> will be a null-terminated string that fits in <i>dstsize</i> bytes (including the terminating null character) when it completes, and the initial character of <i>src</i> will override the null character at the end of <i>dst</i>. If the string pointed to by <i>dst</i> is longer than <i>dstsize</i> bytes when <code>strlcat()</code> is called, the string pointed to by <i>dst</i> will not be changed. The function returns the sum the of lengths of the two strings $strlen(dst) + strlen(src)$. Buffer overflow can be checked as follows:</p> <pre>if (strlcat(dst, src, dstsize) >= dstsize) return -1;</pre>
<code>strchr()</code> , <code>strrchr()</code>	<p>The <code>strchr()</code> function returns a pointer to the first occurrence of <i>c</i> (converted to a char) in string <i>s</i>, or a null pointer if <i>c</i> does not occur in the string. The <code>strrchr()</code> function returns a pointer to the last occurrence of <i>c</i>. The null character terminating a string is considered to be part of the string.</p>
<code>strcmp()</code> , <code>strncmp()</code>	<p>The <code>strcmp()</code> function compares two strings byte-by-byte, according to the ordering of your machine's character set. The function returns an integer greater than, equal to, or less than 0, if the string pointed to by <i>s1</i> is greater than, equal to, or less than the string pointed to by <i>s2</i> respectively. The sign of a non-zero return value is determined by the sign of the difference between the values of the first pair of bytes that differ in the strings being compared. The <code>strncmp()</code> function makes the same comparison but looks at a maximum of <i>n</i> bytes. Bytes following a null byte are not compared.</p>

strcpy(), strncpy(), strncpy()	<p>The <code>strcpy()</code> function copies string <code>s2</code> to <code>s1</code>, including the terminating null character, stopping after the null character has been copied. The <code>strncpy()</code> function copies exactly <code>n</code> bytes, truncating <code>s2</code> or adding null characters to <code>s1</code> if necessary. The result will not be null-terminated if the length of <code>s2</code> is <code>n</code> or more. Each function returns <code>s1</code>.</p> <p>The <code>strncpy()</code> function copies at most <code>dsize-1</code> characters (<code>dsize</code> being the size of the string buffer <code>dst</code>) from <code>src</code> to <code>dst</code>, truncating <code>src</code> if necessary. The result is always null-terminated. The function returns <code>strlen(src)</code>. Buffer overflow can be checked as follows:</p> <pre>if (strncpy(dst, src, dsize) >= dsize) return -1;</pre>
strcspn(), strspn()	<p>The <code>strcspn()</code> function returns the length of the initial segment of string <code>s1</code> that consists entirely of characters not from string <code>s2</code>. The <code>strspn()</code> function returns the length of the initial segment of string <code>s1</code> that consists entirely of characters from string <code>s2</code>.</p>
strdup()	<p>The <code>strdup()</code> function returns a pointer to a new string that is a duplicate of the string pointed to by <code>s1</code>. The returned pointer can be passed to <code>free()</code>. The space for the new string is obtained using <code>malloc(3C)</code>. If the new string cannot be created, a null pointer is returned and <code>errno</code> may be set to <code>ENOMEM</code> to indicate that the storage space available is insufficient.</p>
strlen()	<p>The <code>strlen()</code> function returns the number of bytes in <code>s</code>, not including the terminating null character.</p>
strpbrk()	<p>The <code>strpbrk()</code> function returns a pointer to the first occurrence in string <code>s1</code> of any character from string <code>s2</code>, or a null pointer if no character from <code>s2</code> exists in <code>s1</code>.</p>
strstr()	<p>The <code>strstr()</code> function locates the first occurrence of the string <code>s2</code> (excluding the terminating null character) in string <code>s1</code> and returns a pointer to the located string, or a null pointer if the string is not found. If <code>s2</code> points to a string with zero length (that is, the string ""), the function returns <code>s1</code>.</p>
strtok()	<p>The <code>strtok()</code> function can be used to break the string pointed to by <code>s1</code> into a sequence of tokens, each of which is delimited by one or more characters from the string pointed to by <code>s2</code>. The <code>strtok()</code> function considers the string <code>s1</code> to consist of a sequence of zero or more text tokens separated by spans of one or more characters from the separator string <code>s2</code>. The first call (with pointer <code>s1</code> specified) returns a pointer to the first character of the first token, and will have written a null character into <code>s1</code> immediately following the returned token. The function keeps track of its position in the string between separate calls, so that subsequent calls (which must be made with the first argument being a null pointer) will work through the string <code>s1</code> immediately following that token. In this way subsequent calls will work through the string <code>s1</code> until no tokens remain. The separator string <code>s2</code> may be different from call to call. When no token remains in <code>s1</code>, a null pointer is returned.</p>

strncpy(3C)

`strtok_r()` The `strtok_r()` function has the same functionality as `strtok()` except that a pointer to a string placeholder *lasts* must be supplied by the caller. The *lasts* pointer is to keep track of the next substring in which to search for the next token.

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

SYNOPSIS	<pre>#include <strings.h> int strcasecmp(const char *s1, const char *s2); int strncasecmp(const char *s1, const char *s2, size_t n); #include <string.h> char *strcat(char *s1, const char *s2); char *strncat(char *s1, const char *s2, size_t n); size_t strlcat(char *dst, const char *src, size_t dstsize); char *strchr(const char *s, int c); char *strrchr(const char *s, int c); int strcmp(const char *s1, const char *s2); int strncmp(const char *s1, const char *s2, size_t n); char *strcpy(char *s1, const char *s2); char *strncpy(char *s1, const char *s2, size_t n); size_t strlcpy(char *dst, const char *src, size_t dstsize); size_t strcspn(const char *s1, const char *s2); size_t strspn(const char *s1, const char *s2); char *strdup(const char *s1); size_t strlen(const char *s); char *strpbrk(const char *s1, const char *s2); char *strstr(const char *s1, const char *s2); char *strtok(char *s1, const char *s2); char *strtok_r(char *s1, const char *s2, char **lasts);</pre>
ISO C++	<pre>#include <string.h> const char *strchr(const char *s, int c); const char *strpbrk(const char *s1, const char *s2); const char *strrchr(const char *s, int c); const char *strstr(const char *s1, const char *s2); #include <cstring> char *std::strchr(char *s, int c);</pre>

strncasecmp(3C)

	<pre>char *std::strpbrk(char *s1, const char *s2); char *std::strrchr(char *s, int c); char *std::strstr(char *s1, const char *s2);</pre>
DESCRIPTION	<p>The arguments <i>s</i>, <i>s1</i>, and <i>s2</i> point to strings (arrays of characters terminated by a null character). The <code>strcat()</code>, <code>strncat()</code>, <code>strlcat()</code>, <code>strcpy()</code>, <code>strncpy()</code>, <code>strncpy()</code>, <code>strtok()</code>, and <code>strtok_r()</code> functions all alter their first argument. These functions do not check for overflow of the array pointed to by the first argument.</p>
<code>strcasecmp()</code> , <code>strncasecmp()</code>	<p>The <code>strcasecmp()</code> and <code>strncasecmp()</code> functions are case-insensitive versions of <code>strcmp()</code> and <code>strncmp()</code> respectively, described below. They assume the ASCII character set and ignore differences in case when comparing lower and upper case characters.</p>
<code>strcat()</code> , <code>strncat()</code> , <code>strlcat()</code>	<p>The <code>strcat()</code> function appends a copy of string <i>s2</i>, including the terminating null character, to the end of string <i>s1</i>. The <code>strncat()</code> function appends at most <i>n</i> characters. Each returns a pointer to the null-terminated result. The initial character of <i>s2</i> overrides the null character at the end of <i>s1</i>.</p> <p>The <code>strlcat()</code> function appends at most (<i>dstsize</i>-<code>strlen(dst)</code>-1) characters of <i>src</i> to <i>dst</i> (<i>dstsize</i> being the size of the string buffer <i>dst</i>). If the string pointed to by <i>dst</i> contains a null-terminated string that fits into <i>dstsize</i> bytes when <code>strlcat()</code> is called, the string pointed to by <i>dst</i> will be a null-terminated string that fits in <i>dstsize</i> bytes (including the terminating null character) when it completes, and the initial character of <i>src</i> will override the null character at the end of <i>dst</i>. If the string pointed to by <i>dst</i> is longer than <i>dstsize</i> bytes when <code>strlcat()</code> is called, the string pointed to by <i>dst</i> will not be changed. The function returns the sum the of lengths of the two strings <code>strlen(dst)+strlen(src)</code>. Buffer overflow can be checked as follows:</p> <pre>if (strlcat(dst, src, dstsize) >= dstsize) return -1;</pre>
<code>strchr()</code> , <code>strrchr()</code>	<p>The <code>strchr()</code> function returns a pointer to the first occurrence of <i>c</i> (converted to a char) in string <i>s</i>, or a null pointer if <i>c</i> does not occur in the string. The <code>strrchr()</code> function returns a pointer to the last occurrence of <i>c</i>. The null character terminating a string is considered to be part of the string.</p>
<code>strcmp()</code> , <code>strncmp()</code>	<p>The <code>strcmp()</code> function compares two strings byte-by-byte, according to the ordering of your machine's character set. The function returns an integer greater than, equal to, or less than 0, if the string pointed to by <i>s1</i> is greater than, equal to, or less than the string pointed to by <i>s2</i> respectively. The sign of a non-zero return value is determined by the sign of the difference between the values of the first pair of bytes that differ in the strings being compared. The <code>strncmp()</code> function makes the same comparison but looks at a maximum of <i>n</i> bytes. Bytes following a null byte are not compared.</p>

<code>strcpy()</code> , <code>strncpy()</code> , <code>strncpy()</code> , <code>strncpy()</code>	<p>The <code>strcpy()</code> function copies string <code>s2</code> to <code>s1</code>, including the terminating null character, stopping after the null character has been copied. The <code>strncpy()</code> function copies exactly <code>n</code> bytes, truncating <code>s2</code> or adding null characters to <code>s1</code> if necessary. The result will not be null-terminated if the length of <code>s2</code> is <code>n</code> or more. Each function returns <code>s1</code>.</p> <p>The <code>strncpy()</code> function copies at most <code>dsize-1</code> characters (<code>dsize</code> being the size of the string buffer <code>dst</code>) from <code>src</code> to <code>dst</code>, truncating <code>src</code> if necessary. The result is always null-terminated. The function returns <code>strlen(src)</code>. Buffer overflow can be checked as follows:</p> <pre>if (strncpy(dst, src, dsize) >= dsize) return -1;</pre>
<code>strcspn()</code> , <code>strcspn()</code>	<p>The <code>strcspn()</code> function returns the length of the initial segment of string <code>s1</code> that consists entirely of characters not from string <code>s2</code>. The <code>strspn()</code> function returns the length of the initial segment of string <code>s1</code> that consists entirely of characters from string <code>s2</code>.</p>
<code>strdup()</code>	<p>The <code>strdup()</code> function returns a pointer to a new string that is a duplicate of the string pointed to by <code>s1</code>. The returned pointer can be passed to <code>free()</code>. The space for the new string is obtained using <code>malloc(3C)</code>. If the new string cannot be created, a null pointer is returned and <code>errno</code> may be set to <code>ENOMEM</code> to indicate that the storage space available is insufficient.</p>
<code>strlen()</code>	<p>The <code>strlen()</code> function returns the number of bytes in <code>s</code>, not including the terminating null character.</p>
<code>strpbrk()</code>	<p>The <code>strpbrk()</code> function returns a pointer to the first occurrence in string <code>s1</code> of any character from string <code>s2</code>, or a null pointer if no character from <code>s2</code> exists in <code>s1</code>.</p>
<code>strstr()</code>	<p>The <code>strstr()</code> function locates the first occurrence of the string <code>s2</code> (excluding the terminating null character) in string <code>s1</code> and returns a pointer to the located string, or a null pointer if the string is not found. If <code>s2</code> points to a string with zero length (that is, the string ""), the function returns <code>s1</code>.</p>
<code>strtok()</code>	<p>The <code>strtok()</code> function can be used to break the string pointed to by <code>s1</code> into a sequence of tokens, each of which is delimited by one or more characters from the string pointed to by <code>s2</code>. The <code>strtok()</code> function considers the string <code>s1</code> to consist of a sequence of zero or more text tokens separated by spans of one or more characters from the separator string <code>s2</code>. The first call (with pointer <code>s1</code> specified) returns a pointer to the first character of the first token, and will have written a null character into <code>s1</code> immediately following the returned token. The function keeps track of its position in the string between separate calls, so that subsequent calls (which must be made with the first argument being a null pointer) will work through the string <code>s1</code> immediately following that token. In this way subsequent calls will work through the string <code>s1</code> until no tokens remain. The separator string <code>s2</code> may be different from call to call. When no token remains in <code>s1</code>, a null pointer is returned.</p>

strncasecmp(3C)

`strtok_r()` The `strtok_r()` function has the same functionality as `strtok()` except that a pointer to a string placeholder *lasts* must be supplied by the caller. The *lasts* pointer is to keep track of the next substring in which to search for the next token.

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
MT-Level	See NOTES below.

SEE ALSO `malloc(3C)`, `setlocale(3C)`, `strxfrm(3C)`, `attributes(5)`

NOTES When compiling multithreaded applications, the `_REENTRANT` flag must be defined on the compile line. This flag should only be used in multithreaded applications.

All of these functions assume the default locale "C." For some locales, `strxfrm()` should be applied to the strings before they are passed to the functions.

The `strcasecmp()`, `strcat()`, `strchr()`, `strcmp()`, `strcpy()`, `strcspn()`, `strdup()`, `strlen()`, `strncasecmp()`, `strncat()`, `strncmp()`, `strncpy()`, `strpbrk()`, `strrchr()`, `strspn()`, and `strstr()` functions are MT-Safe in multithreaded applications.

The `strtok()` function is Unsafe in multithreaded applications. The `strtok_r()` function should be used instead.

ISO C++	<pre>#include <string.h> const char *strchr(const char *s, int c); const char *strpbrk(const char *s1, const char *s2); const char *strrchr(const char *s, int c); const char *strstr(const char *s1, const char *s2); #include <cstring> char *std::strchr(char *s, int c);</pre>

strncat(3C)

	<pre>char *std::strpbrk(char *s1, const char *s2); char *std::strrchr(char *s, int c); char *std::strstr(char *s1, const char *s2);</pre>
DESCRIPTION	<p>The arguments <i>s</i>, <i>s1</i>, and <i>s2</i> point to strings (arrays of characters terminated by a null character). The <code>strcat()</code>, <code>strncat()</code>, <code>strlcat()</code>, <code>strcpy()</code>, <code>strncpy()</code>, <code>strncpy()</code>, <code>strtok()</code>, and <code>strtok_r()</code> functions all alter their first argument. These functions do not check for overflow of the array pointed to by the first argument.</p>
<code>strcasemp()</code> , <code>strncasemp()</code>	<p>The <code>strcasemp()</code> and <code>strncasemp()</code> functions are case-insensitive versions of <code>strcmp()</code> and <code>strncmp()</code> respectively, described below. They assume the ASCII character set and ignore differences in case when comparing lower and upper case characters.</p>
<code>strcat()</code> , <code>strncat()</code> , <code>strlcat()</code>	<p>The <code>strcat()</code> function appends a copy of string <i>s2</i>, including the terminating null character, to the end of string <i>s1</i>. The <code>strncat()</code> function appends at most <i>n</i> characters. Each returns a pointer to the null-terminated result. The initial character of <i>s2</i> overrides the null character at the end of <i>s1</i>.</p> <p>The <code>strlcat()</code> function appends at most (<i>dstsize</i>-<code>strlen(dst)</code>-1) characters of <i>src</i> to <i>dst</i> (<i>dstsize</i> being the size of the string buffer <i>dst</i>). If the string pointed to by <i>dst</i> contains a null-terminated string that fits into <i>dstsize</i> bytes when <code>strlcat()</code> is called, the string pointed to by <i>dst</i> will be a null-terminated string that fits in <i>dstsize</i> bytes (including the terminating null character) when it completes, and the initial character of <i>src</i> will override the null character at the end of <i>dst</i>. If the string pointed to by <i>dst</i> is longer than <i>dstsize</i> bytes when <code>strlcat()</code> is called, the string pointed to by <i>dst</i> will not be changed. The function returns the sum the of lengths of the two strings <code>strlen(dst)+strlen(src)</code>. Buffer overflow can be checked as follows:</p> <pre>if (strlcat(dst, src, dstsize) >= dstsize) return -1;</pre>
<code>strchr()</code> , <code>strrchr()</code>	<p>The <code>strchr()</code> function returns a pointer to the first occurrence of <i>c</i> (converted to a char) in string <i>s</i>, or a null pointer if <i>c</i> does not occur in the string. The <code>strrchr()</code> function returns a pointer to the last occurrence of <i>c</i>. The null character terminating a string is considered to be part of the string.</p>
<code>strcmp()</code> , <code>strncmp()</code>	<p>The <code>strcmp()</code> function compares two strings byte-by-byte, according to the ordering of your machine's character set. The function returns an integer greater than, equal to, or less than 0, if the string pointed to by <i>s1</i> is greater than, equal to, or less than the string pointed to by <i>s2</i> respectively. The sign of a non-zero return value is determined by the sign of the difference between the values of the first pair of bytes that differ in the strings being compared. The <code>strncmp()</code> function makes the same comparison but looks at a maximum of <i>n</i> bytes. Bytes following a null byte are not compared.</p>

<code>strcpy()</code> , <code>strncpy()</code> , <code>strncpy()</code>	<p>The <code>strcpy()</code> function copies string <code>s2</code> to <code>s1</code>, including the terminating null character, stopping after the null character has been copied. The <code>strncpy()</code> function copies exactly <code>n</code> bytes, truncating <code>s2</code> or adding null characters to <code>s1</code> if necessary. The result will not be null-terminated if the length of <code>s2</code> is <code>n</code> or more. Each function returns <code>s1</code>.</p> <p>The <code>strncpy()</code> function copies at most <code>dsize-1</code> characters (<code>dsize</code> being the size of the string buffer <code>dst</code>) from <code>src</code> to <code>dst</code>, truncating <code>src</code> if necessary. The result is always null-terminated. The function returns <code>strlen(src)</code>. Buffer overflow can be checked as follows:</p> <pre>if (strncpy(dst, src, dsize) >= dsize) return -1;</pre>
<code>strcspn()</code> , <code>strspn()</code>	<p>The <code>strcspn()</code> function returns the length of the initial segment of string <code>s1</code> that consists entirely of characters not from string <code>s2</code>. The <code>strspn()</code> function returns the length of the initial segment of string <code>s1</code> that consists entirely of characters from string <code>s2</code>.</p>
<code>strdup()</code>	<p>The <code>strdup()</code> function returns a pointer to a new string that is a duplicate of the string pointed to by <code>s1</code>. The returned pointer can be passed to <code>free()</code>. The space for the new string is obtained using <code>malloc(3C)</code>. If the new string cannot be created, a null pointer is returned and <code>errno</code> may be set to <code>ENOMEM</code> to indicate that the storage space available is insufficient.</p>
<code>strlen()</code>	<p>The <code>strlen()</code> function returns the number of bytes in <code>s</code>, not including the terminating null character.</p>
<code>strpbrk()</code>	<p>The <code>strpbrk()</code> function returns a pointer to the first occurrence in string <code>s1</code> of any character from string <code>s2</code>, or a null pointer if no character from <code>s2</code> exists in <code>s1</code>.</p>
<code>strstr()</code>	<p>The <code>strstr()</code> function locates the first occurrence of the string <code>s2</code> (excluding the terminating null character) in string <code>s1</code> and returns a pointer to the located string, or a null pointer if the string is not found. If <code>s2</code> points to a string with zero length (that is, the string ""), the function returns <code>s1</code>.</p>
<code>strtok()</code>	<p>The <code>strtok()</code> function can be used to break the string pointed to by <code>s1</code> into a sequence of tokens, each of which is delimited by one or more characters from the string pointed to by <code>s2</code>. The <code>strtok()</code> function considers the string <code>s1</code> to consist of a sequence of zero or more text tokens separated by spans of one or more characters from the separator string <code>s2</code>. The first call (with pointer <code>s1</code> specified) returns a pointer to the first character of the first token, and will have written a null character into <code>s1</code> immediately following the returned token. The function keeps track of its position in the string between separate calls, so that subsequent calls (which must be made with the first argument being a null pointer) will work through the string <code>s1</code> immediately following that token. In this way subsequent calls will work through the string <code>s1</code> until no tokens remain. The separator string <code>s2</code> may be different from call to call. When no token remains in <code>s1</code>, a null pointer is returned.</p>

strncat(3C)

`strtok_r()` The `strtok_r()` function has the same functionality as `strtok()` except that a pointer to a string placeholder *lasts* must be supplied by the caller. The *lasts* pointer is to keep track of the next substring in which to search for the next token.

strncpy(3C)

	<pre>char *std::strpbrk(char *s1, const char *s2); char *std::strrchr(char *s, int c); char *std::strstr(char *s1, const char *s2);</pre>
DESCRIPTION	<p>The arguments <i>s</i>, <i>s1</i>, and <i>s2</i> point to strings (arrays of characters terminated by a null character). The <code>strcat()</code>, <code>strncat()</code>, <code>strlcat()</code>, <code>strcpy()</code>, <code>strncpy()</code>, <code>strncpy()</code>, <code>strtok()</code>, and <code>strtok_r()</code> functions all alter their first argument. These functions do not check for overflow of the array pointed to by the first argument.</p>
<code>strcasecmp()</code> , <code>strncasecmp()</code>	<p>The <code>strcasecmp()</code> and <code>strncasecmp()</code> functions are case-insensitive versions of <code>strcmp()</code> and <code>strncmp()</code> respectively, described below. They assume the ASCII character set and ignore differences in case when comparing lower and upper case characters.</p>
<code>strcat()</code> , <code>strncat()</code> , <code>strlcat()</code>	<p>The <code>strcat()</code> function appends a copy of string <i>s2</i>, including the terminating null character, to the end of string <i>s1</i>. The <code>strncat()</code> function appends at most <i>n</i> characters. Each returns a pointer to the null-terminated result. The initial character of <i>s2</i> overrides the null character at the end of <i>s1</i>.</p> <p>The <code>strlcat()</code> function appends at most $(dstsize - strlen(dst) - 1)$ characters of <i>src</i> to <i>dst</i> (<i>dstsize</i> being the size of the string buffer <i>dst</i>). If the string pointed to by <i>dst</i> contains a null-terminated string that fits into <i>dstsize</i> bytes when <code>strlcat()</code> is called, the string pointed to by <i>dst</i> will be a null-terminated string that fits in <i>dstsize</i> bytes (including the terminating null character) when it completes, and the initial character of <i>src</i> will override the null character at the end of <i>dst</i>. If the string pointed to by <i>dst</i> is longer than <i>dstsize</i> bytes when <code>strlcat()</code> is called, the string pointed to by <i>dst</i> will not be changed. The function returns the sum the of lengths of the two strings $strlen(dst) + strlen(src)$. Buffer overflow can be checked as follows:</p> <pre>if (strlcat(dst, src, dstsize) >= dstsize) return -1;</pre>
<code>strchr()</code> , <code>strrchr()</code>	<p>The <code>strchr()</code> function returns a pointer to the first occurrence of <i>c</i> (converted to a char) in string <i>s</i>, or a null pointer if <i>c</i> does not occur in the string. The <code>strrchr()</code> function returns a pointer to the last occurrence of <i>c</i>. The null character terminating a string is considered to be part of the string.</p>
<code>strcmp()</code> , <code>strncmp()</code>	<p>The <code>strcmp()</code> function compares two strings byte-by-byte, according to the ordering of your machine's character set. The function returns an integer greater than, equal to, or less than 0, if the string pointed to by <i>s1</i> is greater than, equal to, or less than the string pointed to by <i>s2</i> respectively. The sign of a non-zero return value is determined by the sign of the difference between the values of the first pair of bytes that differ in the strings being compared. The <code>strncmp()</code> function makes the same comparison but looks at a maximum of <i>n</i> bytes. Bytes following a null byte are not compared.</p>

strcpy(), strncpy(), strncpy()	<p>The <code>strcpy()</code> function copies string <code>s2</code> to <code>s1</code>, including the terminating null character, stopping after the null character has been copied. The <code>strncpy()</code> function copies exactly <code>n</code> bytes, truncating <code>s2</code> or adding null characters to <code>s1</code> if necessary. The result will not be null-terminated if the length of <code>s2</code> is <code>n</code> or more. Each function returns <code>s1</code>.</p> <p>The <code>strncpy()</code> function copies at most <code>dsize-1</code> characters (<code>dsize</code> being the size of the string buffer <code>dst</code>) from <code>src</code> to <code>dst</code>, truncating <code>src</code> if necessary. The result is always null-terminated. The function returns <code>strlen(src)</code>. Buffer overflow can be checked as follows:</p> <pre>if (strncpy(dst, src, dsize) >= dsize) return -1;</pre>
strcspn(), strcspn()	<p>The <code>strcspn()</code> function returns the length of the initial segment of string <code>s1</code> that consists entirely of characters not from string <code>s2</code>. The <code>strcspn()</code> function returns the length of the initial segment of string <code>s1</code> that consists entirely of characters from string <code>s2</code>.</p>
strdup()	<p>The <code>strdup()</code> function returns a pointer to a new string that is a duplicate of the string pointed to by <code>s1</code>. The returned pointer can be passed to <code>free()</code>. The space for the new string is obtained using <code>malloc(3C)</code>. If the new string cannot be created, a null pointer is returned and <code>errno</code> may be set to <code>ENOMEM</code> to indicate that the storage space available is insufficient.</p>
strlen()	<p>The <code>strlen()</code> function returns the number of bytes in <code>s</code>, not including the terminating null character.</p>
strpbrk()	<p>The <code>strpbrk()</code> function returns a pointer to the first occurrence in string <code>s1</code> of any character from string <code>s2</code>, or a null pointer if no character from <code>s2</code> exists in <code>s1</code>.</p>
strstr()	<p>The <code>strstr()</code> function locates the first occurrence of the string <code>s2</code> (excluding the terminating null character) in string <code>s1</code> and returns a pointer to the located string, or a null pointer if the string is not found. If <code>s2</code> points to a string with zero length (that is, the string ""), the function returns <code>s1</code>.</p>
strtok()	<p>The <code>strtok()</code> function can be used to break the string pointed to by <code>s1</code> into a sequence of tokens, each of which is delimited by one or more characters from the string pointed to by <code>s2</code>. The <code>strtok()</code> function considers the string <code>s1</code> to consist of a sequence of zero or more text tokens separated by spans of one or more characters from the separator string <code>s2</code>. The first call (with pointer <code>s1</code> specified) returns a pointer to the first character of the first token, and will have written a null character into <code>s1</code> immediately following the returned token. The function keeps track of its position in the string between separate calls, so that subsequent calls (which must be made with the first argument being a null pointer) will work through the string <code>s1</code> immediately following that token. In this way subsequent calls will work through the string <code>s1</code> until no tokens remain. The separator string <code>s2</code> may be different from call to call. When no token remains in <code>s1</code>, a null pointer is returned.</p>

strncpy(3C)

`strtok_r()` The `strtok_r()` function has the same functionality as `strtok()` except that a pointer to a string placeholder *lasts* must be supplied by the caller. The *lasts* pointer is to keep track of the next substring in which to search for the next token.

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
MT-Level	See NOTES below.

SEE ALSO `malloc(3C)`, `setlocale(3C)`, `strxfrm(3C)`, `attributes(5)`

NOTES When compiling multithreaded applications, the `_REENTRANT` flag must be defined on the compile line. This flag should only be used in multithreaded applications.

All of these functions assume the default locale "C." For some locales, `strxfrm()` should be applied to the strings before they are passed to the functions.

The `strcascmp()`, `strcat()`, `strchr()`, `strcmp()`, `strcpy()`, `strcspn()`, `strdup()`, `strlen()`, `strncascmp()`, `strncat()`, `strncmp()`, `strncpy()`, `strpbrk()`, `strrchr()`, `strspn()`, and `strstr()` functions are MT-Safe in multithreaded applications.

The `strtok()` function is Unsafe in multithreaded applications. The `strtok_r()` function should be used instead.

NAME	string, strcasecmp, strncasecmp, strcat, strncat, strlcat, strchr, strrchr, strcmp, strncmp, strcpy, strncpy, strlcpy, strcspn, strspn, strdup, strlen, strpbrk, strstr, strtok, strtok_r – string operations
SYNOPSIS	<pre>#include <strings.h> int strcasecmp(const char *s1, const char *s2); int strncasecmp(const char *s1, const char *s2, size_t n); #include <string.h> char *strcat(char *s1, const char *s2); char *strncat(char *s1, const char *s2, size_t n); size_t strlcat(char *dst, const char *src, size_t dstsize); char *strchr(const char *s, int c); char *strrchr(const char *s, int c); int strcmp(const char *s1, const char *s2); int strncmp(const char *s1, const char *s2, size_t n); char *strcpy(char *s1, const char *s2); char *strncpy(char *s1, const char *s2, size_t n); size_t strlcpy(char *dst, const char *src, size_t dstsize); size_t strcspn(const char *s1, const char *s2); size_t strspn(const char *s1, const char *s2); char *strdup(const char *s1); size_t strlen(const char *s); char *strpbrk(const char *s1, const char *s2); char *strstr(const char *s1, const char *s2); char *strtok(char *s1, const char *s2); char *strtok_r(char *s1, const char *s2, char **lasts);</pre>
ISO C++	<pre>#include <string.h> const char *strchr(const char *s, int c); const char *strpbrk(const char *s1, const char *s2); const char *strrchr(const char *s, int c); const char *strstr(const char *s1, const char *s2); #include <cstring> char *std::strchr(char *s, int c);</pre>

strpbrk(3C)

	<pre>char *std::strpbrk(char *s1, const char *s2); char *std::strrchr(char *s, int c); char *std::strstr(char *s1, const char *s2);</pre>
DESCRIPTION	<p>The arguments <i>s</i>, <i>s1</i>, and <i>s2</i> point to strings (arrays of characters terminated by a null character). The <code>strcat()</code>, <code>strncat()</code>, <code>strlcat()</code>, <code>strcpy()</code>, <code>strncpy()</code>, <code>strncpy()</code>, <code>strtok()</code>, and <code>strtok_r()</code> functions all alter their first argument. These functions do not check for overflow of the array pointed to by the first argument.</p>
<code>strcasemp()</code> , <code>strncasemp()</code>	<p>The <code>strcasemp()</code> and <code>strncasemp()</code> functions are case-insensitive versions of <code>strcmp()</code> and <code>strncmp()</code> respectively, described below. They assume the ASCII character set and ignore differences in case when comparing lower and upper case characters.</p>
<code>strcat()</code> , <code>strncat()</code> , <code>strlcat()</code>	<p>The <code>strcat()</code> function appends a copy of string <i>s2</i>, including the terminating null character, to the end of string <i>s1</i>. The <code>strncat()</code> function appends at most <i>n</i> characters. Each returns a pointer to the null-terminated result. The initial character of <i>s2</i> overrides the null character at the end of <i>s1</i>.</p> <p>The <code>strlcat()</code> function appends at most $(dstsize - strlen(dst) - 1)$ characters of <i>src</i> to <i>dst</i> (<i>dstsize</i> being the size of the string buffer <i>dst</i>). If the string pointed to by <i>dst</i> contains a null-terminated string that fits into <i>dstsize</i> bytes when <code>strlcat()</code> is called, the string pointed to by <i>dst</i> will be a null-terminated string that fits in <i>dstsize</i> bytes (including the terminating null character) when it completes, and the initial character of <i>src</i> will override the null character at the end of <i>dst</i>. If the string pointed to by <i>dst</i> is longer than <i>dstsize</i> bytes when <code>strlcat()</code> is called, the string pointed to by <i>dst</i> will not be changed. The function returns the sum the of lengths of the two strings $strlen(dst) + strlen(src)$. Buffer overflow can be checked as follows:</p> <pre>if (strlcat(dst, src, dstsize) >= dstsize) return -1;</pre>
<code>strchr()</code> , <code>strrchr()</code>	<p>The <code>strchr()</code> function returns a pointer to the first occurrence of <i>c</i> (converted to a char) in string <i>s</i>, or a null pointer if <i>c</i> does not occur in the string. The <code>strrchr()</code> function returns a pointer to the last occurrence of <i>c</i>. The null character terminating a string is considered to be part of the string.</p>
<code>strcmp()</code> , <code>strncmp()</code>	<p>The <code>strcmp()</code> function compares two strings byte-by-byte, according to the ordering of your machine's character set. The function returns an integer greater than, equal to, or less than 0, if the string pointed to by <i>s1</i> is greater than, equal to, or less than the string pointed to by <i>s2</i> respectively. The sign of a non-zero return value is determined by the sign of the difference between the values of the first pair of bytes that differ in the strings being compared. The <code>strncmp()</code> function makes the same comparison but looks at a maximum of <i>n</i> bytes. Bytes following a null byte are not compared.</p>

<code>strcpy()</code> , <code>strncpy()</code> , <code>strncpy()</code>	<p>The <code>strcpy()</code> function copies string <code>s2</code> to <code>s1</code>, including the terminating null character, stopping after the null character has been copied. The <code>strncpy()</code> function copies exactly <code>n</code> bytes, truncating <code>s2</code> or adding null characters to <code>s1</code> if necessary. The result will not be null-terminated if the length of <code>s2</code> is <code>n</code> or more. Each function returns <code>s1</code>.</p> <p>The <code>strncpy()</code> function copies at most <code>dsize-1</code> characters (<code>dsize</code> being the size of the string buffer <code>dst</code>) from <code>src</code> to <code>dst</code>, truncating <code>src</code> if necessary. The result is always null-terminated. The function returns <code>strlen(src)</code>. Buffer overflow can be checked as follows:</p> <pre>if (strncpy(dst, src, dsize) >= dsize) return -1;</pre>
<code>strcspn()</code> , <code>strspn()</code>	<p>The <code>strcspn()</code> function returns the length of the initial segment of string <code>s1</code> that consists entirely of characters not from string <code>s2</code>. The <code>strspn()</code> function returns the length of the initial segment of string <code>s1</code> that consists entirely of characters from string <code>s2</code>.</p>
<code>strdup()</code>	<p>The <code>strdup()</code> function returns a pointer to a new string that is a duplicate of the string pointed to by <code>s1</code>. The returned pointer can be passed to <code>free()</code>. The space for the new string is obtained using <code>malloc(3C)</code>. If the new string cannot be created, a null pointer is returned and <code>errno</code> may be set to <code>ENOMEM</code> to indicate that the storage space available is insufficient.</p>
<code>strlen()</code>	<p>The <code>strlen()</code> function returns the number of bytes in <code>s</code>, not including the terminating null character.</p>
<code>strpbrk()</code>	<p>The <code>strpbrk()</code> function returns a pointer to the first occurrence in string <code>s1</code> of any character from string <code>s2</code>, or a null pointer if no character from <code>s2</code> exists in <code>s1</code>.</p>
<code>strstr()</code>	<p>The <code>strstr()</code> function locates the first occurrence of the string <code>s2</code> (excluding the terminating null character) in string <code>s1</code> and returns a pointer to the located string, or a null pointer if the string is not found. If <code>s2</code> points to a string with zero length (that is, the string ""), the function returns <code>s1</code>.</p>
<code>strtok()</code>	<p>The <code>strtok()</code> function can be used to break the string pointed to by <code>s1</code> into a sequence of tokens, each of which is delimited by one or more characters from the string pointed to by <code>s2</code>. The <code>strtok()</code> function considers the string <code>s1</code> to consist of a sequence of zero or more text tokens separated by spans of one or more characters from the separator string <code>s2</code>. The first call (with pointer <code>s1</code> specified) returns a pointer to the first character of the first token, and will have written a null character into <code>s1</code> immediately following the returned token. The function keeps track of its position in the string between separate calls, so that subsequent calls (which must be made with the first argument being a null pointer) will work through the string <code>s1</code> immediately following that token. In this way subsequent calls will work through the string <code>s1</code> until no tokens remain. The separator string <code>s2</code> may be different from call to call. When no token remains in <code>s1</code>, a null pointer is returned.</p>

strpbrk(3C)

`strtok_r()` The `strtok_r()` function has the same functionality as `strtok()` except that a pointer to a string placeholder *lasts* must be supplied by the caller. The *lasts* pointer is to keep track of the next substring in which to search for the next token.

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
MT-Level	See NOTES below.

NOTES When compiling multithreaded applications, the `_REENTRANT` flag must be defined on the compile line. This flag should only be used in multithreaded applications.

All of these functions assume the default locale "C." For some locales, `strxfrm()` should be applied to the strings before they are passed to the functions.

The `strcascmp()`, `strcat()`, `strchr()`, `strcmp()`, `strcpy()`, `strcspn()`, `strdup()`, `strlen()`, `strncascmp()`, `strncat()`, `strncmp()`, `strncpy()`, `strpbrk()`, `strrchr()`, `strspn()`, and `strstr()` functions are MT-Safe in multithreaded applications.

The `strtok()` function is Unsafe in multithreaded applications. The `strtok_r()` function should be used instead.

NAME	strptime – date and time conversion																						
SYNOPSIS	<pre>#include <time.h> char *strptime(const char *buf, const char *format, struct tm *tm);</pre>																						
Non-zeroing Behavior	<pre>cc [flag ...] file ... -D_STRPTIME_DONTZERO [library ...] char *strptime(const char *buf, const char *format, struct tm *tm);</pre>																						
DESCRIPTION	<p>The <code>strptime()</code> function converts the character string pointed to by <i>buf</i> to values which are stored in the <code>tm</code> structure pointed to by <i>tm</i>, using the format specified by <i>format</i>.</p> <p>The <i>format</i> argument is composed of zero or more conversion specifications. Each conversion specification is composed of a “%” (percent) character followed by one or two conversion characters which specify the replacement required. One or more white space characters (as specified by <code>isspace(3C)</code>) may precede or follow a conversion specification. There must be white-space or other non-alphanumeric characters between any two conversion specifications.</p> <p>A non-zeroing version of <code>strptime()</code>, described below under <code>Non-zeroing Behavior</code>, is provided if <code>_STRPTIME_DONTZERO</code> is defined.</p>																						
Conversion Specifications	<p>The following conversion specifications are supported:</p> <table border="0"> <tr> <td style="padding-right: 20px;">%%</td> <td>Same as %.</td> </tr> <tr> <td>%a</td> <td>Day of week, using the locale’s weekday names; either the abbreviated or full name may be specified.</td> </tr> <tr> <td>%A</td> <td>Same as %a.</td> </tr> <tr> <td>%b</td> <td>Month, using the locale’s month names; either the abbreviated or full name may be specified.</td> </tr> <tr> <td>%B</td> <td>Same as %b.</td> </tr> <tr> <td>%c</td> <td>Locale’s appropriate date and time representation.</td> </tr> <tr> <td>%C</td> <td>Century number (the year divided by 100 and truncated to an integer as a decimal number [1,99]); single digits are preceded by 0. If %C is used without the %y specifier, <code>strptime()</code> assumes the year offset is zero in whichever century is specified. Note the behavior of %C in the absence of %y is not specified by any of the standards or specifications described on the <code>standards(5)</code> manual page, so portable applications should not depend on it. This behavior may change in a future release.</td> </tr> <tr> <td>%d</td> <td>Day of month [1,31]; leading zero is permitted but not required.</td> </tr> <tr> <td>%D</td> <td>Date as %m/%d/%y.</td> </tr> <tr> <td>%e</td> <td>Same as %d.</td> </tr> <tr> <td>%h</td> <td>Same as %b.</td> </tr> </table>	%%	Same as %.	%a	Day of week, using the locale’s weekday names; either the abbreviated or full name may be specified.	%A	Same as %a.	%b	Month, using the locale’s month names; either the abbreviated or full name may be specified.	%B	Same as %b.	%c	Locale’s appropriate date and time representation.	%C	Century number (the year divided by 100 and truncated to an integer as a decimal number [1,99]); single digits are preceded by 0. If %C is used without the %y specifier, <code>strptime()</code> assumes the year offset is zero in whichever century is specified. Note the behavior of %C in the absence of %y is not specified by any of the standards or specifications described on the <code>standards(5)</code> manual page, so portable applications should not depend on it. This behavior may change in a future release.	%d	Day of month [1,31]; leading zero is permitted but not required.	%D	Date as %m/%d/%y.	%e	Same as %d.	%h	Same as %b.
%%	Same as %.																						
%a	Day of week, using the locale’s weekday names; either the abbreviated or full name may be specified.																						
%A	Same as %a.																						
%b	Month, using the locale’s month names; either the abbreviated or full name may be specified.																						
%B	Same as %b.																						
%c	Locale’s appropriate date and time representation.																						
%C	Century number (the year divided by 100 and truncated to an integer as a decimal number [1,99]); single digits are preceded by 0. If %C is used without the %y specifier, <code>strptime()</code> assumes the year offset is zero in whichever century is specified. Note the behavior of %C in the absence of %y is not specified by any of the standards or specifications described on the <code>standards(5)</code> manual page, so portable applications should not depend on it. This behavior may change in a future release.																						
%d	Day of month [1,31]; leading zero is permitted but not required.																						
%D	Date as %m/%d/%y.																						
%e	Same as %d.																						
%h	Same as %b.																						

strptime(3C)

%H	Hour (24-hour clock) [0,23]; leading zero is permitted but not required.
%I	Hour (12-hour clock) [1,12]; leading zero is permitted but not required.
%j	Day number of the year [1,366]; leading zeros are permitted but not required.
%m	Month number [1,12]; leading zero is permitted but not required.
%M	Minute [0-59]; leading zero is permitted but not required.
%n	Any white space.
%p	Locale's equivalent of either a.m. or p.m.
%r	Appropriate time representation in the 12-hour clock format with %p.
%R	Time as %H:%M.
%S	Seconds [0,61]; leading zero is permitted but not required. The range of values is [00,61] rather than [00,59] to allow for the occasional leap second and even more occasional double leap second.
%t	Any white space.
%T	Time as %H:%M:%S.
%U	Week number of the year as a decimal number [0,53], with Sunday as the first day of the week; leading zeros are permitted but not required.
%w	Weekday as a decimal number [0,6], with 0 representing Sunday.
%W	Week number of the year as a decimal number [0,53], with Monday as the first day of the week; leading zero is permitted but not required.
%x	Locale's appropriate date representation.
%X	Locale's appropriate time representation.
%y	The year within century. When a century is not otherwise specified, values in the range 69-99 refer to years in the twentieth century (1969 to 1999 inclusive); values in the range 00-68 refer to years in the twenty-first century (2000 to 2068 inclusive). Leading zeros are permitted but not required.
%Y	Year, including the century (for example, 1993) [1-9999].
%Z	Timezone name or no characters if no time zone information exists. Local timezone information is used as though <code>strptime()</code> called <code>tzset()</code> (see <code>ctime(3C)</code>). Errors may not be detected. This behavior is subject to change in a future release.

**Modified
Conversion
Specifications**

Some conversion specifications can be modified by the E and O modifier characters to indicate that an alternate format or specification should be used rather than the one normally used by the unmodified specification. If the alternate format or specification does not exist in the current locale, the behavior will be as if the unmodified conversion specification were used.

%Ec	Locale's alternate appropriate date and time representation.
%EC	Name of the base year (era) in the locale's alternate representation.
%Ex	Locale's alternate date representation.
%EX	Locale's alternate time representation.
%Ey	Offset from %EC (year only) in the locale's alternate representation.
%EY	Full alternate year representation.
%Od	Day of the month using the locale's alternate numeric symbols.
%Oe	Same as %Od.
%OH	Hour (24-hour clock) using the locale's alternate numeric symbols.
%OI	Hour (12-hour clock) using the locale's alternate numeric symbols.
%Om	Month using the locale's alternate numeric symbols.
%OM	Minutes using the locale's alternate numeric symbols.
%OS	Seconds using the locale's alternate numeric symbols.
%OU	Week number of the year (Sunday as the first day of the week) using the locale's alternate numeric symbols.
%Ow	Number of the weekday (Sunday=0) using the locale's alternate numeric symbols.
%OW	Week number of the year (Monday as the first day of the week) using the locale's alternate numeric symbols.
%Oy	Year (offset from %C) in the locale's alternate representation and using the locale's alternate numeric symbols.

**General
Specifications**

A conversion specification that is an ordinary character is executed by scanning the next character from the buffer. If the character scanned from the buffer differs from the one comprising the specification, the specification fails, and the differing and subsequent characters remain unscanned.

A series of specifications composed of %n, %t, white-space characters or any combination is executed by scanning up to the first character that is not white space (which remains unscanned), or until no more characters can be scanned. White space is defined by isspace(3C).

strptime(3C)

Non-zeroing Behavior

Any other conversion specification is executed by scanning characters until a character matching the next specification is scanned, or until no more characters can be scanned. These characters, except the one matching the next specification, are then compared to the locale values associated with the conversion specifier. If a match is found, values for the appropriate *tm* structure members are set to values corresponding to the locale information. If no match is found, `strptime()` fails and no more characters are scanned.

The month names, weekday names, era names, and alternate numeric symbols can consist of any combination of upper and lower case letters. The user can request that the input date or time specification be in a specific language by setting the `LC_TIME` category using `setlocale(3C)`.

In addition to the behavior described above by various standards, the Solaris implementation of `strptime()` provides the following extensions. These may change at any time in the future. Portable applications should not depend on these extended features:

- If `_STRPTIME_DONTZERO` is not defined, the *tm* struct is zeroed on entry and `strptime()` updates the fields of the *tm* struct associated with the specifiers in the format string.
- If `_STRPTIME_DONTZERO` is defined, `strptime()` does not zero the *tm* struct on entry. Additionally, for some specifiers, `strptime()` will use some values in the input *tm* struct to recalculate the date and re-assign the appropriate members of the *tm* struct.

The following describes extended features regardless of whether `_STRPTIME_DONTZERO` is defined or not defined:

- If `%j` is specified, `tm_yday` is set; if year is given, and if month and day are not given, `strptime()` calculates and sets `tm_mon`, `tm_mday`, and `tm_year`.
- If `%U` or `%W` is specified and if weekday and year are given and month and day of month are not given, `strptime()` calculates and sets `tm_mon`, `tm_mday`, `tm_wday`, and `tm_year`.

The following describes extended features when `_STRPTIME_DONTZERO` is not defined:

- If `%C` is specified and `%y` is not specified, `strptime()` assumes 0 as the year offset, then calculates the year, and assigns `tm_year`.

The following describes extended features when `_STRPTIME_DONTZERO` is defined:

- If `%C` is specified and `%y` is not specified, `strptime()` assumes the year offset of the year value of the `tm_year` member of the input *tm* struct, then calculates the year and assigns `tm_year`.
- If `%j` is specified and neither `%y`, `%Y`, nor `%C` are specified, and neither month nor day of month are specified, `strptime()` assumes the year value given by the value of the `tm_year` field of the input *tm* struct. Then, in addition to setting

`tm_yday`, `strptime()` uses day-of-year and year values to calculate the month and day-of-month, and assigns `tm_month` and `tm_mday`.

- If `%U` or `%W` is specified, and if weekday and/or year are not given, and month and day of month are not given, `strptime()` will assume the weekday value and/or the year value as the value of the `tm_wday` field and/or `tm_year` field of the input `tm` struct. Then, `strptime()` will calculate the month and day-of-month and assign `tm_month`, `tm_mday`, and/or `tm_year`.
- If `%p` is specified and if hour is not specified, `strptime()` will reference, and if needed, update the `tm_hour` member. If the `am_pm` input is p.m. and the input `tm_hour` value is between 0 - 11, `strptime()` will add 12 hours and update `tm_hour`. If the `am_pm` input is a.m. and input `tm_hour` value is between 12 - 23, `strptime()` will subtract 12 hours and update `tm_hour`.

RETURN VALUES Upon successful completion, `strptime()` returns a pointer to the character following the last character parsed. Otherwise, a null pointer is returned.

USAGE Several "same as" formats, and the special processing of white-space characters are provided in order to ease the use of identical *format* strings for `strptime(3C)` and `strptime()`.

The `strptime()` function tries to calculate `tm_year`, `tm_mon`, and `tm_mday` when given incomplete input. This allows the struct `tm` created by `strptime()` to be passed to `mktime(3C)` to produce a `time_t` value for dates and times that are representable by a `time_t`. As an example, since `mktime()` ignores `tm_yday`, `strptime()` calculates `tm_mon` and `tm_mday` as well as filling in `tm_yday` when `%j` is specified without otherwise specifying a month and day within month.

strchr(3C)

NAME	string, strcasecmp, strncasecmp, strcat, strncat, strlcat, strchr, strrchr, strcmp, strncmp, strcpy, strncpy, strlcpy, strcspn, strspn, strdup, strlen, strpbrk, strstr, strtok, strtok_r – string operations
SYNOPSIS	<pre>#include <strings.h> int strcasecmp(const char *s1, const char *s2); int strncasecmp(const char *s1, const char *s2, size_t n); #include <string.h> char *strcat(char *s1, const char *s2); char *strncat(char *s1, const char *s2, size_t n); size_t strlcat(char *dst, const char *src, size_t dstsize); char *strchr(const char *s, int c); char *strrchr(const char *s, int c); int strcmp(const char *s1, const char *s2); int strncmp(const char *s1, const char *s2, size_t n); char *strcpy(char *s1, const char *s2); char *strncpy(char *s1, const char *s2, size_t n); size_t strlcpy(char *dst, const char *src, size_t dstsize); size_t strcspn(const char *s1, const char *s2); size_t strspn(const char *s1, const char *s2); char *strdup(const char *s1); size_t strlen(const char *s); char *strpbrk(const char *s1, const char *s2); char *strstr(const char *s1, const char *s2); char *strtok(char *s1, const char *s2); char *strtok_r(char *s1, const char *s2, char **lasts);</pre>
ISO C++	<pre>#include <string.h> const char *strchr(const char *s, int c); const char *strpbrk(const char *s1, const char *s2); const char *strrchr(const char *s, int c); const char *strstr(const char *s1, const char *s2); #include <cstring> char *std::strchr(char *s, int c);</pre>

	<pre>char *std::strpbrk(char *s1, const char *s2); char *std::strrchr(char *s, int c); char *std::strstr(char *s1, const char *s2);</pre>
DESCRIPTION	<p>The arguments <i>s</i>, <i>s1</i>, and <i>s2</i> point to strings (arrays of characters terminated by a null character). The <code>strcat()</code>, <code>strncat()</code>, <code>strlcat()</code>, <code>strcpy()</code>, <code>strncpy()</code>, <code>strncpy()</code>, <code>strtok()</code>, and <code>strtok_r()</code> functions all alter their first argument. These functions do not check for overflow of the array pointed to by the first argument.</p>
<code>strcasecmp()</code> , <code>strncasecmp()</code>	<p>The <code>strcasecmp()</code> and <code>strncasecmp()</code> functions are case-insensitive versions of <code>strcmp()</code> and <code>strncmp()</code> respectively, described below. They assume the ASCII character set and ignore differences in case when comparing lower and upper case characters.</p>
<code>strcat()</code> , <code>strncat()</code> , <code>strlcat()</code>	<p>The <code>strcat()</code> function appends a copy of string <i>s2</i>, including the terminating null character, to the end of string <i>s1</i>. The <code>strncat()</code> function appends at most <i>n</i> characters. Each returns a pointer to the null-terminated result. The initial character of <i>s2</i> overrides the null character at the end of <i>s1</i>.</p> <p>The <code>strlcat()</code> function appends at most $(dstsize - strlen(dst) - 1)$ characters of <i>src</i> to <i>dst</i> (<i>dstsize</i> being the size of the string buffer <i>dst</i>). If the string pointed to by <i>dst</i> contains a null-terminated string that fits into <i>dstsize</i> bytes when <code>strlcat()</code> is called, the string pointed to by <i>dst</i> will be a null-terminated string that fits in <i>dstsize</i> bytes (including the terminating null character) when it completes, and the initial character of <i>src</i> will override the null character at the end of <i>dst</i>. If the string pointed to by <i>dst</i> is longer than <i>dstsize</i> bytes when <code>strlcat()</code> is called, the string pointed to by <i>dst</i> will not be changed. The function returns the sum of lengths of the two strings $strlen(dst) + strlen(src)$. Buffer overflow can be checked as follows:</p> <pre>if (strlcat(dst, src, dstsize) >= dstsize) return -1;</pre>
<code>strchr()</code> , <code>strrchr()</code>	<p>The <code>strchr()</code> function returns a pointer to the first occurrence of <i>c</i> (converted to a char) in string <i>s</i>, or a null pointer if <i>c</i> does not occur in the string. The <code>strrchr()</code> function returns a pointer to the last occurrence of <i>c</i>. The null character terminating a string is considered to be part of the string.</p>
<code>strcmp()</code> , <code>strncmp()</code>	<p>The <code>strcmp()</code> function compares two strings byte-by-byte, according to the ordering of your machine's character set. The function returns an integer greater than, equal to, or less than 0, if the string pointed to by <i>s1</i> is greater than, equal to, or less than the string pointed to by <i>s2</i> respectively. The sign of a non-zero return value is determined by the sign of the difference between the values of the first pair of bytes that differ in the strings being compared. The <code>strncmp()</code> function makes the same comparison but looks at a maximum of <i>n</i> bytes. Bytes following a null byte are not compared.</p>

strchr(3C)

<code>strcpy()</code> , <code>strncpy()</code> , <code>strncpy()</code>	<p>The <code>strcpy()</code> function copies string <code>s2</code> to <code>s1</code>, including the terminating null character, stopping after the null character has been copied. The <code>strncpy()</code> function copies exactly <code>n</code> bytes, truncating <code>s2</code> or adding null characters to <code>s1</code> if necessary. The result will not be null-terminated if the length of <code>s2</code> is <code>n</code> or more. Each function returns <code>s1</code>.</p> <p>The <code>strncpy()</code> function copies at most <code>dsize-1</code> characters (<code>dsize</code> being the size of the string buffer <code>dst</code>) from <code>src</code> to <code>dst</code>, truncating <code>src</code> if necessary. The result is always null-terminated. The function returns <code>strlen(src)</code>. Buffer overflow can be checked as follows:</p> <pre>if (strncpy(dst, src, dsize) >= dsize) return -1;</pre>
<code>strcspn()</code> , <code>strspn()</code>	<p>The <code>strcspn()</code> function returns the length of the initial segment of string <code>s1</code> that consists entirely of characters not from string <code>s2</code>. The <code>strspn()</code> function returns the length of the initial segment of string <code>s1</code> that consists entirely of characters from string <code>s2</code>.</p>
<code>strdup()</code>	<p>The <code>strdup()</code> function returns a pointer to a new string that is a duplicate of the string pointed to by <code>s1</code>. The returned pointer can be passed to <code>free()</code>. The space for the new string is obtained using <code>malloc(3C)</code>. If the new string cannot be created, a null pointer is returned and <code>errno</code> may be set to <code>ENOMEM</code> to indicate that the storage space available is insufficient.</p>
<code>strlen()</code>	<p>The <code>strlen()</code> function returns the number of bytes in <code>s</code>, not including the terminating null character.</p>
<code>strpbrk()</code>	<p>The <code>strpbrk()</code> function returns a pointer to the first occurrence in string <code>s1</code> of any character from string <code>s2</code>, or a null pointer if no character from <code>s2</code> exists in <code>s1</code>.</p>
<code>strstr()</code>	<p>The <code>strstr()</code> function locates the first occurrence of the string <code>s2</code> (excluding the terminating null character) in string <code>s1</code> and returns a pointer to the located string, or a null pointer if the string is not found. If <code>s2</code> points to a string with zero length (that is, the string ""), the function returns <code>s1</code>.</p>
<code>strtok()</code>	<p>The <code>strtok()</code> function can be used to break the string pointed to by <code>s1</code> into a sequence of tokens, each of which is delimited by one or more characters from the string pointed to by <code>s2</code>. The <code>strtok()</code> function considers the string <code>s1</code> to consist of a sequence of zero or more text tokens separated by spans of one or more characters from the separator string <code>s2</code>. The first call (with pointer <code>s1</code> specified) returns a pointer to the first character of the first token, and will have written a null character into <code>s1</code> immediately following the returned token. The function keeps track of its position in the string between separate calls, so that subsequent calls (which must be made with the first argument being a null pointer) will work through the string <code>s1</code> immediately following that token. In this way subsequent calls will work through the string <code>s1</code> until no tokens remain. The separator string <code>s2</code> may be different from call to call. When no token remains in <code>s1</code>, a null pointer is returned.</p>

`strtok_r()` The `strtok_r()` function has the same functionality as `strtok()` except that a pointer to a string placeholder *lasts* must be supplied by the caller. The *lasts* pointer is to keep track of the next substring in which to search for the next token.

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
MT-Level	See NOTES below.

SEE ALSO `malloc(3C)`, `setlocale(3C)`, `strxfrm(3C)`, `attributes(5)`

NOTES When compiling multithreaded applications, the `_REENTRANT` flag must be defined on the compile line. This flag should only be used in multithreaded applications.

All of these functions assume the default locale "C." For some locales, `strxfrm()` should be applied to the strings before they are passed to the functions.

The `strcasemp()`, `strcat()`, `strchr()`, `strcmp()`, `strcpy()`, `strcspn()`, `strdup()`, `strlen()`, `strncasemp()`, `strncat()`, `strncmp()`, `strncpy()`, `strpbrk()`, `strrchr()`, `strspn()`, and `strstr()` functions are MT-Safe in multithreaded applications.

The `strtok()` function is Unsafe in multithreaded applications. The `strtok_r()` function should be used instead.

strsignal(3C)

NAME strsignal – get name of signal

SYNOPSIS #include <string.h>
char ***strsignal**(int *sig*);

DESCRIPTION The `strsignal()` function maps the signal number in *sig* to a string describing the signal and returns a pointer to that string. It uses the same set of the messages as `psignal(3C)`. The returned string should not be overwritten.

RETURN VALUES The `strsignal()` function returns `NULL` if *sig* is not a valid signal number.

USAGE If the application is linked with `-lintl`, messages returned from this function are in the native language specified by the `LC_MESSAGES` locale category; see `setlocale(3C)`.

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
MT-Level	Safe

SEE ALSO `gettext(3C)`, `psignal(3C)`, `setlocale(3C)`, `str2sig(3C)`, `attributes(5)`

strspn(3C)

	<pre>char *std::strpbrk(char *s1, const char *s2); char *std::strrchr(char *s, int c); char *std::strstr(char *s1, const char *s2);</pre>
DESCRIPTION	<p>The arguments <i>s</i>, <i>s1</i>, and <i>s2</i> point to strings (arrays of characters terminated by a null character). The <code>strcat()</code>, <code>strncat()</code>, <code>strlcat()</code>, <code>strcpy()</code>, <code>strncpy()</code>, <code>strncpy()</code>, <code>strtok()</code>, and <code>strtok_r()</code> functions all alter their first argument. These functions do not check for overflow of the array pointed to by the first argument.</p>
<code>strcasecmp()</code> , <code>strncasecmp()</code>	<p>The <code>strcasecmp()</code> and <code>strncasecmp()</code> functions are case-insensitive versions of <code>strcmp()</code> and <code>strncmp()</code> respectively, described below. They assume the ASCII character set and ignore differences in case when comparing lower and upper case characters.</p>
<code>strcat()</code> , <code>strncat()</code> , <code>strlcat()</code>	<p>The <code>strcat()</code> function appends a copy of string <i>s2</i>, including the terminating null character, to the end of string <i>s1</i>. The <code>strncat()</code> function appends at most <i>n</i> characters. Each returns a pointer to the null-terminated result. The initial character of <i>s2</i> overrides the null character at the end of <i>s1</i>.</p> <p>The <code>strlcat()</code> function appends at most (<i>dstsize</i>-<code>strlen(dst)</code>-1) characters of <i>src</i> to <i>dst</i> (<i>dstsize</i> being the size of the string buffer <i>dst</i>). If the string pointed to by <i>dst</i> contains a null-terminated string that fits into <i>dstsize</i> bytes when <code>strlcat()</code> is called, the string pointed to by <i>dst</i> will be a null-terminated string that fits in <i>dstsize</i> bytes (including the terminating null character) when it completes, and the initial character of <i>src</i> will override the null character at the end of <i>dst</i>. If the string pointed to by <i>dst</i> is longer than <i>dstsize</i> bytes when <code>strlcat()</code> is called, the string pointed to by <i>dst</i> will not be changed. The function returns the sum the of lengths of the two strings <code>strlen(dst)+strlen(src)</code>. Buffer overflow can be checked as follows:</p> <pre>if (strlcat(dst, src, dstsize) >= dstsize) return -1;</pre>
<code>strchr()</code> , <code>strrchr()</code>	<p>The <code>strchr()</code> function returns a pointer to the first occurrence of <i>c</i> (converted to a char) in string <i>s</i>, or a null pointer if <i>c</i> does not occur in the string. The <code>strrchr()</code> function returns a pointer to the last occurrence of <i>c</i>. The null character terminating a string is considered to be part of the string.</p>
<code>strcmp()</code> , <code>strncmp()</code>	<p>The <code>strcmp()</code> function compares two strings byte-by-byte, according to the ordering of your machine's character set. The function returns an integer greater than, equal to, or less than 0, if the string pointed to by <i>s1</i> is greater than, equal to, or less than the string pointed to by <i>s2</i> respectively. The sign of a non-zero return value is determined by the sign of the difference between the values of the first pair of bytes that differ in the strings being compared. The <code>strncmp()</code> function makes the same comparison but looks at a maximum of <i>n</i> bytes. Bytes following a null byte are not compared.</p>

<code>strcpy()</code> , <code>strncpy()</code> , <code>strncpy()</code>	<p>The <code>strcpy()</code> function copies string <code>s2</code> to <code>s1</code>, including the terminating null character, stopping after the null character has been copied. The <code>strncpy()</code> function copies exactly <code>n</code> bytes, truncating <code>s2</code> or adding null characters to <code>s1</code> if necessary. The result will not be null-terminated if the length of <code>s2</code> is <code>n</code> or more. Each function returns <code>s1</code>.</p> <p>The <code>strncpy()</code> function copies at most <code>dsize-1</code> characters (<code>dsize</code> being the size of the string buffer <code>dst</code>) from <code>src</code> to <code>dst</code>, truncating <code>src</code> if necessary. The result is always null-terminated. The function returns <code>strlen(src)</code>. Buffer overflow can be checked as follows:</p> <pre>if (strncpy(dst, src, dsize) >= dsize) return -1;</pre>
<code>strcspn()</code> , <code>strspn()</code>	<p>The <code>strcspn()</code> function returns the length of the initial segment of string <code>s1</code> that consists entirely of characters not from string <code>s2</code>. The <code>strspn()</code> function returns the length of the initial segment of string <code>s1</code> that consists entirely of characters from string <code>s2</code>.</p>
<code>strdup()</code>	<p>The <code>strdup()</code> function returns a pointer to a new string that is a duplicate of the string pointed to by <code>s1</code>. The returned pointer can be passed to <code>free()</code>. The space for the new string is obtained using <code>malloc(3C)</code>. If the new string cannot be created, a null pointer is returned and <code>errno</code> may be set to <code>ENOMEM</code> to indicate that the storage space available is insufficient.</p>
<code>strlen()</code>	<p>The <code>strlen()</code> function returns the number of bytes in <code>s</code>, not including the terminating null character.</p>
<code>strpbrk()</code>	<p>The <code>strpbrk()</code> function returns a pointer to the first occurrence in string <code>s1</code> of any character from string <code>s2</code>, or a null pointer if no character from <code>s2</code> exists in <code>s1</code>.</p>
<code>strstr()</code>	<p>The <code>strstr()</code> function locates the first occurrence of the string <code>s2</code> (excluding the terminating null character) in string <code>s1</code> and returns a pointer to the located string, or a null pointer if the string is not found. If <code>s2</code> points to a string with zero length (that is, the string ""), the function returns <code>s1</code>.</p>
<code>strtok()</code>	<p>The <code>strtok()</code> function can be used to break the string pointed to by <code>s1</code> into a sequence of tokens, each of which is delimited by one or more characters from the string pointed to by <code>s2</code>. The <code>strtok()</code> function considers the string <code>s1</code> to consist of a sequence of zero or more text tokens separated by spans of one or more characters from the separator string <code>s2</code>. The first call (with pointer <code>s1</code> specified) returns a pointer to the first character of the first token, and will have written a null character into <code>s1</code> immediately following the returned token. The function keeps track of its position in the string between separate calls, so that subsequent calls (which must be made with the first argument being a null pointer) will work through the string <code>s1</code> immediately following that token. In this way subsequent calls will work through the string <code>s1</code> until no tokens remain. The separator string <code>s2</code> may be different from call to call. When no token remains in <code>s1</code>, a null pointer is returned.</p>

strspn(3C)

`strtok_r()` | The `strtok_r()` function has the same functionality as `strtok()` except that a pointer to a string placeholder *lasts* must be supplied by the caller. The *lasts* pointer is to keep track of the next substring in which to search for the next token.

ATTRIBUTES | See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
MT-Level	See NOTES below.

SEE ALSO | `malloc(3C)`, `setlocale(3C)`, `strxfrm(3C)`, `attributes(5)`

NOTES | When compiling multithreaded applications, the `_REENTRANT` flag must be defined on the compile line. This flag should only be used in multithreaded applications.

All of these functions assume the default locale "C." For some locales, `strxfrm()` should be applied to the strings before they are passed to the functions.

The `strcasemp()`, `strcat()`, `strchr()`, `strcmp()`, `strcpy()`, `strcspn()`, `strdup()`, `strlen()`, `strncasemp()`, `strncat()`, `strncmp()`, `strncpy()`, `strpbrk()`, `strrchr()`, `strspn()`, and `strstr()` functions are MT-Safe in multithreaded applications.

The `strtok()` function is Unsafe in multithreaded applications. The `strtok_r()` function should be used instead.

NAME	string, strcasecmp, strncasecmp, strcat, strncat, strlcat, strchr, strrchr, strcmp, strncmp, strcpy, strncpy, strlcpy, strcspn, strspn, strdup, strlen, strpbrk, strstr, strtok, strtok_r – string operations
SYNOPSIS	<pre> #include <strings.h> int strcasecmp(const char *s1, const char *s2); int strncasecmp(const char *s1, const char *s2, size_t n); #include <string.h> char *strcat(char *s1, const char *s2); char *strncat(char *s1, const char *s2, size_t n); size_t strlcat(char *dst, const char *src, size_t dstsize); char *strchr(const char *s, int c); char *strrchr(const char *s, int c); int strcmp(const char *s1, const char *s2); int strncmp(const char *s1, const char *s2, size_t n); char *strcpy(char *s1, const char *s2); char *strncpy(char *s1, const char *s2, size_t n); size_t strlcpy(char *dst, const char *src, size_t dstsize); size_t strcspn(const char *s1, const char *s2); size_t strspn(const char *s1, const char *s2); char *strdup(const char *s1); size_t strlen(const char *s); char *strpbrk(const char *s1, const char *s2); char *strstr(const char *s1, const char *s2); char *strtok(char *s1, const char *s2); char *strtok_r(char *s1, const char *s2, char **lasts); </pre>

strstr(3C)

	<pre>char *std::strpbrk(char *s1, const char *s2); char *std::strrchr(char *s, int c); char *std::strstr(char *s1, const char *s2);</pre>
DESCRIPTION	<p>The arguments <i>s</i>, <i>s1</i>, and <i>s2</i> point to strings (arrays of characters terminated by a null character). The <code>strcat()</code>, <code>strncat()</code>, <code>strlcat()</code>, <code>strcpy()</code>, <code>strncpy()</code>, <code>strncpy()</code>, <code>strtok()</code>, and <code>strtok_r()</code> functions all alter their first argument. These functions do not check for overflow of the array pointed to by the first argument.</p>
<code>strcasecmp()</code> , <code>strncasecmp()</code>	<p>The <code>strcasecmp()</code> and <code>strncasecmp()</code> functions are case-insensitive versions of <code>strcmp()</code> and <code>strncmp()</code> respectively, described below. They assume the ASCII character set and ignore differences in case when comparing lower and upper case characters.</p>
<code>strcat()</code> , <code>strncat()</code> , <code>strlcat()</code>	<p>The <code>strcat()</code> function appends a copy of string <i>s2</i>, including the terminating null character, to the end of string <i>s1</i>. The <code>strncat()</code> function appends at most <i>n</i> characters. Each returns a pointer to the null-terminated result. The initial character of <i>s2</i> overrides the null character at the end of <i>s1</i>.</p> <p>The <code>strlcat()</code> function appends at most (<i>dstsize</i>-<code>strlen(dst)</code>-1) characters of <i>src</i> to <i>dst</i> (<i>dstsize</i> being the size of the string buffer <i>dst</i>). If the string pointed to by <i>dst</i> contains a null-terminated string that fits into <i>dstsize</i> bytes when <code>strlcat()</code> is called, the string pointed to by <i>dst</i> will be a null-terminated string that fits in <i>dstsize</i> bytes (including the terminating null character) when it completes, and the initial character of <i>src</i> will override the null character at the end of <i>dst</i>. If the string pointed to by <i>dst</i> is longer than <i>dstsize</i> bytes when <code>strlcat()</code> is called, the string pointed to by <i>dst</i> will not be changed. The function returns the sum the of lengths of the two strings <code>strlen(dst)+strlen(src)</code>. Buffer overflow can be checked as follows:</p> <pre>if (strlcat(dst, src, dstsize) >= dstsize) return -1;</pre>
<code>strchr()</code> , <code>strrchr()</code>	<p>The <code>strchr()</code> function returns a pointer to the first occurrence of <i>c</i> (converted to a char) in string <i>s</i>, or a null pointer if <i>c</i> does not occur in the string. The <code>strrchr()</code> function returns a pointer to the last occurrence of <i>c</i>. The null character terminating a string is considered to be part of the string.</p>
<code>strcmp()</code> , <code>strncmp()</code>	<p>The <code>strcmp()</code> function compares two strings byte-by-byte, according to the ordering of your machine's character set. The function returns an integer greater than, equal to, or less than 0, if the string pointed to by <i>s1</i> is greater than, equal to, or less than the string pointed to by <i>s2</i> respectively. The sign of a non-zero return value is determined by the sign of the difference between the values of the first pair of bytes that differ in the strings being compared. The <code>strncmp()</code> function makes the same comparison but looks at a maximum of <i>n</i> bytes. Bytes following a null byte are not compared.</p>

<code>strcpy()</code> , <code>strncpy()</code> , <code>strncpy()</code>	<p>The <code>strcpy()</code> function copies string <code>s2</code> to <code>s1</code>, including the terminating null character, stopping after the null character has been copied. The <code>strncpy()</code> function copies exactly <code>n</code> bytes, truncating <code>s2</code> or adding null characters to <code>s1</code> if necessary. The result will not be null-terminated if the length of <code>s2</code> is <code>n</code> or more. Each function returns <code>s1</code>.</p> <p>The <code>strncpy()</code> function copies at most <code>dsize-1</code> characters (<code>dsize</code> being the size of the string buffer <code>dst</code>) from <code>src</code> to <code>dst</code>, truncating <code>src</code> if necessary. The result is always null-terminated. The function returns <code>strlen(src)</code>. Buffer overflow can be checked as follows:</p> <pre>if (strncpy(dst, src, dsize) >= dsize) return -1;</pre>
<code>strcspn()</code> , <code>strspn()</code>	<p>The <code>strcspn()</code> function returns the length of the initial segment of string <code>s1</code> that consists entirely of characters not from string <code>s2</code>. The <code>strspn()</code> function returns the length of the initial segment of string <code>s1</code> that consists entirely of characters from string <code>s2</code>.</p>
<code>strdup()</code>	<p>The <code>strdup()</code> function returns a pointer to a new string that is a duplicate of the string pointed to by <code>s1</code>. The returned pointer can be passed to <code>free()</code>. The space for the new string is obtained using <code>malloc(3C)</code>. If the new string cannot be created, a null pointer is returned and <code>errno</code> may be set to <code>ENOMEM</code> to indicate that the storage space available is insufficient.</p>
<code>strlen()</code>	<p>The <code>strlen()</code> function returns the number of bytes in <code>s</code>, not including the terminating null character.</p>
<code>strpbrk()</code>	<p>The <code>strpbrk()</code> function returns a pointer to the first occurrence in string <code>s1</code> of any character from string <code>s2</code>, or a null pointer if no character from <code>s2</code> exists in <code>s1</code>.</p>
<code>strstr()</code>	<p>The <code>strstr()</code> function locates the first occurrence of the string <code>s2</code> (excluding the terminating null character) in string <code>s1</code> and returns a pointer to the located string, or a null pointer if the string is not found. If <code>s2</code> points to a string with zero length (that is, the string <code>"</code>), the function returns <code>s1</code>.</p>
<code>strtok()</code>	<p>The <code>strtok()</code> function can be used to break the string pointed to by <code>s1</code> into a sequence of tokens, each of which is delimited by one or more characters from the string pointed to by <code>s2</code>. The <code>strtok()</code> function considers the string <code>s1</code> to consist of a sequence of zero or more text tokens separated by spans of one or more characters from the separator string <code>s2</code>. The first call (with pointer <code>s1</code> specified) returns a pointer to the first character of the first token, and will have written a null character into <code>s1</code> immediately following the returned token. The function keeps track of its position in the string between separate calls, so that subsequent calls (which must be made with the first argument being a null pointer) will work through the string <code>s1</code> immediately following that token. In this way subsequent calls will work through the string <code>s1</code> until no tokens remain. The separator string <code>s2</code> may be different from call to call. When no token remains in <code>s1</code>, a null pointer is returned.</p>

strstr(3C)

`strtok_r()` The `strtok_r()` function has the same functionality as `strtok()` except that a pointer to a string placeholder *lasts* must be supplied by the caller. The *lasts* pointer is to keep track of the next substring in which to search for the next token.

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
MT-Level	See NOTES below.

SEE ALSO `malloc(3C)`, `setlocale(3C)`, `strxfrm(3C)`, `attributes(5)`

NOTES When compiling multithreaded applications, the `_REENTRANT` flag must be defined on the compile line. This flag should only be used in multithreaded applications.

All of these functions assume the default locale "C." For some locales, `strxfrm()` should be applied to the strings before they are passed to the functions.

The `strcascmp()`, `strcat()`, `strchr()`, `strcmp()`, `strcpy()`, `strcspn()`, `strdup()`, `strlen()`, `strncascmp()`, `strncat()`, `strncmp()`, `strncpy()`, `strpbrk()`, `strrchr()`, `strspn()`, and `strstr()` functions are MT-Safe in multithreaded applications.

The `strtok()` function is Unsafe in multithreaded applications. The `strtok_r()` function should be used instead.

NAME	strtod, atof – convert string to double-precision number
SYNOPSIS	<pre>#include <stdlib.h> double strtod(const char *str, char **endptr); double atof(const char *str);</pre>
DESCRIPTION	<p>The <code>strtod()</code> function converts the initial portion of the string pointed to by <i>str</i> to type <code>double</code> representation. First it decomposes the input string into three parts: an initial, possibly empty, sequence of white-space characters (as specified by <code>isspace(3C)</code>); a subject sequence interpreted as a floating-point constant; and a final string of one or more unrecognized characters, including the terminating null byte of the input string. Then it attempts to convert the subject sequence to a floating-point number, and returns the result.</p> <p>The expected form of the subject sequence is an optional + or – sign, then a non-empty sequence of digits optionally containing a radix character, then an optional exponent part. An exponent part consists of e or E, followed by an optional sign, followed by one or more decimal digits. The subject sequence is defined as the longest initial subsequence of the input string, starting with the first non-white-space character, that is of the expected form. The subject sequence is empty if the input string is empty or consists entirely of white-space characters, or if the first character that is not white space is other than a sign, a digit or a radix character.</p> <p>If the subject sequence has the expected form, the sequence starting with the first digit or the radix character (whichever occurs first) is interpreted as a floating constant of the C language, except that the radix character is used in place of a period, and that if neither an exponent part nor a radix character appears, a radix character is assumed to follow the last digit in the string. If the subject sequence begins with a minus sign, the value resulting from the conversion is negated. A pointer to the final string is stored in the object pointed to by <i>endptr</i>, provided that <i>endptr</i> is not a null pointer.</p> <p>The radix character is defined in the program’s locale (category <code>LC_NUMERIC</code>). In the POSIX locale, or in a locale where the radix character is not defined, the radix character defaults to a period (.).</p> <p>In other than the POSIX locale, other implementation-dependent subject sequence forms may be accepted.</p> <p>If the subject sequence is empty or does not have the expected form, no conversion is performed; the value of <i>str</i> is stored in the object pointed to by <i>endptr</i>, provided that <i>endptr</i> is not a null pointer.</p>
atof()	The <code>atof(str)</code> function call is equivalent to <code>strtod(str, (char **)NULL)</code> .
RETURN VALUES	Upon successful completion, <code>strtod()</code> returns the converted value. If no conversion could be performed, 0 is returned and <code>errno</code> may be set to <code>EINVAL</code> .

strtod(3C)

If the correct value is outside the range of representable values, \pm HUGE is returned (according to the sign of the value), and `errno` is set to `ERANGE`. When the `-Xc` or `-Xa` compilation options are used, `HUGE_VAL` is returned instead of `HUGE`.

If the correct value would cause an underflow, 0 is returned and `errno` is set to `ERANGE`.

If `str` is NaN, then `atof()` returns NaN.

ERRORS The `strtod()` function will fail if:

`ERANGE` The value to be returned would cause overflow or underflow. The `strtod()` function may fail if:

`EINVAL` No conversion could be performed.

USAGE Because 0 is returned on error and is also a valid return on success, an application wishing to check for error situations should set `errno` to 0, then call `strtod()`, then check `errno` and if it is non-zero, assume an error has occurred.

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
MT-Level	MT-Safe with exceptions
CSI	Enabled

SEE ALSO `isspace(3C)`, `localeconv(3C)`, `scanf(3C)`, `setlocale(3C)`, `strtol(3C)`, `attributes(5)`, `standards(5)`

NOTES The `strtod()` and `atof()` functions can be used safely in multithreaded applications, as long as `setlocale(3C)` is not called to change the locale.

The DESCRIPTION and RETURN VALUES sections above are very similar to the wording used by the Single UNIX Specification version 2 and the 1989 C Standard to describe the behavior of the `strtod()` function. Since some users have reported that they find the description confusing, the following notes may be helpful.

1. The `strtod()` function does not modify the string pointed to by `str` and does not `malloc()` space to hold the decomposed portions of the input string.
2. If `endptr` is not `(char **)NULL`, `strtod()` will set the pointer pointed to by `endptr` to the first byte of the "final string of unrecognized characters". (If all input characters were processed, the pointer pointed to by `endptr` will be set to point to the null character at the end of the input string.)
3. If `strtod()` returns 0.0, one of the following occurred:
 - a. The "subject sequence" was not an empty string, but evaluated to 0.0. (In this case, `errno` will be left unchanged.)

- b. The "subject sequence" was an empty string. (In this case, the Single UNIX Specification version 2 allows `errno` to be set to `EINVAL` or to be left unchanged. The C Standard does not specify any specific behavior in this case.)
 - c. The "subject sequence" specified a numeric value that would cause a floating point underflow. (In this case, `errno` may be set to `ERANGE` or may be left unchanged.) Note that the standards do not require that implementations distinguish between these three cases. An application can determine case (b) by making sure that there are no leading white-space characters in the string pointed to by `str` and giving `strtod()` an `endptr` that is not `(char **)NULL`. If `endptr` points to the first character of `str` when `strtod()` returns, you have detected case (b). Case (c) can be detected by looking for a non-zero digit before the exponent part of the "subject sequence". Note, however, that the decimal-point character is locale-dependent.
4. If `strtod()` returns `+HUGE_VAL` or `-HUGE_VAL`, one of the following occurred:
- a. If `+HUGE_VAL` is returned and `errno` is set to `ERANGE`, a floating point overflow occurred while processing a positive value.
 - b. If `-HUGE_VAL` is returned and `errno` is set to `ERANGE`, a floating point overflow occurred while processing a negative value.
 - c. If `strtod()` does not set `errno` to `ERANGE`, the value specified by the "subject string" converted to `+HUGE_VAL` or `-HUGE_VAL`, respectively. Note that if `errno` is set to `ERANGE` when `strtod()` is called, case (c) is indistinguishable from cases (a) and (b).

```

DESCRIPTION

The arguments *s*, *s1*, and *s2* point to strings (arrays of characters terminated by a null character). The `strcat()`, `strncat()`, `strlcat()`, `strcpy()`, `strncpy()`, `strncpy()`, `strtok()`, and `strtok_r()` functions all alter their first argument. These functions do not check for overflow of the array pointed to by the first argument.

```
strcasecmp(),
strncasecmp()
```

The `strcasecmp()` and `strncasecmp()` functions are case-insensitive versions of `strcmp()` and `strncmp()` respectively, described below. They assume the ASCII character set and ignore differences in case when comparing lower and upper case characters.

```
strcat(),
strncat(),
strlcat()
```

The `strcat()` function appends a copy of string *s2*, including the terminating null character, to the end of string *s1*. The `strncat()` function appends at most *n* characters. Each returns a pointer to the null-terminated result. The initial character of *s2* overrides the null character at the end of *s1*.

The `strlcat()` function appends at most $(dstsize - strlen(dst) - 1)$ characters of *src* to *dst* (*dstsize* being the size of the string buffer *dst*). If the string pointed to by *dst* contains a null-terminated string that fits into *dstsize* bytes when `strlcat()` is called, the string pointed to by *dst* will be a null-terminated string that fits in *dstsize* bytes (including the terminating null character) when it completes, and the initial character of *src* will override the null character at the end of *dst*. If the string pointed to by *dst* is longer than *dstsize* bytes when `strlcat()` is called, the string pointed to by *dst* will not be changed. The function returns the sum of lengths of the two strings $strlen(dst) + strlen(src)$. Buffer overflow can be checked as follows:

```
if (strlcat(dst, src, dstsize) >= dstsize)
    return -1;
```

```
strchr(),
strrchr()
```

The `strchr()` function returns a pointer to the first occurrence of *c* (converted to a char) in string *s*, or a null pointer if *c* does not occur in the string. The `strrchr()` function returns a pointer to the last occurrence of *c*. The null character terminating a string is considered to be part of the string.

```
strcmp(),
strncmp()
```

The `strcmp()` function compares two strings byte-by-byte, according to the ordering of your machine's character set. The function returns an integer greater than, equal to, or less than 0, if the string pointed to by *s1* is greater than, equal to, or less than the string pointed to by *s2* respectively. The sign of a non-zero return value is determined by the sign of the difference between the values of the first pair of bytes that differ in the strings being compared. The `strncmp()` function makes the same comparison but looks at a maximum of *n* bytes. Bytes following a null byte are not compared.

strtok(3C)

<code>strcpy()</code> , <code>strncpy()</code> , <code>strncpy()</code>	<p>The <code>strcpy()</code> function copies string <i>s2</i> to <i>s1</i>, including the terminating null character, stopping after the null character has been copied. The <code>strncpy()</code> function copies exactly <i>n</i> bytes, truncating <i>s2</i> or adding null characters to <i>s1</i> if necessary. The result will not be null-terminated if the length of <i>s2</i> is <i>n</i> or more. Each function returns <i>s1</i>.</p> <p>The <code>strncpy()</code> function copies at most <i>dsize-1</i> characters (<i>dsize</i> being the size of the string buffer <i>dst</i>) from <i>src</i> to <i>dst</i>, truncating <i>src</i> if necessary. The result is always null-terminated. The function returns <code>strlen(src)</code>. Buffer overflow can be checked as follows:</p> <pre>if (strncpy(dst, src, dsize) >= dsize) return -1;</pre>
<code>strcspn()</code> , <code>strspn()</code>	<p>The <code>strcspn()</code> function returns the length of the initial segment of string <i>s1</i> that consists entirely of characters not from string <i>s2</i>. The <code>strspn()</code> function returns the length of the initial segment of string <i>s1</i> that consists entirely of characters from string <i>s2</i>.</p>
<code>strdup()</code>	<p>The <code>strdup()</code> function returns a pointer to a new string that is a duplicate of the string pointed to by <i>s1</i>. The returned pointer can be passed to <code>free()</code>. The space for the new string is obtained using <code>malloc(3C)</code>. If the new string cannot be created, a null pointer is returned and <code>errno</code> may be set to <code>ENOMEM</code> to indicate that the storage space available is insufficient.</p>
<code>strlen()</code>	<p>The <code>strlen()</code> function returns the number of bytes in <i>s</i>, not including the terminating null character.</p>
<code>strpbrk()</code>	<p>The <code>strpbrk()</code> function returns a pointer to the first occurrence in string <i>s1</i> of any character from string <i>s2</i>, or a null pointer if no character from <i>s2</i> exists in <i>s1</i>.</p>
<code>strstr()</code>	<p>The <code>strstr()</code> function locates the first occurrence of the string <i>s2</i> (excluding the terminating null character) in string <i>s1</i> and returns a pointer to the located string, or a null pointer if the string is not found. If <i>s2</i> points to a string with zero length (that is, the string ""), the function returns <i>s1</i>.</p>
<code>strtok()</code>	<p>The <code>strtok()</code> function can be used to break the string pointed to by <i>s1</i> into a sequence of tokens, each of which is delimited by one or more characters from the string pointed to by <i>s2</i>. The <code>strtok()</code> function considers the string <i>s1</i> to consist of a sequence of zero or more text tokens separated by spans of one or more characters from the separator string <i>s2</i>. The first call (with pointer <i>s1</i> specified) returns a pointer to the first character of the first token, and will have written a null character into <i>s1</i> immediately following the returned token. The function keeps track of its position in the string between separate calls, so that subsequent calls (which must be made with the first argument being a null pointer) will work through the string <i>s1</i> immediately following that token. In this way subsequent calls will work through the string <i>s1</i> until no tokens remain. The separator string <i>s2</i> may be different from call to call. When no token remains in <i>s1</i>, a null pointer is returned.</p>

`strtok_r()` The `strtok_r()` function has the same functionality as `strtok()` except that a pointer to a string placeholder *lasts* must be supplied by the caller. The *lasts* pointer is to keep track of the next substring in which to search for the next token.

```

DESCRIPTION

The arguments *s*, *s1*, and *s2* point to strings (arrays of characters terminated by a null character). The `strcat()`, `strncat()`, `strlcat()`, `strcpy()`, `strncpy()`, `strncpy()`, `strtok()`, and `strtok_r()` functions all alter their first argument. These functions do not check for overflow of the array pointed to by the first argument.

```
strcasecmp(),  
strncasecmp()
```

The `strcasecmp()` and `strncasecmp()` functions are case-insensitive versions of `strcmp()` and `strncmp()` respectively, described below. They assume the ASCII character set and ignore differences in case when comparing lower and upper case characters.

```
strcat(),  
strncat(),  
strlcat()
```

The `strcat()` function appends a copy of string *s2*, including the terminating null character, to the end of string *s1*. The `strncat()` function appends at most *n* characters. Each returns a pointer to the null-terminated result. The initial character of *s2* overrides the null character at the end of *s1*.

The `strlcat()` function appends at most $(dstsize - strlen(dst) - 1)$ characters of *src* to *dst* (*dstsize* being the size of the string buffer *dst*). If the string pointed to by *dst* contains a null-terminated string that fits into *dstsize* bytes when `strlcat()` is called, the string pointed to by *dst* will be a null-terminated string that fits in *dstsize* bytes (including the terminating null character) when it completes, and the initial character of *src* will override the null character at the end of *dst*. If the string pointed to by *dst* is longer than *dstsize* bytes when `strlcat()` is called, the string pointed to by *dst* will not be changed. The function returns the sum of lengths of the two strings $strlen(dst) + strlen(src)$. Buffer overflow can be checked as follows:

```
if (strlcat(dst, src, dstsize) >= dstsize)  
    return -1;
```

```
strchr(),  
strrchr()
```

The `strchr()` function returns a pointer to the first occurrence of *c* (converted to a char) in string *s*, or a null pointer if *c* does not occur in the string. The `strrchr()` function returns a pointer to the last occurrence of *c*. The null character terminating a string is considered to be part of the string.

```
strcmp(),  
strncmp()
```

The `strcmp()` function compares two strings byte-by-byte, according to the ordering of your machine's character set. The function returns an integer greater than, equal to, or less than 0, if the string pointed to by *s1* is greater than, equal to, or less than the string pointed to by *s2* respectively. The sign of a non-zero return value is determined by the sign of the difference between the values of the first pair of bytes that differ in the strings being compared. The `strncmp()` function makes the same comparison but looks at a maximum of *n* bytes. Bytes following a null byte are not compared.

strtok_r(3C)

<code>strcpy()</code> , <code>strncpy()</code> , <code>strncpy()</code>	<p>The <code>strcpy()</code> function copies string <code>s2</code> to <code>s1</code>, including the terminating null character, stopping after the null character has been copied. The <code>strncpy()</code> function copies exactly <code>n</code> bytes, truncating <code>s2</code> or adding null characters to <code>s1</code> if necessary. The result will not be null-terminated if the length of <code>s2</code> is <code>n</code> or more. Each function returns <code>s1</code>.</p> <p>The <code>strncpy()</code> function copies at most <code>dsize-1</code> characters (<code>dsize</code> being the size of the string buffer <code>dst</code>) from <code>src</code> to <code>dst</code>, truncating <code>src</code> if necessary. The result is always null-terminated. The function returns <code>strlen(src)</code>. Buffer overflow can be checked as follows:</p> <pre>if (strncpy(dst, src, dsize) >= dsize) return -1;</pre>
<code>strcspn()</code> , <code>strspn()</code>	<p>The <code>strcspn()</code> function returns the length of the initial segment of string <code>s1</code> that consists entirely of characters not from string <code>s2</code>. The <code>strspn()</code> function returns the length of the initial segment of string <code>s1</code> that consists entirely of characters from string <code>s2</code>.</p>
<code>strdup()</code>	<p>The <code>strdup()</code> function returns a pointer to a new string that is a duplicate of the string pointed to by <code>s1</code>. The returned pointer can be passed to <code>free()</code>. The space for the new string is obtained using <code>malloc(3C)</code>. If the new string cannot be created, a null pointer is returned and <code>errno</code> may be set to <code>ENOMEM</code> to indicate that the storage space available is insufficient.</p>
<code>strlen()</code>	<p>The <code>strlen()</code> function returns the number of bytes in <code>s</code>, not including the terminating null character.</p>
<code>strpbrk()</code>	<p>The <code>strpbrk()</code> function returns a pointer to the first occurrence in string <code>s1</code> of any character from string <code>s2</code>, or a null pointer if no character from <code>s2</code> exists in <code>s1</code>.</p>
<code>strstr()</code>	<p>The <code>strstr()</code> function locates the first occurrence of the string <code>s2</code> (excluding the terminating null character) in string <code>s1</code> and returns a pointer to the located string, or a null pointer if the string is not found. If <code>s2</code> points to a string with zero length (that is, the string ""), the function returns <code>s1</code>.</p>
<code>strtok()</code>	<p>The <code>strtok()</code> function can be used to break the string pointed to by <code>s1</code> into a sequence of tokens, each of which is delimited by one or more characters from the string pointed to by <code>s2</code>. The <code>strtok()</code> function considers the string <code>s1</code> to consist of a sequence of zero or more text tokens separated by spans of one or more characters from the separator string <code>s2</code>. The first call (with pointer <code>s1</code> specified) returns a pointer to the first character of the first token, and will have written a null character into <code>s1</code> immediately following the returned token. The function keeps track of its position in the string between separate calls, so that subsequent calls (which must be made with the first argument being a null pointer) will work through the string <code>s1</code> immediately following that token. In this way subsequent calls will work through the string <code>s1</code> until no tokens remain. The separator string <code>s2</code> may be different from call to call. When no token remains in <code>s1</code>, a null pointer is returned.</p>

`strtok_r()` The `strtok_r()` function has the same functionality as `strtok()` except that a pointer to a string placeholder *lasts* must be supplied by the caller. The *lasts* pointer is to keep track of the next substring in which to search for the next token.

The `strtok()` function is Unsafe in multithreaded applications. The `strtok_r()` function should be used instead.

strtol(3C)

NAME	strtol, strtoll, atol, atoll, atoi, lltostr, ulltostr – string conversion routines
SYNOPSIS	<pre>#include <stdlib.h> long strtol(const char *str, char **endptr, int base); long long strtoll(const char *str, char **endptr, int base); long atol(const char *str); long long atoll(const char *str); int atoi(const char *str); char *lltostr(long long value, char *endptr); char *ulltostr(unsigned long long value, char *endptr);</pre>
strtol() and strtoll()	<p>The <code>strtol()</code> function converts the initial portion of the string pointed to by <code>str</code> to a type long int representation.</p> <p>The <code>strtoll()</code> function converts the initial portion of the string pointed to by <code>str</code> to a type long long representation.</p> <p>Both functions first decompose the input string into three parts: an initial, possibly empty, sequence of white-space characters (as specified by <code>isspace(3C)</code>); a subject sequence interpreted as an integer represented in some radix determined by the value of <code>base</code>; and a final string of one or more unrecognized characters, including the terminating null byte of the input string. They then attempt to convert the subject sequence to an integer and return the result.</p> <p>If the value of <code>base</code> is 0, the expected form of the subject sequence is that of a decimal constant, octal constant or hexadecimal constant, any of which may be preceded by a + or – sign. A decimal constant begins with a non-zero digit, and consists of a sequence of decimal digits. An octal constant consists of the prefix 0 optionally followed by a sequence of the digits 0 to 7 only. A hexadecimal constant consists of the prefix 0x or 0X followed by a sequence of the decimal digits and letters a (or A) to f (or F) with values 10 to 15 respectively.</p> <p>If the value of <code>base</code> is between 2 and 36, the expected form of the subject sequence is a sequence of letters and digits representing an integer with the radix specified by <code>base</code>, optionally preceded by a + or – sign. The letters from a (or A) to z (or Z) inclusive are ascribed the values 10 to 35; only letters whose ascribed values are less than that of <code>base</code> are permitted. If the value of <code>base</code> is 16, the characters 0x or 0X may optionally precede the sequence of letters and digits, following the sign if present.</p> <p>The subject sequence is defined as the longest initial subsequence of the input string, starting with the first non-white-space character, that is of the expected form. The subject sequence contains no characters if the input string is empty or consists entirely of white-space characters, or if the first non-white-space character is other than a sign or a permissible letter or digit.</p>

If the subject sequence has the expected form and the value of *base* is 0, the sequence of characters starting with the first digit is interpreted as an integer constant. If the subject sequence has the expected form and the value of *base* is between 2 and 36, it is used as the base for conversion, ascribing to each letter its value as given above. If the subject sequence begins with a minus sign, the value resulting from the conversion is negated. A pointer to the final string is stored in the object pointed to by *endptr*, provided that *endptr* is not a null pointer.

In other than the POSIX locale, additional implementation-dependent subject sequence forms may be accepted.

If the subject sequence is empty or does not have the expected form, no conversion is performed; the value of *str* is stored in the object pointed to by *endptr*, provided that *endptr* is not a null pointer.

`atol()`, `atoll()`
and `atoi()`

Except for behavior on error, `atol()` is equivalent to: `strtol(str, (char **)NULL, 10)`.

Except for behavior on error, `atoll()` is equivalent to: `strtoll(str, (char **)NULL, 10)`.

Except for behavior on error, `atoi()` is equivalent to: `(int) strtol(str, (char **)NULL, 10)`.

`lltostr()` and
`ulltostr()`

The `lltostr()` function returns a pointer to the string represented by the long long *value*. The *endptr* argument is assumed to point to the byte following a storage area into which the decimal representation of *value* is to be placed as a string. The `lltostr()` function converts *value* to decimal and produces the string, and returns a pointer to the beginning of the string. No leading zeros are produced, and no terminating null is produced. The low-order digit of the result always occupies memory position *endptr*-1. The behavior of `lltostr()` is undefined if *value* is negative. A single zero digit is produced if *value* is 0.

The `ulltostr()` function is similar to `lltostr()` except that *value* is an unsigned long long.

RETURN VALUES

Upon successful completion, `strtol()`, `strtoll()`, `atol()`, `atoll()`, and `atoi()` return the converted value, if any. If no conversion could be performed, `strtol()` and `strtoll()` return 0 and `errno` may be set to `EINVAL`.

If the correct value is outside the range of representable values, `strtol()` returns `LONG_MAX` or `LONG_MIN` and `strtoll()` returns `LLONG_MAX` or `LLONG_MIN` (according to the sign of the value), and `errno` is set to `ERANGE`.

Upon successful completion, `lltostr()` and `ulltostr()` return a pointer to the converted string.

ERRORS

The `strtol()` and `strtoll()` functions will fail if:

`ERANGE` The value to be returned is not representable. The `strtol()` and `strtoll()` functions may fail if:

strtol(3C)

EINVAL The value of *base* is not supported.

USAGE Because 0, LONG_MIN, LONG_MAX, LLONG_MIN, and LLONG_MAX are returned on error and are also valid returns on success, an application wishing to check for error situations should set `errno` to 0, call the function, then check `errno` and if it is non-zero, assume an error has occurred.

The `strtol()` function no longer accepts values greater than LONG_MAX or LLONG_MAX as valid input. Use `strtoul(3C)` instead.

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE

NAME	strtol, strtoll, atol, atoll, atoi, lltostr, ulltostr – string conversion routines
SYNOPSIS	<pre>#include <stdlib.h> long strtol(const char *str, char **endptr, int base); long long strtoll(const char *str, char **endptr, int base); long atol(const char *str); long long atoll(const char *str); int atoi(const char *str); char *lltostr(long long value, char *endptr); char *ulltostr(unsigned long long value, char *endptr);</pre>
strtol() and strtoll()	<p>The <code>strtol()</code> function converts the initial portion of the string pointed to by <code>str</code> to a type long int representation.</p> <p>The <code>strtoll()</code> function converts the initial portion of the string pointed to by <code>str</code> to a type long long representation.</p> <p>Both functions first decompose the input string into three parts: an initial, possibly empty, sequence of white-space characters (as specified by <code>isspace(3C)</code>); a subject sequence interpreted as an integer represented in some radix determined by the value of <code>base</code>; and a final string of one or more unrecognized characters, including the terminating null byte of the input string. They then attempt to convert the subject sequence to an integer and return the result.</p> <p>If the value of <code>base</code> is 0, the expected form of the subject sequence is that of a decimal constant, octal constant or hexadecimal constant, any of which may be preceded by a + or – sign. A decimal constant begins with a non-zero digit, and consists of a sequence of decimal digits. An octal constant consists of the prefix 0 optionally followed by a sequence of the digits 0 to 7 only. A hexadecimal constant consists of the prefix 0x or 0X followed by a sequence of the decimal digits and letters a (or A) to f (or F) with values 10 to 15 respectively.</p> <p>If the value of <code>base</code> is between 2 and 36, the expected form of the subject sequence is a sequence of letters and digits representing an integer with the radix specified by <code>base</code>, optionally preceded by a + or – sign. The letters from a (or A) to z (or Z) inclusive are ascribed the values 10 to 35; only letters whose ascribed values are less than that of <code>base</code> are permitted. If the value of <code>base</code> is 16, the characters 0x or 0X may optionally precede the sequence of letters and digits, following the sign if present.</p> <p>The subject sequence is defined as the longest initial subsequence of the input string, starting with the first non-white-space character, that is of the expected form. The subject sequence contains no characters if the input string is empty or consists entirely of white-space characters, or if the first non-white-space character is other than a sign or a permissible letter or digit.</p>

strtoll(3C)

If the subject sequence has the expected form and the value of *base* is 0, the sequence of characters starting with the first digit is interpreted as an integer constant. If the subject sequence has the expected form and the value of *base* is between 2 and 36, it is used as the base for conversion, ascribing to each letter its value as given above. If the subject sequence begins with a minus sign, the value resulting from the conversion is negated. A pointer to the final string is stored in the object pointed to by *endptr*, provided that *endptr* is not a null pointer.

In other than the POSIX locale, additional implementation-dependent subject sequence forms may be accepted.

If the subject sequence is empty or does not have the expected form, no conversion is performed; the value of *str* is stored in the object pointed to by *endptr*, provided that *endptr* is not a null pointer.

`atol()`, `atoll()`
and `atoi()`

Except for behavior on error, `atol()` is equivalent to: `strtol(str, (char **)NULL, 10)`.

Except for behavior on error, `atoll()` is equivalent to: `strtoll(str, (char **)NULL, 10)`.

Except for behavior on error, `atoi()` is equivalent to: `(int) strtol(str, (char **)NULL, 10)`.

`lltostr()` **and**
`ulltostr()`

The `lltostr()` function returns a pointer to the string represented by the long long *value*. The *endptr* argument is assumed to point to the byte following a storage area into which the decimal representation of *value* is to be placed as a string. The `lltostr()` function converts *value* to decimal and produces the string, and returns a pointer to the beginning of the string. No leading zeros are produced, and no terminating null is produced. The low-order digit of the result always occupies memory position *endptr*-1. The behavior of `lltostr()` is undefined if *value* is negative. A single zero digit is produced if *value* is 0.

The `ulltostr()` function is similar to `lltostr()` except that *value* is an unsigned long long.

RETURN VALUES

Upon successful completion, `strtol()`, `strtoll()`, `atol()`, `atoll()`, and `atoi()` return the converted value, if any. If no conversion could be performed, `strtol()` and `strtoll()` return 0 and `errno` may be set to `EINVAL`.

If the correct value is outside the range of representable values, `strtol()` returns `LONG_MAX` or `LONG_MIN` and `strtoll()` returns `LLONG_MAX` or `LLONG_MIN` (according to the sign of the value), and `errno` is set to `ERANGE`.

Upon successful completion, `lltostr()` and `ulltostr()` return a pointer to the converted string.

ERRORS

The `strtol()` and `strtoll()` functions will fail if:

`ERANGE` The value to be returned is not representable. The `strtol()` and `strtoll()` functions may fail if:

EINVAL The value of *base* is not supported.

USAGE Because 0, LONG_MIN, LONG_MAX, LLONG_MIN, and LLONG_MAX are returned on error and are also valid returns on success, an application wishing to check for error situations should set `errno` to 0, call the function, then check `errno` and if it is non-zero, assume an error has occurred.

The `strtol()` function no longer accepts values greater than LONG_MAX or LLONG_MAX as valid input. Use `strtoul(3C)` instead.

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

strtoul(3C)

NAME	strtoul, strtoull – convert string to unsigned long
SYNOPSIS	<pre>#include <stdlib.h> unsigned long strtoul(const char *str, char **endptr, int base); unsigned long long strtoull(const char *str, char **endptr, int base);</pre>
DESCRIPTION	<p>The <code>strtoul()</code> function converts the initial portion of the string pointed to by <i>str</i> to a type unsigned long int representation. First it decomposes the input string into three parts: an initial, possibly empty, sequence of white-space characters (as specified by <code>isspace(3C)</code>); a subject sequence interpreted as an integer represented in some radix determined by the value of <i>base</i>; and a final string of one or more unrecognised characters, including the terminating null byte of the input string. Then it attempts to convert the subject sequence to an unsigned integer, and returns the result.</p> <p>If the value of <i>base</i> is 0, the expected form of the subject sequence is that of a decimal constant, octal constant or hexadecimal constant, any of which may be preceded by a + or – sign. A decimal constant begins with a non-zero digit, and consists of a sequence of decimal digits. An octal constant consists of the prefix 0 optionally followed by a sequence of the digits 0 to 7 only. A hexadecimal constant consists of the prefix 0x or 0X followed by a sequence of the decimal digits and letters a (or A) to f (or F) with values 10 to 15 respectively.</p> <p>If the value of <i>base</i> is between 2 and 36, the expected form of the subject sequence is a sequence of letters and digits representing an integer with the radix specified by <i>base</i>, optionally preceded by a + or – sign. The letters from a (or A) to z (or Z) inclusive are ascribed the values 10 to 35; only letters whose ascribed values are less than that of <i>base</i> are permitted. If the value of <i>base</i> is 16, the characters 0x or 0X may optionally precede the sequence of letters and digits, following the sign if present.</p> <p>The subject sequence is defined as the longest initial subsequence of the input string, starting with the first non-white-space character, that is of the expected form. The subject sequence contains no characters if the input string is empty or consists entirely of white-space characters, or if the first non-white-space character is other than a sign or a permissible letter or digit.</p> <p>If the subject sequence has the expected form and the value of <i>base</i> is 0, the sequence of characters starting with the first digit is interpreted as an integer constant. If the subject sequence has the expected form and the value of <i>base</i> is between 2 and 36, it is used as the base for conversion, ascribing to each letter its value as given above. If the subject sequence begins with a minus sign, the value resulting from the conversion is negated. A pointer to the final string is stored in the object pointed to by <i>endptr</i>, provided that <i>endptr</i> is not a null pointer.</p> <p>In other than the POSIX locale, additional implementation-dependent subject sequence forms may be accepted.</p>

If the subject sequence is empty or does not have the expected form, no conversion is performed; the value of *str* is stored in the object pointed to by *endptr*, provided that *endptr* is not a null pointer.

The `strtoull()` function is identical to `strtoul()` except that it returns the value represented by *str* as an unsigned long long.

RETURN VALUES

Upon successful completion `strtoul()` returns the converted value, if any. If no conversion could be performed, 0 is returned and `errno` may be set to `EINVAL`. If the correct value is outside the range of representable values, `ULONG_MAX` is returned and `errno` is set to `ERANGE`.

ERRORS

The `strtoul()` function will fail if:

`EINVAL` The value of *base* is not supported.

`ERANGE` The value to be returned is not representable.

The `strtoul()` function may fail if:

`EINVAL` No conversion could be performed.

USAGE

Because 0 and `ULONG_MAX` are returned on error and are also valid returns on success, an application wishing to check for error situations should set `errno` to 0, then call `strtoul()`, then check `errno` and if it is non-zero, assume an error has occurred.

Unlike `strtod(3C)` and `strtol(3C)`, `strtoul()` must always return a non-negative number; so, using the return value of `strtoul()` for out-of-range numbers with `strtoul()` could cause more severe problems than just loss of precision if those numbers can ever be negative.

strtoks(3C)

NAME	strtoks, wstoktr – code conversion for Process Code and File Code
SYNOPSIS	<pre>#include <widec.h> wchar_t *strtoks(wchar_t *dst, const char *src); char *wstoktr(char *dst, const wchar_t *src);</pre>
DESCRIPTION	<p>The <code>strtoks()</code> and <code>wstoktr()</code> functions convert strings back and forth between File Code representation and Process Code.</p> <p>The <code>strtoks()</code> function takes a character string <i>src</i>, converts it to a Process Code string, terminated by a Process Code null, and places the result into <i>dst</i>.</p> <p>The <code>wstoktr()</code> function takes the Process Code string pointed to by <i>src</i>, converts it to a character string, and places the result into <i>dst</i>.</p>
RETURN VALUES	<p>The <code>strtoks()</code> function returns the Process Code string if it completes successfully. Otherwise, a null pointer will be returned and <code>errno</code> will be set to <code>EILSEQ</code>.</p> <p>The <code>wstoktr()</code> function returns the File Code string if it completes successfully. Otherwise, a null pointer will be returned and <code>errno</code> will be set to <code>EILSEQ</code>.</p>
SEE ALSO	wstring(3C)

NAME	strxfrm – string transformation
SYNOPSIS	<pre>#include <string.h> size_t strxfrm(char *s1, const char *s2, size_t n);</pre>
DESCRIPTION	<p>The <code>strxfrm()</code> function transforms the string pointed to by <code>s2</code> and places the resulting string into the array pointed to by <code>s1</code>. The transformation is such that if <code>strcmp(3C)</code> is applied to two transformed strings, it returns a value greater than, equal to or less than 0, corresponding to the result of <code>strcoll(3C)</code> applied to the same two original strings. No more than <code>n</code> bytes are placed into the resulting array pointed to by <code>s1</code>, including the terminating null byte. If <code>n</code> is 0, <code>s1</code> is permitted to be a null pointer. If copying takes place between objects that overlap, the behavior is undefined.</p>
RETURN VALUES	<p>Upon successful completion, <code>strxfrm()</code> returns the length of the transformed string (not including the terminating null byte). If the value returned is <code>n</code> or more, the contents of the array pointed to by <code>s1</code> are indeterminate.</p> <p>On failure, <code>strxfrm()</code> returns <code>(size_t) -1</code>.</p>
USAGE	<p>The transformation function is such that two transformed strings can be ordered by <code>strcmp(3C)</code> as appropriate to collating sequence information in the program's locale (category <code>LC_COLLATE</code>).</p> <p>The fact that when <code>n</code> is 0, <code>s1</code> is permitted to be a null pointer, is useful to determine the size of the <code>s1</code> array prior to making the transformation.</p> <p>Because no return value is reserved to indicate an error, an application wishing to check for error situations should set <code>errno</code> to 0, then call <code>strcoll(3C)</code>, then check <code>errno</code> and if it is non-zero, assume an error has occurred.</p> <p>This issue is aligned with the ANSI C standard; this does not affect compatibility with XPG3 applications. Reliable error detection by this function was never guaranteed.</p>
EXAMPLES	<p>EXAMPLE 1 A sample of using the <code>strxfrm()</code> function.</p> <p>The value of the following expression is the size of the array needed to hold the transformation of the string pointed to by <code>s</code>.</p> <pre>1 + strxfrm(NULL, s, 0);</pre>
FILES	<pre>/usr/lib/locale/locale/locale.so.* LC_COLLATE database for locale</pre>
ATTRIBUTES	See <code>attributes(5)</code> for descriptions of the following attributes:

strxfrm(3C)

ATTRIBUTE TYPE	ATTRIBUTE VALUE
MT-Level	MT-Safe with exceptions
CSI	Enabled

SEE ALSO localedef(1), setlocale(3C), strcmp(3C), strcoll(3C), wscoll(3C), attributes(5), environ(5), standards(5)

NOTES The `strxfrm()` function can be used safely in a multithreaded application, as long as `setlocale(3C)` is not being called to change the locale.

NAME swab – swap bytes

Default #include <stdlib.h>

```
void swab(const void *src, char *dest, ssize_t nbytes);
```

XPG4, SUS, SUSv2 #include <unistd.h>

```
void swab(const void *src, void *dest, ssize_t nbytes);
```

DESCRIPTION The `swab()` function copies *nbytes* bytes, which are pointed to by *src*, to the object pointed to by *dest*, exchanging adjacent bytes. The *nbytes* argument should be even. If *nbytes* is odd `swab()` copies and exchanges *nbytes*–1 bytes and the disposition of the last byte is unspecified. If copying takes place between objects that overlap, the behavior is undefined. If *nbytes* is negative, `swab()` does nothing.

ERRORS No errors are defined.

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

swapcontext(3C)

NAME	makecontext, swapcontext – manipulate user contexts				
SYNOPSIS	<pre>cc -D__MAKECONTEXT_V2_SOURCE [flag...] file... [library...] #include <ucontext.h> void makecontext (ucontext_t *ucp, void(*func)(), int argc, ...); int swapcontext (ucontext_t *oucp, const ucontext_t *ucp);</pre>				
DESCRIPTION	<p>These functions are useful for implementing user-level context switching between multiple threads of control within a process.</p> <p>The <code>makecontext()</code> function modifies the context specified by <code>ucp</code>, which has been initialized using <code>getcontext(2)</code>. When this context is resumed using <code>swapcontext()</code> or <code>setcontext(2)</code>, program execution continues by calling the function <code>func</code>, passing it the arguments that follow <code>argc</code> in the <code>makecontext()</code> call. The value of <code>argc</code> must match the number of pointer-sized integer arguments passed to <code>func</code>. Otherwise the behavior is undefined.</p> <p>Before a call is made to <code>makecontext()</code>, the context being modified should have a stack allocated for it. The value of <code>argc</code> must match the number of integer arguments passed to <code>func</code>, otherwise the behavior is undefined.</p> <p>The <code>uc_link</code> member is used to determine the context that will be resumed when the context being modified by <code>makecontext()</code> returns. The <code>uc_link</code> member should be initialized prior to the call to <code>makecontext()</code>. If the <code>uc_link</code> member is initialized to <code>NULL</code>, the thread executing <code>func</code> will exit when <code>func</code> returns. See <code>pthread_exit(3THR)</code>.</p> <p>The <code>swapcontext()</code> function saves the current context in the context structure pointed to by <code>oucp</code> and sets the context to the context structure pointed to by <code>ucp</code>.</p> <p>If the <code>ucp</code> or <code>oucp</code> argument points to an illegal address, the behavior is undefined and <code>errno</code> may be set to <code>EFAULT</code>.</p>				
RETURN VALUES	Upon successful completion, <code>swapcontext()</code> returns 0. Otherwise, -1 is returned and <code>errno</code> is set to indicate the error.				
ERRORS	<p>The <code>swapcontext()</code> function will fail if:</p> <table><tr><td>ENOMEM</td><td>The <code>ucp</code> argument does not have enough stack left to complete the operation.</td></tr></table> <p>The <code>swapcontext()</code> function may fail if:</p> <table><tr><td>EFAULT</td><td>The <code>ucp</code> or <code>oucp</code> argument points to an invalid address.</td></tr></table>	ENOMEM	The <code>ucp</code> argument does not have enough stack left to complete the operation.	EFAULT	The <code>ucp</code> or <code>oucp</code> argument points to an invalid address.
ENOMEM	The <code>ucp</code> argument does not have enough stack left to complete the operation.				
EFAULT	The <code>ucp</code> or <code>oucp</code> argument points to an invalid address.				
EXAMPLES	<p>EXAMPLE 1 Alternate execution context on a stack whose memory was allocated using <code>mmap(2)</code>.</p> <pre>#include <stdio.h> #include <ucontext.h> #include <sys/mman.h></pre>				

EXAMPLE 1 Alternate execution context on a stack whose memory was allocated using `mmap(2)`. (Continued)

```
void
assign(long a, int *b)
{
    *b = (int)a;
}

int
main(int argc, char **argv)
{
    ucontext_t uc, back;
    size_t sz = 0x10000;
    int value = 0;

    getcontext (&uc);

    uc.uc_stack.ss_sp = mmap(0, sz,
        PROT_READ | PROT_WRITE | PROT_EXEC,
        MAP_PRIVATE | MAP_ANON, -1, 0);
    uc.uc_stack.ss_size = sz;
    uc.uc_stack.ss_flags = 0;

    uc.uc_link = &back

    makecontext (&uc, assign, 2, 100L, &value);
    swapcontext (&back, &uc);

    printf("done %d\n", value);

    return (0);
}
```

USAGE These functions are useful for implementing user-level context switching between multiple threads of control within a process (co-processing). More effective multiple threads of control can be obtained by using native support for multithreading. See `threads(3THR)`.

swapcontext(3C)

NOTES | The legacy implementation of `makecontext()` for `sparc` and `sparcv9` was in violation of the standard. To use the updated version with the corrected behavior, specify `-D__MAKECONTEXT_V2_SOURCE` when invoking the compiler. See the **EXAMPLES** section for the correct usage.

Future releases of Solaris will enable the corrected behavior by default, thereby eliminating the need to define `__MAKECONTEXT_V2_SOURCE`.

NAME	fwprintf, wprintf, swprintf – print formatted wide-character output
SYNOPSIS	<pre>#include <stdio.h> #include <wchar.h> int fwprintf(FILE *stream, const wchar_t *format, ...); int wprintf(const wchar_t *format, <...>); int swprintf(wchar_t *s, size_t n, const wchar_t *format, ...);</pre>
DESCRIPTION	<p>The <code>fwprintf()</code> function places output on the named output <i>stream</i>. The <code>wprintf()</code> function places output on the standard output stream <code>stdout</code>. The <code>swprintf()</code> function places output followed by the null wide-character in consecutive wide-characters starting at <i>*s</i>; no more than <i>n</i> wide-characters are written, including a terminating null wide-character, which is always added (unless <i>n</i> is zero).</p> <p>Each of these functions converts, formats and prints its arguments under control of the <i>format</i> wide-character string. The <i>format</i> is composed of zero or more directives: <i>ordinary wide-characters</i>, which are simply copied to the output stream and <i>conversion specifications</i>, each of which results in the fetching of zero or more arguments. The results are undefined if there are insufficient arguments for the <i>format</i>. If the <i>format</i> is exhausted while arguments remain, the excess arguments are evaluated but are otherwise ignored.</p> <p>Conversions can be applied to the <i>n</i>th argument after the <i>format</i> in the argument list, rather than to the next unused argument. In this case, the conversion wide-character <code>%</code> (see below) is replaced by the sequence <code>%n\$</code>, where <i>n</i> is a decimal integer in the range <code>[1, NL_ARGMAX]</code>, giving the position of the argument in the argument list. This feature provides for the definition of format wide-character strings that select arguments in an order appropriate to specific languages (see the <code>EXAMPLES</code> section).</p> <p>In format wide-character strings containing the <code>%n\$</code> form of conversion specifications, numbered arguments in the argument list can be referenced from the format wide-character string as many times as required.</p> <p>In format wide-character strings containing the <code>%</code> form of conversion specifications, each argument in the argument list is used exactly once.</p> <p>All forms of the <code>fwprintf()</code> functions allow for the insertion of a language-dependent radix character in the output string, output as a wide-character value. The radix character is defined in the program's locale (category <code>LC_NUMERIC</code>). In the POSIX locale, or in a locale where the radix character is not defined, the radix character defaults to a period (<code>.</code>).</p> <p>Each conversion specification is introduced by the <code>%</code> wide-character or by the wide-character sequence <code>%n\$</code>, after which the following appear in sequence:</p> <ul style="list-style-type: none"> ▪ Zero or more <i>flags</i> (in any order), which modify the meaning of the conversion specification.

swprintf(3C)

- An optional minimum *field width*. If the converted value has fewer wide-characters than the field width, it will be padded with spaces by default on the left; it will be padded on the right, if the left-adjustment flag (-), described below, is given to the field width. The field width takes the form of an asterisk (*), described below, or a decimal integer.
- An optional *precision* that gives the minimum number of digits to appear for the d, i, o, u, x, and X conversions; the number of digits to appear after the radix character for the e, E, and f conversions; the maximum number of significant digits for the g and G conversions; or the maximum number of wide-characters to be printed from a string in s conversions. The precision takes the form of a period (.) followed by either an asterisk (*), described below, or an optional decimal digit string, where a null digit string is treated as 0. If a precision appears with any other conversion wide-character, the behavior is undefined.
- An optional l (ell) specifying that a following c conversion wide-character applies to a `wint_t` argument; an optional l specifying that a following s conversion wide-character applies to a `wchar_t` argument; an optional h specifying that a following d, i, o, u, x, and X conversion wide-character applies to a type `short int` or type `unsigned short int` argument (the argument will have been promoted according to the integral promotions, and its value will be converted to type `short int` or `unsigned short int` before printing); an optional h specifying that a following n conversion wide-character applies to a pointer to a type `short int` argument; an optional l (ell) specifying that a following d, i, o, u, x, and X conversion wide-character applies to a type `long int` or `unsigned long int` argument; an optional l (ell) specifying that a following n conversion wide-character applies to a pointer to a type `long int` argument; or an optional L specifying that a following e, E, f, g, or G conversion wide-character applies to a type `long double` argument. If an h, l, or L appears with any other conversion wide-character, the behavior is undefined.
- A *conversion wide-character* that indicates the type of conversion to be applied.

A field width, or precision, or both, may be indicated by an asterisk (*). In this case an argument of type `int` supplies the field width or precision. Arguments specifying field width, or precision, or both must appear in that order before the argument, if any, to be converted. A negative field width is taken as a - flag followed by a positive field width. A negative precision is taken as if the precision were omitted. In format wide-character strings containing the `%n$` form of a conversion specification, a field width or precision may be indicated by the sequence `*m$`, where *m* is a decimal integer in the range [1, `NL_ARGMAX`] giving the position in the argument list (after the format argument) of an integer argument containing the field width or precision, for example:

```
wprintf(L"%1$d:%2$.*3$d:%4$.*3$d\n", hour, min, precision, sec);
```

The *format* can contain either numbered argument specifications (that is, `%n$` and `*m$`), or unnumbered argument specifications (that is, `%` and `*`), but normally not both. The only exception to this is that `%%` can be mixed with the `%n$` form. The results of mixing numbered and unnumbered argument specifications in a *format*

wide-character string are undefined. When numbered argument specifications are used, specifying the N th argument requires that all the leading arguments, from the first to the $(N-1)$ th, are specified in the format wide-character string.

The flag wide-characters and their meanings are:

'	The integer portion of the result of a decimal conversion (<code>%i</code> , <code>%d</code> , <code>%u</code> , <code>%f</code> , <code>%g</code> , or <code>%G</code>) will be formatted with thousands' grouping wide-characters. For other conversions the behavior is undefined. The non-monetary grouping wide-character is used.
-	The result of the conversion will be left-justified within the field. The conversion will be right-justified if this flag is not specified.
+	The result of a signed conversion will always begin with a sign (+ or -). The conversion will begin with a sign only when a negative value is converted if this flag is not specified.
space	If the first wide-character of a signed conversion is not a sign or if a signed conversion results in no wide-characters, a space will be prefixed to the result. This means that if the space and + flags both appear, the space flag will be ignored.
#	This flag specifies that the value is to be converted to an alternative form. For <code>o</code> conversion, it increases the precision (if necessary) to force the first digit of the result to be 0. For <code>x</code> or <code>X</code> conversions, a non-zero result will have <code>0x</code> (or <code>0X</code>) prefixed to it. For <code>e</code> , <code>E</code> , <code>f</code> , <code>g</code> , or <code>G</code> conversions, the result will always contain a radix character, even if no digits follow it. Without this flag, a radix character appears in the result of these conversions only if a digit follows it. For <code>g</code> and <code>G</code> conversions, trailing zeros will <i>not</i> be removed from the result as they normally are. For other conversions, the behavior is undefined.
0	For <code>d</code> , <code>i</code> , <code>o</code> , <code>u</code> , <code>x</code> , <code>X</code> , <code>e</code> , <code>E</code> , <code>f</code> , <code>g</code> , and <code>G</code> conversions, leading zeros (following any indication of sign or base) are used to pad to the field width; no space padding is performed. If the 0 and - flags both appear, the 0 flag will be ignored. For <code>d</code> , <code>i</code> , <code>o</code> , <code>u</code> , <code>x</code> , and <code>X</code> conversions, if a precision is specified, the 0 flag will be ignored. If the 0 and ' flags both appear, the grouping wide-characters are inserted before zero padding. For other conversions, the behavior is undefined.

The conversion wide-characters and their meanings are:

<code>d, i</code>	The <code>int</code> argument is converted to a signed decimal in the style <code>[-]ddd</code> . The precision specifies the minimum number of digits to appear; if the value being converted can be represented in fewer digits, it will be expanded with leading zeros. The default precision is 1. The result of converting 0 with an explicit precision of 0 is no wide-characters.
-------------------	--

swprintf(3C)

- o The unsigned `int` argument is converted to unsigned octal format in the style *dddd*. The precision specifies the minimum number of digits to appear; if the value being converted can be represented in fewer digits, it will be expanded with leading zeros. The default precision is 1. The result of converting 0 with an explicit precision of 0 is no wide-characters.
- u The unsigned `int` argument is converted to unsigned decimal format in the style *dddd*. The precision specifies the minimum number of digits to appear; if the value being converted can be represented in fewer digits, it will be expanded with leading zeros. The default precision is 1. The result of converting 0 with an explicit precision of 0 is no wide-characters.
- x The unsigned `int` argument is converted to unsigned hexadecimal format in the style *dddd*; the letters `abcdef` are used. The precision specifies the minimum number of digits to appear; if the value being converted can be represented in fewer digits, it will be expanded with leading zeros. The default precision is 1. The result of converting 0 with an explicit precision of 0 is no wide-characters.
- X Behaves the same as the `x` conversion wide-character except that letters `ABCDEF` are used instead of `abcdef`.
- f The `double` argument is converted to decimal notation in the style `[-]ddd.ddd`, where the number of digits after the radix character is equal to the precision specification. If the precision is missing, it is taken as 6; if the precision is explicitly 0 and no `#` flag is present, no radix character appears. If a radix character appears, at least one digit appears before it. The value is rounded to the appropriate number of digits.

The `fwprintf()` family of functions may make available wide-character string representations for infinity and NaN.
- e, E The `double` argument is converted in the style `[-]d.ddde ± dd`, where there is one digit before the radix character (which is non-zero if the argument is non-zero) and the number of digits after it is equal to the precision; if the precision is missing, it is taken as 6; if the precision is 0 and no `#` flag is present, no radix character appears. The value is rounded to the appropriate number of digits. The `E` conversion wide-character will produce a number with `E` instead of `e` introducing the exponent. The exponent always contains at least two digits. If the value is 0, the exponent is 0.

The `fwprintf()` family of functions may make available wide-character string representations for infinity and NaN.
- g, G The `double` argument is converted in the style `f` or `e` (or in the style `E` in the case of a `G` conversion wide-character), with the precision specifying the number of significant digits. If an explicit precision is 0, it is taken as 1. The style used depends on the value converted; style `e` (or `E`) will be used only if the exponent resulting from such a conversion is less than `-4` or

greater than or equal to the precision. Trailing zeros are removed from the fractional portion of the result; a radix character appears only if it is followed by a digit.

The `fwprintf()` family of functions may make available wide-character string representations for infinity and NaN.

- c If no `l` (ell) qualifier is present, the `int` argument is converted to a wide-character as if by calling the `btowc(3C)` function and the resulting wide-character is written. Otherwise the `wint_t` argument is converted to `wchar_t`, and written.
- s If no `l` (ell) qualifier is present, the argument must be a pointer to a character array containing a character sequence beginning in the initial shift state. Characters from the array are converted as if by repeated calls to the `mbrtowc(3C)` function, with the conversion state described by an `mbstate_t` object initialized to zero before the first character is converted, and written up to (but not including) the terminating null wide-character. If the precision is specified, no more than that many wide-characters are written. If the precision is not specified or is greater than the size of the array, the array must contain a null wide-character.

If an `l` (ell) qualifier is present, the argument must be a pointer to an array of type `wchar_t`. Wide characters from the array are written up to (but not including) a terminating null wide-character. If no precision is specified or is greater than the size of the array, the array must contain a null wide-character. If a precision is specified, no more than that many wide-characters are written.
- p The argument must be a pointer to `void`. The value of the pointer is converted to a sequence of printable wide-characters.
- n The argument must be a pointer to an integer into which is written the number of wide-characters written to the output so far by this call to one of the `fwprintf()` functions. No argument is converted.
- C Same as `lc`.
- S Same as `ls`.
- % Output a `%` wide-character; no argument is converted. The entire conversion specification must be `%%`.

If a conversion specification does not match one of the above forms, the behavior is undefined.

In no case does a non-existent or small field width cause truncation of a field; if the result of a conversion is wider than the field width, the field is simply expanded to contain the conversion result. Characters generated by `fwprintf()` and `wprintf()` are printed as if `fputwc(3C)` had been called.

swprintf(3C)

The `st_ctime` and `st_mtime` fields of the file will be marked for update between the call to a successful execution of `fwprintf()` or `wprintf()` and the next successful completion of a call to `fflush(3C)` or `fclose(3C)` on the same stream or a call to `exit(3C)` or `abort(3C)`.

RETURN VALUES Upon successful completion, these functions return the number of wide-characters transmitted excluding the terminating null wide-character in the case of `swprintf()` or a negative value if an output error was encountered.

ERRORS For the conditions under which `fwprintf()` and `wprintf()` will fail and may fail, refer to `fputwc(3C)`.

In addition, all forms of `fwprintf()` may fail if:

`EILSEQ` A wide-character code that does not correspond to a valid character has been detected.

`EINVAL` There are insufficient arguments.

In addition, `wprintf()` and `fwprintf()` may fail if:

`ENOMEM` Insufficient storage space is available.

EXAMPLES **EXAMPLE 1** Print language-dependent date and time format.

To print the language-independent date and time format, the following statement could be used:

```
wprintf(format, weekday, month, day, hour, min);
```

For American usage, *format* could be a pointer to the wide-character string:

```
L"%s, %s %d, %d:%.2d\n"
```

producing the message:

```
Sunday, July 3, 10:02
```

whereas for German usage, *format* could be a pointer to the wide-character string:

```
L"%1$s, %3$d. %2$s, %4$d:%5$.2d\n"
```

producing the message:

```
Sonntag, 3. Juli, 10:02
```

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
MT-Level	MT-Safe with exceptions

SEE ALSO `btowc(3C)`, `fputwc(3C)`, `fwscanf(3C)`, `mbrtowc(3C)`, `setlocale(3C)`, `attributes(5)`

NOTES The `fwprintf()`, `wprintf()`, and `swprintf()` functions can be used safely in multithreaded applications, as long as `setlocale(3C)` is not being called to change the locale.

swscanf(3C)

NAME	<code>fwscanf</code> , <code>wscanf</code> , <code>swscanf</code> , <code>vfwscanf</code> , <code>vswscanf</code> , <code>vswscanf</code> – convert formatted wide-character input
SYNOPSIS	<pre>#include <stdio.h> #include <wchar.h> int fwscanf(FILE *stream, const wchar_t *format, ...); int wscanf(const wchar_t *format, ...); int swscanf(const wchar_t *s, const wchar_t *format, ...); #include <stdarg.h> #include <stdio.h> #include <wchar.h> int vfwscanf(FILE *stream, const wchar_t *format, va_list arg); int vswscanf(const wchar_t *ws, const wchar_t *format, va_list arg); int vswscanf(const wchar_t *format, va_list arg);</pre>
DESCRIPTION	<p>The <code>fwscanf()</code> function reads from the named input <i>stream</i>.</p> <p>The <code>wscanf()</code> function reads from the standard input stream <code>stdin</code>.</p> <p>The <code>swscanf()</code> function reads from the wide-character string <i>s</i>.</p> <p>The <code>vfwscanf()</code>, <code>vswscanf()</code>, and <code>vswscanf()</code> functions are equivalent to the <code>fwscanf()</code>, <code>swscanf()</code>, and <code>wscanf()</code> functions, respectively, except that instead of being called with a variable number of arguments, they are called with an argument list as defined by the <code><stdarg.h></code> header (see <code>stdarg(3HEAD)</code>). These functions do not invoke the <code>va_end()</code> macro. Applications using these functions should call <code>va_end(ap)</code> afterwards to clean up.</p> <p>Each function reads wide-characters, interprets them according to a format, and stores the results in its arguments. Each expects, as arguments, a control wide-character string <i>format</i> described below, and a set of <i>pointer</i> arguments indicating where the converted input should be stored. The result is undefined if there are insufficient arguments for the format. If the format is exhausted while arguments remain, the excess arguments are evaluated but are otherwise ignored.</p> <p>Conversions can be applied to the <i>n</i>th argument after the <i>format</i> in the argument list, rather than to the next unused argument. In this case, the conversion wide-character <code>%</code> (see below) is replaced by the sequence <code>%n\$</code>, where <i>n</i> is a decimal integer in the range <code>[1, NL_ARGMAX]</code>. This feature provides for the definition of format wide-character strings that select arguments in an order appropriate to specific languages. In format wide-character strings containing the <code>%n\$</code> form of conversion specifications, it is unspecified whether numbered arguments in the argument list can be referenced from the format wide-character string more than once.</p>

The *format* can contain either form of a conversion specification, that is, % or %n\$, but the two forms cannot normally be mixed within a single *format* wide-character string. The only exception to this is that %% or %* can be mixed with the %n\$ form.

The `fwscanf()` function in all its forms allows for detection of a language-dependent radix character in the input string, encoded as a wide-character value. The radix character is defined in the program's locale (category `LC_NUMERIC`). In the POSIX locale, or in a locale where the radix character is not defined, the radix character defaults to a period (.).

The format is a wide-character string composed of zero or more directives. Each directive is composed of one of the following: one or more white-space wide-characters (space, tab, newline, vertical-tab or form-feed characters); an ordinary wide-character (neither % nor a white-space character); or a conversion specification. Each conversion specification is introduced by a % or the sequence %n\$ after which the following appear in sequence:

- An optional assignment-suppressing character *.
- An optional non-zero decimal integer that specifies the maximum field width.
- An optional size modifier h, l(ell), or L indicating the size of the receiving object. The conversion wide-characters c, s, and [must be preceded by l(ell) if the corresponding argument is a pointer to `wchar_t` rather than a pointer to a character type. The conversion wide-characters d, i, and n must be preceded by h if the corresponding argument is a pointer to `short int` rather than a pointer to `int`, or by l(ell) if it is a pointer to `long int`. Similarly, the conversion wide-characters o, u, and x must be preceded by h if the corresponding argument is a pointer to `unsigned short int` rather than a pointer to `unsigned int`, or by l(ell) if it is a pointer to `unsigned long int`. The conversion wide-characters e, f, and g must be preceded by l(ell) if the corresponding argument is a pointer to `double` rather than a pointer to `float`, or by L if it is a pointer to `long double`. If an h, l(ell), or L appears with any other conversion wide-character, the behavior is undefined.
- A conversion wide-character that specifies the type of conversion to be applied. The valid conversion wide-characters are described below.

The `fwscanf()` functions execute each directive of the format in turn. If a directive fails, as detailed below, the function returns. Failures are described as input failures (due to the unavailability of input bytes) or matching failures (due to inappropriate input).

A directive composed of one or more white-space wide-characters is executed by reading input until no more valid input can be read, or up to the first wide-character which is not a white-space wide-character, which remains unread.

A directive that is an ordinary wide-character is executed as follows. The next wide-character is read from the input and compared with the wide-character that comprises the directive; if the comparison shows that they are not equivalent, the directive fails, and the differing and subsequent wide-characters remain unread.

swscanf(3C)

A directive that is a conversion specification defines a set of matching input sequences, as described below for each conversion wide-character. A conversion specification is executed in the following steps:

Input white-space wide-characters (as specified by `isspace(3C)`) are skipped, unless the conversion specification includes a `l`, `c`, or `n` conversion character.

An item is read from the input, unless the conversion specification includes an `n` conversion wide-character. An input item is defined as the longest sequence of input wide-characters, not exceeding any specified field width, which is an initial subsequence of a matching sequence. The first wide-character, if any, after the input item remains unread. If the length of the input item is 0, the execution of the conversion specification fails; this condition is a matching failure, unless end-of-file, an encoding error, or a read error prevented input from the stream, in which case it is an input failure.

Except in the case of a `%` conversion wide-character, the input item (or, in the case of a `%n` conversion specification, the count of input wide-characters) is converted to a type appropriate to the conversion wide-character. If the input item is not a matching sequence, the execution of the conversion specification fails; this condition is a matching failure. Unless assignment suppression was indicated by a `*`, the result of the conversion is placed in the object pointed to by the first argument following the *format* argument that has not already received a conversion result if the conversion specification is introduced by `%`, or in the *n*th argument if introduced by the wide-character sequence `%n$`. If this object does not have an appropriate type, or if the result of the conversion cannot be represented in the space provided, the behavior is undefined.

The following conversion wide-characters are valid:

- d Matches an optionally signed decimal integer, whose format is the same as expected for the subject sequence of `wcstol(3C)` with the value 10 for the *base* argument. In the absence of a size modifier, the corresponding argument must be a pointer to `int`.
- i Matches an optionally signed integer, whose format is the same as expected for the subject sequence of `wcstol(3C)` with 0 for the *base* argument. In the absence of a size modifier, the corresponding argument must be a pointer to `int`.
- o Matches an optionally signed octal integer, whose format is the same as expected for the subject sequence of `wcstoul(3C)` with the value 8 for the *base* argument. In the absence of a size modifier, the corresponding argument must be a pointer to `unsigned int`.
- u Matches an optionally signed decimal integer, whose format is the same as expected for the subject sequence of `wcstoul(3C)` with the value 10 for the *base* argument. In the absence of a size modifier, the corresponding argument must be a pointer to `unsigned int`.

- x** Matches an optionally signed hexadecimal integer, whose format is the same as expected for the subject sequence of `wcstoul(3C)` with the value 16 for the *base* argument. In the absence of a size modifier, the corresponding argument must be a pointer to `unsigned int`.
- e,f,g** Matches an optionally signed floating-point number, whose format is the same as expected for the subject sequence of `wcstod(3C)`. In the absence of a size modifier, the corresponding argument must be a pointer to `float`.
- If the `fwprintf()` family of functions generates character string representations for infinity and NaN (a 7858 symbolic entity encoded in floating-point format) to support the ANSI/IEEE Std 754:1985 standard, the `fwscanf()` family of functions will recognize them as input.
- s** Matches a sequence of non white-space wide-characters. If no `l` (`ell`) qualifier is present, characters from the input field are converted as if by repeated calls to the `wcrtomb(3C)` function, with the conversion state described by an `mbstate_t` object initialized to zero before the first wide-character is converted. The corresponding argument must be a pointer to a character array large enough to accept the sequence and the terminating null character, which will be added automatically.
- Otherwise, the corresponding argument must be a pointer to an array of `wchar_t` large enough to accept the sequence and the terminating null wide-character, which will be added automatically.
- [** Matches a non-empty sequence of wide-characters from a set of expected wide-characters (the *scanset*). If no `l` (`ell`) qualifier is present, wide-characters from the input field are converted as if by repeated calls to the `wcrtomb()` function, with the conversion state described by an `mbstate_t` object initialized to zero before the first wide-character is converted. The corresponding argument must be a pointer to a character array large enough to accept the sequence and the terminating null character, which will be added automatically.
- If an `l` (`ell`) qualifier is present, the corresponding argument must be a pointer to an array of `wchar_t` large enough to accept the sequence and the terminating null wide-character, which will be added automatically.
- The conversion specification includes all subsequent `widw` characters in the *format* string up to and including the matching right square bracket (`]`). The wide-characters between the square brackets (the *scanlist*) comprise the *scanset*, unless the wide-character after the left square bracket is a circumflex (`^`), in which case the *scanset* contains all wide-characters that do not appear in the *scanlist* between the circumflex and the right square bracket. If the conversion specification begins with `[]` or `[^]`, the right square bracket is included in the *scanlist* and the next right square bracket is the matching right square bracket that ends the conversion specification; otherwise the first right square bracket is the one that ends the conversion

swscanf(3C)

	specification. If a minus-sign (-) is in the scanlist and is not the first wide-character, nor the second where the first wide-character is a ^, nor the last wide-character, it indicates a range of characters to be matched.
c	Matches a sequence of wide-characters of the number specified by the field width (1 if no field width is present in the conversion specification). If no l (ell) qualifier is present, wide-characters from the input field are converted as if by repeated calls to the <code>wcrtomb()</code> function, with the conversion state described by an <code>mbstate_t</code> object initialized to zero before the first wide-character is converted. The corresponding argument must be a pointer to a character array large enough to accept the sequence. No null character is added. Otherwise, the corresponding argument must be a pointer to an array of <code>wchar_t</code> large enough to accept the sequence. No null wide-character is added.
p	Matches the set of sequences that is the same as the set of sequences that is produced by the <code>%p</code> conversion of the corresponding <code>fwprintf(3C)</code> functions. The corresponding argument must be a pointer to a pointer to <code>void</code> . If the input item is a value converted earlier during the same program execution, the pointer that results will compare equal to that value; otherwise the behavior of the <code>%p</code> conversion is undefined.
n	No input is consumed. The corresponding argument must be a pointer to the integer into which is to be written the number of wide-characters read from the input so far by this call to the <code>fwscanf()</code> functions. Execution of a <code>%n</code> conversion specification does not increment the assignment count returned at the completion of execution of the function.
C	Same as <code>lc</code> .
S	Same as <code>ls</code> .
%	Matches a single %; no conversion or assignment occurs. The complete conversion specification must be <code>%%</code> .

If a conversion specification is invalid, the behavior is undefined.

The conversion characters E, G, and X are also valid and behave the same as, respectively, e, g, and x.

If end-of-file is encountered during input, conversion is terminated. If end-of-file occurs before any wide-characters matching the current conversion specification (except for `%n`) have been read (other than leading white-space, where permitted), execution of the current conversion specification terminates with an input failure. Otherwise, unless execution of the current conversion specification is terminated with a matching failure, execution of the following conversion specification (if any) is terminated with an input failure.

Reaching the end of the string in `swscanf()` is equivalent to encountering end-of-file for `fwscanf()`.

If conversion terminates on a conflicting input, the offending input is left unread in the input. Any trailing white space (including newline) is left unread unless matched by a conversion specification. The success of literal matches and suppressed assignments is only directly determinable via the `%n` conversion specification.

The `fwscanf()` and `wscanf()` functions may mark the `st_atime` field of the file associated with *stream* for update. The `st_atime` field will be marked for update by the first successful execution of `fgetc(3C)`, `fgetwc(3C)`, `fgets(3C)`, `fgetws(3C)`, `fread(3C)`, `getc(3C)`, `getwc(3C)`, `getchar(3C)`, `getwchar(3C)`, `gets(3C)`, `fscanf(3C)` or `fwscanf()` using *stream* that returns data not supplied by a prior call to `ungetc(3C)`.

RETURN VALUES Upon successful completion, these functions return the number of successfully matched and assigned input items; this number can be 0 in the event of an early matching failure. If the input ends before the first matching failure or conversion, EOF is returned. If a read error occurs the error indicator for the stream is set, EOF is returned, and `errno` is set to indicate the error.

ERRORS For the conditions under which the `fwscanf()` functions will fail and may fail, refer to `fgetwc(3C)`.

In addition, `fwscanf()` may fail if:

`EILSEQ` Input byte sequence does not form a valid character.

`EINVAL` There are insufficient arguments.

USAGE In format strings containing the `%` form of conversion specifications, each argument in the argument list is used exactly once.

EXAMPLES **EXAMPLE 1** `wscanf()` example

The call:

```
int i, n; float x; char name[50];
n = wscanf(L"%d%f%s", &i, &x, name);
```

with the input line:

```
25 54.32E-1 Hamster
```

will assign to *n* the value 3, to *i* the value 25, to *x* the value 5.432, and *name* will contain the string Hamster.

The call:

```
int i; float x; char name[50];
(void) wscanf(L"%2d%f*d %[0123456789]", &i, &x, name);
```

with input:

swscanf(3C)

EXAMPLE 1 wscanf () example (Continued)

56789 0123 56a72

will assign 56 to *i*, 789.0 to *x*, skip 0123, and place the string 56\0 in *name*. The next call to `getchar(3C)` will return the character *a*.

NAME	sync_instruction_memory – make modified instructions executable				
SYNOPSIS	void sync_instruction_memory (caddr_t <i>addr</i> , int <i>len</i>);				
DESCRIPTION	<p>The <code>sync_instruction_memory()</code> function performs whatever steps are required to make instructions modified by a program executable.</p> <p>Some processor architectures, including some SPARC processors, have separate and independent instruction and data caches which are not kept consistent by hardware. For example, if the instruction cache contains an instruction from some address and the program then stores a new instruction at that address, the new instruction may not be immediately visible to the instruction fetch mechanism. Software must explicitly invalidate the instruction cache entries for new or changed mappings of pages that might contain executable instructions. The <code>sync_instruction_memory()</code> function performs this function, and/or any other functions needed to make modified instructions between <i>addr</i> and <i>addr+len</i> visible. A program should call <code>sync_instruction_memory()</code> after modifying instructions and before executing them.</p> <p>On processors with unified caches (one cache for both instructions and data) and pipelines which are flushed by a branch instruction, such as the Intel IA architecture, the function may do nothing and just return.</p> <p>The changes are immediately visible to the thread calling <code>sync_instruction_memory()</code> when the call returns, even if the thread should migrate to another processor during or after the call. The changes become visible to other threads in the same manner that stores do; that is, they eventually become visible, but the latency is implementation-dependent.</p> <p>The result of executing <code>sync_instruction_memory()</code> are unpredictable if <i>addr</i> through <i>addr+len-1</i> are not valid for the address space of the program making the call.</p>				
RETURN VALUES	No values are returned.

syscall(3UCB)

NAME	syscall – indirect system call
SYNOPSIS	<pre>/usr/ucb/cc [flag ...] file ... #include <sys/syscall.h> int syscall (number, arg, ...);</pre>
DESCRIPTION	syscall() performs the function whose assembly language interface has the specified <i>number</i> , and arguments <i>arg</i> ... Symbolic constants for functions can be found in the header <sys/syscall.h>.
RETURN VALUES	On error syscall() returns -1 and sets the external variable errno (see intro(2)).
FILES	<sys/syscall.h>
SEE ALSO	intro(2), pipe(2)
NOTES	Use of these interfaces should be restricted to only applications written on BSD platforms. Use of these interfaces with any of the system libraries or in multi-thread applications is unsupported.
WARNINGS	<p>There is no way to use syscall() to call functions such as pipe(2) which return values that do not fit into one hardware register.</p> <p>Since many system calls are implemented as library wrappers around traps to the kernel, these calls may not behave as documented when called from syscall(), which bypasses these wrappers. For these reasons, using syscall() is not recommended.</p>

NAME	sysconf – get configurable system variables																																										
SYNOPSIS	<pre>#include <unistd.h> long sysconf(int <i>name</i>);</pre>																																										
DESCRIPTION	<p>The <code>sysconf()</code> function provides a method for an application to determine the current value of a configurable system limit or option (variable).</p> <p>The <i>name</i> argument represents the system variable to be queried. The following table lists the minimal set of system variables from <code><limits.h></code> and <code><unistd.h></code> that can be returned by <code>sysconf()</code> and the symbolic constants defined in <code><unistd.h></code> that are the corresponding values used for <i>name</i> on the SPARC and IA platforms.</p> <table border="1"> <thead> <tr> <th>Name</th> <th>Return Value</th> <th>Meaning</th> </tr> </thead> <tbody> <tr> <td><code>_SC_2_C_BIND</code></td> <td><code>_POSIX2_C_BIND</code></td> <td>Supports the C language binding option</td> </tr> <tr> <td><code>_SC_2_C_DEV</code></td> <td><code>_POSIX2_C_DEV</code></td> <td>Supports the C language development utilities option</td> </tr> <tr> <td><code>_SC_2_C_VERSION</code></td> <td><code>_POSIX2_C_VERSION</code></td> <td>Integer value indicates version of ISO POSIX-2 standard (Commands)</td> </tr> <tr> <td><code>_SC_2_CHAR_TERM</code></td> <td><code>_POSIX2_CHAR_TERM</code></td> <td>Supports at least one terminal</td> </tr> <tr> <td><code>_SC_2_FORT_DEV</code></td> <td><code>_POSIX2_FORT_DEV</code></td> <td>Supports FORTRAN Development Utilities Option</td> </tr> <tr> <td><code>_SC_2_FORT_RUN</code></td> <td><code>_POSIX2_FORT_RUN</code></td> <td>Supports FORTRAN Run-time Utilities Option</td> </tr> <tr> <td><code>_SC_2_LOCALEDEF</code></td> <td><code>_POSIX2_LOCALEDEF</code></td> <td>Supports creation of locales by the localedef utility</td> </tr> <tr> <td><code>_SC_2_SW_DEV</code></td> <td><code>_POSIX2_SW_DEV</code></td> <td>Supports Software Development Utility Option</td> </tr> <tr> <td><code>_SC_2_UPE</code></td> <td><code>_POSIX2_UPE</code></td> <td>Supports User Portability Utilities Option</td> </tr> <tr> <td><code>_SC_2_VERSION</code></td> <td><code>_POSIX2_VERSION</code></td> <td>Integer value indicates version of ISO POSIX-2 standard (C language binding)</td> </tr> <tr> <td><code>_SC_AIO_LISTIO_MAX</code></td> <td><code>AIO_LISTIO_MAX</code></td> <td>Max number of I/O operations in a single list I/O call supported</td> </tr> <tr> <td><code>_SC_AIO_MAX</code></td> <td><code>AIO_MAX</code></td> <td>Max number of outstanding asynchronous I/O operations supported</td> </tr> <tr> <td><code>_SC_AIO_PRIO_DELTA_MAX</code></td> <td><code>AIO_PRIO_DELTA_MAX</code></td> <td>Max amount by which process can decrease</td> </tr> </tbody> </table>	Name	Return Value	Meaning	<code>_SC_2_C_BIND</code>	<code>_POSIX2_C_BIND</code>	Supports the C language binding option	<code>_SC_2_C_DEV</code>	<code>_POSIX2_C_DEV</code>	Supports the C language development utilities option	<code>_SC_2_C_VERSION</code>	<code>_POSIX2_C_VERSION</code>	Integer value indicates version of ISO POSIX-2 standard (Commands)	<code>_SC_2_CHAR_TERM</code>	<code>_POSIX2_CHAR_TERM</code>	Supports at least one terminal	<code>_SC_2_FORT_DEV</code>	<code>_POSIX2_FORT_DEV</code>	Supports FORTRAN Development Utilities Option	<code>_SC_2_FORT_RUN</code>	<code>_POSIX2_FORT_RUN</code>	Supports FORTRAN Run-time Utilities Option	<code>_SC_2_LOCALEDEF</code>	<code>_POSIX2_LOCALEDEF</code>	Supports creation of locales by the localedef utility	<code>_SC_2_SW_DEV</code>	<code>_POSIX2_SW_DEV</code>	Supports Software Development Utility Option	<code>_SC_2_UPE</code>	<code>_POSIX2_UPE</code>	Supports User Portability Utilities Option	<code>_SC_2_VERSION</code>	<code>_POSIX2_VERSION</code>	Integer value indicates version of ISO POSIX-2 standard (C language binding)	<code>_SC_AIO_LISTIO_MAX</code>	<code>AIO_LISTIO_MAX</code>	Max number of I/O operations in a single list I/O call supported	<code>_SC_AIO_MAX</code>	<code>AIO_MAX</code>	Max number of outstanding asynchronous I/O operations supported	<code>_SC_AIO_PRIO_DELTA_MAX</code>	<code>AIO_PRIO_DELTA_MAX</code>	Max amount by which process can decrease

<code>_SC_THREAD_SAFE_FUNCTIONS</code>	<code>_POSIX_THREAD_SAFE_FUNCTIONS</code>	Supports Thread-Safe Functions option
<code>_SC_THREAD_STACK_MIN</code>	<code>PTHREAD_STACK_MIN</code>	Min byte size of thread stack storage
<code>_SC_THREAD_THREADS_MAX</code>	<code>PTHREAD_THREADS_MAX</code>	Max number of threads per process
<code>_SC_THREADS</code>	<code>_POSIX_THREADS</code>	Supports Threads option
<code>_SC_TIMER_MAX</code>	<code>TIMER_MAX</code>	Max number of timer per process supported
<code>_SC_TIMERS</code>	<code>_POSIX_TIMERS</code>	Supports Timers
<code>_SC_TTY_NAME_MAX</code>	<code>TTYNAME_MAX</code>	Max length of tty

<code>_SC_TZNAME_MAX</code>	<code>TZNAME_MAX</code>	device name Max number of bytes supported for name of a time zone
<code>_SC_VERSION</code>	<code>_POSIX_VERSION</code>	POSIX.1 version supported
<code>_SC_XBS5_ILP32_OFF32</code>	<code>_XBS_ILP32_OFF32</code>	Indicates support for X/Open ILP32 w/32-bit offset build environment
<code>_SC_XBS5_ILP32_OFFBIG</code>	<code>_XBS5_ILP32_OFFBIG</code>	Indicates support for X/Open ILP32 w/64-bit offset build environment
<code>_SC_XBS5_LP64_OFF64</code>	<code>_XBS5_LP64_OFF64</code>	Indicates support of X/Open LP64, 64-bit offset build environment
<code>_SC_XBS5_LPBIG_OFFBIG</code>	<code>_XBS5_LP64_OFF64</code>	Same as <code>_SC_XBS5_LP64_OFF64</code>
<code>_SC_XOPEN_CRYPT</code>	<code>_XOPEN_CRYPT</code>	Supports X/Open Encryption Feature Group
<code>_SC_XOPEN_ENH_I18N</code>	<code>_XOPEN_ENH_I18N</code>	Supports X/Open Enhanced Internationalization Feature Group
<code>_SC_XOPEN_LEGACY</code>	<code>_XOPEN_LEGACY</code>	Supports X/Open Legacy Feature Group
<code>_SC_XOPEN_REALTIME</code>	<code>_XOPEN_REALTIME</code>	Supports X/Open POSIX Realtime Feature Group
<code>_SC_XOPEN_REALTIME_THREADS</code>	<code>_XOPEN_REALTIME_THREADS</code>	Supports X/Open POSIX Realtime Threads Feature Group
<code>_SC_XOPEN_SHM</code>	<code>_XOPEN_SHM</code>	Supports X/Open Shared Memory Feature Group
<code>_SC_XOPEN_UNIX</code>	<code>_XOPEN_UNIX</code>	Supports X/Open CAE Specification, August 1994, System Interfaces and Headers, Issue 4, Version 2
<code>_SC_XOPEN_VERSION</code>	<code>_XOPEN_VERSION</code>	Integer value indicates version of X/Open Portability Guide to which implementation conforms
<code>_SC_XOPEN_XCU_VERSION</code>	<code>_XOPEN_XCU_VERSION</code>	Integer value indicates version of XCU specification to which implementation conforms

sysconf(3C)

RETURN VALUES

Upon successful completion, `sysconf()` returns the current variable value on the system. The value returned will not be more restrictive than the corresponding value described to the application when it was compiled with the implementation's `<limits.h>`, `<unistd.h>` or `<time.h>`. The value will not change during the lifetime of the calling process.

If *name* is an invalid value, `sysconf()` returns `-1` and sets `errno` to indicate the error. If the variable corresponding to *name* is associated with functionality that is not supported by the system, `sysconf()` returns `-1` without changing the value of *errno*.

Calling `sysconf()` with the following returns `-1` without setting `errno`, because no maximum limit can be determined. The system supports at least the minimum values and can support higher values depending upon system resources.

Variable	Minimum supported value
<code>_SC_AIO_MAX</code>	<code>_POSIX_AIO_MAX</code>
<code>_SC_ATEXT_MAX</code>	32
<code>_SC_THREAD_THREADS_MAX</code>	<code>_POSIX_THREAD_THREADS_MAX</code>
<code>_SC_THREAD_KEYS_MAX</code>	<code>_POSIX_THREAD_KEYS_MAX</code>
<code>_SC_THREAD_DESTRUCTOR_ITERATIONS</code>	<code>_POSIX_THREAD_DESTRUCTOR_ITERATIONS</code>

The following SPARC and IA platform variables return `EINVAL`:

<code>_SC_COHER_BLKSZ</code>	<code>_SC_DCACHE_ASSOC</code>
<code>_SC_DCACHE_BLKSZ</code>	<code>_SC_DCACHE_LINESZ</code>
<code>_SC_DCACHE_SZ</code>	<code>_SC_DCACHE_TBLKSZ</code>
<code>_SC_ICACHE_ASSOC</code>	<code>_SC_ICACHE_BLKSZ</code>
<code>_SC_ICACHE_LINESZ</code>	<code>_SC_ICACHE_SZ</code>
<code>_SC_SPLIT_CACHE</code>	

ERRORS

The `sysconf()` function will fail if:

`EINVAL` The value of the *name* argument is invalid.

ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Architecture	SPARC and IA
MT-Level	MT-Safe, Async-Signal-Safe

SEE ALSO

`fpathconf(2)`, `seteuid(2)`, `setrlimit(2)`, `attributes(5)`, `standards(5)`

NOTES

A call to `setrlimit()` can cause the value of `OPEN_MAX` to change.

Multiplying `sysconf(_SC_PHYS_PAGES)` or `sysconf(_SC_AVPHYS_PAGES)` by `sysconf(_SC_PAGESIZE)` to determine memory amount in bytes can exceed the maximum values representable in a long or unsigned long.

The value of `CLK_TCK` can be variable and it should not be assumed that `CLK_TCK` is a compile-time constant.

sysconf(3C)

The `_SC_PHYS_PAGES` and `_SC_AVPHYS_PAGES` variables are specific to Solaris 2.3 or compatible releases.

syslog(3C)

NAME	syslog, openlog, closelog, setlogmask – control system log																
SYNOPSIS	<pre>#include <syslog.h> void openlog(const char *ident, int logopt, int facility); void syslog(int priority, const char *message, .../* arguments */); void closelog(void); int setlogmask(int maskpri);</pre>																
DESCRIPTION	<p>The <code>syslog()</code> function sends a message to <code>syslogd(1M)</code>, which, depending on the configuration of <code>/etc/syslog.conf</code>, logs it in an appropriate system log, writes it to the system console, forwards it to a list of users, or forwards it to <code>syslogd</code> on another host over the network. The logged message includes a message header and a message body. The message header consists of a facility indicator, a severity level indicator, a timestamp, a tag string, and optionally the process ID.</p> <p>The message body is generated from the <i>message</i> and following arguments in the same manner as if these were arguments to <code>printf(3UCB)</code>, except that occurrences of <code>%m</code> in the format string pointed to by the <i>message</i> argument are replaced by the error message string associated with the current value of <code>errno</code>. A trailing NEWLINE character is added if needed.</p> <p>Values of the <i>priority</i> argument are formed by ORing together a <i>severity level</i> value and an optional <i>facility</i> value. If no facility value is specified, the current default facility value is used.</p> <p>Possible values of severity level include:</p> <table><tr><td>LOG_EMERG</td><td>A panic condition. This is normally broadcast to all users.</td></tr><tr><td>LOG_ALERT</td><td>A condition that should be corrected immediately, such as a corrupted system database.</td></tr><tr><td>LOG_CRIT</td><td>Critical conditions, such as hard device errors.</td></tr><tr><td>LOG_ERR</td><td>Errors.</td></tr><tr><td>LOG_WARNING</td><td>Warning messages.</td></tr><tr><td>LOG_NOTICE</td><td>Conditions that are not error conditions, but that may require special handling.</td></tr><tr><td>LOG_INFO</td><td>Informational messages.</td></tr><tr><td>LOG_DEBUG</td><td>Messages that contain information normally of use only when debugging a program.</td></tr></table> <p>The facility indicates the application or system component generating the message. Possible facility values include:</p>	LOG_EMERG	A panic condition. This is normally broadcast to all users.	LOG_ALERT	A condition that should be corrected immediately, such as a corrupted system database.	LOG_CRIT	Critical conditions, such as hard device errors.	LOG_ERR	Errors.	LOG_WARNING	Warning messages.	LOG_NOTICE	Conditions that are not error conditions, but that may require special handling.	LOG_INFO	Informational messages.	LOG_DEBUG	Messages that contain information normally of use only when debugging a program.
LOG_EMERG	A panic condition. This is normally broadcast to all users.																
LOG_ALERT	A condition that should be corrected immediately, such as a corrupted system database.																
LOG_CRIT	Critical conditions, such as hard device errors.																
LOG_ERR	Errors.																
LOG_WARNING	Warning messages.																
LOG_NOTICE	Conditions that are not error conditions, but that may require special handling.																
LOG_INFO	Informational messages.																
LOG_DEBUG	Messages that contain information normally of use only when debugging a program.																

LOG_KERN	Messages generated by the kernel. These cannot be generated by any user processes.
LOG_USER	Messages generated by random user processes. This is the default facility identifier if none is specified.
LOG_MAIL	The mail system.
LOG_DAEMON	System daemons, such as <code>in.ftpd(1M)</code> .
LOG_AUTH	The authorization system: <code>login(1)</code> , <code>su(1M)</code> , <code>getty(1M)</code> .
LOG_LPR	The line printer spooling system: <code>lpr(1B)</code> , <code>lpc(1B)</code> .
LOG_NEWS	Reserved for the USENET network news system.
LOG_UUCP	Reserved for the UUCP system; it does not currently use <code>syslog</code> .
LOG_CRON	The <code>cron/at</code> facility; <code>crontab(1)</code> , <code>at(1)</code> , <code>cron(1M)</code> .
LOG_LOCAL0	Reserved for local use.
LOG_LOCAL1	Reserved for local use.
LOG_LOCAL2	Reserved for local use.
LOG_LOCAL3	Reserved for local use.
LOG_LOCAL4	Reserved for local use.
LOG_LOCAL5	Reserved for local use.
LOG_LOCAL6	Reserved for local use.
LOG_LOCAL7	Reserved for local use.

The `openlog()` function sets process attributes that affect subsequent calls to `syslog()`. The *ident* argument is a string that is prepended to every message. The *logopt* argument indicates logging options. Values for *logopt* are constructed by a bitwise-inclusive OR of zero or more of the following:

LOG_PID	Log the process ID with each message. This is useful for identifying specific daemon processes (for daemons that fork).
LOG_CONS	Write messages to the system console if they cannot be sent to <code>syslogd(1M)</code> . This option is safe to use in daemon processes that have no controlling terminal, since <code>syslog()</code> forks before opening the console.
LOG_NDELAY	Open the connection to <code>syslogd(1M)</code> immediately. Normally the open is delayed until the first message is

syslog(3C)

	logged. This is useful for programs that need to manage the order in which file descriptors are allocated.
LOG_ODELAY	Delay open until <code>syslog()</code> is called.
LOG_NOWAIT	Do not wait for child processes that have been forked to log messages onto the console. This option should be used by processes that enable notification of child termination using <code>SIGCHLD</code> , since <code>syslog()</code> may otherwise block waiting for a child whose exit status has already been collected.

The *facility* argument encodes a default facility to be assigned to all messages that do not have an explicit facility already encoded. The initial default facility is `LOG_USER`.

The `openlog()` and `syslog()` functions may allocate a file descriptor. It is not necessary to call `openlog()` prior to calling `syslog()`.

The `closelog()` function closes any open file descriptors allocated by previous calls to `openlog()` or `syslog()`.

The `setlogmask()` function sets the log priority mask for the current process to *maskpri* and returns the previous mask. If the *maskpri* argument is 0, the current log mask is not modified. Calls by the current process to `syslog()` with a priority not set in *maskpri* are rejected. The mask for an individual priority *pri* is calculated by the macro `LOG_MASK(pri)`; the mask for all priorities up to and including *toppri* is given by the macro `LOG_UPT(toppri)`. The default log mask allows all priorities to be logged.

Symbolic constants for use as values of the *logopt*, *facility*, *priority*, and *maskpri* arguments are defined in the `<syslog.h>` header.

RETURN VALUES

The `setlogmask()` function returns the previous log priority mask. The `closelog()`, `openlog()` and `syslog()` functions return no value.

ERRORS

No errors are defined.

EXAMPLES

EXAMPLE 1 Example of `LOG_ALERT` message.

This call logs a message at priority `LOG_ALERT`:

```
syslog(LOG_ALERT, "who: internal error 23");
```

The FTP daemon `ftpd` would make this call to `openlog()` to indicate that all messages it logs should have an identifying string of `ftpd`, should be treated by `syslogd(1M)` as other messages from system daemons are, should include the process ID of the process logging the message:

```
openlog("ftpd", LOG_PID, LOG_DAEMON);
```

EXAMPLE 1 Example of LOG_ALERT message. (Continued)

Then it would make the following call to `setlogmask()` to indicate that messages at priorities from LOG_EMERG through LOG_ERR should be logged, but that no messages at any other priority should be logged:

```
setlogmask(LOG_UPTO(LOG_ERR));
```

Then, to log a message at priority LOG_INFO, it would make the following call to `syslog`:

```
syslog(LOG_INFO, "Connection from host %d", CallingHost);
```

A locally-written utility could use the following call to `syslog()` to log a message at priority LOG_INFO to be treated by `syslogd(1M)` as other messages to the facility LOG_LOCAL2 are:

```
syslog(LOG_INFO|LOG_LOCAL2, "error: %m");
```

sys_siglist(3UCB)

NAME	<code>psignal</code> , <code>sys_siglist</code> – system signal messages
SYNOPSIS	<pre><code>/usr/ucb/cc[<i>flag</i> ...] <i>file</i> ...</code></pre> <pre><code>void psignal(<i>sig</i>, <i>s</i>);</code></pre> <pre><code>unsigned <i>sig</i>;</code></pre> <pre><code>char *<i>s</i>;</code></pre> <pre><code>char *<i>sys_siglist</i>[];</code></pre>
DESCRIPTION	<p><code>psignal()</code> produces a short message on the standard error file describing the indicated signal. First the argument string <i>s</i> is printed, then a colon, then the name of the signal and a NEWLINE. Most usefully, the argument string is the name of the program which incurred the signal. The signal number should be from among those found in <code><signal.h></code>.</p> <p>To simplify variant formatting of signal names, the vector of message strings <code>sys_siglist</code> is provided; the signal number can be used as an index in this table to get the signal name without the newline. The define <code>NSIG</code> defined in <code><signal.h></code> is the number of messages provided for in the table; it should be checked because new signals may be added to the system before they are added to the table.</p>
SEE ALSO	<code>perror(3C)</code> , <code>signal(3C)</code>
NOTES	Use of these interfaces should be restricted to only applications written on BSD platforms. Use of these interfaces with any of the system libraries or in multi-thread applications is unsupported.

NAME	system – issue a shell command						
SYNOPSIS	<pre>#include <stdlib.h> int system(const char *string);</pre>						
DESCRIPTION	<p>The <code>system()</code> function causes <i>string</i> to be given to the shell as input, as if <i>string</i> had been typed as a command at a terminal. The invoker waits until the shell has completed, then returns the exit status of the shell in the format specified by <code>waitpid(2)</code>.</p> <p>If <i>string</i> is a null pointer, <code>system()</code> checks if the shell exists and is executable. If the shell is available, <code>system()</code> returns a non-zero value; otherwise, it returns 0. If the application is standard-conforming (see <code>standards(5)</code>), <code>system()</code> uses <code>/usr/xpg4/bin/sh</code> (see <code>ksh(1)</code>); otherwise <code>system()</code> uses <code>/usr/bin/sh</code> (see <code>sh(1)</code>).</p>						
RETURN VALUES	The <code>system()</code> function executes <code>vfork(2)</code> to create a child process that in turn invokes one of the <code>exec</code> family of functions (see <code>exec(2)</code>) on the shell to execute <i>string</i> . If <code>vfork()</code> or the <code>exec</code> function fails, <code>system()</code> returns <code>-1</code> and sets <code>errno</code> to indicate the error.						
ERRORS	<p>The <code>system()</code> function fails if:</p> <table border="0"> <tr> <td style="padding-right: 20px;"><code>EAGAIN</code></td> <td>The system-imposed limit on the total number of processes under execution by a single user would be exceeded.</td> </tr> <tr> <td><code>EINTR</code></td> <td>The <code>system()</code> function was interrupted by a signal.</td> </tr> <tr> <td><code>ENOMEM</code></td> <td>The new process requires more memory than is available.</td> </tr> </table>	<code>EAGAIN</code>	The system-imposed limit on the total number of processes under execution by a single user would be exceeded.	<code>EINTR</code>	The <code>system()</code> function was interrupted by a signal.	<code>ENOMEM</code>	The new process requires more memory than is available.
<code>EAGAIN</code>	The system-imposed limit on the total number of processes under execution by a single user would be exceeded.						
<code>EINTR</code>	The <code>system()</code> function was interrupted by a signal.						
<code>ENOMEM</code>	The new process requires more memory than is available.						
USAGE	The <code>system()</code> function manipulates the signal handlers for <code>SIGINT</code> , <code>SIGQUIT</code> , and <code>SIGCHLD</code> . For this reason it is not safe to call <code>system()</code> in a multithreaded process. Concurrent calls to <code>system()</code> will interfere destructively with the disposition of these signals, even if they are not manipulated by other threads in the application. See <code>popen(3C)</code> for a replacement for <code>system()</code> that is thread-safe.

tcdrain(3C)

NAME	tcdrain – wait for transmission of output								
SYNOPSIS	<pre>#include <termios.h> int tcdrain(int <i>fildes</i>);</pre>								
DESCRIPTION	<p>The <code>tcdrain()</code> function waits until all output written to the object referred to by <i>fildes</i> is transmitted. The <i>fildes</i> argument is an open file descriptor associated with a terminal.</p> <p>Any attempts to use <code>tcdrain()</code> from a process which is a member of a background process group on a <i>fildes</i> associated with its controlling terminal, will cause the process group to be sent a SIGTTOU signal. If the calling process is blocking or ignoring SIGTTOU signals, the process is allowed to perform the operation, and no signal is sent.</p>								
RETURN VALUES	Upon successful completion, 0 is returned. Otherwise, -1 is returned and <code>errno</code> is set to indicate the error.								
ERRORS	<p>The <code>tcdrain()</code> function will fail if:</p> <table><tr><td>EBADF</td><td>The <i>fildes</i> argument is not a valid file descriptor.</td></tr><tr><td>EINTR</td><td>A signal interrupted <code>tcdrain()</code>.</td></tr><tr><td>ENOTTY</td><td>The file associated with <i>fildes</i> is not a terminal.</td></tr></table> <p>The <code>tcdrain()</code> function may fail if:</p> <table><tr><td>EIO</td><td>The process group of the writing process is orphaned, and the writing process is not ignoring or blocking SIGTTOU.</td></tr></table>	EBADF	The <i>fildes</i> argument is not a valid file descriptor.	EINTR	A signal interrupted <code>tcdrain()</code> .	ENOTTY	The file associated with <i>fildes</i> is not a terminal.	EIO	The process group of the writing process is orphaned, and the writing process is not ignoring or blocking SIGTTOU.
EBADF	The <i>fildes</i> argument is not a valid file descriptor.								
EINTR	A signal interrupted <code>tcdrain()</code> .								
ENOTTY	The file associated with <i>fildes</i> is not a terminal.								
EIO	The process group of the writing process is orphaned, and the writing process is not ignoring or blocking SIGTTOU.

NAME	tcfLOW – suspend or restart the transmission or reception of data								
SYNOPSIS	<pre>#include <termios.h> int tcfLOW(int fildes, int action);</pre>								
DESCRIPTION	<p>The tcfLOW() function suspends transmission or reception of data on the object referred to by <i>fildes</i>, depending on the value of <i>action</i>. The <i>fildes</i> argument is an open file descriptor associated with a terminal.</p> <ul style="list-style-type: none"> ■ If <i>action</i> is TCOFF, output is suspended. ■ If <i>action</i> is TCOON, suspended output is restarted. ■ If <i>action</i> is TCIOFF, the system transmits a STOP character, which is intended to cause the terminal device to stop transmitting data to the system. ■ If <i>action</i> is TCION, the system transmits a START character, which is intended to cause the terminal device to start transmitting data to the system. <p>The default on the opening of a terminal file is that neither its input nor its output are suspended.</p> <p>Attempts to use tcfLOW() from a process which is a member of a background process group on a <i>fildes</i> associated with its controlling terminal, will cause the process group to be sent a SIGTTOU signal. If the calling process is blocking or ignoring SIGTTOU signals, the process is allowed to perform the operation, and no signal is sent.</p>								
RETURN VALUES	Upon successful completion, 0 is returned. Otherwise, -1 is returned and <i>errno</i> is set to indicate the error.								
ERRORS	<p>The tcfLOW() function will fail if:</p> <table border="0"> <tr> <td style="padding-right: 20px;">EBADF</td> <td>The <i>fildes</i> argument is not a valid file descriptor.</td> </tr> <tr> <td>EINVAL</td> <td>The <i>action</i> argument is not a supported value.</td> </tr> <tr> <td>ENOTTY</td> <td>The file associated with <i>fildes</i> is not a terminal.</td> </tr> </table> <p>The tcfLOW() function may fail if:</p> <table border="0"> <tr> <td style="padding-right: 20px;">EIO</td> <td>The process group of the writing process is orphaned, and the writing process is not ignoring or blocking SIGTTOU.</td> </tr> </table>	EBADF	The <i>fildes</i> argument is not a valid file descriptor.	EINVAL	The <i>action</i> argument is not a supported value.	ENOTTY	The file associated with <i>fildes</i> is not a terminal.	EIO	The process group of the writing process is orphaned, and the writing process is not ignoring or blocking SIGTTOU.
EBADF	The <i>fildes</i> argument is not a valid file descriptor.								
EINVAL	The <i>action</i> argument is not a supported value.								
ENOTTY	The file associated with <i>fildes</i> is not a terminal.

tcflush(3C)

NAME	tcflush – flush non-transmitted output data, non-read input data or both								
SYNOPSIS	<pre>#include <termios.h> int tcflush(int fildes, int queue_selector);</pre>								
DESCRIPTION	<p>Upon successful completion, <code>tcflush()</code> discards data written to the object referred to by <i>fildes</i> (an open file descriptor associated with a terminal) but not transmitted, or data received but not read, depending on the value of <i>queue_selector</i>:</p> <ul style="list-style-type: none">■ If <i>queue_selector</i> is <code>TCIFLUSH</code> it flushes data received but not read.■ If <i>queue_selector</i> is <code>TCOFLUSH</code> it flushes data written but not transmitted.■ If <i>queue_selector</i> is <code>TCIOFLUSH</code> it flushes both data received but not read and data written but not transmitted. <p>Attempts to use <code>tcflush()</code> from a process which is a member of a background process group on a <i>fildes</i> associated with its controlling terminal, will cause the process group to be sent a <code>SIGTTOU</code> signal. If the calling process is blocking or ignoring <code>SIGTTOU</code> signals, the process is allowed to perform the operation, and no signal is sent.</p>								
RETURN VALUES	Upon successful completion, 0 is returned. Otherwise, -1 is returned and <code>errno</code> is set to indicate the error.								
ERRORS	<p>The <code>tcflush()</code> function will fail if:</p> <table><tr><td>EBADF</td><td>The <i>fildes</i> argument is not a valid file descriptor.</td></tr><tr><td>EINVAL</td><td>The <i>queue_selector</i> argument is not a supported value.</td></tr><tr><td>ENOTTY</td><td>The file associated with <i>fildes</i> is not a terminal.</td></tr></table> <p>The <code>tcflush()</code> function may fail if:</p> <table><tr><td>EIO</td><td>The process group of the writing process is orphaned, and the writing process is not ignoring or blocking <code>SIGTTOU</code>.</td></tr></table>	EBADF	The <i>fildes</i> argument is not a valid file descriptor.	EINVAL	The <i>queue_selector</i> argument is not a supported value.	ENOTTY	The file associated with <i>fildes</i> is not a terminal.	EIO	The process group of the writing process is orphaned, and the writing process is not ignoring or blocking <code>SIGTTOU</code> .

NAME	tcgetattr – get the parameters associated with the terminal				
SYNOPSIS	<pre>#include <termios.h> int tcgetattr(int <i>fildev</i>, struct termios *<i>termios_p</i>);</pre>				
DESCRIPTION	<p>The <code>tcgetattr()</code> function gets the parameters associated with the terminal referred to by <i>fildev</i> and stores them in the <code>termios</code> structure (see <code>termio(7I)</code>) referenced by <i>termios_p</i>. The <i>fildev</i> argument is an open file descriptor associated with a terminal.</p> <p>The <i>termios_p</i> argument is a pointer to a <code>termios</code> structure.</p> <p>The <code>tcgetattr()</code> operation is allowed from any process.</p> <p>If the terminal device supports different input and output baud rates, the baud rates stored in the <code>termios</code> structure returned by <code>tcgetattr()</code> reflect the actual baud rates, even if they are equal. If differing baud rates are not supported, the rate returned as the output baud rate is the actual baud rate. If the terminal device does not support split baud rates, the input baud rate stored in the <code>termios</code> structure will be 0.</p>				
RETURN VALUES	Upon successful completion, 0 is returned. Otherwise, -1 is returned and <code>errno</code> is set to indicate the error.				
ERRORS	<p>The <code>tcgetattr()</code> function will fail if:</p> <p>EBADF The <i>fildev</i> argument is not a valid file descriptor.</p> <p>ENOTTY The file associated with <i>fildev</i> is not a terminal.</p>				
ATTRIBUTES	See <code>attributes(5)</code> for descriptions of the following attributes:				
	<table border="1"> <thead> <tr> <th>ATTRIBUTE TYPE</th> <th>ATTRIBUTE VALUE</th> </tr> </thead> <tbody> <tr> <td>MT-Level</td> <td>MT-Safe, and Async-Signal-Safe</td> </tr> </tbody> </table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	MT-Level	MT-Safe, and Async-Signal-Safe

tcgetpgrp(3C)

NAME	tcgetpgrp – get foreground process group ID				
SYNOPSIS	<pre>#include <sys/types.h> #include <unistd.h> pid_t tcgetpgrp (int <i>fildev</i>);</pre>				
DESCRIPTION	<p>The tcgetpgrp () function will return the value of the process group ID of the foreground process group associated with the terminal.</p> <p>If there is no foreground process group, tcgetpgrp () returns a value greater than 1 that does not match the process group ID of any existing process group.</p> <p>The tcgetpgrp () function is allowed from a process that is a member of a background process group; however, the information may be subsequently changed by a process that is a member of a foreground process group.</p>				
RETURN VALUES	Upon successful completion, tcgetpgrp () returns the value of the process group ID of the foreground process associated with the terminal. Otherwise, -1 is returned and errno is set to indicate the error.				
ERRORS	The tcgetpgrp () function will fail if: EBADF The <i>fildev</i> argument is not a valid file descriptor. ENOTTY The calling process does not have a controlling terminal, or the file is not the controlling terminal.				
ATTRIBUTES	See attributes(5) for descriptions of the following attributes:				
	<table border="1"><thead><tr><th>ATTRIBUTE TYPE</th><th>ATTRIBUTE VALUE</th></tr></thead><tbody><tr><td>MT-Level</td><td>MT-Safe, and Async-Signal-Safe</td></tr></tbody></table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	MT-Level	MT-Safe, and Async-Signal-Safe
ATTRIBUTE TYPE	ATTRIBUTE VALUE

SEE ALSO	setpgid(2), setsid(2), tcsetpgrp(3C), attributes(5), termio(7I)				

- NAME** tcgetsid – get process group ID for session leader for controlling terminal
- SYNOPSIS**

```
#include <termios.h>
pid_t tcgetsid(int fildes);
```
- DESCRIPTION** The `tcgetsid()` function obtains the process group ID of the session for which the terminal specified by *fildes* is the controlling terminal.
- RETURN VALUES** Upon successful completion, `tcgetsid()` returns the process group ID associated with the terminal. Otherwise, a value of `(pid_t)-1` is returned and `errno` is set to indicate the error.
- ERRORS** The `tcgetsid()` function will fail if:
- EACCES The *fildes* argument is not associated with a controlling terminal.
 - EBADF The *fildes* argument is not a valid file descriptor.
 - ENOTTY The file associated with *fildes* is not a terminal.
- ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
MT-Level	MT-Safe

tcsendbreak(3C)

NAME	tcsendbreak – send a “break” for a specific duration						
SYNOPSIS	<pre>#include <termios.h> int tcsendbreak(int <i>fdes</i>, int <i>duration</i>);</pre>						
DESCRIPTION	<p>The <i>fdes</i> argument is an open file descriptor associated with a terminal.</p> <p>If the terminal is using asynchronous serial data transmission, <code>tcsendbreak()</code> will cause transmission of a continuous stream of zero-valued bits for a specific duration. If <i>duration</i> is 0, it will cause transmission of zero-valued bits for at least 0.25 seconds, and not more than 0.5 seconds. If <i>duration</i> is not 0, it behaves in a way similar to <code>tcdrain(3C)</code>.</p> <p>If the terminal is not using asynchronous serial data transmission, it sends data to generate a break condition or returns without taking any action.</p> <p>Attempts to use <code>tcsendbreak()</code> from a process which is a member of a background process group on a <i>fdes</i> associated with its controlling terminal will cause the process group to be sent a SIGTTOU signal. If the calling process is blocking or ignoring SIGTTOU signals, the process is allowed to perform the operation, and no signal is sent.</p>						
RETURN VALUES	Upon successful completion, 0 is returned. Otherwise, -1 is returned and <code>errno</code> is set to indicate the error.						
ERRORS	<p>The <code>tcsendbreak()</code> function will fail if:</p> <table><tr><td>EBADF</td><td>The <i>fdes</i> argument is not a valid file descriptor.</td></tr><tr><td>ENOTTY</td><td>The file associated with <i>fdes</i> is not a terminal.</td></tr></table> <p>The <code>tcsendbreak()</code> function may fail if:</p> <table><tr><td>EIO</td><td>The process group of the writing process is orphaned, and the writing process is not ignoring or blocking SIGTTOU.</td></tr></table>	EBADF	The <i>fdes</i> argument is not a valid file descriptor.	ENOTTY	The file associated with <i>fdes</i> is not a terminal.	EIO	The process group of the writing process is orphaned, and the writing process is not ignoring or blocking SIGTTOU.
EBADF	The <i>fdes</i> argument is not a valid file descriptor.						
ENOTTY	The file associated with <i>fdes</i> is not a terminal.						
EIO	The process group of the writing process is orphaned, and the writing process is not ignoring or blocking SIGTTOU.						
ATTRIBUTES	See <code>attributes(5)</code> for descriptions of the following attributes:						
	<table border="1"><thead><tr><th>ATTRIBUTE TYPE</th><th>ATTRIBUTE VALUE</th></tr></thead><tbody><tr><td>MT-Level</td><td>MT-Safe, and Async-Signal-Safe</td></tr></tbody></table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	MT-Level	MT-Safe, and Async-Signal-Safe		
ATTRIBUTE TYPE	ATTRIBUTE VALUE						
MT-Level	MT-Safe, and Async-Signal-Safe

NAME	tcsetattr – set the parameters associated with the terminal
SYNOPSIS	<pre>#include <termios.h> int tcsetattr(int <i>fildev</i>, int <i>optional_actions</i>, const struct termios *<i>termios_p</i>);</pre>
DESCRIPTION	<p>The <code>tcsetattr()</code> function sets the parameters associated with the terminal referred to by the open file descriptor <i>fildev</i> (an open file descriptor associated with a terminal) from the <code>termios</code> structure (see <code>termio(7I)</code>) referenced by <i>termios_p</i> as follows:</p> <ul style="list-style-type: none"> ■ If <i>optional_actions</i> is <code>TCSANOW</code>, the change will occur immediately. ■ If <i>optional_actions</i> is <code>TCSADRAIN</code>, the change will occur after all output written to <i>fildev</i> is transmitted. This function should be used when changing parameters that affect output. ■ If <i>optional_actions</i> is <code>TCSAFLUSH</code>, the change will occur after all output written to <i>fildev</i> is transmitted, and all input so far received but not read will be discarded before the change is made. <p>If the output baud rate stored in the <code>termios</code> structure pointed to by <i>termios_p</i> is the zero baud rate, <code>B0</code>, the modem control lines will no longer be asserted. Normally, this will disconnect the line.</p> <p>If the input baud rate stored in the <code>termios</code> structure pointed to by <i>termios_p</i> is 0, the input baud rate given to the hardware will be the same as the output baud rate stored in the <code>termios</code> structure.</p> <p>The <code>tcsetattr()</code> function will return successfully if it was able to perform any of the requested actions, even if some of the requested actions could not be performed. It will set all the attributes that implementation supports as requested and leave all the attributes not supported by the implementation unchanged. If no part of the request can be honoured, it will return <code>-1</code> and set <code>errno</code> to <code>EINVAL</code>. If the input and output baud rates differ and are a combination that is not supported, neither baud rate is changed. A subsequent call to <code>tcgetattr(3C)</code> will return the actual state of the terminal device (reflecting both the changes made and not made in the previous <code>tcsetattr()</code> call). The <code>tcsetattr()</code> function will not change the values in the <code>termios</code> structure whether or not it actually accepts them.</p> <p>The effect of <code>tcsetattr()</code> is undefined if the value of the <code>termios</code> structure pointed to by <i>termios_p</i> was not derived from the result of a call to <code>tcgetattr(3C)</code> on <i>fildev</i>; an application should modify only fields and flags defined by this document between the call to <code>tcgetattr(3C)</code> and <code>tcsetattr()</code>, leaving all other fields and flags unmodified.</p> <p>No actions defined by this document, other than a call to <code>tcsetattr()</code> or a close of the last file descriptor in the system associated with this terminal device, will cause any of the terminal attributes defined by this document to change.</p>

tcsetattr(3C)

Attempts to use `tcsetattr()` from a process which is a member of a background process group on a *fildev* associated with its controlling terminal, will cause the process group to be sent a SIGTTOU signal. If the calling process is blocking or ignoring SIGTTOU signals, the process is allowed to perform the operation, and no signal is sent.

USAGE If trying to change baud rates, applications should call `tcsetattr()` then call `tcgetattr(3C)` in order to determine what baud rates were actually selected.

RETURN VALUES Upon successful completion, 0 is returned. Otherwise, -1 is returned and `errno` is set to indicate the error.

ERRORS The `tcsetattr()` function will fail if:

- EBADF The *fildev* argument is not a valid file descriptor.
- EINTR A signal interrupted `tcsetattr()`.
- EINVAL The *optional_actions* argument is not a supported value, or an attempt was made to change an attribute represented in the `termios` structure to an unsupported value.
- ENOTTY The file associated with *fildev* is not a terminal.

The `tcsetattr()` function may fail if:

- EIO The process group of the writing process is orphaned, and the writing process is not ignoring or blocking SIGTTOU.

tdelete(3C)

NAME	tsearch, tfind, tdelete, twalk – manage binary search trees
SYNOPSIS	<pre>#include <search.h> void *tsearch(const void *key, void **rootp, int (*compar)(const void *, const void *)); void *tfind(const void *key, void * const *rootp, int (*compar)(const void *, const void *)); void *tdelete(const void *key, void **rootp, int (*compar)(const void *, const void *)); void twalk(const void *root, void(*action)(void *, VISIT, int));</pre>
DESCRIPTION	<p>The <code>tsearch()</code>, <code>tfind()</code>, <code>tdelete()</code>, and <code>twalk()</code> functions are routines for manipulating binary search trees. They are generalized from <i>Knuth (6.2.2) Algorithms T and D</i>. All comparisons are done with a user-supplied routine. This routine is called with two arguments, the pointers to the elements being compared. It returns an integer less than, equal to, or greater than 0, according to whether the first argument is to be considered less than, equal to or greater than the second argument. The comparison function need not compare every byte, so arbitrary data may be contained in the elements in addition to the values being compared.</p> <p>The <code>tsearch()</code> function is used to build and access the tree. The <code>key</code> argument is a pointer to a datum to be accessed or stored. If there is a datum in the tree equal to <code>*key</code> (the value pointed to by <code>key</code>), a pointer to this found datum is returned. Otherwise, <code>*key</code> is inserted, and a pointer to it returned. Only pointers are copied, so the calling routine must store the data. The <code>rootp</code> argument points to a variable that points to the root of the tree. A null value for the variable pointed to by <code>rootp</code> denotes an empty tree; in this case, the variable will be set to point to the datum which will be at the root of the new tree.</p> <p>Like <code>tsearch()</code>, <code>tfind()</code> will search for a datum in the tree, returning a pointer to it if found. However, if it is not found, <code>tfind()</code> will return a null pointer. The arguments for <code>tfind()</code> are the same as for <code>tsearch()</code>.</p> <p>The <code>tdelete()</code> function deletes a node from a binary search tree. The arguments are the same as for <code>tsearch()</code>. The variable pointed to by <code>rootp</code> will be changed if the deleted node was the root of the tree. <code>tdelete()</code> returns a pointer to the parent of the deleted node, or a null pointer if the node is not found.</p> <p>The <code>twalk()</code> function traverses a binary search tree. The <code>root</code> argument is the root of the tree to be traversed. (Any node in a tree may be used as the root for a walk below that node.) <code>action</code> is the name of a routine to be invoked at each node. This routine is, in turn, called with three arguments. The first argument is the address of the node being visited. The second argument is a value from an enumeration data type</p> <pre>typedef enum { preorder, postorder, endorder, leaf } VISIT;(defined in <search.h>), depending on whether this is the first, second or third time that the node has been visited (during a depth-first, left-to-right traversal of the tree), or whether the node is a</pre>

leaf. The third argument is the level of the node in the tree, with the root being level zero.

The pointers to the key and the root of the tree should be of type pointer-to-element, and cast to type pointer-to-character. Similarly, although declared as type pointer-to-character, the value returned should be cast into type pointer-to-element.

RETURN VALUES

If the node is found, both `tsearch()` and `tfind()` return a pointer to it. If not, `tfind()` returns a null pointer, and `tsearch()` returns a pointer to the inserted item.

A null pointer is returned by `tsearch()` if there is not enough space available to create a new node.

A null pointer is returned by `tsearch()`, `tfind()` and `tdelete()` if `rootp` is a null pointer on entry.

The `tdelete()` function returns a pointer to the parent of the deleted node, or a null pointer if the node is not found.

The `twalk()` function returns no value.

ERRORS

No errors are defined.

USAGE

The `root` argument to `twalk()` is one level of indirection less than the `rootp` arguments to `tsearch()` and `tdelete()`.

There are two nomenclatures used to refer to the order in which tree nodes are visited. `tsearch()` uses preorder, postorder and endorder to refer respectively to visiting a node before any of its children, after its left child and before its right, and after both its children. The alternate nomenclature uses preorder, inorder and postorder to refer to the same visits, which could result in some confusion over the meaning of postorder.

If the calling function alters the pointer to the root, results are unpredictable.

EXAMPLES

EXAMPLE 1 A sample program of using `tsearch` function.

The following code reads in strings and stores structures containing a pointer to each string and a count of its length. It then walks the tree, printing out the stored strings and their lengths in alphabetical order.

```
#include <string.h>
#include <stdio.h>
#include <search.h>
struct node {
    char *string;
    int length;
};
char string_space[10000];
struct node nodes[500];
void *root = NULL;
```

tdelete(3C)

EXAMPLE 1 A sample program of using *tsearch* function. (Continued)

```
int node_compare(const void *node1, const void *node2) {
    return strcmp(((const struct node *) node1)->string,
                 ((const struct node *) node2)->string);
}

void print_node(const void *node, VISIT order, int level) {
    if (order == preorder || order == leaf) {
        printf("length=%d, string=%20s\n",
              (*(struct node **)node)->length,
              (*(struct node **)node)->string);
    }
}

main( )
{
    char *strptr = string_space;
    struct node *nodeptr = nodes;
    int i = 0;

    while (gets(strptr) != NULL && i++ < 500) {
        nodeptr->string = strptr;
        nodeptr->length = strlen(strptr);
        (void) tsearch((void *)nodeptr,
                      &root, node_compare);
        strptr += nodeptr->length + 1;
        nodeptr++;
    }
    twalk(root, print_node);
}
```

NAME	tell – return a file offset for a file descriptor				
SYNOPSIS	<pre>#include <unistd.h> off_t tell(int fd);</pre>				
DESCRIPTION	The <code>tell()</code> function obtains the current value of the file-position indicator for the file descriptor <i>fd</i> .				
RETURN VALUES	<p>Upon successful completion, <code>tell()</code> returns the current value of the file-position indicator for <i>fd</i> measured in bytes from the beginning of the file.</p> <p>Otherwise, it returns <code>-1</code> and sets <code>errno</code> to indicate the error.</p>				
ERRORS	<p>The <code>tell()</code> function will fail if:</p> <p><code>EBADF</code> The file descriptor <i>fd</i> is not an open file descriptor.</p> <p><code>EOVERFLOW</code> The current file offset cannot be represented correctly in an object of type <code>off_t</code>.</p> <p><code>ESPIPE</code> The file descriptor <i>fd</i> is associated with a pipe or FIFO.</p>				
USAGE	The <code>tell()</code> function is equivalent to <code>lseek(fd, 0, SEEK_CUR)</code> .				
ATTRIBUTES	See <code>attributes(5)</code> for descriptions of the following attributes:

tellmdir(3C)

NAME tellmdir – current location of a named directory stream

SYNOPSIS

```
#include <dirent.h>
long int tellmdir(DIR *dirp);
```

DESCRIPTION The `tellmdir()` function obtains the current location associated with the directory stream specified by *dirp*.

If the most recent operation on the directory stream was a `seekdir(3C)`, the directory position returned from the `tellmdir()` is the same as that supplied as a *loc* argument for `seekdir()`.

RETURN VALUES Upon successful completion, `tellmdir()` returns the current location of the specified directory stream.

ERRORS The `tellmdir()` function will fail if:

`E_OVERFLOW` The current location of the directory cannot be stored in an object of type `long`.

NAME	tmpnam, tmpnam_r, tmpnam – create a name for a temporary file
SYNOPSIS	<pre>#include <stdio.h> char *tmpnam(char *s); char *tmpnam_r(char *s); char *tmpnam(const char *dir, const char *pfx);</pre>
DESCRIPTION	<p>These functions generate file names that can be used safely for a temporary file.</p> <p>tmpnam() The tmpnam() function always generates a file name using the path prefix defined as P_tmpdir in the <stdio.h> header. On Solaris systems, the default value for P_tmpdir is /var/tmp. If s is NULL, tmpnam() leaves its result in an internal static area and returns a pointer to that area. The next call to tmpnam() will destroy the contents of the area. If s is not NULL, it is assumed to be the address of an array of at least L_tmpnam bytes, where L_tmpnam is a constant defined in <stdio.h>; tmpnam() places its result in that array and returns s.</p> <p>tmpnam_r() The tmpnam_r() function has the same functionality as tmpnam() except that if s is a null pointer, the function returns NULL.</p> <p>tmpnam() The tmpnam() function allows the user to control the choice of a directory. The argument dir points to the name of the directory in which the file is to be created. If dir is NULL or points to a string that is not a name for an appropriate directory, the path prefix defined as P_tmpdir in the <stdio.h> header is used. If that directory is not accessible, /tmp is used. If, however, the TMPDIR environment variable is set in the user's environment, its value is used as the temporary-file directory.</p> <p>Many applications prefer that temporary files have certain initial character sequences in their names. The pfx argument may be NULL or point to a string of up to five characters to be used as the initial characters of the temporary-file name.</p> <p>Upon successful completion, tmpnam() uses malloc(3C) to allocate space for a string, puts the generated pathname in that space, and returns a pointer to it. The pointer is suitable for use in a subsequent call to free(). If tmpnam() cannot return the expected result for any reason (for example, malloc() failed), or if none of the above-mentioned attempts to find an appropriate directory was successful, a null pointer is returned and errno is set to indicate the error.</p>
ERRORS	<p>The tmpnam() function will fail if:</p> <p>ENOMEM Insufficient storage space is available.</p>
USAGE	<p>These functions generate a different file name each time they are called.</p> <p>Files created using these functions and either fopen(3C) or creat(2) are temporary only in the sense that they reside in a directory intended for temporary use, and their names are unique. It is the user's responsibility to remove the file when its use is ended.</p>

tempnam(3C)

If called more than `TMP_MAX` (defined in `<stdio.h>`) times in a single process, these functions start recycling previously used names.

Between the time a file name is created and the file is opened, it is possible for some other process to create a file with the same name. This can never happen if that other process is using these functions or `mktemp(3C)` and the file names are chosen to render duplication by other means unlikely.

The `tempnam()` function is unsafe in multithreaded applications. The `tempnam_r()` function is safe in multithreaded applications and should be used instead.

When compiling multithreaded applications, the `_REENTRANT` flag must be defined on the compile line. This flag should be used only with multithreaded applications.

textdomain(3C)

NAME	gettext, dgettext, dcgettext, ngettext, dngettext, dcgettext, textdomain, bindtextdomain, bind_textdomain_codeset – message handling functions
Solaris and GNU-compatible	<pre>#include <libintl.h> char *gettext (const char *msgid); char *dgettext (const char *domainname, const char *msgid); char *textdomain (const char *domainname); char *bindtextdomain (const char *domainname, const char *dirname); #include <libintl.h> #include <locale.h> char *dcgettext (const char *domainname, const char *msgid, int category);</pre>
GNU-compatible	<pre>#include <libintl.h> char *ngettext (const char *msgid1, const char *msgid2, unsigned long int n); char *dngettext (const char *domainname, const char *msgid1, const char *msgid2, unsigned long int n); char *bind_textdomain_codeset (const char *domainname, const char *codeset); #include <libintl.h> #include <locale.h> char *dcngettext (const char *domainname, const char *msgid1, const char *msgid2, unsigned long int n, int category);</pre>
DESCRIPTION	<p>The <code>gettext()</code>, <code>dgettext()</code>, and <code>dcgettext()</code> functions attempt to retrieve a target string based on the specified <code>msgid</code> argument within the context of a specific domain and the current locale. The length of strings returned by <code>gettext()</code>, <code>dgettext()</code>, and <code>dcgettext()</code> is undetermined until the function is called. The <code>msgid</code> argument is a null-terminated string.</p> <p>The <code>ngettext()</code>, <code>dngettext()</code>, and <code>dcngettext()</code> functions are equivalent to <code>gettext()</code>, <code>dgettext()</code>, and <code>dcgettext()</code>, respectively, except for the handling of plural forms. These functions work only with GNU-compatible message catalogues. The <code>ngettext()</code>, <code>dngettext()</code>, and <code>dcngettext()</code> functions search for the message string using the <code>msgid1</code> argument as the key and the <code>n</code> argument to determine the plural form. If no message catalogues are found, <code>msgid1</code> is returned if <code>n == 1</code>, otherwise <code>msgid2</code> is returned.</p> <p>The <code>NLSPATH</code> environment variable (see <code>environ(5)</code>) is searched first for the location of the <code>LC_MESSAGES</code> catalogue. The setting of the <code>LC_MESSAGES</code> category of the current locale determines the locale used by <code>gettext()</code> and <code>dgettext()</code> for string retrieval. The <code>category</code> argument determines the locale used by <code>dcgettext()</code>. If <code>NLSPATH</code> is not defined and the current locale is "C", <code>gettext()</code>, <code>dgettext()</code>, and</p>

`dcgettext()` simply return the message string that was passed. In a locale other than "C", if `NLSPATH` is not defined or if a message catalogue is not found in any of the components specified by `NLSPATH`, the routines search for the message catalogue using the scheme described in the following paragraph.

The `LANGUAGE` environment variable is examined to determine the GNU-compatible message catalogues to be used. The value of `LANGUAGE` is a list of locale names separated by a colon (':') character. If `LANGUAGE` is defined, each locale name is tried in the specified order and if a GNU-compatible message catalogue is found, the message is returned. If a GNU-compatible message catalogue is found but failed to find a corresponding `msgid`, the `msgid` string is return. If `LANGUAGE` is not defined or if a Solaris message catalogue is found or no GNU-compatible message catalogue is found in processing `LANGUAGE`, the pathname used to locate the message catalogue is `dirname/locale/category/domainname.mo`, where `dirname` is the directory specified by `bindtextdomain()`, `locale` is a locale name, and `category` is either `LC_MESSAGES` if `gettext()`, `dgettext()`, `ngettext()`, or `dngettext()` is called, or `LC_XXX` where the name is the same as the locale category name specified by the `category` argument to `dcgettext()` or `dcngettext()`.

For `gettext()` and `ngettext()`, the domain used is set by the last valid call to `textdomain()`. If a valid call to `textdomain()` has not been made, the default domain (called `messages`) is used.

For `dgettext()`, `dcgettext()`, `dngettext()`, and `dcngettext()`, the domain used is specified by the `domainname` argument. The `domainname` argument is equivalent in syntax and meaning to the `domainname` argument to `textdomain()`, except that the selection of the domain is valid only for the duration of the `dgettext()`, `dcgettext()`, `dngettext()`, or `dcngettext()` function call.

The `textdomain()` function sets or queries the name of the current domain of the active `LC_MESSAGES` locale category. The `domainname` argument is a null-terminated string that can contain only the characters allowed in legal filenames.

The `domainname` argument is the unique name of a domain on the system. If there are multiple versions of the same domain on one system, namespace collisions can be avoided by using `bindtextdomain()`. If `textdomain()` is not called, a default domain is selected. The setting of domain made by the last valid call to `textdomain()` remains valid across subsequent calls to `setlocale(3C)`, and `gettext()`.

The `domainname` argument is applied to the currently active `LC_MESSAGES` locale.

The current setting of the domain can be queried without affecting the current state of the domain by calling `textdomain()` with `domainname` set to the null pointer. Calling `textdomain()` with a `domainname` argument of a null string sets the domain to the default domain (`messages`).

The `bindtextdomain()` function binds the path predicate for a message domain `domainname` to the value contained in `dirname`. If `domainname` is a non-empty string and has not been bound previously, `bindtextdomain()` binds `domainname` with `dirname`.

textdomain(3C)

If *domainname* is a non-empty string and has been bound previously, `bindtextdomain()` replaces the old binding with *dirname*. The *dirname* argument can be an absolute or relative pathname being resolved when `gettext()`, `dgettext()`, or `dcgettext()` are called. If *domainname* is a null pointer or an empty string, `bindtextdomain()` returns NULL. User defined domain names cannot begin with the string `SYS_`. Domain names beginning with this string are reserved for system use.

The `bind_textdomain_codeset()` function can be used to specify the output codeset for message catalogues for domain *domainname*. The *codeset* argument must be a valid codeset name that can be used for the `iconv_open(3C)` function, or a null pointer. If the *codeset* argument is the null pointer, `bind_textdomain_codeset()` returns the currently selected codeset for the domain with the name *domainname*. It returns a null pointer if a codeset has not yet been selected. The `bind_textdomain_codeset()` function can be used multiple times. If used multiple times with the same *domainname* argument, the later call overrides the settings made by the earlier one. The `bind_textdomain_codeset()` function returns a pointer to a string containing the name of the selected codeset. The string is allocated internally in the function and must not be changed by the user.

RETURN VALUES

The `gettext()`, `dgettext()`, and `dcgettext()` functions return the message string if the search succeeds. Otherwise they return the *msgid* string.

The `ngettext()`, `dngettext()`, and `dcngettext()` functions return the message string if the search succeeds. If the search fails, *msgid1* is returned if *n* == 1. Otherwise *msgid2* is returned.

The individual bytes of the string returned by `gettext()`, `dgettext()`, `dcgettext()`, `ngettext()`, `dngettext()`, or `dcngettext()` can contain any value other than NULL. If *msgid* is a null pointer, the return value is undefined. The string returned must not be modified by the program and can be invalidated by a subsequent call to `bind_textdomain_codeset()` or `setlocale(3C)`. If the *domainname* argument to `dgettext()`, `dcgettext()`, `dngettext()`, or `dcngettext()` is a null pointer, the the domain currently bound by `textdomain()` is used.

The normal return value from `textdomain()` is a pointer to a string containing the current setting of the domain. If *domainname* is a null pointer, `textdomain()` returns a pointer to the string containing the current domain. If `textdomain()` was not previously called and *domainname* is a null string, the name of the default domain is returned. The name of the default domain is `messages`. If `textdomain()` fails, a null pointer is returned.

The return value from `bindtextdomain()` is a null-terminated string containing *dirname* or the directory binding associated with *domainname* if *dirname* is NULL. If no binding is found, the default return value is `/usr/lib/locale`. If *domainname* is a null pointer or an empty string, `bindtextdomain()` takes no action and returns a null pointer. The string returned must not be modified by the caller. If `bindtextdomain()` fails, a null pointer is returned.

USAGE These functions impose no limit on message length. However, a text *domainname* is limited to TEXTDOMAINMAX (256) bytes.

The `gettext()`, `dgettext()`, `dcgettext()`, `ngettext()`, `dngettext()`, `dcngettext()`, `textdomain()`, and `bindtextdomain()` functions can be used safely in multithreaded applications, as long as `setlocale(3C)` is not being called to change the locale.

The `gettext()`, `dgettext()`, `dcgettext()`, `textdomain()`, and `bindtextdomain()` functions work with both Solaris message catalogues and GNU-compatible message catalogues. The `ngettext()`, `dngettext()`, `dcngettext()`, and `bind_textdomain_codeset()` functions work only with GNU-compatible message catalogues. See `msgfmt(1)` for information about Solaris message catalogues and GNU-compatible message catalogues.

FILES `/usr/lib/locale`
 default path predicate for message domain files

`/usr/lib/locale/locale/LC_MESSAGES/domainname.mo`
 system default location for file containing messages for language *locale* and *domainname*

`/usr/lib/locale/locale/LC_XXX/domainname.mo`
 system default location for file containing messages for language *locale* and *domainname* for `dcgettext()` calls where `LC_XXX` is `LC_CTYPE`, `LC_NUMERIC`, `LC_TIME`, `LC_COLLATE`, `LC_MONETARY`, or `LC_MESSAGES`

`dirname/locale/LC_MESSAGES/domainname.mo`
 location for file containing messages for domain *domainname* and path predicate *dirname* after a successful call to `bindtextdomain()`

`dirname/locale/LC_XXX/domainname.mo`
 location for files containing messages for domain *domainname*, language *locale*, and path predicate *dirname* after a successful call to `bindtextdomain()` for `dcgettext()` calls where `LC_XXX` is one of `LC_CTYPE`, `LC_NUMERIC`, `LC_TIME`, `LC_COLLATE`, `LC_MONETARY`, or `LC_MESSAGES`

tfind(3C)

NAME	tsearch, tfind, tdelete, twalk – manage binary search trees
SYNOPSIS	<pre>#include <search.h> void *tsearch(const void *key, void **rootp, int (*compar)(const void *, const void *)); void *tfind(const void *key, void * const *rootp, int (*compar)(const void *, const void *)); void *tdelete(const void *key, void **rootp, int (*compar)(const void *, const void *)); void twalk(const void *root, void(*action)(void *, VISIT, int));</pre>
DESCRIPTION	<p>The <code>tsearch()</code>, <code>tfind()</code>, <code>tdelete()</code>, and <code>twalk()</code> functions are routines for manipulating binary search trees. They are generalized from <i>Knuth (6.2.2) Algorithms T and D</i>. All comparisons are done with a user-supplied routine. This routine is called with two arguments, the pointers to the elements being compared. It returns an integer less than, equal to, or greater than 0, according to whether the first argument is to be considered less than, equal to or greater than the second argument. The comparison function need not compare every byte, so arbitrary data may be contained in the elements in addition to the values being compared.</p> <p>The <code>tsearch()</code> function is used to build and access the tree. The <code>key</code> argument is a pointer to a datum to be accessed or stored. If there is a datum in the tree equal to <code>*key</code> (the value pointed to by <code>key</code>), a pointer to this found datum is returned. Otherwise, <code>*key</code> is inserted, and a pointer to it returned. Only pointers are copied, so the calling routine must store the data. The <code>rootp</code> argument points to a variable that points to the root of the tree. A null value for the variable pointed to by <code>rootp</code> denotes an empty tree; in this case, the variable will be set to point to the datum which will be at the root of the new tree.</p> <p>Like <code>tsearch()</code>, <code>tfind()</code> will search for a datum in the tree, returning a pointer to it if found. However, if it is not found, <code>tfind()</code> will return a null pointer. The arguments for <code>tfind()</code> are the same as for <code>tsearch()</code>.</p> <p>The <code>tdelete()</code> function deletes a node from a binary search tree. The arguments are the same as for <code>tsearch()</code>. The variable pointed to by <code>rootp</code> will be changed if the deleted node was the root of the tree. <code>tdelete()</code> returns a pointer to the parent of the deleted node, or a null pointer if the node is not found.</p> <p>The <code>twalk()</code> function traverses a binary search tree. The <code>root</code> argument is the root of the tree to be traversed. (Any node in a tree may be used as the root for a walk below that node.) <code>action</code> is the name of a routine to be invoked at each node. This routine is, in turn, called with three arguments. The first argument is the address of the node being visited. The second argument is a value from an enumeration data type</p> <pre>typedef enum { preorder, postorder, endorder, leaf } VISIT;(defined in <search.h>), depending on whether this is the first, second or third time that the node has been visited (during a depth-first, left-to-right traversal of the tree), or whether the node is a</pre>

leaf. The third argument is the level of the node in the tree, with the root being level zero.

The pointers to the key and the root of the tree should be of type pointer-to-element, and cast to type pointer-to-character. Similarly, although declared as type pointer-to-character, the value returned should be cast into type pointer-to-element.

RETURN VALUES

If the node is found, both `tsearch()` and `tfind()` return a pointer to it. If not, `tfind()` returns a null pointer, and `tsearch()` returns a pointer to the inserted item.

A null pointer is returned by `tsearch()` if there is not enough space available to create a new node.

A null pointer is returned by `tsearch()`, `tfind()` and `tdelete()` if `rootp` is a null pointer on entry.

The `tdelete()` function returns a pointer to the parent of the deleted node, or a null pointer if the node is not found.

The `twalk()` function returns no value.

ERRORS

No errors are defined.

USAGE

The `root` argument to `twalk()` is one level of indirection less than the `rootp` arguments to `tsearch()` and `tdelete()`.

There are two nomenclatures used to refer to the order in which tree nodes are visited. `tsearch()` uses preorder, postorder and endorder to refer respectively to visiting a node before any of its children, after its left child and before its right, and after both its children. The alternate nomenclature uses preorder, inorder and postorder to refer to the same visits, which could result in some confusion over the meaning of postorder.

If the calling function alters the pointer to the root, results are unpredictable.

EXAMPLES

EXAMPLE 1 A sample program of using `tsearch` function.

The following code reads in strings and stores structures containing a pointer to each string and a count of its length. It then walks the tree, printing out the stored strings and their lengths in alphabetical order.

```
#include <string.h>
#include <stdio.h>
#include <search.h>
struct node {
    char *string;
    int length;
};
char string_space[10000];
struct node nodes[500];
void *root = NULL;
```

tfind(3C)

EXAMPLE 1 A sample program of using *tsearch* function. (Continued)

```
int node_compare(const void *node1, const void *node2) {
    return strcmp(((const struct node *) node1)->string,
                 ((const struct node *) node2)->string);
}

NAME	times – get process times
SYNOPSIS	<pre> /usr/ucb/cc [flag ...] file ... #include <sys/param.h> #include <sys/types.h> #include <sys/times.h> int times (tmsp); register struct tms *tmsp; </pre>
DESCRIPTION	<p>The <code>times()</code> function returns time-accounting information for the current process and for the terminated child processes of the current process. All times are reported in clock ticks. The number of clock ticks per second is defined by the variable <code>CLK_TCK</code>, found in the header <code><limits.h></code>.</p> <p>A structure with the following members is returned by <code>times()</code>:</p> <pre> time_t tms_utime; /* user time */ time_t tms_stime; /* system time */ time_t tms_cutime; /* user time, children */ time_t tms_cstime; /* system time, children */ </pre> <p>The children's times are the sum of the children's process times and their children's times.</p>
RETURN VALUES	Upon successful completion, <code>times()</code> returns 0. Otherwise, it returns -1.
SEE ALSO	<code>time(1)</code> , <code>time(2)</code> , <code>wait(2)</code> , <code>getrusage(3C)</code>
NOTES	<p>Use of these interfaces should be restricted to only applications written on BSD platforms. Use of these interfaces with any of the system libraries or in multi-threaded applications is unsupported.</p> <p>The <code>times()</code> function has been superseded by <code>getrusage(3C)</code>.</p>

tmpfile(3C)

NAME	tmpfile – create a temporary file												
SYNOPSIS	<pre>#include <stdio.h> FILE *tmpfile(void);</pre>												
DESCRIPTION	<p>The <code>tmpfile()</code> function creates a temporary file and opens a corresponding stream. The file will automatically be deleted when all references to the file are closed. The file is opened as in <code>fopen(3C)</code> for update (<code>w+</code>).</p> <p>The largest value that can be represented correctly in an object of type <code>off_t</code> will be established as the offset maximum in the open file description.</p>												
RETURN VALUES	Upon successful completion, <code>tmpfile()</code> returns a pointer to the stream of the file that is created. Otherwise, it returns a null pointer and sets <code>errno</code> to indicate the error.												
ERRORS	<p>The <code>tmpfile()</code> function will fail if:</p> <table><tr><td><code>EINTR</code></td><td>A signal was caught during the execution of <code>tmpfile()</code>.</td></tr><tr><td><code>EMFILE</code></td><td>There are <code>OPEN_MAX</code> file descriptors currently open in the calling process.</td></tr><tr><td><code>ENFILE</code></td><td>The maximum allowable number of files is currently open in the system.</td></tr><tr><td><code>ENOSPC</code></td><td>The directory or file system which would contain the new file cannot be expanded.</td></tr></table> <p>The <code>tmpfile()</code> function may fail if:</p> <table><tr><td><code>EMFILE</code></td><td>There are <code>FOPEN_MAX</code> streams currently open in the calling process.</td></tr><tr><td><code>ENOMEM</code></td><td>Insufficient storage space is available.</td></tr></table>	<code>EINTR</code>	A signal was caught during the execution of <code>tmpfile()</code> .	<code>EMFILE</code>	There are <code>OPEN_MAX</code> file descriptors currently open in the calling process.	<code>ENFILE</code>	The maximum allowable number of files is currently open in the system.	<code>ENOSPC</code>	The directory or file system which would contain the new file cannot be expanded.	<code>EMFILE</code>	There are <code>FOPEN_MAX</code> streams currently open in the calling process.	<code>ENOMEM</code>	Insufficient storage space is available.
<code>EINTR</code>	A signal was caught during the execution of <code>tmpfile()</code> .												
<code>EMFILE</code>	There are <code>OPEN_MAX</code> file descriptors currently open in the calling process.												
<code>ENFILE</code>	The maximum allowable number of files is currently open in the system.												
<code>ENOSPC</code>	The directory or file system which would contain the new file cannot be expanded.												
<code>EMFILE</code>	There are <code>FOPEN_MAX</code> streams currently open in the calling process.												
<code>ENOMEM</code>	Insufficient storage space is available.												
USAGE	<p>The stream refers to a file which is unlinked. If the process is killed in the period between file creation and unlinking, a permanent file may be left behind.</p> <p>The <code>tmpfile()</code> function has a transitional interface for 64-bit file offsets. See <code>lf64(5)</code>.</p>												
SEE ALSO	<code>unlink(2)</code> , <code>fopen(3C)</code> , <code>tmpnam(3C)</code> , <code>lf64(5)</code>												

NAME	tmpnam, tmpnam_r, tmpnam – create a name for a temporary file
SYNOPSIS	<pre>#include <stdio.h> char *tmpnam(char *s); char *tmpnam_r(char *s); char *tmpnam(const char *dir, const char *pfx);</pre>
DESCRIPTION	<p>These functions generate file names that can be used safely for a temporary file.</p> <p>tmpnam() The tmpnam() function always generates a file name using the path prefix defined as P_tmpdir in the <stdio.h> header. On Solaris systems, the default value for P_tmpdir is /var/tmp. If s is NULL, tmpnam() leaves its result in an internal static area and returns a pointer to that area. The next call to tmpnam() will destroy the contents of the area. If s is not NULL, it is assumed to be the address of an array of at least L_tmpnam bytes, where L_tmpnam is a constant defined in <stdio.h>; tmpnam() places its result in that array and returns s.</p> <p>tmpnam_r() The tmpnam_r() function has the same functionality as tmpnam() except that if s is a null pointer, the function returns NULL.</p> <p>tmpnam() The tmpnam() function allows the user to control the choice of a directory. The argument dir points to the name of the directory in which the file is to be created. If dir is NULL or points to a string that is not a name for an appropriate directory, the path prefix defined as P_tmpdir in the <stdio.h> header is used. If that directory is not accessible, /tmp is used. If, however, the TMPDIR environment variable is set in the user's environment, its value is used as the temporary-file directory.</p> <p>Many applications prefer that temporary files have certain initial character sequences in their names. The pfx argument may be NULL or point to a string of up to five characters to be used as the initial characters of the temporary-file name.</p> <p>Upon successful completion, tmpnam() uses malloc(3C) to allocate space for a string, puts the generated pathname in that space, and returns a pointer to it. The pointer is suitable for use in a subsequent call to free(). If tmpnam() cannot return the expected result for any reason (for example, malloc() failed), or if none of the above-mentioned attempts to find an appropriate directory was successful, a null pointer is returned and errno is set to indicate the error.</p>
ERRORS	<p>The tmpnam() function will fail if:</p> <p>ENOMEM Insufficient storage space is available.</p>
USAGE	<p>These functions generate a different file name each time they are called.</p> <p>Files created using these functions and either fopen(3C) or creat(2) are temporary only in the sense that they reside in a directory intended for temporary use, and their names are unique. It is the user's responsibility to remove the file when its use is ended.</p>

tmpnam(3C)

If called more than `TMP_MAX` (defined in `<stdio.h>`) times in a single process, these functions start recycling previously used names.

Between the time a file name is created and the file is opened, it is possible for some other process to create a file with the same name. This can never happen if that other process is using these functions or `mktemp(3C)` and the file names are chosen to render duplication by other means unlikely.

The `tmpnam()` function is unsafe in multithreaded applications. The `tempnam()` function is safe in multithreaded applications and should be used instead.

When compiling multithreaded applications, the `_REENTRANT` flag must be defined on the compile line. This flag should be used only with multithreaded applications.

NAME	truncate, ftruncate – set a file to a specified length														
SYNOPSIS	<pre>#include <unistd.h> int truncate(const char *path, off_t length); int ftruncate(int fildes, off_t length);</pre>														
DESCRIPTION	<p>The <code>truncate()</code> function causes the regular file named by <i>path</i> to have a size of <i>length</i> bytes.</p> <p>The <code>ftruncate()</code> function causes the regular file referenced by <i>fildes</i> to have a size of <i>length</i> bytes.</p> <p>The effect of <code>ftruncate()</code> and <code>truncate()</code> on other types of files is unspecified. If the file previously was larger than <i>length</i>, the extra data is lost. If it was previously shorter than <i>length</i>, bytes between the old and new lengths are read as zeroes. With <code>ftruncate()</code>, the file must be open for writing; for <code>truncate()</code>, the process must have write permission for the file.</p> <p>If the request would cause the file size to exceed the soft file size limit for the process, the request will fail and the implementation will generate the SIGXFSZ signal for the process.</p> <p>These functions do not modify the file offset for any open file descriptions associated with the file. On successful completion, if the file size is changed, these functions will mark for update the <code>st_ctime</code> and <code>st_mtime</code> fields of the file, and if the file is a regular file, the <code>S_ISUID</code> and <code>S_ISGID</code> bits of the file mode may be cleared.</p>														
RETURN VALUES	Upon successful completion, <code>ftruncate()</code> and <code>truncate()</code> return 0. Otherwise, <code>-1</code> is returned and <code>errno</code> is set to indicate the error.														
ERRORS	<p>The <code>ftruncate()</code> and <code>truncate()</code> functions will fail if:</p> <table border="0"> <tr> <td style="padding-right: 20px;">EINTR</td> <td>A signal was caught during execution.</td> </tr> <tr> <td>EINVAL</td> <td>The <i>length</i> argument was less than 0.</td> </tr> <tr> <td>EFBIG or EINVAL</td> <td>The <i>length</i> argument was greater than the maximum file size.</td> </tr> <tr> <td>EIO</td> <td>An I/O error occurred while reading from or writing to a file system.</td> </tr> </table> <p>The <code>truncate()</code> function will fail if:</p> <table border="0"> <tr> <td style="padding-right: 20px;">EACCES</td> <td>A component of the path prefix denies search permission, or write permission is denied on the file.</td> </tr> <tr> <td>EFAULT</td> <td>The <i>path</i> argument points outside the process' allocated address space.</td> </tr> <tr> <td>EINVAL</td> <td>The <i>path</i> argument is not an ordinary file.</td> </tr> </table>	EINTR	A signal was caught during execution.	EINVAL	The <i>length</i> argument was less than 0.	EFBIG or EINVAL	The <i>length</i> argument was greater than the maximum file size.	EIO	An I/O error occurred while reading from or writing to a file system.	EACCES	A component of the path prefix denies search permission, or write permission is denied on the file.	EFAULT	The <i>path</i> argument points outside the process' allocated address space.	EINVAL	The <i>path</i> argument is not an ordinary file.
EINTR	A signal was caught during execution.														
EINVAL	The <i>length</i> argument was less than 0.														
EFBIG or EINVAL	The <i>length</i> argument was greater than the maximum file size.														
EIO	An I/O error occurred while reading from or writing to a file system.														
EACCES	A component of the path prefix denies search permission, or write permission is denied on the file.														
EFAULT	The <i>path</i> argument points outside the process' allocated address space.														
EINVAL	The <i>path</i> argument is not an ordinary file.														

truncate(3C)

EISDIR	The named file is a directory.
ELOOP	Too many symbolic links were encountered in resolving <i>path</i> .
EMFILE	The maximum number of file descriptors available to the process has been reached.
ENAMETOOLONG	The length of the specified pathname exceeds <code>PATH_MAX</code> bytes, or the length of a component of the pathname exceeds <code>NAME_MAX</code> bytes.
ENOENT	A component of <i>path</i> does not name an existing file or <i>path</i> is an empty string.
ENFILE	Additional space could not be allocated for the system file table.
ENOTDIR	A component of the path prefix of <i>path</i> is not a directory.
ENOLINK	The <i>path</i> argument points to a remote machine and the link to that machine is no longer active.
EROFS	The named file resides on a read-only file system.
The <code>ftruncate()</code> function will fail if:	
EAGAIN	The file exists, mandatory file/record locking is set, and there are outstanding record locks on the file (see <code>chmod(2)</code>).
EBADF or EINVAL	The <i>fildev</i> argument is not a file descriptor open for writing.
EFBIG	The file is a regular file and <i>length</i> is greater than the offset maximum established in the open file description associated with <i>fildev</i> .
EINVAL	The <i>fildev</i> argument references a file that was opened without write permission.
EINVAL	The <i>fildev</i> argument does not correspond to an ordinary file.
ENOLINK	The <i>fildev</i> argument points to a remote machine and the link to that machine is no longer active.
The <code>truncate()</code> function may fail if:	
ENAMETOOLONG	Pathname resolution of a symbolic link produced an intermediate result whose

USAGE The `truncate()` and `ftruncate()` functions have transitional interfaces for 64-bit file offsets. See `lf64(5)`.

tsearch(3C)

NAME	tsearch, tfind, tdelete, twalk – manage binary search trees
SYNOPSIS	<pre>#include <search.h> void *tsearch(const void *key, void **rootp, int (*compar)(const void *, const void *)); void *tfind(const void *key, void * const *rootp, int (*compar)(const void *, const void *)); void *tdelete(const void *key, void **rootp, int (*compar)(const void *, const void *)); void twalk(const void *root, void(*action)(void *, VISIT, int));</pre>
DESCRIPTION	<p>The <code>tsearch()</code>, <code>tfind()</code>, <code>tdelete()</code>, and <code>twalk()</code> functions are routines for manipulating binary search trees. They are generalized from <i>Knuth (6.2.2) Algorithms T and D</i>. All comparisons are done with a user-supplied routine. This routine is called with two arguments, the pointers to the elements being compared. It returns an integer less than, equal to, or greater than 0, according to whether the first argument is to be considered less than, equal to or greater than the second argument. The comparison function need not compare every byte, so arbitrary data may be contained in the elements in addition to the values being compared.</p> <p>The <code>tsearch()</code> function is used to build and access the tree. The <code>key</code> argument is a pointer to a datum to be accessed or stored. If there is a datum in the tree equal to <code>*key</code> (the value pointed to by <code>key</code>), a pointer to this found datum is returned. Otherwise, <code>*key</code> is inserted, and a pointer to it returned. Only pointers are copied, so the calling routine must store the data. The <code>rootp</code> argument points to a variable that points to the root of the tree. A null value for the variable pointed to by <code>rootp</code> denotes an empty tree; in this case, the variable will be set to point to the datum which will be at the root of the new tree.</p> <p>Like <code>tsearch()</code>, <code>tfind()</code> will search for a datum in the tree, returning a pointer to it if found. However, if it is not found, <code>tfind()</code> will return a null pointer. The arguments for <code>tfind()</code> are the same as for <code>tsearch()</code>.</p> <p>The <code>tdelete()</code> function deletes a node from a binary search tree. The arguments are the same as for <code>tsearch()</code>. The variable pointed to by <code>rootp</code> will be changed if the deleted node was the root of the tree. <code>tdelete()</code> returns a pointer to the parent of the deleted node, or a null pointer if the node is not found.</p> <p>The <code>twalk()</code> function traverses a binary search tree. The <code>root</code> argument is the root of the tree to be traversed. (Any node in a tree may be used as the root for a walk below that node.) <code>action</code> is the name of a routine to be invoked at each node. This routine is, in turn, called with three arguments. The first argument is the address of the node being visited. The second argument is a value from an enumeration data type</p> <pre>typedef enum { preorder, postorder, endorder, leaf } VISIT;(defined in <search.h>), depending on whether this is the first, second or third time that the node has been visited (during a depth-first, left-to-right traversal of the tree), or whether the node is a</pre>

leaf. The third argument is the level of the node in the tree, with the root being level zero.

The pointers to the key and the root of the tree should be of type pointer-to-element, and cast to type pointer-to-character. Similarly, although declared as type pointer-to-character, the value returned should be cast into type pointer-to-element.

RETURN VALUES

If the node is found, both `tsearch()` and `tfind()` return a pointer to it. If not, `tfind()` returns a null pointer, and `tsearch()` returns a pointer to the inserted item.

A null pointer is returned by `tsearch()` if there is not enough space available to create a new node.

A null pointer is returned by `tsearch()`, `tfind()` and `tdelete()` if `rootp` is a null pointer on entry.

The `tdelete()` function returns a pointer to the parent of the deleted node, or a null pointer if the node is not found.

The `twalk()` function returns no value.

ERRORS

No errors are defined.

USAGE

The `root` argument to `twalk()` is one level of indirection less than the `rootp` arguments to `tsearch()` and `tdelete()`.

There are two nomenclatures used to refer to the order in which tree nodes are visited. `tsearch()` uses preorder, postorder and endorder to refer respectively to visiting a node before any of its children, after its left child and before its right, and after both its children. The alternate nomenclature uses preorder, inorder and postorder to refer to the same visits, which could result in some confusion over the meaning of postorder.

If the calling function alters the pointer to the root, results are unpredictable.

EXAMPLES

EXAMPLE 1 A sample program of using `tsearch` function.

The following code reads in strings and stores structures containing a pointer to each string and a count of its length. It then walks the tree, printing out the stored strings and their lengths in alphabetical order.

```
#include <string.h>
#include <stdio.h>
#include <search.h>
struct node {
    char *string;
    int length;
};
char string_space[10000];
struct node nodes[500];
void *root = NULL;
```

tsearch(3C)

EXAMPLE 1 A sample program of using *tsearch* function. (Continued)

```
int node_compare(const void *node1, const void *node2) {
    return strcmp(((const struct node *) node1)->string,
                 ((const struct node *) node2)->string);
}

void print_node(const void *node, VISIT order, int level) {
    if (order == preorder || order == leaf) {
        printf("length=%d, string=%20s\n",
              (*(struct node **)node)->length,
              (*(struct node **)node)->string);
    }
}

main( )
{
    char *strptr = string_space;
    struct node *nodeptr = nodes;
    int i = 0;

    while (gets(strptr) != NULL && i++ < 500) {
        nodeptr->string = strptr;
        nodeptr->length = strlen(strptr);
        (void) tsearch((void *)nodeptr,
                      &root, node_compare);
        strptr += nodeptr->length + 1;
        nodeptr++;
    }
    twalk(root, print_node);
}
```

SEE ALSO *bsearch(3C)*, *hsearch(3C)*, *lsearch(3C)*, *attributes(5)*

NAME | ttyname, ttyname_r – find pathname of a terminal

SYNOPSIS | #include <unistd.h>
char *ttyname(int fildes);
char *ttyname_r(int fildes, char *name, int namelen);

POSIX | cc [flag ...] file ... -D_POSIX_PTHREAD_SEMANTICS [library ...]
int ttyname_r(int fildes, char *name, size_t namesize);

DESCRIPTION | The ttyname() function returns a pointer to a string containing the null-terminated path name of the terminal device associated with file descriptor *fildes*. The return value may point to static data whose content is overwritten by each call.

The ttyname_r() function has the same functionality as ttyname() except that the caller must supply a buffer *name* with length *namelen* to store the result; this buffer must be at least `_POSIX_PATH_MAX` in size (defined in `<limits.h>`). The POSIX version (see standards(5)) of ttyname_r() takes a *namesize* parameter of type `size_t`.

RETURN VALUES | Upon successful completion, ttyname() and ttyname_r() return a pointer to a string. Otherwise, a null pointer is returned and `errno` is set to indicate the error.

The POSIX ttyname_r() returns zero if successful, or the error number upon failure.

ERRORS | The ttyname_r() function will fail if:

ERANGE The size of the buffer is smaller than the result to be returned.

The ttyname() function may fail if:

EBADF The *fildes* argument is not a valid file descriptor.

ENOTTY The *fildes* argument does not refer to a terminal device.

FILES | /dev/* device file

ATTRIBUTES | See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
MT-Level	See NOTES below.

SEE ALSO | Intro(3), gettext(3C), setlocale(3C), attributes(5), standards(5)

NOTES | When compiling multithreaded programs, see Intro(3), *Notes On Multithreaded Applications*.

If the application is linked with `-lintl`, then messages printed from this function are in the native language specified by the `LC_MESSAGES` locale category; see setlocale(3C).

ttyname(3C)

The return value points to static data whose content is overwritten by each call.

The `ttyname()` is Unsafe in multithreaded applications. The `ttyname_r()` function is MT-Safe, and should be used instead.

Solaris 2.4 and earlier releases provided definitions of the `ttyname_r()` interface as specified in POSIX.1c Draft 6. The final POSIX.1c standard changed the interface as described above. Support for the Draft 6 interface is provided for compatibility only and may not be supported in future releases. New applications and libraries should use the POSIX standard interface.

NAME	ttyslot – find the slot of the current user in the user accounting database				
SYNOPSIS	<pre>#include <stdlib.h> int ttyslot(void);</pre>				
DESCRIPTION	The <code>ttyslot()</code> function returns the index of the current user's entry in the user accounting database, <code>/var/adm/utmpx</code> . The current user's entry is an entry for which the <code>utline</code> member matches the name of a terminal device associated with any of the process's file descriptors 0, 1 or 2. The index is an ordinal number representing the record number in the database of the current user's entry. The first entry in the database is represented by the return value 0.				
RETURN VALUES	Upon successful completion, <code>ttyslot()</code> returns the index of the current user's entry in the user accounting database. If an error was encountered while searching for the terminal name or if none of the above file descriptors are associated with a terminal device, <code>-1</code> is returned.

twalk(3C)

NAME	tsearch, tfind, tdelete, twalk – manage binary search trees
SYNOPSIS	<pre>#include <search.h> void *tsearch(const void *key, void **rootp, int (*compar)(const void *, const void *)); void *tfind(const void *key, void * const *rootp, int (*compar)(const void *, const void *)); void *tdelete(const void *key, void **rootp, int (*compar)(const void *, const void *)); void twalk(const void *root, void(*action)(void *, VISIT, int));</pre>
DESCRIPTION	<p>The <code>tsearch()</code>, <code>tfind()</code>, <code>tdelete()</code>, and <code>twalk()</code> functions are routines for manipulating binary search trees. They are generalized from <i>Knuth (6.2.2) Algorithms T and D</i>. All comparisons are done with a user-supplied routine. This routine is called with two arguments, the pointers to the elements being compared. It returns an integer less than, equal to, or greater than 0, according to whether the first argument is to be considered less than, equal to or greater than the second argument. The comparison function need not compare every byte, so arbitrary data may be contained in the elements in addition to the values being compared.</p> <p>The <code>tsearch()</code> function is used to build and access the tree. The <code>key</code> argument is a pointer to a datum to be accessed or stored. If there is a datum in the tree equal to <code>*key</code> (the value pointed to by <code>key</code>), a pointer to this found datum is returned. Otherwise, <code>*key</code> is inserted, and a pointer to it returned. Only pointers are copied, so the calling routine must store the data. The <code>rootp</code> argument points to a variable that points to the root of the tree. A null value for the variable pointed to by <code>rootp</code> denotes an empty tree; in this case, the variable will be set to point to the datum which will be at the root of the new tree.</p> <p>Like <code>tsearch()</code>, <code>tfind()</code> will search for a datum in the tree, returning a pointer to it if found. However, if it is not found, <code>tfind()</code> will return a null pointer. The arguments for <code>tfind()</code> are the same as for <code>tsearch()</code>.</p> <p>The <code>tdelete()</code> function deletes a node from a binary search tree. The arguments are the same as for <code>tsearch()</code>. The variable pointed to by <code>rootp</code> will be changed if the deleted node was the root of the tree. <code>tdelete()</code> returns a pointer to the parent of the deleted node, or a null pointer if the node is not found.</p> <p>The <code>twalk()</code> function traverses a binary search tree. The <code>root</code> argument is the root of the tree to be traversed. (Any node in a tree may be used as the root for a walk below that node.) <code>action</code> is the name of a routine to be invoked at each node. This routine is, in turn, called with three arguments. The first argument is the address of the node being visited. The second argument is a value from an enumeration data type</p> <pre>typedef enum { preorder, postorder, endorder, leaf } VISIT;(defined in <search.h>), depending on whether this is the first, second or third time that the node has been visited (during a depth-first, left-to-right traversal of the tree), or whether the node is a</pre>

leaf. The third argument is the level of the node in the tree, with the root being level zero.

The pointers to the key and the root of the tree should be of type pointer-to-element, and cast to type pointer-to-character. Similarly, although declared as type pointer-to-character, the value returned should be cast into type pointer-to-element.

RETURN VALUES

If the node is found, both `tsearch()` and `tfind()` return a pointer to it. If not, `tfind()` returns a null pointer, and `tsearch()` returns a pointer to the inserted item.

A null pointer is returned by `tsearch()` if there is not enough space available to create a new node.

A null pointer is returned by `tsearch()`, `tfind()` and `tdelete()` if `rootp` is a null pointer on entry.

The `tdelete()` function returns a pointer to the parent of the deleted node, or a null pointer if the node is not found.

The `twalk()` function returns no value.

ERRORS

No errors are defined.

USAGE

The `root` argument to `twalk()` is one level of indirection less than the `rootp` arguments to `tsearch()` and `tdelete()`.

There are two nomenclatures used to refer to the order in which tree nodes are visited. `tsearch()` uses preorder, postorder and endorder to refer respectively to visiting a node before any of its children, after its left child and before its right, and after both its children. The alternate nomenclature uses preorder, inorder and postorder to refer to the same visits, which could result in some confusion over the meaning of postorder.

If the calling function alters the pointer to the root, results are unpredictable.

EXAMPLES

EXAMPLE 1 A sample program of using `tsearch` function.

The following code reads in strings and stores structures containing a pointer to each string and a count of its length. It then walks the tree, printing out the stored strings and their lengths in alphabetical order.

```
#include <string.h>
#include <stdio.h>
#include <search.h>
struct node {
    char *string;
    int length;
};
char string_space[10000];
struct node nodes[500];
void *root = NULL;
```

twalk(3C)

EXAMPLE 1 A sample program of using *tsearch* function. (Continued)

```
int node_compare(const void *node1, const void *node2) {
    return strcmp(((const struct node *) node1)->string,
                 ((const struct node *) node2)->string);
}

void print_node(const void *node, VISIT order, int level) {
    if (order == preorder || order == leaf) {
        printf("length=%d, string=%20s\n",
              (*(struct node **)node)->length,
              (*(struct node **)node)->string);
    }
}

main( )
{
    char *strptr = string_space;
    struct node *nodeptr = nodes;
    int i = 0;

    while (gets(strptr) != NULL && i++ < 500) {
        nodeptr->string = strptr;
        nodeptr->length = strlen(strptr);
        (void) tsearch((void *)nodeptr,
                      &root, node_compare);
        strptr += nodeptr->length + 1;
        nodeptr++;
    }
    twalk(root, print_node);
}
```

ATTRIBUTES See *attributes(5)* for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
MT-Level	Safe

SEE ALSO *bsearch(3C)*, *hsearch(3C)*, *lsearch(3C)*, *attributes(5)*

NAME	ctime, ctime_r, localtime, localtime_r, gmtime, gmtime_r, asctime, asctime_r, tzset – convert date and time to string
SYNOPSIS	<pre>#include <time.h> char *ctime(const time_t *clock); struct tm *localtime(const time_t *clock); struct tm *gmtime(const time_t *clock); char *asctime(const struct tm *tm); extern time_t timezone, altzone; extern int daylight; extern char *tzname[2]; void tzset(void); char *ctime_r(const time_t *clock, char *buf, int buflen); struct tm *localtime_r(const time_t *clock, struct tm *res); struct tm *gmtime_r(const time_t *clock, struct tm *res); char *asctime_r(const struct tm *tm, char *buf, int buflen);</pre>
POSIX	<pre>cc [flag...] file... -D_POSIX_PTHREAD_SEMANTICS [library...] char *ctime_r(const time_t *clock, char *buf); char *asctime_r(const struct tm *tm, char *buf);</pre>
DESCRIPTION	<p>The <code>ctime()</code> function converts the time pointed to by <code>clock</code>, representing the time in seconds since the Epoch (00:00:00 UTC, January 1, 1970), to local time in the form of a 26-character string, as shown below. Time zone and daylight savings corrections are made before string generation. The fields are in constant width:</p> <pre>Fri Sep 13 00:00:00 1986\n\0</pre> <p>The <code>ctime()</code> function is equivalent to:</p> <pre>asctime(localtime(clock))</pre> <p>The <code>ctime()</code>, <code>asctime()</code>, <code>gmtime()</code>, and <code>localtime()</code> functions return values in one of two static objects: a broken-down time structure and an array of <code>char</code>. Execution of any of the functions can overwrite the information returned in either of these objects by any of the other functions.</p> <p>The <code>ctime_r()</code> function has the same functionality as <code>ctime()</code> except that the caller must supply a buffer <code>buf</code> with length <code>buflen</code> to store the result; <code>buf</code> must be at least 26 bytes. The POSIX <code>ctime_r()</code> function does not take a <code>buflen</code> parameter.</p>

tzset(3C)

The `localtime()` and `gmtime()` functions return pointers to `tm` structures (see below). The `localtime()` function corrects for the main time zone and possible alternate (“daylight savings”) time zone; the `gmtime()` function converts directly to Coordinated Universal Time (UTC), which is what the UNIX system uses internally.

The `localtime_r()` and `gmtime_r()` functions have the same functionality as `localtime()` and `gmtime()` respectively, except that the caller must supply a buffer *res* to store the result.

The `asctime()` function converts a `tm` structure to a 26-character string, as shown in the previous example, and returns a pointer to the string.

The `asctime_r()` function has the same functionality as `asctime()` except that the caller must supply a buffer *buf* with length *buflen* for the result to be stored. The *buf* argument must be at least 26 bytes. The POSIX `asctime_r()` function does not take a *buflen* parameter. The `asctime_r()` function returns a pointer to *buf* upon success. In case of failure, `NULL` is returned and `errno` is set.

Declarations of all the functions and externals, and the `tm` structure, are in the `<time.h>` header. The members of the `tm` structure are:

```
int    tm_sec;    /* seconds after the minute - [0, 61] */
        /* for leap seconds */
int    tm_min;    /* minutes after the hour - [0, 59] */
int    tm_hour;   /* hour since midnight - [0, 23] */
int    tm_mday;   /* day of the month - [1, 31] */
int    tm_mon;    /* months since January - [0, 11] */
int    tm_year;   /* years since 1900 */
int    tm_wday;   /* days since Sunday - [0, 6] */
int    tm_yday;   /* days since January 1 - [0, 365] */
int    tm_isdst;  /* flag for alternate daylight savings time */
```

The value of `tm_isdst` is positive if daylight savings time is in effect, zero if daylight savings time is not in effect, and negative if the information is not available. Previously, the value of `tm_isdst` was defined as non-zero if daylight savings was in effect.

The external `time_t` variable `altzone` contains the difference, in seconds, between Coordinated Universal Time and the alternate time zone. The external variable `timezone` contains the difference, in seconds, between UTC and local standard time. The external variable `daylight` indicates whether time should reflect daylight savings time. Both `timezone` and `altzone` default to 0 (UTC). The external variable `daylight` is non-zero if an alternate time zone exists. The time zone names are contained in the external variable `tzname`, which by default is set to:

```
char *tzname[2] = { "GMT", "" };
```

These functions know about the peculiarities of this conversion for various time periods for the U.S. (specifically, the years 1974, 1975, and 1987). They start handling the new daylight savings time starting with the first Sunday in April, 1987.

The `tzset()` function uses the contents of the environment variable `TZ` to override the value of the different external variables. It is called by `asctime()` and can also be called by the user. See `environ(5)` for a description of the `TZ` environment variable.

Starting and ending times are relative to the current local time zone. If the alternate time zone start and end dates and the time are not provided, the days for the United States that year will be used and the time will be 2 AM. If the start and end dates are provided but the time is not provided, the time will be 2 AM. The effects of `tzset()` change the values of the external variables `timezone`, `altzone`, `daylight`, and `tzname`.

Note that in most installations, `TZ` is set to the correct value by default when the user logs on, using the local `/etc/default/init` file (see `TIMEZONE(4)`).

ERRORS The `ctime_r()` and `asctime_r()` functions will fail if:

ERANGE The length of the buffer supplied by the caller is not large enough to store the result.

USAGE These functions do not support localized date and time formats. The `strftime(3C)` function can be used when localization is required.

The `localtime()`, `localtime_r()`, `gmtime()`, `gmtime_r()`, `ctime()`, and `ctime_r()` functions assume Gregorian dates. Times before the adoption of the Gregorian calendar will not match historical records.

EXAMPLES **EXAMPLE 1** Examples of the `tzset()` function.

The `tzset()` function scans the contents of the environment variable and assigns the different fields to the respective variable. For example, the most complete setting for New Jersey in 1986 could be:

```
EST5EDT4,116/2:00:00,298/2:00:00
```

or simply

```
EST5EDT
```

An example of a southern hemisphere setting such as the Cook Islands could be

```
KDT9:30KST10:00,63/5:00,302/20:00
```

In the longer version of the New Jersey example of `TZ`, `tzname[0]` is `EST`, `timezone` is set to `5*60*60`, `tzname[1]` is `EDT`, `altzone` is set to `4*60*60`, the starting date of the alternate time zone is the 117th day at 2 AM, the ending date of the alternate time zone is the 299th day at 2 AM (using zero-based Julian days), and `daylight` is set positive. Starting and ending times are relative to the current local time zone. If the alternate time zone start and end dates and the time are not provided, the days for the United States that year will be used and the time will be 2 AM. If the start and end dates are provided but the time is not provided, the time will be 2 AM. The effects of `tzset()` are thus to change the values of the external variables `timezone`, `altzone`, `daylight`, and `tzname`. The `ctime()`, `localtime()`, `mktime()`, and `strftime()` functions also update these external variables as if they had called `tzset()` at the

tzset(3C)

EXAMPLE 1 Examples of the tzset () function. (Continued)

time specified by the time_t or struct tm value that they are converting.

BUGS The zoneinfo timezone data files do not transition past Tue Jan 19 03:14:07 2038 UTC. Therefore for 64-bit applications using zoneinfo timezones, calculations beyond this date might not use the correct offset from standard time, and could return incorrect values. This affects the 64-bit version of localtime (), localtime_r (), ctime (), and ctime_r ().

ATTRIBUTES See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
MT-Level	MT-Safe with exceptions
CSI	Enabled

SEE ALSO time(2), Intro(3), getenv(3C), mktime(3C), printf(3C), putenv(3C), setlocale(3C), strftime(3C), TIMEZONE(4), attributes(5), environ(5)

NOTES When compiling multithreaded programs, see Intro(3), *Notes On Multithreaded Applications*.

The return values for ctime (), localtime (), and gmtime () point to static data whose content is overwritten by each call.

Setting the time during the interval of change from timezone to altzone or vice versa can produce unpredictable results. The system administrator must change the Julian start and end days annually.

The asctime (), ctime (), gmtime (), and localtime () functions are unsafe in multithread applications. The asctime_r () and gmtime_r () functions are MT-Safe. The ctime_r (), localtime_r (), and tzset () functions are MT-Safe in multithread applications, as long as no user-defined function directly modifies one of the following variables: timezone, altzone, daylight, and tzname. These four variables are not MT-Safe to access. They are modified by the tzset () function in an MT-Safe manner. The mktime (), localtime_r (), and ctime_r () functions call tzset ().

Solaris 2.4 and earlier releases provided definitions of the ctime_r (), localtime_r (), gmtime_r (), and asctime_r () functions as specified in POSIX.1c Draft 6. The final POSIX.1c standard changed the interface for ctime_r () and asctime_r (). Support for the Draft 6 interface is provided for compatibility only and might not be supported in future releases. New applications and libraries should use the POSIX standard interface.

For POSIX.1c-compliant applications, the `_POSIX_PTHREAD_SEMANTICS` and `_REENTRANT` flags are automatically turned on by defining the `_POSIX_C_SOURCE` flag with a value `>= 199506L`.

ualarm(3C)

NAME	ualarm – schedule signal after interval in microseconds
SYNOPSIS	<pre>#include <unistd.h> useconds_t ualarm(useconds_t <i>useconds</i>, useconds_t <i>interval</i>);</pre>
DESCRIPTION	<p>The <code>ualarm()</code> function causes the <code>SIGALRM</code> signal to be generated for the calling process after the number of real-time microseconds specified by the <i>useconds</i> argument has elapsed. When the <i>interval</i> argument is non-zero, repeated timeout notification occurs with a period in microseconds specified by the <i>interval</i> argument. If the notification signal, <code>SIGALRM</code>, is not caught or ignored, the calling process is terminated.</p> <p>Because of scheduling delays, resumption of execution when the signal is caught may be delayed an arbitrary amount of time.</p> <p>Interactions between <code>ualarm()</code> and either <code>alarm(2)</code> or <code>sleep(3C)</code> are unspecified.</p>
RETURN VALUES	The <code>ualarm()</code> function returns the number of microseconds remaining from the previous <code>ualarm()</code> call. If no timeouts are pending or if <code>ualarm()</code> has not previously been called, <code>ualarm()</code> returns 0.
ERRORS	No errors are defined.
USAGE	The <code>ualarm()</code> function is a simplified interface to <code>setitimer(2)</code> , and uses the <code>ITIMER_REAL</code> interval timer.
SEE ALSO	<code>alarm(2)</code> , <code>setitimer(2)</code> , <code>sighold(3C)</code> , <code>signal(3C)</code> , <code>sleep(3C)</code> , <code>usleep(3C)</code>

NAME	lckpwnf, ulckpwnf – manipulate shadow password database lock file				
SYNOPSIS	<pre>#include <shadow.h> int lckpwnf(void); int ulckpwnf(void);</pre>				
DESCRIPTION	<p>The lckpwnf() and ulckpwnf() functions enable modification access to the password databases through the lock file. A process first uses lckpwnf() to lock the lock file, thereby gaining exclusive rights to modify the /etc/passwd or /etc/shadow password database. See passwd(4) and shadow(4). Upon completing modifications, a process should release the lock on the lock file using ulckpwnf(). This mechanism prevents simultaneous modification of the password databases. The lock file, /etc/.pwd.lock, is used to coordinate modification access to the password databases /etc/passwd and /etc/shadow.</p>				
RETURN VALUES	<p>If lckpwnf() is successful in locking the file within 15 seconds, it returns 0. If unsuccessful (for example, /etc/.pwd.lock is already locked), it returns -1.</p> <p>If ulckpwnf() is successful in unlocking the file /etc/.pwd.lock, it returns 0. If unsuccessful (for example, /etc/.pwd.lock is already unlocked), it returns -1.</p>				
USAGE	These routines are for internal use only; compatibility is not guaranteed.				
FILES	<pre>/etc/passwd password database /etc/shadow shadow password database /etc/.pwd.lock lock file</pre>

ulltostr(3C)

NAME	strtol, strtoll, atol, atoll, atoi, lltostr, ulltostr – string conversion routines
SYNOPSIS	<pre>#include <stdlib.h> long strtol(const char *str, char **endptr, int base); long long strtoll(const char *str, char **endptr, int base); long atol(const char *str); long long atoll(const char *str); int atoi(const char *str); char *lltostr(long long value, char *endptr); char *ulltostr(unsigned long long value, char *endptr);</pre>
strtol() and strtoll()	<p>The <code>strtol()</code> function converts the initial portion of the string pointed to by <code>str</code> to a type long int representation.</p> <p>The <code>strtoll()</code> function converts the initial portion of the string pointed to by <code>str</code> to a type long long representation.</p> <p>Both functions first decompose the input string into three parts: an initial, possibly empty, sequence of white-space characters (as specified by <code>isspace(3C)</code>); a subject sequence interpreted as an integer represented in some radix determined by the value of <code>base</code>; and a final string of one or more unrecognized characters, including the terminating null byte of the input string. They then attempt to convert the subject sequence to an integer and return the result.</p> <p>If the value of <code>base</code> is 0, the expected form of the subject sequence is that of a decimal constant, octal constant or hexadecimal constant, any of which may be preceded by a + or – sign. A decimal constant begins with a non-zero digit, and consists of a sequence of decimal digits. An octal constant consists of the prefix 0 optionally followed by a sequence of the digits 0 to 7 only. A hexadecimal constant consists of the prefix 0x or 0X followed by a sequence of the decimal digits and letters a (or A) to f (or F) with values 10 to 15 respectively.</p> <p>If the value of <code>base</code> is between 2 and 36, the expected form of the subject sequence is a sequence of letters and digits representing an integer with the radix specified by <code>base</code>, optionally preceded by a + or – sign. The letters from a (or A) to z (or Z) inclusive are ascribed the values 10 to 35; only letters whose ascribed values are less than that of <code>base</code> are permitted. If the value of <code>base</code> is 16, the characters 0x or 0X may optionally precede the sequence of letters and digits, following the sign if present.</p> <p>The subject sequence is defined as the longest initial subsequence of the input string, starting with the first non-white-space character, that is of the expected form. The subject sequence contains no characters if the input string is empty or consists entirely of white-space characters, or if the first non-white-space character is other than a sign or a permissible letter or digit.</p>

If the subject sequence has the expected form and the value of *base* is 0, the sequence of characters starting with the first digit is interpreted as an integer constant. If the subject sequence has the expected form and the value of *base* is between 2 and 36, it is used as the base for conversion, ascribing to each letter its value as given above. If the subject sequence begins with a minus sign, the value resulting from the conversion is negated. A pointer to the final string is stored in the object pointed to by *endptr*, provided that *endptr* is not a null pointer.

In other than the POSIX locale, additional implementation-dependent subject sequence forms may be accepted.

If the subject sequence is empty or does not have the expected form, no conversion is performed; the value of *str* is stored in the object pointed to by *endptr*, provided that *endptr* is not a null pointer.

`atol()`, `atoll()`
and `atoi()`

Except for behavior on error, `atol()` is equivalent to: `strtol(str, (char **)NULL, 10)`.

Except for behavior on error, `atoll()` is equivalent to: `strtoll(str, (char **)NULL, 10)`.

Except for behavior on error, `atoi()` is equivalent to: `(int) strtol(str, (char **)NULL, 10)`.

`lltostr()` and
`ulltostr()`

The `lltostr()` function returns a pointer to the string represented by the long long *value*. The *endptr* argument is assumed to point to the byte following a storage area into which the decimal representation of *value* is to be placed as a string. The `lltostr()` function converts *value* to decimal and produces the string, and returns a pointer to the beginning of the string. No leading zeros are produced, and no terminating null is produced. The low-order digit of the result always occupies memory position *endptr*-1. The behavior of `lltostr()` is undefined if *value* is negative. A single zero digit is produced if *value* is 0.

The `ulltostr()` function is similar to `lltostr()` except that *value* is an unsigned long long.

RETURN VALUES

Upon successful completion, `strtol()`, `strtoll()`, `atol()`, `atoll()`, and `atoi()` return the converted value, if any. If no conversion could be performed, `strtol()` and `strtoll()` return 0 and `errno` may be set to `EINVAL`.

If the correct value is outside the range of representable values, `strtol()` returns `LONG_MAX` or `LONG_MIN` and `strtoll()` returns `LLONG_MAX` or `LLONG_MIN` (according to the sign of the value), and `errno` is set to `ERANGE`.

Upon successful completion, `lltostr()` and `ulltostr()` return a pointer to the converted string.

ERRORS

The `strtol()` and `strtoll()` functions will fail if:

`ERANGE` The value to be returned is not representable. The `strtol()` and `strtoll()` functions may fail if:

ulltostr(3C)

EINVAL The value of *base* is not supported.

USAGE Because 0, LONG_MIN, LONG_MAX, LLONG_MIN, and LLONG_MAX are returned on error and are also valid returns on success, an application wishing to check for error situations should set `errno` to 0, call the function, then check `errno` and if it is non-zero, assume an error has occurred.

The `strtol()` function no longer accepts values greater than LONG_MAX or LLONG_MAX as valid input. Use `strtoul(3C)` instead.

NAME	umem_alloc, umem_zalloc, umem_free, umem_nofail_callback – fast, scalable memory allocation
SYNOPSIS	<pre>cc [flag ...] file... -lumem [library ...] #include <umem.h> void *umem_alloc(size_t size, int flags); void *umem_zalloc(size_t size, int flags); void umem_free(void *buf, size_t size); void umem_nofail_callback((int (*callback)(void))); void *malloc(size_t size); void *calloc(size_t nelem, size_t elsize); void free(void *ptr); void *memalign(size_t alignment, size_t size); void *realloc(void *ptr, size_t size); void *valloc(size_t size);</pre>
DESCRIPTION	<p>The <code>umem_alloc()</code> function returns a pointer to a block of <i>size</i> bytes suitably aligned for any variable type. The initial contents of memory allocated using <code>umem_alloc()</code> is undefined. The <i>flags</i> argument determines the behavior of <code>umem_alloc()</code> if it is unable to fulfill the request. The <i>flags</i> argument can take the following values:</p> <p><code>UMEM_DEFAULT</code> Return <code>NULL</code> on failure.</p> <p><code>UMEM_NOFAIL</code> Call an optional <i>callback</i> (set with <code>umem_nofail_callback()</code>) on failure. The <i>callback</i> takes no arguments and can finish by:</p> <ul style="list-style-type: none"> ■ returning <code>UMEM_CALLBACK_RETRY</code>, in which case the allocation will be retried. If the allocation fails, the callback will be invoked again. ■ returning <code>UMEM_CALLBACK_EXIT(status)</code>, in which case <code>exit(2)</code> is invoked with <i>status</i> as its argument. The <code>exit()</code> function is called only once. If multiple threads return from the <code>UMEM_NOFAIL</code> callback with <code>UMEM_CALLBACK_EXIT(status)</code>, one will call <code>exit()</code> while the other blocks until <code>exit()</code> terminates the program. ■ invoking a context-changing function (<code>setcontext(2)</code>) or a non-local jump (<code>longjmp(3C)</code> or <code>siglongjmp(3C)</code>), or ending the current thread of control (<code>thr_exit(3THR)</code> or <code>pthread_exit(3THR)</code>). The application is responsible for any necessary cleanup. The state of <code>libumem</code> remains consistent. <p>If no callback has been set or the callback has been set to <code>NULL</code>, <code>umem_alloc(..., UMEM_NOFAIL)</code> behaves as though the callback returned <code>UMEM_CALLBACK_EXIT(255)</code>.</p>

umem_alloc(3MALLOC)

The `libumem` library can call callbacks from any place that a `UMEM_NOFAIL` allocation is issued. In multithreaded applications, callbacks are expected to perform their own concurrency management.

The function call `umem_alloc(0, flag)` always returns `NULL`. The function call `umem_free(NULL, 0)` is allowed.

The `umem_zalloc()` function has the same semantics as `umem_alloc()`, but the block of memory is initialized to zeros before it is returned.

The `umem_free()` function frees blocks previously allocated using `umem_alloc()` and `umem_zalloc()`. The buffer address and size must exactly match the original allocation. Memory must not be returned piecemeal.

The `umem_nofail_callback()` function sets the process-wide `UMEM_NOFAIL` callback. See the description of `UMEM_NOFAIL` for more information.

The `malloc()`, `calloc()`, `free()`, `memalign()`, `realloc()`, and `valloc()` functions are as described in `malloc(3C)`. The `libumem` library provides these functions for backwards-compatibility with the standard functions.

ENVIRONMENT VARIABLES

See `umem_debug(3MALLOC)` for environment variables that effect the debugging features of the `libumem` library.

UMEM_OPTIONS

Contains a list of comma-separated options. Unrecognized options are ignored. The options that are supported are:

`backend=sbrk`
`backend=mmap`

Set the underlying function used to allocate memory. This option can be set to `sbrk` (the default) for an `sbrk(2)`-based source or `mmap` for an `mmap(2)`-based source. If set to a value that is not supported, `sbrk` will be used.

EXAMPLES

EXAMPLE 1 Using the `umem_alloc()` function

```
#include <stdio.h>
#include <umem.h>
...
char *buf = umem_alloc(1024, UMEM_DEFAULT);

if (buf == NULL) {
    fprintf(stderr, "out of memory\n");
}
```

EXAMPLE 1 Using the umem_alloc() function (Continued)

```

        return (1);
    }
    /* cannot assume anything about buf's contents */
    ...
    umem_free(buf, 1024);
    ...

```

EXAMPLE 2 Using the umem_zalloc() function

```

#include <stdio.h>
#include <umem.h>
...
char *buf = umem_zalloc(1024, UMEM_DEFAULT);

if (buf == NULL) {
    fprintf(stderr, "out of memory\n");
    return (1);
}
/* buf contains zeros */
...
umem_free(buf, 1024);
...

```

EXAMPLE 3 Using UMEM_NOFAIL

```

#include <stdlib.h>
#include <stdio.h>
#include <umem.h>

/*
 * Note that the allocation code below does not have to
 * check for umem_alloc() returning NULL
 */
int
my_failure_handler(void)
{
    (void) fprintf(stderr, "out of memory\n");
    return (UMEM_CALLBACK_EXIT(255));
}
...
umem_nofail_callback(my_failure_handler);
...
int i;
char *buf[100];

for (i = 0; i < 100; i++)
    buf[i] = umem_alloc(1024 * 1024, UMEM_NOFAIL);
...
for (i = 0; i < 100; i++)
    umem_free(buf[i], 1024 * 1024);
...

```

umem_alloc(3MALLOC)

EXAMPLE 4 Using UMEM_NOFAIL in a multithreaded application

```
#define _REENTRANT
#include <thread.h>
#include <stdio.h>
#include <umem.h>

void *
start_func(void *the_arg)
{
    int *info = (int *)the_arg;
    char *buf = umem_alloc(1024 * 1024, UMEM_NOFAIL);

    /* does not need to check for buf == NULL */
    buf[0] = 0;
    ...
    /*
     * if there were other UMEM_NOFAIL allocations,
     * we would need to arrange for buf to be
     * umem_free()ed upon failure.
     */
    ...
    umem_free(buf, 1024 * 1024);
    return (the_arg);
}
...
int
my_failure_handler(void)
{
    /* terminate the current thread with status NULL */
    thr_exit(NULL);
}
...
umem_nofail_callback(my_failure_handler);
...
int my_arg;

thread_t tid;
void *status;

(void) thr_create(NULL, NULL, start_func, &my_arg, 0,
                 NULL);
...
while (thr_join(0, &tid, &status) != 0)
    ;

if (status == NULL) {
    (void) fprintf(stderr, "thread %d ran out of memory\n",
                  tid);
}
...
```

ATTRIBUTES See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Interface Stability	malloc(), calloc(), free(), realloc(), and valloc() are Standard. memalign() is Stable. umem_alloc(), umem_zalloc(), umem_free(), and umem_nofail_callback() are Evolving.

Solaris Modular Debugger Guide

WARNINGS Any of the following can cause undefined results:

- Passing a pointer returned from umem_alloc() or umem_zalloc() to free() or realloc().
- Passing a pointer returned from malloc(), calloc(), valloc(), memalign(), or realloc() to umem_free().
- Writing past the end of a buffer allocated using umem_alloc() or umem_zalloc().
- Performing UMEM_NOFAIL allocations from an atexit(3C) handler.

If the UMEM_NOFAIL callback performs UMEM_NOFAIL allocations, infinite recursion can occur.

NOTES The following list compares the features of the malloc(3C), bsdmalloc(3MALLOC), malloc(3MALLOC), mtmalloc(3MALLOC), and the libumem functions.

- The malloc(3C), bsdmalloc(3MALLOC), and malloc(3MALLOC) functions have no support for concurrency. The libumem and mtmalloc(3MALLOC) functions support concurrent allocations.
- The bsdmalloc(3MALLOC) functions afford better performance but are space-inefficient.
- The malloc(3MALLOC) functions are space-efficient but have slower performance.
- The standard, fully SCD-compliant malloc(3C) functions are a trade-off between performance and space-efficiency.
- The mtmalloc(3MALLOC) functions provide fast, concurrent malloc() implementations that are not space-efficient.
- The libumem functions provide a fast, concurrent allocation implementation that in most cases is more space-efficient than mtmalloc(3MALLOC).

umem_cache_alloc(3MALLOC)

NAME	umem_cache_create, umem_cache_destroy, umem_cache_alloc, umem_cache_free – allocation cache manipulation																		
SYNOPSIS	<pre>cc [<i>flag ...</i>] <i>file...</i> -lumem [<i>library ...</i>] #include <umem.h> umem_cache_t * umem_cache_create(char *<i>debug_name</i>, size_t <i>bufsize</i>, size_t <i>align</i>, umem_constructor_t *<i>constructor</i>, umem_destructor_t *<i>destructor</i>, umem_reclaim_t *<i>reclaim</i>, void *<i>callback_data</i>, vmem_t *<i>source</i>, int <i>cflags</i>); void umem_cache_destroy(umem_cache_t *<i>cache</i>); void umem_cache_alloc(umem_cache_t *<i>cache</i>, int <i>flags</i>); void umem_cache_free(umem_cache_t *<i>cache</i>, void *<i>buffer</i>);</pre>																		
DESCRIPTION	<p>These functions create, destroy, and use an "object cache". An object cache is a collection of buffers of a single size, with optional content caching enabled by the use of callbacks (see Cache Callbacks). Object caches are MT-Safe. Multiple allocations and freeing of memory from different threads can proceed simultaneously. Object caches are faster and use less space per buffer than malloc(3MALLOC) and umem_alloc(3MALLOC). For more information about object caching, see "The Slab Allocator: An Object-Caching Kernel Memory Allocator" and "Magazines and vmem: Extending the Slab Allocator to Many CPUs and Arbitrary Resources".</p> <p>The umem_cache_create() function creates object caches. Once a cache has been created, objects can be requested from and returned to the cache using umem_cache_alloc() and umem_cache_free(), respectively. A cache with no outstanding buffers can be destroyed with umem_cache_destroy().</p>																		
Creating and Destroying Caches	<p>The umem_cache_create() function creates a cache of objects and takes as arguments the following:</p> <table><tr><td><i>debug_name</i></td><td>A human-readable name for debugging purposes.</td></tr><tr><td><i>bufsize</i></td><td>The size, in bytes, of the buffers in this cache.</td></tr><tr><td><i>align</i></td><td>The minimum alignment required for buffers in this cache. This parameter must be a power of 2. If 0, it is replaced with the minimum required alignment for the current architecture.</td></tr><tr><td><i>constructor</i></td><td>The callback to construct an object.</td></tr><tr><td><i>destructor</i></td><td>The callback to destroy an object.</td></tr><tr><td><i>reclaim</i></td><td>The callback to reclaim objects.</td></tr><tr><td><i>callback_data</i></td><td>An opaque pointer passed to the callbacks.</td></tr><tr><td><i>source</i></td><td>This parameter must be NULL.</td></tr><tr><td><i>cflags</i></td><td>This parameter must be either 0 or UMC_NODEBUG. If UMC_NODEBUG, all debugging features are disabled for</td></tr></table>	<i>debug_name</i>	A human-readable name for debugging purposes.	<i>bufsize</i>	The size, in bytes, of the buffers in this cache.	<i>align</i>	The minimum alignment required for buffers in this cache. This parameter must be a power of 2. If 0, it is replaced with the minimum required alignment for the current architecture.	<i>constructor</i>	The callback to construct an object.	<i>destructor</i>	The callback to destroy an object.	<i>reclaim</i>	The callback to reclaim objects.	<i>callback_data</i>	An opaque pointer passed to the callbacks.	<i>source</i>	This parameter must be NULL.	<i>cflags</i>	This parameter must be either 0 or UMC_NODEBUG. If UMC_NODEBUG, all debugging features are disabled for
<i>debug_name</i>	A human-readable name for debugging purposes.																		
<i>bufsize</i>	The size, in bytes, of the buffers in this cache.																		
<i>align</i>	The minimum alignment required for buffers in this cache. This parameter must be a power of 2. If 0, it is replaced with the minimum required alignment for the current architecture.																		
<i>constructor</i>	The callback to construct an object.																		
<i>destructor</i>	The callback to destroy an object.																		
<i>reclaim</i>	The callback to reclaim objects.																		
<i>callback_data</i>	An opaque pointer passed to the callbacks.																		
<i>source</i>	This parameter must be NULL.																		
<i>cflags</i>	This parameter must be either 0 or UMC_NODEBUG. If UMC_NODEBUG, all debugging features are disabled for																		

umem_cache_alloc(3MALLOC)

this cache. See umem_debug(3MALLOC).

Each cache can have up to three associated callbacks:

```
int constructor(void *buffer, void *callback_data, int flags);
void destructor(void *buffer, void *callback_data);
void reclaim(void *callback_data);
```

The *callback_data* argument is always equal to the value passed to `umem_cache_create()`, thereby allowing a client to use the same callback functions for multiple caches, but with customized behavior.

The reclaim callback is called when the umem function is requesting more memory from the operating system. This callback can be used by clients who retain objects longer than they are strictly needed (for example, caching non-active state). A typical reclaim callback might return to the cache ten per cent of the unneeded buffers.

The constructor and destructor callbacks enable the management of buffers with the constructed state. The constructor takes as arguments a buffer with undefined contents, some callback data, and the flags to use for any allocations. This callback should transform the buffer into the constructed state.

The destructor callback takes as an argument a constructed object and prepares it for return to the general pool of memory. The destructor should undo any state that the constructor created. For debugging, the destructor can also check that the buffer is in the constructed state, to catch incorrectly freed buffers. See `umem_debug(3MALLOC)` for further information on debugging support.

The `umem_cache_destroy()` function destroys an object cache. If the cache has any outstanding allocations, the behavior is undefined.

Allocating Objects

The `umem_cache_alloc()` function takes as arguments:

<i>cache</i>	a cache pointer
<i>flags</i>	flags that determine the behavior if <code>umem_cache_alloc()</code> is unable to fulfill the allocation request

If successful, `umem_cache_alloc()` returns a pointer to the beginning of an object of *bufsize* length.

There are three cases to consider:

- A new buffer needed to be allocated. If the cache was created with a constructor, it is applied to the buffer and the resulting object is returned.
- The object cache was able to use a previously freed buffer. If the cache was created with a constructor, the object is returned unchanged from when it was freed.
- The allocation of a new buffer failed. The *flags* argument determines the behavior:

umem_cache_alloc(3MALLOC)

	UMEM_DEFAULT	The <code>umem_cache_alloc()</code> function returns NULL if the allocation fails.
	UMEM_NOFAIL	The <code>umem_cache_alloc()</code> function cannot return NULL. A callback is used to determine what action occurs. See <code>umem_alloc(3MALLOC)</code> for more information.
Freeing Objects	The <code>umem_cache_free()</code> function takes as arguments: <i>cache</i> a cache pointer <i>buf</i> a pointer previously returned from <code>umem_cache_alloc()</code> . This argument must not be NULL. If the cache was created with a constructor callback, the object must be returned to the constructed state before it is freed. Undefined behavior results if an object is freed multiple times, if an object is modified after it is freed, or if an object is freed to a cache other than the one from which it was allocated.	
Caches with Constructors	When a constructor callback is in use, there is essentially a contract between the cache and its clients. The cache guarantees that all objects returned from <code>umem_cache_alloc()</code> will be in the constructed state, and the client guarantees that it will return the object to the constructed state before handing it to <code>umem_cache_free()</code> .	
RETURN VALUES	Upon failure, the <code>umem_cache_create()</code> function returns a null pointer.	
ERRORS	The <code>umem_cache_create()</code> function will fail if: EAGAIN There is not enough memory available to allocate the cache data structure. EINVAL The <i>debug_name</i> argument is NULL, the <i>align</i> argument is not a power of two or is larger than the system pagesize, or the <i>bufsize</i> argument is 0. ENOMEM The <code>libumem</code> library could not be initialized, or the <i>bufsize</i> argument is too large and its use would cause integer overflow to occur.	
EXAMPLES	EXAMPLE 1 Use a fixed-size structure with no constructor callback. <pre>#include <umem.h> typedef struct my_obj { long my_data1; } my_obj_t; /*</pre>	

EXAMPLE 1 Use a fixed-size structure with no constructor callback. (Continued)

```

* my_objs can be freed at any time. The contents of
* my_data1 is undefined at allocation time.
*/

umem_cache_t *my_obj_cache;

...
my_obj_cache = umem_cache_create("my_obj", sizeof (my_obj_t),
    0, NULL, NULL, NULL, NULL, NULL, 0);
...
my_obj_t *cur = umem_cache_alloc(my_obj_cache, UMEM_DEFAULT);
...
/* use cur */
...
umem_cache_free(my_obj_cache, cur);
...

```

EXAMPLE 2 Use an object with a mutex.

```

#define _REENTRANT
#include <synch.h>
#include <umem.h>

typedef struct my_obj {
    mutex_t my_mutex;
    long my_data;
} my_obj_t;

/*
* my_objs can only be freed when my_mutex is unlocked.
*/
int
my_obj_constructor(void *buf, void *ignored, int flags)
{
    my_obj_t *myobj = buf;

    (void) mutex_init(&my_obj->my_mutex, USYNC_THREAD, NULL);

    return (0);
}

void
my_obj_destructor(void *buf, void *ignored)
{
    my_obj_t *myobj = buf;

    (void) mutex_destroy(&my_obj->my_mutex);
}

umem_cache_t *my_obj_cache;

...
my_obj_cache = umem_cache_create("my_obj", sizeof (my_obj_t),
    0, my_obj_constructor, my_obj_destructor, NULL, NULL,

```

umem_cache_alloc(3MALLOC)

EXAMPLE 2 Use an object with a mutex. *(Continued)*

```
        NULL, 0);
...
my_obj_t *cur = umem_cache_alloc(my_obj_cache, UMEM_DEFAULT);
cur->my_data = 0;          /* cannot assume anything about my_data */
...
umem_cache_free(my_obj_cache, cur);
...
```

EXAMPLE 3 Use a more complex object with a mutex.

```
#define _REENTRANT
#include <assert.h>
#include <synch.h>
#include <umem.h>

typedef struct my_obj {

Bonwick, Jeff and Jonathan Adams, "Magazines and vmem: Extending the Slab Allocator to Many CPUs and Arbitrary Resources", Proceedings of the Summer 2001 Usenix Conference.

WARNINGS Any of the following can cause undefined results:

- Destroying a cache that has outstanding allocated buffers.
- Using a cache after it has been destroyed.
- Calling `umem_cache_free()` on the same buffer multiple times.
- Passing a `NULL` pointer to `umem_cache_free()`.

- Writing past the end of a buffer.
- Reading from or writing to a buffer after it has been freed.
- Performing UMEM_NOFAIL allocations from an atexit(3C) handler.

Per-cache callbacks can be called from a variety of contexts. The use of functions that modify the active context, such as `setcontext(2)`, `swapcontext(3C)`, and `thr_exit(3THR)`, or functions that are unsafe for use in multithreaded applications, such as `longjmp(3C)` and `siglongjmp(3C)`, result in undefined behavior.

A constructor callback that performs allocations must pass its *flags* argument unchanged to `umem_alloc(3MALLOC)` and `umem_cache_alloc()`. Any allocations made with a different *flags* argument results in undefined behavior. The constructor must correctly handle the failure of any allocations it makes.

NOTES Object caches make the following guarantees about objects:

- If the cache has a constructor callback, it is applied to every object before it is returned from `umem_cache_alloc()` for the first time.
- If the cache has a constructor callback, an object passed to `umem_cache_free()` and later returned from `umem_cache_alloc()` is not modified between the two events.
- If the cache has a destructor, it is applied to all objects before their underlying storage is returned.

No other guarantees are made. In particular, even if there are buffers recently freed to the cache, `umem_cache_alloc()` can fail.

umem_cache_create(3MALLOC)

NAME	umem_cache_create, umem_cache_destroy, umem_cache_alloc, umem_cache_free – allocation cache manipulation																		
SYNOPSIS	<pre>cc [flag ...] file... -lumem [library ...] #include <umem.h> umem_cache_t * umem_cache_create(char *debug_name, size_t bufsize, size_t align, umem_constructor_t *constructor, umem_destructor_t *destructor, umem_reclaim_t *reclaim, void *callback_data, vmem_t *source, int cflags); void umem_cache_destroy(umem_cache_t *cache); void umem_cache_alloc(umem_cache_t *cache, int flags); void umem_cache_free(umem_cache_t *cache, void *buffer);</pre>																		
DESCRIPTION	<p>These functions create, destroy, and use an "object cache". An object cache is a collection of buffers of a single size, with optional content caching enabled by the use of callbacks (see Cache Callbacks). Object caches are MT-Safe. Multiple allocations and freeing of memory from different threads can proceed simultaneously. Object caches are faster and use less space per buffer than malloc(3MALLOC) and umem_alloc(3MALLOC). For more information about object caching, see "The Slab Allocator: An Object-Caching Kernel Memory Allocator" and "Magazines and vmem: Extending the Slab Allocator to Many CPUs and Arbitrary Resources".</p> <p>The umem_cache_create() function creates object caches. Once a cache has been created, objects can be requested from and returned to the cache using umem_cache_alloc() and umem_cache_free(), respectively. A cache with no outstanding buffers can be destroyed with umem_cache_destroy().</p>																		
Creating and Destroying Caches	<p>The umem_cache_create() function creates a cache of objects and takes as arguments the following:</p> <table border="0" style="width: 100%;"> <tr> <td style="padding-right: 20px;"><i>debug_name</i></td> <td>A human-readable name for debugging purposes.</td> </tr> <tr> <td><i>bufsize</i></td> <td>The size, in bytes, of the buffers in this cache.</td> </tr> <tr> <td><i>align</i></td> <td>The minimum alignment required for buffers in this cache. This parameter must be a power of 2. If 0, it is replaced with the minimum required alignment for the current architecture.</td> </tr> <tr> <td><i>constructor</i></td> <td>The callback to construct an object.</td> </tr> <tr> <td><i>destructor</i></td> <td>The callback to destroy an object.</td> </tr> <tr> <td><i>reclaim</i></td> <td>The callback to reclaim objects.</td> </tr> <tr> <td><i>callback_data</i></td> <td>An opaque pointer passed to the callbacks.</td> </tr> <tr> <td><i>source</i></td> <td>This parameter must be NULL.</td> </tr> <tr> <td><i>cflags</i></td> <td>This parameter must be either 0 or UMC_NODEBUG. If UMC_NODEBUG, all debugging features are disabled for</td> </tr> </table>	<i>debug_name</i>	A human-readable name for debugging purposes.	<i>bufsize</i>	The size, in bytes, of the buffers in this cache.	<i>align</i>	The minimum alignment required for buffers in this cache. This parameter must be a power of 2. If 0, it is replaced with the minimum required alignment for the current architecture.	<i>constructor</i>	The callback to construct an object.	<i>destructor</i>	The callback to destroy an object.	<i>reclaim</i>	The callback to reclaim objects.	<i>callback_data</i>	An opaque pointer passed to the callbacks.	<i>source</i>	This parameter must be NULL.	<i>cflags</i>	This parameter must be either 0 or UMC_NODEBUG. If UMC_NODEBUG, all debugging features are disabled for
<i>debug_name</i>	A human-readable name for debugging purposes.																		
<i>bufsize</i>	The size, in bytes, of the buffers in this cache.																		
<i>align</i>	The minimum alignment required for buffers in this cache. This parameter must be a power of 2. If 0, it is replaced with the minimum required alignment for the current architecture.																		
<i>constructor</i>	The callback to construct an object.																		
<i>destructor</i>	The callback to destroy an object.																		
<i>reclaim</i>	The callback to reclaim objects.																		
<i>callback_data</i>	An opaque pointer passed to the callbacks.																		
<i>source</i>	This parameter must be NULL.																		
<i>cflags</i>	This parameter must be either 0 or UMC_NODEBUG. If UMC_NODEBUG, all debugging features are disabled for																		

umem_cache_create(3MALLOC)

this cache. See umem_debug(3MALLOC).

Each cache can have up to three associated callbacks:

```
int constructor(void *buffer, void *callback_data, int flags);
void destructor(void *buffer, void *callback_data);
void reclaim(void *callback_data);
```

The *callback_data* argument is always equal to the value passed to `umem_cache_create()`, thereby allowing a client to use the same callback functions for multiple caches, but with customized behavior.

The reclaim callback is called when the umem function is requesting more memory from the operating system. This callback can be used by clients who retain objects longer than they are strictly needed (for example, caching non-active state). A typical reclaim callback might return to the cache ten per cent of the unneeded buffers.

The constructor and destructor callbacks enable the management of buffers with the constructed state. The constructor takes as arguments a buffer with undefined contents, some callback data, and the flags to use for any allocations. This callback should transform the buffer into the constructed state.

The destructor callback takes as an argument a constructed object and prepares it for return to the general pool of memory. The destructor should undo any state that the constructor created. For debugging, the destructor can also check that the buffer is in the constructed state, to catch incorrectly freed buffers. See `umem_debug(3MALLOC)` for further information on debugging support.

The `umem_cache_destroy()` function destroys an object cache. If the cache has any outstanding allocations, the behavior is undefined.

Allocating Objects

The `umem_cache_alloc()` function takes as arguments:

<i>cache</i>	a cache pointer
<i>flags</i>	flags that determine the behavior if <code>umem_cache_alloc()</code> is unable to fulfill the allocation request

If successful, `umem_cache_alloc()` returns a pointer to the beginning of an object of *bufsize* length.

There are three cases to consider:

- A new buffer needed to be allocated. If the cache was created with a constructor, it is applied to the buffer and the resulting object is returned.
- The object cache was able to use a previously freed buffer. If the cache was created with a constructor, the object is returned unchanged from when it was freed.
- The allocation of a new buffer failed. The *flags* argument determines the behavior:

umem_cache_create(3MALLOC)

	UMEM_DEFAULT	The <code>umem_cache_alloc()</code> function returns NULL if the allocation fails.
	UMEM_NOFAIL	The <code>umem_cache_alloc()</code> function cannot return NULL. A callback is used to determine what action occurs. See <code>umem_alloc(3MALLOC)</code> for more information.
Freeing Objects	The <code>umem_cache_free()</code> function takes as arguments: <i>cache</i> a cache pointer <i>buf</i> a pointer previously returned from <code>umem_cache_alloc()</code> . This argument must not be NULL. If the cache was created with a constructor callback, the object must be returned to the constructed state before it is freed. Undefined behavior results if an object is freed multiple times, if an object is modified after it is freed, or if an object is freed to a cache other than the one from which it was allocated.	
Caches with Constructors	When a constructor callback is in use, there is essentially a contract between the cache and its clients. The cache guarantees that all objects returned from <code>umem_cache_alloc()</code> will be in the constructed state, and the client guarantees that it will return the object to the constructed state before handing it to <code>umem_cache_free()</code> .	
RETURN VALUES	Upon failure, the <code>umem_cache_create()</code> function returns a null pointer.	
ERRORS	The <code>umem_cache_create()</code> function will fail if: EAGAIN There is not enough memory available to allocate the cache data structure. EINVAL The <i>debug_name</i> argument is NULL, the <i>align</i> argument is not a power of two or is larger than the system pagesize, or the <i>bufsize</i> argument is 0. ENOMEM The <code>libumem</code> library could not be initialized, or the <i>bufsize</i> argument is too large and its use would cause integer overflow to occur.	
EXAMPLES	EXAMPLE 1 Use a fixed-size structure with no constructor callback. <pre>#include <umem.h> typedef struct my_obj { long my_data1; } my_obj_t; /*</pre>	

EXAMPLE 1 Use a fixed-size structure with no constructor callback. (Continued)

```

* my_objs can be freed at any time. The contents of
* my_data1 is undefined at allocation time.
*/

umem_cache_t *my_obj_cache;

...
my_obj_cache = umem_cache_create("my_obj", sizeof (my_obj_t),
    0, NULL, NULL, NULL, NULL, NULL, 0);
...
my_obj_t *cur = umem_cache_alloc(my_obj_cache, UMEM_DEFAULT);
...
/* use cur */
...
umem_cache_free(my_obj_cache, cur);
...

```

EXAMPLE 2 Use an object with a mutex.

```

#define _REENTRANT
#include <synch.h>
#include <umem.h>

typedef struct my_obj {
    mutex_t my_mutex;
    long my_data;
} my_obj_t;

/*
* my_objs can only be freed when my_mutex is unlocked.
*/
int
my_obj_constructor(void *buf, void *ignored, int flags)
{
    my_obj_t *myobj = buf;

    (void) mutex_init(&my_obj->my_mutex, USYNC_THREAD, NULL);

    return (0);
}

void
my_obj_destructor(void *buf, void *ignored)
{
    my_obj_t *myobj = buf;

    (void) mutex_destroy(&my_obj->my_mutex);
}

umem_cache_t *my_obj_cache;

...
my_obj_cache = umem_cache_create("my_obj", sizeof (my_obj_t),
    0, my_obj_constructor, my_obj_destructor, NULL, NULL,

```

umem_cache_create(3MALLOC)

EXAMPLE 2 Use an object with a mutex. (Continued)

```
        NULL, 0);
...
my_obj_t *cur = umem_cache_alloc(my_obj_cache, UMEM_DEFAULT);
cur->my_data = 0;          /* cannot assume anything about my_data */
...
umem_cache_free(my_obj_cache, cur);
...
```

EXAMPLE 3 Use a more complex object with a mutex.

```
#define _REENTRANT
#include <assert.h>
#include <synch.h>
#include <umem.h>

typedef struct my_obj {
    mutex_t my_mutex;
    cond_t my_cv;
    struct bar *my_barlist;
    unsigned my_refcount;
} my_obj_t;

/*
 * my_objs can only be freed when my_barlist == NULL,
 * my_refcount == 0, there are no waiters on my_cv, and
 * my_mutex is unlocked.
 */

int
my_obj_constructor(void *buf, void *ignored, int flags)
{
    my_obj_t *myobj = buf;

    (void) mutex_init(&my_obj->my_mutex, USYNC_THREAD, NULL);
    (void) cond_init(&my_obj->my_cv, USYNC_THREAD, NULL);
    myobj->my_barlist = NULL;
    myobj->my_refcount = 0;

    return (0);
}

void
my_obj_destructor(void *buf, void *ignored)
{
    my_obj_t *myobj = buf;

    assert(myobj->my_refcount == 0);
    assert(myobj->my_barlist == NULL);
    (void) cond_destroy(&my_obj->my_cv);
    (void) mutex_destroy(&my_obj->my_mutex);
}

umem_cache_t *my_obj_cache;
```

EXAMPLE 3 Use a more complex object with a mutex. (Continued)

```

...
my_obj_cache = umem_cache_create("my_obj", sizeof (my_obj_t),
    0, my_obj_constructor, my_obj_destructor, NULL, NULL,
    NULL, 0);
...
my_obj_t *cur = umem_cache_alloc(my_obj_cache, UMEM_DEFAULT);
...
/* use cur */
...
umem_cache_free(my_obj_cache, cur);
...

```

EXAMPLE 4 Use objects with a subordinate buffer while reusing callbacks.

```

#include assert.h>
#include umem.h>

typedef struct my_obj {
    char *my_buffer;
    size_t my_size;
} my_obj_t;

/*
 * my_size and the my_buffer pointer should never be changed
 */

int
my_obj_constructor(void *buf, void *arg, int flags)
{
    size_t sz = (size_t)arg;

    my_obj_t *myobj = buf;

    if ((myobj->my_buffer = umem_alloc(sz, flags)) == NULL)
        return (1);

    my_size = sz;

    return (0);
}

void
my_obj_destructor(void *buf, void *arg)
{
    size_t sz = (size_t)arg;

    my_obj_t *myobj = buf;

    assert(sz == buf->my_size);
    umem_free(myobj->my_buffer, sz);
}

...
umem_cache_t *my_obj_4k_cache;

```

umem_cache_create(3MALLOC)

EXAMPLE 4 Use objects with a subordinate buffer while reusing callbacks. *(Continued)*

```
umem_cache_t *my_obj_8k_cache;
...
my_obj_cache_4k = umem_cache_create("my_obj_4k", sizeof (my_obj_t),
    0, my_obj_constructor, my_obj_destructor, NULL, (void *)4096,
    NULL, 0);

my_obj_cache_8k = umem_cache_create("my_obj_8k", sizeof (my_obj_t),
    0, my_obj_constructor, my_obj_destructor, NULL, (void *)8192,
    NULL, 0);
...
my_obj_t *my_obj_4k = umem_cache_alloc(my_obj_4k_cache,
    UMEM_DEFAULT);
my_obj_t *my_obj_8k = umem_cache_alloc(my_obj_8k_cache,
    UMEM_DEFAULT);
/* no assumptions should be made about the contents of the buffers */
...
/* make sure to return them to the correct cache */
umem_cache_free(my_obj_4k_cache, my_obj_4k);
umem_cache_free(my_obj_8k_cache, my_obj_8k);
...
```

See the **EXAMPLES** section of `umem_alloc(3MALLOC)` for examples involving the `UMEM_NOFAIL` flag.

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Interface Stability	Evolving
MT-Level	MT-Safe

SEE ALSO `setcontext(2)`, `atexit(3C)`, `libumem(3LIB)`, `longjmp(3C)`, `swapcontext(3C)`, `thr_exit(3THR)`, `umem_alloc(3MALLOC)`, `umem_debug(3MALLOC)`, `attributes(5)`

Bonwick, Jeff and Jonathan Adams, "Magazines and vmem: Extending the Slab Allocator to Many CPUs and Arbitrary Resources", Proceedings of the Summer 2001 Usenix Conference.

WARNINGS Any of the following can cause undefined results:

- Destroying a cache that has outstanding allocated buffers.
- Using a cache after it has been destroyed.
- Calling `umem_cache_free()` on the same buffer multiple times.
- Passing a `NULL` pointer to `umem_cache_free()`.

- Writing past the end of a buffer.
- Reading from or writing to a buffer after it has been freed.
- Performing UMEM_NOFAIL allocations from an atexit(3C) handler.

Per-cache callbacks can be called from a variety of contexts. The use of functions that modify the active context, such as `setcontext(2)`, `swapcontext(3C)`, and `thr_exit(3THR)`, or functions that are unsafe for use in multithreaded applications, such as `longjmp(3C)` and `siglongjmp(3C)`, result in undefined behavior.

A constructor callback that performs allocations must pass its *flags* argument unchanged to `umem_alloc(3MALLOC)` and `umem_cache_alloc()`. Any allocations made with a different *flags* argument results in undefined behavior. The constructor must correctly handle the failure of any allocations it makes.

NOTES Object caches make the following guarantees about objects:

- If the cache has a constructor callback, it is applied to every object before it is returned from `umem_cache_alloc()` for the first time.
- If the cache has a constructor callback, an object passed to `umem_cache_free()` and later returned from `umem_cache_alloc()` is not modified between the two events.
- If the cache has a destructor, it is applied to all objects before their underlying storage is returned.

No other guarantees are made. In particular, even if there are buffers recently freed to the cache, `umem_cache_alloc()` can fail.

umem_cache_destroy(3MALLOC)

NAME	umem_cache_create, umem_cache_destroy, umem_cache_alloc, umem_cache_free – allocation cache manipulation																		
SYNOPSIS	<pre>cc [<i>flag ...</i>] <i>file...</i> -lumem [<i>library ...</i>] #include <umem.h> umem_cache_t * umem_cache_create(char *<i>debug_name</i>, size_t <i>bufsize</i>, size_t <i>align</i>, umem_constructor_t *<i>constructor</i>, umem_destructor_t *<i>destructor</i>, umem_reclaim_t *<i>reclaim</i>, void *<i>callback_data</i>, vmem_t *<i>source</i>, int <i>cflags</i>); void umem_cache_destroy(umem_cache_t *<i>cache</i>); void umem_cache_alloc(umem_cache_t *<i>cache</i>, int <i>flags</i>); void umem_cache_free(umem_cache_t *<i>cache</i>, void *<i>buffer</i>);</pre>																		
DESCRIPTION	<p>These functions create, destroy, and use an "object cache". An object cache is a collection of buffers of a single size, with optional content caching enabled by the use of callbacks (see Cache Callbacks). Object caches are MT-Safe. `umem_cache_destroy(3MALLOC)`

this cache. See `umem_debug(3MALLOC)`.

Each cache can have up to three associated callbacks:

```
int constructor(void *buffer, void *callback_data, int flags);
void destructor(void *buffer, void *callback_data);
void reclaim(void *callback_data);
```

The `callback_data` argument is always equal to the value passed to `umem_cache_create()`, thereby allowing a client to use the same callback functions for multiple caches, but with customized behavior.

The reclaim callback is called when the `umem` function is requesting more memory from the operating system. This callback can be used by clients who retain objects longer than they are strictly needed (for example, caching non-active state). A typical reclaim callback might return to the cache ten per cent of the unneeded buffers.

The constructor and destructor callbacks enable the management of buffers with the constructed state. The constructor takes as arguments a buffer with undefined contents, some callback data, and the flags to use for any allocations. This callback should transform the buffer into the constructed state.

The destructor callback takes as an argument a constructed object and prepares it for return to the general pool of memory. The destructor should undo any state that the constructor created. For debugging, the destructor can also check that the buffer is in the constructed state, to catch incorrectly freed buffers. See `umem_debug(3MALLOC)` for further information on debugging support.

The `umem_cache_destroy()` function destroys an object cache. If the cache has any outstanding allocations, the behavior is undefined.

Allocating Objects

The `umem_cache_alloc()` function takes as arguments:

<i>cache</i>	a cache pointer
<i>flags</i>	flags that determine the behavior if <code>umem_cache_alloc()</code> is unable to fulfill the allocation request

If successful, `umem_cache_alloc()` returns a pointer to the beginning of an object of *bufsize* length.

There are three cases to consider:

- A new buffer needed to be allocated. If the cache was created with a constructor, it is applied to the buffer and the resulting object is returned.
- The object cache was able to use a previously freed buffer. If the cache was created with a constructor, the object is returned unchanged from when it was freed.
- The allocation of a new buffer failed. The *flags* argument determines the behavior:

umem_cache_destroy(3MALLOC)

	UMEM_DEFAULT	The <code>umem_cache_alloc()</code> function returns NULL if the allocation fails.
	UMEM_NOFAIL	The <code>umem_cache_alloc()</code> function cannot return NULL. A callback is used to determine what action occurs. See <code>umem_alloc(3MALLOC)</code> for more information.
Freeing Objects	The <code>umem_cache_free()</code> function takes as arguments: <i>cache</i> a cache pointer <i>buf</i> a pointer previously returned from <code>umem_cache_alloc()</code> . This argument must not be NULL. If the cache was created with a constructor callback, the object must be returned to the constructed state before it is freed. Undefined behavior results if an object is freed multiple times, if an object is modified after it is freed, or if an object is freed to a cache other than the one from which it was allocated.	
Caches with Constructors	When a constructor callback is in use, there is essentially a contract between the cache and its clients. The cache guarantees that all objects returned from <code>umem_cache_alloc()</code> will be in the constructed state, and the client guarantees that it will return the object to the constructed state before handing it to <code>umem_cache_free()</code> .	
RETURN VALUES	Upon failure, the <code>umem_cache_create()</code> function returns a null pointer.	
ERRORS	The <code>umem_cache_create()</code> function will fail if: EAGAIN There is not enough memory available to allocate the cache data structure. EINVAL The <i>debug_name</i> argument is NULL, the <i>align</i> argument is not a power of two or is larger than the system pagesize, or the <i>bufsize</i> argument is 0. ENOMEM The <code>libumem</code> library could not be initialized, or the <i>bufsize</i> argument is too large and its use would cause integer overflow to occur.	
EXAMPLES	EXAMPLE 1 Use a fixed-size structure with no constructor callback. <pre>#include <umem.h> typedef struct my_obj { long my_data1; } my_obj_t; /*</pre>	

EXAMPLE 1 Use a fixed-size structure with no constructor callback. (Continued)

```

* my_objs can be freed at any time. The contents of
* my_data1 is undefined at allocation time.
*/

umem_cache_t *my_obj_cache;

...
my_obj_cache = umem_cache_create("my_obj", sizeof (my_obj_t),
    0, NULL, NULL, NULL, NULL, NULL, 0);
...
my_obj_t *cur = umem_cache_alloc(my_obj_cache, UMEM_DEFAULT);
...
/* use cur */
...
umem_cache_free(my_obj_cache, cur);
...

```

EXAMPLE 2 Use an object with a mutex.

```

#define _REENTRANT
#include <synch.h>
#include <umem.h>

typedef struct my_obj {
    mutex_t my_mutex;
    long my_data;
} my_obj_t;

/*
* my_objs can only be freed when my_mutex is unlocked.
*/
int
my_obj_constructor(void *buf, void *ignored, int flags)
{
    my_obj_t *myobj = buf;

    (void) mutex_init(&my_obj->my_mutex, USYNC_THREAD, NULL);

    return (0);
}

void
my_obj_destructor(void *buf, void *ignored)
{
    my_obj_t *myobj = buf;

    (void) mutex_destroy(&my_obj->my_mutex);
}

umem_cache_t *my_obj_cache;

...
my_obj_cache = umem_cache_create("my_obj", sizeof (my_obj_t),
    0, my_obj_constructor, my_obj_destructor, NULL, NULL,

```

umem_cache_destroy(3MALLOC)

EXAMPLE 2 Use an object with a mutex. *(Continued)*

```
        NULL, 0);
...
my_obj_t *cur = umem_cache_alloc(my_obj_cache, UMEM_DEFAULT);
cur->my_data = 0;          /* cannot assume anything about my_data */
...
umem_cache_free(my_obj_cache, cur);
...
```

EXAMPLE 3 Use a more complex object with a mutex.

```
#define _REENTRANT
#include <assert.h>
#include <synch.h>
#include <umem.h>

typedef struct my_obj {
    mutex_t my_mutex;
    cond_t my_cv;
    struct bar *my_barlist;
    unsigned my_refcount;
} my_obj_t;

/*
 * my_objs can only be freed when my_barlist == NULL,
 * my_refcount == 0, there are no waiters on my_cv, and
 * my_mutex is unlocked.
 */

int
my_obj_constructor(void *buf, void *ignored, int flags)
{
    my_obj_t *myobj = buf;

    (void) mutex_init(&my_obj->my_mutex, USYNC_THREAD, NULL);
    (void) cond_init(&my_obj->my_cv, USYNC_THREAD, NULL);
    myobj->my_barlist = NULL;
    myobj->my_refcount = 0;

    return (0);
}

void
my_obj_destructor(void *buf, void *ignored)
{
    my_obj_t *myobj = buf;

    assert(myobj->my_refcount == 0);
    assert(myobj->my_barlist == NULL);
    (void) cond_destroy(&my_obj->my_cv);
    (void) mutex_destroy(&my_obj->my_mutex);
}

umem_cache_t *my_obj_cache;
```

EXAMPLE 3 Use a more complex object with a mutex. (Continued)

```

...
my_obj_cache = umem_cache_create("my_obj", sizeof (my_obj_t),
    0, my_obj_constructor, my_obj_destructor, NULL, NULL,
    NULL, 0);
...
my_obj_t *cur = umem_cache_alloc(my_obj_cache, UMEM_DEFAULT);
...
/* use cur */
...
umem_cache_free(my_obj_cache, cur);
...

```

EXAMPLE 4 Use objects with a subordinate buffer while reusing callbacks.

```

#include assert.h>
#include umem.h>

typedef struct my_obj {
    char *my_buffer;
    size_t my_size;
} my_obj_t;

/*
 * my_size and the my_buffer pointer should never be changed
 */

int
my_obj_constructor(void *buf, void *arg, int flags)
{
    size_t sz = (size_t)arg;

    my_obj_t *myobj = buf;

    if ((myobj->my_buffer = umem_alloc(sz, flags)) == NULL)
        return (1);

    my_size = sz;

    return (0);
}

void
my_obj_destructor(void *buf, void *arg)
{
    size_t sz = (size_t)arg;

    my_obj_t *myobj = buf;

    assert(sz == buf->my_size);
    umem_free(myobj->my_buffer, sz);
}

...
umem_cache_t *my_obj_4k_cache;

```

umem_cache_destroy(3MALLOC)

EXAMPLE 4 Use objects with a subordinate buffer while reusing callbacks. (Continued)

```
umem_cache_t *my_obj_8k_cache;
...
my_obj_cache_4k = umem_cache_create("my_obj_4k", sizeof (my_obj_t),
    0, my_obj_constructor, my_obj_destructor, NULL, (void *)4096,
    NULL, 0);

my_obj_cache_8k = umem_cache_create("my_obj_8k", sizeof (my_obj_t),
    0, my_obj_constructor, my_obj_destructor, NULL, (void *)8192,
    NULL, 0);
...
my_obj_t *my_obj_4k = umem_cache_alloc(my_obj_4k_cache,
    UMEM_DEFAULT);
my_obj_t *my_obj_8k = umem_cache_alloc(my_obj_8k_cache,
    UMEM_DEFAULT);
/* no assumptions should be made about the contents of the buffers */
...
/* make sure to return them to the correct cache */
umem_cache_free(my_obj_4k_cache, my_obj_4k);
umem_cache_free(my_obj_8k_cache, my_obj_8k);
...
```

See the EXAMPLES section of umem_alloc(3MALLOC) for examples involving the UMEM_NOFAIL flag.

WARNINGS Any of the following can cause undefined results:

- Destroying a cache that has outstanding allocated buffers.
- Using a cache after it has been destroyed.
- Calling umem_cache_free() on the same buffer multiple times.
- Passing a NULL pointer to umem_cache_free().

- Writing past the end of a buffer.
- Reading from or writing to a buffer after it has been freed.
- Performing UMEM_NOFAIL allocations from an atexit(3C) handler.

Per-cache callbacks can be called from a variety of contexts. The use of functions that modify the active context, such as `setcontext(2)`, `swapcontext(3C)`, and `thr_exit(3THR)`, or functions that are unsafe for use in multithreaded applications, such as `longjmp(3C)` and `siglongjmp(3C)`, result in undefined behavior.

A constructor callback that performs allocations must pass its *flags* argument unchanged to `umem_alloc(3MALLOC)` and `umem_cache_alloc()`. Any allocations made with a different *flags* argument results in undefined behavior. The constructor must correctly handle the failure of any allocations it makes.

NOTES Object caches make the following guarantees about objects:

- If the cache has a constructor callback, it is applied to every object before it is returned from `umem_cache_alloc()` for the first time.
- If the cache has a constructor callback, an object passed to `umem_cache_free()` and later returned from `umem_cache_alloc()` is not modified between the two events.
- If the cache has a destructor, it is applied to all objects before their underlying storage is returned.

No other guarantees are made. In particular, even if there are buffers recently freed to the cache, `umem_cache_alloc()` can fail.

umem_cache_free(3MALLOC)

NAME	umem_cache_create, umem_cache_destroy, umem_cache_alloc, umem_cache_free – allocation cache manipulation																		
SYNOPSIS	<pre>cc [<i>flag ...</i>] <i>file...</i> -lumem [<i>library ...</i>] #include <umem.h> umem_cache_t * umem_cache_create(char *<i>debug_name</i>, size_t <i>bufsize</i>, size_t <i>align</i>, umem_constructor_t *<i>constructor</i>, umem_destructor_t *<i>destructor</i>, umem_reclaim_t *<i>reclaim</i>, void *<i>callback_data</i>, vmem_t *<i>source</i>, int <i>cflags</i>); void umem_cache_destroy(umem_cache_t *<i>cache</i>); void umem_cache_alloc(umem_cache_t *<i>cache</i>, int <i>flags</i>); void umem_cache_free(umem_cache_t *<i>cache</i>, void *<i>buffer</i>);</pre>																		
DESCRIPTION	<p>These functions create, destroy, and use an "object cache". An object cache is a collection of buffers of a single size, with optional content caching enabled by the use of callbacks (see Cache Callbacks). Object caches are MT-Safe. Multiple allocations and freeing of memory from different threads can proceed simultaneously. Object caches are faster and use less space per buffer than malloc(3MALLOC) and umem_alloc(3MALLOC). For more information about object caching, see "The Slab Allocator: An Object-Caching Kernel Memory Allocator" and "Magazines and vmem: Extending the Slab Allocator to Many CPUs and Arbitrary Resources".</p> <p>The umem_cache_create() function creates object caches. Once a cache has been created, objects can be requested from and returned to the cache using umem_cache_alloc() and umem_cache_free(), respectively. A cache with no outstanding buffers can be destroyed with umem_cache_destroy().</p>																		
Creating and Destroying Caches	<p>The umem_cache_create() function creates a cache of objects and takes as arguments the following:</p> <table><tr><td><i>debug_name</i></td><td>A human-readable name for debugging purposes.</td></tr><tr><td><i>bufsize</i></td><td>The size, in bytes, of the buffers in this cache.</td></tr><tr><td><i>align</i></td><td>The minimum alignment required for buffers in this cache. This parameter must be a power of 2. If 0, it is replaced with the minimum required alignment for the current architecture.</td></tr><tr><td><i>constructor</i></td><td>The callback to construct an object.</td></tr><tr><td><i>destructor</i></td><td>The callback to destroy an object.</td></tr><tr><td><i>reclaim</i></td><td>The callback to reclaim objects.</td></tr><tr><td><i>callback_data</i></td><td>An opaque pointer passed to the callbacks.</td></tr><tr><td><i>source</i></td><td>This parameter must be NULL.</td></tr><tr><td><i>cflags</i></td><td>This parameter must be either 0 or UMC_NODEBUG. If UMC_NODEBUG, all debugging features are disabled for</td></tr></table>	<i>debug_name</i>	A human-readable name for debugging purposes.	<i>bufsize</i>	The size, in bytes, of the buffers in this cache.	<i>align</i>	The minimum alignment required for buffers in this cache. This parameter must be a power of 2. If 0, it is replaced with the minimum required alignment for the current architecture.	<i>constructor</i>	The callback to construct an object.	<i>destructor</i>	The callback to destroy an object.	<i>reclaim</i>	The callback to reclaim objects.	<i>callback_data</i>	An opaque pointer passed to the callbacks.	<i>source</i>	This parameter must be NULL.	<i>cflags</i>	This parameter must be either 0 or UMC_NODEBUG. If UMC_NODEBUG, all debugging features are disabled for
<i>debug_name</i>	A human-readable name for debugging purposes.																		
<i>bufsize</i>	The size, in bytes, of the buffers in this cache.																		
<i>align</i>	The minimum alignment required for buffers in this cache. This parameter must be a power of 2. If 0, it is replaced with the minimum required alignment for the current architecture.																		
<i>constructor</i>	The callback to construct an object.																		
<i>destructor</i>	The callback to destroy an object.																		
<i>reclaim</i>	The callback to reclaim objects.																		
<i>callback_data</i>	An opaque pointer passed to the callbacks.																		
<i>source</i>	This parameter must be NULL.																		
<i>cflags</i>	This parameter must be either 0 or UMC_NODEBUG. If UMC_NODEBUG, all debugging features are disabled for																		

umem_cache_free(3MALLOC)

this cache. See umem_debug(3MALLOC).

Each cache can have up to three associated callbacks:

```
int constructor(void *buffer, void *callback_data, int flags);
void destructor(void *buffer, void *callback_data);
void reclaim(void *callback_data);
```

The *callback_data* argument is always equal to the value passed to `umem_cache_create()`, thereby allowing a client to use the same callback functions for multiple caches, but with customized behavior.

The reclaim callback is called when the umem function is requesting more memory from the operating system. This callback can be used by clients who retain objects longer than they are strictly needed (for example, caching non-active state). A typical reclaim callback might return to the cache ten per cent of the unneeded buffers.

The constructor and destructor callbacks enable the management of buffers with the constructed state. The constructor takes as arguments a buffer with undefined contents, some callback data, and the flags to use for any allocations. This callback should transform the buffer into the constructed state.

The destructor callback takes as an argument a constructed object and prepares it for return to the general pool of memory. The destructor should undo any state that the constructor created. For debugging, the destructor can also check that the buffer is in the constructed state, to catch incorrectly freed buffers. See `umem_debug(3MALLOC)` for further information on debugging support.

The `umem_cache_destroy()` function destroys an object cache. If the cache has any outstanding allocations, the behavior is undefined.

Allocating Objects

The `umem_cache_alloc()` function takes as arguments:

<i>cache</i>	a cache pointer
<i>flags</i>	flags that determine the behavior if <code>umem_cache_alloc()</code> is unable to fulfill the allocation request

If successful, `umem_cache_alloc()` returns a pointer to the beginning of an object of *bufsize* length.

There are three cases to consider:

- A new buffer needed to be allocated. If the cache was created with a constructor, it is applied to the buffer and the resulting object is returned.
- The object cache was able to use a previously freed buffer. If the cache was created with a constructor, the object is returned unchanged from when it was freed.
- The allocation of a new buffer failed. The *flags* argument determines the behavior:

umem_cache_free(3MALLOC)

	UMEM_DEFAULT	The <code>umem_cache_alloc()</code> function returns NULL if the allocation fails.
	UMEM_NOFAIL	The <code>umem_cache_alloc()</code> function cannot return NULL. A callback is used to determine what action occurs. See <code>umem_alloc(3MALLOC)</code> for more information.
Freeing Objects	The <code>umem_cache_free()</code> function takes as arguments: <i>cache</i> a cache pointer <i>buf</i> a pointer previously returned from <code>umem_cache_alloc()</code> . This argument must not be NULL. If the cache was created with a constructor callback, the object must be returned to the constructed state before it is freed. Undefined behavior results if an object is freed multiple times, if an object is modified after it is freed, or if an object is freed to a cache other than the one from which it was allocated.	
Caches with Constructors	When a constructor callback is in use, there is essentially a contract between the cache and its clients. The cache guarantees that all objects returned from <code>umem_cache_alloc()</code> will be in the constructed state, and the client guarantees that it will return the object to the constructed state before handing it to <code>umem_cache_free()</code> .	
RETURN VALUES	Upon failure, the <code>umem_cache_create()</code> function returns a null pointer.	
ERRORS	The <code>umem_cache_create()</code> function will fail if: EAGAIN There is not enough memory available to allocate the cache data structure. EINVAL The <i>debug_name</i> argument is NULL, the <i>align</i> argument is not a power of two or is larger than the system pagesize, or the <i>bufsize</i> argument is 0. ENOMEM The <code>libumem</code> library could not be initialized, or the <i>bufsize</i> argument is too large and its use would cause integer overflow to occur.	
EXAMPLES	EXAMPLE 1 Use a fixed-size structure with no constructor callback. <pre>#include <umem.h> typedef struct my_obj { long my_data1; } my_obj_t; /*</pre>	

EXAMPLE 1 Use a fixed-size structure with no constructor callback. (Continued)

```

* my_objs can be freed at any time. The contents of
* my_data1 is undefined at allocation time.
*/

umem_cache_t *my_obj_cache;

...
my_obj_cache = umem_cache_create("my_obj", sizeof (my_obj_t),
    0, NULL, NULL, NULL, NULL, 0);
...
my_obj_t *cur = umem_cache_alloc(my_obj_cache, UMEM_DEFAULT);
...
/* use cur */
...
umem_cache_free(my_obj_cache, cur);
...

```

EXAMPLE 2 Use an object with a mutex.

```

#define _REENTRANT
#include <synch.h>
#include <umem.h>

typedef struct my_obj {
    mutex_t my_mutex;
    long my_data;
} my_obj_t;

/*
* my_objs can only be freed when my_mutex is unlocked.
*/
int
my_obj_constructor(void *buf, void *ignored, int flags)
{
    my_obj_t *myobj = buf;

    (void) mutex_init(&my_obj->my_mutex, USYNC_THREAD, NULL);

    return (0);
}

void
my_obj_destructor(void *buf, void *ignored)
{
    my_obj_t *myobj = buf;

    (void) mutex_destroy(&my_obj->my_mutex);
}

umem_cache_t *my_obj_cache;

...
my_obj_cache = umem_cache_create("my_obj", sizeof (my_obj_t),
    0, my_obj_constructor, my_obj_destructor, NULL, NULL,

```

umem_cache_free(3MALLOC)

EXAMPLE 2 Use an object with a mutex. (Continued)

```
        NULL, 0);
...
my_obj_t *cur = umem_cache_alloc(my_obj_cache, UMEM_DEFAULT);
cur->my_data = 0;          /* cannot assume anything about my_data */
...
umem_cache_free(my_obj_cache, cur);
...
```

EXAMPLE 3 Use a more complex object with a mutex.

```
#define _REENTRANT
#include <assert.h>
#include <synch.h>
#include <umem.h>

typedef struct my_obj {
    mutex_t my_mutex;
    cond_t my_cv;
    struct bar *my_barlist;
    unsigned my_refcount;
} my_obj_t;

/*
 * my_objs can only be freed when my_barlist == NULL,
 * my_refcount == 0, there are no waiters on my_cv, and
 * my_mutex is unlocked.
 */

int
my_obj_constructor(void *buf, void *ignored, int flags)
{
    my_obj_t *myobj = buf;

    (void) mutex_init(&my_obj->my_mutex, USYNC_THREAD, NULL);
    (void) cond_init(&my_obj->my_cv, USYNC_THREAD, NULL);
    myobj->my_barlist = NULL;
    myobj->my_refcount = 0;

    return (0);
}

void
my_obj_destructor(void *buf, void *ignored)
{
    my_obj_t *myobj = buf;

    assert(myobj->my_refcount == 0);
    assert(myobj->my_barlist == NULL);
    (void) cond_destroy(&my_obj->my_cv);
    (void) mutex_destroy(&my_obj->my_mutex);
}

umem_cache_t *my_obj_cache;
```

EXAMPLE 3 Use a more complex object with a mutex. (Continued)

```

...
my_obj_cache = umem_cache_create("my_obj", sizeof (my_obj_t),
    0, my_obj_constructor, my_obj_destructor, NULL, NULL,
    NULL, 0);
...
my_obj_t *cur = umem_cache_alloc(my_obj_cache, UMEM_DEFAULT);
...
/* use cur */
...
umem_cache_free(my_obj_cache, cur);
...

```

EXAMPLE 4 Use objects with a subordinate buffer while reusing callbacks.

```

#include assert.h>
#include umem.h>

typedef struct my_obj {
    char *my_buffer;
    size_t my_size;
} my_obj_t;

/*
 * my_size and the my_buffer pointer should never be changed
 */

int
my_obj_constructor(void *buf, void *arg, int flags)
{
    size_t sz = (size_t)arg;

    my_obj_t *myobj = buf;

    if ((myobj->my_buffer = umem_alloc(sz, flags)) == NULL)
        return (1);

    my_size = sz;

    return (0);
}

void
my_obj_destructor(void *buf, void *arg)
{
    size_t sz = (size_t)arg;

    my_obj_t *myobj = buf;

    assert(sz == buf->my_size);
    umem_free(myobj->my_buffer, sz);
}

...
umem_cache_t *my_obj_4k_cache;

```

umem_cache_free(3MALLOC)

EXAMPLE 4 Use objects with a subordinate buffer while reusing callbacks. (Continued)

```
umem_cache_t *my_obj_8k_cache;
...
my_obj_cache_4k = umem_cache_create("my_obj_4k", sizeof (my_obj_t),
    0, my_obj_constructor, my_obj_destructor, NULL, (void *)4096,
    NULL, 0);

my_obj_cache_8k = umem_cache_create("my_obj_8k", sizeof (my_obj_t),
    0, my_obj_constructor, my_obj_destructor, NULL, (void *)8192,
    NULL, 0);
...
my_obj_t *my_obj_4k = umem_cache_alloc(my_obj_4k_cache,
    UMEM_DEFAULT);
my_obj_t *my_obj_8k = umem_cache_alloc(my_obj_8k_cache,
    UMEM_DEFAULT);
/* no assumptions should be made about the contents of the buffers */
...
/* make sure to return them to the correct cache */
umem_cache_free(my_obj_4k_cache, my_obj_4k);
umem_cache_free(my_obj_8k_cache, my_obj_8k);
...
```

See the **EXAMPLES** section of `umem_alloc(3MALLOC)` for examples involving the `UMEM_NOFAIL` flag.

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Interface Stability	Evolving
MT-Level	MT-Safe

SEE ALSO `setcontext(2)`, `atexit(3C)`, `libumem(3LIB)`, `longjmp(3C)`, `swapcontext(3C)`, `thr_exit(3THR)`, `umem_alloc(3MALLOC)`, `umem_debug(3MALLOC)`, `attributes(5)`

Bonwick, Jeff, "The Slab Allocator: An Object-Caching Kernel Memory Allocator", Proceedings of the Summer 1994 Usenix Conference.

Bonwick, Jeff and Jonathan Adams, "Magazines and vmem: Extending the Slab Allocator to Many CPUs and Arbitrary Resources", Proceedings of the Summer 2001 Usenix Conference.

WARNINGS Any of the following can cause undefined results:

- Destroying a cache that has outstanding allocated buffers.
- Using a cache after it has been destroyed.
- Calling `umem_cache_free()` on the same buffer multiple times.
- Passing a `NULL` pointer to `umem_cache_free()`.

- Writing past the end of a buffer.
- Reading from or writing to a buffer after it has been freed.
- Performing UMEM_NOFAIL allocations from an atexit(3C) handler.

Per-cache callbacks can be called from a variety of contexts. The use of functions that modify the active context, such as `setcontext(2)`, `swapcontext(3C)`, and `thr_exit(3THR)`, or functions that are unsafe for use in multithreaded applications, such as `longjmp(3C)` and `siglongjmp(3C)`, result in undefined behavior.

A constructor callback that performs allocations must pass its *flags* argument unchanged to `umem_alloc(3MALLOC)` and `umem_cache_alloc()`. Any allocations made with a different *flags* argument results in undefined behavior. The constructor must correctly handle the failure of any allocations it makes.

NOTES Object caches make the following guarantees about objects:

- If the cache has a constructor callback, it is applied to every object before it is returned from `umem_cache_alloc()` for the first time.
- If the cache has a constructor callback, an object passed to `umem_cache_free()` and later returned from `umem_cache_alloc()` is not modified between the two events.
- If the cache has a destructor, it is applied to all objects before their underlying storage is returned.

No other guarantees are made. In particular, even if there are buffers recently freed to the cache, `umem_cache_alloc()` can fail.

umem_debug(3MALLOC)

NAME	umem_debug – debugging features of the umem library
SYNOPSIS	<pre>cc [<i>flag...</i>] <i>file...</i> -lumem [<i>library...</i>] #include <umem.h></pre>
DESCRIPTION	<p>The <code>libumem</code> library provides debugging features that detect memory leaks, buffer overruns, multiple frees, use of uninitialized data, use of freed data, and many other common programming errors. The activation of the run-time debugging features is controlled by environment variables.</p> <p>When the library detects an error, it writes a description of the error to an internal buffer that is readable with the <code>::umem_status mdb(1) dcmd</code> and then calls <code>abort(3C)</code>.</p>
ENVIRONMENT VARIABLES	<p>UMEM_DEBUG This variable contains a list of comma-separated options. Unrecognized options are ignored. Possible options include:</p> <p>audit[=<i>frames</i>] This option enables the recording of auditing information, including thread ID, high-resolution time stamp, and stack trace for the last action (allocation or free) on every allocation. If transaction logging (see <code>UMEM_LOGGING</code>) is enabled, this auditing information is also logged.</p> <p>The <i>frames</i> parameter sets the number of stack frames recorded in the auditing structure. The upper bound for frames is implementation-defined. If a larger value is requested, the upper bound is used instead.</p> <p>If <i>frames</i> is not specified or is not an integer, the default value of 15 is used.</p> <p>This option also enables the <code>guards</code> option.</p> <p>contents[=<i>count</i>] If auditing and contents logging (see <code>UMEM_LOGGING</code>) are enabled, the first <i>count</i> bytes of each buffer are logged when they are freed. If a buffer is shorter than <i>count</i> bytes, it is logged in its entirety.</p> <p>If <i>count</i> is not specified or is not an integer, the default value of 256 is used.</p> <p>default This option is equivalent to <code>audit,contents,guards</code>.</p> <p>guards This option enables filling allocated and freed buffers with special patterns to help detect the use of uninitialized data and previously freed buffers. It also enables an 8-byte redzone after each buffer that contains <code>0xfeedfacefeedfaceULL</code>.</p>

umem_debug(3MALLOC)

When an object is freed, it is filled with `0xdeadbeef`. When an object is allocated, the `0xdeadbeef` pattern is verified and replaced with `0xbaddcafe`. The redzone is checked every time a buffer is allocated or freed.

For caches with either constructors or destructors, or both, `umem_cache_alloc(3MALLOC)` and `umem_cache_free(3MALLOC)` apply the cache's constructor and destructor, respectively, instead of caching constructed objects. The presence of `assert(3C)`s in the destructor verifying that the buffer is in the constructed state can be used to detect any objects returned in an improper state. See `umem_cache_create(3MALLOC)` for details.

verbose

The library writes error descriptions to standard error before aborting. These messages are not localized.

UMEM_LOGGING

To be enabled, this variable should be set to a comma-separated list of in-memory logs. The logs available are:

transaction[=*size*]

If the `audit` debugging option is set (see `UMEM_DEBUG`), the audit structures from previous transactions are entered into this log.

contents[=*size*]

If the `audit` debugging option is set, the contents of objects are recorded in this log as they are freed.

If the "contents" debugging option was not set, 256 bytes of each freed buffer are saved.

fail[=*size*]

Records are entered into this log for every failed allocation.

For any of these options, if *size* is not specified, the default value of 64k is used. The *size* parameter must be an integer that can be qualified with K, M, G, or T to specify kilobytes, megabytes, gigabytes, or terabytes, respectively.

Logs that are not listed or that have either a size of 0 or an invalid size are disabled.

The log is disabled if during initialization the requested amount of storage cannot be allocated.

umem_debug(3MALLOC)

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Interface Stability	Unstable
MT-Level	MT-Safe

SEE ALSO `mdb(1)`, `abort(3C)`, `signal(3C)`, `umem_cache_create(3MALLOC)`, `attributes(5)`

Solaris Modular Debugger Guide

WARNINGS When `libumem` aborts the process using `abort(3C)`, any existing signal handler for `SIGABRT` is called. If the signal handler performs allocations, undefined behavior can result.

NOTES Some of the debugging features work only for allocations smaller than 16 kilobytes in size. Allocations larger than 16 kilobytes could have reduced support.

Activating any of the library's debugging features could significantly increase the library's memory footprint and decrease its performance.

NAME	umem_alloc, umem_zalloc, umem_free, umem_nofail_callback – fast, scalable memory allocation
SYNOPSIS	<pre>cc [flag ...] file... -lumem [library ...] #include <umem.h> void *umem_alloc(size_t size, int flags); void *umem_zalloc(size_t size, int flags); void umem_free(void *buf, size_t size); void umem_nofail_callback((int (*callback)(void))); void *malloc(size_t size); void *calloc(size_t nelem, size_t elsize); void free(void *ptr); void *memalign(size_t alignment, size_t size); void *realloc(void *ptr, size_t size); void *valloc(size_t size);</pre>
DESCRIPTION	<p>The <code>umem_alloc()</code> function returns a pointer to a block of <i>size</i> bytes suitably aligned for any variable type. The initial contents of memory allocated using <code>umem_alloc()</code> is undefined. The <i>flags</i> argument determines the behavior of <code>umem_alloc()</code> if it is unable to fulfill the request. The <i>flags</i> argument can take the following values:</p> <p><code>UMEM_DEFAULT</code> Return <code>NULL</code> on failure.</p> <p><code>UMEM_NOFAIL</code> Call an optional <i>callback</i> (set with <code>umem_nofail_callback()</code>) on failure. The <i>callback</i> takes no arguments and can finish by:</p> <ul style="list-style-type: none"> ■ returning <code>UMEM_CALLBACK_RETRY</code>, in which case the allocation will be retried. If the allocation fails, the callback will be invoked again. ■ returning <code>UMEM_CALLBACK_EXIT(status)</code>, in which case <code>exit(2)</code> is invoked with <i>status</i> as its argument. The <code>exit()</code> function is called only once. If multiple threads return from the <code>UMEM_NOFAIL</code> callback with <code>UMEM_CALLBACK_EXIT(status)</code>, one will call <code>exit()</code> while the other blocks until <code>exit()</code> terminates the program. ■ invoking a context-changing function (<code>setcontext(2)</code>) or a non-local jump (<code>longjmp(3C)</code> or <code>siglongjmp(3C)</code>), or ending the current thread of control (<code>thr_exit(3THR)</code> or <code>pthread_exit(3THR)</code>). The application is responsible for any necessary cleanup. The state of <code>libumem</code> remains consistent. <p>If no callback has been set or the callback has been set to <code>NULL</code>, <code>umem_alloc(..., UMEM_NOFAIL)</code> behaves as though the callback returned <code>UMEM_CALLBACK_EXIT(255)</code>.</p>

umem_free(3MALLOC)

The libumem library can call callbacks from any place that a UMEM_NOFAIL allocation is issued. In multithreaded applications, callbacks are expected to perform their own concurrency management.

The function call `umem_alloc(0, flag)` always returns NULL. The function call `umem_free(NULL, 0)` is allowed.

The `umem_zalloc()` function has the same semantics as `umem_alloc()`, but the block of memory is initialized to zeros before it is returned.

The `umem_free()` function frees blocks previously allocated using `umem_alloc()` and `umem_zalloc()`. The buffer address and size must exactly match the original allocation. Memory must not be returned piecemeal.

The `umem_nofail_callback()` function sets the process-wide UMEM_NOFAIL callback. See the description of UMEM_NOFAIL for more information.

The `malloc()`, `calloc()`, `free()`, `memalign()`, `realloc()`, and `valloc()` functions are as described in `malloc(3C)`. The libumem library provides these functions for backwards-compatibility with the standard functions.

ENVIRONMENT VARIABLES

See `umem_debug(3MALLOC)` for environment variables that effect the debugging features of the libumem library.

UMEM_OPTIONS

Contains a list of comma-separated options. Unrecognized options are ignored. The options that are supported are:

backend=sbrk
backend=mmap

Set the underlying function used to allocate memory. This option can be set to `sbrk` (the default) for an `sbrk(2)`-based source or `mmap` for an `mmap(2)`-based source. If set to a value that is not supported, `sbrk` will be used.

EXAMPLES

EXAMPLE 1 Using the `umem_alloc()` function

```
#include <stdio.h>
#include <umem.h>
...
char *buf = umem_alloc(1024, UMEM_DEFAULT);

if (buf == NULL) {
    fprintf(stderr, "out of memory\n");
}
```

EXAMPLE 1 Using the `umem_alloc()` function (Continued)

```

        return (1);
    }
    /* cannot assume anything about buf's contents */
    ...
    umem_free(buf, 1024);
    ...

```

EXAMPLE 2 Using the `umem_zalloc()` function

```

#include <stdio.h>
#include <umem.h>
...
char *buf = umem_zalloc(1024, UMEM_DEFAULT);

if (buf == NULL) {
    fprintf(stderr, "out of memory\n");
    return (1);
}
/* buf contains zeros */
...
umem_free(buf, 1024);
...

```

EXAMPLE 3 Using `UMEM_NOFAIL`

```

#include <stdlib.h>
#include <stdio.h>
#include <umem.h>

/*
 * Note that the allocation code below does not have to
 * check for umem_alloc() returning NULL
 */
int
my_failure_handler(void)
{
    (void) fprintf(stderr, "out of memory\n");
    return (UMEM_CALLBACK_EXIT(255));
}
...
umem_nofail_callback(my_failure_handler);
...
int i;
char *buf[100];

for (i = 0; i < 100; i++)
    buf[i] = umem_alloc(1024 * 1024, UMEM_NOFAIL);
...
for (i = 0; i < 100; i++)
    umem_free(buf[i], 1024 * 1024);
...

```

umem_free(3MALLOC)

EXAMPLE 4 Using UMEM_NOFAIL in a multithreaded application

```
#define _REENTRANT
#include <thread.h>
#include <stdio.h>
#include <umem.h>

void *
start_func(void *the_arg)
{
    int *info = (int *)the_arg;
    char *buf = umem_alloc(1024 * 1024, UMEM_NOFAIL);

    /* does not need to check for buf == NULL */
    buf[0] = 0;
    ...
    /*
     * if there were other UMEM_NOFAIL allocations,
     * we would need to arrange for buf to be
     * umem_free()ed upon failure.
     */
    ...
    umem_free(buf, 1024 * 1024);
    return (the_arg);
}
...
int
my_failure_handler(void)
{
    /* terminate the current thread with status NULL */
    thr_exit(NULL);
}
...
umem_nofail_callback(my_failure_handler);
...
int my_arg;

thread_t tid;
void *status;

(void) thr_create(NULL, NULL, start_func, &my_arg, 0,
                 NULL);
...
while (thr_join(0, &tid, &status) != 0)
    ;

if (status == NULL) {
    (void) fprintf(stderr, "thread %d ran out of memory\n",
                  tid);
}
...
```

ATTRIBUTES See attributes(5) for descriptions of the following attributes:

Solaris Modular Debugger Guide

WARNINGS Any of the following can cause undefined results:

- Passing a pointer returned from umem_alloc() or umem_zalloc() to free() or realloc().
- Passing a pointer returned from malloc(), calloc(), valloc(), memalign(), or realloc() to umem_free().
- Writing past the end of a buffer allocated using umem_alloc() or umem_zalloc().
- Performing UMEM_NOFAIL allocations from an atexit(3C) handler.

If the UMEM_NOFAIL callback performs UMEM_NOFAIL allocations, infinite recursion can occur.

NOTES The following list compares the features of the malloc(3C), bsdmalloc(3MALLOC), malloc(3MALLOC), mtmalloc(3MALLOC), and the libumem functions.

- The malloc(3C), bsdmalloc(3MALLOC), and malloc(3MALLOC) functions have no support for concurrency. The libumem and mtmalloc(3MALLOC) functions support concurrent allocations.
- The bsdmalloc(3MALLOC) functions afford better performance but are space-inefficient.
- The malloc(3MALLOC) functions are space-efficient but have slower performance.
- The standard, fully SCD-compliant malloc(3C) functions are a trade-off between performance and space-efficiency.
- The mtmalloc(3MALLOC) functions provide fast, concurrent malloc() implementations that are not space-efficient.
- The libumem functions provide a fast, concurrent allocation implementation that in most cases is more space-efficient than mtmalloc(3MALLOC).

umem_nofail_callback(3MALLOC)

NAME	umem_alloc, umem_zalloc, umem_free, umem_nofail_callback – fast, scalable memory allocation

umem_nofail_callback(3MALLOC)

The libumem library can call callbacks from any place that a UMEM_NOFAIL allocation is issued. In multithreaded applications, callbacks are expected to perform their own concurrency management.

The function call `umem_alloc(0, flag)` always returns `NULL`. The function call `umem_free(NULL, 0)` is allowed.

The `umem_zalloc()` function has the same semantics as `umem_alloc()`, but the block of memory is initialized to zeros before it is returned.

The `umem_free()` function frees blocks previously allocated using `umem_alloc()` and `umem_zalloc()`. The buffer address and size must exactly match the original allocation. Memory must not be returned piecemeal.

The `umem_nofail_callback()` function sets the process-wide UMEM_NOFAIL callback. See the description of UMEM_NOFAIL for more information.

The `malloc()`, `calloc()`, `free()`, `memalign()`, `realloc()`, and `valloc()` functions are as described in `malloc(3C)`. The libumem library provides these functions for backwards-compatibility with the standard functions.

ENVIRONMENT VARIABLES

See `umem_debug(3MALLOC)` for environment variables that effect the debugging features of the libumem library.

UMEM_OPTIONS

Contains a list of comma-separated options. Unrecognized options are ignored. The options that are supported are:

`backend=sbrk`
`backend=mmap`

Set the underlying function used to allocate memory. This option can be set to `sbrk` (the default) for an `sbrk(2)`-based source or `mmap` for an `mmap(2)`-based source. If set to a value that is not supported, `sbrk` will be used.

EXAMPLES

EXAMPLE 1 Using the `umem_alloc()` function

```
#include <stdio.h>
#include <umem.h>
...
char *buf = umem_alloc(1024, UMEM_DEFAULT);

if (buf == NULL) {
    fprintf(stderr, "out of memory\n");
}
```

umem_nofail_callback(3MALLOC)

EXAMPLE 1 Using the `umem_alloc()` function *(Continued)*

```
        return (1);
    }
    /* cannot assume anything about buf's contents */
    ...
    umem_free(buf, 1024);
    ...
```

EXAMPLE 2 Using the `umem_zalloc()` function

```
#include <stdio.h>
#include <umem.h>
...
char *buf = umem_zalloc(1024, UMEM_DEFAULT);

if (buf == NULL) {
    fprintf(stderr, "out of memory\n");
    return (1);
}
/* buf contains zeros */
...
umem_free(buf, 1024);
...
```

EXAMPLE 3 Using `UMEM_NOFAIL`

```
#include <stdlib.h>
#include <stdio.h>
#include <umem.h>

/*
 * Note that the allocation code below does not have to
 * check for umem_alloc() returning NULL
 */
int
my_failure_handler(void)
{
    (void) fprintf(stderr, "out of memory\n");
    return (UMEM_CALLBACK_EXIT(255));
}
...
umem_nofail_callback(my_failure_handler);
...
int i;
char *buf[100];

for (i = 0; i < 100; i++)
    buf[i] = umem_alloc(1024 * 1024, UMEM_NOFAIL);
...
for (i = 0; i < 100; i++)
    umem_free(buf[i], 1024 * 1024);
...
```

EXAMPLE 4 Using UMEM_NOFAIL in a multithreaded application

```

#define _REENTRANT
#include <thread.h>
#include <stdio.h>
#include <umem.h>

void *
start_func(void *the_arg)
{
    int *info = (int *)the_arg;
    char *buf = umem_alloc(1024 * 1024, UMEM_NOFAIL);

    /* does not need to check for buf == NULL */
    buf[0] = 0;
    ...
    /*
     * if there were other UMEM_NOFAIL allocations,
     * we would need to arrange for buf to be
     * umem_free()ed upon failure.
     */
    ...
    umem_free(buf, 1024 * 1024);
    return (the_arg);
}
...
int
my_failure_handler(void)
{
    /* terminate the current thread with status NULL */
    thr_exit(NULL);
}
...
umem_nofail_callback(my_failure_handler);
...
int my_arg;

thread_t tid;
void *status;

(void) thr_create(NULL, NULL, start_func, &my_arg, 0,
                 NULL);
...
while (thr_join(0, &tid, &status) != 0)
    ;

if (status == NULL) {
    (void) fprintf(stderr, "thread %d ran out of memory\n",
                  tid);
}
...

```

umem_zalloc(3MALLOC)

The `libumem` library can call callbacks from any place that a `UMEM_NOFAIL` allocation is issued. In multithreaded applications, callbacks are expected to perform their own concurrency management.

The function call `umem_alloc(0, flag)` always returns `NULL`. The function call `umem_free(NULL, 0)` is allowed.

The `umem_zalloc()` function has the same semantics as `umem_alloc()`, but the block of memory is initialized to zeros before it is returned.

The `umem_free()` function frees blocks previously allocated using `umem_alloc()` and `umem_zalloc()`. The buffer address and size must exactly match the original allocation. Memory must not be returned piecemeal.

The `umem_nofail_callback()` function sets the process-wide `UMEM_NOFAIL` callback. See the description of `UMEM_NOFAIL` for more information.

The `malloc()`, `calloc()`, `free()`, `memalign()`, `realloc()`, and `valloc()` functions are as described in `malloc(3C)`. The `libumem` library provides these functions for backwards-compatibility with the standard functions.

ENVIRONMENT VARIABLES

See `umem_debug(3MALLOC)` for environment variables that effect the debugging features of the `libumem` library.

UMEM_OPTIONS

Contains a list of comma-separated options. Unrecognized options are ignored. The options that are supported are:

`backend=sbrk`
`backend=mmap`

Set the underlying function used to allocate memory. This option can be set to `sbrk` (the default) for an `sbrk(2)`-based source or `mmap` for an `mmap(2)`-based source. If set to a value that is not supported, `sbrk` will be used.

EXAMPLES

EXAMPLE 1 Using the `umem_alloc()` function

```
#include <stdio.h>
#include <umem.h>
...
char *buf = umem_alloc(1024, UMEM_DEFAULT);

if (buf == NULL) {
    fprintf(stderr, "out of memory\n");
}
```

EXAMPLE 1 Using the umem_alloc() function (Continued)

```

        return (1);
    }
    /* cannot assume anything about buf's contents */
    ...
    umem_free(buf, 1024);
    ...

```

EXAMPLE 2 Using the umem_zalloc() function

```

#include <stdio.h>
#include <umem.h>
...
char *buf = umem_zalloc(1024, UMEM_DEFAULT);

if (buf == NULL) {
    fprintf(stderr, "out of memory\n");
    return (1);
}
/* buf contains zeros */
...
umem_free(buf, 1024);
...

```

EXAMPLE 3 Using UMEM_NOFAIL

```

#include <stdlib.h>
#include <stdio.h>
#include <umem.h>

/*
 * Note that the allocation code below does not have to
 * check for umem_alloc() returning NULL
 */
int
my_failure_handler(void)
{
    (void) fprintf(stderr, "out of memory\n");
    return (UMEM_CALLBACK_EXIT(255));
}
...
umem_nofail_callback(my_failure_handler);
...
int i;
char *buf[100];

for (i = 0; i < 100; i++)
    buf[i] = umem_alloc(1024 * 1024, UMEM_NOFAIL);
...
for (i = 0; i < 100; i++)
    umem_free(buf[i], 1024 * 1024);
...

```

umem_zalloc(3MALLOC)

EXAMPLE 4 Using UMEM_NOFAIL in a multithreaded application

```
#define _REENTRANT
#include <thread.h>
#include <stdio.h>
#include <umem.h>

void *
start_func(void *the_arg)
{
    int *info = (int *)the_arg;
    char *buf = umem_alloc(1024 * 1024, UMEM_NOFAIL);

    /* does not need to check for buf == NULL */
    buf[0] = 0;
    ...
    /*
     * if there were other UMEM_NOFAIL allocations,
     * we would need to arrange for buf to be
     * umem_free()ed upon failure.
     */
    ...
    umem_free(buf, 1024 * 1024);
    return (the_arg);
}
...
int
my_failure_handler(void)
{
    /* terminate the current thread with status NULL */
    thr_exit(NULL);
}
...
umem_nofail_callback(my_failure_handler);
...
int my_arg;

thread_t tid;
void *status;

(void) thr_create(NULL, NULL, start_func, &my_arg, 0,
                 NULL);
...
while (thr_join(0, &tid, &status) != 0)
    ;

if (status == NULL) {
    (void) fprintf(stderr, "thread %d ran out of memory\n",
                  tid);
}
...
```

ATTRIBUTES See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Interface Stability	malloc(), calloc(), free(), realloc(), and valloc() are Standard. memalign() is Stable. umem_alloc(), umem_zalloc(), umem_free(), and umem_nofail_callback() are Evolving.

Solaris Modular Debugger Guide

WARNINGS Any of the following can cause undefined results:

- Passing a pointer returned from umem_alloc() or umem_zalloc() to free() or realloc().
- Passing a pointer returned from malloc(), calloc(), valloc(), memalign(), or realloc() to umem_free().
- Writing past the end of a buffer allocated using umem_alloc() or umem_zalloc().
- Performing UMEM_NOFAIL allocations from an atexit(3C) handler.

If the UMEM_NOFAIL callback performs UMEM_NOFAIL allocations, infinite recursion can occur.

NOTES The following list compares the features of the malloc(3C), bsdmalloc(3MALLOC), malloc(3MALLOC), mtmalloc(3MALLOC), and the libumem functions.

- The malloc(3C), bsdmalloc(3MALLOC), and malloc(3MALLOC) functions have no support for concurrency. The libumem and mtmalloc(3MALLOC) functions support concurrent allocations.
- The bsdmalloc(3MALLOC) functions afford better performance but are space-inefficient.
- The malloc(3MALLOC) functions are space-efficient but have slower performance.
- The standard, fully SCD-compliant malloc(3C) functions are a trade-off between performance and space-efficiency.
- The mtmalloc(3MALLOC) functions provide fast, concurrent malloc() implementations that are not space-efficient.
- The libumem functions provide a fast, concurrent allocation implementation that in most cases is more space-efficient than mtmalloc(3MALLOC).

ungetc(3C)

NAME	ungetc – push byte back into input stream				
SYNOPSIS	<pre>#include <stdio.h> int ungetc(int c, FILE *stream);</pre>				
DESCRIPTION	<p>The <code>ungetc()</code> function pushes the byte specified by <code>c</code> (converted to an unsigned char) back onto the input stream pointed to by <code>stream</code>. The pushed-back bytes will be returned by subsequent reads on that stream in the reverse order of their pushing. A successful intervening call (with the stream pointed to by <code>stream</code>) to a file-positioning function (<code>fseek(3C)</code>, <code>fsetpos(3C)</code> or <code>rewind(3C)</code>) discards any pushed-back bytes for the stream. The external storage corresponding to the stream is unchanged.</p> <p>Four bytes of push-back are guaranteed. If <code>ungetc()</code> is called too many times on the same stream without an intervening read or file-positioning operation on that stream, the operation may fail.</p> <p>If the value of <code>c</code> equals that of the macro <code>EOF</code>, the operation fails and the input stream is unchanged.</p> <p>A successful call to <code>ungetc()</code> clears the end-of-file indicator for the stream. The value of the file-position indicator for the stream after reading or discarding all pushed-back bytes will be the same as it was before the bytes were pushed back. The file-position indicator is decremented by each successful call to <code>ungetc()</code>; if its value was 0 before a call, its value is indeterminate after the call.</p>				
RETURN VALUES	Upon successful completion, <code>ungetc()</code> returns the byte pushed back after conversion. Otherwise it returns <code>EOF</code> .				
ERRORS	No errors are defined.				
ATTRIBUTES	See <code>attributes(5)</code> for descriptions of the following attributes:

NAME	ungetwc – push wide-character code back into input stream				
SYNOPSIS	<pre>#include <stdio.h> #include <wchar.h> wint_t ungetwc(wint_t wc, FILE *stream);</pre>				
DESCRIPTION	<p>The <code>ungetwc()</code> function pushes the character corresponding to the wide character code specified by <code>wc</code> back onto the input stream pointed to by <code>stream</code>. The pushed-back characters will be returned by subsequent reads on that stream in the reverse order of their pushing. A successful intervening call (with the stream pointed to by <code>stream</code>) to a file-positioning function (<code>fseek(3C)</code>, <code>fsetpos(3C)</code> or <code>rewind(3C)</code>) discards any pushed-back characters for the stream. The external storage corresponding to the stream is unchanged.</p> <p>One character of push-back is guaranteed. If <code>ungetwc()</code> is called too many times on the same stream without an intervening read or file-positioning operation on that stream, the operation may fail.</p> <p>If the value of <code>wc</code> equals that of the macro <code>WEOF</code>, the operation fails and the input stream is unchanged.</p> <p>A successful call to <code>ungetwc()</code> clears the end-of-file indicator for the stream. The value of the file-position indicator for the stream after reading or discarding all pushed-back characters will be the same as it was before the characters were pushed back. The file-position indicator is decremented (by one or more) by each successful call to <code>ungetwc()</code>; if its value was 0 before a call, its value is indeterminate after the call.</p>				
RETURN VALUES	Upon successful completion, <code>ungetwc()</code> returns the wide-character code corresponding to the pushed-back character. Otherwise it returns <code>WEOF</code> .				
ERRORS	<p>The <code>ungetwc()</code> function may fail if:</p> <p>EILSEQ An invalid character sequence is detected, or a wide-character code does not correspond to a valid character.</p>

NAME	getutxent, getutxid, getutxline, pututxline, setutxent, endutxent, utmpxname, getutmp, getutmpx, updwtmp, updwtmpx – user accounting database functions
SYNOPSIS	<pre>#include <utmpx.h> struct utmpx *getutxent (void); struct utmpx *getutxid (const struct utmpx *id); struct utmpx *getutxline (const struct utmpx *line); struct utmpx *pututxline (const struct utmpx *utmpx); void setutxent (void); void endutxent (void); int utmpxname (const char *file); void getutmp (struct utmpx *utmpx, struct utmp *utmp); void getutmpx (struct utmp *utmp, struct utmpx *utmpx); void updwtmp (char *wfile, struct utmp *utmp); void updwtmpx (char *wfilex, struct utmpx *utmpx);</pre>
DESCRIPTION	<p>These functions provide access to the user accounting database, utmpx (see utmpx(4)). Entries in the database are described by the definitions and data structures in <utmpx.h>.</p> <p>The utmpx structure contains the following members:</p> <pre>char ut_user[32]; /* user login name */ char ut_id[4]; /* /etc/inittab id (usually line #) */ char ut_line[32]; /* device name (console, lnxx) */ pid_t ut_pid; /* process id */ short ut_type; /* type of entry */ struct exit_status ut_exit; /* exit status of a process */ /* marked as DEAD_PROCESS */ struct timeval ut_tv; /* time entry was made */ int ut_session; /* session ID, used for windowing */ short ut_syslen; /* significant length of ut_host */ /* including terminating null */ char ut_host[257]; /* host name, if remote */</pre> <p>The exit_status structure includes the following members:</p> <pre>short e_termination; /* termination status */ short e_exit; /* exit status */</pre> <p>getutxent () The getutxent () function reads in the next entry from a utmpx database. If the database is not already open, it opens it. If it reaches the end of the database, it fails.</p> <p>getutxid () The getutxid () function searches forward from the current point in the utmpx database until it finds an entry with a ut_type matching id->ut_type, if the type specified is RUN_LVL, BOOT_TIME, OLD_TIME, or NEW_TIME. If the type specified in</p>

updwtmp(3C)

	<p><i>id</i> is INIT_PROCESS, LOGIN_PROCESS, USER_PROCESS, or DEAD_PROCESS, then <code>getutxid()</code> will return a pointer to the first entry whose type is one of these four and whose <code>ut_id</code> member matches <i>id</i>-><code>ut_id</code>. If the end of database is reached without a match, it fails.</p>
<code>getutxline()</code>	<p>The <code>getutxline()</code> function searches forward from the current point in the <code>utmpx</code> database until it finds an entry of the type LOGIN_PROCESS or USER_PROCESS which also has a <code>ut_line</code> string matching the <i>line</i>-><code>ut_line</code> string. If the end of the database is reached without a match, it fails.</p>
<code>pututxline()</code>	<p>The <code>pututxline()</code> function writes the supplied <code>utmpx</code> structure into the <code>utmpx</code> database. It uses <code>getutxid()</code> to search forward for the proper place if it finds that it is not already at the proper place. It is expected that normally the user of <code>pututxline()</code> will have searched for the proper entry using one of the <code>getutx()</code> routines. If so, <code>pututxline()</code> will not search. If <code>pututxline()</code> does not find a matching slot for the new entry, it will add a new entry to the end of the database. It returns a pointer to the <code>utmpx</code> structure. When called by a non-root user, <code>pututxline()</code> invokes a <code>setuid()</code> root program to verify and write the entry, since the <code>utmpx</code> database is normally writable only by root. In this event, the <code>ut_name</code> member must correspond to the actual user name associated with the process; the <code>ut_type</code> member must be either USER_PROCESS or DEAD_PROCESS; and the <code>ut_line</code> member must be a device special file and be writable by the user.</p>
<code>setutxent()</code>	<p>The <code>setutxent()</code> function resets the input stream to the beginning. This should be done before each search for a new entry if it is desired that the entire database be examined.</p>
<code>endutxent()</code>	<p>The <code>endutxent()</code> function closes the currently open database.</p>
<code>utmpxname()</code>	<p>The <code>utmpxname()</code> function allows the user to change the name of the database file examined from <code>/var/adm/utmpx</code> to any other file, most often <code>/var/adm/wtmpx</code>. If the file does not exist, this will not be apparent until the first attempt to reference the file is made. The <code>utmpxname()</code> function does not open the file, but closes the old file if it is currently open and saves the new file name. The new file name must end with the "x" character to allow the name of the corresponding <code>utmp</code> file to be easily obtainable.; otherwise, an error value of 0 is returned. The function returns 1 on success.</p>
<code>getutmp()</code>	<p>The <code>getutmp()</code> function copies the information stored in the members of the <code>utmpx</code> structure to the corresponding members of the <code>utmp</code> structure. If the information in any member of <code>utmpx</code> does not fit in the corresponding <code>utmp</code> member, the data is silently truncated. (See <code>getutent(3C)</code> for <code>utmp</code> structure)</p>
<code>getutmpx()</code>	<p>The <code>getutmpx()</code> function copies the information stored in the members of the <code>utmp</code> structure to the corresponding members of the <code>utmpx</code> structure. (See <code>getutent(3C)</code> for <code>utmp</code> structure)</p>
<code>updwtmp()</code>	<p>The <code>updwtmp()</code> function can be used in two ways.</p>

	<p>If <i>wfile</i> is <code>/var/adm/wtmp</code>, the <code>utmp</code> format record supplied by the caller is converted to a <code>utmpx</code> format record and the <code>/var/adm/wtmpx</code> file is updated (because the <code>/var/adm/wtmp</code> file no longer exists, operations on <code>wtmp</code> are converted to operations on <code>wtmpx</code> by the library functions).</p> <p>If <i>wfile</i> is a file other than <code>/var/adm/wtmp</code>, it is assumed to be an old file in <code>utmp</code> format and is updated directly with the <code>utmp</code> format record supplied by the caller.</p>
<code>updwtmpx()</code>	<p>The <code>updwtmpx()</code> function writes the contents of the <code>utmpx</code> structure pointed to by <i>utmpx</i> to the database.</p>
utmpx structure	<p>The values of the <code>e_termination</code> and <code>e_exit</code> members of the <code>ut_exit</code> structure are valid only for records of type <code>DEAD_PROCESS</code>. For <code>utmpx</code> entries created by <code>init(1M)</code>, these values are set according to the result of the <code>wait()</code> call that <code>init</code> performs on the process when the process exits. See the <code>wait(2)</code> manual page for the values <code>init</code> uses. Applications creating <code>utmpx</code> entries can set <code>ut_exit</code> values using the following code example:</p> <pre>u->ut_exit.e_termination = WTERMSIG(process->p_exit) u->ut_exit.e_exit = WEXITSTATUS(process->p_exit)</pre> <p>See <code>wstat(3XFN)</code> for descriptions of the <code>WTERMSIG</code> and <code>WEXITSTATUS</code> macros.</p> <p>The <code>ut_session</code> member is not acted upon by the operating system. It is used by applications interested in creating <code>utmpx</code> entries.</p> <p>For records of type <code>USER_PROCESS</code>, the <code>nonuser()</code> and <code>nonuserx()</code> macros use the value of the <code>ut_exit.e_exit</code> member to mark <code>utmpx</code> entries as real logins (as opposed to multiple <code>xterms</code> started by the same user on a window system). This allows the system utilities that display users to obtain an accurate indication of the number of actual users, while still permitting each <code>pty</code> to have a <code>utmpx</code> record (as most applications expect.). The <code>NONROOT_USER</code> macro defines the value that <code>login</code> places in the <code>ut_exit.e_exit</code> member.</p>
RETURN VALUES	<p>Upon successful completion, <code>getutxent()</code>, <code>getutxid()</code>, and <code>getutxline()</code> each return a pointer to a <code>utmpx</code> structure containing a copy of the requested entry in the user accounting database. Otherwise a null pointer is returned.</p> <p>The return value may point to a static area which is overwritten by a subsequent call to <code>getutxid()</code> or <code>getutxline()</code>.</p> <p>Upon successful completion, <code>pututxline()</code> returns a pointer to a <code>utmpx</code> structure containing a copy of the entry added to the user accounting database. Otherwise a null pointer is returned.</p> <p>The <code>endutxent()</code> and <code>setutxent()</code> functions return no value.</p> <p>A null pointer is returned upon failure to read, whether for permissions or having reached the end of file, or upon failure to write.</p>

updwtmp(3C)

USAGE These functions use buffered standard I/O for input, but `pututxline()` uses an unbuffered write to avoid race conditions between processes trying to modify the `utmpx` and `wtmpx` files.

Applications should not access the `utmpx` and `wtmpx` databases directly, but should use these functions to ensure that these databases are maintained consistently.

FILES

<code>/var/adm/utmpx</code>	user access and accounting information
<code>/var/adm/wtmpx</code>	history of user access and accounting information

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
MT-Level	Unsafe

SEE ALSO `wait(2)`, `getutent(3C)`, `ttyslot(3C)`, `utmpx(4)`, `attributes(5)`, `wstat(3XFN)`

NOTES The most current entry is saved in a static structure. Multiple accesses require that it be copied before further accesses are made. On each call to either `getutxid()` or `getutxline()`, the routine examines the static structure before performing more I/O. If the contents of the static structure match what it is searching for, it looks no further. For this reason, to use `getutxline()` to search for multiple occurrences it would be necessary to zero out the static after each success, or `getutxline()` would just return the same structure over and over again. There is one exception to the rule about emptying the structure before further reads are done. The implicit read done by `pututxline()` (if it finds that it is not already at the correct place in the file) will not hurt the contents of the static structure returned by the `getutxent()`, `getutxid()`, or `getutxline()` routines, if the user has just modified those contents and passed the pointer back to `pututxline()`.

NAME	getutxent, getutxid, getutxline, pututxline, setutxent, endutxent, utmpxname, getutmp, getutmpx, updwtmp, updwtmpx – user accounting database functions
SYNOPSIS	<pre>#include <utmpx.h> struct utmpx *getutxent (void); struct utmpx *getutxid (const struct utmpx *id); struct utmpx *getutxline (const struct utmpx *line); struct utmpx *pututxline (const struct utmpx *utmpx); void setutxent (void); void endutxent (void); int utmpxname (const char *file); void getutmp (struct utmpx *utmpx, struct utmp *utmp); void getutmpx (struct utmp *utmp, struct utmpx *utmpx); void updwtmp (char *wfile, struct utmp *utmp); void updwtmpx (char *wfilex, struct utmpx *utmpx);</pre>
DESCRIPTION	<p>These functions provide access to the user accounting database, utmpx (see utmpx(4)). Entries in the database are described by the definitions and data structures in <utmpx.h>.</p> <p>The utmpx structure contains the following members:</p> <pre>char ut_user[32]; /* user login name */ char ut_id[4]; /* /etc/inittab id (usually line #) */ char ut_line[32]; /* device name (console, lnxx) */ pid_t ut_pid; /* process id */ short ut_type; /* type of entry */ struct exit_status ut_exit; /* exit status of a process */ /* marked as DEAD_PROCESS */ struct timeval ut_tv; /* time entry was made */ int ut_session; /* session ID, used for windowing */ short ut_syslen; /* significant length of ut_host */ /* including terminating null */ char ut_host[257]; /* host name, if remote */</pre> <p>The exit_status structure includes the following members:</p> <pre>short e_termination; /* termination status */ short e_exit; /* exit status */</pre> <p>getutxent () The getutxent () function reads in the next entry from a utmpx database. If the database is not already open, it opens it. If it reaches the end of the database, it fails.</p> <p>getutxid () The getutxid () function searches forward from the current point in the utmpx database until it finds an entry with a ut_type matching id->ut_type, if the type specified is RUN_LVL, BOOT_TIME, OLD_TIME, or NEW_TIME. If the type specified in</p>

updwtmpx(3C)

	<p><i>id</i> is INIT_PROCESS, LOGIN_PROCESS, USER_PROCESS, or DEAD_PROCESS, then <code>getutxid()</code> will return a pointer to the first entry whose type is one of these four and whose <code>ut_id</code> member matches <i>id</i>-><code>ut_id</code>. If the end of database is reached without a match, it fails.</p>
<code>getutxline()</code>	<p>The <code>getutxline()</code> function searches forward from the current point in the <code>utmpx</code> database until it finds an entry of the type LOGIN_PROCESS or USER_PROCESS which also has a <code>ut_line</code> string matching the <i>line</i>-><code>ut_line</code> string. If the end of the database is reached without a match, it fails.</p>
<code>pututxline()</code>	<p>The <code>pututxline()</code> function writes the supplied <code>utmpx</code> structure into the <code>utmpx</code> database. It uses <code>getutxid()</code> to search forward for the proper place if it finds that it is not already at the proper place. It is expected that normally the user of <code>pututxline()</code> will have searched for the proper entry using one of the <code>getutx()</code> routines. If so, <code>pututxline()</code> will not search. If <code>pututxline()</code> does not find a matching slot for the new entry, it will add a new entry to the end of the database. It returns a pointer to the <code>utmpx</code> structure. When called by a non-root user, <code>pututxline()</code> invokes a <code>setuid()</code> root program to verify and write the entry, since the <code>utmpx</code> database is normally writable only by root. In this event, the <code>ut_name</code> member must correspond to the actual user name associated with the process; the <code>ut_type</code> member must be either USER_PROCESS or DEAD_PROCESS; and the <code>ut_line</code> member must be a device special file and be writable by the user.</p>
<code>setutxent()</code>	<p>The <code>setutxent()</code> function resets the input stream to the beginning. This should be done before each search for a new entry if it is desired that the entire database be examined.</p>
<code>endutxent()</code>	<p>The <code>endutxent()</code> function closes the currently open database.</p>
<code>utmpxname()</code>	<p>The <code>utmpxname()</code> function allows the user to change the name of the database file examined from <code>/var/adm/utmpx</code> to any other file, most often <code>/var/adm/wtmpx</code>. If the file does not exist, this will not be apparent until the first attempt to reference the file is made. The <code>utmpxname()</code> function does not open the file, but closes the old file if it is currently open and saves the new file name. The new file name must end with the "x" character to allow the name of the corresponding <code>utmp</code> file to be easily obtainable.; otherwise, an error value of 0 is returned. The function returns 1 on success.</p>
<code>getutmp()</code>	<p>The <code>getutmp()</code> function copies the information stored in the members of the <code>utmpx</code> structure to the corresponding members of the <code>utmp</code> structure. If the information in any member of <code>utmpx</code> does not fit in the corresponding <code>utmp</code> member, the data is silently truncated. (See <code>getutent(3C)</code> for <code>utmp</code> structure)</p>
<code>getutmpx()</code>	<p>The <code>getutmpx()</code> function copies the information stored in the members of the <code>utmp</code> structure to the corresponding members of the <code>utmpx</code> structure. (See <code>getutent(3C)</code> for <code>utmp</code> structure)</p>
<code>updwtmp()</code>	<p>The <code>updwtmp()</code> function can be used in two ways.</p>

If *wfile* is `/var/adm/wtmp`, the `utmp` format record supplied by the caller is converted to a `utmpx` format record and the `/var/adm/wtmpx` file is updated (because the `/var/adm/wtmp` file no longer exists, operations on `wtmp` are converted to operations on `wtmpx` by the library functions).

If *wfile* is a file other than `/var/adm/wtmp`, it is assumed to be an old file in `utmp` format and is updated directly with the `utmp` format record supplied by the caller.

`updwtmpx()` The `updwtmpx()` function writes the contents of the `utmpx` structure pointed to by *utmpx* to the database.

utmpx structure The values of the `e_termination` and `e_exit` members of the `ut_exit` structure are valid only for records of type `DEAD_PROCESS`. For `utmpx` entries created by `init(1M)`, these values are set according to the result of the `wait()` call that `init` performs on the process when the process exits. See the `wait(2)` manual page for the values `init` uses. Applications creating `utmpx` entries can set `ut_exit` values using the following code example:

```
u->ut_exit.e_termination = WTERMSIG(process->p_exit)
u->ut_exit.e_exit = WEXITSTATUS(process->p_exit)
```

See `wstat(3XFN)` for descriptions of the `WTERMSIG` and `WEXITSTATUS` macros.

The `ut_session` member is not acted upon by the operating system. It is used by applications interested in creating `utmpx` entries.

For records of type `USER_PROCESS`, the `nonuser()` and `nonuserx()` macros use the value of the `ut_exit.e_exit` member to mark `utmpx` entries as real logins (as opposed to multiple `xterms` started by the same user on a window system). This allows the system utilities that display users to obtain an accurate indication of the number of actual users, while still permitting each `pty` to have a `utmpx` record (as most applications expect.). The `NONROOT_USER` macro defines the value that `login` places in the `ut_exit.e_exit` member.

RETURN VALUES Upon successful completion, `getutxent()`, `getutxid()`, and `getutxline()` each return a pointer to a `utmpx` structure containing a copy of the requested entry in the user accounting database. Otherwise a null pointer is returned.

The return value may point to a static area which is overwritten by a subsequent call to `getutxid()` or `getutxline()`.

Upon successful completion, `pututxline()` returns a pointer to a `utmpx` structure containing a copy of the entry added to the user accounting database. Otherwise a null pointer is returned.

The `endutxent()` and `setutxent()` functions return no value.

A null pointer is returned upon failure to read, whether for permissions or having reached the end of file, or upon failure to write.

updwtmpx(3C)

USAGE These functions use buffered standard I/O for input, but `pututxline()` uses an unbuffered write to avoid race conditions between processes trying to modify the `utmpx` and `wtmpx` files.

Applications should not access the `utmpx` and `wtmpx` databases directly, but should use these functions to ensure that these databases are maintained consistently.

<code>/var/adm/wtmpx</code>	history of user access and accounting information

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
MT-Level	Unsafe

SEE ALSO `wait(2)`, `getutent(3C)`, `ttyslot(3C)`, `utmpx(4)`, `attributes(5)`, `wstat(3XFN)`

NOTES The most current entry is saved in a static structure. Multiple accesses require that it be copied before further accesses are made. On each call to either `getutxid()` or `getutxline()`, the routine examines the static structure before performing more I/O. If the contents of the static structure match what it is searching for, it looks no further. For this reason, to use `getutxline()` to search for multiple occurrences it would be necessary to zero out the static after each success, or `getutxline()` would just return the same structure over and over again. There is one exception to the rule about emptying the structure before further reads are done. The implicit read done by `pututxline()` (if it finds that it is not already at the correct place in the file) will not hurt the contents of the static structure returned by the `getutxent()`, `getutxid()`, or `getutxline()` routines, if the user has just modified those contents and passed the pointer back to `pututxline()`.

NAME	usleep – suspend execution for interval in microseconds				
SYNOPSIS	<pre>#include <unistd.h> int usleep(useconds_t <i>useconds</i>);</pre>				
DESCRIPTION	<p>The <code>usleep()</code> function suspends the caller from execution for the number of microseconds specified by the <i>useconds</i> argument. (A microsecond is .000001 seconds.) Because of other activity, or because of the time spent in processing the call, the actual suspension time may be longer than the amount of time specified.</p> <p>If the value of <i>useconds</i> is 0, then the call has no effect.</p> <p>In a single-threaded program (one not linked with <code>-lthread</code> or <code>-lpthread</code>), the <code>usleep()</code> function uses the process's realtime interval timer to indicate to the system when the process should be woken up.</p> <p>There is one real-time interval timer for each process. The <code>usleep()</code> function will not interfere with a previous setting of this timer. If the process has set this timer prior to calling <code>usleep()</code>, and if the time specified by <i>useconds</i> equals or exceeds the interval timer's prior setting, the caller will be woken up shortly before the timer was set to expire.</p> <p>Interactions between <code>usleep()</code> and either <code>alarm(2)</code> or <code>sleep(3C)</code> are unspecified.</p> <p>In a multithreaded program (one linked with <code>-lthread</code> or <code>-lpthread</code>), <code>usleep()</code> is implemented by a call to <code>nanosleep(3RT)</code> and does not modify the state of the alarm signal or the realtime interval timer. There is no interaction between this version of <code>usleep()</code> and either <code>alarm(2)</code> or <code>sleep(3C)</code>.</p>				
RETURN VALUES	On completion, <code>usleep()</code> returns 0. There are no error retruns.				
ERRORS	No errors are returned.				
USAGE	The <code>usleep()</code> function is included for its historical usage. The <code>nanosleep(3RT)</code> function is preferred over this function.				
ATTRIBUTES	See <code>attributes(5)</code> for descriptions of the following attributes:

NOTES	In a multithreaded program, only the invoking thread is suspended from execution.				

utmpname(3C)

NAME	gettutent, getutid, getutline, pututline, setutent, endutent, utmpname – user accounting database functions
SYNOPSIS	<pre>#include <utmp.h> struct utmp *gettutent(void); struct utmp *getutid(const struct utmp *id); struct utmp *getutline(const struct utmp *line); struct utmp *pututline(const struct utmp *utmp); void setutent(void); void endutent(void); int utmpname(const char *file);</pre>
DESCRIPTION	<p>These functions provide access to the user accounting database, <code>utmp</code>. Entries in the database are described by the definitions and data structures in <code><utmp.h></code>.</p> <p>The <code>utmp</code> structure contains the following members:</p> <pre>char ut_user[8]; /* user login name */ char ut_id[4]; /* /sbin/inittab id (usually line #) */ char ut_line[12]; /* device name (console, lnxx) */ short ut_pid; /* process id */ short ut_type; /* type of entry */ struct exit_status ut_exit; /* exit status of a process */ /* marked as DEAD_PROCESS */ time_t ut_time; /* time entry was made */</pre> <p>The structure <code>exit_status</code> includes the following members:</p> <pre>short e_termination; /* termination status */ short e_exit; /* exit status */</pre>
<code>gettutent()</code>	The <code>gettutent()</code> function reads in the next entry from a <code>utmp</code> database. If the database is not already open, it opens it. If it reaches the end of the database, it fails.
<code>getutid()</code>	The <code>getutid()</code> function searches forward from the current point in the <code>utmp</code> database until it finds an entry with a <code>ut_type</code> matching <code>id->ut_type</code> if the type specified is <code>RUN_LVL</code> , <code>BOOT_TIME</code> , <code>OLD_TIME</code> , or <code>NEW_TIME</code> . If the type specified in <code>id</code> is <code>INIT_PROCESS</code> , <code>LOGIN_PROCESS</code> , <code>USER_PROCESS</code> , or <code>DEAD_PROCESS</code> , then <code>getutid()</code> will return a pointer to the first entry whose type is one of these four and whose <code>ut_id</code> member matches <code>id->ut_id</code> . If the end of database is reached without a match, it fails.
<code>getutline()</code>	The <code>getutline()</code> function searches forward from the current point in the <code>utmp</code> database until it finds an entry of the type <code>LOGIN_PROCESS</code> or <code>ut_line</code> string matching the <code>line->ut_line</code> string. If the end of database is reached without a match, it fails.

pututline()	The pututline() function writes the supplied utmp structure into the utmp database. It uses getutid() to search forward for the proper place if it finds that it is not already at the proper place. It is expected that normally the user of pututline() will have searched for the proper entry using one of the these functions. If so, pututline() will not search. If pututline() does not find a matching slot for the new entry, it will add a new entry to the end of the database. It returns a pointer to the utmp structure. When called by a non-root user, pututline() invokes a setuid() root program to verify and write the entry, since the utmp database is normally writable only by root. In this event, the ut_name member must correspond to the actual user name associated with the process; the ut_type member must be either USER_PROCESS or DEAD_PROCESS; and the ut_line member must be a device special file and be writable by the user.
setutent()	The setutent() function resets the input stream to the beginning. This reset should be done before each search for a new entry if it is desired that the entire database be examined.
endutent()	The endutent() function closes the currently open database.
utmpname()	The utmpname() function allows the user to change the name of the database file examined to another file. If the file does not exist, this will not be apparent until the first attempt to reference the file is made. The utmpname() function does not open the file but closes the old file if it is currently open and saves the new file name.

RETURN VALUES A null pointer is returned upon failure to read, whether for permissions or having reached the end of file, or upon failure to write. If the file name given is longer than 79 characters, utmpname() returns 0. Otherwise, it returns 1.

USAGE These functions use buffered standard I/O for input, but pututline() uses an unbuffered non-standard write to avoid race conditions between processes trying to modify the utmp and wtmp databases.

Applications should not access the utmp and wtmp databases directly, but should use these functions to ensure that these databases are maintained consistently. Using these functions, however, may cause applications to fail if user accounting data cannot be represented properly in the utmp structure (for example, on a system where PIDs can exceed 32767). Use the functions described on the getutxent(3C) manual page instead.

ATTRIBUTES See attributes(5) for descriptions of the following attributes:

utmpname(3C)

NOTES | The most current entry is saved in a static structure. Multiple accesses require that it be copied before further accesses are made. On each call to either `getutid()` or `getutline()`, the function examines the static structure before performing more I/O. If the contents of the static structure match what it is searching for, it looks no further. For this reason, to use `getutline()` to search for multiple occurrences, it would be necessary to zero out the static area after each success, or `getutline()` would just return the same structure over and over again. There is one exception to the rule about emptying the structure before further reads are done. The implicit read done by `pututline()` (if it finds that it is not already at the correct place in the file) will not hurt the contents of the static structure returned by the `getutent()`, `getutid()` or `getutline()` functions, if the user has just modified those contents and passed the pointer back to `pututline()`.

NAME	getutxent, getutxid, getutxline, pututxline, setutxent, endutxent, utmpxname, getutmp, getutmpx, updwtmp, updwtmpx – user accounting database functions
SYNOPSIS	<pre>#include <utmpx.h> struct utmpx *getutxent (void); struct utmpx *getutxid (const struct utmpx *id); struct utmpx *getutxline (const struct utmpx *line); struct utmpx *pututxline (const struct utmpx *utmpx); void setutxent (void); void endutxent (void); int utmpxname (const char *file); void getutmp (struct utmpx *utmpx, struct utmp *utmp); void getutmpx (struct utmp *utmp, struct utmpx *utmpx); void updwtmp (char *wfile, struct utmp *utmp); void updwtmpx (char *wfilex, struct utmpx *utmpx);</pre>
DESCRIPTION	<p>These functions provide access to the user accounting database, utmpx (see utmpx(4)). Entries in the database are described by the definitions and data structures in <utmpx.h>.</p> <p>The utmpx structure contains the following members:</p> <pre>char ut_user[32]; /* user login name */ char ut_id[4]; /* /etc/inittab id (usually line #) */ char ut_line[32]; /* device name (console, lnxx) */ pid_t ut_pid; /* process id */ short ut_type; /* type of entry */ struct exit_status ut_exit; /* exit status of a process */ /* marked as DEAD_PROCESS */ struct timeval ut_tv; /* time entry was made */ int ut_session; /* session ID, used for windowing */ short ut_syslen; /* significant length of ut_host */ /* including terminating null */ char ut_host[257]; /* host name, if remote */</pre> <p>The exit_status structure includes the following members:</p> <pre>short e_termination; /* termination status */ short e_exit; /* exit status */</pre> <p>getutxent () The getutxent () function reads in the next entry from a utmpx database. If the database is not already open, it opens it. If it reaches the end of the database, it fails.</p> <p>getutxid () The getutxid () function searches forward from the current point in the utmpx database until it finds an entry with a ut_type matching id->ut_type, if the type specified is RUN_LVL, BOOT_TIME, OLD_TIME, or NEW_TIME. If the type specified in</p>

utmpxname(3C)

	<p><i>id</i> is INIT_PROCESS, LOGIN_PROCESS, USER_PROCESS, or DEAD_PROCESS, then <code>getutxid()</code> will return a pointer to the first entry whose type is one of these four and whose <code>ut_id</code> member matches <i>id</i>-><code>ut_id</code>. If the end of database is reached without a match, it fails.</p>
<code>getutxline()</code>	<p>The <code>getutxline()</code> function searches forward from the current point in the <code>utmpx</code> database until it finds an entry of the type LOGIN_PROCESS or USER_PROCESS which also has a <code>ut_line</code> string matching the <i>line</i>-><code>ut_line</code> string. If the end of the database is reached without a match, it fails.</p>
<code>pututxline()</code>	<p>The <code>pututxline()</code> function writes the supplied <code>utmpx</code> structure into the <code>utmpx</code> database. It uses <code>getutxid()</code> to search forward for the proper place if it finds that it is not already at the proper place. It is expected that normally the user of <code>pututxline()</code> will have searched for the proper entry using one of the <code>getutx()</code> routines. If so, <code>pututxline()</code> will not search. If <code>pututxline()</code> does not find a matching slot for the new entry, it will add a new entry to the end of the database. It returns a pointer to the <code>utmpx</code> structure. When called by a non-root user, <code>pututxline()</code> invokes a <code>setuid()</code> root program to verify and write the entry, since the <code>utmpx</code> database is normally writable only by root. In this event, the <code>ut_name</code> member must correspond to the actual user name associated with the process; the <code>ut_type</code> member must be either USER_PROCESS or DEAD_PROCESS; and the <code>ut_line</code> member must be a device special file and be writable by the user.</p>
<code>setutxent()</code>	<p>The <code>setutxent()</code> function resets the input stream to the beginning. This should be done before each search for a new entry if it is desired that the entire database be examined.</p>
<code>endutxent()</code>	<p>The <code>endutxent()</code> function closes the currently open database.</p>
<code>utmpxname()</code>	<p>The <code>utmpxname()</code> function allows the user to change the name of the database file examined from <code>/var/adm/utmpx</code> to any other file, most often <code>/var/adm/wtmpx</code>. If the file does not exist, this will not be apparent until the first attempt to reference the file is made. The <code>utmpxname()</code> function does not open the file, but closes the old file if it is currently open and saves the new file name. The new file name must end with the "x" character to allow the name of the corresponding <code>utmp</code> file to be easily obtainable.; otherwise, an error value of 0 is returned. The function returns 1 on success.</p>
<code>getutmp()</code>	<p>The <code>getutmp()</code> function copies the information stored in the members of the <code>utmpx</code> structure to the corresponding members of the <code>utmp</code> structure. If the information in any member of <code>utmpx</code> does not fit in the corresponding <code>utmp</code> member, the data is silently truncated. (See <code>getutent(3C)</code> for <code>utmp</code> structure)</p>
<code>getutmpx()</code>	<p>The <code>getutmpx()</code> function copies the information stored in the members of the <code>utmp</code> structure to the corresponding members of the <code>utmpx</code> structure. (See <code>getutent(3C)</code> for <code>utmp</code> structure)</p>
<code>updwtmp()</code>	<p>The <code>updwtmp()</code> function can be used in two ways.</p>

If *wfile* is `/var/adm/wtmp`, the `utmp` format record supplied by the caller is converted to a `utmpx` format record and the `/var/adm/wtmpx` file is updated (because the `/var/adm/wtmp` file no longer exists, operations on `wtmp` are converted to operations on `wtmpx` by the library functions).

If *wfile* is a file other than `/var/adm/wtmp`, it is assumed to be an old file in `utmp` format and is updated directly with the `utmp` format record supplied by the caller.

`updwtmpx()` The `updwtmpx()` function writes the contents of the `utmpx` structure pointed to by *utmpx* to the database.

utmpx structure The values of the `e_termination` and `e_exit` members of the `ut_exit` structure are valid only for records of type `DEAD_PROCESS`. For `utmpx` entries created by `init(1M)`, these values are set according to the result of the `wait()` call that `init` performs on the process when the process exits. See the `wait(2)` manual page for the values `init` uses. Applications creating `utmpx` entries can set `ut_exit` values using the following code example:

```
u->ut_exit.e_termination = WTERMSIG(process->p_exit)
u->ut_exit.e_exit = WEXITSTATUS(process->p_exit)
```

See `wstat(3XFN)` for descriptions of the `WTERMSIG` and `WEXITSTATUS` macros.

The `ut_session` member is not acted upon by the operating system. It is used by applications interested in creating `utmpx` entries.

For records of type `USER_PROCESS`, the `nonuser()` and `nonuserx()` macros use the value of the `ut_exit.e_exit` member to mark `utmpx` entries as real logins (as opposed to multiple `xterms` started by the same user on a window system). This allows the system utilities that display users to obtain an accurate indication of the number of actual users, while still permitting each `pty` to have a `utmpx` record (as most applications expect.). The `NONROOT_USER` macro defines the value that `login` places in the `ut_exit.e_exit` member.

RETURN VALUES Upon successful completion, `getutxent()`, `getutxid()`, and `getutxline()` each return a pointer to a `utmpx` structure containing a copy of the requested entry in the user accounting database. Otherwise a null pointer is returned.

The return value may point to a static area which is overwritten by a subsequent call to `getutxid()` or `getutxline()`.

Upon successful completion, `pututxline()` returns a pointer to a `utmpx` structure containing a copy of the entry added to the user accounting database. Otherwise a null pointer is returned.

The `endutxent()` and `setutxent()` functions return no value.

A null pointer is returned upon failure to read, whether for permissions or having reached the end of file, or upon failure to write.

utmpxname(3C)

USAGE These functions use buffered standard I/O for input, but `pututxline()` uses an unbuffered write to avoid race conditions between processes trying to modify the `utmpx` and `wtmpx` files.

Applications should not access the `utmpx` and `wtmpx` databases directly, but should use these functions to ensure that these databases are maintained consistently.

NOTES The most current entry is saved in a static structure. Multiple accesses require that it be copied before further accesses are made. On each call to either `getutxid()` or `getutxline()`, the routine examines the static structure before performing more I/O. If the contents of the static structure match what it is searching for, it looks no further. For this reason, to use `getutxline()` to search for multiple occurrences it would be necessary to zero out the static after each success, or `getutxline()` would just return the same structure over and over again. There is one exception to the rule about emptying the structure before further reads are done. The implicit read done by `pututxline()` (if it finds that it is not already at the correct place in the file) will not hurt the contents of the static structure returned by the `getutxent()`, `getutxid()`, or `getutxline()` routines, if the user has just modified those contents and passed the pointer back to `pututxline()`.

NAME	malloc, calloc, free, memalign, realloc, valloc, alloca – memory allocator
SYNOPSIS	<pre>#include <stdlib.h> void *malloc(size_t size); void *calloc(size_t nelem, size_t elsize); void free(void *ptr); void *memalign(size_t alignment, size_t size); void *realloc(void *ptr, size_t size); void *valloc(size_t size); #include <alloca.h> void *alloca(size_t size);</pre>
DESCRIPTION	<p>The <code>malloc()</code> and <code>free()</code> functions provide a simple, general-purpose memory allocation package. The <code>malloc()</code> function returns a pointer to a block of at least <i>size</i> bytes suitably aligned for any use. If the space assigned by <code>malloc()</code> is overrun, the results are undefined.</p> <p>The argument to <code>free()</code> is a pointer to a block previously allocated by <code>malloc()</code>, <code>calloc()</code>, or <code>realloc()</code>. After <code>free()</code> is executed, this space is made available for further allocation by the application, though not returned to the system. Memory is returned to the system only upon termination of the application. If <i>ptr</i> is a null pointer, no action occurs. If a random number is passed to <code>free()</code>, the results are undefined.</p> <p>The <code>calloc()</code> function allocates space for an array of <i>nelem</i> elements of size <i>elsize</i>. The space is initialized to zeros.</p> <p>The <code>memalign()</code> function allocates <i>size</i> bytes on a specified alignment boundary and returns a pointer to the allocated block. The value of the returned address is guaranteed to be an even multiple of <i>alignment</i>. The value of <i>alignment</i> must be a power of two and must be greater than or equal to the size of a word.</p> <p>The <code>realloc()</code> function changes the size of the block pointed to by <i>ptr</i> to <i>size</i> bytes and returns a pointer to the (possibly moved) block. The contents will be unchanged up to the lesser of the new and old sizes. If <i>ptr</i> is NULL, <code>realloc()</code> behaves like <code>malloc()</code> for the specified size. If <i>size</i> is 0 and <i>ptr</i> is not a null pointer, the space pointed to is made available for further allocation by the application, though not returned to the system. Memory is returned to the system only upon termination of the application.</p> <p>The <code>valloc()</code> function has the same effect as <code>malloc()</code>, except that the allocated memory will be aligned to a multiple of the value returned by <code>sysconf(_SC_PAGESIZE)</code>.</p>

valloc(3C)

The `alloca()` function allocates *size* bytes of space in the stack frame of the caller, and returns a pointer to the allocated block. This temporary space is automatically freed when the caller returns. If the allocated block is beyond the current stack limit, the resulting behavior is undefined.

RETURN VALUES Upon successful completion, each of the allocation functions returns a pointer to space suitably aligned (after possible pointer coercion) for storage of any type of object.

If there is no available memory, `malloc()`, `realloc()`, `memalign()`, `valloc()`, and `calloc()` return a null pointer. When `realloc()` is called with *size* > 0 and returns `NULL`, the block pointed to by *ptr* is left intact. If *size*, *nelem*, or *elsize* is 0, either a null pointer or a unique pointer that can be passed to `free()` is returned.

If `malloc()`, `calloc()`, or `realloc()` returns unsuccessfully, `errno` will be set to indicate the error. The `free()` function does not set `errno`.

ERRORS The `malloc()`, `calloc()`, and `realloc()` functions will fail if:

`ENOMEM` The physical limits of the system are exceeded by *size* bytes of memory which cannot be allocated.

`EAGAIN` There is not enough memory available to allocate *size* bytes of memory; but the application could try again later.

USAGE Portable applications should avoid using `valloc()` but should instead use `malloc()` or `mmap(2)`. On systems with a large page size, the number of successful `valloc()` operations might be 0.

Comparative features of `malloc(3C)`, `bsdmalloc(3MALLOC)`, and `malloc(3MALLOC)` are as follows:

- The `bsdmalloc(3MALLOC)` routines afford better performance, but are space-inefficient.
- The `malloc(3MALLOC)` routines are space-efficient, but have slower performance.
- The standard, fully SCD-compliant `malloc` routines are a trade-off between performance and space-efficiency.

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Interface Stability	<code>malloc()</code> , <code>calloc()</code> , <code>free()</code> , <code>realloc()</code> , <code>valloc()</code> are Standard; <code>memalign()</code> and <code>alloca()</code> are Stable.
MT-Level	Safe

SEE ALSO `brk(2)`, `getrlimit(2)`, `bsdmalloc(3MALLOC)`, `malloc(3MALLOC)`, `mapmalloc(3MALLOC)`, `watchmalloc(3MALLOC)`, `attributes(5)`

WARNINGS Undefined results will occur if the size requested for a block of memory exceeds the maximum size of a process's heap, which can be obtained with `getrlimit(2)`

The `alloca()` function is machine-, compiler-, and most of all, system-dependent. Its use is strongly discouraged.

valloc(3MALLOC)

NAME	watchmalloc, cfree, memalign, valloc – debugging memory allocator
SYNOPSIS	<pre>#include <stdlib.h> void *malloc(size_t size); void free(void *ptr); void *realloc(void *ptr, size_t size); void *memalign(size_t alignment, size_t size); void *valloc(size_t size); void *calloc(size_t nelem, size_t elsize); void cfree(void *ptr, size_t nelem, size_t elsize); #include <malloc.h> int mallopt(int cmd, int value); struct mallinfo mallinfo(void);</pre>
DESCRIPTION	<p>The collection of malloc() functions in this shared object are an optional replacement for the standard versions of the same functions in the system C library. See malloc(3C). They provide a more strict interface than the standard versions and enable enforcement of the interface through the watchpoint facility of /proc. See proc(4).</p> <p>Any dynamically linked application can be run with these functions in place of the standard functions if the following string is present in the environment (see ld.so.1(1)):</p> <pre>LD_PRELOAD=watchmalloc.so.1</pre> <p>The individual function interfaces are identical to the standard ones as described in malloc(3C). However, laxities provided in the standard versions are not permitted when the watchpoint facility is enabled (see WATCHPOINTS below):</p> <ul style="list-style-type: none">■ Memory may not be freed more than once.■ A pointer to freed memory may not be used in a call to realloc().■ A call to malloc() immediately following a call to free() will not return the same space.■ Any reference to memory that has been freed yields undefined results. <p>To enforce these restrictions partially, without great loss in speed as compared to the watchpoint facility described below, a freed block of memory is overwritten with the pattern 0xdeadbeef before returning from free(). The malloc() function returns with the allocated memory filled with the pattern 0xbaddcafe as a precaution against applications incorrectly expecting to receive back unmodified memory from the last free(). The calloc() function always returns with the memory zero-filled.</p>

WATCHPOINTS

Entry points for `malloc()` and `mallinfo()` are provided as empty routines, and are present only because some `malloc()` implementations provide them.

The watchpoint facility of `/proc` can be applied by a process to itself. The functions in `watchmalloc.so.1` use this feature if the following string is present in the environment:

```
MALLOC_DEBUG=WATCH
```

This causes every block of freed memory to be covered with `WA_WRITE` watched areas. If the application attempts to write any part of freed memory, it will trigger a watchpoint trap, resulting in a `SIGTRAP` signal, which normally produces an application core dump.

A header is maintained before each block of allocated memory. Each header is covered with a watched area, thereby providing a red zone before and after each block of allocated memory (the header for the subsequent memory block serves as the trailing red zone for its preceding memory block). Writing just before or just after a memory block returned by `malloc()` will trigger a watchpoint trap.

Watchpoints incur a large performance penalty. Requesting `MALLOC_DEBUG=WATCH` can cause the application to run 10 to 100 times slower, depending on the use made of allocated memory.

Further options are enabled by specifying a comma-separated string of options:

```
MALLOC_DEBUG=WATCH,RW,STOP
```

<code>WATCH</code>	Enables <code>WA_WRITE</code> watched areas as described above.
<code>RW</code>	Enables both <code>WA_READ</code> and <code>WA_WRITE</code> watched areas. An attempt either to read or write freed memory or the red zones will trigger a watchpoint trap. This incurs even more overhead and can cause the application to run up to 1000 times slower.
<code>STOP</code>	The process will stop showing a <code>FLTWATCH</code> machine fault if it triggers a watchpoint trap, rather than dumping core with a <code>SIGTRAP</code> signal. This allows a debugger to be attached to the live process at the point where it underwent the watchpoint trap. Also, the various <code>/proc</code> tools described in <code>proc(1)</code> can be used to examine the stopped process.

One of `WATCH` or `RW` must be specified, else the watchpoint facility is not engaged. `RW` overrides `WATCH`. Unrecognized options are silently ignored.

`valloc(3MALLOC)`

LIMITATIONS Sizes of memory blocks allocated by `malloc()` are rounded up to the the worst-case alignment size, 8 bytes for 32-bit processes and 16 bytes for 64-bit processes. Accessing the extra space allocated for a memory block is technically a memory violation but is in fact innocuous. Such accesses are not detected by the watchpoint facility of `watchmalloc`.

Interposition of `watchmalloc.so.1` fails innocuously if the target application is statically linked with respect to its `malloc()` functions.

SEE ALSO `proc(1)`, `bsdmalloc(3MALLOC)`, `calloc(3C)`, `free(3C)`, `malloc(3C)`, `malloc(3MALLOC)`, `mapmalloc(3MALLOC)`, `memalign(3C)`, `realloc(3C)`, `valloc(3C)`, `libmapmalloc(3LIB)`, `proc(4)`, `attributes(5)`

NAME	vprintf, vfprintf, vsprintf, vsnprintf – print formatted output of a variable argument list
SYNOPSIS	<pre>#include <stdio.h> #include <stdarg.h> int vprintf(const char *format, va_list ap); int vfprintf(FILE *stream, const char *format, va_list ap); int vsprintf(char *s, const char *format, va_list ap); int vsnprintf(char *s, size_t n, const char *format, va_list ap);</pre>
DESCRIPTION	<p>The vprintf(), vfprintf(), vsprintf() and vsnprintf() functions are the same as printf(), fprintf(), sprintf(), and snprintf(), respectively, except that instead of being called with a variable number of arguments, they are called with an argument list as defined in the <stdarg.h> header. See printf(3C) and stdarg(3HEAD).</p> <p>The <stdarg.h> header defines the type va_list and a set of macros for advancing through a list of arguments whose number and types may vary. The argument ap to the vprint family of functions is of type va_list. This argument is used with the <stdarg.h> header file macros va_start(), va_arg(), and va_end() (see stdarg(3HEAD)). The EXAMPLES section below demonstrates the use of va_start() and va_end() with vprintf().</p> <p>The macro va_alist() is used as the parameter list in a function definition, as in the function called error() in the example below. The macro va_start(ap, parmN), where ap is of type va_list and parmN is the rightmost parameter (just before ...), must be called before any attempt to traverse and access unnamed arguments is made. The va_end(ap) macro must be invoked when all desired arguments have been accessed. The argument list in ap can be traversed again if va_start() is called again after va_end(). In the example below, the error() arguments (arg1, arg2, ...) are passed to vfprintf() in the argument ap.</p>
RETURN VALUES	The vprintf(), vfprintf(), and vsprintf() functions return the number of characters transmitted (not including \0 in the case of vsprintf()). The vsnprintf() function returns the number of characters formatted, that is, the number of characters that would have been written to the buffer if it were large enough. Each function returns a negative value if an output error was encountered.
ERRORS	<p>The vprintf() and vfprintf() functions will fail if either the stream is unbuffered or the stream's buffer needed to be flushed and:</p> <p>EFBIG The file is a regular file and an attempt was made to write at or beyond the offset maximum.</p>
EXAMPLES	<p>EXAMPLE 1 Using vprintf() to write an error routine.</p> <p>The following demonstrates how vfprintf() could be used to write an error routine:</p>

fprintf(3C)

EXAMPLE 1 Using `vfprintf()` to write an error routine. (Continued)

```
#include <stdio.h>
#include <stdarg.h>
. . .
/*
 * error should be called like
 *     error(function_name, format, arg1, ...);
 */
void error(char *function_name, char *format, ...)
{
    va_list ap;
    va_start(ap, format);
    /* print out name of function causing error */
    (void) fprintf(stderr, "ERR in %s: ", function_name);
    /* print out remainder of message */
    (void) vfprintf(stderr, format, ap);
    va_end(ap);
    (void) abort;
}
```

NAME	printf, fprintf, sprintf, vprintf, vfprintf, vsprintf – formatted output conversion
SYNOPSIS	<pre> /usr/ucb/cc [flag ...] file ... #include <stdio.h> int printf(format, ...); const char *format; int fprintf(stream, format, va_list); FILE *stream; char *format; va_dcl; char *sprintf(s, format, va_list); char *s, *format; va_dcl; int vprintf(format, ap); char *format; va_list ap; int vfprintf(stream, format, ap); FILE *stream; char *format; va_list ap; char *vsprintf(s, format, ap); char *s, *format; va_list ap; </pre>
DESCRIPTION	<p>printf() places output on the standard output stream stdout. fprintf() places output on the named output stream. sprintf() places “output,” followed by the NULL character (\0), in consecutive bytes starting at *s; it is the user’s responsibility to ensure that enough storage is available.</p> <p>vprintf(), vfprintf(), and vsprintf() are the same as printf(), fprintf(), and sprintf() respectively, except that instead of being called with a variable number of arguments, they are called with an argument list as defined by varargs(3HEAD).</p> <p>Each of these functions converts, formats, and prints its args under control of the format. The format is a character string which contains two types of objects: plain characters, which are simply copied to the output stream, and conversion specifications, each of which causes conversion and printing of zero or more args. The results are undefined if there are insufficient args for the format. If the format is exhausted while args remain, the excess args are simply ignored.</p> <p>Each conversion specification is introduced by the character %. After the %, the following appear in sequence:</p>

fprintf(3UCB)

- Zero or more *flags*, which modify the meaning of the conversion specification.
- An optional decimal digit string specifying a minimum *field width*. If the converted value has fewer characters than the field width, it will be padded on the left (or right, if the left-adjustment flag '-', described below, has been given) to the field width. The padding is with blanks unless the field width digit string starts with a zero, in which case the padding is with zeros.
- A *precision* that gives the minimum number of digits to appear for the d, i, o, u, x, or X conversions, the number of digits to appear after the decimal point for the e, E, and f conversions, the maximum number of significant digits for the g and G conversion, or the maximum number of characters to be printed from a string in s conversion. The precision takes the form of a period (.) followed by a decimal digit string; a NULL digit string is treated as zero. Padding specified by the precision overrides the padding specified by the field width.
- An optional l (ell) specifying that a following d, i, o, u, x, or X conversion character applies to a long integer *arg*. An l before any other conversion character is ignored.
- A character that indicates the type of conversion to be applied.

A field width or precision or both may be indicated by an asterisk (*) instead of a digit string. In this case, an integer *arg* supplies the field width or precision. The *arg* that is actually converted is not fetched until the conversion letter is seen, so the *args* specifying field width or precision must appear *before* the *arg* (if any) to be converted. A negative field width argument is taken as a '-' flag followed by a positive field width. If the precision argument is negative, it will be changed to zero.

The flag characters and their meanings are:

-	The result of the conversion will be left-justified within the field.
+	The result of a signed conversion will always begin with a sign (+ or -).
blank	If the first character of a signed conversion is not a sign, a blank will be prefixed to the result. This implies that if the blank and + flags both appear, the blank flag will be ignored.
#	This flag specifies that the value is to be converted to an "alternate form." For c, d, i, s, and u conversions, the flag has no effect. For o conversion, it increases the precision to force the first digit of the result to be a zero. For x or X conversion, a non-zero result will have 0x or 0X prefixed to it. For e, E, f, g, and G conversions, the result will always contain a decimal point, even if no digits follow the point (normally, a decimal point appears in the result of these conversions only if a digit follows it). For g and G conversions, trailing zeroes will <i>not</i> be removed from the result (which they normally are).

The conversion characters and their meanings are:

d,i,o,u,x,X	The integer <i>arg</i> is converted to signed decimal (d or i), unsigned octal (o), unsigned decimal (u), or unsigned hexadecimal notation (x and X), respectively; the letters abcdef are used for x conversion and the letters ABCDEF for X conversion. The precision specifies the minimum number of digits to appear; if the value being converted can be represented in fewer digits, it will be expanded with leading zeroes. (For compatibility with older versions, padding with leading zeroes may alternatively be specified by prepending a zero to the field width. This does not imply an octal value for the field width.) The default precision is 1. The result of converting a zero value with a precision of zero is a NULL string.
f	The float or double <i>arg</i> is converted to decimal notation in the style <code>[-]ddd.ddd</code> where the number of digits after the decimal point is equal to the precision specification. If the precision is missing, 6 digits are given; if the precision is explicitly 0, no digits and no decimal point are printed.
e,E	The float or double <i>arg</i> is converted in the style <code>[-]d.ddd_{e±ddd}</code> , where there is one digit before the decimal point and the number of digits after it is equal to the precision; when the precision is missing, 6 digits are produced; if the precision is zero, no decimal point appears. The E format code will produce a number with E instead of e introducing the exponent. The exponent always contains at least two digits.
g,G	The float or double <i>arg</i> is printed in style f or e (or in style E in the case of a G format code), with the precision specifying the number of significant digits. The style used depends on the value converted: style e or E will be used only if the exponent resulting from the conversion is less than -4 or greater than the precision. Trailing zeroes are removed from the result; a decimal point appears only if it is followed by a digit.
The e, E f, g, and G formats print IEEE indeterminate values (infinity or not-a-number) as "Infinity" or "NaN" respectively.	
c	The character <i>arg</i> is printed.
s	The <i>arg</i> is taken to be a string (character pointer) and characters from the string are printed until a NULL character (<code>\0</code>) is encountered or until the number of characters indicated by the precision specification is reached. If the precision is missing, it is taken to be infinite, so all characters up to the first NULL character are printed. A NULL value for <i>arg</i> will yield undefined results.
%	Print a %; no argument is converted.

`fprintf(3UCB)`

In no case does a non-existent or small field width cause truncation of a field; if the result of a conversion is wider than the field width, the field is simply expanded to contain the conversion result. Padding takes place only if the specified field width exceeds the actual width. Characters generated by `printf()` and `fprintf()` are printed as if `putc(3C)` had been called.

RETURN VALUES Upon success, `printf()` and `fprintf()` return the number of characters transmitted, excluding the null character. `vprintf()` and `fprintf()` return the number of characters transmitted. `sprintf()` and `vsprintf()` always return `s`. If an output error is encountered, `printf()`, `fprintf()`, `vprintf()`, and `fprintf()` return EOF.

EXAMPLES **EXAMPLE 1** Examples of the `printf` Command To Print a Date and Time

To print a date and time in the form "Sunday, July 3, 10:02," where *weekday* and *month* are pointers to NULL-terminated strings:

```
printf("%s, %s %i, %d:%.2d", weekday, month, day, hour, min);
```

EXAMPLE 2 Examples of the `printf` Command To Print to Five Decimal Places

To print to five decimal places:

```
printf("pi = %.5f", 4 * atan(1. 0));
```

SEE ALSO `econvert(3C)`, `putc(3C)`, `scanf(3C)`, `vprintf(3C)`, `varargs(3HEAD)`

NOTES Use of these interfaces should be restricted to only applications written on BSD platforms. Use of these interfaces with any of the system libraries or in multi-thread applications is unsupported.

Very wide fields (>128 characters) fail.

NAME	scanf, fscanf, sscanf, vscanf, vfscanf, vsscanf – convert formatted input
SYNOPSIS	<pre>#include <stdio.h> int scanf(const char *format, ...); int fscanf(FILE*stream, const char *format, ...); int sscanf(const char *s, const char *format, ...); #include <stdarg.h> #include <stdio.h> int vscanf(const char *format, va_list arg); int vfscanf(FILE *stream, const char *format, va_list arg); int vsscanf(const char *s, const char *format, va_list arg);</pre>
DESCRIPTION	<p>The <code>scanf()</code> function reads from the standard input stream <code>stdin</code>.</p> <p>The <code>fscanf()</code> function reads from the named input <i>stream</i>.</p> <p>The <code>sscanf()</code> function reads from the string <i>s</i>.</p> <p>The <code>vscanf()</code>, <code>vfscanf()</code>, and <code>vsscanf()</code> functions are equivalent to the <code>scanf()</code>, <code>fscanf()</code>, and <code>sscanf()</code> functions, respectively, except that instead of being called with a variable number of arguments, they are called with an argument list as defined by the <code><stdarg.h></code> header (see <code>stdarg(3HEAD)</code>). These functions do not invoke the <code>va_end()</code> macro. Applications using these functions should call <code>va_end(ap)</code> afterwards to clean up.</p> <p>Each function reads bytes, interprets them according to a format, and stores the results in its arguments. Each expects, as arguments, a control string <i>format</i> described below, and a set of <i>pointer</i> arguments indicating where the converted input should be stored. The result is undefined if there are insufficient arguments for the format. If the format is exhausted while arguments remain, the excess arguments are evaluated but are otherwise ignored.</p> <p>Conversions can be applied to the <i>n</i>th argument after the <i>format</i> in the argument list, rather than to the next unused argument. In this case, the conversion character <code>%</code> (see below) is replaced by the sequence <code>%n\$</code>, where <i>n</i> is a decimal integer in the range <code>[1, NL_ARGMAX]</code>. This feature provides for the definition of format strings that select arguments in an order appropriate to specific languages. In format strings containing the <code>%n\$</code> form of conversion specifications, it is unspecified whether numbered arguments in the argument list can be referenced from the format string more than once.</p> <p>The <i>format</i> can contain either form of a conversion specification, that is, <code>%</code> or <code>%n\$</code>, but the two forms cannot normally be mixed within a single <i>format</i> string. The only exception to this is that <code>%%</code> or <code>/*</code> can be mixed with the <code>%n\$</code> form.</p>

vfscanf(3C)

The `scanf()` function in all its forms allows for detection of a language-dependent radix character in the input string. The radix character is defined in the program's locale (category `LC_NUMERIC`). In the POSIX locale, or in a locale where the radix character is not defined, the radix character defaults to a period (`.`).

The format is a character string, beginning and ending in its initial shift state, if any, composed of zero or more directives. Each directive is composed of one of the following:

- one or more *white-space characters* (space, tab, newline, vertical-tab or form-feed characters);
- an *ordinary character* (neither `%` nor a white-space character); or
- a *conversion specification*.

Conversion Specifications

Each conversion specification is introduced by the character `%` or the character sequence `%n$`, after which the following appear in sequence:

- An optional assignment-suppressing character `*`.
- An optional non-zero decimal integer that specifies the maximum field width.
- An optional size modifier `h`, `l` (ell), `ll` (ell ell), or `L` indicating the size of the receiving object. The conversion characters `d`, `i`, and `n` must be preceded by `h` if the corresponding argument is a pointer to `short int` rather than a pointer to `int`, by `l` (ell) if it is a pointer to `long int`, or by `ll` (ell ell) if it is a pointer to `long long int`. Similarly, the conversion characters `o`, `u`, and `x` must be preceded by `h` if the corresponding argument is a pointer to `unsigned short int` rather than a pointer to `unsigned int`, by `l` (ell) if it is a pointer to `unsigned long int`, or by `ll` (ell ell) if it is a pointer to `unsigned long long int`. The conversion characters `e`, `f`, and `g` must be preceded by `l` (ell) if the corresponding argument is a pointer to `double` rather than a pointer to `float`, or by `L` if it is a pointer to `long double`. Finally, the conversion characters `c`, `s`, and `[` must be preceded by `l` (ell) if the corresponding argument is a pointer to `wchar_t` rather than a pointer to a character type. If an `h`, `l` (ell), `ll` (ell ell), or `L` appears with any other conversion character, the behavior is undefined.
- A conversion character that specifies the type of conversion to be applied. The valid conversion characters are described below.

The `scanf()` functions execute each directive of the format in turn. If a directive fails, as detailed below, the function returns. Failures are described as input failures (due to the unavailability of input bytes) or matching failures (due to inappropriate input).

A directive composed of one or more white-space characters is executed by reading input until no more valid input can be read, or up to the first byte which is not a white-space character which remains unread.

A directive that is an ordinary character is executed as follows. The next byte is read from the input and compared with the byte that comprises the directive; if the comparison shows that they are not equivalent, the directive fails, and the differing and subsequent bytes remain unread.

A directive that is a conversion specification defines a set of matching input sequences, as described below for each conversion character. A conversion specification is executed in the following steps:

Input white-space characters (as specified by `isspace(3C)`) are skipped, unless the conversion specification includes a `[\, c, C, or n` conversion character.

An item is read from the input, unless the conversion specification includes an `n` conversion character. An input item is defined as the longest sequence of input bytes (up to any specified maximum field width, which may be measured in characters or bytes dependent on the conversion character) which is an initial subsequence of a matching sequence. The first byte, if any, after the input item remains unread. If the length of the input item is 0, the execution of the conversion specification fails; this condition is a matching failure, unless end-of-file, an encoding error, or a read error prevented input from the stream, in which case it is an input failure.

Except in the case of a `%` conversion character, the input item (or, in the case of a `%n` conversion specification, the count of input bytes) is converted to a type appropriate to the conversion character. If the input item is not a matching sequence, the execution of the conversion specification fails; this condition is a matching failure. Unless assignment suppression was indicated by a `*`, the result of the conversion is placed in the object pointed to by the first argument following the *format* argument that has not already received a conversion result if the conversion specification is introduced by `%`, or in the *n*th argument if introduced by the character sequence `%n$`. If this object does not have an appropriate type, or if the result of the conversion cannot be represented in the space provided, the behavior is undefined.

Conversion Characters

The following conversion characters are valid:

- d Matches an optionally signed decimal integer, whose format is the same as expected for the subject sequence of `strtol(3C)` with the value 10 for the *base* argument. In the absence of a size modifier, the corresponding argument must be a pointer to `int`.
- i Matches an optionally signed integer, whose format is the same as expected for the subject sequence of `strtol()` with 0 for the *base* argument. In the absence of a size modifier, the corresponding argument must be a pointer to `int`.
- o Matches an optionally signed octal integer, whose format is the same as expected for the subject sequence of `strtoul(3C)` with the value 8 for the *base* argument. In the absence of a size modifier, the corresponding argument must be a pointer to unsigned `int`.

vfscanf(3C)

u	Matches an optionally signed decimal integer, whose format is the same as expected for the subject sequence of <code>strtoul()</code> with the value 10 for the <i>base</i> argument. In the absence of a size modifier, the corresponding argument must be a pointer to <code>unsigned int</code> .
x	Matches an optionally signed hexadecimal integer, whose format is the same as expected for the subject sequence of <code>strtoul()</code> with the value 16 for the <i>base</i> argument. In the absence of a size modifier, the corresponding argument must be a pointer to <code>unsigned int</code> .
e,f,g	Matches an optionally signed floating-point number, whose format is the same as expected for the subject sequence of <code>strtod(3C)</code> . In the absence of a size modifier, the corresponding argument must be a pointer to <code>float</code> . If the <code>printf(3C)</code> family of functions generates character string representations for infinity and NaN (a 7858 symbolic entity encoded in floating-point format) to support the ANSI/IEEE Std 754: 1985 standard, the <code>scanf()</code> family of functions will recognize them as input.
s	Matches a sequence of bytes that are not white-space characters. The corresponding argument must be a pointer to the initial byte of an array of <code>char</code> , <code>signed char</code> , or <code>unsigned char</code> large enough to accept the sequence and a terminating null character code, which will be added automatically. If an <code>l</code> (<code>ell</code>) qualifier is present, the input is a sequence of characters that begins in the initial shift state. Each character is converted to a wide-character as if by a call to the <code>mbrtowc(3C)</code> function, with the conversion state described by an <code>mbstate_t</code> object initialized to zero before the first character is converted. The corresponding argument must be a pointer to an array of <code>wchar_t</code> large enough to accept the sequence and the terminating null wide-character, which will be added automatically.
[Matches a non-empty sequence of characters from a set of expected characters (the <i>scanset</i>). The normal skip over white-space characters is suppressed in this case. The corresponding argument must be a pointer to the initial byte of an array of <code>char</code> , <code>signed char</code> , or <code>unsigned char</code> large enough to accept the sequence and a terminating null byte, which will be added automatically. If an <code>l</code> (<code>ell</code>) qualifier is present, the input is a sequence of characters that begins in the initial shift state. Each character in the sequence is converted to a wide-character as if by a call to the <code>mbrtowc()</code> function, with the conversion state described by an <code>mbstate_t</code> object initialized to zero before the first character is converted. The corresponding argument must be a pointer to an array of <code>wchar_t</code> large enough to accept the sequence and the terminating null wide-character, which will be added automatically.

The conversion specification includes all subsequent characters in the *format* string up to and including the matching right square bracket (]). The characters between the square brackets (the *scanlist*) comprise the scanset, unless the character after the left square bracket is a circumflex (^), in which case the scanset contains all characters that do not appear in the scanlist between the circumflex and the right square bracket. If the conversion specification begins with [] or [^], the right square bracket is included in the scanlist and the next right square bracket is the matching right square bracket that ends the conversion specification; otherwise the first right square bracket is the one that ends the conversion specification. If a - is in the scanlist and is not the first character, nor the second where the first character is a ^, nor the last character, it indicates a range of characters to be matched.

c Matches a sequence of characters of the number specified by the field width (1 if no field width is present in the conversion specification). The corresponding argument must be a pointer to the initial byte of an array of `char`, `signed char`, or `unsigned char` large enough to accept the sequence. No null byte is added. The normal skip over white-space characters is suppressed in this case.

If an `l` (ell) qualifier is present, the input is a sequence of characters that begins in the initial shift state. Each character in the sequence is converted to a wide-character as if by a call to the `mbrtowc()` function, with the conversion state described by an `mbstate_t` object initialized to zero before the first character is converted. The corresponding argument must be a pointer to an array of `wchar_t` large enough to accept the resulting sequence of wide-characters. No null wide-character is added.

p Matches the set of sequences that is the same as the set of sequences that is produced by the `%p` conversion of the corresponding `printf(3C)` functions. The corresponding argument must be a pointer to a pointer to `void`. If the input item is a value converted earlier during the same program execution, the pointer that results will compare equal to that value; otherwise the behavior of the `%p` conversion is undefined.

n No input is consumed. The corresponding argument must be a pointer to the integer into which is to be written the number of bytes read from the input so far by this call to the `scanf()` functions. Execution of a `%n` conversion specification does not increment the assignment count returned at the completion of execution of the function.

C Same as `lc`.

S Same as `ls`.

% Matches a single `%`; no conversion or assignment occurs. The complete conversion specification must be `%%`.

If a conversion specification is invalid, the behavior is undefined.

vfscanf(3C)

The conversion characters E, G, and X are also valid and behave the same as, respectively, e, g, and x.

If end-of-file is encountered during input, conversion is terminated. If end-of-file occurs before any bytes matching the current conversion specification (except for %n) have been read (other than leading white-space characters, where permitted), execution of the current conversion specification terminates with an input failure. Otherwise, unless execution of the current conversion specification is terminated with a matching failure, execution of the following conversion specification (if any) is terminated with an input failure.

Reaching the end of the string in `sscanf()` is equivalent to encountering end-of-file for `fscanf()`.

If conversion terminates on a conflicting input, the offending input is left unread in the input. Any trailing white space (including newline characters) is left unread unless matched by a conversion specification. The success of literal matches and suppressed assignments is only directly determinable via the %n conversion specification.

The `fscanf()` and `scanf()` functions may mark the `st_atime` field of the file associated with *stream* for update. The `st_atime` field will be marked for update by the first successful execution of `fgetc(3C)`, `fgets(3C)`, `fread(3C)`, `fscanf()`, `getc(3C)`, `getchar(3C)`, `gets(3C)`, or `scanf()` using *stream* that returns data not supplied by a prior call to `ungetc(3C)`.

RETURN VALUES

Upon successful completion, these functions return the number of successfully matched and assigned input items; this number can be 0 in the event of an early matching failure. If the input ends before the first matching failure or conversion, EOF is returned. If a read error occurs the error indicator for the stream is set, EOF is returned, and `errno` is set to indicate the error.

ERRORS

For the conditions under which the `scanf()` functions will fail and may fail, refer to `fgetc(3C)` or `fgetwc(3C)`.

In addition, `fscanf()` may fail if:

EILSEQ Input byte sequence does not form a valid character.

EINVAL There are insufficient arguments.

USAGE

If the application calling the `scanf()` functions has any objects of type `wint_t` or `wchar_t`, it must also include the header `<wchar.h>` to have these objects defined.

EXAMPLES

EXAMPLE 1 The call:

```
int i, n; float x; char name[50];
n = scanf("%d%f%s", &i, &x, name)
```

with the input line:

```
25 54.32E-1 Hamster
```

EXAMPLE 1 The call: (Continued)

will assign to *n* the value 3, to *i* the value 25, to *x* the value 5.432, and *name* will contain the string Hamster.

EXAMPLE 2 The call:

```
int i; float x; char name[50];
(void) scanf("%2d%f%*d %[0123456789]", &i, &x, name);
```

with input:

```
56789 0123 56a72
```

will assign 56 to *i*, 789.0 to *x*, skip 0123, and place the string 56\0 in *name*. The next call to `getchar(3C)` will return the character a.

vfwprintf(3C)

NAME	vfwprintf, vwprintf, vswprintf – wide-character formatted output of a stdarg argument list				
SYNOPSIS	<pre>#include <stdarg.h> #include <stdio.h> #include <wchar.h> int vwprintf(const wchar_t *format, va_list arg); int vfwprintf(FILE *stream, const wchar_t *format, va_list arg); int vswprintf(wchar_t *s, size_t n, const wchar_t *format, va_list arg);</pre>				
DESCRIPTION	<p>The vwprintf(), vfwprintf(), and vswprintf() functions are the same as wprintf(), fwprintf(), and swprintf() respectively, except that instead of being called with a variable number of arguments, they are called with an argument list as defined by <stdarg.h>. See stdarg(3HEAD).</p> <p>These functions do not invoke the va_end() macro. However, as these functions do invoke the va_arg() macro, the value of ap after the return is indeterminate.</p>				
RETURN VALUES	Refer to fwprintf(3C).				
ERRORS	Refer to fwprintf(3C).				
USAGE	Applications using these functions should call va_end(ap) afterwards to clean up.				
ATTRIBUTES	See attributes(5) for descriptions of the following attributes:				
	<table border="1"><thead><tr><th>ATTRIBUTE TYPE</th><th>ATTRIBUTE VALUE</th></tr></thead><tbody><tr><td>MT-Level</td><td>MT-Safe with exceptions</td></tr></tbody></table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	MT-Level	MT-Safe with exceptions
ATTRIBUTE TYPE	ATTRIBUTE VALUE				
MT-Level	MT-Safe with exceptions				
SEE ALSO	fwprintf(3C), setlocale(3C), attributes(5), stdarg(3HEAD)				
NOTES	The vwprintf(), vfwprintf(), and vswprintf() functions can be used safely in multithreaded applications, as long as setlocale(3C) is not being called to change the locale.				

NAME	<code>fwscanf</code> , <code>wscanf</code> , <code>swscanf</code> , <code>vfwscanf</code> , <code>vscanf</code> , <code>vswscanf</code> – convert formatted wide-character input
SYNOPSIS	<pre>#include <stdio.h> #include <wchar.h> int fwscanf(FILE *stream, const wchar_t *format, ...); int wscanf(const wchar_t *format, ...); int swscanf(const wchar_t *s, const wchar_t *format, ...); #include <stdarg.h> #include <stdio.h> #include <wchar.h> int vfwscanf(FILE *stream, const wchar_t *format, va_list arg); int vscanf(const wchar_t *ws, const wchar_t *format, va_list arg); int vswscanf(const wchar_t *format, va_list arg);</pre>
DESCRIPTION	<p>The <code>fwscanf()</code> function reads from the named input <i>stream</i>.</p> <p>The <code>wscanf()</code> function reads from the standard input stream <code>stdin</code>.</p> <p>The <code>swscanf()</code> function reads from the wide-character string <i>s</i>.</p> <p>The <code>vfwscanf()</code>, <code>vscanf()</code>, and <code>vswscanf()</code> functions are equivalent to the <code>fwscanf()</code>, <code>swscanf()</code>, and <code>wscanf()</code> functions, respectively, except that instead of being called with a variable number of arguments, they are called with an argument list as defined by the <code><stdarg.h></code> header (see <code>stdarg(3HEAD)</code>). These functions do not invoke the <code>va_end()</code> macro. Applications using these functions should call <code>va_end(ap)</code> afterwards to clean up.</p> <p>Each function reads wide-characters, interprets them according to a format, and stores the results in its arguments. Each expects, as arguments, a control wide-character string <i>format</i> described below, and a set of <i>pointer</i> arguments indicating where the converted input should be stored. The result is undefined if there are insufficient arguments for the format. If the format is exhausted while arguments remain, the excess arguments are evaluated but are otherwise ignored.</p> <p>Conversions can be applied to the <i>n</i>th argument after the <i>format</i> in the argument list, rather than to the next unused argument. In this case, the conversion wide-character % (see below) is replaced by the sequence <code>%n\$</code>, where <i>n</i> is a decimal integer in the range <code>[1, NL_ARGMAX]</code>. This feature provides for the definition of format wide-character strings that select arguments in an order appropriate to specific languages. In format wide-character strings containing the <code>%n\$</code> form of conversion specifications, it is unspecified whether numbered arguments in the argument list can be referenced from the format wide-character string more than once.</p>

vwscanf(3C)

The *format* can contain either form of a conversion specification, that is, % or %n\$, but the two forms cannot normally be mixed within a single *format* wide-character string. The only exception to this is that %% or %* can be mixed with the %n\$ form.

The `fwscanf()` function in all its forms allows for detection of a language-dependent radix character in the input string, encoded as a wide-character value. The radix character is defined in the program's locale (category `LC_NUMERIC`). In the POSIX locale, or in a locale where the radix character is not defined, the radix character defaults to a period (.).

The format is a wide-character string composed of zero or more directives. Each directive is composed of one of the following: one or more white-space wide-characters (space, tab, newline, vertical-tab or form-feed characters); an ordinary wide-character (neither % nor a white-space character); or a conversion specification. Each conversion specification is introduced by a % or the sequence %n\$ after which the following appear in sequence:

- An optional assignment-suppressing character *.
- An optional non-zero decimal integer that specifies the maximum field width.
- An optional size modifier h, l(ell), or L indicating the size of the receiving object. The conversion wide-characters c, s, and [must be preceded by l (ell) if the corresponding argument is a pointer to `wchar_t` rather than a pointer to a character type. The conversion wide-characters d, i, and n must be preceded by h if the corresponding argument is a pointer to `short int` rather than a pointer to `int`, or by l (ell) if it is a pointer to `long int`. Similarly, the conversion wide-characters o, u, and x must be preceded by h if the corresponding argument is a pointer to `unsigned short int` rather than a pointer to `unsigned int`, or by l (ell) if it is a pointer to `unsigned long int`. The conversion wide-characters e, f, and g must be preceded by l (ell) if the corresponding argument is a pointer to `double` rather than a pointer to `float`, or by L if it is a pointer to `long double`. If an h, l (ell), or L appears with any other conversion wide-character, the behavior is undefined.
- A conversion wide-character that specifies the type of conversion to be applied. The valid conversion wide-characters are described below.

The `fwscanf()` functions execute each directive of the format in turn. If a directive fails, as detailed below, the function returns. Failures are described as input failures (due to the unavailability of input bytes) or matching failures (due to inappropriate input).

A directive composed of one or more white-space wide-characters is executed by reading input until no more valid input can be read, or up to the first wide-character which is not a white-space wide-character, which remains unread.

A directive that is an ordinary wide-character is executed as follows. The next wide-character is read from the input and compared with the wide-character that comprises the directive; if the comparison shows that they are not equivalent, the directive fails, and the differing and subsequent wide-characters remain unread.

A directive that is a conversion specification defines a set of matching input sequences, as described below for each conversion wide-character. A conversion specification is executed in the following steps:

Input white-space wide-characters (as specified by `iswspace(3C)`) are skipped, unless the conversion specification includes a `l`, `c`, or `n` conversion character.

An item is read from the input, unless the conversion specification includes an `n` conversion wide-character. An input item is defined as the longest sequence of input wide-characters, not exceeding any specified field width, which is an initial subsequence of a matching sequence. The first wide-character, if any, after the input item remains unread. If the length of the input item is 0, the execution of the conversion specification fails; this condition is a matching failure, unless end-of-file, an encoding error, or a read error prevented input from the stream, in which case it is an input failure.

Except in the case of a `%` conversion wide-character, the input item (or, in the case of a `%n` conversion specification, the count of input wide-characters) is converted to a type appropriate to the conversion wide-character. If the input item is not a matching sequence, the execution of the conversion specification fails; this condition is a matching failure. Unless assignment suppression was indicated by a `*`, the result of the conversion is placed in the object pointed to by the first argument following the *format* argument that has not already received a conversion result if the conversion specification is introduced by `%`, or in the *n*th argument if introduced by the wide-character sequence `%n$`. If this object does not have an appropriate type, or if the result of the conversion cannot be represented in the space provided, the behavior is undefined.

The following conversion wide-characters are valid:

- d Matches an optionally signed decimal integer, whose format is the same as expected for the subject sequence of `wcstol(3C)` with the value 10 for the *base* argument. In the absence of a size modifier, the corresponding argument must be a pointer to `int`.
- i Matches an optionally signed integer, whose format is the same as expected for the subject sequence of `wcstol(3C)` with 0 for the *base* argument. In the absence of a size modifier, the corresponding argument must be a pointer to `int`.
- o Matches an optionally signed octal integer, whose format is the same as expected for the subject sequence of `wcstoul(3C)` with the value 8 for the *base* argument. In the absence of a size modifier, the corresponding argument must be a pointer to `unsigned int`.
- u Matches an optionally signed decimal integer, whose format is the same as expected for the subject sequence of `wcstoul(3C)` with the value 10 for the *base* argument. In the absence of a size modifier, the corresponding argument must be a pointer to `unsigned int`.

vwscanf(3C)

- x** Matches an optionally signed hexadecimal integer, whose format is the same as expected for the subject sequence of `wcstoul(3C)` with the value 16 for the *base* argument. In the absence of a size modifier, the corresponding argument must be a pointer to `unsigned int`.
- e,f,g** Matches an optionally signed floating-point number, whose format is the same as expected for the subject sequence of `wcstod(3C)`. In the absence of a size modifier, the corresponding argument must be a pointer to `float`.
- If the `fwprintf()` family of functions generates character string representations for infinity and NaN (a 7858 symbolic entity encoded in floating-point format) to support the ANSI/IEEE Std 754:1985 standard, the `fwscanf()` family of functions will recognize them as input.
- s** Matches a sequence of non white-space wide-characters. If no `l` (ell) qualifier is present, characters from the input field are converted as if by repeated calls to the `wcrtomb(3C)` function, with the conversion state described by an `mbstate_t` object initialized to zero before the first wide-character is converted. The corresponding argument must be a pointer to a character array large enough to accept the sequence and the terminating null character, which will be added automatically.
- Otherwise, the corresponding argument must be a pointer to an array of `wchar_t` large enough to accept the sequence and the terminating null wide-character, which will be added automatically.
- [** Matches a non-empty sequence of wide-characters from a set of expected wide-characters (the *scanset*). If no `l` (ell) qualifier is present, wide-characters from the input field are converted as if by repeated calls to the `wcrtomb()` function, with the conversion state described by an `mbstate_t` object initialized to zero before the first wide-character is converted. The corresponding argument must be a pointer to a character array large enough to accept the sequence and the terminating null character, which will be added automatically.
- If an `l` (ell) qualifier is present, the corresponding argument must be a pointer to an array of `wchar_t` large enough to accept the sequence and the terminating null wide-character, which will be added automatically.
- The conversion specification includes all subsequent `widw` characters in the *format* string up to and including the matching right square bracket (`]`). The wide-characters between the square brackets (the *scanlist*) comprise the scanset, unless the wide-character after the left square bracket is a circumflex (`^`), in which case the scanset contains all wide-characters that do not appear in the scanlist between the circumflex and the right square bracket. If the conversion specification begins with `[]` or `[^]`, the right square bracket is included in the scanlist and the next right square bracket is the matching right square bracket that ends the conversion specification; otherwise the first right square bracket is the one that ends the conversion

specification. If a minus-sign (-) is in the scanlist and is not the first wide-character, nor the second where the first wide-character is a ^, nor the last wide-character, it indicates a range of characters to be matched.

- c** Matches a sequence of wide-characters of the number specified by the field width (1 if no field width is present in the conversion specification). If no l (ell) qualifier is present, wide-characters from the input field are converted as if by repeated calls to the `wcrtomb()` function, with the conversion state described by an `mbstate_t` object initialized to zero before the first wide-character is converted. The corresponding argument must be a pointer to a character array large enough to accept the sequence. No null character is added.
- Otherwise, the corresponding argument must be a pointer to an array of `wchar_t` large enough to accept the sequence. No null wide-character is added.
- p** Matches the set of sequences that is the same as the set of sequences that is produced by the `%p` conversion of the corresponding `fwprintf(3C)` functions. The corresponding argument must be a pointer to a pointer to `void`. If the input item is a value converted earlier during the same program execution, the pointer that results will compare equal to that value; otherwise the behavior of the `%p` conversion is undefined.
- n** No input is consumed. The corresponding argument must be a pointer to the integer into which is to be written the number of wide-characters read from the input so far by this call to the `vfwscanf()` functions. Execution of a `%n` conversion specification does not increment the assignment count returned at the completion of execution of the function.
- C** Same as `lc`.
- S** Same as `ls`.
- %** Matches a single `%`; no conversion or assignment occurs. The complete conversion specification must be `%%`.

If a conversion specification is invalid, the behavior is undefined.

The conversion characters `E`, `G`, and `X` are also valid and behave the same as, respectively, `e`, `g`, and `x`.

If end-of-file is encountered during input, conversion is terminated. If end-of-file occurs before any wide-characters matching the current conversion specification (except for `%n`) have been read (other than leading white-space, where permitted), execution of the current conversion specification terminates with an input failure. Otherwise, unless execution of the current conversion specification is terminated with a matching failure, execution of the following conversion specification (if any) is terminated with an input failure.

vwscanf(3C)

Reaching the end of the string in `swscanf()` is equivalent to encountering end-of-file for `fwscanf()`.

If conversion terminates on a conflicting input, the offending input is left unread in the input. Any trailing white space (including newline) is left unread unless matched by a conversion specification. The success of literal matches and suppressed assignments is only directly determinable via the `%n` conversion specification.

The `fwscanf()` and `wscanf()` functions may mark the `st_atime` field of the file associated with *stream* for update. The `st_atime` field will be marked for update by the first successful execution of `fgetc(3C)`, `fgetwc(3C)`, `fgets(3C)`, `fgetws(3C)`, `fread(3C)`, `getc(3C)`, `getwc(3C)`, `getchar(3C)`, `getwchar(3C)`, `gets(3C)`, `fscanf(3C)` or `fwscanf()` using *stream* that returns data not supplied by a prior call to `ungetc(3C)`.

RETURN VALUES

Upon successful completion, these functions return the number of successfully matched and assigned input items; this number can be 0 in the event of an early matching failure. If the input ends before the first matching failure or conversion, EOF is returned. If a read error occurs the error indicator for the stream is set, EOF is returned, and `errno` is set to indicate the error.

ERRORS

For the conditions under which the `fwscanf()` functions will fail and may fail, refer to `fgetwc(3C)`.

In addition, `fwscanf()` may fail if:

EILSEQ Input byte sequence does not form a valid character.

EINVAL There are insufficient arguments.

USAGE

In format strings containing the `%` form of conversion specifications, each argument in the argument list is used exactly once.

EXAMPLES

EXAMPLE 1 `wscanf()` example

The call:

```
int i, n; float x; char name[50];
n = wscanf(L"%d%f%s", &i, &x, name);
```

with the input line:

```
25 54.32E-1 Hamster
```

will assign to *n* the value 3, to *i* the value 25, to *x* the value 5.432, and *name* will contain the string Hamster.

The call:

```
int i; float x; char name[50];
(void) wscanf(L"%2d%f*d %[0123456789]", &i, &x, name);
```

with input:

EXAMPLE 1 wscanf () example (Continued)

56789 0123 56a72

will assign 56 to *i*, 789.0 to *x*, skip 0123, and place the string 56\0 in *name*. The next call to `getchar(3C)` will return the character *a*.

vlfmt(3C)

NAME	vlfmt – display error message in standard format and pass to logging and monitoring services
SYNOPSIS	<pre>#include <pfmt.h> #include <stdarg.h> int vlfmt(FILE *stream, long flag, const char *format, va_list ap);</pre>
DESCRIPTION	<p>The vlfmt () function is identical to lfmt(3C), except that it is called with an argument list as defined by <stdarg.h>.</p> <p>The <stdarg.h> header defines the type va_list and a set of macros for advancing through a list of arguments whose number and types may vary. The ap argument is of type va_list. This argument is used with the <stdarg.h> macros va_start (), va_arg (), and va_end (). See stdarg(3HEAD). The example in the EXAMPLES section below demonstrates their use with vlfmt ().</p>
RETURN VALUES	Upon successful completion, vlfmt () returns the number of bytes transmitted. Otherwise, -1 is returned if there was a write error to stream, or -2 is returned if unable to log and/or display at console.
EXAMPLES	<p>EXAMPLE 1 Use of vlfmt () to write an errlog () routine.</p> <p>The following example demonstrates how vlfmt () could be used to write an errlog () routine. The va_alist () macro is used as the parameter list in a function definition. The va_start (ap, ...) call, where ap is of type va_list, must be invoked before any attempt to traverse and access unnamed arguments. Calls to va_arg (ap, atype) traverse the argument list. Each execution of va_arg () expands to an expression with the value and type of the next argument in the list ap, which is the same object initialized by va_start (). The atype argument is the type that the returned argument is expected to be. The va_end (ap) macro must be invoked when all desired arguments have been accessed. The argument list in ap can be traversed again if va_start () is called again after va_end (). In the example below, va_arg () is executed first to retrieve the format string passed to errlog (). The remaining errlog () arguments (arg1, arg2, ...) are passed to vlfmt () in the argument ap.</p> <pre>#include <pfmt.h> #include <stdarg.h> /* * errlog should be called like * errlog(log_info, format, arg1, ...); */ void errlog(long log_info, ...) { va_list ap; char *format; va_start(ap,); format = va_arg(ap, char *); (void) vlfmt(stderr, log_info MM_ERROR, format, ap); va_end(ap); (void) abort(); }</pre>

EXAMPLE 1 Use of `vlfmt()` to write an `errlog()` routine. *(Continued)*

USAGE Since `vlfmt()` uses `gettxt(3C)`, it is recommended that `vlfmt()` not be used.

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

vprintf(3C)

NAME	vprintf, vfprintf, vsprintf, vsnprintf – print formatted output of a variable argument list
SYNOPSIS	<pre>#include <stdio.h> #include <stdarg.h> int vprintf(const char *format, va_list ap); int vfprintf(FILE *stream, const char *format, va_list ap); int vsprintf(char *s, const char *format, va_list ap); int vsnprintf(char *s, size_t n, const char *format, va_list ap);</pre>
DESCRIPTION	<p>The vprintf(), vfprintf(), vsprintf() and vsnprintf() functions are the same as printf(), fprintf(), sprintf(), and snprintf(), respectively, except that instead of being called with a variable number of arguments, they are called with an argument list as defined in the <stdarg.h> header. See printf(3C) and stdarg(3HEAD).</p> <p>The <stdarg.h> header defines the type va_list and a set of macros for advancing through a list of arguments whose number and types may vary. The argument ap to the vprint family of functions is of type va_list. This argument is used with the <stdarg.h> header file macros va_start(), va_arg(), and va_end() (see stdarg(3HEAD)). The EXAMPLES section below demonstrates the use of va_start() and va_end() with vprintf().</p> <p>The macro va_alist() is used as the parameter list in a function definition, as in the function called error() in the example below. The macro va_start(ap, parmN), where ap is of type va_list and parmN is the rightmost parameter (just before ...), must be called before any attempt to traverse and access unnamed arguments is made. The va_end(ap) macro must be invoked when all desired arguments have been accessed. The argument list in ap can be traversed again if va_start() is called again after va_end(). In the example below, the error() arguments (arg1, arg2, ...) are passed to vfprintf() in the argument ap.</p>
RETURN VALUES	The vprintf(), vfprintf(), and vsprintf() functions return the number of characters transmitted (not including \0 in the case of vsprintf()). The vsnprintf() function returns the number of characters formatted, that is, the number of characters that would have been written to the buffer if it were large enough. Each function returns a negative value if an output error was encountered.
ERRORS	The vprintf() and vfprintf() functions will fail if either the stream is unbuffered or the stream's buffer needed to be flushed and: EFBIG The file is a regular file and an attempt was made to write at or beyond the offset maximum.
EXAMPLES	<p>EXAMPLE 1 Using vprintf() to write an error routine.</p> <p>The following demonstrates how vfprintf() could be used to write an error routine:</p>

EXAMPLE 1 Using `vprintf()` to write an error routine. *(Continued)*

```
#include <stdio.h>
#include <stdarg.h>
. . .
/*
 * error should be called like
 *     error(function_name, format, arg1, ...);
 */
void error(char *function_name, char *format, ...)
{
    va_list ap;
    va_start(ap, format);
    /* print out name of function causing error */
    (void) fprintf(stderr, "ERR in %s: ", function_name);
    /* print out remainder of message */
    (void) vfprintf(stderr, format, ap);
    va_end(ap);
    (void) abort;
}
```

vprintf(3UCB)

NAME	printf, fprintf, sprintf, vprintf, vfprintf, vsprintf – formatted output conversion
SYNOPSIS	<pre>/usr/ucb/cc [flag ...] file ... #include <stdio.h> int printf(format, ...); const char *format; int fprintf(stream, format, va_list); FILE *stream; char *format; va_dcl; char *sprintf(s, format, va_list); char *s, *format; va_dcl; int vprintf(format, ap); char *format; va_list ap; int vfprintf(stream, format, ap); FILE *stream; char *format; va_list ap; char *vsprintf(s, format, ap); char *s, *format; va_list ap;</pre>
DESCRIPTION	<p>printf() places output on the standard output stream stdout. fprintf() places output on the named output stream. sprintf() places “output,” followed by the NULL character (\0), in consecutive bytes starting at *s; it is the user’s responsibility to ensure that enough storage is available.</p> <p>vprintf(), vfprintf(), and vsprintf() are the same as printf(), fprintf(), and sprintf() respectively, except that instead of being called with a variable number of arguments, they are called with an argument list as defined by varargs(3HEAD).</p> <p>Each of these functions converts, formats, and prints its args under control of the format. The format is a character string which contains two types of objects: plain characters, which are simply copied to the output stream, and conversion specifications, each of which causes conversion and printing of zero or more args. The results are undefined if there are insufficient args for the format. If the format is exhausted while args remain, the excess args are simply ignored.</p> <p>Each conversion specification is introduced by the character %. After the %, the following appear in sequence:</p>

- Zero or more *flags*, which modify the meaning of the conversion specification.
- An optional decimal digit string specifying a minimum *field width*. If the converted value has fewer characters than the field width, it will be padded on the left (or right, if the left-adjustment flag ‘-’, described below, has been given) to the field width. The padding is with blanks unless the field width digit string starts with a zero, in which case the padding is with zeros.
- A *precision* that gives the minimum number of digits to appear for the `d`, `i`, `o`, `u`, `x`, or `X` conversions, the number of digits to appear after the decimal point for the `e`, `E`, and `f` conversions, the maximum number of significant digits for the `g` and `G` conversion, or the maximum number of characters to be printed from a string in `s` conversion. The precision takes the form of a period (.) followed by a decimal digit string; a `NULL` digit string is treated as zero. Padding specified by the precision overrides the padding specified by the field width.
- An optional `l` (ell) specifying that a following `d`, `i`, `o`, `u`, `x`, or `X` conversion character applies to a long integer *arg*. An `l` before any other conversion character is ignored.
- A character that indicates the type of conversion to be applied.

A field width or precision or both may be indicated by an asterisk (*) instead of a digit string. In this case, an integer *arg* supplies the field width or precision. The *arg* that is actually converted is not fetched until the conversion letter is seen, so the *args* specifying field width or precision must appear *before* the *arg* (if any) to be converted. A negative field width argument is taken as a ‘-’ flag followed by a positive field width. If the precision argument is negative, it will be changed to zero.

The flag characters and their meanings are:

-	The result of the conversion will be left-justified within the field.
+	The result of a signed conversion will always begin with a sign (+ or -).
blank	If the first character of a signed conversion is not a sign, a blank will be prefixed to the result. This implies that if the blank and + flags both appear, the blank flag will be ignored.
#	This flag specifies that the value is to be converted to an “alternate form.” For <code>c</code> , <code>d</code> , <code>i</code> , <code>s</code> , and <code>u</code> conversions, the flag has no effect. For <code>o</code> conversion, it increases the precision to force the first digit of the result to be a zero. For <code>x</code> or <code>X</code> conversion, a non-zero result will have <code>0x</code> or <code>0X</code> prefixed to it. For <code>e</code> , <code>E</code> , <code>f</code> , <code>g</code> , and <code>G</code> conversions, the result will always contain a decimal point, even if no digits follow the point (normally, a decimal point appears in the result of these conversions only if a digit follows it). For <code>g</code> and <code>G</code> conversions, trailing zeroes will <i>not</i> be removed from the result (which they normally are).

The conversion characters and their meanings are:

vprintf(3UCB)

d,i,o,u,x,X	The integer <i>arg</i> is converted to signed decimal (d or i), unsigned octal (o), unsigned decimal (u), or unsigned hexadecimal notation (x and X), respectively; the letters abcdef are used for x conversion and the letters ABCDEF for X conversion. The precision specifies the minimum number of digits to appear; if the value being converted can be represented in fewer digits, it will be expanded with leading zeroes. (For compatibility with older versions, padding with leading zeroes may alternatively be specified by prepending a zero to the field width. This does not imply an octal value for the field width.) The default precision is 1. The result of converting a zero value with a precision of zero is a NULL string.
f	The float or double <i>arg</i> is converted to decimal notation in the style <code>[-]ddd.ddd</code> where the number of digits after the decimal point is equal to the precision specification. If the precision is missing, 6 digits are given; if the precision is explicitly 0, no digits and no decimal point are printed.
e,E	The float or double <i>arg</i> is converted in the style <code>[-]d.ddd_{e±}ddd</code> , where there is one digit before the decimal point and the number of digits after it is equal to the precision; when the precision is missing, 6 digits are produced; if the precision is zero, no decimal point appears. The E format code will produce a number with E instead of e introducing the exponent. The exponent always contains at least two digits.
g,G	The float or double <i>arg</i> is printed in style f or e (or in style E in the case of a G format code), with the precision specifying the number of significant digits. The style used depends on the value converted: style e or E will be used only if the exponent resulting from the conversion is less than -4 or greater than the precision. Trailing zeroes are removed from the result; a decimal point appears only if it is followed by a digit.
The e, E f, g, and G formats print IEEE indeterminate values (infinity or not-a-number) as "Infinity" or "NaN" respectively.	
c	The character <i>arg</i> is printed.
s	The <i>arg</i> is taken to be a string (character pointer) and characters from the string are printed until a NULL character (\0) is encountered or until the number of characters indicated by the precision specification is reached. If the precision is missing, it is taken to be infinite, so all characters up to the first NULL character are printed. A NULL value for <i>arg</i> will yield undefined results.
%	Print a %; no argument is converted.

vprintf(3UCB)

In no case does a non-existent or small field width cause truncation of a field; if the result of a conversion is wider than the field width, the field is simply expanded to contain the conversion result. Padding takes place only if the specified field width exceeds the actual width. Characters generated by `printf()` and `fprintf()` are printed as if `putc(3C)` had been called.

RETURN VALUES

Upon success, `printf()` and `fprintf()` return the number of characters transmitted, excluding the null character. `vprintf()` and `vfprintf()` return the number of characters transmitted. `sprintf()` and `vsprintf()` always return `s`. If an output error is encountered, `printf()`, `fprintf()`, `vprintf()`, and `vfprintf()` return EOF.

EXAMPLES

EXAMPLE 1 Examples of the `printf` Command To Print a Date and Time

To print a date and time in the form "Sunday, July 3, 10:02," where *weekday* and *month* are pointers to NULL-terminated strings:

```
printf("%s, %s %i, %d:%.2d", weekday, month, day, hour, min);
```

EXAMPLE 2 Examples of the `printf` Command To Print to Five Decimal Places

To print to five decimal places:

```
printf("pi = %.5f", 4 * atan(1. 0));
```

SEE ALSO

`econvert(3C)`, `putc(3C)`, `scanf(3C)`, `vprintf(3C)`, `varargs(3HEAD)`

NOTES

Use of these interfaces should be restricted to only applications written on BSD platforms. Use of these interfaces with any of the system libraries or in multi-thread applications is unsupported.

Very wide fields (>128 characters) fail.

vscanf(3C)

NAME	<code>scanf</code> , <code>fscanf</code> , <code>sscanf</code> , <code>vscanf</code> , <code>vfscanf</code> , <code>vsscanf</code> – convert formatted input
SYNOPSIS	<pre>#include <stdio.h> int scanf(const char *<i>format</i>, ...); int fscanf(FILE*<i>stream</i>, const char *<i>format</i>, ...); int sscanf(const char *<i>s</i>, const char *<i>format</i>, ...); #include <stdarg.h> #include <stdio.h> int vscanf(const char *<i>format</i>, va_list <i>arg</i>); int vfscanf(FILE *<i>stream</i>, const char *<i>format</i>, va_list <i>arg</i>); int vsscanf(const char *<i>s</i>, const char *<i>format</i>, va_list <i>arg</i>);</pre>
DESCRIPTION	<p>The <code>scanf()</code> function reads from the standard input stream <code>stdin</code>.</p> <p>The <code>fscanf()</code> function reads from the named input <i>stream</i>.</p> <p>The <code>sscanf()</code> function reads from the string <i>s</i>.</p> <p>The <code>vscanf()</code>, <code>vfscanf()</code>, and <code>vsscanf()</code> functions are equivalent to the <code>scanf()</code>, <code>fscanf()</code>, and <code>sscanf()</code> functions, respectively, except that instead of being called with a variable number of arguments, they are called with an argument list as defined by the <code><stdarg.h></code> header (see <code>stdarg(3HEAD)</code>). These functions do not invoke the <code>va_end()</code> macro. Applications using these functions should call <code>va_end(ap)</code> afterwards to clean up.</p> <p>Each function reads bytes, interprets them according to a format, and stores the results in its arguments. Each expects, as arguments, a control string <i>format</i> described below, and a set of <i>pointer</i> arguments indicating where the converted input should be stored. The result is undefined if there are insufficient arguments for the format. If the format is exhausted while arguments remain, the excess arguments are evaluated but are otherwise ignored.</p> <p>Conversions can be applied to the <i>n</i>th argument after the <i>format</i> in the argument list, rather than to the next unused argument. In this case, the conversion character <code>%</code> (see below) is replaced by the sequence <code>%n\$</code>, where <i>n</i> is a decimal integer in the range <code>[1, NL_ARGMAX]</code>. This feature provides for the definition of format strings that select arguments in an order appropriate to specific languages. In format strings containing the <code>%n\$</code> form of conversion specifications, it is unspecified whether numbered arguments in the argument list can be referenced from the format string more than once.</p> <p>The <i>format</i> can contain either form of a conversion specification, that is, <code>%</code> or <code>%n\$</code>, but the two forms cannot normally be mixed within a single <i>format</i> string. The only exception to this is that <code>%%</code> or <code>%*</code> can be mixed with the <code>%n\$</code> form.</p>

The `scanf()` function in all its forms allows for detection of a language-dependent radix character in the input string. The radix character is defined in the program's locale (category `LC_NUMERIC`). In the POSIX locale, or in a locale where the radix character is not defined, the radix character defaults to a period (`.`).

The format is a character string, beginning and ending in its initial shift state, if any, composed of zero or more directives. Each directive is composed of one of the following:

- one or more *white-space characters* (space, tab, newline, vertical-tab or form-feed characters);
- an *ordinary character* (neither `%` nor a white-space character); or
- a *conversion specification*.

Conversion Specifications

Each conversion specification is introduced by the character `%` or the character sequence `%n$`, after which the following appear in sequence:

- An optional assignment-suppressing character `*`.
- An optional non-zero decimal integer that specifies the maximum field width.
- An optional size modifier `h`, `l` (ell), `ll` (ell ell), or `L` indicating the size of the receiving object. The conversion characters `d`, `i`, and `n` must be preceded by `h` if the corresponding argument is a pointer to `short int` rather than a pointer to `int`, by `l` (ell) if it is a pointer to `long int`, or by `ll` (ell ell) if it is a pointer to `long long int`. Similarly, the conversion characters `o`, `u`, and `x` must be preceded by `h` if the corresponding argument is a pointer to `unsigned short int` rather than a pointer to `unsigned int`, by `l` (ell) if it is a pointer to `unsigned long int`, or by `ll` (ell ell) if it is a pointer to `unsigned long long int`. The conversion characters `e`, `f`, and `g` must be preceded by `l` (ell) if the corresponding argument is a pointer to `double` rather than a pointer to `float`, or by `L` if it is a pointer to `long double`. Finally, the conversion characters `c`, `s`, and `[]` must be preceded by `l` (ell) if the corresponding argument is a pointer to `wchar_t` rather than a pointer to a character type. If an `h`, `l` (ell), `ll` (ell ell), or `L` appears with any other conversion character, the behavior is undefined.
- A conversion character that specifies the type of conversion to be applied. The valid conversion characters are described below.

The `scanf()` functions execute each directive of the format in turn. If a directive fails, as detailed below, the function returns. Failures are described as input failures (due to the unavailability of input bytes) or matching failures (due to inappropriate input).

A directive composed of one or more white-space characters is executed by reading input until no more valid input can be read, or up to the first byte which is not a white-space character which remains unread.

vscanf(3C)

A directive that is an ordinary character is executed as follows. The next byte is read from the input and compared with the byte that comprises the directive; if the comparison shows that they are not equivalent, the directive fails, and the differing and subsequent bytes remain unread.

A directive that is a conversion specification defines a set of matching input sequences, as described below for each conversion character. A conversion specification is executed in the following steps:

Input white-space characters (as specified by `isspace(3C)`) are skipped, unless the conversion specification includes a `[\, c, C, or n` conversion character.

An item is read from the input, unless the conversion specification includes an `n` conversion character. An input item is defined as the longest sequence of input bytes (up to any specified maximum field width, which may be measured in characters or bytes dependent on the conversion character) which is an initial subsequence of a matching sequence. The first byte, if any, after the input item remains unread. If the length of the input item is 0, the execution of the conversion specification fails; this condition is a matching failure, unless end-of-file, an encoding error, or a read error prevented input from the stream, in which case it is an input failure.

Except in the case of a `%` conversion character, the input item (or, in the case of a `%n` conversion specification, the count of input bytes) is converted to a type appropriate to the conversion character. If the input item is not a matching sequence, the execution of the conversion specification fails; this condition is a matching failure. Unless assignment suppression was indicated by a `*`, the result of the conversion is placed in the object pointed to by the first argument following the *format* argument that has not already received a conversion result if the conversion specification is introduced by `%`, or in the *n*th argument if introduced by the character sequence `%n$`. If this object does not have an appropriate type, or if the result of the conversion cannot be represented in the space provided, the behavior is undefined.

Conversion Characters

The following conversion characters are valid:

- `d` Matches an optionally signed decimal integer, whose format is the same as expected for the subject sequence of `strtol(3C)` with the value 10 for the *base* argument. In the absence of a size modifier, the corresponding argument must be a pointer to `int`.
- `i` Matches an optionally signed integer, whose format is the same as expected for the subject sequence of `strtol()` with 0 for the *base* argument. In the absence of a size modifier, the corresponding argument must be a pointer to `int`.
- `o` Matches an optionally signed octal integer, whose format is the same as expected for the subject sequence of `strtoul(3C)` with the value 8 for the *base* argument. In the absence of a size modifier, the corresponding argument must be a pointer to `unsigned int`.

- u Matches an optionally signed decimal integer, whose format is the same as expected for the subject sequence of `strtoul()` with the value 10 for the *base* argument. In the absence of a size modifier, the corresponding argument must be a pointer to `unsigned int`.
- x Matches an optionally signed hexadecimal integer, whose format is the same as expected for the subject sequence of `strtoul()` with the value 16 for the *base* argument. In the absence of a size modifier, the corresponding argument must be a pointer to `unsigned int`.
- e,f,g Matches an optionally signed floating-point number, whose format is the same as expected for the subject sequence of `strtod(3C)`. In the absence of a size modifier, the corresponding argument must be a pointer to `float`.
- If the `printf(3C)` family of functions generates character string representations for infinity and NaN (a 7858 symbolic entity encoded in floating-point format) to support the ANSI/IEEE Std 754: 1985 standard, the `scanf()` family of functions will recognize them as input.
- s Matches a sequence of bytes that are not white-space characters. The corresponding argument must be a pointer to the initial byte of an array of `char`, `signed char`, or `unsigned char` large enough to accept the sequence and a terminating null character code, which will be added automatically.
- If an `l` (`ell`) qualifier is present, the input is a sequence of characters that begins in the initial shift state. Each character is converted to a wide-character as if by a call to the `mbrtowc(3C)` function, with the conversion state described by an `mbstate_t` object initialized to zero before the first character is converted. The corresponding argument must be a pointer to an array of `wchar_t` large enough to accept the sequence and the terminating null wide-character, which will be added automatically.
- [Matches a non-empty sequence of characters from a set of expected characters (the *scanset*). The normal skip over white-space characters is suppressed in this case. The corresponding argument must be a pointer to the initial byte of an array of `char`, `signed char`, or `unsigned char` large enough to accept the sequence and a terminating null byte, which will be added automatically.
- If an `l` (`ell`) qualifier is present, the input is a sequence of characters that begins in the initial shift state. Each character in the sequence is converted to a wide-character as if by a call to the `mbrtowc()` function, with the conversion state described by an `mbstate_t` object initialized to zero before the first character is converted. The corresponding argument must be a pointer to an array of `wchar_t` large enough to accept the sequence and the terminating null wide-character, which will be added automatically.

vscanf(3C)

The conversion specification includes all subsequent characters in the *format* string up to and including the matching right square bracket (]). The characters between the square brackets (the *scanlist*) comprise the scanset, unless the character after the left square bracket is a circumflex (^), in which case the scanset contains all characters that do not appear in the scanlist between the circumflex and the right square bracket. If the conversion specification begins with [] or [^], the right square bracket is included in the scanlist and the next right square bracket is the matching right square bracket that ends the conversion specification; otherwise the first right square bracket is the one that ends the conversion specification. If a - is in the scanlist and is not the first character, nor the second where the first character is a ^, nor the last character, it indicates a range of characters to be matched.

c Matches a sequence of characters of the number specified by the field width (1 if no field width is present in the conversion specification). The corresponding argument must be a pointer to the initial byte of an array of `char`, `signed char`, or `unsigned char` large enough to accept the sequence. No null byte is added. The normal skip over white-space characters is suppressed in this case.

If an l (ell) qualifier is present, the input is a sequence of characters that begins in the initial shift state. Each character in the sequence is converted to a wide-character as if by a call to the `mbrtowc()` function, with the conversion state described by an `mbstate_t` object initialized to zero before the first character is converted. The corresponding argument must be a pointer to an array of `wchar_t` large enough to accept the resulting sequence of wide-characters. No null wide-character is added.

p Matches the set of sequences that is the same as the set of sequences that is produced by the `%p` conversion of the corresponding `printf(3C)` functions. The corresponding argument must be a pointer to a pointer to `void`. If the input item is a value converted earlier during the same program execution, the pointer that results will compare equal to that value; otherwise the behavior of the `%p` conversion is undefined.

n No input is consumed. The corresponding argument must be a pointer to the integer into which is to be written the number of bytes read from the input so far by this call to the `scanf()` functions. Execution of a `%n` conversion specification does not increment the assignment count returned at the completion of execution of the function.

C Same as `lc`.

S Same as `ls`.

% Matches a single %; no conversion or assignment occurs. The complete conversion specification must be `%%`.

If a conversion specification is invalid, the behavior is undefined.

The conversion characters E, G, and X are also valid and behave the same as, respectively, e, g, and x.

If end-of-file is encountered during input, conversion is terminated. If end-of-file occurs before any bytes matching the current conversion specification (except for %n) have been read (other than leading white-space characters, where permitted), execution of the current conversion specification terminates with an input failure. Otherwise, unless execution of the current conversion specification is terminated with a matching failure, execution of the following conversion specification (if any) is terminated with an input failure.

Reaching the end of the string in `sscanf()` is equivalent to encountering end-of-file for `fscanf()`.

If conversion terminates on a conflicting input, the offending input is left unread in the input. Any trailing white space (including newline characters) is left unread unless matched by a conversion specification. The success of literal matches and suppressed assignments is only directly determinable via the %n conversion specification.

The `fscanf()` and `scanf()` functions may mark the `st_atime` field of the file associated with *stream* for update. The `st_atime` field will be marked for update by the first successful execution of `fgetc(3C)`, `fgets(3C)`, `fread(3C)`, `fscanf()`, `getc(3C)`, `getchar(3C)`, `gets(3C)`, or `scanf()` using *stream* that returns data not supplied by a prior call to `ungetc(3C)`.

RETURN VALUES

Upon successful completion, these functions return the number of successfully matched and assigned input items; this number can be 0 in the event of an early matching failure. If the input ends before the first matching failure or conversion, EOF is returned. If a read error occurs the error indicator for the stream is set, EOF is returned, and `errno` is set to indicate the error.

ERRORS

For the conditions under which the `scanf()` functions will fail and may fail, refer to `fgetc(3C)` or `fgetwc(3C)`.

In addition, `fscanf()` may fail if:

EILSEQ Input byte sequence does not form a valid character.

EINVAL There are insufficient arguments.

USAGE

If the application calling the `scanf()` functions has any objects of type `wint_t` or `wchar_t`, it must also include the header `<wchar.h>` to have these objects defined.

EXAMPLES

EXAMPLE 1 The call:

```
int i, n; float x; char name[50];
n = scanf("%d%f%s", &i, &x, name)
```

with the input line:

```
25 54.32E-1 Hamster
```

vscanf(3C)

EXAMPLE 1 The call: *(Continued)*

will assign to *n* the value 3, to *i* the value 25, to *x* the value 5.432, and *name* will contain the string Hamster.

EXAMPLE 2 The call:

```
int i; float x; char name[50];
(void) scanf("%2d%f%d %[0123456789]", &i, &x, name);
```

with input:

```
56789 0123 56a72
```

will assign 56 to *i*, 789.0 to *x*, skip 0123, and place the string 56\0 in *name*. The next call to `getchar(3C)` will return the character a.

NAME	vprintf, vfprintf, vsprintf, vsnprintf – print formatted output of a variable argument list
SYNOPSIS	<pre>#include <stdio.h> #include <stdarg.h> int vprintf(const char *format, va_list ap); int vfprintf(FILE *stream, const char *format, va_list ap); int vsprintf(char *s, const char *format, va_list ap); int vsnprintf(char *s, size_t n, const char *format, va_list ap);</pre>
DESCRIPTION	<p>The <code>vprintf()</code>, <code>vfprintf()</code>, <code>vsprintf()</code> and <code>vsnprintf()</code> functions are the same as <code>printf()</code>, <code>fprintf()</code>, <code>sprintf()</code>, and <code>snprintf()</code>, respectively, except that instead of being called with a variable number of arguments, they are called with an argument list as defined in the <code><stdarg.h></code> header. See <code>printf(3C)</code> and <code>stdarg(3HEAD)</code>.</p> <p>The <code><stdarg.h></code> header defines the type <code>va_list</code> and a set of macros for advancing through a list of arguments whose number and types may vary. The argument <code>ap</code> to the <code>vprint</code> family of functions is of type <code>va_list</code>. This argument is used with the <code><stdarg.h></code> header file macros <code>va_start()</code>, <code>va_arg()</code>, and <code>va_end()</code> (see <code>stdarg(3HEAD)</code>). The EXAMPLES section below demonstrates the use of <code>va_start()</code> and <code>va_end()</code> with <code>vprintf()</code>.</p> <p>The macro <code>va_alist()</code> is used as the parameter list in a function definition, as in the function called <code>error()</code> in the example below. The macro <code>va_start(ap, parmN)</code>, where <code>ap</code> is of type <code>va_list</code> and <code>parmN</code> is the rightmost parameter (just before <code>...</code>), must be called before any attempt to traverse and access unnamed arguments is made. The <code>va_end(ap)</code> macro must be invoked when all desired arguments have been accessed. The argument list in <code>ap</code> can be traversed again if <code>va_start()</code> is called again after <code>va_end()</code>. In the example below, the <code>error()</code> arguments (<code>arg1, arg2, ...</code>) are passed to <code>vfprintf()</code> in the argument <code>ap</code>.</p>
RETURN VALUES	The <code>vprintf()</code> , <code>vfprintf()</code> , and <code>vsprintf()</code> functions return the number of characters transmitted (not including <code>\0</code> in the case of <code>vsprintf()</code>). The <code>vsnprintf()</code> function returns the number of characters formatted, that is, the number of characters that would have been written to the buffer if it were large enough. Each function returns a negative value if an output error was encountered.
ERRORS	<p>The <code>vprintf()</code> and <code>vfprintf()</code> functions will fail if either the <code>stream</code> is unbuffered or the <code>stream's</code> buffer needed to be flushed and:</p> <p>EFBIG The file is a regular file and an attempt was made to write at or beyond the offset maximum.</p>
EXAMPLES	<p>EXAMPLE 1 Using <code>vprintf()</code> to write an error routine.</p> <p>The following demonstrates how <code>vfprintf()</code> could be used to write an error routine:</p>

vsnprintf(3C)

EXAMPLE 1 Using `vprintf()` to write an error routine. *(Continued)*

```
#include <stdio.h>
#include <stdarg.h>
. . .
/*
 * error should be called like
 *     error(function_name, format, arg1, ...);
 */
void error(char *function_name, char *format, ...)
{
    va_list ap;
    va_start(ap, format);
    /* print out name of function causing error */
    (void) fprintf(stderr, "ERR in %s: ", function_name);
    /* print out remainder of message */
    (void) vfprintf(stderr, format, ap);
    va_end(ap);
    (void) abort;
}
```

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
MT-Level	MT-Safe

SEE ALSO `printf(3C)`, `attributes(5)`, `stdarg(3HEAD)`

NAME	vprintf, vfprintf, vsprintf, vsnprintf – print formatted output of a variable argument list
SYNOPSIS	<pre>#include <stdio.h> #include <stdarg.h> int vprintf(const char *format, va_list ap); int vfprintf(FILE *stream, const char *format, va_list ap); int vsprintf(char *s, const char *format, va_list ap); int vsnprintf(char *s, size_t n, const char *format, va_list ap);</pre>
DESCRIPTION	<p>The <code>vprintf()</code>, <code>vfprintf()</code>, <code>vsprintf()</code> and <code>vsnprintf()</code> functions are the same as <code>printf()</code>, <code>fprintf()</code>, <code>sprintf()</code>, and <code>snprintf()</code>, respectively, except that instead of being called with a variable number of arguments, they are called with an argument list as defined in the <code><stdarg.h></code> header. See <code>printf(3C)</code> and <code>stdarg(3HEAD)</code>.</p> <p>The <code><stdarg.h></code> header defines the type <code>va_list</code> and a set of macros for advancing through a list of arguments whose number and types may vary. The argument <code>ap</code> to the <code>vprint</code> family of functions is of type <code>va_list</code>. This argument is used with the <code><stdarg.h></code> header file macros <code>va_start()</code>, <code>va_arg()</code>, and <code>va_end()</code> (see <code>stdarg(3HEAD)</code>). The EXAMPLES section below demonstrates the use of <code>va_start()</code> and <code>va_end()</code> with <code>vprintf()</code>.</p> <p>The macro <code>va_alist()</code> is used as the parameter list in a function definition, as in the function called <code>error()</code> in the example below. The macro <code>va_start(ap, parmN)</code>, where <code>ap</code> is of type <code>va_list</code> and <code>parmN</code> is the rightmost parameter (just before <code>...</code>), must be called before any attempt to traverse and access unnamed arguments is made. The <code>va_end(ap)</code> macro must be invoked when all desired arguments have been accessed. The argument list in <code>ap</code> can be traversed again if <code>va_start()</code> is called again after <code>va_end()</code>. In the example below, the <code>error()</code> arguments (<code>arg1, arg2, ...</code>) are passed to <code>vfprintf()</code> in the argument <code>ap</code>.</p>
RETURN VALUES	The <code>vprintf()</code> , <code>vfprintf()</code> , and <code>vsprintf()</code> functions return the number of characters transmitted (not including <code>\0</code> in the case of <code>vsprintf()</code>). The <code>vsnprintf()</code> function returns the number of characters formatted, that is, the number of characters that would have been written to the buffer if it were large enough. Each function returns a negative value if an output error was encountered.
ERRORS	<p>The <code>vprintf()</code> and <code>vfprintf()</code> functions will fail if either the <code>stream</code> is unbuffered or the <code>stream's</code> buffer needed to be flushed and:</p> <p>EFBIG The file is a regular file and an attempt was made to write at or beyond the offset maximum.</p>
EXAMPLES	<p>EXAMPLE 1 Using <code>vprintf()</code> to write an error routine.</p> <p>The following demonstrates how <code>vfprintf()</code> could be used to write an error routine:</p>

vsprintf(3C)

EXAMPLE 1 Using `vprintf()` to write an error routine. *(Continued)*

```
#include <stdio.h>
#include <stdarg.h>
. . .
/*
 * error should be called like
 * error(function_name, format, arg1, ...);
 */
void error(char *function_name, char *format, ...)
{
    va_list ap;
    va_start(ap, format);
    /* print out name of function causing error */
    (void) fprintf(stderr, "ERR in %s: ", function_name);
    /* print out remainder of message */
    (void) vfprintf(stderr, format, ap);
    va_end(ap);
    (void) abort;
}
```

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE

NAME	printf, fprintf, sprintf, vprintf, vfprintf, vsprintf – formatted output conversion
SYNOPSIS	<pre> /usr/ucb/cc [flag ...] file ... #include <stdio.h> int printf(format, ...); const char *format; int fprintf(stream, format, va_list); FILE *stream; char *format; va_dcl; char *sprintf(s, format, va_list); char *s, *format; va_dcl; int vprintf(format, ap); char *format; va_list ap; int vfprintf(stream, format, ap); FILE *stream; char *format; va_list ap; char *vsprintf(s, format, ap); char *s, *format; va_list ap; </pre>
DESCRIPTION	<p>printf() places output on the standard output stream <code>stdout</code>. fprintf() places output on the named output <code>stream</code>. sprintf() places “output,” followed by the NULL character (<code>\0</code>), in consecutive bytes starting at <code>*s</code>; it is the user’s responsibility to ensure that enough storage is available.</p> <p>vprintf(), vfprintf(), and vsprintf() are the same as printf(), fprintf(), and sprintf() respectively, except that instead of being called with a variable number of arguments, they are called with an argument list as defined by <code>varargs(3HEAD)</code>.</p> <p>Each of these functions converts, formats, and prints its <i>args</i> under control of the <i>format</i>. The <i>format</i> is a character string which contains two types of objects: plain characters, which are simply copied to the output stream, and conversion specifications, each of which causes conversion and printing of zero or more <i>args</i>. The results are undefined if there are insufficient <i>args</i> for the format. If the format is exhausted while <i>args</i> remain, the excess <i>args</i> are simply ignored.</p> <p>Each conversion specification is introduced by the character <code>%</code>. After the <code>%</code>, the following appear in sequence:</p>

vsprintf(3UCB)

- Zero or more *flags*, which modify the meaning of the conversion specification.
- An optional decimal digit string specifying a minimum *field width*. If the converted value has fewer characters than the field width, it will be padded on the left (or right, if the left-adjustment flag '-', described below, has been given) to the field width. The padding is with blanks unless the field width digit string starts with a zero, in which case the padding is with zeros.
- A *precision* that gives the minimum number of digits to appear for the d, i, o, u, x, or X conversions, the number of digits to appear after the decimal point for the e, E, and f conversions, the maximum number of significant digits for the g and G conversion, or the maximum number of characters to be printed from a string in s conversion. The precision takes the form of a period (.) followed by a decimal digit string; a NULL digit string is treated as zero. Padding specified by the precision overrides the padding specified by the field width.
- An optional l (ell) specifying that a following d, i, o, u, x, or X conversion character applies to a long integer *arg*. An l before any other conversion character is ignored.
- A character that indicates the type of conversion to be applied.

A field width or precision or both may be indicated by an asterisk (*) instead of a digit string. In this case, an integer *arg* supplies the field width or precision. The *arg* that is actually converted is not fetched until the conversion letter is seen, so the *args* specifying field width or precision must appear *before* the *arg* (if any) to be converted. A negative field width argument is taken as a '-' flag followed by a positive field width. If the precision argument is negative, it will be changed to zero.

The flag characters and their meanings are:

-	The result of the conversion will be left-justified within the field.
+	The result of a signed conversion will always begin with a sign (+ or -).
blank	If the first character of a signed conversion is not a sign, a blank will be prefixed to the result. This implies that if the blank and + flags both appear, the blank flag will be ignored.
#	This flag specifies that the value is to be converted to an "alternate form." For c, d, i, s, and u conversions, the flag has no effect. For o conversion, it increases the precision to force the first digit of the result to be a zero. For x or X conversion, a non-zero result will have 0x or 0X prefixed to it. For e, E, f, g, and G conversions, the result will always contain a decimal point, even if no digits follow the point (normally, a decimal point appears in the result of these conversions only if a digit follows it). For g and G conversions, trailing zeroes will <i>not</i> be removed from the result (which they normally are).

The conversion characters and their meanings are:

d,i,o,u,x,X	The integer <i>arg</i> is converted to signed decimal (d or i), unsigned octal (o), unsigned decimal (u), or unsigned hexadecimal notation (x and X), respectively; the letters abcdef are used for x conversion and the letters ABCDEF for X conversion. The precision specifies the minimum number of digits to appear; if the value being converted can be represented in fewer digits, it will be expanded with leading zeroes. (For compatibility with older versions, padding with leading zeroes may alternatively be specified by prepending a zero to the field width. This does not imply an octal value for the field width.) The default precision is 1. The result of converting a zero value with a precision of zero is a NULL string.
f	The float or double <i>arg</i> is converted to decimal notation in the style <code>[-]ddd.ddd</code> where the number of digits after the decimal point is equal to the precision specification. If the precision is missing, 6 digits are given; if the precision is explicitly 0, no digits and no decimal point are printed.
e,E	The float or double <i>arg</i> is converted in the style <code>[-]d.ddd_{e±}ddd</code> , where there is one digit before the decimal point and the number of digits after it is equal to the precision; when the precision is missing, 6 digits are produced; if the precision is zero, no decimal point appears. The E format code will produce a number with E instead of e introducing the exponent. The exponent always contains at least two digits.
g,G	The float or double <i>arg</i> is printed in style f or e (or in style E in the case of a G format code), with the precision specifying the number of significant digits. The style used depends on the value converted: style e or E will be used only if the exponent resulting from the conversion is less than -4 or greater than the precision. Trailing zeroes are removed from the result; a decimal point appears only if it is followed by a digit.
The e, E f, g, and G formats print IEEE indeterminate values (infinity or not-a-number) as "Infinity" or "NaN" respectively.	
c	The character <i>arg</i> is printed.
s	The <i>arg</i> is taken to be a string (character pointer) and characters from the string are printed until a NULL character (<code>\0</code>) is encountered or until the number of characters indicated by the precision specification is reached. If the precision is missing, it is taken to be infinite, so all characters up to the first NULL character are printed. A NULL value for <i>arg</i> will yield undefined results.
%	Print a %; no argument is converted.

vsprintf(3UCB)

In no case does a non-existent or small field width cause truncation of a field; if the result of a conversion is wider than the field width, the field is simply expanded to contain the conversion result. Padding takes place only if the specified field width exceeds the actual width. Characters generated by `printf()` and `fprintf()` are printed as if `putc(3C)` had been called.

RETURN VALUES Upon success, `printf()` and `fprintf()` return the number of characters transmitted, excluding the null character. `vprintf()` and `vfprintf()` return the number of characters transmitted. `sprintf()` and `vsprintf()` always return `s`. If an output error is encountered, `printf()`, `fprintf()`, `vprintf()`, and `vfprintf()` return EOF.

EXAMPLES **EXAMPLE 1** Examples of the `printf` Command To Print a Date and Time

To print a date and time in the form "Sunday, July 3, 10:02," where *weekday* and *month* are pointers to NULL-terminated strings:

```
printf("%s, %s %i, %d:%.2d", weekday, month, day, hour, min);
```

EXAMPLE 2 Examples of the `printf` Command To Print to Five Decimal Places

To print to five decimal places:

```
printf("pi = %.5f", 4 * atan(1. 0));
```

SEE ALSO `econvert(3C)`, `putc(3C)`, `scanf(3C)`, `vprintf(3C)`, `varargs(3HEAD)`

NOTES Use of these interfaces should be restricted to only applications written on BSD platforms. Use of these interfaces with any of the system libraries or in multi-thread applications is unsupported.

Very wide fields (>128 characters) fail.

NAME	scanf, fscanf, sscanf, vscanf, vfscanf, vsscanf – convert formatted input
SYNOPSIS	<pre>#include <stdio.h> int scanf(const char *format, ...); int fscanf(FILE*stream, const char *format, ...); int sscanf(const char *s, const char *format, ...); #include <stdarg.h> #include <stdio.h> int vscanf(const char *format, va_list arg); int vfscanf(FILE *stream, const char *format, va_list arg); int vsscanf(const char *s, const char *format, va_list arg);</pre>
DESCRIPTION	<p>The <code>scanf()</code> function reads from the standard input stream <code>stdin</code>.</p> <p>The <code>fscanf()</code> function reads from the named input <i>stream</i>.</p> <p>The <code>sscanf()</code> function reads from the string <i>s</i>.</p> <p>The <code>vscanf()</code>, <code>vfscanf()</code>, and <code>vsscanf()</code> functions are equivalent to the <code>scanf()</code>, <code>fscanf()</code>, and <code>sscanf()</code> functions, respectively, except that instead of being called with a variable number of arguments, they are called with an argument list as defined by the <code><stdarg.h></code> header (see <code>stdarg(3HEAD)</code>). These functions do not invoke the <code>va_end()</code> macro. Applications using these functions should call <code>va_end(ap)</code> afterwards to clean up.</p> <p>Each function reads bytes, interprets them according to a format, and stores the results in its arguments. Each expects, as arguments, a control string <i>format</i> described below, and a set of <i>pointer</i> arguments indicating where the converted input should be stored. The result is undefined if there are insufficient arguments for the format. If the format is exhausted while arguments remain, the excess arguments are evaluated but are otherwise ignored.</p> <p>Conversions can be applied to the <i>n</i>th argument after the <i>format</i> in the argument list, rather than to the next unused argument. In this case, the conversion character <code>%</code> (see below) is replaced by the sequence <code>%n\$</code>, where <i>n</i> is a decimal integer in the range <code>[1, NL_ARGMAX]</code>. This feature provides for the definition of format strings that select arguments in an order appropriate to specific languages. In format strings containing the <code>%n\$</code> form of conversion specifications, it is unspecified whether numbered arguments in the argument list can be referenced from the format string more than once.</p> <p>The <i>format</i> can contain either form of a conversion specification, that is, <code>%</code> or <code>%n\$</code>, but the two forms cannot normally be mixed within a single <i>format</i> string. The only exception to this is that <code>%%</code> or <code>%*</code> can be mixed with the <code>%n\$</code> form.</p>

The `scanf()` function in all its forms allows for detection of a language-dependent radix character in the input string. The radix character is defined in the program's locale (category `LC_NUMERIC`). In the POSIX locale, or in a locale where the radix character is not defined, the radix character defaults to a period (`.`).

The format is a character string, beginning and ending in its initial shift state, if any, composed of zero or more directives. Each directive is composed of one of the following:

- one or more *white-space characters* (space, tab, newline, vertical-tab or form-feed characters);
- an *ordinary character* (neither `%` nor a white-space character); or
- a *conversion specification*.

Conversion Specifications

Each conversion specification is introduced by the character `%` or the character sequence `%n$`, after which the following appear in sequence:

- An optional assignment-suppressing character `*`.
- An optional non-zero decimal integer that specifies the maximum field width.
- An optional size modifier `h`, `l` (ell), `ll` (ell ell), or `L` indicating the size of the receiving object. The conversion characters `d`, `i`, and `n` must be preceded by `h` if the corresponding argument is a pointer to `short int` rather than a pointer to `int`, by `l` (ell) if it is a pointer to `long int`, or by `ll` (ell ell) if it is a pointer to `long long int`. Similarly, the conversion characters `o`, `u`, and `x` must be preceded by `h` if the corresponding argument is a pointer to `unsigned short int` rather than a pointer to `unsigned int`, by `l` (ell) if it is a pointer to `unsigned long int`, or by `ll` (ell ell) if it is a pointer to `unsigned long long int`. The conversion characters `e`, `f`, and `g` must be preceded by `l` (ell) if the corresponding argument is a pointer to `double` rather than a pointer to `float`, or by `L` if it is a pointer to `long double`. Finally, the conversion characters `c`, `s`, and `[]` must be preceded by `l` (ell) if the corresponding argument is a pointer to `wchar_t` rather than a pointer to a character type. If an `h`, `l` (ell), `ll` (ell ell), or `L` appears with any other conversion character, the behavior is undefined.
- A conversion character that specifies the type of conversion to be applied. The valid conversion characters are described below.

The `scanf()` functions execute each directive of the format in turn. If a directive fails, as detailed below, the function returns. Failures are described as input failures (due to the unavailability of input bytes) or matching failures (due to inappropriate input).

A directive composed of one or more white-space characters is executed by reading input until no more valid input can be read, or up to the first byte which is not a white-space character which remains unread.

A directive that is an ordinary character is executed as follows. The next byte is read from the input and compared with the byte that comprises the directive; if the comparison shows that they are not equivalent, the directive fails, and the differing and subsequent bytes remain unread.

A directive that is a conversion specification defines a set of matching input sequences, as described below for each conversion character. A conversion specification is executed in the following steps:

Input white-space characters (as specified by `isspace(3C)`) are skipped, unless the conversion specification includes a `[\, c, C, or n` conversion character.

An item is read from the input, unless the conversion specification includes an `n` conversion character. An input item is defined as the longest sequence of input bytes (up to any specified maximum field width, which may be measured in characters or bytes dependent on the conversion character) which is an initial subsequence of a matching sequence. The first byte, if any, after the input item remains unread. If the length of the input item is 0, the execution of the conversion specification fails; this condition is a matching failure, unless end-of-file, an encoding error, or a read error prevented input from the stream, in which case it is an input failure.

Except in the case of a `%` conversion character, the input item (or, in the case of a `%n` conversion specification, the count of input bytes) is converted to a type appropriate to the conversion character. If the input item is not a matching sequence, the execution of the conversion specification fails; this condition is a matching failure. Unless assignment suppression was indicated by a `*`, the result of the conversion is placed in the object pointed to by the first argument following the *format* argument that has not already received a conversion result if the conversion specification is introduced by `%`, or in the *n*th argument if introduced by the character sequence `%n$`. If this object does not have an appropriate type, or if the result of the conversion cannot be represented in the space provided, the behavior is undefined.

Conversion Characters

The following conversion characters are valid:

- d Matches an optionally signed decimal integer, whose format is the same as expected for the subject sequence of `strtol(3C)` with the value 10 for the *base* argument. In the absence of a size modifier, the corresponding argument must be a pointer to `int`.
- i Matches an optionally signed integer, whose format is the same as expected for the subject sequence of `strtol()` with 0 for the *base* argument. In the absence of a size modifier, the corresponding argument must be a pointer to `int`.
- o Matches an optionally signed octal integer, whose format is the same as expected for the subject sequence of `strtoul(3C)` with the value 8 for the *base* argument. In the absence of a size modifier, the corresponding argument must be a pointer to `unsigned int`.

vsscanf(3C)

u	Matches an optionally signed decimal integer, whose format is the same as expected for the subject sequence of <code>strtoul()</code> with the value 10 for the <i>base</i> argument. In the absence of a size modifier, the corresponding argument must be a pointer to <code>unsigned int</code> .
x	Matches an optionally signed hexadecimal integer, whose format is the same as expected for the subject sequence of <code>strtoul()</code> with the value 16 for the <i>base</i> argument. In the absence of a size modifier, the corresponding argument must be a pointer to <code>unsigned int</code> .
e,f,g	Matches an optionally signed floating-point number, whose format is the same as expected for the subject sequence of <code>strtod(3C)</code> . In the absence of a size modifier, the corresponding argument must be a pointer to <code>float</code> . If the <code>printf(3C)</code> family of functions generates character string representations for infinity and NaN (a 7858 symbolic entity encoded in floating-point format) to support the ANSI/IEEE Std 754: 1985 standard, the <code>scanf()</code> family of functions will recognize them as input.
s	Matches a sequence of bytes that are not white-space characters. The corresponding argument must be a pointer to the initial byte of an array of <code>char</code> , <code>signed char</code> , or <code>unsigned char</code> large enough to accept the sequence and a terminating null character code, which will be added automatically. If an <code>l</code> (<code>ell</code>) qualifier is present, the input is a sequence of characters that begins in the initial shift state. Each character is converted to a wide-character as if by a call to the <code>mbrtowc(3C)</code> function, with the conversion state described by an <code>mbstate_t</code> object initialized to zero before the first character is converted. The corresponding argument must be a pointer to an array of <code>wchar_t</code> large enough to accept the sequence and the terminating null wide-character, which will be added automatically.
[Matches a non-empty sequence of characters from a set of expected characters (the <i>scanset</i>). The normal skip over white-space characters is suppressed in this case. The corresponding argument must be a pointer to the initial byte of an array of <code>char</code> , <code>signed char</code> , or <code>unsigned char</code> large enough to accept the sequence and a terminating null byte, which will be added automatically. If an <code>l</code> (<code>ell</code>) qualifier is present, the input is a sequence of characters that begins in the initial shift state. Each character in the sequence is converted to a wide-character as if by a call to the <code>mbrtowc()</code> function, with the conversion state described by an <code>mbstate_t</code> object initialized to zero before the first character is converted. The corresponding argument must be a pointer to an array of <code>wchar_t</code> large enough to accept the sequence and the terminating null wide-character, which will be added automatically.

The conversion specification includes all subsequent characters in the *format* string up to and including the matching right square bracket (]). The characters between the square brackets (the *scanlist*) comprise the scanset, unless the character after the left square bracket is a circumflex (^), in which case the scanset contains all characters that do not appear in the scanlist between the circumflex and the right square bracket. If the conversion specification begins with [] or [^], the right square bracket is included in the scanlist and the next right square bracket is the matching right square bracket that ends the conversion specification; otherwise the first right square bracket is the one that ends the conversion specification. If a - is in the scanlist and is not the first character, nor the second where the first character is a ^, nor the last character, it indicates a range of characters to be matched.

c Matches a sequence of characters of the number specified by the field width (1 if no field width is present in the conversion specification). The corresponding argument must be a pointer to the initial byte of an array of `char`, `signed char`, or `unsigned char` large enough to accept the sequence. No null byte is added. The normal skip over white-space characters is suppressed in this case.

If an `l` (ell) qualifier is present, the input is a sequence of characters that begins in the initial shift state. Each character in the sequence is converted to a wide-character as if by a call to the `mbrtowc()` function, with the conversion state described by an `mbstate_t` object initialized to zero before the first character is converted. The corresponding argument must be a pointer to an array of `wchar_t` large enough to accept the resulting sequence of wide-characters. No null wide-character is added.

p Matches the set of sequences that is the same as the set of sequences that is produced by the `%p` conversion of the corresponding `printf(3C)` functions. The corresponding argument must be a pointer to a pointer to `void`. If the input item is a value converted earlier during the same program execution, the pointer that results will compare equal to that value; otherwise the behavior of the `%p` conversion is undefined.

n No input is consumed. The corresponding argument must be a pointer to the integer into which is to be written the number of bytes read from the input so far by this call to the `scanf()` functions. Execution of a `%n` conversion specification does not increment the assignment count returned at the completion of execution of the function.

C Same as `lc`.

S Same as `ls`.

% Matches a single `%`; no conversion or assignment occurs. The complete conversion specification must be `%%`.

If a conversion specification is invalid, the behavior is undefined.

vscanf(3C)

The conversion characters E, G, and X are also valid and behave the same as, respectively, e, g, and x.

If end-of-file is encountered during input, conversion is terminated. If end-of-file occurs before any bytes matching the current conversion specification (except for %n) have been read (other than leading white-space characters, where permitted), execution of the current conversion specification terminates with an input failure. Otherwise, unless execution of the current conversion specification is terminated with a matching failure, execution of the following conversion specification (if any) is terminated with an input failure.

Reaching the end of the string in `vscanf()` is equivalent to encountering end-of-file for `fscanf()`.

If conversion terminates on a conflicting input, the offending input is left unread in the input. Any trailing white space (including newline characters) is left unread unless matched by a conversion specification. The success of literal matches and suppressed assignments is only directly determinable via the %n conversion specification.

The `fscanf()` and `scanf()` functions may mark the `st_atime` field of the file associated with *stream* for update. The `st_atime` field will be marked for update by the first successful execution of `fgetc(3C)`, `fgets(3C)`, `fread(3C)`, `fscanf()`, `getc(3C)`, `getchar(3C)`, `gets(3C)`, or `scanf()` using *stream* that returns data not supplied by a prior call to `ungetc(3C)`.

RETURN VALUES

Upon successful completion, these functions return the number of successfully matched and assigned input items; this number can be 0 in the event of an early matching failure. If the input ends before the first matching failure or conversion, EOF is returned. If a read error occurs the error indicator for the stream is set, EOF is returned, and `errno` is set to indicate the error.

ERRORS

For the conditions under which the `scanf()` functions will fail and may fail, refer to `fgetc(3C)` or `fgetwc(3C)`.

In addition, `fscanf()` may fail if:

EILSEQ Input byte sequence does not form a valid character.

EINVAL There are insufficient arguments.

USAGE

If the application calling the `scanf()` functions has any objects of type `wint_t` or `wchar_t`, it must also include the header `<wchar.h>` to have these objects defined.

EXAMPLES

EXAMPLE 1 The call:

```
int i, n; float x; char name[50];
n = scanf("%d%f%s", &i, &x, name)
```

with the input line:

```
25 54.32E-1 Hamster
```

EXAMPLE 1 The call: (Continued)

will assign to *n* the value 3, to *i* the value 25, to *x* the value 5.432, and *name* will contain the string Hamster.

EXAMPLE 2 The call:

```
int i; float x; char name[50];
(void) scanf("%2d%f%*d %[0123456789]", &i, &x, name);
```

with input:

```
56789 0123 56a72
```

will assign 56 to *i*, 789.0 to *x*, skip 0123, and place the string 56\0 in *name*. The next call to `getchar(3C)` will return the character a.

NAME	fwscanf, wscanf, swscanf, vfwscanf, vwscanf, vswscanf – convert formatted wide-character input
SYNOPSIS	<pre>#include <stdio.h> #include <wchar.h> int fwscanf(FILE *stream, const wchar_t *format, ...); int wscanf(const wchar_t *format, ...); int swscanf(const wchar_t *s, const wchar_t *format, ...); #include <stdarg.h> #include <stdio.h> #include <wchar.h> int vfwscanf(FILE *stream, const wchar_t *format, va_list arg); int vwscanf(const wchar_t *ws, const wchar_t *format, va_list arg); int vswscanf(const wchar_t *format, va_list arg);</pre>
DESCRIPTION	<p>The <code>fwscanf()</code> function reads from the named input <i>stream</i>.</p> <p>The <code>wscanf()</code> function reads from the standard input stream <code>stdin</code>.</p> <p>The <code>swscanf()</code> function reads from the wide-character string <i>s</i>.</p> <p>The <code>vfwscanf()</code>, <code>vwscanf()</code>, and <code>vswscanf()</code> functions are equivalent to the <code>fwscanf()</code>, <code>swscanf()</code>, and <code>wscanf()</code> functions, respectively, except that instead of being called with a variable number of arguments, they are called with an argument list as defined by the <code><stdarg.h></code> header (see <code>stdarg(3HEAD)</code>). These functions do not invoke the <code>va_end()</code> macro. Applications using these functions should call <code>va_end(ap)</code> afterwards to clean up.</p> <p>Each function reads wide-characters, interprets them according to a format, and stores the results in its arguments. Each expects, as arguments, a control wide-character string <i>format</i> described below, and a set of <i>pointer</i> arguments indicating where the converted input should be stored. The result is undefined if there are insufficient arguments for the format. If the format is exhausted while arguments remain, the excess arguments are evaluated but are otherwise ignored.</p> <p>Conversions can be applied to the <i>n</i>th argument after the <i>format</i> in the argument list, rather than to the next unused argument. In this case, the conversion wide-character % (see below) is replaced by the sequence <code>%n\$</code>, where <i>n</i> is a decimal integer in the range <code>[1, NL_ARGMAX]</code>. This feature provides for the definition of format wide-character strings that select arguments in an order appropriate to specific languages. In format wide-character strings containing the <code>%n\$</code> form of conversion specifications, it is unspecified whether numbered arguments in the argument list can be referenced from the format wide-character string more than once.</p>

vswscanf(3C)

The *format* can contain either form of a conversion specification, that is, % or %n\$, but the two forms cannot normally be mixed within a single *format* wide-character string. The only exception to this is that %% or %* can be mixed with the %n\$ form.

The `fwscanf()` function in all its forms allows for detection of a language-dependent radix character in the input string, encoded as a wide-character value. The radix character is defined in the program's locale (category `LC_NUMERIC`). In the POSIX locale, or in a locale where the radix character is not defined, the radix character defaults to a period (.).

The format is a wide-character string composed of zero or more directives. Each directive is composed of one of the following: one or more white-space wide-characters (space, tab, newline, vertical-tab or form-feed characters); an ordinary wide-character (neither % nor a white-space character); or a conversion specification. Each conversion specification is introduced by a % or the sequence %n\$ after which the following appear in sequence:

- An optional assignment-suppressing character *.
- An optional non-zero decimal integer that specifies the maximum field width.
- An optional size modifier h, l(ell), or L indicating the size of the receiving object. The conversion wide-characters c, s, and [must be preceded by l(ell) if the corresponding argument is a pointer to `wchar_t` rather than a pointer to a character type. The conversion wide-characters d, i, and n must be preceded by h if the corresponding argument is a pointer to `short int` rather than a pointer to `int`, or by l(ell) if it is a pointer to `long int`. Similarly, the conversion wide-characters o, u, and x must be preceded by h if the corresponding argument is a pointer to `unsigned short int` rather than a pointer to `unsigned int`, or by l(ell) if it is a pointer to `unsigned long int`. The conversion wide-characters e, f, and g must be preceded by l(ell) if the corresponding argument is a pointer to `double` rather than a pointer to `float`, or by L if it is a pointer to `long double`. If an h, l(ell), or L appears with any other conversion wide-character, the behavior is undefined.
- A conversion wide-character that specifies the type of conversion to be applied. The valid conversion wide-characters are described below.

The `fwscanf()` functions execute each directive of the format in turn. If a directive fails, as detailed below, the function returns. Failures are described as input failures (due to the unavailability of input bytes) or matching failures (due to inappropriate input).

A directive composed of one or more white-space wide-characters is executed by reading input until no more valid input can be read, or up to the first wide-character which is not a white-space wide-character, which remains unread.

A directive that is an ordinary wide-character is executed as follows. The next wide-character is read from the input and compared with the wide-character that comprises the directive; if the comparison shows that they are not equivalent, the directive fails, and the differing and subsequent wide-characters remain unread.

A directive that is a conversion specification defines a set of matching input sequences, as described below for each conversion wide-character. A conversion specification is executed in the following steps:

Input white-space wide-characters (as specified by `isspace(3C)`) are skipped, unless the conversion specification includes a `l`, `c`, or `n` conversion character.

An item is read from the input, unless the conversion specification includes an `n` conversion wide-character. An input item is defined as the longest sequence of input wide-characters, not exceeding any specified field width, which is an initial subsequence of a matching sequence. The first wide-character, if any, after the input item remains unread. If the length of the input item is 0, the execution of the conversion specification fails; this condition is a matching failure, unless end-of-file, an encoding error, or a read error prevented input from the stream, in which case it is an input failure.

Except in the case of a `%` conversion wide-character, the input item (or, in the case of a `%n` conversion specification, the count of input wide-characters) is converted to a type appropriate to the conversion wide-character. If the input item is not a matching sequence, the execution of the conversion specification fails; this condition is a matching failure. Unless assignment suppression was indicated by a `*`, the result of the conversion is placed in the object pointed to by the first argument following the *format* argument that has not already received a conversion result if the conversion specification is introduced by `%`, or in the *n*th argument if introduced by the wide-character sequence `%n$`. If this object does not have an appropriate type, or if the result of the conversion cannot be represented in the space provided, the behavior is undefined.

The following conversion wide-characters are valid:

- d Matches an optionally signed decimal integer, whose format is the same as expected for the subject sequence of `wcstol(3C)` with the value 10 for the *base* argument. In the absence of a size modifier, the corresponding argument must be a pointer to `int`.
- i Matches an optionally signed integer, whose format is the same as expected for the subject sequence of `wcstol(3C)` with 0 for the *base* argument. In the absence of a size modifier, the corresponding argument must be a pointer to `int`.
- o Matches an optionally signed octal integer, whose format is the same as expected for the subject sequence of `wcstoul(3C)` with the value 8 for the *base* argument. In the absence of a size modifier, the corresponding argument must be a pointer to `unsigned int`.
- u Matches an optionally signed decimal integer, whose format is the same as expected for the subject sequence of `wcstoul(3C)` with the value 10 for the *base* argument. In the absence of a size modifier, the corresponding argument must be a pointer to `unsigned int`.

vswscanf(3C)

- | | |
|-------|---|
| x | Matches an optionally signed hexadecimal integer, whose format is the same as expected for the subject sequence of <code>wcstoul(3C)</code> with the value 16 for the <i>base</i> argument. In the absence of a size modifier, the corresponding argument must be a pointer to <code>unsigned int</code> . |
| e,f,g | Matches an optionally signed floating-point number, whose format is the same as expected for the subject sequence of <code>wcstod(3C)</code> . In the absence of a size modifier, the corresponding argument must be a pointer to <code>float</code> .

If the <code>fwprintf()</code> family of functions generates character string representations for infinity and NaN (a 7858 symbolic entity encoded in floating-point format) to support the ANSI/IEEE Std 754:1985 standard, the <code>fwscanf()</code> family of functions will recognize them as input. |
| s | Matches a sequence of non white-space wide-characters. If no <code>l</code> (ell) qualifier is present, characters from the input field are converted as if by repeated calls to the <code>wcrtomb(3C)</code> function, with the conversion state described by an <code>mbstate_t</code> object initialized to zero before the first wide-character is converted. The corresponding argument must be a pointer to a character array large enough to accept the sequence and the terminating null character, which will be added automatically.

Otherwise, the corresponding argument must be a pointer to an array of <code>wchar_t</code> large enough to accept the sequence and the terminating null wide-character, which will be added automatically. |
| [| Matches a non-empty sequence of wide-characters from a set of expected wide-characters (the <i>scanset</i>). If no <code>l</code> (ell) qualifier is present, wide-characters from the input field are converted as if by repeated calls to the <code>wcrtomb()</code> function, with the conversion state described by an <code>mbstate_t</code> object initialized to zero before the first wide-character is converted. The corresponding argument must be a pointer to a character array large enough to accept the sequence and the terminating null character, which will be added automatically.

If an <code>l</code> (ell) qualifier is present, the corresponding argument must be a pointer to an array of <code>wchar_t</code> large enough to accept the sequence and the terminating null wide-character, which will be added automatically.

The conversion specification includes all subsequent <code>widw</code> characters in the <i>format</i> string up to and including the matching right square bracket (<code>]</code>). The wide-characters between the square brackets (the <i>scanlist</i>) comprise the scanset, unless the wide-character after the left square bracket is a circumflex (<code>^</code>), in which case the scanset contains all wide-characters that do not appear in the scanlist between the circumflex and the right square bracket. If the conversion specification begins with <code>[]</code> or <code>[^]</code> , the right square bracket is included in the scanlist and the next right square bracket is the matching right square bracket that ends the conversion specification; otherwise the first right square bracket is the one that ends the conversion |

specification. If a minus-sign (-) is in the scanlist and is not the first wide-character, nor the second where the first wide-character is a ^, nor the last wide-character, it indicates a range of characters to be matched.

- | | |
|---|--|
| c | Matches a sequence of wide-characters of the number specified by the field width (1 if no field width is present in the conversion specification). If no l (ell) qualifier is present, wide-characters from the input field are converted as if by repeated calls to the <code>wcrtomb()</code> function, with the conversion state described by an <code>mbstate_t</code> object initialized to zero before the first wide-character is converted. The corresponding argument must be a pointer to a character array large enough to accept the sequence. No null character is added. |
| | Otherwise, the corresponding argument must be a pointer to an array of <code>wchar_t</code> large enough to accept the sequence. No null wide-character is added. |
| p | Matches the set of sequences that is the same as the set of sequences that is produced by the <code>%p</code> conversion of the corresponding <code>fwprintf(3C)</code> functions. The corresponding argument must be a pointer to a pointer to <code>void</code> . If the input item is a value converted earlier during the same program execution, the pointer that results will compare equal to that value; otherwise the behavior of the <code>%p</code> conversion is undefined. |
| n | No input is consumed. The corresponding argument must be a pointer to the integer into which is to be written the number of wide-characters read from the input so far by this call to the <code>fwscanf()</code> functions. Execution of a <code>%n</code> conversion specification does not increment the assignment count returned at the completion of execution of the function. |
| C | Same as <code>lc</code> . |
| S | Same as <code>ls</code> . |
| % | Matches a single <code>%</code> ; no conversion or assignment occurs. The complete conversion specification must be <code>%%</code> . |

If a conversion specification is invalid, the behavior is undefined.

The conversion characters E, G, and X are also valid and behave the same as, respectively, e, g, and x.

If end-of-file is encountered during input, conversion is terminated. If end-of-file occurs before any wide-characters matching the current conversion specification (except for `%n`) have been read (other than leading white-space, where permitted), execution of the current conversion specification terminates with an input failure. Otherwise, unless execution of the current conversion specification is terminated with a matching failure, execution of the following conversion specification (if any) is terminated with an input failure.

vswscanf(3C)

Reaching the end of the string in `swscanf()` is equivalent to encountering end-of-file for `fwscanf()`.

If conversion terminates on a conflicting input, the offending input is left unread in the input. Any trailing white space (including newline) is left unread unless matched by a conversion specification. The success of literal matches and suppressed assignments is only directly determinable via the `%n` conversion specification.

The `fwscanf()` and `wscanf()` functions may mark the `st_atime` field of the file associated with *stream* for update. The `st_atime` field will be marked for update by the first successful execution of `fgetc(3C)`, `fgetwc(3C)`, `fgets(3C)`, `fgetws(3C)`, `fread(3C)`, `getc(3C)`, `getwc(3C)`, `getchar(3C)`, `getwchar(3C)`, `gets(3C)`, `fscanf(3C)` or `fwscanf()` using *stream* that returns data not supplied by a prior call to `ungetc(3C)`.

RETURN VALUES

Upon successful completion, these functions return the number of successfully matched and assigned input items; this number can be 0 in the event of an early matching failure. If the input ends before the first matching failure or conversion, EOF is returned. If a read error occurs the error indicator for the stream is set, EOF is returned, and `errno` is set to indicate the error.

ERRORS

For the conditions under which the `fwscanf()` functions will fail and may fail, refer to `fgetwc(3C)`.

In addition, `fwscanf()` may fail if:

EILSEQ Input byte sequence does not form a valid character.

EINVAL There are insufficient arguments.

USAGE

In format strings containing the `%` form of conversion specifications, each argument in the argument list is used exactly once.

EXAMPLES

EXAMPLE 1 `wscanf()` example

The call:

```
int i, n; float x; char name[50];
n = wscanf(L"%d%f%s", &i, &x, name);
```

with the input line:

```
25 54.32E-1 Hamster
```

will assign to *n* the value 3, to *i* the value 25, to *x* the value 5.432, and *name* will contain the string Hamster.

The call:

```
int i; float x; char name[50];
(void) wscanf(L"%2d%f*d %[0123456789]", &i, &x, name);
```

with input:

EXAMPLE 1 wscanf () example (Continued)

```
56789 0123 56a72
```

will assign 56 to *i*, 789.0 to *x*, skip 0123, and place the string 56\0 in *name*. The next call to `getchar(3C)` will return the character *a*.

vwscanf(3C)

NAME	<code>fwscanf</code> , <code>wscanf</code> , <code>swscanf</code> , <code>vwscanf</code> , <code>vwscanf</code> , <code>vswscanf</code> – convert formatted wide-character input
SYNOPSIS	<pre>#include <stdio.h> #include <wchar.h> int fwscanf(FILE *stream, const wchar_t *format, ...); int wscanf(const wchar_t *format, ...); int swscanf(const wchar_t *s, const wchar_t *format, ...); #include <stdarg.h> #include <stdio.h> #include <wchar.h> int vwscanf(FILE *stream, const wchar_t *format, va_list arg); int vswscanf(const wchar_t *ws, const wchar_t *format, va_list arg); int vswscanf(const wchar_t *format, va_list arg);</pre>
DESCRIPTION	<p>The <code>fwscanf()</code> function reads from the named input <i>stream</i>.</p> <p>The <code>wscanf()</code> function reads from the standard input stream <code>stdin</code>.</p> <p>The <code>swscanf()</code> function reads from the wide-character string <i>s</i>.</p> <p>The <code>vwscanf()</code>, <code>vswscanf()</code>, and <code>vswscanf()</code> functions are equivalent to the <code>fwscanf()</code>, <code>swscanf()</code>, and <code>wscanf()</code> functions, respectively, except that instead of being called with a variable number of arguments, they are called with an argument list as defined by the <code><stdarg.h></code> header (see <code>stdarg(3HEAD)</code>). These functions do not invoke the <code>va_end()</code> macro. Applications using these functions should call <code>va_end(ap)</code> afterwards to clean up.</p> <p>Each function reads wide-characters, interprets them according to a format, and stores the results in its arguments. Each expects, as arguments, a control wide-character string <i>format</i> described below, and a set of <i>pointer</i> arguments indicating where the converted input should be stored. The result is undefined if there are insufficient arguments for the format. If the format is exhausted while arguments remain, the excess arguments are evaluated but are otherwise ignored.</p> <p>Conversions can be applied to the <i>n</i>th argument after the <i>format</i> in the argument list, rather than to the next unused argument. In this case, the conversion wide-character <code>%</code> (see below) is replaced by the sequence <code>%n\$</code>, where <i>n</i> is a decimal integer in the range <code>[1, NL_ARGMAX]</code>. This feature provides for the definition of format wide-character strings that select arguments in an order appropriate to specific languages. In format wide-character strings containing the <code>%n\$</code> form of conversion specifications, it is unspecified whether numbered arguments in the argument list can be referenced from the format wide-character string more than once.</p>

The *format* can contain either form of a conversion specification, that is, % or %n\$, but the two forms cannot normally be mixed within a single *format* wide-character string. The only exception to this is that %% or %* can be mixed with the %n\$ form.

The `fwscanf()` function in all its forms allows for detection of a language-dependent radix character in the input string, encoded as a wide-character value. The radix character is defined in the program's locale (category `LC_NUMERIC`). In the POSIX locale, or in a locale where the radix character is not defined, the radix character defaults to a period (.).

The format is a wide-character string composed of zero or more directives. Each directive is composed of one of the following: one or more white-space wide-characters (space, tab, newline, vertical-tab or form-feed characters); an ordinary wide-character (neither % nor a white-space character); or a conversion specification. Each conversion specification is introduced by a % or the sequence %n\$ after which the following appear in sequence:

- An optional assignment-suppressing character *.
- An optional non-zero decimal integer that specifies the maximum field width.
- An optional size modifier h, l(ell), or L indicating the size of the receiving object. The conversion wide-characters c, s, and [must be preceded by l(ell) if the corresponding argument is a pointer to `wchar_t` rather than a pointer to a character type. The conversion wide-characters d, i, and n must be preceded by h if the corresponding argument is a pointer to `short int` rather than a pointer to `int`, or by l(ell) if it is a pointer to `long int`. Similarly, the conversion wide-characters o, u, and x must be preceded by h if the corresponding argument is a pointer to `unsigned short int` rather than a pointer to `unsigned int`, or by l(ell) if it is a pointer to `unsigned long int`. The conversion wide-characters e, f, and g must be preceded by l(ell) if the corresponding argument is a pointer to `double` rather than a pointer to `float`, or by L if it is a pointer to `long double`. If an h, l(ell), or L appears with any other conversion wide-character, the behavior is undefined.
- A conversion wide-character that specifies the type of conversion to be applied. The valid conversion wide-characters are described below.

The `fwscanf()` functions execute each directive of the format in turn. If a directive fails, as detailed below, the function returns. Failures are described as input failures (due to the unavailability of input bytes) or matching failures (due to inappropriate input).

A directive composed of one or more white-space wide-characters is executed by reading input until no more valid input can be read, or up to the first wide-character which is not a white-space wide-character, which remains unread.

A directive that is an ordinary wide-character is executed as follows. The next wide-character is read from the input and compared with the wide-character that comprises the directive; if the comparison shows that they are not equivalent, the directive fails, and the differing and subsequent wide-characters remain unread.

vwscanf(3C)

A directive that is a conversion specification defines a set of matching input sequences, as described below for each conversion wide-character. A conversion specification is executed in the following steps:

Input white-space wide-characters (as specified by `isspace(3C)`) are skipped, unless the conversion specification includes a `l`, `c`, or `n` conversion character.

An item is read from the input, unless the conversion specification includes an `n` conversion wide-character. An input item is defined as the longest sequence of input wide-characters, not exceeding any specified field width, which is an initial subsequence of a matching sequence. The first wide-character, if any, after the input item remains unread. If the length of the input item is 0, the execution of the conversion specification fails; this condition is a matching failure, unless end-of-file, an encoding error, or a read error prevented input from the stream, in which case it is an input failure.

Except in the case of a `%` conversion wide-character, the input item (or, in the case of a `%n` conversion specification, the count of input wide-characters) is converted to a type appropriate to the conversion wide-character. If the input item is not a matching sequence, the execution of the conversion specification fails; this condition is a matching failure. Unless assignment suppression was indicated by a `*`, the result of the conversion is placed in the object pointed to by the first argument following the *format* argument that has not already received a conversion result if the conversion specification is introduced by `%`, or in the *n*th argument if introduced by the wide-character sequence `%n$`. If this object does not have an appropriate type, or if the result of the conversion cannot be represented in the space provided, the behavior is undefined.

The following conversion wide-characters are valid:

- d Matches an optionally signed decimal integer, whose format is the same as expected for the subject sequence of `wcstol(3C)` with the value 10 for the *base* argument. In the absence of a size modifier, the corresponding argument must be a pointer to `int`.
- i Matches an optionally signed integer, whose format is the same as expected for the subject sequence of `wcstol(3C)` with 0 for the *base* argument. In the absence of a size modifier, the corresponding argument must be a pointer to `int`.
- o Matches an optionally signed octal integer, whose format is the same as expected for the subject sequence of `wcstoul(3C)` with the value 8 for the *base* argument. In the absence of a size modifier, the corresponding argument must be a pointer to `unsigned int`.
- u Matches an optionally signed decimal integer, whose format is the same as expected for the subject sequence of `wcstoul(3C)` with the value 10 for the *base* argument. In the absence of a size modifier, the corresponding argument must be a pointer to `unsigned int`.

- x** Matches an optionally signed hexadecimal integer, whose format is the same as expected for the subject sequence of `wcstoul(3C)` with the value 16 for the *base* argument. In the absence of a size modifier, the corresponding argument must be a pointer to `unsigned int`.
- e,f,g** Matches an optionally signed floating-point number, whose format is the same as expected for the subject sequence of `wcstod(3C)`. In the absence of a size modifier, the corresponding argument must be a pointer to `float`.
- If the `fwprintf()` family of functions generates character string representations for infinity and NaN (a 7858 symbolic entity encoded in floating-point format) to support the ANSI/IEEE Std 754:1985 standard, the `fwscanf()` family of functions will recognize them as input.
- s** Matches a sequence of non white-space wide-characters. If no `l` (`ell`) qualifier is present, characters from the input field are converted as if by repeated calls to the `wcrtomb(3C)` function, with the conversion state described by an `mbstate_t` object initialized to zero before the first wide-character is converted. The corresponding argument must be a pointer to a character array large enough to accept the sequence and the terminating null character, which will be added automatically.
- Otherwise, the corresponding argument must be a pointer to an array of `wchar_t` large enough to accept the sequence and the terminating null wide-character, which will be added automatically.
- [** Matches a non-empty sequence of wide-characters from a set of expected wide-characters (the *scanset*). If no `l` (`ell`) qualifier is present, wide-characters from the input field are converted as if by repeated calls to the `wcrtomb()` function, with the conversion state described by an `mbstate_t` object initialized to zero before the first wide-character is converted. The corresponding argument must be a pointer to a character array large enough to accept the sequence and the terminating null character, which will be added automatically.
- If an `l` (`ell`) qualifier is present, the corresponding argument must be a pointer to an array of `wchar_t` large enough to accept the sequence and the terminating null wide-character, which will be added automatically.
- The conversion specification includes all subsequent `widw` characters in the *format* string up to and including the matching right square bracket (`]`). The wide-characters between the square brackets (the *scanlist*) comprise the *scanset*, unless the wide-character after the left square bracket is a circumflex (`^`), in which case the *scanset* contains all wide-characters that do not appear in the *scanlist* between the circumflex and the right square bracket. If the conversion specification begins with `[]` or `[^]`, the right square bracket is included in the *scanlist* and the next right square bracket is the matching right square bracket that ends the conversion specification; otherwise the first right square bracket is the one that ends the conversion

vwscanf(3C)

	specification. If a minus-sign (-) is in the scanlist and is not the first wide-character, nor the second where the first wide-character is a ^, nor the last wide-character, it indicates a range of characters to be matched.
c	Matches a sequence of wide-characters of the number specified by the field width (1 if no field width is present in the conversion specification). If no l (ell) qualifier is present, wide-characters from the input field are converted as if by repeated calls to the <code>wcrtomb()</code> function, with the conversion state described by an <code>mbstate_t</code> object initialized to zero before the first wide-character is converted. The corresponding argument must be a pointer to a character array large enough to accept the sequence. No null character is added. Otherwise, the corresponding argument must be a pointer to an array of <code>wchar_t</code> large enough to accept the sequence. No null wide-character is added.
p	Matches the set of sequences that is the same as the set of sequences that is produced by the <code>%p</code> conversion of the corresponding <code>fwprintf(3C)</code> functions. The corresponding argument must be a pointer to a pointer to <code>void</code> . If the input item is a value converted earlier during the same program execution, the pointer that results will compare equal to that value; otherwise the behavior of the <code>%p</code> conversion is undefined.
n	No input is consumed. The corresponding argument must be a pointer to the integer into which is to be written the number of wide-characters read from the input so far by this call to the <code>fwscanf()</code> functions. Execution of a <code>%n</code> conversion specification does not increment the assignment count returned at the completion of execution of the function.
C	Same as <code>lc</code> .
S	Same as <code>ls</code> .
%	Matches a single %; no conversion or assignment occurs. The complete conversion specification must be <code>%%</code> .

If a conversion specification is invalid, the behavior is undefined.

The conversion characters E, G, and X are also valid and behave the same as, respectively, e, g, and x.

If end-of-file is encountered during input, conversion is terminated. If end-of-file occurs before any wide-characters matching the current conversion specification (except for `%n`) have been read (other than leading white-space, where permitted), execution of the current conversion specification terminates with an input failure. Otherwise, unless execution of the current conversion specification is terminated with a matching failure, execution of the following conversion specification (if any) is terminated with an input failure.

Reaching the end of the string in `swscanf()` is equivalent to encountering end-of-file for `fwscanf()`.

If conversion terminates on a conflicting input, the offending input is left unread in the input. Any trailing white space (including newline) is left unread unless matched by a conversion specification. The success of literal matches and suppressed assignments is only directly determinable via the `%n` conversion specification.

The `fwscanf()` and `wscanf()` functions may mark the `st_atime` field of the file associated with *stream* for update. The `st_atime` field will be marked for update by the first successful execution of `fgetc(3C)`, `fgetwc(3C)`, `fgets(3C)`, `fgetws(3C)`, `fread(3C)`, `getc(3C)`, `getwc(3C)`, `getchar(3C)`, `getwchar(3C)`, `gets(3C)`, `fscanf(3C)` or `fwscanf()` using *stream* that returns data not supplied by a prior call to `ungetc(3C)`.

RETURN VALUES

Upon successful completion, these functions return the number of successfully matched and assigned input items; this number can be 0 in the event of an early matching failure. If the input ends before the first matching failure or conversion, EOF is returned. If a read error occurs the error indicator for the stream is set, EOF is returned, and `errno` is set to indicate the error.

ERRORS

For the conditions under which the `fwscanf()` functions will fail and may fail, refer to `fgetwc(3C)`.

In addition, `fwscanf()` may fail if:

`EILSEQ` Input byte sequence does not form a valid character.

`EINVAL` There are insufficient arguments.

USAGE

In format strings containing the `%` form of conversion specifications, each argument in the argument list is used exactly once.

EXAMPLES

EXAMPLE 1 `wscanf()` example

The call:

```
int i, n; float x; char name[50];
n = wscanf(L"%d%f%s", &i, &x, name);
```

with the input line:

```
25 54.32E-1 Hamster
```

will assign to *n* the value 3, to *i* the value 25, to *x* the value 5.432, and *name* will contain the string Hamster.

The call:

```
int i; float x; char name[50];
(void) wscanf(L"%2d%f*d %[0123456789]", &i, &x, name);
```

with input:

vwscanf(3C)

EXAMPLE 1 `wscanf()` example (Continued)

56789 0123 56a72

will assign 56 to *i*, 789.0 to *x*, skip 0123, and place the string 56\0 in *name*. The next call to `getchar(3C)` will return the character a.

NAME	wait3, wait4 – wait for process to terminate or stop				
SYNOPSIS	<pre>#include <sys/wait.h> #include <sys/time.h> #include <sys/resource.h> pid_t wait3(int *statusp, int options, struct rusage *rusage); pid_t wait4(pid_t pid, int *statusp, int options, struct rusage *rusage);</pre>				
DESCRIPTION	<p>The <code>wait3()</code> function delays its caller until a signal is received or one of its child processes terminates or stops due to tracing. If any child process has died or stopped due to tracing and this has not already been reported, return is immediate, returning the process ID and status of one of those children. If that child process has died, it is discarded. If there are no children, <code>-1</code> is returned immediately. If there are only running or stopped but reported children, the calling process is blocked.</p> <p>If <code>statusp</code> is not a null pointer, then on return from a successful <code>wait3()</code> call, the status of the child process is stored in the integer pointed to by <code>statusp</code>. <code>*statusp</code> indicates the cause of termination and other information about the terminated process in the following manner:</p> <ul style="list-style-type: none"> ■ If the low-order 8 bits of <code>*statusp</code> are equal to <code>0177</code>, the child process has stopped; the 8 bits higher up from the low-order 8 bits of <code>*statusp</code> contain the number of the signal that caused the process to stop. See <code>signal(3HEAD)</code>. ■ If the low-order 8 bits of <code>*statusp</code> are non-zero and are not equal to <code>0177</code>, the child process terminated due to a signal; the low-order 7 bits of <code>*statusp</code> contain the number of the signal that terminated the process. In addition, if the low-order seventh bit of <code>*statusp</code> (that is, bit <code>0200</code>) is set, a “core image” of the process was produced; see <code>signal(3HEAD)</code>. ■ Otherwise, the child process terminated due to an <code>exit()</code> call; the 8 bits higher up from the low-order 8 bits of <code>*statusp</code> contain the low-order 8 bits of the argument that the child process passed to <code>exit()</code>; see <code>exit(2)</code>. <p>The <code>options</code> argument is constructed from the bitwise inclusive OR of zero or more of the following flags, defined in <code><sys/wait.h></code>:</p> <table border="0" style="width: 100%;"> <tr> <td style="padding-right: 20px;"><code>WNOHANG</code></td> <td>Execution of the calling process is not suspended if status is not immediately available for any child process.</td> </tr> <tr> <td><code>WUNTRACED</code></td> <td>The status of any child processes that are stopped, and whose status has not yet been reported since they stopped, are also reported to the requesting process.</td> </tr> </table> <p>If <code>rusage</code> is not a null pointer, a summary of the resources used by the terminated process and all its children is returned. Only the user time used and the system time used are currently available. They are returned in the <code>ru_utime</code> and <code>ru_stime</code>, members of the <code>rusage</code> structure, respectively.</p>	<code>WNOHANG</code>	Execution of the calling process is not suspended if status is not immediately available for any child process.	<code>WUNTRACED</code>	The status of any child processes that are stopped, and whose status has not yet been reported since they stopped, are also reported to the requesting process.
<code>WNOHANG</code>	Execution of the calling process is not suspended if status is not immediately available for any child process.				
<code>WUNTRACED</code>	The status of any child processes that are stopped, and whose status has not yet been reported since they stopped, are also reported to the requesting process.				

wait3(3C)

When the `WNOHANG` option is specified and no processes have status to report, `wait3()` returns 0. The `WNOHANG` and `WUNTRACED` options may be combined by the bitwise OR operation of the two values.

The `wait4()` function is an extended interface. With a `pid` argument of 0, it is equivalent to `wait3()`. If `pid` has a nonzero value, then `wait4()` returns status only for the indicated process ID, but not for any other child processes. The status can be evaluated using the macros defined by `wstat(3XFN)`.

RETURN VALUES

If `wait3()` or `wait4()` returns due to a stopped or terminated child process, the process ID of the child is returned to the calling process. Otherwise, `-1` is returned and `errno` is set to indicate the error.

If `wait3()` or `wait4()` return due to the delivery of a signal to the calling process, `-1` is returned and `errno` is set to `EINTR`. If `WNOHANG` was set in `options`, it has at least one child process specified by `pid` for which status is not available, and status is not available for any process specified by `pid`, 0 is returned. Otherwise, `-1` is returned and `errno` is set to indicate the error.

The `wait3()` and `wait4()` functions return 0 if `WNOHANG` is specified and there are no stopped or exited children, and return the process ID of the child process if they return due to a stopped or terminated child process. Otherwise, they return `-1` and set `errno` to indicate the error.

ERRORS

The `wait3()` and `wait4()` functions will fail and return immediately if:

- `ECHILD` The calling process has no existing unwaited-for child processes.
- `EFAULT` The `statusp` or `rusage` arguments point to an illegal address.
- `EINTR` The function was interrupted by a signal. The value of the location pointed to by `statusp` is undefined.
- `EINVAL` The value of `options` is not valid.

The `wait4()` function may fail if:

- `ECHILD` The process specified by `pid` does not exist or is not a child of the calling process.

The `wait3()` and `wait4()` functions will terminate prematurely, return `-1`, and set `errno` to `EINTR` upon the arrival of a signal whose `SA_RESTART` bit in its flags field is not set (see `sigaction(2)`).

SEE ALSO

`kill(1)`, `exit(2)`, `wait(2)`, `waitid(2)`, `waitpid(2)`, `getrusage(3C)`, `signal(3C)`, `proc(4)`, `signal(3HEAD)`, `wstat(3XFN)`

NOTES

If a parent process terminates without waiting on its children, the initialization process (process ID = 1) inherits the children.

wait3(3C)

The `wait3()` and `wait4()` functions are automatically restarted when a process receives a signal while awaiting termination of a child process, unless the `SA_RESTART` bit is not set in the flags for that signal.

wait3(3UCB)

NAME	wait, wait3, wait4, waitpid, WIFSTOPPED, WIFSIGNALED, WIFEXITED – wait for process to terminate or stop
SYNOPSIS	<pre>/usr/ucb/cc [flag ...] file ... #include <sys/wait.h> int wait(statusp); int *statusp; int waitpid(pid, statusp, options); int pid; int *statusp; int options; #include <sys/time.h> #include <sys/resource.h> int wait3(statusp, options, rusage); int *statusp; int options; struct rusage *rusage; int wait4(pid, statusp, options, rusage); int pid; int *statusp; int options; struct rusage *rusage; WIFSTOPPED(status); int status; WIFSIGNALED(status); int status; WIFEXITED(status); int status;</pre>
DESCRIPTION	<p>wait() delays its caller until a signal is received or one of its child processes terminates or stops due to tracing. If any child process has died or stopped due to tracing and this has not been reported using wait(), return is immediate, returning the process ID and exit status of one of those children. If that child process has died, it is discarded. If there are no children, return is immediate with the value -1 returned. If there are only running or stopped but reported children, the calling process is blocked.</p> <p>If status is not a NULL pointer, then on return from a successful wait() call the status of the child process whose process ID is the return value of wait() is stored in the wait() union pointed to by status. The w_status member of that union is an int; it indicates the cause of termination and other information about the terminated process in the following manner:</p>

- If the low-order 8 bits of `w_status` are equal to 0177, the child process has stopped; the 8 bits higher up from the low-order 8 bits of `w_status` contain the number of the signal that caused the process to stop. See `ptrace(2)` and `sigvec(3UCB)`.
- If the low-order 8 bits of `w_status` are non-zero and are not equal to 0177, the child process terminated due to a signal; the low-order 7 bits of `w_status` contain the number of the signal that terminated the process. In addition, if the low-order seventh bit of `w_status` (that is, bit 0200) is set, a “core image” of the process was produced; see `sigvec(3UCB)`.
- Otherwise, the child process terminated due to an `exit()` call; the 8 bits higher up from the low-order 8 bits of `w_status` contain the low-order 8 bits of the argument that the child process passed to `exit()`; see `exit(2)`.

`waitpid()` behaves identically to `wait()` if `pid` has a value of `-1` and `options` has a value of zero. Otherwise, the behavior of `waitpid()` is modified by the values of `pid` and `options` as follows:

`pid` specifies a set of child processes for which status is requested. `waitpid()` only returns the status of a child process from this set.

- If `pid` is equal to `-1`, status is requested for any child process. In this respect, `waitpid()` is then equivalent to `wait()`.
- If `pid` is greater than zero, it specifies the process ID of a single child process for which status is requested.
- If `pid` is equal to zero, status is requested for any child process whose process group ID is equal to that of the calling process.
- If `pid` is less than `-1`, status is requested for any child process whose process group ID is equal to the absolute value of `pid`.

`options` is constructed from the bitwise inclusive OR of zero or more of the following flags, defined in the header `<sys/wait.h>`:

<code>WNOHANG</code>	<code>waitpid()</code> does not suspend execution of the calling process if status is not immediately available for one of the child processes specified by <code>pid</code> .
<code>WUNTRACED</code>	The status of any child processes specified by <code>pid</code> that are stopped, and whose status has not yet been reported since they stopped, are also reported to the requesting process.

`wait3()` is an alternate interface that allows both non-blocking status collection and the collection of the status of children stopped by any means. The `status` parameter is defined as above. The `options` parameter is used to indicate the call should not block if there are no processes that have status to report (`WNOHANG`), and/or that children of the current process that are stopped due to a `SIGTTIN`, `SIGTTOU`, `SIGTSTP`, or `SIGSTOP` signal are eligible to have their status reported as well (`WUNTRACED`). A terminated child is discarded after it reports status, and a stopped process will not

wait3(3UCB)

report its status more than once. If *rusage* is not a NULL pointer, a summary of the resources used by the terminated process and all its children is returned. Only the user time used and the system time used are currently available. They are returned in `rusage.ru_utime` and `rusage.ru_stime`, respectively.

When the `WNOHANG` option is specified and no processes have status to report, `wait3()` returns 0. The `WNOHANG` and `WUNTRACED` options may be combined by ORing the two values.

`wait4()` is another alternate interface. With a *pid* argument of 0, it is equivalent to `wait3()`. If *pid* has a nonzero value, then `wait4()` returns status only for the indicated process ID, but not for any other child processes.

`WIFSTOPPED`, `WIFSIGNALED`, `WIFEXITED`, are macros that take an argument *status*, of type `int`, as returned by `wait()`, or `wait3()`, or `wait4()`. `WIFSTOPPED` evaluates to true (1) when the process for which the `wait()` call was made is stopped, or to false (0) otherwise. `WIFSIGNALED` evaluates to true when the process was terminated with a signal. `WIFEXITED` evaluates to true when the process exited by using an `exit(2)` call.

RETURN VALUES

If `wait()` or `waitpid()` returns due to a stopped or terminated child process, the process ID of the child is returned to the calling process. Otherwise, a value of -1 is returned and `errno` is set to indicate the error.

If `wait()` or `waitpid()` return due to the delivery of a signal to the calling process, a value of -1 is returned and `errno` is set to `EINTR`. If `waitpid()` function was invoked with `WNOHANG` set in *options*, it has at least one child process specified by *pid* for which status is not available, and status is not available for any process specified by *pid*, a value of zero is returned. Otherwise, a value of -1 is returned, and `errno` is set to indicate the error.

`wait3()` and `wait4()` returns 0 if `WNOHANG` is specified and there are no stopped or exited children, and returns the process ID of the child process if it returns due to a stopped or terminated child process. Otherwise, they returns a value of -1 and sets `errno` to indicate the error.

ERRORS

`wait()`, `wait3()` or `wait4()` will fail and return immediately if one or more of the following are true:

<code>ECHILD</code>	The calling process has no existing unwaited-for child processes.
<code>EFAULT</code>	The <i>status</i> or <i>rusage</i> arguments point to an illegal address.

`waitpid()` may set `errno` to:

<code>ECHILD</code>	The process or process group specified by <i>pid</i> does not exist or is not a child of the calling process.
<code>EINTR</code>	The function was interrupted by a signal. The value of the location pointed to by <i>statusp</i> is undefined.

EINVAL The value of *options* is not valid.

`wait()`, and `wait3()`, and `wait4()` will terminate prematurely, return `-1`, and set `errno` to `EINTR` upon the arrival of a signal whose `SV_INTERRUPT` bit in its flags field is set (see `sigvec(3UCB)` and `siginterrupt(3UCB)`). `signal(3UCB)`, sets this bit for any signal it catches.

SEE ALSO `exit(2)`, `ptrace(2)`, `wait(2)`, `waitpid(2)`, `getrusage(3C)`, `siginterrupt(3UCB)`, `signal(3UCB)`, `sigvec(3UCB)`, `signal(3C)`

NOTES Use of these interfaces should be restricted to only applications written on BSD platforms. Use of these interfaces with any of the system libraries or in multi-thread applications is unsupported.

If a parent process terminates without waiting on its children, the initialization process (process ID = 1) inherits the children.

`wait()`, and `wait3()`, and `wait4()` are automatically restarted when a process receives a signal while awaiting termination of a child process, unless the `SV_INTERRUPT` bit is set in the flags for that signal.

Calls to `wait()` with an argument of 0 should be cast to type `'int *'`, as in:

```
wait((int *)0)
```

Previous SunOS releases used union `wait*statusp` and union `wait status` in place of `int *statusp` and `int status`. The union contained a member `w_status` that could be treated in the same way as `status`.

Other members of the `wait` union could be used to extract this information more conveniently:

- If the `w_stopval` member had the value `WSTOPPED`, the child process had stopped; the value of the `w_stopsig` member was the signal that stopped the process.
- If the `w_termsig` member was non-zero, the child process terminated due to a signal; the value of the `w_termsig` member was the number of the signal that terminated the process. If the `w_coredump` member was non-zero, a core dump was produced.
- Otherwise, the child process terminated due to a call to `exit()`. The value of the `w_retcode` member was the low-order 8 bits of the argument that the child process passed to `exit()`.

union `wait` is obsolete in light of the new specifications provided by *IEEE Std 1003.1-1988* and endorsed by *SVID89* and *XPG3*. SunOS Release 4.1 supports `unionwait` for backward compatibility, but it will disappear in a future release.

wait(3UCB)

NAME	wait, wait3, wait4, waitpid, WIFSTOPPED, WIFSIGNALED, WIFEXITED – wait for process to terminate or stop
SYNOPSIS	<pre>/usr/ucb/cc [flag ...] file ... #include <sys/wait.h> int wait(statusp); int *statusp; int waitpid(pid, statusp, options); int pid; int *statusp; int options; #include <sys/time.h> #include <sys/resource.h> int wait3(statusp, options, rusage); int *statusp; int options; struct rusage *rusage; int wait4(pid, statusp, options, rusage); int pid; int *statusp; int options; struct rusage *rusage; WIFSTOPPED(status); int status; WIFSIGNALED(status); int status; WIFEXITED(status); int status;</pre>
DESCRIPTION	<p>wait () delays its caller until a signal is received or one of its child processes terminates or stops due to tracing. If any child process has died or stopped due to tracing and this has not been reported using wait (), return is immediate, returning the process ID and exit status of one of those children. If that child process has died, it is discarded. If there are no children, return is immediate with the value -1 returned. If there are only running or stopped but reported children, the calling process is blocked.</p> <p>If status is not a NULL pointer, then on return from a successful wait () call the status of the child process whose process ID is the return value of wait () is stored in the wait () union pointed to by status. The w_status member of that union is an int; it indicates the cause of termination and other information about the terminated process in the following manner:</p>

- If the low-order 8 bits of `w_status` are equal to 0177, the child process has stopped; the 8 bits higher up from the low-order 8 bits of `w_status` contain the number of the signal that caused the process to stop. See `ptrace(2)` and `sigvec(3UCB)`.
- If the low-order 8 bits of `w_status` are non-zero and are not equal to 0177, the child process terminated due to a signal; the low-order 7 bits of `w_status` contain the number of the signal that terminated the process. In addition, if the low-order seventh bit of `w_status` (that is, bit 0200) is set, a “core image” of the process was produced; see `sigvec(3UCB)`.
- Otherwise, the child process terminated due to an `exit()` call; the 8 bits higher up from the low-order 8 bits of `w_status` contain the low-order 8 bits of the argument that the child process passed to `exit()`; see `exit(2)`.

`waitpid()` behaves identically to `wait()` if `pid` has a value of `-1` and `options` has a value of zero. Otherwise, the behavior of `waitpid()` is modified by the values of `pid` and `options` as follows:

`pid` specifies a set of child processes for which status is requested. `waitpid()` only returns the status of a child process from this set.

- If `pid` is equal to `-1`, status is requested for any child process. In this respect, `waitpid()` is then equivalent to `wait()`.
- If `pid` is greater than zero, it specifies the process ID of a single child process for which status is requested.
- If `pid` is equal to zero, status is requested for any child process whose process group ID is equal to that of the calling process.
- If `pid` is less than `-1`, status is requested for any child process whose process group ID is equal to the absolute value of `pid`.

`options` is constructed from the bitwise inclusive OR of zero or more of the following flags, defined in the header `<sys/wait.h>`:

WNOHANG	<code>waitpid()</code> does not suspend execution of the calling process if status is not immediately available for one of the child processes specified by <code>pid</code> .
WUNTRACED	The status of any child processes specified by <code>pid</code> that are stopped, and whose status has not yet been reported since they stopped, are also reported to the requesting process.

`wait3()` is an alternate interface that allows both non-blocking status collection and the collection of the status of children stopped by any means. The `status` parameter is defined as above. The `options` parameter is used to indicate the call should not block if there are no processes that have status to report (`WNOHANG`), and/or that children of the current process that are stopped due to a `SIGTTIN`, `SIGTTOU`, `SIGTSTP`, or `SIGSTOP` signal are eligible to have their status reported as well (`WUNTRACED`). A terminated child is discarded after it reports status, and a stopped process will not

wait(3UCB)

report its status more than once. If *rusage* is not a NULL pointer, a summary of the resources used by the terminated process and all its children is returned. Only the user time used and the system time used are currently available. They are returned in `rusage.ru_utime` and `rusage.ru_stime`, respectively.

When the `WNOHANG` option is specified and no processes have status to report, `wait3()` returns 0. The `WNOHANG` and `WUNTRACED` options may be combined by ORing the two values.

`wait4()` is another alternate interface. With a *pid* argument of 0, it is equivalent to `wait3()`. If *pid* has a nonzero value, then `wait4()` returns status only for the indicated process ID, but not for any other child processes.

`WIFSTOPPED`, `WIFSIGNALED`, `WIFEXITED`, are macros that take an argument *status*, of type `int`, as returned by `wait()`, or `wait3()`, or `wait4()`. `WIFSTOPPED` evaluates to true (1) when the process for which the `wait()` call was made is stopped, or to false (0) otherwise. `WIFSIGNALED` evaluates to true when the process was terminated with a signal. `WIFEXITED` evaluates to true when the process exited by using an `exit(2)` call.

RETURN VALUES

If `wait()` or `waitpid()` returns due to a stopped or terminated child process, the process ID of the child is returned to the calling process. Otherwise, a value of -1 is returned and `errno` is set to indicate the error.

If `wait()` or `waitpid()` return due to the delivery of a signal to the calling process, a value of -1 is returned and `errno` is set to `EINTR`. If `waitpid()` function was invoked with `WNOHANG` set in *options*, it has at least one child process specified by *pid* for which status is not available, and status is not available for any process specified by *pid*, a value of zero is returned. Otherwise, a value of -1 is returned, and `errno` is set to indicate the error.

`wait3()` and `wait4()` returns 0 if `WNOHANG` is specified and there are no stopped or exited children, and returns the process ID of the child process if it returns due to a stopped or terminated child process. Otherwise, they returns a value of -1 and sets `errno` to indicate the error.

ERRORS

`wait()`, `wait3()` or `wait4()` will fail and return immediately if one or more of the following are true:

<code>ECHILD</code>	The calling process has no existing unwaited-for child processes.
<code>EFAULT</code>	The <i>status</i> or <i>rusage</i> arguments point to an illegal address.

`waitpid()` may set `errno` to:

<code>ECHILD</code>	The process or process group specified by <i>pid</i> does not exist or is not a child of the calling process.
<code>EINTR</code>	The function was interrupted by a signal. The value of the location pointed to by <i>statusp</i> is undefined.

EINVAL The value of *options* is not valid.

`wait()`, and `wait3()`, and `wait4()` will terminate prematurely, return `-1`, and set `errno` to `EINTR` upon the arrival of a signal whose `SV_INTERRUPT` bit in its flags field is set (see `sigvec(3UCB)` and `siginterrupt(3UCB)`). `signal(3UCB)`, sets this bit for any signal it catches.

SEE ALSO `exit(2)`, `ptrace(2)`, `wait(2)`, `waitpid(2)`, `getrusage(3C)`, `siginterrupt(3UCB)`, `signal(3UCB)`, `sigvec(3UCB)`, `signal(3C)`

NOTES Use of these interfaces should be restricted to only applications written on BSD platforms. Use of these interfaces with any of the system libraries or in multi-thread applications is unsupported.

If a parent process terminates without waiting on its children, the initialization process (process ID = 1) inherits the children.

`wait()`, and `wait3()`, and `wait4()` are automatically restarted when a process receives a signal while awaiting termination of a child process, unless the `SV_INTERRUPT` bit is set in the flags for that signal.

Calls to `wait()` with an argument of 0 should be cast to type `'int *'`, as in:

```
wait((int *)0)
```

Previous SunOS releases used union `wait*statusp` and union `wait status` in place of `int *statusp` and `int status`. The union contained a member `w_status` that could be treated in the same way as `status`.

Other members of the `wait` union could be used to extract this information more conveniently:

- If the `w_stopval` member had the value `WSTOPPED`, the child process had stopped; the value of the `w_stopsig` member was the signal that stopped the process.
- If the `w_termsig` member was non-zero, the child process terminated due to a signal; the value of the `w_termsig` member was the number of the signal that terminated the process. If the `w_coredump` member was non-zero, a core dump was produced.
- Otherwise, the child process terminated due to a call to `exit()`. The value of the `w_retcode` member was the low-order 8 bits of the argument that the child process passed to `exit()`.

union `wait` is obsolete in light of the new specifications provided by *IEEE Std 1003.1-1988* and endorsed by *SVID89* and *XPG3*. SunOS Release 4.1 supports `unionwait` for backward compatibility, but it will disappear in a future release.

wait4(3C)

NAME	wait3, wait4 – wait for process to terminate or stop				
SYNOPSIS	<pre>#include <sys/wait.h> #include <sys/time.h> #include <sys/resource.h> pid_t wait3(int *statusp, int options, struct rusage *rusage); pid_t wait4(pid_t pid, int *statusp, int options, struct rusage *rusage);</pre>				
DESCRIPTION	<p>The <code>wait3()</code> function delays its caller until a signal is received or one of its child processes terminates or stops due to tracing. If any child process has died or stopped due to tracing and this has not already been reported, return is immediate, returning the process ID and status of one of those children. If that child process has died, it is discarded. If there are no children, <code>-1</code> is returned immediately. If there are only running or stopped but reported children, the calling process is blocked.</p> <p>If <code>statusp</code> is not a null pointer, then on return from a successful <code>wait3()</code> call, the status of the child process is stored in the integer pointed to by <code>statusp</code>. <code>*statusp</code> indicates the cause of termination and other information about the terminated process in the following manner:</p> <ul style="list-style-type: none">■ If the low-order 8 bits of <code>*statusp</code> are equal to <code>0177</code>, the child process has stopped; the 8 bits higher up from the low-order 8 bits of <code>*statusp</code> contain the number of the signal that caused the process to stop. See <code>signal(3HEAD)</code>.■ If the low-order 8 bits of <code>*statusp</code> are non-zero and are not equal to <code>0177</code>, the child process terminated due to a signal; the low-order 7 bits of <code>*statusp</code> contain the number of the signal that terminated the process. In addition, if the low-order seventh bit of <code>*statusp</code> (that is, bit <code>0200</code>) is set, a “core image” of the process was produced; see <code>signal(3HEAD)</code>.■ Otherwise, the child process terminated due to an <code>exit()</code> call; the 8 bits higher up from the low-order 8 bits of <code>*statusp</code> contain the low-order 8 bits of the argument that the child process passed to <code>exit()</code>; see <code>exit(2)</code>. <p>The <code>options</code> argument is constructed from the bitwise inclusive OR of zero or more of the following flags, defined in <code><sys/wait.h></code>:</p> <table><tr><td><code>WNOHANG</code></td><td>Execution of the calling process is not suspended if status is not immediately available for any child process.</td></tr><tr><td><code>WUNTRACED</code></td><td>The status of any child processes that are stopped, and whose status has not yet been reported since they stopped, are also reported to the requesting process.</td></tr></table> <p>If <code>rusage</code> is not a null pointer, a summary of the resources used by the terminated process and all its children is returned. Only the user time used and the system time used are currently available. They are returned in the <code>ru_utime</code> and <code>ru_stime</code>, members of the <code>rusage</code> structure, respectively.</p>	<code>WNOHANG</code>	Execution of the calling process is not suspended if status is not immediately available for any child process.	<code>WUNTRACED</code>	The status of any child processes that are stopped, and whose status has not yet been reported since they stopped, are also reported to the requesting process.
<code>WNOHANG</code>	Execution of the calling process is not suspended if status is not immediately available for any child process.				
<code>WUNTRACED</code>	The status of any child processes that are stopped, and whose status has not yet been reported since they stopped, are also reported to the requesting process.				

When the `WNOHANG` option is specified and no processes have status to report, `wait3()` returns 0. The `WNOHANG` and `WUNTRACED` options may be combined by the bitwise OR operation of the two values.

The `wait4()` function is an extended interface. With a `pid` argument of 0, it is equivalent to `wait3()`. If `pid` has a nonzero value, then `wait4()` returns status only for the indicated process ID, but not for any other child processes. The status can be evaluated using the macros defined by `wstat(3XFN)`.

RETURN VALUES

If `wait3()` or `wait4()` returns due to a stopped or terminated child process, the process ID of the child is returned to the calling process. Otherwise, `-1` is returned and `errno` is set to indicate the error.

If `wait3()` or `wait4()` return due to the delivery of a signal to the calling process, `-1` is returned and `errno` is set to `EINTR`. If `WNOHANG` was set in `options`, it has at least one child process specified by `pid` for which status is not available, and status is not available for any process specified by `pid`, 0 is returned. Otherwise, `-1` is returned and `errno` is set to indicate the error.

The `wait3()` and `wait4()` functions return 0 if `WNOHANG` is specified and there are no stopped or exited children, and return the process ID of the child process if they return due to a stopped or terminated child process. Otherwise, they return `-1` and set `errno` to indicate the error.

ERRORS

The `wait3()` and `wait4()` functions will fail and return immediately if:

<code>ECHILD</code>	The calling process has no existing unwaited-for child processes.
<code>EFAULT</code>	The <code>statusp</code> or <code>rusage</code> arguments point to an illegal address.
<code>EINTR</code>	The function was interrupted by a signal. The value of the location pointed to by <code>statusp</code> is undefined.
<code>EINVAL</code>	The value of <code>options</code> is not valid.

The `wait4()` function may fail if:

<code>ECHILD</code>	The process specified by <code>pid</code> does not exist or is not a child of the calling process.
---------------------	--

The `wait3()` and `wait4()` functions will terminate prematurely, return `-1`, and set `errno` to `EINTR` upon the arrival of a signal whose `SA_RESTART` bit in its flags field is not set (see `sigaction(2)`).

SEE ALSO

`kill(1)`, `exit(2)`, `wait(2)`, `waitid(2)`, `waitpid(2)`, `getrusage(3C)`, `signal(3C)`, `proc(4)`, `signal(3HEAD)`, `wstat(3XFN)`

NOTES

If a parent process terminates without waiting on its children, the initialization process (process ID = 1) inherits the children.

wait4(3C)

The `wait3()` and `wait4()` functions are automatically restarted when a process receives a signal while awaiting termination of a child process, unless the `SA_RESTART` bit is not set in the flags for that signal.

NAME	wait, wait3, wait4, waitpid, WIFSTOPPED, WIFSIGNALED, WIFEXITED – wait for process to terminate or stop
SYNOPSIS	<pre> /usr/ucb/cc [flag ...] file ... #include <sys/wait.h> int wait(statusp); int *statusp; int waitpid(pid, statusp, options); int pid; int *statusp; int options; #include <sys/time.h> #include <sys/resource.h> int wait3(statusp, options, rusage); int *statusp; int options; struct rusage *rusage; int wait4(pid, statusp, options, rusage); int pid; int *statusp; int options; struct rusage *rusage; WIFSTOPPED(status); int status; WIFSIGNALED(status); int status; WIFEXITED(status); int status; </pre>
DESCRIPTION	<p>wait() delays its caller until a signal is received or one of its child processes terminates or stops due to tracing. If any child process has died or stopped due to tracing and this has not been reported using wait(), return is immediate, returning the process ID and exit status of one of those children. If that child process has died, it is discarded. If there are no children, return is immediate with the value -1 returned. If there are only running or stopped but reported children, the calling process is blocked.</p> <p>If <i>status</i> is not a NULL pointer, then on return from a successful wait() call the status of the child process whose process ID is the return value of wait() is stored in the wait() union pointed to by <i>status</i>. The <i>w_status</i> member of that union is an <i>int</i>; it indicates the cause of termination and other information about the terminated process in the following manner:</p>

wait4(3UCB)

- If the low-order 8 bits of `w_status` are equal to 0177, the child process has stopped; the 8 bits higher up from the low-order 8 bits of `w_status` contain the number of the signal that caused the process to stop. See `ptrace(2)` and `sigvec(3UCB)`.
- If the low-order 8 bits of `w_status` are non-zero and are not equal to 0177, the child process terminated due to a signal; the low-order 7 bits of `w_status` contain the number of the signal that terminated the process. In addition, if the low-order seventh bit of `w_status` (that is, bit 0200) is set, a “core image” of the process was produced; see `sigvec(3UCB)`.
- Otherwise, the child process terminated due to an `exit()` call; the 8 bits higher up from the low-order 8 bits of `w_status` contain the low-order 8 bits of the argument that the child process passed to `exit()`; see `exit(2)`.

`waitpid()` behaves identically to `wait()` if `pid` has a value of `-1` and `options` has a value of zero. Otherwise, the behavior of `waitpid()` is modified by the values of `pid` and `options` as follows:

`pid` specifies a set of child processes for which status is requested. `waitpid()` only returns the status of a child process from this set.

- If `pid` is equal to `-1`, status is requested for any child process. In this respect, `waitpid()` is then equivalent to `wait()`.
- If `pid` is greater than zero, it specifies the process ID of a single child process for which status is requested.
- If `pid` is equal to zero, status is requested for any child process whose process group ID is equal to that of the calling process.
- If `pid` is less than `-1`, status is requested for any child process whose process group ID is equal to the absolute value of `pid`.

`options` is constructed from the bitwise inclusive OR of zero or more of the following flags, defined in the header `<sys/wait.h>`:

<code>WNOHANG</code>	<code>waitpid()</code> does not suspend execution of the calling process if status is not immediately available for one of the child processes specified by <code>pid</code> .
<code>WUNTRACED</code>	The status of any child processes specified by <code>pid</code> that are stopped, and whose status has not yet been reported since they stopped, are also reported to the requesting process.

`wait3()` is an alternate interface that allows both non-blocking status collection and the collection of the status of children stopped by any means. The `status` parameter is defined as above. The `options` parameter is used to indicate the call should not block if there are no processes that have status to report (`WNOHANG`), and/or that children of the current process that are stopped due to a `SIGTTIN`, `SIGTTOU`, `SIGTSTP`, or `SIGSTOP` signal are eligible to have their status reported as well (`WUNTRACED`). A terminated child is discarded after it reports status, and a stopped process will not

report its status more than once. If *rusage* is not a `NULL` pointer, a summary of the resources used by the terminated process and all its children is returned. Only the user time used and the system time used are currently available. They are returned in `rusage.ru_utime` and `rusage.ru_stime`, respectively.

When the `WNOHANG` option is specified and no processes have status to report, `wait3()` returns 0. The `WNOHANG` and `WUNTRACED` options may be combined by ORing the two values.

`wait4()` is another alternate interface. With a *pid* argument of 0, it is equivalent to `wait3()`. If *pid* has a nonzero value, then `wait4()` returns status only for the indicated process ID, but not for any other child processes.

`WIFSTOPPED`, `WIFSIGNALED`, `WIFEXITED`, are macros that take an argument *status*, of type `int`, as returned by `wait()`, or `wait3()`, or `wait4()`. `WIFSTOPPED` evaluates to true (1) when the process for which the `wait()` call was made is stopped, or to false (0) otherwise. `WIFSIGNALED` evaluates to true when the process was terminated with a signal. `WIFEXITED` evaluates to true when the process exited by using an `exit(2)` call.

RETURN VALUES

If `wait()` or `waitpid()` returns due to a stopped or terminated child process, the process ID of the child is returned to the calling process. Otherwise, a value of `-1` is returned and `errno` is set to indicate the error.

If `wait()` or `waitpid()` return due to the delivery of a signal to the calling process, a value of `-1` is returned and `errno` is set to `EINTR`. If `waitpid()` function was invoked with `WNOHANG` set in *options*, it has at least one child process specified by *pid* for which status is not available, and status is not available for any process specified by *pid*, a value of zero is returned. Otherwise, a value of `-1` is returned, and `errno` is set to indicate the error.

`wait3()` and `wait4()` returns 0 if `WNOHANG` is specified and there are no stopped or exited children, and returns the process ID of the child process if it returns due to a stopped or terminated child process. Otherwise, they returns a value of `-1` and sets `errno` to indicate the error.

ERRORS

`wait()`, `wait3()` or `wait4()` will fail and return immediately if one or more of the following are true:

- | | |
|---------------------|---|
| <code>ECHILD</code> | The calling process has no existing unwaited-for child processes. |
| <code>EFAULT</code> | The <i>status</i> or <i>rusage</i> arguments point to an illegal address. |

`waitpid()` may set `errno` to:

- | | |
|---------------------|--|
| <code>ECHILD</code> | The process or process group specified by <i>pid</i> does not exist or is not a child of the calling process. |
| <code>EINTR</code> | The function was interrupted by a signal. The value of the location pointed to by <i>statusp</i> is undefined. |

wait4(3UCB)

EINVAL The value of *options* is not valid.

`wait()`, and `wait3()`, and `wait4()` will terminate prematurely, return `-1`, and set `errno` to `EINTR` upon the arrival of a signal whose `SV_INTERRUPT` bit in its flags field is set (see `sigvec(3UCB)` and `siginterrupt(3UCB)`). `signal(3UCB)`, sets this bit for any signal it catches.

SEE ALSO `exit(2)`, `ptrace(2)`, `wait(2)`, `waitpid(2)`, `getrusage(3C)`, `siginterrupt(3UCB)`, `signal(3UCB)`, `sigvec(3UCB)`, `signal(3C)`

NOTES Use of these interfaces should be restricted to only applications written on BSD platforms. Use of these interfaces with any of the system libraries or in multi-thread applications is unsupported.

If a parent process terminates without waiting on its children, the initialization process (process ID = 1) inherits the children.

`wait()`, and `wait3()`, and `wait4()` are automatically restarted when a process receives a signal while awaiting termination of a child process, unless the `SV_INTERRUPT` bit is set in the flags for that signal.

Calls to `wait()` with an argument of 0 should be cast to type `'int *'`, as in:

```
wait((int *)0)
```

Previous SunOS releases used union `wait*statusp` and union `wait status` in place of `int *statusp` and `int status`. The union contained a member `w_status` that could be treated in the same way as `status`.

Other members of the `wait` union could be used to extract this information more conveniently:

- If the `w_stopval` member had the value `WSTOPPED`, the child process had stopped; the value of the `w_stopsig` member was the signal that stopped the process.
- If the `w_termsig` member was non-zero, the child process terminated due to a signal; the value of the `w_termsig` member was the number of the signal that terminated the process. If the `w_coredump` member was non-zero, a core dump was produced.
- Otherwise, the child process terminated due to a call to `exit()`. The value of the `w_retcode` member was the low-order 8 bits of the argument that the child process passed to `exit()`.

union `wait` is obsolete in light of the new specifications provided by *IEEE Std 1003.1-1988* and endorsed by *SVID89* and *XPG3*. SunOS Release 4.1 supports `unionwait` for backward compatibility, but it will disappear in a future release.

NAME	wait, wait3, wait4, waitpid, WIFSTOPPED, WIFSIGNALED, WIFEXITED – wait for process to terminate or stop
SYNOPSIS	<pre> /usr/ucb/cc [flag ...] file ... #include <sys/wait.h> int wait(statusp); int *statusp; int waitpid(pid, statusp, options); int pid; int *statusp; int options; #include <sys/time.h> #include <sys/resource.h> int wait3(statusp, options, rusage); int *statusp; int options; struct rusage *rusage; int wait4(pid, statusp, options, rusage); int pid; int *statusp; int options; struct rusage *rusage; WIFSTOPPED(status); int status; WIFSIGNALED(status); int status; WIFEXITED(status); int status; </pre>
DESCRIPTION	<p>wait() delays its caller until a signal is received or one of its child processes terminates or stops due to tracing. If any child process has died or stopped due to tracing and this has not been reported using wait(), return is immediate, returning the process ID and exit status of one of those children. If that child process has died, it is discarded. If there are no children, return is immediate with the value -1 returned. If there are only running or stopped but reported children, the calling process is blocked.</p> <p>If <i>status</i> is not a NULL pointer, then on return from a successful wait() call the status of the child process whose process ID is the return value of wait() is stored in the wait() union pointed to by <i>status</i>. The <i>w_status</i> member of that union is an <i>int</i>; it indicates the cause of termination and other information about the terminated process in the following manner:</p>

waitpid(3UCB)

- If the low-order 8 bits of `w_status` are equal to 0177, the child process has stopped; the 8 bits higher up from the low-order 8 bits of `w_status` contain the number of the signal that caused the process to stop. See `ptrace(2)` and `sigvec(3UCB)`.
- If the low-order 8 bits of `w_status` are non-zero and are not equal to 0177, the child process terminated due to a signal; the low-order 7 bits of `w_status` contain the number of the signal that terminated the process. In addition, if the low-order seventh bit of `w_status` (that is, bit 0200) is set, a “core image” of the process was produced; see `sigvec(3UCB)`.
- Otherwise, the child process terminated due to an `exit()` call; the 8 bits higher up from the low-order 8 bits of `w_status` contain the low-order 8 bits of the argument that the child process passed to `exit()`; see `exit(2)`.

`waitpid()` behaves identically to `wait()` if `pid` has a value of `-1` and `options` has a value of zero. Otherwise, the behavior of `waitpid()` is modified by the values of `pid` and `options` as follows:

`pid` specifies a set of child processes for which status is requested. `waitpid()` only returns the status of a child process from this set.

- If `pid` is equal to `-1`, status is requested for any child process. In this respect, `waitpid()` is then equivalent to `wait()`.
- If `pid` is greater than zero, it specifies the process ID of a single child process for which status is requested.
- If `pid` is equal to zero, status is requested for any child process whose process group ID is equal to that of the calling process.
- If `pid` is less than `-1`, status is requested for any child process whose process group ID is equal to the absolute value of `pid`.

`options` is constructed from the bitwise inclusive OR of zero or more of the following flags, defined in the header `<sys/wait.h>`:

WNOHANG	<code>waitpid()</code> does not suspend execution of the calling process if status is not immediately available for one of the child processes specified by <code>pid</code> .
WUNTRACED	The status of any child processes specified by <code>pid</code> that are stopped, and whose status has not yet been reported since they stopped, are also reported to the requesting process.

`wait3()` is an alternate interface that allows both non-blocking status collection and the collection of the status of children stopped by any means. The `status` parameter is defined as above. The `options` parameter is used to indicate the call should not block if there are no processes that have status to report (`WNOHANG`), and/or that children of the current process that are stopped due to a `SIGTTIN`, `SIGTTOU`, `SIGTSTP`, or `SIGSTOP` signal are eligible to have their status reported as well (`WUNTRACED`). A terminated child is discarded after it reports status, and a stopped process will not

report its status more than once. If *rusage* is not a `NULL` pointer, a summary of the resources used by the terminated process and all its children is returned. Only the user time used and the system time used are currently available. They are returned in `rusage.ru_utime` and `rusage.ru_stime`, respectively.

When the `WNOHANG` option is specified and no processes have status to report, `wait3()` returns 0. The `WNOHANG` and `WUNTRACED` options may be combined by ORing the two values.

`wait4()` is another alternate interface. With a *pid* argument of 0, it is equivalent to `wait3()`. If *pid* has a nonzero value, then `wait4()` returns status only for the indicated process ID, but not for any other child processes.

`WIFSTOPPED`, `WIFSIGNALED`, `WIFEXITED`, are macros that take an argument *status*, of type `int`, as returned by `wait()`, or `wait3()`, or `wait4()`. `WIFSTOPPED` evaluates to true (1) when the process for which the `wait()` call was made is stopped, or to false (0) otherwise. `WIFSIGNALED` evaluates to true when the process was terminated with a signal. `WIFEXITED` evaluates to true when the process exited by using an `exit(2)` call.

RETURN VALUES

If `wait()` or `waitpid()` returns due to a stopped or terminated child process, the process ID of the child is returned to the calling process. Otherwise, a value of `-1` is returned and `errno` is set to indicate the error.

If `wait()` or `waitpid()` return due to the delivery of a signal to the calling process, a value of `-1` is returned and `errno` is set to `EINTR`. If `waitpid()` function was invoked with `WNOHANG` set in *options*, it has at least one child process specified by *pid* for which status is not available, and status is not available for any process specified by *pid*, a value of zero is returned. Otherwise, a value of `-1` is returned, and `errno` is set to indicate the error.

`wait3()` and `wait4()` returns 0 if `WNOHANG` is specified and there are no stopped or exited children, and returns the process ID of the child process if it returns due to a stopped or terminated child process. Otherwise, they returns a value of `-1` and sets `errno` to indicate the error.

ERRORS

`wait()`, `wait3()` or `wait4()` will fail and return immediately if one or more of the following are true:

- | | |
|---------------------|---|
| <code>ECHILD</code> | The calling process has no existing unwaited-for child processes. |
| <code>EFAULT</code> | The <i>status</i> or <i>rusage</i> arguments point to an illegal address. |

`waitpid()` may set `errno` to:

- | | |
|---------------------|--|
| <code>ECHILD</code> | The process or process group specified by <i>pid</i> does not exist or is not a child of the calling process. |
| <code>EINTR</code> | The function was interrupted by a signal. The value of the location pointed to by <i>statusp</i> is undefined. |

waitpid(3UCB)

EINVAL The value of *options* is not valid.

`wait()`, and `wait3()`, and `wait4()` will terminate prematurely, return `-1`, and set `errno` to `EINTR` upon the arrival of a signal whose `SV_INTERRUPT` bit in its flags field is set (see `sigvec(3UCB)` and `siginterrupt(3UCB)`). `signal(3UCB)`, sets this bit for any signal it catches.

SEE ALSO `exit(2)`, `ptrace(2)`, `wait(2)`, `waitpid(2)`, `getrusage(3C)`, `siginterrupt(3UCB)`, `signal(3UCB)`, `sigvec(3UCB)`, `signal(3C)`

NOTES Use of these interfaces should be restricted to only applications written on BSD platforms. Use of these interfaces with any of the system libraries or in multi-thread applications is unsupported.

If a parent process terminates without waiting on its children, the initialization process (process ID = 1) inherits the children.

`wait()`, and `wait3()`, and `wait4()` are automatically restarted when a process receives a signal while awaiting termination of a child process, unless the `SV_INTERRUPT` bit is set in the flags for that signal.

Calls to `wait()` with an argument of 0 should be cast to type `'int *'`, as in:

```
wait((int *)0)
```

Previous SunOS releases used union `wait*statusp` and union `wait status` in place of `int *statusp` and `int status`. The union contained a member `w_status` that could be treated in the same way as `status`.

Other members of the `wait` union could be used to extract this information more conveniently:

- If the `w_stopval` member had the value `WSTOPPED`, the child process had stopped; the value of the `w_stopsig` member was the signal that stopped the process.
- If the `w_termsig` member was non-zero, the child process terminated due to a signal; the value of the `w_termsig` member was the number of the signal that terminated the process. If the `w_coredump` member was non-zero, a core dump was produced.
- Otherwise, the child process terminated due to a call to `exit()`. The value of the `w_retcode` member was the low-order 8 bits of the argument that the child process passed to `exit()`.

union `wait` is obsolete in light of the new specifications provided by *IEEE Std 1003.1-1988* and endorsed by *SVID89* and *XPG3*. SunOS Release 4.1 supports `unionwait` for backward compatibility, but it will disappear in a future release.

NAME	walkcontext, printstack – walk stack pointed to by ucontext
SYNOPSIS	<pre>#include <ucontext.h> int walkcontext(const ucontext_t *uptr, int (*operate_func)(uintptr_t, int, void *), void *usrarg); int printstack(int fd);</pre>
DESCRIPTION	<p>The <code>walkcontext()</code> function walks the call stack pointed to by <code>uptr</code>, which can be obtained by a call to <code>getcontext(2)</code> or from a signal handler installed with the <code>SA_SIGINFO</code> flag. The <code>walkcontext()</code> function calls the user-supplied function <code>operate_func</code> for each routine found on the call stack and each signal handler invoked. The user function is passed three arguments: the PC at which the call or signal occurred, the signal number that occurred at this PC (0 if no signal occurred), and the third argument passed to <code>walkcontext()</code>. If the user function returns a non-zero value, <code>walkcontext()</code> returns without completing the callstack walk.</p> <p>The <code>printstack()</code> function uses <code>walkcontext()</code> to print a symbolic stack trace to the specified file descriptor. This is useful for reporting errors from signal handlers. The <code>printstack()</code> function uses <code>dladdr1()</code> (see <code>dladdr(3DL)</code>) to obtain symbolic symbol names. As a result, only global symbols are reported as symbol names by <code>printstack()</code>.</p>
RETURN VALUES	Upon successful completion, <code>walkstack()</code> and <code>printstack()</code> return 0. If <code>walkstack()</code> cannot read the stack or the stack trace appears corrupted, both functions return -1.
ERRORS	No error values are defined.
USAGE	<p>The <code>walkcontext()</code> function is typically used to obtain information about the call stack for error reporting, performance analysis, or diagnostic purposes. Many library functions are not Async-Signal-Safe and should not be used from a signal handler. If <code>walkcontext()</code> is to be called from a signal handler, careful programming is required. In particular, <code>stdio(3C)</code> and <code>malloc(3C)</code> cannot be used.</p> <p>The <code>printstack()</code> function is Async-Signal-Safe and can be called from a signal handler. The output format from <code>printstack()</code> is unstable, as it varies with the scope of the routines.</p> <p>Tail-call optimizations on SPARC eliminate stack frames that would otherwise be present. For example, if the code is of the form</p> <pre>#include <stdio.h> main() { bar(); exit(0); } bar()</pre>

walkcontext(3C)

```
{
    int a;
    a = foo(fileno(stdout));
    return (a);
}

foo(int file)
{
    printstack(file);
}
```

compiling without optimization will yield a stack trace of the form

```
/tmp/q:foo+0x8
/tmp/q:bar+0x14
/tmp/q:main+0x4
/tmp/q:_start+0xb8
```

whereas with higher levels of optimization the output is

```
/tmp/q:main+0x10
/tmp/q:_start+0xb8
```

since both the call to `foo()` in `main` and the call to `bar()` in `foo()` are handled as tail calls that perform a return or restore in the delay slot. For further information, see *The SPARC Architecture Manual*.

NAME	watchmalloc, cfree, memalign, valloc – debugging memory allocator
SYNOPSIS	<pre>#include <stdlib.h> void *malloc(size_t size); void free(void *ptr); void *realloc(void *ptr, size_t size); void *memalign(size_t alignment, size_t size); void *valloc(size_t size); void *calloc(size_t nelem, size_t elsize); void cfree(void *ptr, size_t nelem, size_t elsize); #include <malloc.h> int mallopt(int cmd, int value); struct mallinfo mallinfo(void);</pre>
DESCRIPTION	<p>The collection of <code>malloc()</code> functions in this shared object are an optional replacement for the standard versions of the same functions in the system C library. See <code>malloc(3C)</code>. They provide a more strict interface than the standard versions and enable enforcement of the interface through the watchpoint facility of <code>/proc</code>. See <code>proc(4)</code>.</p> <p>Any dynamically linked application can be run with these functions in place of the standard functions if the following string is present in the environment (see <code>ld.so.1(1)</code>):</p> <pre>LD_PRELOAD=watchmalloc.so.1</pre> <p>The individual function interfaces are identical to the standard ones as described in <code>malloc(3C)</code>. However, laxities provided in the standard versions are not permitted when the watchpoint facility is enabled (see <code>WATCHPOINTS</code> below):</p> <ul style="list-style-type: none"> ■ Memory may not be freed more than once. ■ A pointer to freed memory may not be used in a call to <code>realloc()</code>. ■ A call to <code>malloc()</code> immediately following a call to <code>free()</code> will not return the same space. ■ Any reference to memory that has been freed yields undefined results. <p>To enforce these restrictions partially, without great loss in speed as compared to the watchpoint facility described below, a freed block of memory is overwritten with the pattern <code>0xdeadbeef</code> before returning from <code>free()</code>. The <code>malloc()</code> function returns with the allocated memory filled with the pattern <code>0xbaddcafe</code> as a precaution against applications incorrectly expecting to receive back unmodified memory from the last <code>free()</code>. The <code>calloc()</code> function always returns with the memory zero-filled.</p>

watchmalloc(3MALLOC)

Entry points for `mallopt()` and `mallinfo()` are provided as empty routines, and are present only because some `malloc()` implementations provide them.

WATCHPOINTS

The watchpoint facility of `/proc` can be applied by a process to itself. The functions in `watchmalloc.so.1` use this feature if the following string is present in the environment:

```
MALLOC_DEBUG=WATCH
```

This causes every block of freed memory to be covered with `WA_WRITE` watched areas. If the application attempts to write any part of freed memory, it will trigger a watchpoint trap, resulting in a `SIGTRAP` signal, which normally produces an application core dump.

A header is maintained before each block of allocated memory. Each header is covered with a watched area, thereby providing a red zone before and after each block of allocated memory (the header for the subsequent memory block serves as the trailing red zone for its preceding memory block). Writing just before or just after a memory block returned by `malloc()` will trigger a watchpoint trap.

Watchpoints incur a large performance penalty. Requesting `MALLOC_DEBUG=WATCH` can cause the application to run 10 to 100 times slower, depending on the use made of allocated memory.

Further options are enabled by specifying a comma-separated string of options:

```
MALLOC_DEBUG=WATCH,RW,STOP
```

WATCH	Enables <code>WA_WRITE</code> watched areas as described above.
RW	Enables both <code>WA_READ</code> and <code>WA_WRITE</code> watched areas. An attempt either to read or write freed memory or the red zones will trigger a watchpoint trap. This incurs even more overhead and can cause the application to run up to 1000 times slower.
STOP	The process will stop showing a <code>FLTWATCH</code> machine fault if it triggers a watchpoint trap, rather than dumping core with a <code>SIGTRAP</code> signal. This allows a debugger to be attached to the live process at the point where it underwent the watchpoint trap. Also, the various <code>/proc</code> tools described in <code>proc(1)</code> can be used to examine the stopped process.

One of `WATCH` or `RW` must be specified, else the watchpoint facility is not engaged. `RW` overrides `WATCH`. Unrecognized options are silently ignored.

watchmalloc(3MALLOC)

LIMITATIONS Sizes of memory blocks allocated by `malloc()` are rounded up to the the worst-case alignment size, 8 bytes for 32-bit processes and 16 bytes for 64-bit processes. Accessing the extra space allocated for a memory block is technically a memory violation but is in fact innocuous. Such accesses are not detected by the watchpoint facility of `watchmalloc`.

Interposition of `watchmalloc.so.1` fails innocuously if the target application is statically linked with respect to its `malloc()` functions.

watof(3C)

NAME	<code>wcstod</code> , <code>wstod</code> , <code>watof</code> – convert wide character string to double-precision number
SYNOPSIS	<pre>#include <wchar.h> double wcstod(const wchar_t *nptr, wchar_t **endptr); double wstod(const wchar_t *nptr, wchar_t **endptr); double watof(wchar_t *nptr);</pre>
DESCRIPTION	<p>The <code>wcstod()</code> and <code>wstod()</code> functions convert the initial portion of the wide character string pointed to by <code>nptr</code> to double representation. They first decompose the input wide character string into three parts: an initial, possibly empty, sequence of white-space wide character codes (as specified by <code>iswspace(3C)</code>); a subject sequence interpreted as a floating-point constant; and a final wide-character string of one or more unrecognised wide-character codes, including the terminating null wide character code of the input wide character string. They then attempt to convert the subject sequence to a floating-point number, and return the result.</p> <p>The expected form of the subject sequence is an optional '+' or '-' sign, then a non-empty sequence of digits optionally containing a radix, then an optional exponent part. An exponent part consists of 'e' or 'E', followed by an optional sign, followed by one or more decimal digits. The subject sequence is defined as the longest initial subsequence of the input wide character string, starting with the first non-white-space wide-character code, that is of the expected form. The subject sequence contains no wide-character codes if the input wide character string is empty or consists entirely of white-space wide-character codes, or if the first wide-character code that is not white space other than a sign, a digit or a radix.</p> <p>If the subject sequence has the expected form, the sequence of wide-character codes starting with the first digit or the radix (whichever occurs first) is interpreted as a floating constant as defined in the C language, except that the radix is used in place of a period, and that if neither an exponent part nor a radix appears, a radix is assumed to follow the last digit in the wide character string. If the subject sequence begins with a minus sign (-), the value resulting from the conversion is negated. A pointer to the final wide character string is stored in the object pointed to by <code>endptr</code>, provided that <code>endptr</code> is not a null pointer.</p> <p>The radix is defined in the program's locale (category <code>LC_NUMERIC</code>). In the POSIX locale, or in a locale where the radix is not defined, the radix defaults to a period (.).</p> <p>In other than the POSIX locale, other implementation-dependent subject sequence forms may be accepted.</p> <p>If the subject sequence is empty or does not have the expected form, no conversion is performed; the value of <code>nptr</code> is stored in the object pointed to by <code>endptr</code>, provided that <code>endptr</code> is not a null pointer.</p> <p>The <code>watof(str)</code> function is equivalent to <code>wstod(str, (wchar_t **)NULL)</code>.</p>

RETURN VALUES

The `wcstod()` and `wstod()` functions return the converted value, if any. If no conversion could be performed, 0 is returned and `errno` may be set to `EINVAL`.

If the correct value is outside the range of representable values, `±HUGE_VAL` is returned (according to the sign of the value), and `errno` is set to `ERANGE`.

If the correct value would cause underflow, 0 is returned, and `errno` is set to `ERANGE`.

ERRORS

The `wcstod()` and `wstod()` functions will fail if:

`ERANGE` The value to be returned would cause overflow or underflow.

The `wcstod()` and `wcstod()` functions may fail if:

`EINVAL` No conversion could be performed.

USAGE

Because 0 is returned on error and is also a valid return on success, an application wishing to check for error situations should set `errno` to 0 call `wcstod()` or `wstod()`, then check `errno` and if it is non-zero, assume an error has occurred.

ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE

watoi(3C)

NAME	<code>wcstol</code> , <code>wstol</code> , <code>watol</code> , <code>watoll</code> , <code>watoi</code> – convert wide character string to long integer
SYNOPSIS	<pre>#include <wchar.h> long int wcstol(const wchar_t *nptr, wchar_t **endptr, int base); #include <wdec.h> long int wstol(const wchar_t *nptr, wchar_t **endptr, int base); long watol(wchar_t *nptr); long long watoll(wchar_t *nptr); int watoi(wchar_t *nptr);</pre>
DESCRIPTION	<p>The <code>wcstol()</code> and <code>wstol()</code> functions convert the initial portion of the wide character string pointed to by <code>nptr</code> to <code>long int</code> representation. They first decompose the input wide character string into three parts: an initial, possibly empty, sequence of white-space wide-character codes (as specified by <code>iswspace(3C)</code>), a subject sequence interpreted as an integer represented in some radix determined by the value of <code>base</code>; and a final wide character string of one or more unrecognised wide character codes, including the terminating null wide-character code of the input wide character string. They then attempt to convert the subject sequence to an integer, and return the result.</p> <p>If the value of <code>base</code> is 0, the expected form of the subject sequence is that of a decimal constant, octal constant or hexadecimal constant, any of which may be preceded by a '+' or '-' sign. A decimal constant begins with a non-zero digit, and consists of a sequence of decimal digits. An octal constant consists of the prefix '0' optionally followed by a sequence of the digits '0' to '7' only. A hexadecimal constant consists of the prefix '0x' or '0X' followed by a sequence of the decimal digits and letters 'a' (or 'A') to 'f' (or 'F') with values 10 to 15 respectively.</p> <p>If the value of <code>base</code> is between 2 and 36, the expected form of the subject sequence is a sequence of letters and digits representing an integer with the radix specified by <code>base</code>, optionally preceded by a '+' or '-' sign, but not including an integer suffix. The letters from 'a' (or 'A') to 'z' (or 'Z') inclusive are ascribed the values 10 to 35; only letters whose ascribed values are less than that of <code>base</code> are permitted. If the value of <code>base</code> is 16, the wide-character code representations of '0x' or '0X' may optionally precede the sequence of letters and digits, following the sign if present.</p> <p>The subject sequence is defined as the longest initial subsequence of the input wide character string, starting with the first non-white-space wide-character code, that is of the expected form. The subject sequence contains no wide-character codes if the input wide character string is empty or consists entirely of white-space wide-character code, or if the first non-white-space wide-character code is other than a sign or a permissible letter or digit.</p> <p>If the subject sequence has the expected form and the value of <code>base</code> is 0, the sequence of wide-character codes starting with the first digit is interpreted as an integer constant. If the subject sequence has the expected form and the value of <code>base</code> is between 2 and 36, it is used as the base for conversion, ascribing to each letter its</p>

value as given above. If the subject sequence begins with a minus sign (-), the value resulting from the conversion is negated. A pointer to the final wide character string is stored in the object pointed to by *endptr*, provided that *endptr* is not a null pointer.

In other than the POSIX locale, additional implementation-dependent subject sequence forms may be accepted.

If the subject sequence is empty or does not have the expected form, no conversion is performed; the value of *nptr* is stored in the object pointed to by *endptr*, provided that *endptr* is not a null pointer.

The `watol()` function is equivalent to `wstol(str, (wchar_t **)NULL, 10)`.

The `watoll()` function is the long-long (double long) version of `watol()`.

The `watoi()` function is equivalent to `(int)watol()`.

RETURN VALUES Upon successful completion, `wcstol()` and `wstol()` return the converted value, if any. If no conversion could be performed, 0 is returned, and `errno` may be set to indicate the error. If the correct value is outside the range of representable values, `{LONG_MAX}` or `{LONG_MIN}` is returned (according to the sign of the value), and `errno` is set to `ERANGE`.

ERRORS The `wcstol()` and `wstol()` functions will fail if:

`EINVAL` The value of *base* is not supported.

`ERANGE` The value to be returned is not representable.

The `wcstol()` and `wstol()` functions may fail if:

`EINVAL` No conversion could be performed.

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
MT-Level	MT-Safe

SEE ALSO `iswalph(3C)`, `iswspace(3C)`, `scanf(3C)`, `wcstod(3C)`, `attributes(5)`

NOTES Because 0, `{LONG_MIN}`, and `{LONG_MAX}` are returned on error and are also valid returns on success, an application wishing to check for error situations should set `errno` to 0, call `wcstol()` or `wstol()`, then check `errno` and if it is non-zero assume an error has occurred.

Truncation from long long to long can take place upon assignment or by an explicit cast.

watol(3C)

NAME	<code>wcstol</code> , <code>wstol</code> , <code>watol</code> , <code>watoll</code> , <code>watoi</code> – convert wide character string to long integer
SYNOPSIS	<pre>#include <wchar.h> long int wcstol(const wchar_t *nptr, wchar_t **endptr, int base); #include <wdec.h> long int wstol(const wchar_t *nptr, wchar_t **endptr, int base); long watol(wchar_t *nptr); long long watoll(wchar_t *nptr); int watoi(wchar_t *nptr);</pre>
DESCRIPTION	<p>The <code>wcstol()</code> and <code>wstol()</code> functions convert the initial portion of the wide character string pointed to by <code>nptr</code> to <code>long int</code> representation. NOTES

Because 0, `{LONG_MIN}`, and `{LONG_MAX}` are returned on error and are also valid returns on success, an application wishing to check for error situations should set `errno` to 0, call `wcstol()` or `wstol()`, then check `errno` and if it is non-zero assume an error has occurred.

Truncation from long long to long can take place upon assignment or by an explicit cast.

wcrtomb(3C)

NAME	wcrtomb – convert a wide-character code to a character (restartable)				
SYNOPSIS	<pre>#include <stdio.h> size_t wcrtomb(char *s, wchar_t wc, mbstate_t *ps);</pre>				
DESCRIPTION	<p>If <i>s</i> is a null pointer, the <code>wcrtomb()</code> function is equivalent to the call:</p> <pre>wcrtomb(buf, L'\0', ps)</pre> where <i>buf</i> is an internal buffer. <p>If <i>s</i> is not a null pointer, the <code>wcrtomb()</code> function determines the number of bytes needed to represent the character that corresponds to the wide-character given by <i>wc</i> (including any shift sequences), and stores the resulting bytes in the array whose first element is pointed to by <i>s</i>. At most <code>MB_CUR_MAX</code> bytes are stored. If <i>wc</i> is a null wide-character, a null byte is stored, preceded by any shift sequence needed to restore the initial shift state. The resulting state described is the initial conversion state.</p> <p>If <i>ps</i> is a null pointer, the <code>wcrtomb()</code> function uses its own internal <code>mbstate_t</code> object, which is initialized at program startup to the initial conversion state. Otherwise, the <code>mbstate_t</code> object pointed to by <i>ps</i> is used to completely describe the current conversion state of the associated character sequence. Solaris will behave as if no function defined in the Solaris Reference Manual calls <code>wcrtomb()</code>.</p> <p>The behavior of this function is affected by the <code>LC_CTYPE</code> category of the current locale. See <code>environ(5)</code>.</p>				
RETURN VALUES	The <code>wcrtomb()</code> function returns the number of bytes stored in the array object (including any shift sequences). When <i>wc</i> is not a valid wide-character, an encoding error occurs. In this case, the function stores the value of the macros <code>EILSEQ</code> in <code>errno</code> and returns <code>(size_t)-1</code> ; the conversion state is undefined.				
ERRORS	The <code>wcrtomb()</code> function may fail if:				
	<table><tr><td><code>EINVAL</code></td><td>The <i>ps</i> argument points to an object that contains an invalid conversion state.</td></tr><tr><td><code>EILSEQ</code></td><td>Invalid wide-character code is detected.</td></tr></table>	<code>EINVAL</code>	The <i>ps</i> argument points to an object that contains an invalid conversion state.	<code>EILSEQ</code>	Invalid wide-character code is detected.
<code>EINVAL</code>	The <i>ps</i> argument points to an object that contains an invalid conversion state.				
<code>EILSEQ</code>	Invalid wide-character code is detected.				
USAGE	If <i>ps</i> is not a null pointer, <code>wcrtomb()</code> uses the <code>mbstate_t</code> object pointed to by <i>ps</i> and the function can be used safely in multithreaded applications, as long as <code>setlocale(3C)</code> is not being called to change the locale. If <i>ps</i> is a null pointer, <code>wcrtomb()</code> uses its internal <code>mbstate_t</code> object and the function is Unsafe in multithreaded applications.

NAME	wcstring, wcscat, wscat, wcsncat, wsncat, wscmp, wscmp, wcsncmp, wsncmp, wcsncpy, wscpy, wcsncpy, wsncpy, wcslen, wslen, wcschr, wschr, wcsrchr, wsrchr, windex, wrindex, wcpbrk, wspbrk, wcsvcs, wcsspn, wssp, wcscspn, wscspn, wstok, wstok – wide-character string operations
SYNOPSIS	<pre>#include <wchar.h> wchar_t *wcscat(wchar_t *ws1, const wchar_t *ws2); wchar_t *wcsncat(wchar_t *ws1, const wchar_t *ws2, size_t n); int wscmp(const wchar_t *ws1, const wchar_t *ws2); int wcsncmp(const wchar_t *ws1, const wchar_t *ws2, size_t n); wchar_t *wscpy(wchar_t *ws1, const wchar_t *ws2); wchar_t *wcsncpy(wchar_t *ws1, const wchar_t *ws2, size_t n); size_t wcslen(const wchar_t *ws); wchar_t *wcschr(const wchar_t *ws, wchar_t wc); wchar_t *wcsrchr(const wchar_t *ws, wchar_t wc); wchar_t *wcpbrk(const wchar_t *ws1, const wchar_t *ws2); wchar_t *wcsvcs(const wchar_t *ws1, const wchar_t *ws2); size_t wcsspn(const wchar_t *ws1, const wchar_t *ws2); size_t wcscspn(const wchar_t *ws1, const wchar_t *ws2); wchar_t *wstok(wchar_t *ws1, const wchar_t *ws2); wchar_t *wstok(wchar_t *ws1, const wchar_t *ws2, wchar_t **ptr); #include <widec.h> wchar_t *wscat(wchar_t *ws1, const wchar_t *ws2); wchar_t *wsncat(wchar_t *ws1, const wchar_t *ws2, size_t n); int wscmp(const wchar_t *ws1, const wchar_t *ws2); int wsncmp(const wchar_t *ws1, const wchar_t *ws2, size_t n); wchar_t *wscpy(wchar_t *ws1, const wchar_t *ws2); wchar_t *wsncpy(wchar_t *ws1, const wchar_t *ws2, size_t n); size_t wslen(const wchar_t *ws); wchar_t *wschr(const wchar_t *ws, wchar_t wc); wchar_t *wsrchr(const wchar_t *ws, wchar_t wc); wchar_t *wspbrk(const wchar_t *ws1, const wchar_t *ws2); size_t wssp(const wchar_t *ws1, const wchar_t *ws2);</pre>
XPG4 and SUS	
Default and other standards	

	<pre> size_t wcspn(const wchar_t *ws1, const wchar_t *ws2); wchar_t *wstok(wchar_t *ws1, const wchar_t *ws2); wchar_t *windex(const wchar_t *ws, wchar_t wc); wchar_t *wrindex(const wchar_t *ws, wchar_t wc); </pre>
ISO C++	<pre> #include <wchar.h> const wchar_t *wcschr(const wchar_t *ws, wchar_t wc); const wchar_t *wcspbrk(const wchar_t *ws1, const wchar_t *ws2); const wchar_t *wcsrchr(const wchar_t *ws, wchar_t wc); #include <cwchar> wchar_t *std::wcschr(wchar_t *ws, wchar_t wc); wchar_t *std::wcspbrk(wchar_t *ws1, const wchar_t *ws2); wchar_t *std::wcsrchr(wchar_t *ws, wchar_t wc); </pre>
DESCRIPTION	<p>These functions operate on wide-character strings terminated by <code>wchar_t</code> <code>NULL</code> characters. During appending or copying, these routines do not check for an overflow condition of the receiving string. In the following, <i>ws</i>, <i>ws1</i>, and <i>ws2</i> point to wide-character strings terminated by a <code>wchar_t</code> <code>NULL</code>.</p>
wscat() , wscat()	<p>The <code>wscat()</code> and <code>wscat()</code> functions append a copy of the wide-character string pointed to by <i>ws2</i> (including the terminating null wide-character code) to the end of the wide-character string pointed to by <i>ws1</i>. The initial wide-character code of <i>ws2</i> overwrites the null wide-character code at the end of <i>ws1</i>. If copying takes place between objects that overlap, the behavior is undefined. Both functions return <i>s1</i>; no return value is reserved to indicate an error.</p>
wcsncat() , wsncat()	<p>The <code>wcsncat()</code> and <code>wsncat()</code> functions append not more than <i>n</i> wide-character codes (a null wide-character code and wide-character codes that follow it are not appended) from the array pointed to by <i>ws2</i> to the end of the wide-character string pointed to by <i>ws1</i>. The initial wide-character code of <i>ws2</i> overwrites the null wide-character code at the end of <i>ws1</i>. A terminating null wide-character code is always appended to the result. Both functions return <i>ws1</i>; no return value is reserved to indicate an error.</p>
wcscmp() , wscmp()	<p>The <code>wcscmp()</code> and <code>wscmp()</code> functions compare the wide-character string pointed to by <i>ws1</i> to the wide-character string pointed to by <i>ws2</i>. The sign of a non-zero return value is determined by the sign of the difference between the values of the first pair of wide-character codes that differ in the objects being compared. Upon completion, both functions return an integer greater than, equal to, or less than zero, if the wide-character string pointed to by <i>ws1</i> is greater than, equal to, or less than the wide-character string pointed to by <i>ws2</i>.</p>

wcscat(3C)

wcsncmp() , wsncmp()	The <code>wcsncmp()</code> and <code>wsncmp()</code> functions compare not more than <i>n</i> wide-character codes (wide-character codes that follow a null wide character code are not compared) from the array pointed to by <i>ws1</i> to the array pointed to by <i>ws2</i> . The sign of a non-zero return value is determined by the sign of the difference between the values of the first pair of wide-character codes that differ in the objects being compared. Upon successful completion, both functions return an integer greater than, equal to, or less than zero, if the possibly null-terminated array pointed to by <i>ws1</i> is greater than, equal to, or less than the possibly null-terminated array pointed to by <i>ws2</i> .
wcscpy() , wscpy()	The <code>wcscpy()</code> and <code>wscpy()</code> functions copy the wide-character string pointed to by <i>ws2</i> (including the terminating null wide-character code) into the array pointed to by <i>ws1</i> . If copying takes place between objects that overlap, the behavior is undefined. Both functions return <i>ws1</i> ; no return value is reserved to indicate an error.
wcsncpy() , wsncpy()	The <code>wcsncpy()</code> and <code>wsncpy()</code> functions copy not more than <i>n</i> wide-character codes (wide-character codes that follow a null wide character code are not copied) from the array pointed to by <i>ws2</i> to the array pointed to by <i>ws1</i> . If copying takes place between objects that overlap, the behavior is undefined. If the array pointed to by <i>ws2</i> is a wide-character string that is shorter than <i>n</i> wide-character codes, null wide-character codes are appended to the copy in the array pointed to by <i>ws1</i> , until a total <i>n</i> wide-character codes are written. Both functions return <i>ws1</i> ; no return value is reserved to indicate an error.
wcslen() , wslen()	The <code>wcslen()</code> and <code>wslen()</code> functions compute the number of wide-character codes in the wide-character string to which <i>ws</i> points, not including the terminating null wide-character code. Both functions return <i>ws</i> ; no return value is reserved to indicate an error.
wcschr() , wschr()	The <code>wcschr()</code> and <code>wschr()</code> functions locate the first occurrence of <i>wc</i> in the wide-character string pointed to by <i>ws</i> . The value of <i>wc</i> must be a character representable as a type <code>wchar_t</code> and must be a wide-character code corresponding to a valid character in the current locale. The terminating null wide-character code is considered to be part of the wide-character string. Upon completion, both functions return a pointer to the wide-character code, or a null pointer if the wide-character code is not found.
wcsrchr() , wsrchr()	The <code>wcsrchr()</code> and <code>wsrchr()</code> functions locate the last occurrence of <i>wc</i> in the wide-character string pointed to by <i>ws</i> . The value of <i>wc</i> must be a character representable as a type <code>wchar_t</code> and must be a wide-character code corresponding to a valid character in the current locale. The terminating null wide-character code is considered to be part of the wide-character string. Upon successful completion, both functions return a pointer to the wide-character code, or a null pointer if <i>wc</i> does not occur in the wide-character string.
windex() , wrindex()	The <code>windex()</code> and <code>wrindex()</code> functions behave the same as <code>wschr()</code> and <code>wsrchr()</code> , respectively.

wcspbrk() , wspbrk()	The <code>wcspbrk()</code> and <code>wspbrk()</code> functions locate the first occurrence in the wide character string pointed to by <code>ws1</code> of any wide-character code from the wide-character string pointed to by <code>ws2</code> . Upon successful completion, the function returns a pointer to the wide-character code, or a null pointer if no wide-character code from <code>ws2</code> occurs in <code>ws1</code> .
wcswcs()	The <code>wcswcs()</code> function locates the first occurrence in the wide-character string pointed to by <code>ws1</code> of the sequence of wide-character codes (excluding the terminating null wide-character code) in the wide-character string pointed to by <code>ws2</code> . Upon successful completion, the function returns a pointer to the located wide-character string, or a null pointer if the wide-character string is not found. If <code>ws2</code> points to a wide-character string with zero length, the function returns <code>ws1</code> .
wcsspn() , wsspnl()	The <code>wcsspn()</code> and <code>wsspnl()</code> functions compute the length of the maximum initial segment of the wide-character string pointed to by <code>ws1</code> which consists entirely of wide-character codes from the wide-character string pointed to by <code>ws2</code> . Both functions return the length <code>ws1</code> ; no return value is reserved to indicate an error.
wcscspn() , wscspnl()	The <code>wcscspn()</code> and <code>wscspnl()</code> functions compute the length of the maximum initial segment of the wide-character string pointed to by <code>ws1</code> which consists entirely of wide-character codes <i>not</i> from the wide-character string pointed to by <code>ws2</code> . Both functions return the length of the initial substring of <code>ws1</code> ; no return value is reserved to indicate an error.
wcstok() , wstok()	A sequence of calls to the <code>wcstok()</code> and <code>wstok()</code> functions break the wide-character string pointed to by <code>ws1</code> into a sequence of tokens, each of which is delimited by a wide-character code from the wide-character string pointed to by <code>ws2</code> .
Default and other standards	<p>The third argument points to a caller-provided <code>wchar_t</code> pointer into which the <code>wcstok()</code> function stores information necessary for it to continue scanning the same wide-character string. This argument is not available with the XPG4 and SUS versions of <code>wcstok()</code>, nor is it available with the <code>wstok()</code> function. See <code>standards(5)</code>.</p> <p>The first call in the sequence has <code>ws1</code> as its first argument, and is followed by calls with a null pointer as their first argument. The separator string pointed to by <code>ws2</code> may be different from call to call.</p> <p>The first call in the sequence searches the wide-character string pointed to by <code>ws1</code> for the first wide-character code that is <i>not</i> contained in the current separator string pointed to by <code>ws2</code>. If no such wide-character code is found, then there are no tokens in the wide-character string pointed to by <code>ws1</code>, and <code>wcstok()</code> and <code>wstok()</code> return a null pointer. If such a wide-character code is found, it is the start of the first token.</p> <p>The <code>wcstok()</code> and <code>wstok()</code> functions then search from that point for a wide-character code that <i>is</i> contained in the current separator string. If no such wide-character code is found, the current token extends to the end of the wide-character string pointed to by <code>ws1</code>, and subsequent searches for a token will</p>

wcscat(3C)

return a null pointer. If such a wide-character code is found, it is overwritten by a null wide character, which terminates the current token. The `wcstok()` and `wstok()` functions save a pointer to the following wide-character code, from which the next search for a token will start.

Each subsequent call, with a null pointer as the value of the first argument, starts searching from the saved pointer and behaves as described above.

Upon successful completion, both functions return a pointer to the first wide-character code of a token. Otherwise, if there is no token, a null pointer is returned.

The initial wide-character code of <i>ws2</i> overwrites the null wide-character code at the end of <i>ws1</i>. A terminating null wide-character code is always appended to the result. Both functions return <i>ws1</i>; no return value is reserved to indicate an error.</p>
wscmp(), wscmp()	<p>The <code>wscmp()</code> and <code>wscmp()</code> functions compare the wide-character string pointed to by <i>ws1</i> to the wide-character string pointed to by <i>ws2</i>. The sign of a non-zero return value is determined by the sign of the difference between the values of the first pair of wide-character codes that differ in the objects being compared. Upon completion, both functions return an integer greater than, equal to, or less than zero, if the wide-character string pointed to by <i>ws1</i> is greater than, equal to, or less than the wide-character string pointed to by <i>ws2</i>.</p>

wcsncmp() , wsncmp()	The <code>wcsncmp()</code> and <code>wsncmp()</code> functions compare not more than <i>n</i> wide-character codes (wide-character codes that follow a null wide character code are not compared) from the array pointed to by <i>ws1</i> to the array pointed to by <i>ws2</i> . The sign of a non-zero return value is determined by the sign of the difference between the values of the first pair of wide-character codes that differ in the objects being compared. Upon successful completion, both functions return an integer greater than, equal to, or less than zero, if the possibly null-terminated array pointed to by <i>ws1</i> is greater than, equal to, or less than the possibly null-terminated array pointed to by <i>ws2</i> .
wscpy() , wscopy()	The <code>wscpy()</code> and <code>wscopy()</code> functions copy the wide-character string pointed to by <i>ws2</i> (including the terminating null wide-character code) into the array pointed to by <i>ws1</i> . If copying takes place between objects that overlap, the behavior is undefined. Both functions return <i>ws1</i> ; no return value is reserved to indicate an error.
wcsncpy() , wsncpy()	The <code>wcsncpy()</code> and <code>wsncpy()</code> functions copy not more than <i>n</i> wide-character codes (wide-character codes that follow a null wide character code are not copied) from the array pointed to by <i>ws2</i> to the array pointed to by <i>ws1</i> . If copying takes place between objects that overlap, the behavior is undefined. If the array pointed to by <i>ws2</i> is a wide-character string that is shorter than <i>n</i> wide-character codes, null wide-character codes are appended to the copy in the array pointed to by <i>ws1</i> , until a total <i>n</i> wide-character codes are written. Both functions return <i>ws1</i> ; no return value is reserved to indicate an error.
wcslen() , wslen()	The <code>wcslen()</code> and <code>wslen()</code> functions compute the number of wide-character codes in the wide-character string to which <i>ws</i> points, not including the terminating null wide-character code. Both functions return <i>ws</i> ; no return value is reserved to indicate an error.
wcschr() , wschr()	The <code>wcschr()</code> and <code>wschr()</code> functions locate the first occurrence of <i>wc</i> in the wide-character string pointed to by <i>ws</i> . The value of <i>wc</i> must be a character representable as a type <code>wchar_t</code> and must be a wide-character code corresponding to a valid character in the current locale. The terminating null wide-character code is considered to be part of the wide-character string. Upon completion, both functions return a pointer to the wide-character code, or a null pointer if the wide-character code is not found.
wcsrchr() , wsrchr()	The <code>wcsrchr()</code> and <code>wsrchr()</code> functions locate the last occurrence of <i>wc</i> in the wide-character string pointed to by <i>ws</i> . The value of <i>wc</i> must be a character representable as a type <code>wchar_t</code> and must be a wide-character code corresponding to a valid character in the current locale. The terminating null wide-character code is considered to be part of the wide-character string. Upon successful completion, both functions return a pointer to the wide-character code, or a null pointer if <i>wc</i> does not occur in the wide-character string.
windex() , wrindex()	The <code>windex()</code> and <code>wrindex()</code> functions behave the same as <code>wschr()</code> and <code>wsrchr()</code> , respectively.

wcschr(3C)

wcspbrk() , wspbrk()	The <code>wcspbrk()</code> and <code>wspbrk()</code> functions locate the first occurrence in the wide character string pointed to by <code>ws1</code> of any wide-character code from the wide-character string pointed to by <code>ws2</code> . Upon successful completion, the function returns a pointer to the wide-character code, or a null pointer if no wide-character code from <code>ws2</code> occurs in <code>ws1</code> .
wcswcs()	The <code>wcswcs()</code> function locates the first occurrence in the wide-character string pointed to by <code>ws1</code> of the sequence of wide-character codes (excluding the terminating null wide-character code) in the wide-character string pointed to by <code>ws2</code> . Upon successful completion, the function returns a pointer to the located wide-character string, or a null pointer if the wide-character string is not found. If <code>ws2</code> points to a wide-character string with zero length, the function returns <code>ws1</code> .
wcsspn() , wsspnl()	The <code>wcsspn()</code> and <code>wsspnl()</code> functions compute the length of the maximum initial segment of the wide-character string pointed to by <code>ws1</code> which consists entirely of wide-character codes from the wide-character string pointed to by <code>ws2</code> . Both functions return the length <code>ws1</code> ; no return value is reserved to indicate an error.
wcscspn() , wscspnl()	The <code>wcscspn()</code> and <code>wscspnl()</code> functions compute the length of the maximum initial segment of the wide-character string pointed to by <code>ws1</code> which consists entirely of wide-character codes <i>not</i> from the wide-character string pointed to by <code>ws2</code> . Both functions return the length of the initial substring of <code>ws1</code> ; no return value is reserved to indicate an error.
wcstok() , wstok()	A sequence of calls to the <code>wcstok()</code> and <code>wstok()</code> functions break the wide-character string pointed to by <code>ws1</code> into a sequence of tokens, each of which is delimited by a wide-character code from the wide-character string pointed to by <code>ws2</code> .
Default and other standards	<p>The third argument points to a caller-provided <code>wchar_t</code> pointer into which the <code>wcstok()</code> function stores information necessary for it to continue scanning the same wide-character string. This argument is not available with the XPG4 and SUS versions of <code>wcstok()</code>, nor is it available with the <code>wstok()</code> function. See <code>standards(5)</code>.</p> <p>The first call in the sequence has <code>ws1</code> as its first argument, and is followed by calls with a null pointer as their first argument. The separator string pointed to by <code>ws2</code> may be different from call to call.</p> <p>The first call in the sequence searches the wide-character string pointed to by <code>ws1</code> for the first wide-character code that is <i>not</i> contained in the current separator string pointed to by <code>ws2</code>. If no such wide-character code is found, then there are no tokens in the wide-character string pointed to by <code>ws1</code>, and <code>wcstok()</code> and <code>wstok()</code> return a null pointer. If such a wide-character code is found, it is the start of the first token.</p> <p>The <code>wcstok()</code> and <code>wstok()</code> functions then search from that point for a wide-character code that <i>is</i> contained in the current separator string. If no such wide-character code is found, the current token extends to the end of the wide-character string pointed to by <code>ws1</code>, and subsequent searches for a token will</p>

wcschr(3C)

return a null pointer. If such a wide-character code is found, it is overwritten by a null wide character, which terminates the current token. The `wcstok()` and `wstok()` functions save a pointer to the following wide-character code, from which the next search for a token will start.

Each subsequent call, with a null pointer as the value of the first argument, starts searching from the saved pointer and behaves as described above.

Upon successful completion, both functions return a pointer to the first wide-character code of a token. Otherwise, if there is no token, a null pointer is returned.

	<pre> size_t wscspn(const wchar_t *ws1, const wchar_t *ws2); wchar_t *wstok(wchar_t *ws1, const wchar_t *ws2); wchar_t *windex(const wchar_t *ws, wchar_t wc); wchar_t *wrindex(const wchar_t *ws, wchar_t wc); </pre>
ISO C++	<pre> #include <wchar.h> const wchar_t *wcschr(const wchar_t *ws, wchar_t wc); const wchar_t *wcspbrk(const wchar_t *ws1, const wchar_t *ws2); const wchar_t *wcsrchr(const wchar_t *ws, wchar_t wc); #include <cwchar> wchar_t *std::wcschr(wchar_t *ws, wchar_t wc); wchar_t *std::wcspbrk(wchar_t *ws1, const wchar_t *ws2); wchar_t *std::wcsrchr(wchar_t *ws, wchar_t wc); </pre>
DESCRIPTION	<p>These functions operate on wide-character strings terminated by <code>wchar_t NULL</code> characters. During appending or copying, these routines do not check for an overflow condition of the receiving string. In the following, <i>ws</i>, <i>ws1</i>, and <i>ws2</i> point to wide-character strings terminated by a <code>wchar_t NULL</code>.</p>
wscat(), wscat()	<p>The <code>wscat()</code> and <code>wscat()</code> functions append a copy of the wide-character string pointed to by <i>ws2</i> (including the terminating null wide-character code) to the end of the wide-character string pointed to by <i>ws1</i>. The initial wide-character code of <i>ws2</i> overwrites the null wide-character code at the end of <i>ws1</i>. If copying takes place between objects that overlap, the behavior is undefined. Both functions return <i>s1</i>; no return value is reserved to indicate an error.</p>
wcsncat(), wsncat()	<p>The <code>wcsncat()</code> and <code>wsncat()</code> functions append not more than <i>n</i> wide-character codes (a null wide-character code and wide-character codes that follow it are not appended) from the array pointed to by <i>ws2</i> to the end of the wide-character string pointed to by <i>ws1</i>. The initial wide-character code of <i>ws2</i> overwrites the null wide-character code at the end of <i>ws1</i>. A terminating null wide-character code is always appended to the result. Both functions return <i>ws1</i>; no return value is reserved to indicate an error.</p>
wscmp(), wscmp()	<p>The <code>wscmp()</code> and <code>wscmp()</code> functions compare the wide-character string pointed to by <i>ws1</i> to the wide-character string pointed to by <i>ws2</i>. The sign of a non-zero return value is determined by the sign of the difference between the values of the first pair of wide-character codes that differ in the objects being compared. Upon completion, both functions return an integer greater than, equal to, or less than zero, if the wide-character string pointed to by <i>ws1</i> is greater than, equal to, or less than the wide-character string pointed to by <i>ws2</i>.</p>

wcscmp(3C)

wcsncmp(), wsncmp()	The <code>wcsncmp()</code> and <code>wsncmp()</code> functions compare not more than <i>n</i> wide-character codes (wide-character codes that follow a null wide character code are not compared) from the array pointed to by <i>ws1</i> to the array pointed to by <i>ws2</i> . The sign of a non-zero return value is determined by the sign of the difference between the values of the first pair of wide-character codes that differ in the objects being compared. Upon successful completion, both functions return an integer greater than, equal to, or less than zero, if the possibly null-terminated array pointed to by <i>ws1</i> is greater than, equal to, or less than the possibly null-terminated array pointed to by <i>ws2</i> .
wcscpy(), wscpy()	The <code>wcscpy()</code> and <code>wscpy()</code> functions copy the wide-character string pointed to by <i>ws2</i> (including the terminating null wide-character code) into the array pointed to by <i>ws1</i> . If copying takes place between objects that overlap, the behavior is undefined. Both functions return <i>ws1</i> ; no return value is reserved to indicate an error.
wcsncpy(), wsncpy()	The <code>wcsncpy()</code> and <code>wsncpy()</code> functions copy not more than <i>n</i> wide-character codes (wide-character codes that follow a null wide character code are not copied) from the array pointed to by <i>ws2</i> to the array pointed to by <i>ws1</i> . If copying takes place between objects that overlap, the behavior is undefined. If the array pointed to by <i>ws2</i> is a wide-character string that is shorter than <i>n</i> wide-character codes, null wide-character codes are appended to the copy in the array pointed to by <i>ws1</i> , until a total <i>n</i> wide-character codes are written. Both functions return <i>ws1</i> ; no return value is reserved to indicate an error.
wcslen(), wslen()	The <code>wcslen()</code> and <code>wslen()</code> functions compute the number of wide-character codes in the wide-character string to which <i>ws</i> points, not including the terminating null wide-character code. Both functions return <i>ws</i> ; no return value is reserved to indicate an error.
wcschr(), wschr()	The <code>wcschr()</code> and <code>wschr()</code> functions locate the first occurrence of <i>wc</i> in the wide-character string pointed to by <i>ws</i> . The value of <i>wc</i> must be a character representable as a type <code>wchar_t</code> and must be a wide-character code corresponding to a valid character in the current locale. The terminating null wide-character code is considered to be part of the wide-character string. Upon completion, both functions return a pointer to the wide-character code, or a null pointer if the wide-character code is not found.
wcsrchr(), wsrchr()	The <code>wcsrchr()</code> and <code>wsrchr()</code> functions locate the last occurrence of <i>wc</i> in the wide-character string pointed to by <i>ws</i> . The value of <i>wc</i> must be a character representable as a type <code>wchar_t</code> and must be a wide-character code corresponding to a valid character in the current locale. The terminating null wide-character code is considered to be part of the wide-character string. Upon successful completion, both functions return a pointer to the wide-character code, or a null pointer if <i>wc</i> does not occur in the wide-character string.
windex(), wrintdex()	The <code>windex()</code> and <code>wrintdex()</code> functions behave the same as <code>wschr()</code> and <code>wsrchr()</code> , respectively.

wcspbrk() , wspbrk()	The <code>wcspbrk()</code> and <code>wspbrk()</code> functions locate the first occurrence in the wide character string pointed to by <code>ws1</code> of any wide-character code from the wide-character string pointed to by <code>ws2</code> . Upon successful completion, the function returns a pointer to the wide-character code, or a null pointer if no wide-character code from <code>ws2</code> occurs in <code>ws1</code> .
wcswcs()	The <code>wcswcs()</code> function locates the first occurrence in the wide-character string pointed to by <code>ws1</code> of the sequence of wide-character codes (excluding the terminating null wide-character code) in the wide-character string pointed to by <code>ws2</code> . Upon successful completion, the function returns a pointer to the located wide-character string, or a null pointer if the wide-character string is not found. If <code>ws2</code> points to a wide-character string with zero length, the function returns <code>ws1</code> .
wcsspn() , wsspnl()	The <code>wcsspn()</code> and <code>wsspnl()</code> functions compute the length of the maximum initial segment of the wide-character string pointed to by <code>ws1</code> which consists entirely of wide-character codes from the wide-character string pointed to by <code>ws2</code> . Both functions return the length <code>ws1</code> ; no return value is reserved to indicate an error.
wcscspn() , wscspnl()	The <code>wcscspn()</code> and <code>wscspnl()</code> functions compute the length of the maximum initial segment of the wide-character string pointed to by <code>ws1</code> which consists entirely of wide-character codes <i>not</i> from the wide-character string pointed to by <code>ws2</code> . Both functions return the length of the initial substring of <code>ws1</code> ; no return value is reserved to indicate an error.
wcstok() , wstok()	A sequence of calls to the <code>wcstok()</code> and <code>wstok()</code> functions break the wide-character string pointed to by <code>ws1</code> into a sequence of tokens, each of which is delimited by a wide-character code from the wide-character string pointed to by <code>ws2</code> .
Default and other standards	<p>The third argument points to a caller-provided <code>wchar_t</code> pointer into which the <code>wcstok()</code> function stores information necessary for it to continue scanning the same wide-character string. This argument is not available with the XPG4 and SUS versions of <code>wcstok()</code>, nor is it available with the <code>wstok()</code> function. See <code>standards(5)</code>.</p> <p>The first call in the sequence has <code>ws1</code> as its first argument, and is followed by calls with a null pointer as their first argument. The separator string pointed to by <code>ws2</code> may be different from call to call.</p> <p>The first call in the sequence searches the wide-character string pointed to by <code>ws1</code> for the first wide-character code that is <i>not</i> contained in the current separator string pointed to by <code>ws2</code>. If no such wide-character code is found, then there are no tokens in the wide-character string pointed to by <code>ws1</code>, and <code>wcstok()</code> and <code>wstok()</code> return a null pointer. If such a wide-character code is found, it is the start of the first token.</p> <p>The <code>wcstok()</code> and <code>wstok()</code> functions then search from that point for a wide-character code that <i>is</i> contained in the current separator string. If no such wide-character code is found, the current token extends to the end of the wide-character string pointed to by <code>ws1</code>, and subsequent searches for a token will</p>

wscmp(3C)

return a null pointer. If such a wide-character code is found, it is overwritten by a null wide character, which terminates the current token. The `wcstok()` and `wstok()` functions save a pointer to the following wide-character code, from which the next search for a token will start.

Each subsequent call, with a null pointer as the value of the first argument, starts searching from the saved pointer and behaves as described above.

Upon successful completion, both functions return a pointer to the first wide-character code of a token. Otherwise, if there is no token, a null pointer is returned.

NAME	wscoll, wscoll – wide character string comparison using collating information						
SYNOPSIS	<pre>#include <wchar.h> int wscoll(const wchar_t *ws1, const wchar_t *ws2); int wscoll(const wchar_t *ws1, const wchar_t *ws2);</pre>						
DESCRIPTION	The <code>wscoll()</code> and <code>wscoll()</code> functions compare the wide character string pointed to by <code>ws1</code> to the wide character string pointed to by <code>ws2</code> , both interpreted as appropriate to the <code>LC_COLLATE</code> category of the current locale.						
RETURN VALUES	Upon successful completion, <code>wscoll()</code> and <code>wscoll()</code> return an integer greater than, equal to, or less than 0, depending upon whether the wide character string pointed to by <code>ws1</code> is greater than, equal to, or less than the wide character string pointed to by <code>ws2</code> , when both are interpreted as appropriate to the current locale. On error, <code>wscoll()</code> and <code>wscoll()</code> may set <code>errno</code> , but no return value is reserved to indicate an error.						
ERRORS	<p>The <code>wscoll()</code> and <code>wscoll()</code> functions may fail if:</p> <p><code>EINVAL</code> The <code>ws1</code> or <code>ws2</code> arguments contain wide character codes outside the domain of the collating sequence.</p> <p><code>ENOSYS</code> The function is not supported.</p>						
USAGE	<p>Because no return value is reserved to indicate an error, an application wishing to check for error situations should set <code>errno</code> to 0, call either <code>wscoll()</code> or <code>wscoll()</code>, then check <code>errno</code> and if it is non-zero, assume an error has occurred.</p> <p>The <code>wcsxfrm(3C)</code> and <code>wscmp(3C)</code> functions should be used for sorting large lists.</p> <p>The <code>wscoll()</code> and <code>wscoll()</code> functions can be used safely in multithreaded applications as long as <code>setlocale(3C)</code> is not being called to change the locale.</p>

XPG4 and SUS Default and other standards	

	<pre> size_t wscspn(const wchar_t *ws1, const wchar_t *ws2); wchar_t *wstok(wchar_t *ws1, const wchar_t *ws2); wchar_t *windex(const wchar_t *ws, wchar_t wc); wchar_t *wrindex(const wchar_t *ws, wchar_t wc); </pre>
ISO C++	<pre> #include <wchar.h> const wchar_t *wcschr(const wchar_t *ws, wchar_t wc); const wchar_t *wcspbrk(const wchar_t *ws1, const wchar_t *ws2); const wchar_t *wcsrchr(const wchar_t *ws, wchar_t wc); #include <cwchar> wchar_t *std::wcschr(wchar_t *ws, wchar_t wc); wchar_t *std::wcspbrk(wchar_t *ws1, const wchar_t *ws2); wchar_t *std::wcsrchr(wchar_t *ws, wchar_t wc); </pre>
DESCRIPTION	<p>These functions operate on wide-character strings terminated by <code>wchar_t</code> <code>NULL</code> characters. During appending or copying, these routines do not check for an overflow condition of the receiving string. In the following, <i>ws</i>, <i>ws1</i>, and <i>ws2</i> point to wide-character strings terminated by a <code>wchar_t</code> <code>NULL</code>.</p>
wscat(), wscat()	<p>The <code>wscat()</code> and <code>wscat()</code> functions append a copy of the wide-character string pointed to by <i>ws2</i> (including the terminating null wide-character code) to the end of the wide-character string pointed to by <i>ws1</i>. The initial wide-character code of <i>ws2</i> overwrites the null wide-character code at the end of <i>ws1</i>. If copying takes place between objects that overlap, the behavior is undefined. Both functions return <i>s1</i>; no return value is reserved to indicate an error.</p>
wcsncat(), wsncat()	<p>The <code>wcsncat()</code> and <code>wsncat()</code> functions append not more than <i>n</i> wide-character codes (a null wide-character code and wide-character codes that follow it are not appended) from the array pointed to by <i>ws2</i> to the end of the wide-character string pointed to by <i>ws1</i>. The initial wide-character code of <i>ws2</i> overwrites the null wide-character code at the end of <i>ws1</i>. A terminating null wide-character code is always appended to the result. Both functions return <i>ws1</i>; no return value is reserved to indicate an error.</p>
wscmp(), wscmp()	<p>The <code>wscmp()</code> and <code>wscmp()</code> functions compare the wide-character string pointed to by <i>ws1</i> to the wide-character string pointed to by <i>ws2</i>. The sign of a non-zero return value is determined by the sign of the difference between the values of the first pair of wide-character codes that differ in the objects being compared. Upon completion, both functions return an integer greater than, equal to, or less than zero, if the wide-character string pointed to by <i>ws1</i> is greater than, equal to, or less than the wide-character string pointed to by <i>ws2</i>.</p>

wcscpy(3C)

wcsncmp(), wsncmp()	The <code>wcsncmp()</code> and <code>wsncmp()</code> functions compare not more than <i>n</i> wide-character codes (wide-character codes that follow a null wide character code are not compared) from the array pointed to by <i>ws1</i> to the array pointed to by <i>ws2</i> . The sign of a non-zero return value is determined by the sign of the difference between the values of the first pair of wide-character codes that differ in the objects being compared. Upon successful completion, both functions return an integer greater than, equal to, or less than zero, if the possibly null-terminated array pointed to by <i>ws1</i> is greater than, equal to, or less than the possibly null-terminated array pointed to by <i>ws2</i> .
wcscpy(), wscpy()	The <code>wcscpy()</code> and <code>wscpy()</code> functions copy the wide-character string pointed to by <i>ws2</i> (including the terminating null wide-character code) into the array pointed to by <i>ws1</i> . If copying takes place between objects that overlap, the behavior is undefined. Both functions return <i>ws1</i> ; no return value is reserved to indicate an error.
wcsncpy(), wsncpy()	The <code>wcsncpy()</code> and <code>wsncpy()</code> functions copy not more than <i>n</i> wide-character codes (wide-character codes that follow a null wide character code are not copied) from the array pointed to by <i>ws2</i> to the array pointed to by <i>ws1</i> . If copying takes place between objects that overlap, the behavior is undefined. If the array pointed to by <i>ws2</i> is a wide-character string that is shorter than <i>n</i> wide-character codes, null wide-character codes are appended to the copy in the array pointed to by <i>ws1</i> , until a total <i>n</i> wide-character codes are written. Both functions return <i>ws1</i> ; no return value is reserved to indicate an error.
wcslen(), wslen()	The <code>wcslen()</code> and <code>wslen()</code> functions compute the number of wide-character codes in the wide-character string to which <i>ws</i> points, not including the terminating null wide-character code. Both functions return <i>ws</i> ; no return value is reserved to indicate an error.
wcschr(), wschr()	The <code>wcschr()</code> and <code>wschr()</code> functions locate the first occurrence of <i>wc</i> in the wide-character string pointed to by <i>ws</i> . The value of <i>wc</i> must be a character representable as a type <code>wchar_t</code> and must be a wide-character code corresponding to a valid character in the current locale. The terminating null wide-character code is considered to be part of the wide-character string. Upon completion, both functions return a pointer to the wide-character code, or a null pointer if the wide-character code is not found.
wcsrchr(), wsrchr()	The <code>wcsrchr()</code> and <code>wsrchr()</code> functions locate the last occurrence of <i>wc</i> in the wide-character string pointed to by <i>ws</i> . The value of <i>wc</i> must be a character representable as a type <code>wchar_t</code> and must be a wide-character code corresponding to a valid character in the current locale. The terminating null wide-character code is considered to be part of the wide-character string. Upon successful completion, both functions return a pointer to the wide-character code, or a null pointer if <i>wc</i> does not occur in the wide-character string.
windex(), wrindex()	The <code>windex()</code> and <code>wrindex()</code> functions behave the same as <code>wschr()</code> and <code>wsrchr()</code> , respectively.

wcspbrk() , wspbrk()	The <code>wcspbrk()</code> and <code>wspbrk()</code> functions locate the first occurrence in the wide character string pointed to by <code>ws1</code> of any wide-character code from the wide-character string pointed to by <code>ws2</code> . Upon successful completion, the function returns a pointer to the wide-character code, or a null pointer if no wide-character code from <code>ws2</code> occurs in <code>ws1</code> .
wcswcs()	The <code>wcswcs()</code> function locates the first occurrence in the wide-character string pointed to by <code>ws1</code> of the sequence of wide-character codes (excluding the terminating null wide-character code) in the wide-character string pointed to by <code>ws2</code> . Upon successful completion, the function returns a pointer to the located wide-character string, or a null pointer if the wide-character string is not found. If <code>ws2</code> points to a wide-character string with zero length, the function returns <code>ws1</code> .
wcsspn() , wsspnl()	The <code>wcsspn()</code> and <code>wsspnl()</code> functions compute the length of the maximum initial segment of the wide-character string pointed to by <code>ws1</code> which consists entirely of wide-character codes from the wide-character string pointed to by <code>ws2</code> . Both functions return the length <code>ws1</code> ; no return value is reserved to indicate an error.
wcscspn() , wscspnl()	The <code>wcscspn()</code> and <code>wscspnl()</code> functions compute the length of the maximum initial segment of the wide-character string pointed to by <code>ws1</code> which consists entirely of wide-character codes <i>not</i> from the wide-character string pointed to by <code>ws2</code> . Both functions return the length of the initial substring of <code>ws1</code> ; no return value is reserved to indicate an error.
wcstok() , wstok()	A sequence of calls to the <code>wcstok()</code> and <code>wstok()</code> functions break the wide-character string pointed to by <code>ws1</code> into a sequence of tokens, each of which is delimited by a wide-character code from the wide-character string pointed to by <code>ws2</code> .
Default and other standards	<p>The third argument points to a caller-provided <code>wchar_t</code> pointer into which the <code>wcstok()</code> function stores information necessary for it to continue scanning the same wide-character string. This argument is not available with the XPG4 and SUS versions of <code>wcstok()</code>, nor is it available with the <code>wstok()</code> function. See <code>standards(5)</code>.</p> <p>The first call in the sequence has <code>ws1</code> as its first argument, and is followed by calls with a null pointer as their first argument. The separator string pointed to by <code>ws2</code> may be different from call to call.</p> <p>The first call in the sequence searches the wide-character string pointed to by <code>ws1</code> for the first wide-character code that is <i>not</i> contained in the current separator string pointed to by <code>ws2</code>. If no such wide-character code is found, then there are no tokens in the wide-character string pointed to by <code>ws1</code>, and <code>wcstok()</code> and <code>wstok()</code> return a null pointer. If such a wide-character code is found, it is the start of the first token.</p> <p>The <code>wcstok()</code> and <code>wstok()</code> functions then search from that point for a wide-character code that <i>is</i> contained in the current separator string. If no such wide-character code is found, the current token extends to the end of the wide-character string pointed to by <code>ws1</code>, and subsequent searches for a token will</p>

wcscpy(3C)

return a null pointer. If such a wide-character code is found, it is overwritten by a null wide character, which terminates the current token. The `wcstok()` and `wstok()` functions save a pointer to the following wide-character code, from which the next search for a token will start.

Each subsequent call, with a null pointer as the value of the first argument, starts searching from the saved pointer and behaves as described above.

Upon successful completion, both functions return a pointer to the first wide-character code of a token. Otherwise, if there is no token, a null pointer is returned.

Default and other standards	

wcscspn(3C)

	<pre> size_t wcscspn(const wchar_t *ws1, const wchar_t *ws2); wchar_t *wstok(wchar_t *ws1, const wchar_t *ws2); wchar_t *windex(const wchar_t *ws, wchar_t wc); wchar_t *wrindex(const wchar_t *ws, wchar_t wc); </pre>
ISO C++	<pre> #include <wchar.h> const wchar_t *wcschr(const wchar_t *ws, wchar_t wc); const wchar_t *wcspbrk(const wchar_t *ws1, const wchar_t *ws2); const wchar_t *wcsrchr(const wchar_t *ws, wchar_t wc); #include <cwchar> wchar_t *std::wcschr(wchar_t *ws, wchar_t wc); wchar_t *std::wcspbrk(wchar_t *ws1, const wchar_t *ws2); wchar_t *std::wcsrchr(wchar_t *ws, wchar_t wc); </pre>
DESCRIPTION	<p>These functions operate on wide-character strings terminated by <code>wchar_t NULL</code> characters. During appending or copying, these routines do not check for an overflow condition of the receiving string. In the following, <i>ws</i>, <i>ws1</i>, and <i>ws2</i> point to wide-character strings terminated by a <code>wchar_t NULL</code>.</p>
wcscat(), wscat()	<p>The <code>wcscat()</code> and <code>wscat()</code> functions append a copy of the wide-character string pointed to by <i>ws2</i> (including the terminating null wide-character code) to the end of the wide-character string pointed to by <i>ws1</i>. The initial wide-character code of <i>ws2</i> overwrites the null wide-character code at the end of <i>ws1</i>. If copying takes place between objects that overlap, the behavior is undefined. Both functions return <i>s1</i>; no return value is reserved to indicate an error.</p>
wcsncat(), wsncat()	<p>The <code>wcsncat()</code> and <code>wsncat()</code> functions append not more than <i>n</i> wide-character codes (a null wide-character code and wide-character codes that follow it are not appended) from the array pointed to by <i>ws2</i> to the end of the wide-character string pointed to by <i>ws1</i>. The initial wide-character code of <i>ws2</i> overwrites the null wide-character code at the end of <i>ws1</i>. A terminating null wide-character code is always appended to the result. Both functions return <i>ws1</i>; no return value is reserved to indicate an error.</p>
wcscmp(), wscmp()	<p>The <code>wcscmp()</code> and <code>wscmp()</code> functions compare the wide-character string pointed to by <i>ws1</i> to the wide-character string pointed to by <i>ws2</i>. The sign of a non-zero return value is determined by the sign of the difference between the values of the first pair of wide-character codes that differ in the objects being compared. Upon completion, both functions return an integer greater than, equal to, or less than zero, if the wide-character string pointed to by <i>ws1</i> is greater than, equal to, or less than the wide-character string pointed to by <i>ws2</i>.</p>

wcsncmp() , wsncmp()	The <code>wcsncmp()</code> and <code>wsncmp()</code> functions compare not more than <i>n</i> wide-character codes (wide-character codes that follow a null wide character code are not compared) from the array pointed to by <i>ws1</i> to the array pointed to by <i>ws2</i> . The sign of a non-zero return value is determined by the sign of the difference between the values of the first pair of wide-character codes that differ in the objects being compared. Upon successful completion, both functions return an integer greater than, equal to, or less than zero, if the possibly null-terminated array pointed to by <i>ws1</i> is greater than, equal to, or less than the possibly null-terminated array pointed to by <i>ws2</i> .
wscpy() , wscopy()	The <code>wscpy()</code> and <code>wscopy()</code> functions copy the wide-character string pointed to by <i>ws2</i> (including the terminating null wide-character code) into the array pointed to by <i>ws1</i> . If copying takes place between objects that overlap, the behavior is undefined. Both functions return <i>ws1</i> ; no return value is reserved to indicate an error.
wcsncpy() , wsncpy()	The <code>wcsncpy()</code> and <code>wsncpy()</code> functions copy not more than <i>n</i> wide-character codes (wide-character codes that follow a null wide character code are not copied) from the array pointed to by <i>ws2</i> to the array pointed to by <i>ws1</i> . If copying takes place between objects that overlap, the behavior is undefined. If the array pointed to by <i>ws2</i> is a wide-character string that is shorter than <i>n</i> wide-character codes, null wide-character codes are appended to the copy in the array pointed to by <i>ws1</i> , until a total <i>n</i> wide-character codes are written. Both functions return <i>ws1</i> ; no return value is reserved to indicate an error.
wcslen() , wslen()	The <code>wcslen()</code> and <code>wslen()</code> functions compute the number of wide-character codes in the wide-character string to which <i>ws</i> points, not including the terminating null wide-character code. Both functions return <i>ws</i> ; no return value is reserved to indicate an error.
wcschr() , wschr()	The <code>wcschr()</code> and <code>wschr()</code> functions locate the first occurrence of <i>wc</i> in the wide-character string pointed to by <i>ws</i> . The value of <i>wc</i> must be a character representable as a type <code>wchar_t</code> and must be a wide-character code corresponding to a valid character in the current locale. The terminating null wide-character code is considered to be part of the wide-character string. Upon completion, both functions return a pointer to the wide-character code, or a null pointer if the wide-character code is not found.
wcsrchr() , wsrchr()	The <code>wcsrchr()</code> and <code>wsrchr()</code> functions locate the last occurrence of <i>wc</i> in the wide-character string pointed to by <i>ws</i> . The value of <i>wc</i> must be a character representable as a type <code>wchar_t</code> and must be a wide-character code corresponding to a valid character in the current locale. The terminating null wide-character code is considered to be part of the wide-character string. Upon successful completion, both functions return a pointer to the wide-character code, or a null pointer if <i>wc</i> does not occur in the wide-character string.
windex() , wrindex()	The <code>windex()</code> and <code>wrindex()</code> functions behave the same as <code>wschr()</code> and <code>wsrchr()</code> , respectively.

wcscspn(3C)

wcspbrk() , wspbrk()	The <code>wcspbrk()</code> and <code>wspbrk()</code> functions locate the first occurrence in the wide character string pointed to by <code>ws1</code> of any wide-character code from the wide-character string pointed to by <code>ws2</code> . Upon successful completion, the function returns a pointer to the wide-character code, or a null pointer if no wide-character code from <code>ws2</code> occurs in <code>ws1</code> .
wcswcs()	The <code>wcswcs()</code> function locates the first occurrence in the wide-character string pointed to by <code>ws1</code> of the sequence of wide-character codes (excluding the terminating null wide-character code) in the wide-character string pointed to by <code>ws2</code> . Upon successful completion, the function returns a pointer to the located wide-character string, or a null pointer if the wide-character string is not found. If <code>ws2</code> points to a wide-character string with zero length, the function returns <code>ws1</code> .
wcsspn() , wsspnl()	The <code>wcsspn()</code> and <code>wsspnl()</code> functions compute the length of the maximum initial segment of the wide-character string pointed to by <code>ws1</code> which consists entirely of wide-character codes from the wide-character string pointed to by <code>ws2</code> . Both functions return the length <code>ws1</code> ; no return value is reserved to indicate an error.
wcscspn() , wcscspnl()	The <code>wcscspn()</code> and <code>wcscspnl()</code> functions compute the length of the maximum initial segment of the wide-character string pointed to by <code>ws1</code> which consists entirely of wide-character codes <i>not</i> from the wide-character string pointed to by <code>ws2</code> . Both functions return the length of the initial substring of <code>ws1</code> ; no return value is reserved to indicate an error.
wcstok() , wstok()	A sequence of calls to the <code>wcstok()</code> and <code>wstok()</code> functions break the wide-character string pointed to by <code>ws1</code> into a sequence of tokens, each of which is delimited by a wide-character code from the wide-character string pointed to by <code>ws2</code> .
Default and other standards	<p>The third argument points to a caller-provided <code>wchar_t</code> pointer into which the <code>wcstok()</code> function stores information necessary for it to continue scanning the same wide-character string. This argument is not available with the XPG4 and SUS versions of <code>wcstok()</code>, nor is it available with the <code>wstok()</code> function. See <code>standards(5)</code>.</p> <p>The first call in the sequence has <code>ws1</code> as its first argument, and is followed by calls with a null pointer as their first argument. The separator string pointed to by <code>ws2</code> may be different from call to call.</p> <p>The first call in the sequence searches the wide-character string pointed to by <code>ws1</code> for the first wide-character code that is <i>not</i> contained in the current separator string pointed to by <code>ws2</code>. If no such wide-character code is found, then there are no tokens in the wide-character string pointed to by <code>ws1</code>, and <code>wcstok()</code> and <code>wstok()</code> return a null pointer. If such a wide-character code is found, it is the start of the first token.</p> <p>The <code>wcstok()</code> and <code>wstok()</code> functions then search from that point for a wide-character code that <i>is</i> contained in the current separator string. If no such wide-character code is found, the current token extends to the end of the wide-character string pointed to by <code>ws1</code>, and subsequent searches for a token will</p>

wcscspn(3C)

return a null pointer. If such a wide-character code is found, it is overwritten by a null wide character, which terminates the current token. The `wcstok()` and `wstok()` functions save a pointer to the following wide-character code, from which the next search for a token will start.

Each subsequent call, with a null pointer as the value of the first argument, starts searching from the saved pointer and behaves as described above.

Upon successful completion, both functions return a pointer to the first wide-character code of a token. Otherwise, if there is no token, a null pointer is returned.

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE

wcsetno(3C)

NAME	<code>cset</code> , <code>csetlen</code> , <code>csetcol</code> , <code>csetno</code> , <code>wcsetno</code> – get information on EUC codesets				
SYNOPSIS	<pre>#include <euc.h> int csetlen(int <i>codeset</i>); int csetcol(int <i>codeset</i>); int csetno(unsigned char <i>c</i>); #include <widec.h> int wcsetno(wchar_t <i>pc</i>);</pre>				
DESCRIPTION	<p>Both <code>csetlen()</code> and <code>csetcol()</code> take a code set number <i>codeset</i>, which must be 0, 1, 2, or 3. The <code>csetlen()</code> function returns the number of bytes needed to represent a character of the given Extended Unix Code (EUC) code set, excluding the single-shift characters SS2 and SS3 for codesets 2 and 3. The <code>csetcol()</code> function returns the number of columns a character in the given EUC code set would take on the display.</p> <p>The <code>csetno()</code> function is implemented as a macro that returns a codeset number (0, 1, 2, or 3) for the EUC character whose first byte is <i>c</i>. For example,</p> <pre>#include<euc.h> . . . x+=csetcol(csetno(c));</pre> <p>increments a counter “<i>x</i>” (such as the cursor position) by the width of the character whose first byte is <i>c</i>.</p> <p>The <code>wcsetno()</code> function is implemented as a macro that returns a codeset number (0, 1, 2, or 3) for the given process code character <i>pc</i>. For example,</p> <pre>#include<euc.h> #include<widec.h> . . . x+=csetcol(wcsetno(pc));</pre> <p>increments a counter “<i>x</i>” (such as the cursor position) by the width of the Process Code character <i>pc</i>.</p>				
USAGE	The <code>cset()</code> , <code>csetlen()</code> , <code>csetcol()</code> , <code>csetno()</code> , and <code>wcsetno()</code> functions can be used safely in multithreaded applications, as long as <code>setlocale(3C)</code> is not being called to change the locale.

NAME	wcsftime – convert date and time to wide character string						
SYNOPSIS	#include <wchar.h>						
XPG4 and SUS	size_t wcsftime (wchar_t *wcs, size_t maxsize, const char *format, const struct tm *timptr);						
Default and other standards	size_t wcsftime (wchar_t *wcs, size_t maxsize, const wchar_t *format, const struct tm *timptr);						
DESCRIPTION	<p>The <code>wcsftime()</code> function is equivalent to the <code>strftime(3C)</code> function, except that:</p> <ul style="list-style-type: none"> ■ The argument <code>wcs</code> points to the initial element of an array of wide-characters into which the generated output is to be placed. ■ The argument <code>maxsize</code> indicates the maximum number of wide-characters to be placed in the output array. ■ The argument <code>format</code> is a wide-character string and the conversion specifications are replaced by corresponding sequences of wide-characters. ■ The return value indicates the number of wide-characters placed in the output array. <p>If copying takes place between objects that overlap, the behavior is undefined.</p>						
RETURN VALUES	<p>If the total number of resulting wide character codes (including the terminating null wide-character code) is no more than <code>maxsize</code>, <code>wcsftime()</code> returns the number of wide-character codes placed into the array pointed to by <code>wcs</code>, not including the terminating null wide-character code. Otherwise, 0 is returned and the contents of the array are indeterminate.</p> <p>The <code>wcsftime()</code> function uses <code>malloc(3C)</code> and should <code>malloc()</code> fail, <code>errno</code> will be set by <code>malloc()</code>.</p>						
ATTRIBUTES	See <code>attributes(5)</code> for descriptions of the following attributes:						
	<table border="1"> <thead> <tr> <th>ATTRIBUTE TYPE</th> <th>ATTRIBUTE VALUE</th> </tr> </thead> <tbody> <tr> <td>MT-Level</td> <td>MT-Safe with exceptions</td> </tr> <tr> <td>CSI</td> <td>Enabled</td> </tr> </tbody> </table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	MT-Level	MT-Safe with exceptions	CSI	Enabled
ATTRIBUTE TYPE	ATTRIBUTE VALUE						
MT-Level	MT-Safe with exceptions						
CSI	Enabled						
SEE ALSO	<code>malloc(3C)</code> , <code>setlocale(3C)</code> , <code>strftime(3C)</code> , <code>attributes(5)</code> , <code>standards(5)</code>						
NOTES	The <code>wcsftime()</code> function can be used safely in multithreaded applications, as long as <code>setlocale(3C)</code> is not being called to change the locale.						

wcslen(3C)

NAME	wcstring, wscat, wscat, wcsncat, wsncat, wscmp, wscmp, wcsncmp, wsncmp, wcsncpy, wcsncpy, wcsncpy, wsncpy, wcslen, wslen, wcschr, wschr, wcsrchr, wschr, windex, wrindex, wcsprk, wspbrk, wswcs, wcsspn, wssp, wcspspn, wcspspn, wstok, wstok – wide-character string operations
SYNOPSIS	<pre>#include <wchar.h> wchar_t *wscat(wchar_t *ws1, const wchar_t *ws2); wchar_t *wcsncat(wchar_t *ws1, const wchar_t *ws2, size_t n); int wscmp(const wchar_t *ws1, const wchar_t *ws2); int wcsncmp(const wchar_t *ws1, const wchar_t *ws2, size_t n); wchar_t *wcsncpy(wchar_t *ws1, const wchar_t *ws2); wchar_t *wcsncpy(wchar_t *ws1, const wchar_t *ws2, size_t n); size_t wcslen(const wchar_t *ws); wchar_t *wcschr(const wchar_t *ws, wchar_t wc); wchar_t *wcsrchr(const wchar_t *ws, wchar_t wc); wchar_t *wspbrk(const wchar_t *ws1, const wchar_t *ws2); wchar_t *wswcs(const wchar_t *ws1, const wchar_t *ws2); size_t wcsspn(const wchar_t *ws1, const wchar_t *ws2); size_t wcspspn(const wchar_t *ws1, const wchar_t *ws2); wchar_t *wstok(wchar_t *ws1, const wchar_t *ws2); wchar_t *wstok(wchar_t *ws1, const wchar_t *ws2, wchar_t **ptr); #include <widec.h> wchar_t *wscat(wchar_t *ws1, const wchar_t *ws2); wchar_t *wsncat(wchar_t *ws1, const wchar_t *ws2, size_t n); int wscmp(const wchar_t *ws1, const wchar_t *ws2); int wsncmp(const wchar_t *ws1, const wchar_t *ws2, size_t n); wchar_t *wscpy(wchar_t *ws1, const wchar_t *ws2); wchar_t *wsncpy(wchar_t *ws1, const wchar_t *ws2, size_t n); size_t wslen(const wchar_t *ws); wchar_t *wschr(const wchar_t *ws, wchar_t wc); wchar_t *wsrchr(const wchar_t *ws, wchar_t wc); wchar_t *wspbrk(const wchar_t *ws1, const wchar_t *ws2); size_t wssp(const wchar_t *ws1, const wchar_t *ws2);</pre>
XPG4 and SUS	
Default and other standards	

	<pre> size_t wscspn(const wchar_t *ws1, const wchar_t *ws2); wchar_t *wstok(wchar_t *ws1, const wchar_t *ws2); wchar_t *windex(const wchar_t *ws, wchar_t wc); wchar_t *wrindex(const wchar_t *ws, wchar_t wc); </pre>
ISO C++	<pre> #include <wchar.h> const wchar_t *wcschr(const wchar_t *ws, wchar_t wc); const wchar_t *wcspbrk(const wchar_t *ws1, const wchar_t *ws2); const wchar_t *wcsrchr(const wchar_t *ws, wchar_t wc); #include <cwchar> wchar_t *std::wcschr(wchar_t *ws, wchar_t wc); wchar_t *std::wcspbrk(wchar_t *ws1, const wchar_t *ws2); wchar_t *std::wcsrchr(wchar_t *ws, wchar_t wc); </pre>
DESCRIPTION	<p>These functions operate on wide-character strings terminated by <code>wchar_t</code> <code>NULL</code> characters. During appending or copying, these routines do not check for an overflow condition of the receiving string. In the following, <i>ws</i>, <i>ws1</i>, and <i>ws2</i> point to wide-character strings terminated by a <code>wchar_t</code> <code>NULL</code>.</p>
wscat() , wscat()	<p>The <code>wscat()</code> and <code>wscat()</code> functions append a copy of the wide-character string pointed to by <i>ws2</i> (including the terminating null wide-character code) to the end of the wide-character string pointed to by <i>ws1</i>. The initial wide-character code of <i>ws2</i> overwrites the null wide-character code at the end of <i>ws1</i>. If copying takes place between objects that overlap, the behavior is undefined. Both functions return <i>s1</i>; no return value is reserved to indicate an error.</p>
wcsncat() , wsncat()	<p>The <code>wcsncat()</code> and <code>wsncat()</code> functions append not more than <i>n</i> wide-character codes (a null wide-character code and wide-character codes that follow it are not appended) from the array pointed to by <i>ws2</i> to the end of the wide-character string pointed to by <i>ws1</i>. The initial wide-character code of <i>ws2</i> overwrites the null wide-character code at the end of <i>ws1</i>. A terminating null wide-character code is always appended to the result. Both functions return <i>ws1</i>; no return value is reserved to indicate an error.</p>
wscmp() , wscmp()	<p>The <code>wscmp()</code> and <code>wscmp()</code> functions compare the wide-character string pointed to by <i>ws1</i> to the wide-character string pointed to by <i>ws2</i>. The sign of a non-zero return value is determined by the sign of the difference between the values of the first pair of wide-character codes that differ in the objects being compared. Upon completion, both functions return an integer greater than, equal to, or less than zero, if the wide-character string pointed to by <i>ws1</i> is greater than, equal to, or less than the wide-character string pointed to by <i>ws2</i>.</p>

wcslen(3C)

wcsncmp(), wsncmp()	The <code>wcsncmp()</code> and <code>wsncmp()</code> functions compare not more than <i>n</i> wide-character codes (wide-character codes that follow a null wide character code are not compared) from the array pointed to by <i>ws1</i> to the array pointed to by <i>ws2</i> . The sign of a non-zero return value is determined by the sign of the difference between the values of the first pair of wide-character codes that differ in the objects being compared. Upon successful completion, both functions return an integer greater than, equal to, or less than zero, if the possibly null-terminated array pointed to by <i>ws1</i> is greater than, equal to, or less than the possibly null-terminated array pointed to by <i>ws2</i> .
wcscpy(), wscpy()	The <code>wcscpy()</code> and <code>wscpy()</code> functions copy the wide-character string pointed to by <i>ws2</i> (including the terminating null wide-character code) into the array pointed to by <i>ws1</i> . If copying takes place between objects that overlap, the behavior is undefined. Both functions return <i>ws1</i> ; no return value is reserved to indicate an error.
wcsncpy(), wsncpy()	The <code>wcsncpy()</code> and <code>wsncpy()</code> functions copy not more than <i>n</i> wide-character codes (wide-character codes that follow a null wide character code are not copied) from the array pointed to by <i>ws2</i> to the array pointed to by <i>ws1</i> . If copying takes place between objects that overlap, the behavior is undefined. If the array pointed to by <i>ws2</i> is a wide-character string that is shorter than <i>n</i> wide-character codes, null wide-character codes are appended to the copy in the array pointed to by <i>ws1</i> , until a total <i>n</i> wide-character codes are written. Both functions return <i>ws1</i> ; no return value is reserved to indicate an error.
wcslen(), wslen()	The <code>wcslen()</code> and <code>wslen()</code> functions compute the number of wide-character codes in the wide-character string to which <i>ws</i> points, not including the terminating null wide-character code. Both functions return <i>ws</i> ; no return value is reserved to indicate an error.
wcschr(), wschr()	The <code>wcschr()</code> and <code>wschr()</code> functions locate the first occurrence of <i>wc</i> in the wide-character string pointed to by <i>ws</i> . The value of <i>wc</i> must be a character representable as a type <code>wchar_t</code> and must be a wide-character code corresponding to a valid character in the current locale. The terminating null wide-character code is considered to be part of the wide-character string. Upon completion, both functions return a pointer to the wide-character code, or a null pointer if the wide-character code is not found.
wcsrchr(), wsrchr()	The <code>wcsrchr()</code> and <code>wsrchr()</code> functions locate the last occurrence of <i>wc</i> in the wide-character string pointed to by <i>ws</i> . The value of <i>wc</i> must be a character representable as a type <code>wchar_t</code> and must be a wide-character code corresponding to a valid character in the current locale. The terminating null wide-character code is considered to be part of the wide-character string. Upon successful completion, both functions return a pointer to the wide-character code, or a null pointer if <i>wc</i> does not occur in the wide-character string.
windex(), wrintdex()	The <code>windex()</code> and <code>wrintdex()</code> functions behave the same as <code>wschr()</code> and <code>wsrchr()</code> , respectively.

wcspbrk(), wspbrk()	The <code>wcspbrk()</code> and <code>wspbrk()</code> functions locate the first occurrence in the wide character string pointed to by <code>ws1</code> of any wide-character code from the wide-character string pointed to by <code>ws2</code> . Upon successful completion, the function returns a pointer to the wide-character code, or a null pointer if no wide-character code from <code>ws2</code> occurs in <code>ws1</code> .
wcswcs()	The <code>wcswcs()</code> function locates the first occurrence in the wide-character string pointed to by <code>ws1</code> of the sequence of wide-character codes (excluding the terminating null wide-character code) in the wide-character string pointed to by <code>ws2</code> . Upon successful completion, the function returns a pointer to the located wide-character string, or a null pointer if the wide-character string is not found. If <code>ws2</code> points to a wide-character string with zero length, the function returns <code>ws1</code> .
wcsspn(), wsspnl()	The <code>wcsspn()</code> and <code>wsspnl()</code> functions compute the length of the maximum initial segment of the wide-character string pointed to by <code>ws1</code> which consists entirely of wide-character codes from the wide-character string pointed to by <code>ws2</code> . Both functions return the length <code>ws1</code> ; no return value is reserved to indicate an error.
wcscspn(), wscspnl()	The <code>wcscspn()</code> and <code>wscspnl()</code> functions compute the length of the maximum initial segment of the wide-character string pointed to by <code>ws1</code> which consists entirely of wide-character codes <i>not</i> from the wide-character string pointed to by <code>ws2</code> . Both functions return the length of the initial substring of <code>ws1</code> ; no return value is reserved to indicate an error.
wcstok(), wstok()	A sequence of calls to the <code>wcstok()</code> and <code>wstok()</code> functions break the wide-character string pointed to by <code>ws1</code> into a sequence of tokens, each of which is delimited by a wide-character code from the wide-character string pointed to by <code>ws2</code> .
Default and other standards	<p>The third argument points to a caller-provided <code>wchar_t</code> pointer into which the <code>wcstok()</code> function stores information necessary for it to continue scanning the same wide-character string. This argument is not available with the XPG4 and SUS versions of <code>wcstok()</code>, nor is it available with the <code>wstok()</code> function. See <code>standards(5)</code>.</p> <p>The first call in the sequence has <code>ws1</code> as its first argument, and is followed by calls with a null pointer as their first argument. The separator string pointed to by <code>ws2</code> may be different from call to call.</p> <p>The first call in the sequence searches the wide-character string pointed to by <code>ws1</code> for the first wide-character code that is <i>not</i> contained in the current separator string pointed to by <code>ws2</code>. If no such wide-character code is found, then there are no tokens in the wide-character string pointed to by <code>ws1</code>, and <code>wcstok()</code> and <code>wstok()</code> return a null pointer. If such a wide-character code is found, it is the start of the first token.</p> <p>The <code>wcstok()</code> and <code>wstok()</code> functions then search from that point for a wide-character code that <i>is</i> contained in the current separator string. If no such wide-character code is found, the current token extends to the end of the wide-character string pointed to by <code>ws1</code>, and subsequent searches for a token will</p>

wcslen(3C)

return a null pointer. If such a wide-character code is found, it is overwritten by a null wide character, which terminates the current token. The `wcstok()` and `wstok()` functions save a pointer to the following wide-character code, from which the next search for a token will start.

Each subsequent call, with a null pointer as the value of the first argument, starts searching from the saved pointer and behaves as described above.

Upon successful completion, both functions return a pointer to the first wide-character code of a token. Otherwise, if there is no token, a null pointer is returned.

wcsncat(3C)

	<pre> size_t wscspn(const wchar_t *ws1, const wchar_t *ws2); wchar_t *wstok(wchar_t *ws1, const wchar_t *ws2); wchar_t *windex(const wchar_t *ws, wchar_t wc); wchar_t *wrindex(const wchar_t *ws, wchar_t wc); </pre>
ISO C++	<pre> #include <wchar.h> const wchar_t *wcschr(const wchar_t *ws, wchar_t wc); const wchar_t *wcspbrk(const wchar_t *ws1, const wchar_t *ws2); const wchar_t *wcsrchr(const wchar_t *ws, wchar_t wc); #include <cwchar> wchar_t *std::wcschr(wchar_t *ws, wchar_t wc); wchar_t *std::wcspbrk(wchar_t *ws1, const wchar_t *ws2); wchar_t *std::wcsrchr(wchar_t *ws, wchar_t wc); </pre>
DESCRIPTION	<p>These functions operate on wide-character strings terminated by <code>wchar_t</code> <code>NULL</code> characters. During appending or copying, these routines do not check for an overflow condition of the receiving string. In the following, <i>ws</i>, <i>ws1</i>, and <i>ws2</i> point to wide-character strings terminated by a <code>wchar_t</code> <code>NULL</code>.</p>
wscat(), wscat()	<p>The <code>wscat()</code> and <code>wscat()</code> functions append a copy of the wide-character string pointed to by <i>ws2</i> (including the terminating null wide-character code) to the end of the wide-character string pointed to by <i>ws1</i>. The initial wide-character code of <i>ws2</i> overwrites the null wide-character code at the end of <i>ws1</i>. If copying takes place between objects that overlap, the behavior is undefined. Both functions return <i>s1</i>; no return value is reserved to indicate an error.</p>
wcsncat(), wsncat()	<p>The <code>wcsncat()</code> and <code>wsncat()</code> functions append not more than <i>n</i> wide-character codes (a null wide-character code and wide-character codes that follow it are not appended) from the array pointed to by <i>ws2</i> to the end of the wide-character string pointed to by <i>ws1</i>. The initial wide-character code of <i>ws2</i> overwrites the null wide-character code at the end of <i>ws1</i>. A terminating null wide-character code is always appended to the result. Both functions return <i>ws1</i>; no return value is reserved to indicate an error.</p>
wcscmp(), wcscmp()	<p>The <code>wcscmp()</code> and <code>wcscmp()</code> functions compare the wide-character string pointed to by <i>ws1</i> to the wide-character string pointed to by <i>ws2</i>. The sign of a non-zero return value is determined by the sign of the difference between the values of the first pair of wide-character codes that differ in the objects being compared. Upon completion, both functions return an integer greater than, equal to, or less than zero, if the wide-character string pointed to by <i>ws1</i> is greater than, equal to, or less than the wide-character string pointed to by <i>ws2</i>.</p>

wcsncmp() , wsncmp()	The <code>wcsncmp()</code> and <code>wsncmp()</code> functions compare not more than <i>n</i> wide-character codes (wide-character codes that follow a null wide character code are not compared) from the array pointed to by <i>ws1</i> to the array pointed to by <i>ws2</i> . The sign of a non-zero return value is determined by the sign of the difference between the values of the first pair of wide-character codes that differ in the objects being compared. Upon successful completion, both functions return an integer greater than, equal to, or less than zero, if the possibly null-terminated array pointed to by <i>ws1</i> is greater than, equal to, or less than the possibly null-terminated array pointed to by <i>ws2</i> .
wscpy() , wscopy()	The <code>wscpy()</code> and <code>wscopy()</code> functions copy the wide-character string pointed to by <i>ws2</i> (including the terminating null wide-character code) into the array pointed to by <i>ws1</i> . If copying takes place between objects that overlap, the behavior is undefined. Both functions return <i>ws1</i> ; no return value is reserved to indicate an error.
wcsncpy() , wsncpy()	The <code>wcsncpy()</code> and <code>wsncpy()</code> functions copy not more than <i>n</i> wide-character codes (wide-character codes that follow a null wide character code are not copied) from the array pointed to by <i>ws2</i> to the array pointed to by <i>ws1</i> . If copying takes place between objects that overlap, the behavior is undefined. If the array pointed to by <i>ws2</i> is a wide-character string that is shorter than <i>n</i> wide-character codes, null wide-character codes are appended to the copy in the array pointed to by <i>ws1</i> , until a total <i>n</i> wide-character codes are written. Both functions return <i>ws1</i> ; no return value is reserved to indicate an error.
wcslen() , wslen()	The <code>wcslen()</code> and <code>wslen()</code> functions compute the number of wide-character codes in the wide-character string to which <i>ws</i> points, not including the terminating null wide-character code. Both functions return <i>ws</i> ; no return value is reserved to indicate an error.
wcschr() , wschr()	The <code>wcschr()</code> and <code>wschr()</code> functions locate the first occurrence of <i>wc</i> in the wide-character string pointed to by <i>ws</i> . The value of <i>wc</i> must be a character representable as a type <code>wchar_t</code> and must be a wide-character code corresponding to a valid character in the current locale. The terminating null wide-character code is considered to be part of the wide-character string. Upon completion, both functions return a pointer to the wide-character code, or a null pointer if the wide-character code is not found.
wcsrchr() , wsrchr()	The <code>wcsrchr()</code> and <code>wsrchr()</code> functions locate the last occurrence of <i>wc</i> in the wide-character string pointed to by <i>ws</i> . The value of <i>wc</i> must be a character representable as a type <code>wchar_t</code> and must be a wide-character code corresponding to a valid character in the current locale. The terminating null wide-character code is considered to be part of the wide-character string. Upon successful completion, both functions return a pointer to the wide-character code, or a null pointer if <i>wc</i> does not occur in the wide-character string.
windex() , wrindex()	The <code>windex()</code> and <code>wrindex()</code> functions behave the same as <code>wschr()</code> and <code>wsrchr()</code> , respectively.

wcsncat(3C)

wcspbrk() , wspbrk()	The <code>wcspbrk()</code> and <code>wspbrk()</code> functions locate the first occurrence in the wide character string pointed to by <code>ws1</code> of any wide-character code from the wide-character string pointed to by <code>ws2</code> . Upon successful completion, the function returns a pointer to the wide-character code, or a null pointer if no wide-character code from <code>ws2</code> occurs in <code>ws1</code> .
wcswcs()	The <code>wcswcs()</code> function locates the first occurrence in the wide-character string pointed to by <code>ws1</code> of the sequence of wide-character codes (excluding the terminating null wide-character code) in the wide-character string pointed to by <code>ws2</code> . Upon successful completion, the function returns a pointer to the located wide-character string, or a null pointer if the wide-character string is not found. If <code>ws2</code> points to a wide-character string with zero length, the function returns <code>ws1</code> .
wcsspn() , wsspnl()	The <code>wcsspn()</code> and <code>wsspnl()</code> functions compute the length of the maximum initial segment of the wide-character string pointed to by <code>ws1</code> which consists entirely of wide-character codes from the wide-character string pointed to by <code>ws2</code> . Both functions return the length <code>ws1</code> ; no return value is reserved to indicate an error.
wcscspn() , wcscspnl()	The <code>wcscspn()</code> and <code>wcscspnl()</code> functions compute the length of the maximum initial segment of the wide-character string pointed to by <code>ws1</code> which consists entirely of wide-character codes <i>not</i> from the wide-character string pointed to by <code>ws2</code> . Both functions return the length of the initial substring of <code>ws1</code> ; no return value is reserved to indicate an error.
wcstok() , wstok()	A sequence of calls to the <code>wcstok()</code> and <code>wstok()</code> functions break the wide-character string pointed to by <code>ws1</code> into a sequence of tokens, each of which is delimited by a wide-character code from the wide-character string pointed to by <code>ws2</code> .
Default and other standards	<p>The third argument points to a caller-provided <code>wchar_t</code> pointer into which the <code>wcstok()</code> function stores information necessary for it to continue scanning the same wide-character string. This argument is not available with the XPG4 and SUS versions of <code>wcstok()</code>, nor is it available with the <code>wstok()</code> function. See <code>standards(5)</code>.</p> <p>The first call in the sequence has <code>ws1</code> as its first argument, and is followed by calls with a null pointer as their first argument. The separator string pointed to by <code>ws2</code> may be different from call to call.</p> <p>The first call in the sequence searches the wide-character string pointed to by <code>ws1</code> for the first wide-character code that is <i>not</i> contained in the current separator string pointed to by <code>ws2</code>. If no such wide-character code is found, then there are no tokens in the wide-character string pointed to by <code>ws1</code>, and <code>wcstok()</code> and <code>wstok()</code> return a null pointer. If such a wide-character code is found, it is the start of the first token.</p> <p>The <code>wcstok()</code> and <code>wstok()</code> functions then search from that point for a wide-character code that <i>is</i> contained in the current separator string. If no such wide-character code is found, the current token extends to the end of the wide-character string pointed to by <code>ws1</code>, and subsequent searches for a token will</p>

wcsncat(3C)

return a null pointer. If such a wide-character code is found, it is overwritten by a null wide character, which terminates the current token. The `wcstok()` and `wstok()` functions save a pointer to the following wide-character code, from which the next search for a token will start.

Each subsequent call, with a null pointer as the value of the first argument, starts searching from the saved pointer and behaves as described above.

Upon successful completion, both functions return a pointer to the first wide-character code of a token. Otherwise, if there is no token, a null pointer is returned.

Upon completion, both functions return an integer greater than, equal to, or less than zero, if the wide-character string pointed to by <i>ws1</i> is greater than, equal to, or less than the wide-character string pointed to by <i>ws2</i>.</p>

wcsncmp(3C)

wcsncmp(), wsncmp()	The <code>wcsncmp()</code> and <code>wsncmp()</code> functions compare not more than <i>n</i> wide-character codes (wide-character codes that follow a null wide character code are not compared) from the array pointed to by <i>ws1</i> to the array pointed to by <i>ws2</i> . The sign of a non-zero return value is determined by the sign of the difference between the values of the first pair of wide-character codes that differ in the objects being compared. Upon successful completion, both functions return an integer greater than, equal to, or less than zero, if the possibly null-terminated array pointed to by <i>ws1</i> is greater than, equal to, or less than the possibly null-terminated array pointed to by <i>ws2</i> .
wcscpy(), wscpy()	The <code>wcscpy()</code> and <code>wscpy()</code> functions copy the wide-character string pointed to by <i>ws2</i> (including the terminating null wide-character code) into the array pointed to by <i>ws1</i> . If copying takes place between objects that overlap, the behavior is undefined. Both functions return <i>ws1</i> ; no return value is reserved to indicate an error.
wcsncpy(), wsncpy()	The <code>wcsncpy()</code> and <code>wsncpy()</code> functions copy not more than <i>n</i> wide-character codes (wide-character codes that follow a null wide character code are not copied) from the array pointed to by <i>ws2</i> to the array pointed to by <i>ws1</i> . If copying takes place between objects that overlap, the behavior is undefined. If the array pointed to by <i>ws2</i> is a wide-character string that is shorter than <i>n</i> wide-character codes, null wide-character codes are appended to the copy in the array pointed to by <i>ws1</i> , until a total <i>n</i> wide-character codes are written. Both functions return <i>ws1</i> ; no return value is reserved to indicate an error.
wcslen(), wslen()	The <code>wcslen()</code> and <code>wslen()</code> functions compute the number of wide-character codes in the wide-character string to which <i>ws</i> points, not including the terminating null wide-character code. Both functions return <i>ws</i> ; no return value is reserved to indicate an error.
wcschr(), wschr()	The <code>wcschr()</code> and <code>wschr()</code> functions locate the first occurrence of <i>wc</i> in the wide-character string pointed to by <i>ws</i> . The value of <i>wc</i> must be a character representable as a type <code>wchar_t</code> and must be a wide-character code corresponding to a valid character in the current locale. The terminating null wide-character code is considered to be part of the wide-character string. Upon completion, both functions return a pointer to the wide-character code, or a null pointer if the wide-character code is not found.
wcsrchr(), wsrchr()	The <code>wcsrchr()</code> and <code>wsrchr()</code> functions locate the last occurrence of <i>wc</i> in the wide-character string pointed to by <i>ws</i> . The value of <i>wc</i> must be a character representable as a type <code>wchar_t</code> and must be a wide-character code corresponding to a valid character in the current locale. The terminating null wide-character code is considered to be part of the wide-character string. Upon successful completion, both functions return a pointer to the wide-character code, or a null pointer if <i>wc</i> does not occur in the wide-character string.
windex(), wrintdex()	The <code>windex()</code> and <code>wrintdex()</code> functions behave the same as <code>wschr()</code> and <code>wsrchr()</code> , respectively.

wcspbrk() , wspbrk()	The <code>wcspbrk()</code> and <code>wspbrk()</code> functions locate the first occurrence in the wide character string pointed to by <code>ws1</code> of any wide-character code from the wide-character string pointed to by <code>ws2</code> . Upon successful completion, the function returns a pointer to the wide-character code, or a null pointer if no wide-character code from <code>ws2</code> occurs in <code>ws1</code> .
wcswcs()	The <code>wcswcs()</code> function locates the first occurrence in the wide-character string pointed to by <code>ws1</code> of the sequence of wide-character codes (excluding the terminating null wide-character code) in the wide-character string pointed to by <code>ws2</code> . Upon successful completion, the function returns a pointer to the located wide-character string, or a null pointer if the wide-character string is not found. If <code>ws2</code> points to a wide-character string with zero length, the function returns <code>ws1</code> .
wcsspn() , wsspnl()	The <code>wcsspn()</code> and <code>wsspnl()</code> functions compute the length of the maximum initial segment of the wide-character string pointed to by <code>ws1</code> which consists entirely of wide-character codes from the wide-character string pointed to by <code>ws2</code> . Both functions return the length <code>ws1</code> ; no return value is reserved to indicate an error.
wcscspn() , wscspnl()	The <code>wcscspn()</code> and <code>wscspnl()</code> functions compute the length of the maximum initial segment of the wide-character string pointed to by <code>ws1</code> which consists entirely of wide-character codes <i>not</i> from the wide-character string pointed to by <code>ws2</code> . Both functions return the length of the initial substring of <code>ws1</code> ; no return value is reserved to indicate an error.
wcstok() , wstok()	A sequence of calls to the <code>wcstok()</code> and <code>wstok()</code> functions break the wide-character string pointed to by <code>ws1</code> into a sequence of tokens, each of which is delimited by a wide-character code from the wide-character string pointed to by <code>ws2</code> .
Default and other standards	<p>The third argument points to a caller-provided <code>wchar_t</code> pointer into which the <code>wcstok()</code> function stores information necessary for it to continue scanning the same wide-character string. This argument is not available with the XPG4 and SUS versions of <code>wcstok()</code>, nor is it available with the <code>wstok()</code> function. See <code>standards(5)</code>.</p> <p>The first call in the sequence has <code>ws1</code> as its first argument, and is followed by calls with a null pointer as their first argument. The separator string pointed to by <code>ws2</code> may be different from call to call.</p> <p>The first call in the sequence searches the wide-character string pointed to by <code>ws1</code> for the first wide-character code that is <i>not</i> contained in the current separator string pointed to by <code>ws2</code>. If no such wide-character code is found, then there are no tokens in the wide-character string pointed to by <code>ws1</code>, and <code>wcstok()</code> and <code>wstok()</code> return a null pointer. If such a wide-character code is found, it is the start of the first token.</p> <p>The <code>wcstok()</code> and <code>wstok()</code> functions then search from that point for a wide-character code that <i>is</i> contained in the current separator string. If no such wide-character code is found, the current token extends to the end of the wide-character string pointed to by <code>ws1</code>, and subsequent searches for a token will</p>

wcsncmp(3C)

return a null pointer. If such a wide-character code is found, it is overwritten by a null wide character, which terminates the current token. The `wcstok()` and `wstok()` functions save a pointer to the following wide-character code, from which the next search for a token will start.

Each subsequent call, with a null pointer as the value of the first argument, starts searching from the saved pointer and behaves as described above.

Upon successful completion, both functions return a pointer to the first wide-character code of a token. Otherwise, if there is no token, a null pointer is returned.

wcsncpy(3C)

	<pre> size_t wscspn(const wchar_t *ws1, const wchar_t *ws2); wchar_t *wstok(wchar_t *ws1, const wchar_t *ws2); wchar_t *windex(const wchar_t *ws, wchar_t wc); wchar_t *wrindex(const wchar_t *ws, wchar_t wc); </pre>
ISO C++	<pre> #include <wchar.h> const wchar_t *wcschr(const wchar_t *ws, wchar_t wc); const wchar_t *wcspbrk(const wchar_t *ws1, const wchar_t *ws2); const wchar_t *wcsrchr(const wchar_t *ws, wchar_t wc); #include <cwchar> wchar_t *std::wcschr(wchar_t *ws, wchar_t wc); wchar_t *std::wcspbrk(wchar_t *ws1, const wchar_t *ws2); wchar_t *std::wcsrchr(wchar_t *ws, wchar_t wc); </pre>
DESCRIPTION	<p>These functions operate on wide-character strings terminated by <code>wchar_t</code> <code>NULL</code> characters. During appending or copying, these routines do not check for an overflow condition of the receiving string. In the following, <i>ws</i>, <i>ws1</i>, and <i>ws2</i> point to wide-character strings terminated by a <code>wchar_t</code> <code>NULL</code>.</p>
wscat(), wscat()	<p>The <code>wscat()</code> and <code>wscat()</code> functions append a copy of the wide-character string pointed to by <i>ws2</i> (including the terminating null wide-character code) to the end of the wide-character string pointed to by <i>ws1</i>. The initial wide-character code of <i>ws2</i> overwrites the null wide-character code at the end of <i>ws1</i>. If copying takes place between objects that overlap, the behavior is undefined. Both functions return <i>s1</i>; no return value is reserved to indicate an error.</p>
wcsncat(), wsncat()	<p>The <code>wcsncat()</code> and <code>wsncat()</code> functions append not more than <i>n</i> wide-character codes (a null wide-character code and wide-character codes that follow it are not appended) from the array pointed to by <i>ws2</i> to the end of the wide-character string pointed to by <i>ws1</i>. The initial wide-character code of <i>ws2</i> overwrites the null wide-character code at the end of <i>ws1</i>. A terminating null wide-character code is always appended to the result. Both functions return <i>ws1</i>; no return value is reserved to indicate an error.</p>
wcscmp(), wcscmp()	<p>The <code>wcscmp()</code> and <code>wcscmp()</code> functions compare the wide-character string pointed to by <i>ws1</i> to the wide-character string pointed to by <i>ws2</i>. The sign of a non-zero return value is determined by the sign of the difference between the values of the first pair of wide-character codes that differ in the objects being compared. Upon completion, both functions return an integer greater than, equal to, or less than zero, if the wide-character string pointed to by <i>ws1</i> is greater than, equal to, or less than the wide-character string pointed to by <i>ws2</i>.</p>

wcsncmp() , wsncmp()	The <code>wcsncmp()</code> and <code>wsncmp()</code> functions compare not more than <i>n</i> wide-character codes (wide-character codes that follow a null wide character code are not compared) from the array pointed to by <i>ws1</i> to the array pointed to by <i>ws2</i> . The sign of a non-zero return value is determined by the sign of the difference between the values of the first pair of wide-character codes that differ in the objects being compared. Upon successful completion, both functions return an integer greater than, equal to, or less than zero, if the possibly null-terminated array pointed to by <i>ws1</i> is greater than, equal to, or less than the possibly null-terminated array pointed to by <i>ws2</i> .
wscpy() , wscopy()	The <code>wscpy()</code> and <code>wscopy()</code> functions copy the wide-character string pointed to by <i>ws2</i> (including the terminating null wide-character code) into the array pointed to by <i>ws1</i> . If copying takes place between objects that overlap, the behavior is undefined. Both functions return <i>ws1</i> ; no return value is reserved to indicate an error.
wcsncpy() , wsncpy()	The <code>wcsncpy()</code> and <code>wsncpy()</code> functions copy not more than <i>n</i> wide-character codes (wide-character codes that follow a null wide character code are not copied) from the array pointed to by <i>ws2</i> to the array pointed to by <i>ws1</i> . If copying takes place between objects that overlap, the behavior is undefined. If the array pointed to by <i>ws2</i> is a wide-character string that is shorter than <i>n</i> wide-character codes, null wide-character codes are appended to the copy in the array pointed to by <i>ws1</i> , until a total <i>n</i> wide-character codes are written. Both functions return <i>ws1</i> ; no return value is reserved to indicate an error.
wcslen() , wslen()	The <code>wcslen()</code> and <code>wslen()</code> functions compute the number of wide-character codes in the wide-character string to which <i>ws</i> points, not including the terminating null wide-character code. Both functions return <i>ws</i> ; no return value is reserved to indicate an error.
wcschr() , wschr()	The <code>wcschr()</code> and <code>wschr()</code> functions locate the first occurrence of <i>wc</i> in the wide-character string pointed to by <i>ws</i> . The value of <i>wc</i> must be a character representable as a type <code>wchar_t</code> and must be a wide-character code corresponding to a valid character in the current locale. The terminating null wide-character code is considered to be part of the wide-character string. Upon completion, both functions return a pointer to the wide-character code, or a null pointer if the wide-character code is not found.
wcsrchr() , wsrchr()	The <code>wcsrchr()</code> and <code>wsrchr()</code> functions locate the last occurrence of <i>wc</i> in the wide-character string pointed to by <i>ws</i> . The value of <i>wc</i> must be a character representable as a type <code>wchar_t</code> and must be a wide-character code corresponding to a valid character in the current locale. The terminating null wide-character code is considered to be part of the wide-character string. Upon successful completion, both functions return a pointer to the wide-character code, or a null pointer if <i>wc</i> does not occur in the wide-character string.
windex() , wrindex()	The <code>windex()</code> and <code>wrindex()</code> functions behave the same as <code>wschr()</code> and <code>wsrchr()</code> , respectively.

wcsncpy(3C)

wcspbrk() , wspbrk()	The <code>wcspbrk()</code> and <code>wspbrk()</code> functions locate the first occurrence in the wide character string pointed to by <code>ws1</code> of any wide-character code from the wide-character string pointed to by <code>ws2</code> . Upon successful completion, the function returns a pointer to the wide-character code, or a null pointer if no wide-character code from <code>ws2</code> occurs in <code>ws1</code> .
wcswcs()	The <code>wcswcs()</code> function locates the first occurrence in the wide-character string pointed to by <code>ws1</code> of the sequence of wide-character codes (excluding the terminating null wide-character code) in the wide-character string pointed to by <code>ws2</code> . Upon successful completion, the function returns a pointer to the located wide-character string, or a null pointer if the wide-character string is not found. If <code>ws2</code> points to a wide-character string with zero length, the function returns <code>ws1</code> .
wcsspn() , wsspnl()	The <code>wcsspn()</code> and <code>wsspnl()</code> functions compute the length of the maximum initial segment of the wide-character string pointed to by <code>ws1</code> which consists entirely of wide-character codes from the wide-character string pointed to by <code>ws2</code> . Both functions return the length <code>ws1</code> ; no return value is reserved to indicate an error.
wcscspn() , wscspnl()	The <code>wcscspn()</code> and <code>wscspnl()</code> functions compute the length of the maximum initial segment of the wide-character string pointed to by <code>ws1</code> which consists entirely of wide-character codes <i>not</i> from the wide-character string pointed to by <code>ws2</code> . Both functions return the length of the initial substring of <code>ws1</code> ; no return value is reserved to indicate an error.
wcstok() , wstok()	A sequence of calls to the <code>wcstok()</code> and <code>wstok()</code> functions break the wide-character string pointed to by <code>ws1</code> into a sequence of tokens, each of which is delimited by a wide-character code from the wide-character string pointed to by <code>ws2</code> .
Default and other standards	<p>The third argument points to a caller-provided <code>wchar_t</code> pointer into which the <code>wcstok()</code> function stores information necessary for it to continue scanning the same wide-character string. This argument is not available with the XPG4 and SUS versions of <code>wcstok()</code>, nor is it available with the <code>wstok()</code> function. See <code>standards(5)</code>.</p> <p>The first call in the sequence has <code>ws1</code> as its first argument, and is followed by calls with a null pointer as their first argument. The separator string pointed to by <code>ws2</code> may be different from call to call.</p> <p>The first call in the sequence searches the wide-character string pointed to by <code>ws1</code> for the first wide-character code that is <i>not</i> contained in the current separator string pointed to by <code>ws2</code>. If no such wide-character code is found, then there are no tokens in the wide-character string pointed to by <code>ws1</code>, and <code>wcstok()</code> and <code>wstok()</code> return a null pointer. If such a wide-character code is found, it is the start of the first token.</p> <p>The <code>wcstok()</code> and <code>wstok()</code> functions then search from that point for a wide-character code that <i>is</i> contained in the current separator string. If no such wide-character code is found, the current token extends to the end of the wide-character string pointed to by <code>ws1</code>, and subsequent searches for a token will</p>

wcsncpy(3C)

return a null pointer. If such a wide-character code is found, it is overwritten by a null wide character, which terminates the current token. The `wcstok()` and `wstok()` functions save a pointer to the following wide-character code, from which the next search for a token will start.

Each subsequent call, with a null pointer as the value of the first argument, starts searching from the saved pointer and behaves as described above.

Upon successful completion, both functions return a pointer to the first wide-character code of a token. Otherwise, if there is no token, a null pointer is returned.

Upon completion, both functions return an integer greater than, equal to, or less than zero, if the wide-character string pointed to by <i>ws1</i> is greater than, equal to, or less than the wide-character string pointed to by <i>ws2</i>.</p>

wcspbrk(3C)

wcsncmp(), wsncmp()	The <code>wcsncmp()</code> and <code>wsncmp()</code> functions compare not more than <i>n</i> wide-character codes (wide-character codes that follow a null wide character code are not compared) from the array pointed to by <i>ws1</i> to the array pointed to by <i>ws2</i> . The sign of a non-zero return value is determined by the sign of the difference between the values of the first pair of wide-character codes that differ in the objects being compared. Upon successful completion, both functions return an integer greater than, equal to, or less than zero, if the possibly null-terminated array pointed to by <i>ws1</i> is greater than, equal to, or less than the possibly null-terminated array pointed to by <i>ws2</i> .
wcscopy(), wscopy()	The <code>wcscopy()</code> and <code>wscopy()</code> functions copy the wide-character string pointed to by <i>ws2</i> (including the terminating null wide-character code) into the array pointed to by <i>ws1</i> . If copying takes place between objects that overlap, the behavior is undefined. Both functions return <i>ws1</i> ; no return value is reserved to indicate an error.
wcsncpy(), wsncpy()	The <code>wcsncpy()</code> and <code>wsncpy()</code> functions copy not more than <i>n</i> wide-character codes (wide-character codes that follow a null wide character code are not copied) from the array pointed to by <i>ws2</i> to the array pointed to by <i>ws1</i> . If copying takes place between objects that overlap, the behavior is undefined. If the array pointed to by <i>ws2</i> is a wide-character string that is shorter than <i>n</i> wide-character codes, null wide-character codes are appended to the copy in the array pointed to by <i>ws1</i> , until a total <i>n</i> wide-character codes are written. Both functions return <i>ws1</i> ; no return value is reserved to indicate an error.
wcslen(), wslen()	The <code>wcslen()</code> and <code>wslen()</code> functions compute the number of wide-character codes in the wide-character string to which <i>ws</i> points, not including the terminating null wide-character code. Both functions return <i>ws</i> ; no return value is reserved to indicate an error.
wcschr(), wschr()	The <code>wcschr()</code> and <code>wschr()</code> functions locate the first occurrence of <i>wc</i> in the wide-character string pointed to by <i>ws</i> . The value of <i>wc</i> must be a character representable as a type <code>wchar_t</code> and must be a wide-character code corresponding to a valid character in the current locale. The terminating null wide-character code is considered to be part of the wide-character string. Upon completion, both functions return a pointer to the wide-character code, or a null pointer if the wide-character code is not found.
wcsrchr(), wsrchr()	The <code>wcsrchr()</code> and <code>wsrchr()</code> functions locate the last occurrence of <i>wc</i> in the wide-character string pointed to by <i>ws</i> . The value of <i>wc</i> must be a character representable as a type <code>wchar_t</code> and must be a wide-character code corresponding to a valid character in the current locale. The terminating null wide-character code is considered to be part of the wide-character string. Upon successful completion, both functions return a pointer to the wide-character code, or a null pointer if <i>wc</i> does not occur in the wide-character string.
windex(), wrintdex()	The <code>windex()</code> and <code>wrintdex()</code> functions behave the same as <code>wschr()</code> and <code>wsrchr()</code> , respectively.

wcpbrk(), wspbrk()	The <code>wcpbrk()</code> and <code>wspbrk()</code> functions locate the first occurrence in the wide character string pointed to by <code>ws1</code> of any wide-character code from the wide-character string pointed to by <code>ws2</code> . Upon successful completion, the function returns a pointer to the wide-character code, or a null pointer if no wide-character code from <code>ws2</code> occurs in <code>ws1</code> .
wcswcs()	The <code>wcswcs()</code> function locates the first occurrence in the wide-character string pointed to by <code>ws1</code> of the sequence of wide-character codes (excluding the terminating null wide-character code) in the wide-character string pointed to by <code>ws2</code> . Upon successful completion, the function returns a pointer to the located wide-character string, or a null pointer if the wide-character string is not found. If <code>ws2</code> points to a wide-character string with zero length, the function returns <code>ws1</code> .
wcsspn(), wsspnl()	The <code>wcsspn()</code> and <code>wsspnl()</code> functions compute the length of the maximum initial segment of the wide-character string pointed to by <code>ws1</code> which consists entirely of wide-character codes from the wide-character string pointed to by <code>ws2</code> . Both functions return the length <code>ws1</code> ; no return value is reserved to indicate an error.
wcscspnl(), wscspnl()	The <code>wcscspnl()</code> and <code>wscspnl()</code> functions compute the length of the maximum initial segment of the wide-character string pointed to by <code>ws1</code> which consists entirely of wide-character codes <i>not</i> from the wide-character string pointed to by <code>ws2</code> . Both functions return the length of the initial substring of <code>ws1</code> ; no return value is reserved to indicate an error.
wcstok(), wstok()	A sequence of calls to the <code>wcstok()</code> and <code>wstok()</code> functions break the wide-character string pointed to by <code>ws1</code> into a sequence of tokens, each of which is delimited by a wide-character code from the wide-character string pointed to by <code>ws2</code> .
Default and other standards	<p>The third argument points to a caller-provided <code>wchar_t</code> pointer into which the <code>wcstok()</code> function stores information necessary for it to continue scanning the same wide-character string. This argument is not available with the XPG4 and SUS versions of <code>wcstok()</code>, nor is it available with the <code>wstok()</code> function. See <code>standards(5)</code>.</p> <p>The first call in the sequence has <code>ws1</code> as its first argument, and is followed by calls with a null pointer as their first argument. The separator string pointed to by <code>ws2</code> may be different from call to call.</p> <p>The first call in the sequence searches the wide-character string pointed to by <code>ws1</code> for the first wide-character code that is <i>not</i> contained in the current separator string pointed to by <code>ws2</code>. If no such wide-character code is found, then there are no tokens in the wide-character string pointed to by <code>ws1</code>, and <code>wcstok()</code> and <code>wstok()</code> return a null pointer. If such a wide-character code is found, it is the start of the first token.</p> <p>The <code>wcstok()</code> and <code>wstok()</code> functions then search from that point for a wide-character code that <i>is</i> contained in the current separator string. If no such wide-character code is found, the current token extends to the end of the wide-character string pointed to by <code>ws1</code>, and subsequent searches for a token will</p>

wcspbrk(3C)

return a null pointer. If such a wide-character code is found, it is overwritten by a null wide character, which terminates the current token. The `wcstok()` and `wstok()` functions save a pointer to the following wide-character code, from which the next search for a token will start.

Each subsequent call, with a null pointer as the value of the first argument, starts searching from the saved pointer and behaves as described above.

Upon successful completion, both functions return a pointer to the first wide-character code of a token. Otherwise, if there is no token, a null pointer is returned.

wcsrchr(3C)

	<pre> size_t wscspn(const wchar_t *ws1, const wchar_t *ws2); wchar_t *wstok(wchar_t *ws1, const wchar_t *ws2); wchar_t *windex(const wchar_t *ws, wchar_t wc); wchar_t *wrindex(const wchar_t *ws, wchar_t wc); </pre>
ISO C++	<pre> #include <wchar.h> const wchar_t *wcschr(const wchar_t *ws, wchar_t wc); const wchar_t *wcspbrk(const wchar_t *ws1, const wchar_t *ws2); const wchar_t *wcsrchr(const wchar_t *ws, wchar_t wc); #include <cwchar> wchar_t *std::wcschr(wchar_t *ws, wchar_t wc); wchar_t *std::wcspbrk(wchar_t *ws1, const wchar_t *ws2); wchar_t *std::wcsrchr(wchar_t *ws, wchar_t wc); </pre>
DESCRIPTION	<p>These functions operate on wide-character strings terminated by <code>wchar_t</code> <code>NULL</code> characters. During appending or copying, these routines do not check for an overflow condition of the receiving string. In the following, <i>ws</i>, <i>ws1</i>, and <i>ws2</i> point to wide-character strings terminated by a <code>wchar_t</code> <code>NULL</code>.</p>
wscat(), wscat()	<p>The <code>wscat()</code> and <code>wscat()</code> functions append a copy of the wide-character string pointed to by <i>ws2</i> (including the terminating null wide-character code) to the end of the wide-character string pointed to by <i>ws1</i>. The initial wide-character code of <i>ws2</i> overwrites the null wide-character code at the end of <i>ws1</i>. If copying takes place between objects that overlap, the behavior is undefined. Both functions return <i>s1</i>; no return value is reserved to indicate an error.</p>
wcsncat(), wsncat()	<p>The <code>wcsncat()</code> and <code>wsncat()</code> functions append not more than <i>n</i> wide-character codes (a null wide-character code and wide-character codes that follow it are not appended) from the array pointed to by <i>ws2</i> to the end of the wide-character string pointed to by <i>ws1</i>. The initial wide-character code of <i>ws2</i> overwrites the null wide-character code at the end of <i>ws1</i>. A terminating null wide-character code is always appended to the result. Both functions return <i>ws1</i>; no return value is reserved to indicate an error.</p>
wscmp(), wscmp()	<p>The <code>wscmp()</code> and <code>wscmp()</code> functions compare the wide-character string pointed to by <i>ws1</i> to the wide-character string pointed to by <i>ws2</i>. The sign of a non-zero return value is determined by the sign of the difference between the values of the first pair of wide-character codes that differ in the objects being compared. Upon completion, both functions return an integer greater than, equal to, or less than zero, if the wide-character string pointed to by <i>ws1</i> is greater than, equal to, or less than the wide-character string pointed to by <i>ws2</i>.</p>

wcsncmp() , wsncmp()	The <code>wcsncmp()</code> and <code>wsncmp()</code> functions compare not more than <i>n</i> wide-character codes (wide-character codes that follow a null wide character code are not compared) from the array pointed to by <i>ws1</i> to the array pointed to by <i>ws2</i> . The sign of a non-zero return value is determined by the sign of the difference between the values of the first pair of wide-character codes that differ in the objects being compared. Upon successful completion, both functions return an integer greater than, equal to, or less than zero, if the possibly null-terminated array pointed to by <i>ws1</i> is greater than, equal to, or less than the possibly null-terminated array pointed to by <i>ws2</i> .
wscpy() , wscopy()	The <code>wscpy()</code> and <code>wscopy()</code> functions copy the wide-character string pointed to by <i>ws2</i> (including the terminating null wide-character code) into the array pointed to by <i>ws1</i> . If copying takes place between objects that overlap, the behavior is undefined. Both functions return <i>ws1</i> ; no return value is reserved to indicate an error.
wcsncpy() , wsncpy()	The <code>wcsncpy()</code> and <code>wsncpy()</code> functions copy not more than <i>n</i> wide-character codes (wide-character codes that follow a null wide character code are not copied) from the array pointed to by <i>ws2</i> to the array pointed to by <i>ws1</i> . If copying takes place between objects that overlap, the behavior is undefined. If the array pointed to by <i>ws2</i> is a wide-character string that is shorter than <i>n</i> wide-character codes, null wide-character codes are appended to the copy in the array pointed to by <i>ws1</i> , until a total <i>n</i> wide-character codes are written. Both functions return <i>ws1</i> ; no return value is reserved to indicate an error.
wcslen() , wslen()	The <code>wcslen()</code> and <code>wslen()</code> functions compute the number of wide-character codes in the wide-character string to which <i>ws</i> points, not including the terminating null wide-character code. Both functions return <i>ws</i> ; no return value is reserved to indicate an error.
wcschr() , wschr()	The <code>wcschr()</code> and <code>wschr()</code> functions locate the first occurrence of <i>wc</i> in the wide-character string pointed to by <i>ws</i> . The value of <i>wc</i> must be a character representable as a type <code>wchar_t</code> and must be a wide-character code corresponding to a valid character in the current locale. The terminating null wide-character code is considered to be part of the wide-character string. Upon completion, both functions return a pointer to the wide-character code, or a null pointer if the wide-character code is not found.
wcsrchr() , wsrchr()	The <code>wcsrchr()</code> and <code>wsrchr()</code> functions locate the last occurrence of <i>wc</i> in the wide-character string pointed to by <i>ws</i> . The value of <i>wc</i> must be a character representable as a type <code>wchar_t</code> and must be a wide-character code corresponding to a valid character in the current locale. The terminating null wide-character code is considered to be part of the wide-character string. Upon successful completion, both functions return a pointer to the wide-character code, or a null pointer if <i>wc</i> does not occur in the wide-character string.
windex() , wrindex()	The <code>windex()</code> and <code>wrindex()</code> functions behave the same as <code>wschr()</code> and <code>wsrchr()</code> , respectively.

wcsrchr(3C)

wcspbrk(), wspbrk()	The <code>wcspbrk()</code> and <code>wspbrk()</code> functions locate the first occurrence in the wide character string pointed to by <code>ws1</code> of any wide-character code from the wide-character string pointed to by <code>ws2</code> . Upon successful completion, the function returns a pointer to the wide-character code, or a null pointer if no wide-character code from <code>ws2</code> occurs in <code>ws1</code> .
wcswcs()	The <code>wcswcs()</code> function locates the first occurrence in the wide-character string pointed to by <code>ws1</code> of the sequence of wide-character codes (excluding the terminating null wide-character code) in the wide-character string pointed to by <code>ws2</code> . Upon successful completion, the function returns a pointer to the located wide-character string, or a null pointer if the wide-character string is not found. If <code>ws2</code> points to a wide-character string with zero length, the function returns <code>ws1</code> .
wcsspn(), wsspnl()	The <code>wcsspn()</code> and <code>wsspnl()</code> functions compute the length of the maximum initial segment of the wide-character string pointed to by <code>ws1</code> which consists entirely of wide-character codes from the wide-character string pointed to by <code>ws2</code> . Both functions return the length <code>ws1</code> ; no return value is reserved to indicate an error.
wcscspn(), wscspnl()	The <code>wcscspn()</code> and <code>wscspnl()</code> functions compute the length of the maximum initial segment of the wide-character string pointed to by <code>ws1</code> which consists entirely of wide-character codes <i>not</i> from the wide-character string pointed to by <code>ws2</code> . Both functions return the length of the initial substring of <code>ws1</code> ; no return value is reserved to indicate an error.
wcstok(), wstok()	A sequence of calls to the <code>wcstok()</code> and <code>wstok()</code> functions break the wide-character string pointed to by <code>ws1</code> into a sequence of tokens, each of which is delimited by a wide-character code from the wide-character string pointed to by <code>ws2</code> .
Default and other standards	<p>The third argument points to a caller-provided <code>wchar_t</code> pointer into which the <code>wcstok()</code> function stores information necessary for it to continue scanning the same wide-character string. This argument is not available with the XPG4 and SUS versions of <code>wcstok()</code>, nor is it available with the <code>wstok()</code> function. See <code>standards(5)</code>.</p> <p>The first call in the sequence has <code>ws1</code> as its first argument, and is followed by calls with a null pointer as their first argument. The separator string pointed to by <code>ws2</code> may be different from call to call.</p> <p>The first call in the sequence searches the wide-character string pointed to by <code>ws1</code> for the first wide-character code that is <i>not</i> contained in the current separator string pointed to by <code>ws2</code>. If no such wide-character code is found, then there are no tokens in the wide-character string pointed to by <code>ws1</code>, and <code>wcstok()</code> and <code>wstok()</code> return a null pointer. If such a wide-character code is found, it is the start of the first token.</p> <p>The <code>wcstok()</code> and <code>wstok()</code> functions then search from that point for a wide-character code that <i>is</i> contained in the current separator string. If no such wide-character code is found, the current token extends to the end of the wide-character string pointed to by <code>ws1</code>, and subsequent searches for a token will</p>

wcsrchr(3C)

return a null pointer. If such a wide-character code is found, it is overwritten by a null wide character, which terminates the current token. The `wcstok()` and `wstok()` functions save a pointer to the following wide-character code, from which the next search for a token will start.

Each subsequent call, with a null pointer as the value of the first argument, starts searching from the saved pointer and behaves as described above.

Upon successful completion, both functions return a pointer to the first wide-character code of a token. Otherwise, if there is no token, a null pointer is returned.

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE

wcsrtombs(3C)

NAME	wcsrtombs – convert a wide-character string to a character string (restartable)				
SYNOPSIS	<pre>#include <wchar.h> size_t wcsrtombs(char *dst, const wchar_t **src, size_t len, mbstate_t *ps);</pre>				
DESCRIPTION	<p>The <code>wcsrtombs()</code> function converts a sequence of wide-characters from the array indirectly pointed to by <code>src</code> into a sequence of corresponding characters, beginning in the conversion state described by the object pointed to by <code>ps</code>. If <code>dst</code> is not a null pointer, the converted characters are then stored into the array pointed to by <code>dst</code>. Conversion continues up to and including a terminating null wide-character, which is also stored. Conversion stops earlier in the following cases:</p> <ul style="list-style-type: none">■ When a code is reached that does not correspond to a valid character.■ When the next character would exceed the limit of <code>len</code> total bytes to be stored in the array pointed to by <code>dst</code> (and <code>dst</code> is not a null pointer). <p>Each conversion takes place as if by a call to the <code>wcrtomb()</code> function.</p> <p>If <code>dst</code> is not a null pointer, the pointer object pointed to by <code>src</code> is assigned either a null pointer (if conversion stopped due to reaching a terminating null wide-character) or the address just past the last wide-character converted (if any). If conversion stopped due to reaching a terminating null wide-character, the resulting state described is the initial conversion state.</p> <p>If <code>ps</code> is a null pointer, the <code>wcsrtombs()</code> function uses its own internal <code>mbstate_t</code> object, which is initialized at program startup to the initial conversion state. Otherwise, the <code>mbstate_t</code> object pointed to by <code>ps</code> is used to completely describe the current conversion state of the associated character sequence. Solaris will behave as if no function defined in the Solaris Reference Manual calls <code>wcsrtombs()</code>.</p> <p>The behavior of this function is affected by the <code>LC_CTYPE</code> category of the current locale. See <code>environ(5)</code>.</p>				
RETURN VALUES	<p>If conversion stops because a code is reached that does not correspond to a valid character, an encoding error occurs. In this case, the <code>wcsrtombs()</code> function stores the value of the macro <code>EILSEQ</code> in <code>errno</code> and returns <code>(size_t)-1</code>; the conversion state is undefined. Otherwise, it returns the number of bytes in the resulting character sequence, not including the terminating null (if any).</p>				
ERRORS	<p>The <code>wcsrtombs()</code> function may fail if:</p> <table><tr><td><code>EINVAL</code></td><td>The <code>ps</code> argument points to an object that contains an invalid conversion state.</td></tr><tr><td><code>EILSEQ</code></td><td>A wide-character code does not correspond to a valid character.</td></tr></table>	<code>EINVAL</code>	The <code>ps</code> argument points to an object that contains an invalid conversion state.	<code>EILSEQ</code>	A wide-character code does not correspond to a valid character.
<code>EINVAL</code>	The <code>ps</code> argument points to an object that contains an invalid conversion state.				
<code>EILSEQ</code>	A wide-character code does not correspond to a valid character.				
USAGE	<p>If <code>ps</code> is not a null pointer, <code>wcsrtombs()</code> uses the <code>mbstate_t</code> object pointed to by <code>ps</code> and the function can be used safely in multithreaded applications, as long as <code>setlocale(3C)</code> is not being called to change the locale. If <code>ps</code> is a null pointer,</p>				

wcsrtombs(3C)

wcsrtombs() uses its internal `mbstate_t` object and the function is Unsafe in multithreaded applications.

XPG4 and SUS	
Default and other standards	

	<pre> size_t wcsspn(const wchar_t *ws1, const wchar_t *ws2); wchar_t *wstok(wchar_t *ws1, const wchar_t *ws2); wchar_t *windex(const wchar_t *ws, wchar_t wc); wchar_t *wrindex(const wchar_t *ws, wchar_t wc); </pre>
ISO C++	<pre> #include <wchar.h> const wchar_t *wcschr(const wchar_t *ws, wchar_t wc); const wchar_t *wcspbrk(const wchar_t *ws1, const wchar_t *ws2); const wchar_t *wcsrchr(const wchar_t *ws, wchar_t wc); #include <cwchar> wchar_t *std::wcschr(wchar_t *ws, wchar_t wc); wchar_t *std::wcspbrk(wchar_t *ws1, const wchar_t *ws2); wchar_t *std::wcsrchr(wchar_t *ws, wchar_t wc); </pre>
DESCRIPTION	<p>These functions operate on wide-character strings terminated by <code>wchar_t</code> <code>NULL</code> characters. During appending or copying, these routines do not check for an overflow condition of the receiving string. In the following, <i>ws</i>, <i>ws1</i>, and <i>ws2</i> point to wide-character strings terminated by a <code>wchar_t</code> <code>NULL</code>.</p>
wscat(), wscat()	<p>The <code>wscat()</code> and <code>wscat()</code> functions append a copy of the wide-character string pointed to by <i>ws2</i> (including the terminating null wide-character code) to the end of the wide-character string pointed to by <i>ws1</i>. The initial wide-character code of <i>ws2</i> overwrites the null wide-character code at the end of <i>ws1</i>. If copying takes place between objects that overlap, the behavior is undefined. Both functions return <i>s1</i>; no return value is reserved to indicate an error.</p>
wcsncat(), wsncat()	<p>The <code>wcsncat()</code> and <code>wsncat()</code> functions append not more than <i>n</i> wide-character codes (a null wide-character code and wide-character codes that follow it are not appended) from the array pointed to by <i>ws2</i> to the end of the wide-character string pointed to by <i>ws1</i>. The initial wide-character code of <i>ws2</i> overwrites the null wide-character code at the end of <i>ws1</i>. A terminating null wide-character code is always appended to the result. Both functions return <i>ws1</i>; no return value is reserved to indicate an error.</p>
wcscmp(), wcscmp()	<p>The <code>wcscmp()</code> and <code>wcscmp()</code> functions compare the wide-character string pointed to by <i>ws1</i> to the wide-character string pointed to by <i>ws2</i>. The sign of a non-zero return value is determined by the sign of the difference between the values of the first pair of wide-character codes that differ in the objects being compared. Upon completion, both functions return an integer greater than, equal to, or less than zero, if the wide-character string pointed to by <i>ws1</i> is greater than, equal to, or less than the wide-character string pointed to by <i>ws2</i>.</p>

wcsspn(3C)

wcsncmp(), wsncmp()	The <code>wcsncmp()</code> and <code>wsncmp()</code> functions compare not more than <i>n</i> wide-character codes (wide-character codes that follow a null wide character code are not compared) from the array pointed to by <i>ws1</i> to the array pointed to by <i>ws2</i> . The sign of a non-zero return value is determined by the sign of the difference between the values of the first pair of wide-character codes that differ in the objects being compared. Upon successful completion, both functions return an integer greater than, equal to, or less than zero, if the possibly null-terminated array pointed to by <i>ws1</i> is greater than, equal to, or less than the possibly null-terminated array pointed to by <i>ws2</i> .
wcscpy(), wscpy()	The <code>wcscpy()</code> and <code>wscpy()</code> functions copy the wide-character string pointed to by <i>ws2</i> (including the terminating null wide-character code) into the array pointed to by <i>ws1</i> . If copying takes place between objects that overlap, the behavior is undefined. Both functions return <i>ws1</i> ; no return value is reserved to indicate an error.
wcsncpy(), wsncpy()	The <code>wcsncpy()</code> and <code>wsncpy()</code> functions copy not more than <i>n</i> wide-character codes (wide-character codes that follow a null wide character code are not copied) from the array pointed to by <i>ws2</i> to the array pointed to by <i>ws1</i> . If copying takes place between objects that overlap, the behavior is undefined. If the array pointed to by <i>ws2</i> is a wide-character string that is shorter than <i>n</i> wide-character codes, null wide-character codes are appended to the copy in the array pointed to by <i>ws1</i> , until a total <i>n</i> wide-character codes are written. Both functions return <i>ws1</i> ; no return value is reserved to indicate an error.
wcslen(), wslen()	The <code>wcslen()</code> and <code>wslen()</code> functions compute the number of wide-character codes in the wide-character string to which <i>ws</i> points, not including the terminating null wide-character code. Both functions return <i>ws</i> ; no return value is reserved to indicate an error.
wcschr(), wschr()	The <code>wcschr()</code> and <code>wschr()</code> functions locate the first occurrence of <i>wc</i> in the wide-character string pointed to by <i>ws</i> . The value of <i>wc</i> must be a character representable as a type <code>wchar_t</code> and must be a wide-character code corresponding to a valid character in the current locale. The terminating null wide-character code is considered to be part of the wide-character string. Upon completion, both functions return a pointer to the wide-character code, or a null pointer if the wide-character code is not found.
wcsrchr(), wsrchr()	The <code>wcsrchr()</code> and <code>wsrchr()</code> functions locate the last occurrence of <i>wc</i> in the wide-character string pointed to by <i>ws</i> . The value of <i>wc</i> must be a character representable as a type <code>wchar_t</code> and must be a wide-character code corresponding to a valid character in the current locale. The terminating null wide-character code is considered to be part of the wide-character string. Upon successful completion, both functions return a pointer to the wide-character code, or a null pointer if <i>wc</i> does not occur in the wide-character string.
windex(), wrintdex()	The <code>windex()</code> and <code>wrintdex()</code> functions behave the same as <code>wschr()</code> and <code>wsrchr()</code> , respectively.

wcspbrk(), wspbrk()	The <code>wcspbrk()</code> and <code>wspbrk()</code> functions locate the first occurrence in the wide character string pointed to by <code>ws1</code> of any wide-character code from the wide-character string pointed to by <code>ws2</code> . Upon successful completion, the function returns a pointer to the wide-character code, or a null pointer if no wide-character code from <code>ws2</code> occurs in <code>ws1</code> .
wcswcs()	The <code>wcswcs()</code> function locates the first occurrence in the wide-character string pointed to by <code>ws1</code> of the sequence of wide-character codes (excluding the terminating null wide-character code) in the wide-character string pointed to by <code>ws2</code> . Upon successful completion, the function returns a pointer to the located wide-character string, or a null pointer if the wide-character string is not found. If <code>ws2</code> points to a wide-character string with zero length, the function returns <code>ws1</code> .
wcsspn(), wsspn()	The <code>wcsspn()</code> and <code>wsspn()</code> functions compute the length of the maximum initial segment of the wide-character string pointed to by <code>ws1</code> which consists entirely of wide-character codes from the wide-character string pointed to by <code>ws2</code> . Both functions return the length <code>ws1</code> ; no return value is reserved to indicate an error.
wcscspn(), wscspn()	The <code>wcscspn()</code> and <code>wscspn()</code> functions compute the length of the maximum initial segment of the wide-character string pointed to by <code>ws1</code> which consists entirely of wide-character codes <i>not</i> from the wide-character string pointed to by <code>ws2</code> . Both functions return the length of the initial substring of <code>ws1</code> ; no return value is reserved to indicate an error.
wcstok(), wstok()	A sequence of calls to the <code>wcstok()</code> and <code>wstok()</code> functions break the wide-character string pointed to by <code>ws1</code> into a sequence of tokens, each of which is delimited by a wide-character code from the wide-character string pointed to by <code>ws2</code> .
Default and other standards	<p>The third argument points to a caller-provided <code>wchar_t</code> pointer into which the <code>wcstok()</code> function stores information necessary for it to continue scanning the same wide-character string. This argument is not available with the XPG4 and SUS versions of <code>wcstok()</code>, nor is it available with the <code>wstok()</code> function. See <code>standards(5)</code>.</p> <p>The first call in the sequence has <code>ws1</code> as its first argument, and is followed by calls with a null pointer as their first argument. The separator string pointed to by <code>ws2</code> may be different from call to call.</p> <p>The first call in the sequence searches the wide-character string pointed to by <code>ws1</code> for the first wide-character code that is <i>not</i> contained in the current separator string pointed to by <code>ws2</code>. If no such wide-character code is found, then there are no tokens in the wide-character string pointed to by <code>ws1</code>, and <code>wcstok()</code> and <code>wstok()</code> return a null pointer. If such a wide-character code is found, it is the start of the first token.</p> <p>The <code>wcstok()</code> and <code>wstok()</code> functions then search from that point for a wide-character code that <i>is</i> contained in the current separator string. If no such wide-character code is found, the current token extends to the end of the wide-character string pointed to by <code>ws1</code>, and subsequent searches for a token will</p>

wcsspn(3C)

return a null pointer. If such a wide-character code is found, it is overwritten by a null wide character, which terminates the current token. The `wcstok()` and `wstok()` functions save a pointer to the following wide-character code, from which the next search for a token will start.

Each subsequent call, with a null pointer as the value of the first argument, starts searching from the saved pointer and behaves as described above.

Upon successful completion, both functions return a pointer to the first wide-character code of a token. Otherwise, if there is no token, a null pointer is returned.

NAME | wcsstr – find a wide-character substring

SYNOPSIS | #include <wchar.h>
 wchar_t *wcsstr(const wchar_t *ws1, const wchar_t *ws2);

ISO C++ | #include <wchar.h>
 const wchar_t *wcsstr(const wchar_t *ws1, const wchar_t *ws2);
 #include <cwchar>
 wchar_t *std::wcsstr(wchar_t *ws1, const wchar_t *ws2);

DESCRIPTION | The `wcsstr()` function locates the first occurrence in the wide-character string pointed to by `ws1` of the sequence of wide-characters (excluding the terminating null wide-character) in the wide-character string pointed to by `ws2`.

RETURN VALUES | On successful completion, `wcsstr()` returns a pointer to the located wide-character string, or a null pointer if the wide-character string is not found.
 If `ws2` points to a wide-character string with zero length, the function returns `ws1`.

ERRORS | No errors are defined.

ATTRIBUTES | See `attributes(5)` for descriptions of the following attributes:

wcstod(3C)

NAME	<code>wcstod</code> , <code>wstod</code> , <code>watof</code> – convert wide character string to double-precision number
SYNOPSIS	<pre>#include <wchar.h> double wcstod(const wchar_t *nptr, wchar_t **endptr); double wstod(const wchar_t *nptr, wchar_t **endptr); double watof(wchar_t *nptr);</pre>
DESCRIPTION	<p>The <code>wcstod()</code> and <code>wstod()</code> functions convert the initial portion of the wide character string pointed to by <code>nptr</code> to double representation. They first decompose the input wide character string into three parts: an initial, possibly empty, sequence of white-space wide character codes (as specified by <code>iswspace(3C)</code>); a subject sequence interpreted as a floating-point constant; and a final wide-character string of one or more unrecognised wide-character codes, including the terminating null wide character code of the input wide character string. They then attempt to convert the subject sequence to a floating-point number, and return the result.</p> <p>The expected form of the subject sequence is an optional '+' or '-' sign, then a non-empty sequence of digits optionally containing a radix, then an optional exponent part. An exponent part consists of 'e' or 'E', followed by an optional sign, followed by one or more decimal digits. The subject sequence is defined as the longest initial subsequence of the input wide character string, starting with the first non-white-space wide-character code, that is of the expected form. The subject sequence contains no wide-character codes if the input wide character string is empty or consists entirely of white-space wide-character codes, or if the first wide-character code that is not white space other than a sign, a digit or a radix.</p> <p>If the subject sequence has the expected form, the sequence of wide-character codes starting with the first digit or the radix (whichever occurs first) is interpreted as a floating constant as defined in the C language, except that the radix is used in place of a period, and that if neither an exponent part nor a radix appears, a radix is assumed to follow the last digit in the wide character string. If the subject sequence begins with a minus sign (-), the value resulting from the conversion is negated. A pointer to the final wide character string is stored in the object pointed to by <code>endptr</code>, provided that <code>endptr</code> is not a null pointer.</p> <p>The radix is defined in the program's locale (category <code>LC_NUMERIC</code>). In the POSIX locale, or in a locale where the radix is not defined, the radix defaults to a period (.).</p> <p>In other than the POSIX locale, other implementation-dependent subject sequence forms may be accepted.</p> <p>If the subject sequence is empty or does not have the expected form, no conversion is performed; the value of <code>nptr</code> is stored in the object pointed to by <code>endptr</code>, provided that <code>endptr</code> is not a null pointer.</p> <p>The <code>watof(str)</code> function is equivalent to <code>wstod(str, (wchar_t **)NULL)</code>.</p>

RETURN VALUES The `wcstod()` and `wstod()` functions return the converted value, if any. If no conversion could be performed, 0 is returned and `errno` may be set to `EINVAL`.

If the correct value is outside the range of representable values, `±HUGE_VAL` is returned (according to the sign of the value), and `errno` is set to `ERANGE`.

If the correct value would cause underflow, 0 is returned, and `errno` is set to `ERANGE`.

ERRORS The `wcstod()` and `wstod()` functions will fail if:

`ERANGE` The value to be returned would cause overflow or underflow.

The `wcstod()` and `wstod()` functions may fail if:

`EINVAL` No conversion could be performed.

USAGE Because 0 is returned on error and is also a valid return on success, an application wishing to check for error situations should set `errno` to 0 call `wcstod()` or `wstod()`, then check `errno` and if it is non-zero, assume an error has occurred.

wcstok(3C)

NAME	wcstring, wcsconcat, wscat, wcsncat, wsncat, wscmp, wscmp, wcsncmp, wsncmp, wscpy, wscpy, wcsncpy, wsncpy, wcslen, wslen, wcschr, wschr, wcsrchr, wsrchr, windex, wrindex, wcsprk, wspbrk, wswcs, wcsspn, wssp, wcspspn, wscpspn, wcstok, wstok – wide-character string operations
SYNOPSIS	<pre>#include <wchar.h> wchar_t *wcsconcat(wchar_t *ws1, const wchar_t *ws2); wchar_t *wcsncat(wchar_t *ws1, const wchar_t *ws2, size_t n); int wscmp(const wchar_t *ws1, const wchar_t *ws2); int wcsncmp(const wchar_t *ws1, const wchar_t *ws2, size_t n); wchar_t *wscpy(wchar_t *ws1, const wchar_t *ws2); wchar_t *wcsncpy(wchar_t *ws1, const wchar_t *ws2, size_t n); size_t wcslen(const wchar_t *ws); wchar_t *wcschr(const wchar_t *ws, wchar_t wc); wchar_t *wcsrchr(const wchar_t *ws, wchar_t wc); wchar_t *wcpbrk(const wchar_t *ws1, const wchar_t *ws2); wchar_t *wswcs(const wchar_t *ws1, const wchar_t *ws2); size_t wcsspn(const wchar_t *ws1, const wchar_t *ws2); size_t wcspspn(const wchar_t *ws1, const wchar_t *ws2); wchar_t *wcstok(wchar_t *ws1, const wchar_t *ws2); wchar_t *wcstok(wchar_t *ws1, const wchar_t *ws2, wchar_t **ptr); #include <widec.h> wchar_t *wscat(wchar_t *ws1, const wchar_t *ws2); wchar_t *wsncat(wchar_t *ws1, const wchar_t *ws2, size_t n); int wscmp(const wchar_t *ws1, const wchar_t *ws2); int wsncmp(const wchar_t *ws1, const wchar_t *ws2, size_t n); wchar_t *wscpy(wchar_t *ws1, const wchar_t *ws2); wchar_t *wsncpy(wchar_t *ws1, const wchar_t *ws2, size_t n); size_t wslen(const wchar_t *ws); wchar_t *wschr(const wchar_t *ws, wchar_t wc); wchar_t *wsrchr(const wchar_t *ws, wchar_t wc); wchar_t *wcpbrk(const wchar_t *ws1, const wchar_t *ws2); size_t wssp(const wchar_t *ws1, const wchar_t *ws2);</pre>
XPG4 and SUS	
Default and other standards	

	<pre> size_t wcspn(const wchar_t *ws1, const wchar_t *ws2); wchar_t *wstok(wchar_t *ws1, const wchar_t *ws2); wchar_t *windex(const wchar_t *ws, wchar_t wc); wchar_t *wrindex(const wchar_t *ws, wchar_t wc); </pre>
ISO C++	<pre> #include <wchar.h> const wchar_t *wcschr(const wchar_t *ws, wchar_t wc); const wchar_t *wcspbrk(const wchar_t *ws1, const wchar_t *ws2); const wchar_t *wcsrchr(const wchar_t *ws, wchar_t wc); #include <cwchar> wchar_t *std::wcschr(wchar_t *ws, wchar_t wc); wchar_t *std::wcspbrk(wchar_t *ws1, const wchar_t *ws2); wchar_t *std::wcsrchr(wchar_t *ws, wchar_t wc); </pre>
DESCRIPTION	<p>These functions operate on wide-character strings terminated by <code>wchar_t</code> <code>NULL</code> characters. During appending or copying, these routines do not check for an overflow condition of the receiving string. In the following, <i>ws</i>, <i>ws1</i>, and <i>ws2</i> point to wide-character strings terminated by a <code>wchar_t</code> <code>NULL</code>.</p>
wscat(), wscat()	<p>The <code>wscat()</code> and <code>wscat()</code> functions append a copy of the wide-character string pointed to by <i>ws2</i> (including the terminating null wide-character code) to the end of the wide-character string pointed to by <i>ws1</i>. The initial wide-character code of <i>ws2</i> overwrites the null wide-character code at the end of <i>ws1</i>. If copying takes place between objects that overlap, the behavior is undefined. Both functions return <i>s1</i>; no return value is reserved to indicate an error.</p>
wcsncat(), wsncat()	<p>The <code>wcsncat()</code> and <code>wsncat()</code> functions append not more than <i>n</i> wide-character codes (a null wide-character code and wide-character codes that follow it are not appended) from the array pointed to by <i>ws2</i> to the end of the wide-character string pointed to by <i>ws1</i>. The initial wide-character code of <i>ws2</i> overwrites the null wide-character code at the end of <i>ws1</i>. A terminating null wide-character code is always appended to the result. Both functions return <i>ws1</i>; no return value is reserved to indicate an error.</p>
wcscmp(), wcscmp()	<p>The <code>wcscmp()</code> and <code>wcscmp()</code> functions compare the wide-character string pointed to by <i>ws1</i> to the wide-character string pointed to by <i>ws2</i>. The sign of a non-zero return value is determined by the sign of the difference between the values of the first pair of wide-character codes that differ in the objects being compared. Upon completion, both functions return an integer greater than, equal to, or less than zero, if the wide-character string pointed to by <i>ws1</i> is greater than, equal to, or less than the wide-character string pointed to by <i>ws2</i>.</p>

wcstok(3C)

wcsncmp(), wsncmp()	The <code>wcsncmp()</code> and <code>wsncmp()</code> functions compare not more than <i>n</i> wide-character codes (wide-character codes that follow a null wide character code are not compared) from the array pointed to by <i>ws1</i> to the array pointed to by <i>ws2</i> . The sign of a non-zero return value is determined by the sign of the difference between the values of the first pair of wide-character codes that differ in the objects being compared. Upon successful completion, both functions return an integer greater than, equal to, or less than zero, if the possibly null-terminated array pointed to by <i>ws1</i> is greater than, equal to, or less than the possibly null-terminated array pointed to by <i>ws2</i> .
wcscpy(), wscpy()	The <code>wcscpy()</code> and <code>wscpy()</code> functions copy the wide-character string pointed to by <i>ws2</i> (including the terminating null wide-character code) into the array pointed to by <i>ws1</i> . If copying takes place between objects that overlap, the behavior is undefined. Both functions return <i>ws1</i> ; no return value is reserved to indicate an error.
wcsncpy(), wsncpy()	The <code>wcsncpy()</code> and <code>wsncpy()</code> functions copy not more than <i>n</i> wide-character codes (wide-character codes that follow a null wide character code are not copied) from the array pointed to by <i>ws2</i> to the array pointed to by <i>ws1</i> . If copying takes place between objects that overlap, the behavior is undefined. If the array pointed to by <i>ws2</i> is a wide-character string that is shorter than <i>n</i> wide-character codes, null wide-character codes are appended to the copy in the array pointed to by <i>ws1</i> , until a total <i>n</i> wide-character codes are written. Both functions return <i>ws1</i> ; no return value is reserved to indicate an error.
wcslen(), wslen()	The <code>wcslen()</code> and <code>wslen()</code> functions compute the number of wide-character codes in the wide-character string to which <i>ws</i> points, not including the terminating null wide-character code. Both functions return <i>ws</i> ; no return value is reserved to indicate an error.
wcschr(), wschr()	The <code>wcschr()</code> and <code>wschr()</code> functions locate the first occurrence of <i>wc</i> in the wide-character string pointed to by <i>ws</i> . The value of <i>wc</i> must be a character representable as a type <code>wchar_t</code> and must be a wide-character code corresponding to a valid character in the current locale. The terminating null wide-character code is considered to be part of the wide-character string. Upon completion, both functions return a pointer to the wide-character code, or a null pointer if the wide-character code is not found.
wcsrchr(), wsrchr()	The <code>wcsrchr()</code> and <code>wsrchr()</code> functions locate the last occurrence of <i>wc</i> in the wide-character string pointed to by <i>ws</i> . The value of <i>wc</i> must be a character representable as a type <code>wchar_t</code> and must be a wide-character code corresponding to a valid character in the current locale. The terminating null wide-character code is considered to be part of the wide-character string. Upon successful completion, both functions return a pointer to the wide-character code, or a null pointer if <i>wc</i> does not occur in the wide-character string.
windex(), wrindex()	The <code>windex()</code> and <code>wrindex()</code> functions behave the same as <code>wschr()</code> and <code>wsrchr()</code> , respectively.

wcspbrk(), wspbrk()	The <code>wcspbrk()</code> and <code>wspbrk()</code> functions locate the first occurrence in the wide character string pointed to by <code>ws1</code> of any wide-character code from the wide-character string pointed to by <code>ws2</code> . Upon successful completion, the function returns a pointer to the wide-character code, or a null pointer if no wide-character code from <code>ws2</code> occurs in <code>ws1</code> .
wcswcs()	The <code>wcswcs()</code> function locates the first occurrence in the wide-character string pointed to by <code>ws1</code> of the sequence of wide-character codes (excluding the terminating null wide-character code) in the wide-character string pointed to by <code>ws2</code> . Upon successful completion, the function returns a pointer to the located wide-character string, or a null pointer if the wide-character string is not found. If <code>ws2</code> points to a wide-character string with zero length, the function returns <code>ws1</code> .
wcsspn(), wsspnl()	The <code>wcsspn()</code> and <code>wsspnl()</code> functions compute the length of the maximum initial segment of the wide-character string pointed to by <code>ws1</code> which consists entirely of wide-character codes from the wide-character string pointed to by <code>ws2</code> . Both functions return the length <code>ws1</code> ; no return value is reserved to indicate an error.
wcscspn(), wscspnl()	The <code>wcscspn()</code> and <code>wscspnl()</code> functions compute the length of the maximum initial segment of the wide-character string pointed to by <code>ws1</code> which consists entirely of wide-character codes <i>not</i> from the wide-character string pointed to by <code>ws2</code> . Both functions return the length of the initial substring of <code>ws1</code> ; no return value is reserved to indicate an error.
wcstok(), wstok()	A sequence of calls to the <code>wcstok()</code> and <code>wstok()</code> functions break the wide-character string pointed to by <code>ws1</code> into a sequence of tokens, each of which is delimited by a wide-character code from the wide-character string pointed to by <code>ws2</code> .
Default and other standards	<p>The third argument points to a caller-provided <code>wchar_t</code> pointer into which the <code>wcstok()</code> function stores information necessary for it to continue scanning the same wide-character string. This argument is not available with the XPG4 and SUS versions of <code>wcstok()</code>, nor is it available with the <code>wstok()</code> function. See <code>standards(5)</code>.</p> <p>The first call in the sequence has <code>ws1</code> as its first argument, and is followed by calls with a null pointer as their first argument. The separator string pointed to by <code>ws2</code> may be different from call to call.</p> <p>The first call in the sequence searches the wide-character string pointed to by <code>ws1</code> for the first wide-character code that is <i>not</i> contained in the current separator string pointed to by <code>ws2</code>. If no such wide-character code is found, then there are no tokens in the wide-character string pointed to by <code>ws1</code>, and <code>wcstok()</code> and <code>wstok()</code> return a null pointer. If such a wide-character code is found, it is the start of the first token.</p> <p>The <code>wcstok()</code> and <code>wstok()</code> functions then search from that point for a wide-character code that <i>is</i> contained in the current separator string. If no such wide-character code is found, the current token extends to the end of the wide-character string pointed to by <code>ws1</code>, and subsequent searches for a token will</p>

wcstok(3C)

return a null pointer. If such a wide-character code is found, it is overwritten by a null wide character, which terminates the current token. The `wcstok()` and `wstok()` functions save a pointer to the following wide-character code, from which the next search for a token will start.

Each subsequent call, with a null pointer as the value of the first argument, starts searching from the saved pointer and behaves as described above.

Upon successful completion, both functions return a pointer to the first wide-character code of a token. Otherwise, if there is no token, a null pointer is returned.

NAME	wcstol, wstol, watol, watoll, watoi – convert wide character string to long integer
SYNOPSIS	<pre>#include <wchar.h> long int wcstol(const wchar_t *nptr, wchar_t **endptr, int base); #include <widec.h> long int wstol(const wchar_t *nptr, wchar_t **endptr, int base); long watol(wchar_t *nptr); long long watoll(wchar_t *nptr); int watoi(wchar_t *nptr);</pre>
DESCRIPTION	<p>The <code>wcstol()</code> and <code>wstol()</code> functions convert the initial portion of the wide character string pointed to by <code>nptr</code> to long int representation. They first decompose the input wide character string into three parts: an initial, possibly empty, sequence of white-space wide-character codes (as specified by <code>iswspace(3C)</code>), a subject sequence interpreted as an integer represented in some radix determined by the value of <code>base</code>; and a final wide character string of one or more unrecognised wide character codes, including the terminating null wide-character code of the input wide character string. They then attempt to convert the subject sequence to an integer, and return the result.</p> <p>If the value of <code>base</code> is 0, the expected form of the subject sequence is that of a decimal constant, octal constant or hexadecimal constant, any of which may be preceded by a '+' or '-' sign. A decimal constant begins with a non-zero digit, and consists of a sequence of decimal digits. An octal constant consists of the prefix '0' optionally followed by a sequence of the digits '0' to '7' only. A hexadecimal constant consists of the prefix '0x' or '0X' followed by a sequence of the decimal digits and letters 'a' (or 'A') to 'f' (or 'F') with values 10 to 15 respectively.</p> <p>If the value of <code>base</code> is between 2 and 36, the expected form of the subject sequence is a sequence of letters and digits representing an integer with the radix specified by <code>base</code>, optionally preceded by a '+' or '-' sign, but not including an integer suffix. The letters from 'a' (or 'A') to 'z' (or 'Z') inclusive are ascribed the values 10 to 35; only letters whose ascribed values are less than that of <code>base</code> are permitted. If the value of <code>base</code> is 16, the wide-character code representations of '0x' or '0X' may optionally precede the sequence of letters and digits, following the sign if present.</p> <p>The subject sequence is defined as the longest initial subsequence of the input wide character string, starting with the first non-white-space wide-character code, that is of the expected form. The subject sequence contains no wide-character codes if the input wide character string is empty or consists entirely of white-space wide-character code, or if the first non-white-space wide-character code is other than a sign or a permissible letter or digit.</p> <p>If the subject sequence has the expected form and the value of <code>base</code> is 0, the sequence of wide-character codes starting with the first digit is interpreted as an integer constant. If the subject sequence has the expected form and the value of <code>base</code> is between 2 and 36, it is used as the base for conversion, ascribing to each letter its</p>

wcstol(3C)

value as given above. If the subject sequence begins with a minus sign (-), the value resulting from the conversion is negated. A pointer to the final wide character string is stored in the object pointed to by *endptr*, provided that *endptr* is not a null pointer.

In other than the POSIX locale, additional implementation-dependent subject sequence forms may be accepted.

If the subject sequence is empty or does not have the expected form, no conversion is performed; the value of *nptr* is stored in the object pointed to by *endptr*, provided that *endptr* is not a null pointer.

The `watol()` function is equivalent to `wstol(str, (wchar_t **)NULL, 10)`.

The `watoll()` function is the long-long (double long) version of `watol()`.

The `watoi()` function is equivalent to `(int)watol()`.

RETURN VALUES Upon successful completion, `wcstol()` and `wstol()` return the converted value, if any. If no conversion could be performed, 0 is returned, and `errno` may be set to indicate the error. If the correct value is outside the range of representable values, `{LONG_MAX}` or `{LONG_MIN}` is returned (according to the sign of the value), and `errno` is set to `ERANGE`.

ERRORS The `wcstol()` and `wstol()` functions will fail if:

`EINVAL` The value of *base* is not supported.

`ERANGE` The value to be returned is not representable.

The `wcstol()` and `wstol()` functions may fail if:

`EINVAL` No conversion could be performed.

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
MT-Level	MT-Safe

SEE ALSO `iswalphabet(3C)`, `iswspace(3C)`, `scanf(3C)`, `wcstod(3C)`, `attributes(5)`

NOTES Because 0, `{LONG_MIN}`, and `{LONG_MAX}` are returned on error and are also valid returns on success, an application wishing to check for error situations should set `errno` to 0, call `wcstol()` or `wstol()`, then check `errno` and if it is non-zero assume an error has occurred.

Truncation from long long to long can take place upon assignment or by an explicit cast.

NAME	wcstombs – convert a wide-character string to a character string						
SYNOPSIS	<pre>#include <stdlib.h> size_t wcstombs(char *s, const wchar_t *pwcs, size_t n);</pre>						
DESCRIPTION	<p>The <code>wcstombs()</code> function converts the sequence of wide-character codes from the array pointed to by <code>pwcs</code> into a sequence of characters and stores these characters into the array pointed to by <code>s</code>, stopping if a character would exceed the limit of <code>n</code> total bytes or if a null byte is stored. Each wide-character code is converted as if by a call to <code>wctomb(3C)</code>.</p> <p>The behavior of this function is affected by the <code>LC_CTYPE</code> category of the current locale.</p> <p>No more than <code>n</code> bytes will be modified in the array pointed to by <code>s</code>. If copying takes place between objects that overlap, the behavior is undefined. If <code>s</code> is a null pointer, <code>wcstombs()</code> returns the length required to convert the entire array regardless of the value of <code>n</code>, but no values are stored.</p>						
RETURN VALUES	<p>If a wide-character code is encountered that does not correspond to a valid character (of one or more bytes each), <code>wcstombs()</code> returns <code>(size_t)-1</code>. Otherwise, <code>wcstombs()</code> returns the number of bytes stored in the character array, not including any terminating null byte. The array will not be null-terminated if the value returned is <code>n</code>.</p>						
ERRORS	<p>The <code>wcstombs()</code> function may fail if:</p> <p>EILSEQ A wide-character code does not correspond to a valid character.</p>						
ATTRIBUTES	<p>See <code>attributes(5)</code> for descriptions of the following attributes:</p> <table border="1" style="width: 100%; border-collapse: collapse;"> <thead> <tr> <th style="text-align: left;">ATTRIBUTE TYPE</th> <th style="text-align: left;">ATTRIBUTE VALUE</th> </tr> </thead> <tbody> <tr> <td>MT-Level</td> <td>MT-Safe</td> </tr> <tr> <td>CSI</td> <td>Enabled</td> </tr> </tbody> </table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	MT-Level	MT-Safe	CSI	Enabled

wcstoul(3C)

NAME	wcstoul – convert wide character string to unsigned long
SYNOPSIS	<pre>#include <wchar.h> unsigned long int wcstoul(const wchar_t *nptr, wchar_t **endptr, int base);</pre>
DESCRIPTION	<p>The <code>wcstoul()</code> function converts the initial portion of the wide character string pointed to by <code>nptr</code> to unsigned long int representation. It first decomposes the input wide-character string into three parts: an initial, possibly empty, sequence of white-space wide-character codes (as specified by the function <code>iswspace(3C)</code>); a subject sequence interpreted as an integer represented in some radix determined by the value of <code>base</code>; and a final wide-character string of one or more unrecognized wide character codes, including the terminating null wide-character code of the input wide character string. It then attempts to convert the subject sequence to an unsigned integer, and returns the result.</p> <p>If the value of <code>base</code> is 0, the expected form of the subject sequence is that of a decimal constant, an octal constant, or a hexadecimal constant, any of which may be preceded by a '+' or a '-' sign. A decimal constant begins with a non-zero digit, and consists of a sequence of decimal digits. An octal constant consists of the prefix '0', optionally followed by a sequence of the digits '0' to '7' only. A hexadecimal constant consists of the prefix '0x' or '0X', followed by a sequence of the decimal digits and letters 'a' (or 'A') to 'f' (or 'F'), with values 10 to 15, respectively.</p> <p>If the value of <code>base</code> is between 2 and 36, the expected form of the subject sequence is a sequence of letters and digits representing an integer with the radix specified by <code>base</code>, optionally preceded by a '+' or a '-' sign, but not including an integer suffix. The letters from 'a' (or 'A') to 'z' (or 'Z') inclusive are ascribed the values 10 to 35; only letters whose ascribed values are less than that of <code>base</code> are permitted. If the value of <code>base</code> is 16, the wide-character codes '0x' or '0X' may optionally precede the sequence of letters and digits, following the sign, if present.</p> <p>The subject sequence is defined as the longest initial subsequence of the input wide-character string, starting with the first wide-character code that is not a white space and is of the expected form. The subject sequence contains no wide-character codes if the input wide-character string is empty or consists entirely of white-space wide-character codes, or if the first wide-character code that is not a white space is other than a sign or a permissible letter or digit.</p> <p>If the subject sequence has the expected form and the value of <code>base</code> is 0, the sequence of wide-character codes starting with the first digit is interpreted as an integer constant. If the subject sequence has the expected form and the value of <code>base</code> is between 2 and 36, it is used as the base for conversion, ascribing to each letter its value as given above. If the subject sequence begins with a minus sign, the value resulting from the conversion is negated. A pointer to the final wide character string is stored in the object pointed to by <code>endptr</code>, provided that <code>endptr</code> is not a null pointer.</p> <p>In other than the POSIX locale, additional subject sequence forms may be accepted.</p>

If the subject sequence is empty or does not have the expected form, no conversion is performed; the value of *nptr* is stored in the object pointed to by *endptr*, provided that *endptr* is not a null pointer.

Because 0 and `ULONG_MAX` are returned on error and 0 is also a valid return on success, an application wishing to check for error situations should set `errno` to 0, call `wcstoul()`, then check `errno` and if it is non-zero, assume an error has occurred.

RETURN VALUE Upon successful completion, `wcstoul()` returns the converted value, if any, and does not change the setting of `errno`. If no conversion could be performed, 0 is returned and `errno` may be set to indicate the error. If the correct value is outside the range of representable values, `ULONG_MAX` is returned and `errno` is set to `ERANGE`.

ERRORS The `wcstoul()` function will fail if:

`EINVAL` The value of *base* is not supported.

`ERANGE` The value to be returned is not representable.

The `wcstoul()` function may fail if:

`EINVAL` No conversion could be performed.

USAGE Unlike `wcstod(3C)` and `wcstol(3C)`, `wcstoul()` must always return a non-negative number; using the return value of `wcstoul()` for out-of-range numbers with `wcstoul()` could cause more severe problems than just loss of precision if those numbers can ever be negative.

	<pre> size_t wcspn(const wchar_t *ws1, const wchar_t *ws2); wchar_t *wstok(wchar_t *ws1, const wchar_t *ws2); wchar_t *windex(const wchar_t *ws, wchar_t wc); wchar_t *wrindex(const wchar_t *ws, wchar_t wc); </pre>
ISO C++	<pre> #include <wchar.h> const wchar_t *wcschr(const wchar_t *ws, wchar_t wc); const wchar_t *wcspbrk(const wchar_t *ws1, const wchar_t *ws2); const wchar_t *wcsrchr(const wchar_t *ws, wchar_t wc); #include <cwchar> wchar_t *std::wcschr(wchar_t *ws, wchar_t wc); wchar_t *std::wcspbrk(wchar_t *ws1, const wchar_t *ws2); wchar_t *std::wcsrchr(wchar_t *ws, wchar_t wc); </pre>
DESCRIPTION	<p>These functions operate on wide-character strings terminated by <code>wchar_t</code> <code>NULL</code> characters. During appending or copying, these routines do not check for an overflow condition of the receiving string. In the following, <i>ws</i>, <i>ws1</i>, and <i>ws2</i> point to wide-character strings terminated by a <code>wchar_t</code> <code>NULL</code>.</p>
wscat(), wscat()	<p>The <code>wscat()</code> and <code>wscat()</code> functions append a copy of the wide-character string pointed to by <i>ws2</i> (including the terminating null wide-character code) to the end of the wide-character string pointed to by <i>ws1</i>. The initial wide-character code of <i>ws2</i> overwrites the null wide-character code at the end of <i>ws1</i>. If copying takes place between objects that overlap, the behavior is undefined. Both functions return <i>s1</i>; no return value is reserved to indicate an error.</p>
wcsncat(), wsncat()	<p>The <code>wcsncat()</code> and <code>wsncat()</code> functions append not more than <i>n</i> wide-character codes (a null wide-character code and wide-character codes that follow it are not appended) from the array pointed to by <i>ws2</i> to the end of the wide-character string pointed to by <i>ws1</i>. The initial wide-character code of <i>ws2</i> overwrites the null wide-character code at the end of <i>ws1</i>. A terminating null wide-character code is always appended to the result. Both functions return <i>ws1</i>; no return value is reserved to indicate an error.</p>
wcscmp(), wscmp()	<p>The <code>wcscmp()</code> and <code>wscmp()</code> functions compare the wide-character string pointed to by <i>ws1</i> to the wide-character string pointed to by <i>ws2</i>. The sign of a non-zero return value is determined by the sign of the difference between the values of the first pair of wide-character codes that differ in the objects being compared. Upon completion, both functions return an integer greater than, equal to, or less than zero, if the wide-character string pointed to by <i>ws1</i> is greater than, equal to, or less than the wide-character string pointed to by <i>ws2</i>.</p>

wcstring(3C)

wcsncmp() , wsncmp()	The <code>wcsncmp()</code> and <code>wsncmp()</code> functions compare not more than <i>n</i> wide-character codes (wide-character codes that follow a null wide character code are not compared) from the array pointed to by <i>ws1</i> to the array pointed to by <i>ws2</i> . The sign of a non-zero return value is determined by the sign of the difference between the values of the first pair of wide-character codes that differ in the objects being compared. Upon successful completion, both functions return an integer greater than, equal to, or less than zero, if the possibly null-terminated array pointed to by <i>ws1</i> is greater than, equal to, or less than the possibly null-terminated array pointed to by <i>ws2</i> .
wcscpy() , wscpy()	The <code>wcscpy()</code> and <code>wscpy()</code> functions copy the wide-character string pointed to by <i>ws2</i> (including the terminating null wide-character code) into the array pointed to by <i>ws1</i> . If copying takes place between objects that overlap, the behavior is undefined. Both functions return <i>ws1</i> ; no return value is reserved to indicate an error.
wcsncpy() , wsncpy()	The <code>wcsncpy()</code> and <code>wsncpy()</code> functions copy not more than <i>n</i> wide-character codes (wide-character codes that follow a null wide character code are not copied) from the array pointed to by <i>ws2</i> to the array pointed to by <i>ws1</i> . If copying takes place between objects that overlap, the behavior is undefined. If the array pointed to by <i>ws2</i> is a wide-character string that is shorter than <i>n</i> wide-character codes, null wide-character codes are appended to the copy in the array pointed to by <i>ws1</i> , until a total <i>n</i> wide-character codes are written. Both functions return <i>ws1</i> ; no return value is reserved to indicate an error.
wcslen() , wslen()	The <code>wcslen()</code> and <code>wslen()</code> functions compute the number of wide-character codes in the wide-character string to which <i>ws</i> points, not including the terminating null wide-character code. Both functions return <i>ws</i> ; no return value is reserved to indicate an error.
wcschr() , wschr()	The <code>wcschr()</code> and <code>wschr()</code> functions locate the first occurrence of <i>wc</i> in the wide-character string pointed to by <i>ws</i> . The value of <i>wc</i> must be a character representable as a type <code>wchar_t</code> and must be a wide-character code corresponding to a valid character in the current locale. The terminating null wide-character code is considered to be part of the wide-character string. Upon completion, both functions return a pointer to the wide-character code, or a null pointer if the wide-character code is not found.
wcsrchr() , wsrchr()	The <code>wcsrchr()</code> and <code>wsrchr()</code> functions locate the last occurrence of <i>wc</i> in the wide-character string pointed to by <i>ws</i> . The value of <i>wc</i> must be a character representable as a type <code>wchar_t</code> and must be a wide-character code corresponding to a valid character in the current locale. The terminating null wide-character code is considered to be part of the wide-character string. Upon successful completion, both functions return a pointer to the wide-character code, or a null pointer if <i>wc</i> does not occur in the wide-character string.
windex() , wrindex()	The <code>windex()</code> and <code>wrindex()</code> functions behave the same as <code>wschr()</code> and <code>wsrchr()</code> , respectively.

wcspbrk() , wspbrk()	The <code>wcspbrk()</code> and <code>wspbrk()</code> functions locate the first occurrence in the wide character string pointed to by <code>ws1</code> of any wide-character code from the wide-character string pointed to by <code>ws2</code> . Upon successful completion, the function returns a pointer to the wide-character code, or a null pointer if no wide-character code from <code>ws2</code> occurs in <code>ws1</code> .
wcswcs()	The <code>wcswcs()</code> function locates the first occurrence in the wide-character string pointed to by <code>ws1</code> of the sequence of wide-character codes (excluding the terminating null wide-character code) in the wide-character string pointed to by <code>ws2</code> . Upon successful completion, the function returns a pointer to the located wide-character string, or a null pointer if the wide-character string is not found. If <code>ws2</code> points to a wide-character string with zero length, the function returns <code>ws1</code> .
wcsspn() , wsspnl()	The <code>wcsspn()</code> and <code>wsspnl()</code> functions compute the length of the maximum initial segment of the wide-character string pointed to by <code>ws1</code> which consists entirely of wide-character codes from the wide-character string pointed to by <code>ws2</code> . Both functions return the length <code>ws1</code> ; no return value is reserved to indicate an error.
wcscspn() , wscspnl()	The <code>wcscspn()</code> and <code>wscspnl()</code> functions compute the length of the maximum initial segment of the wide-character string pointed to by <code>ws1</code> which consists entirely of wide-character codes <i>not</i> from the wide-character string pointed to by <code>ws2</code> . Both functions return the length of the initial substring of <code>ws1</code> ; no return value is reserved to indicate an error.
wcstok() , wstok()	A sequence of calls to the <code>wcstok()</code> and <code>wstok()</code> functions break the wide-character string pointed to by <code>ws1</code> into a sequence of tokens, each of which is delimited by a wide-character code from the wide-character string pointed to by <code>ws2</code> .
Default and other standards	<p>The third argument points to a caller-provided <code>wchar_t</code> pointer into which the <code>wcstok()</code> function stores information necessary for it to continue scanning the same wide-character string. This argument is not available with the XPG4 and SUS versions of <code>wcstok()</code>, nor is it available with the <code>wstok()</code> function. See <code>standards(5)</code>.</p> <p>The first call in the sequence has <code>ws1</code> as its first argument, and is followed by calls with a null pointer as their first argument. The separator string pointed to by <code>ws2</code> may be different from call to call.</p> <p>The first call in the sequence searches the wide-character string pointed to by <code>ws1</code> for the first wide-character code that is <i>not</i> contained in the current separator string pointed to by <code>ws2</code>. If no such wide-character code is found, then there are no tokens in the wide-character string pointed to by <code>ws1</code>, and <code>wcstok()</code> and <code>wstok()</code> return a null pointer. If such a wide-character code is found, it is the start of the first token.</p> <p>The <code>wcstok()</code> and <code>wstok()</code> functions then search from that point for a wide-character code that <i>is</i> contained in the current separator string. If no such wide-character code is found, the current token extends to the end of the wide-character string pointed to by <code>ws1</code>, and subsequent searches for a token will</p>

wcstring(3C)

return a null pointer. If such a wide-character code is found, it is overwritten by a null wide character, which terminates the current token. The `wcstok()` and `wstok()` functions save a pointer to the following wide-character code, from which the next search for a token will start.

Each subsequent call, with a null pointer as the value of the first argument, starts searching from the saved pointer and behaves as described above.

Upon successful completion, both functions return a pointer to the first wide-character code of a token. Otherwise, if there is no token, a null pointer is returned.

Upon completion, both functions return an integer greater than, equal to, or less than zero, if the wide-character string pointed to by <i>ws1</i> is greater than, equal to, or less than the wide-character string pointed to by <i>ws2</i>.</p>

wcsncmp() , wsncmp()	The <code>wcsncmp()</code> and <code>wsncmp()</code> functions compare not more than <i>n</i> wide-character codes (wide-character codes that follow a null wide character code are not compared) from the array pointed to by <i>ws1</i> to the array pointed to by <i>ws2</i> . The sign of a non-zero return value is determined by the sign of the difference between the values of the first pair of wide-character codes that differ in the objects being compared. Upon successful completion, both functions return an integer greater than, equal to, or less than zero, if the possibly null-terminated array pointed to by <i>ws1</i> is greater than, equal to, or less than the possibly null-terminated array pointed to by <i>ws2</i> .
wscpy() , wscopy()	The <code>wscpy()</code> and <code>wscopy()</code> functions copy the wide-character string pointed to by <i>ws2</i> (including the terminating null wide-character code) into the array pointed to by <i>ws1</i> . If copying takes place between objects that overlap, the behavior is undefined. Both functions return <i>ws1</i> ; no return value is reserved to indicate an error.
wcsncpy() , wsncpy()	The <code>wcsncpy()</code> and <code>wsncpy()</code> functions copy not more than <i>n</i> wide-character codes (wide-character codes that follow a null wide character code are not copied) from the array pointed to by <i>ws2</i> to the array pointed to by <i>ws1</i> . If copying takes place between objects that overlap, the behavior is undefined. If the array pointed to by <i>ws2</i> is a wide-character string that is shorter than <i>n</i> wide-character codes, null wide-character codes are appended to the copy in the array pointed to by <i>ws1</i> , until a total <i>n</i> wide-character codes are written. Both functions return <i>ws1</i> ; no return value is reserved to indicate an error.
wcslen() , wslen()	The <code>wcslen()</code> and <code>wslen()</code> functions compute the number of wide-character codes in the wide-character string to which <i>ws</i> points, not including the terminating null wide-character code. Both functions return <i>ws</i> ; no return value is reserved to indicate an error.
wcschr() , wschr()	The <code>wcschr()</code> and <code>wschr()</code> functions locate the first occurrence of <i>wc</i> in the wide-character string pointed to by <i>ws</i> . The value of <i>wc</i> must be a character representable as a type <code>wchar_t</code> and must be a wide-character code corresponding to a valid character in the current locale. The terminating null wide-character code is considered to be part of the wide-character string. Upon completion, both functions return a pointer to the wide-character code, or a null pointer if the wide-character code is not found.
wcsrchr() , wsrchr()	The <code>wcsrchr()</code> and <code>wsrchr()</code> functions locate the last occurrence of <i>wc</i> in the wide-character string pointed to by <i>ws</i> . The value of <i>wc</i> must be a character representable as a type <code>wchar_t</code> and must be a wide-character code corresponding to a valid character in the current locale. The terminating null wide-character code is considered to be part of the wide-character string. Upon successful completion, both functions return a pointer to the wide-character code, or a null pointer if <i>wc</i> does not occur in the wide-character string.
windex() , wrindex()	The <code>windex()</code> and <code>wrindex()</code> functions behave the same as <code>wschr()</code> and <code>wsrchr()</code> , respectively.

wcswcs(3C)

wcspbrk() , wspbrk()	The <code>wcspbrk()</code> and <code>wspbrk()</code> functions locate the first occurrence in the wide character string pointed to by <code>ws1</code> of any wide-character code from the wide-character string pointed to by <code>ws2</code> . Upon successful completion, the function returns a pointer to the wide-character code, or a null pointer if no wide-character code from <code>ws2</code> occurs in <code>ws1</code> .
wcswcs()	The <code>wcswcs()</code> function locates the first occurrence in the wide-character string pointed to by <code>ws1</code> of the sequence of wide-character codes (excluding the terminating null wide-character code) in the wide-character string pointed to by <code>ws2</code> . Upon successful completion, the function returns a pointer to the located wide-character string, or a null pointer if the wide-character string is not found. If <code>ws2</code> points to a wide-character string with zero length, the function returns <code>ws1</code> .
wcsspn() , wsspnl()	The <code>wcsspn()</code> and <code>wsspnl()</code> functions compute the length of the maximum initial segment of the wide-character string pointed to by <code>ws1</code> which consists entirely of wide-character codes from the wide-character string pointed to by <code>ws2</code> . Both functions return the length <code>ws1</code> ; no return value is reserved to indicate an error.
wcscspn() , wscspnl()	The <code>wcscspn()</code> and <code>wscspnl()</code> functions compute the length of the maximum initial segment of the wide-character string pointed to by <code>ws1</code> which consists entirely of wide-character codes <i>not</i> from the wide-character string pointed to by <code>ws2</code> . Both functions return the length of the initial substring of <code>ws1</code> ; no return value is reserved to indicate an error.
wcstok() , wstok()	A sequence of calls to the <code>wcstok()</code> and <code>wstok()</code> functions break the wide-character string pointed to by <code>ws1</code> into a sequence of tokens, each of which is delimited by a wide-character code from the wide-character string pointed to by <code>ws2</code> .
Default and other standards	<p>The third argument points to a caller-provided <code>wchar_t</code> pointer into which the <code>wcstok()</code> function stores information necessary for it to continue scanning the same wide-character string. This argument is not available with the XPG4 and SUS versions of <code>wcstok()</code>, nor is it available with the <code>wstok()</code> function. See <code>standards(5)</code>.</p> <p>The first call in the sequence has <code>ws1</code> as its first argument, and is followed by calls with a null pointer as their first argument. The separator string pointed to by <code>ws2</code> may be different from call to call.</p> <p>The first call in the sequence searches the wide-character string pointed to by <code>ws1</code> for the first wide-character code that is <i>not</i> contained in the current separator string pointed to by <code>ws2</code>. If no such wide-character code is found, then there are no tokens in the wide-character string pointed to by <code>ws1</code>, and <code>wcstok()</code> and <code>wstok()</code> return a null pointer. If such a wide-character code is found, it is the start of the first token.</p> <p>The <code>wcstok()</code> and <code>wstok()</code> functions then search from that point for a wide-character code that <i>is</i> contained in the current separator string. If no such wide-character code is found, the current token extends to the end of the wide-character string pointed to by <code>ws1</code>, and subsequent searches for a token will</p>

return a null pointer. If such a wide-character code is found, it is overwritten by a null wide character, which terminates the current token. The `wcstok()` and `wstok()` functions save a pointer to the following wide-character code, from which the next search for a token will start.

Each subsequent call, with a null pointer as the value of the first argument, starts searching from the saved pointer and behaves as described above.

Upon successful completion, both functions return a pointer to the first wide-character code of a token. Otherwise, if there is no token, a null pointer is returned.

wcswidth(3C)

NAME	wcswidth – number of column positions of a wide-character string						
SYNOPSIS	<pre>#include <wchar.h> int wcswidth(const wchar_t *pwcs, size_t n);</pre>						
DESCRIPTION	The <code>wcswidth()</code> function determines the number of column positions required for <i>n</i> wide-character codes (or fewer than <i>n</i> wide-character codes if a null wide-character code is encountered before <i>n</i> wide-character codes are exhausted) in the string pointed to by <i>pwcs</i> .						
RETURN VALUES	The <code>wcswidth()</code> function either returns 0 (if <i>pwcs</i> points to a null wide-character code), or returns the number of column positions to be occupied by the wide-character string pointed to by <i>pwcs</i> , or returns -1 (if any of the first <i>n</i> wide-character codes in the wide-character string pointed to by <i>pwcs</i> is not a printing wide-character code).						
ERRORS	No errors are defined.						
ATTRIBUTES	See <code>attributes(5)</code> for descriptions of the following attributes:

NAME	wcsxfrm, wsxfrm – wide character string transformation				
SYNOPSIS	<pre>#include <wchar.h> size_t wcsxfrm(wchar_t *ws1, const wchar_t *ws2, size_t n); size_t wsxfrm(wchar_t *ws1, const wchar_t *ws2, size_t n);</pre>				
DESCRIPTION	<p>The <code>wcsxfrm()</code> and <code>wsxfrm()</code> functions transform the wide character string pointed to by <code>ws2</code> and place the resulting wide character string into the array pointed to by <code>ws1</code>. The transformation is such that if either the <code>wcscmp(3C)</code> or <code>wscmp(3C)</code> functions are applied to two transformed wide strings, they return a value greater than, equal to, or less than 0, corresponding to the result of the <code>wscoll(3C)</code> or <code>wscoll(3C)</code> function applied to the same two original wide character strings. No more than <code>n</code> wide-character codes are placed into the resulting array pointed to by <code>ws1</code>, including the terminating null wide-character code. If <code>n</code> is 0, <code>ws1</code> is permitted to be a null pointer. If copying takes place between objects that overlap, the behavior is undefined.</p>				
RETURN VALUES	<p>The <code>wcsxfrm()</code> and <code>wsxfrm()</code> functions return the length of the transformed wide character string (not including the terminating null wide-character code). If the value returned is <code>n</code> or more, the contents of the array pointed to by <code>ws1</code> are indeterminate.</p> <p>On error, <code>wcsxfrm()</code> and <code>wsxfrm()</code> return <code>(size_t)-1</code> and set <code>errno</code> to indicate the error.</p>				
ERRORS	<p>The <code>wcsxfrm()</code> and <code>wsxfrm()</code> functions may fail if:</p> <table border="0"> <tr> <td style="padding-right: 20px;">EINVAL</td> <td>The wide character string pointed to by <code>ws2</code> contains wide-character codes outside the domain of the collating sequence.</td> </tr> <tr> <td>ENOSYS</td> <td>The function is not supported.</td> </tr> </table>	EINVAL	The wide character string pointed to by <code>ws2</code> contains wide-character codes outside the domain of the collating sequence.	ENOSYS	The function is not supported.
EINVAL	The wide character string pointed to by <code>ws2</code> contains wide-character codes outside the domain of the collating sequence.				
ENOSYS	The function is not supported.				
USAGE	<p>The transformation function is such that two transformed wide character strings can be ordered by the <code>wcscmp()</code> or <code>wscmp()</code> functions as appropriate to collating sequence information in the program's locale (category <code>LC_COLLATE</code>).</p> <p>The fact that when <code>n</code> is 0, <code>ws1</code> is permitted to be a null pointer, is useful to determine the size of the <code>ws1</code> array prior to making the transformation.</p> <p>Because no return value is reserved to indicate an error, an application wishing to check for error situations should set <code>errno</code> to 0, call <code>wcsxfrm()</code> or <code>wsxfrm()</code>, then check <code>errno</code> and if it is non-zero, assume an error has occurred.</p> <p>The <code>wcsxfrm()</code> and <code>wsxfrm()</code> functions can be used safely in multithreaded applications as long as <code>setlocale(3C)</code> is not being called to change the locale.</p>

NAME	wctob – wide-character to single-byte conversion				
SYNOPSIS	<pre>#include <stdio.h> #include <wchar.h> int wctob(wint_t c);</pre>				
DESCRIPTION	<p>The <code>wctob()</code> function determines whether <code>c</code> corresponds to a member of the extended character set whose character representation is a single byte when in the initial shift state.</p> <p>The behavior of this function is affected by the <code>LC_CTYPE</code> category of the current locale. See <code>environ(5)</code>.</p>				
RETURN VALUES	The <code>wctob()</code> function returns EOF if <code>c</code> does not correspond to a character with length one in the initial shift state. Otherwise, it returns the single-byte representation of that character.				
ERRORS	No errors are defined.				
ATTRIBUTES	See <code>attributes(5)</code> for descriptions of the following attributes:				
	<table border="1"> <thead> <tr> <th>ATTRIBUTE TYPE</th> <th>ATTRIBUTE VALUE</th> </tr> </thead> <tbody> <tr> <td>MT-Level</td> <td>MT-Safe with exceptions</td> </tr> </tbody> </table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	MT-Level	MT-Safe with exceptions
ATTRIBUTE TYPE	ATTRIBUTE VALUE

SEE ALSO	<code>btowc(3C)</code> , <code>setlocale(3C)</code> , <code>attributes(5)</code> , <code>environ(5)</code>				
NOTES	The <code>wctob()</code> function can be used safely in multithreaded applications, as long as <code>setlocale(3C)</code> is not being called to change the locale.				

wctomb(3C)

NAME	wctomb – convert a wide-character code to a character						
SYNOPSIS	<pre>#include <stdlib.h> int wctomb(char *s, wchar_t <i>wchar</i>);</pre>						
DESCRIPTION	<p>The <code>wctomb()</code> function determines the number of bytes needed to represent the character corresponding to the wide-character code whose value is <i>wchar</i>. It stores the character representation (possibly multiple bytes) in the array object pointed to by <i>s</i> (if <i>s</i> is not a null pointer). At most <code>MB_CUR_MAX</code> bytes are stored.</p> <p>A call with <i>s</i> as a null pointer causes this function to return 0. The behavior of this function is affected by the <code>LC_CTYPE</code> category of the current locale.</p>						
RETURN VALUES	<p>If <i>s</i> is a null pointer, <code>wctomb()</code> returns 0 value. If <i>s</i> is not a null pointer, <code>wctomb()</code> returns <code>-1</code> if the value of <i>wchar</i> does not correspond to a valid character, or returns the number of bytes that constitute the character corresponding to the value of <i>wchar</i>.</p> <p>In no case will the value returned be greater than the value of the <code>MB_CUR_MAX</code> macro.</p>						
ERRORS	No errors are defined.						
USAGE	The <code>wctomb()</code> function can be used safely in a multithreaded application, as long as <code>setlocale(3C)</code> is not being called to change the locale.						
ATTRIBUTES	See <code>attributes(5)</code> for descriptions of the following attributes:

NAME	wctrans – define character mapping						
SYNOPSIS	<pre>#include <wctype.h> wctrans_t wctrans(const char *charclass);</pre>						
DESCRIPTION	<p>The <code>wctrans()</code> function is defined for valid character mapping names identified in the current locale. The <i>charclass</i> is a string identifying a generic character mapping name for which codeset-specific information is required. The following character mapping names are defined in all locales – "tolower" and "toupper".</p> <p>The function returns a value of type <code>wctrans_t</code>, which can be used as the second argument to subsequent calls of <code>towctrans(3C)</code>. The <code>wctrans()</code> function determines values of <code>wctrans_t</code> according to the rules of the coded character set defined by character mapping information in the program's locale (category <code>LC_CTYPE</code>). The values returned by <code>wctrans()</code> are valid until a call to <code>setlocale(3C)</code> that modifies the category <code>LC_CTYPE</code>.</p>						
RETURN VALUES	The <code>wctrans()</code> function returns 0 if the given character mapping name is not valid for the current locale (category <code>LC_CTYPE</code>), otherwise it returns a non-zero object of type <code>wctrans_t</code> that can be used in calls to <code>towctrans(3C)</code> .						
ERRORS	<p>The <code>wctrans()</code> function may fail if:</p> <p><code>EINVAL</code> The character mapping name pointed to by <i>charclass</i> is not valid in the current locale.</p>						
ATTRIBUTES	See <code>attributes(5)</code> for descriptions of the following attributes:

NAME	wcwidth – number of column positions of a wide-character code
SYNOPSIS	<pre>#include <wchar.h> int wcwidth(wchar_t <i>wc</i>);</pre>
DESCRIPTION	The <code>wcwidth()</code> function determines the number of column positions required for the wide character <i>wc</i> . The value of <i>wc</i> must be a character representable as a <code>wchar_t</code> , and must be a wide-character code corresponding to a valid character in the current locale.
RETURN VALUES	The <code>wcwidth()</code> function either returns 0 (if <i>wc</i> is a null wide-character code), or returns the number of column positions to be occupied by the wide-character code <i>wc</i> , or returns -1 (if <i>wc</i> does not correspond to a printing wide-character code).
ERRORS	No errors are defined.
ATTRIBUTES	See <code>attributes(5)</code> for descriptions of the following attributes:

WIFEXITED(3UCB)

NAME	<code>wait</code> , <code>wait3</code> , <code>wait4</code> , <code>waitpid</code> , <code>WIFSTOPPED</code> , <code>WIFSIGNALED</code> , <code>WIFEXITED</code> – wait for process to terminate or stop
SYNOPSIS	<pre><code>/usr/ucb/cc [flag ...] file ... #include <sys/wait.h> int wait(<i>statusp</i>); int *<i>statusp</i>; int waitpid(<i>pid</i>, <i>statusp</i>, <i>options</i>); int <i>pid</i>; int *<i>statusp</i>; int <i>options</i>; #include <sys/time.h> #include <sys/resource.h> int wait3(<i>statusp</i>, <i>options</i>, <i>rusage</i>); int *<i>statusp</i>; int <i>options</i>; struct rusage *<i>rusage</i>; int wait4(<i>pid</i>, <i>statusp</i>, <i>options</i>, <i>rusage</i>); int <i>pid</i>; int *<i>statusp</i>; int <i>options</i>; struct rusage *<i>rusage</i>; WIFSTOPPED(<i>status</i>); int <i>status</i>; WIFSIGNALED(<i>status</i>); int <i>status</i>; WIFEXITED(<i>status</i>); int <i>status</i>;</code></pre>
DESCRIPTION	<p><code>wait()</code> delays its caller until a signal is received or one of its child processes terminates or stops due to tracing. If any child process has died or stopped due to tracing and this has not been reported using <code>wait()</code>, return is immediate, returning the process ID and exit status of one of those children. If that child process has died, it is discarded. If there are no children, return is immediate with the value <code>-1</code> returned. If there are only running or stopped but reported children, the calling process is blocked.</p> <p>If <i>status</i> is not a NULL pointer, then on return from a successful <code>wait()</code> call the status of the child process whose process ID is the return value of <code>wait()</code> is stored in the <code>wait()</code> union pointed to by <i>status</i>. The <code>w_status</code> member of that union is an <code>int</code>; it indicates the cause of termination and other information about the terminated process in the following manner:</p>

- If the low-order 8 bits of `w_status` are equal to 0177, the child process has stopped; the 8 bits higher up from the low-order 8 bits of `w_status` contain the number of the signal that caused the process to stop. See `ptrace(2)` and `sigvec(3UCB)`.
- If the low-order 8 bits of `w_status` are non-zero and are not equal to 0177, the child process terminated due to a signal; the low-order 7 bits of `w_status` contain the number of the signal that terminated the process. In addition, if the low-order seventh bit of `w_status` (that is, bit 0200) is set, a “core image” of the process was produced; see `sigvec(3UCB)`.
- Otherwise, the child process terminated due to an `exit()` call; the 8 bits higher up from the low-order 8 bits of `w_status` contain the low-order 8 bits of the argument that the child process passed to `exit()`; see `exit(2)`.

`waitpid()` behaves identically to `wait()` if `pid` has a value of `-1` and `options` has a value of zero. Otherwise, the behavior of `waitpid()` is modified by the values of `pid` and `options` as follows:

`pid` specifies a set of child processes for which status is requested. `waitpid()` only returns the status of a child process from this set.

- If `pid` is equal to `-1`, status is requested for any child process. In this respect, `waitpid()` is then equivalent to `wait()`.
- If `pid` is greater than zero, it specifies the process ID of a single child process for which status is requested.
- If `pid` is equal to zero, status is requested for any child process whose process group ID is equal to that of the calling process.
- If `pid` is less than `-1`, status is requested for any child process whose process group ID is equal to the absolute value of `pid`.

`options` is constructed from the bitwise inclusive OR of zero or more of the following flags, defined in the header `<sys/wait.h>`:

WNOHANG	<code>waitpid()</code> does not suspend execution of the calling process if status is not immediately available for one of the child processes specified by <code>pid</code> .
WUNTRACED	The status of any child processes specified by <code>pid</code> that are stopped, and whose status has not yet been reported since they stopped, are also reported to the requesting process.

`wait3()` is an alternate interface that allows both non-blocking status collection and the collection of the status of children stopped by any means. The `status` parameter is defined as above. The `options` parameter is used to indicate the call should not block if there are no processes that have status to report (`WNOHANG`), and/or that children of the current process that are stopped due to a `SIGTTIN`, `SIGTTOU`, `SIGTSTP`, or `SIGSTOP` signal are eligible to have their status reported as well (`WUNTRACED`). A terminated child is discarded after it reports status, and a stopped process will not report its status more than once. If `rusage` is not a `NULL` pointer, a summary of the

WIFEXITED(3UCB)

resources used by the terminated process and all its children is returned. Only the user time used and the system time used are currently available. They are returned in `rusage.ru_utime` and `rusage.ru_stime`, respectively.

When the `WNOHANG` option is specified and no processes have status to report, `wait3()` returns 0. The `WNOHANG` and `WUNTRACED` options may be combined by ORing the two values.

`wait4()` is another alternate interface. With a *pid* argument of 0, it is equivalent to `wait3()`. If *pid* has a nonzero value, then `wait4()` returns status only for the indicated process ID, but not for any other child processes.

`WIFSTOPPED`, `WIFSIGNALED`, `WIFEXITED`, are macros that take an argument *status*, of type `int`, as returned by `wait()`, or `wait3()`, or `wait4()`. `WIFSTOPPED` evaluates to true (1) when the process for which the `wait()` call was made is stopped, or to false (0) otherwise. `WIFSIGNALED` evaluates to true when the process was terminated with a signal. `WIFEXITED` evaluates to true when the process exited by using an `exit(2)` call.

RETURN VALUES

If `wait()` or `waitpid()` returns due to a stopped or terminated child process, the process ID of the child is returned to the calling process. Otherwise, a value of `-1` is returned and `errno` is set to indicate the error.

If `wait()` or `waitpid()` return due to the delivery of a signal to the calling process, a value of `-1` is returned and `errno` is set to `EINTR`. If `waitpid()` function was invoked with `WNOHANG` set in *options*, it has at least one child process specified by *pid* for which status is not available, and status is not available for any process specified by *pid*, a value of zero is returned. Otherwise, a value of `-1` is returned, and `errno` is set to indicate the error.

`wait3()` and `wait4()` returns 0 if `WNOHANG` is specified and there are no stopped or exited children, and returns the process ID of the child process if it returns due to a stopped or terminated child process. Otherwise, they returns a value of `-1` and sets `errno` to indicate the error.

ERRORS

`wait()`, `wait3()` or `wait4()` will fail and return immediately if one or more of the following are true:

ECHILD The calling process has no existing unwaited-for child processes.

EFAULT The *status* or *rusage* arguments point to an illegal address.

`waitpid()` may set `errno` to:

ECHILD The process or process group specified by *pid* does not exist or is not a child of the calling process.

EINTR The function was interrupted by a signal. The value of the location pointed to by *statusp* is undefined.

EINVAL The value of *options* is not valid.

`wait()`, and `wait3()`, and `wait4()` will terminate prematurely, return `-1`, and set `errno` to `EINTR` upon the arrival of a signal whose `SV_INTERRUPT` bit in its flags field is set (see `sigvec(3UCB)` and `siginterrupt(3UCB)`). `signal(3UCB)`, sets this bit for any signal it catches.

SEE ALSO `exit(2)`, `ptrace(2)`, `wait(2)`, `waitpid(2)`, `getrusage(3C)`, `siginterrupt(3UCB)`, `signal(3UCB)`, `sigvec(3UCB)`, `signal(3C)`

NOTES Use of these interfaces should be restricted to only applications written on BSD platforms. Use of these interfaces with any of the system libraries or in multi-thread applications is unsupported.

If a parent process terminates without waiting on its children, the initialization process (process ID = 1) inherits the children.

`wait()`, and `wait3()`, and `wait4()` are automatically restarted when a process receives a signal while awaiting termination of a child process, unless the `SV_INTERRUPT` bit is set in the flags for that signal.

Calls to `wait()` with an argument of 0 should be cast to type `'int *'`, as in:

```
wait((int *)0)
```

Previous SunOS releases used union `wait*statusp` and union `wait status` in place of `int *statusp` and `int status`. The union contained a member `w_status` that could be treated in the same way as `status`.

Other members of the `wait` union could be used to extract this information more conveniently:

- If the `w_stopval` member had the value `WSTOPPED`, the child process had stopped; the value of the `w_stopsig` member was the signal that stopped the process.
- If the `w_termsig` member was non-zero, the child process terminated due to a signal; the value of the `w_termsig` member was the number of the signal that terminated the process. If the `w_coredump` member was non-zero, a core dump was produced.
- Otherwise, the child process terminated due to a call to `exit()`. The value of the `w_retcode` member was the low-order 8 bits of the argument that the child process passed to `exit()`.

union `wait` is obsolete in light of the new specifications provided by *IEEE Std 1003.1-1988* and endorsed by *SVID89* and *XPG3*. SunOS Release 4.1 supports `unionwait` for backward compatibility, but it will disappear in a future release.

WIFSIGNALED(3UCB)

NAME	<code>wait, wait3, wait4, waitpid, WIFSTOPPED, WIFSIGNALED, WIFEXITED</code> – wait for process to terminate or stop
SYNOPSIS	<pre><code>/usr/ucb/cc [flag ...] file ... #include <sys/wait.h> int wait(statusp); int *statusp; int waitpid(pid, statusp, options); int pid; int *statusp; int options; #include <sys/time.h> #include <sys/resource.h> int wait3(statusp, options, rusage); int *statusp; int options; struct rusage *rusage; int wait4(pid, statusp, options, rusage); int pid; int *statusp; int options; struct rusage *rusage; WIFSTOPPED(status); int status; WIFSIGNALED(status); int status; WIFEXITED(status); int status;</code></pre>
DESCRIPTION	<p><code>wait()</code> delays its caller until a signal is received or one of its child processes terminates or stops due to tracing. If any child process has died or stopped due to tracing and this has not been reported using <code>wait()</code>, return is immediate, returning the process ID and exit status of one of those children. If that child process has died, it is discarded. If there are no children, return is immediate with the value <code>-1</code> returned. If there are only running or stopped but reported children, the calling process is blocked.</p> <p>If <code>status</code> is not a <code>NULL</code> pointer, then on return from a successful <code>wait()</code> call the status of the child process whose process ID is the return value of <code>wait()</code> is stored in the <code>wait()</code> union pointed to by <code>status</code>. The <code>w_status</code> member of that union is an <code>int</code>; it indicates the cause of termination and other information about the terminated process in the following manner:</p>

- If the low-order 8 bits of `w_status` are equal to 0177, the child process has stopped; the 8 bits higher up from the low-order 8 bits of `w_status` contain the number of the signal that caused the process to stop. See `ptrace(2)` and `sigvec(3UCB)`.
- If the low-order 8 bits of `w_status` are non-zero and are not equal to 0177, the child process terminated due to a signal; the low-order 7 bits of `w_status` contain the number of the signal that terminated the process. In addition, if the low-order seventh bit of `w_status` (that is, bit 0200) is set, a “core image” of the process was produced; see `sigvec(3UCB)`.
- Otherwise, the child process terminated due to an `exit()` call; the 8 bits higher up from the low-order 8 bits of `w_status` contain the low-order 8 bits of the argument that the child process passed to `exit()`; see `exit(2)`.

`waitpid()` behaves identically to `wait()` if `pid` has a value of `-1` and `options` has a value of zero. Otherwise, the behavior of `waitpid()` is modified by the values of `pid` and `options` as follows:

`pid` specifies a set of child processes for which status is requested. `waitpid()` only returns the status of a child process from this set.

- If `pid` is equal to `-1`, status is requested for any child process. In this respect, `waitpid()` is then equivalent to `wait()`.
- If `pid` is greater than zero, it specifies the process ID of a single child process for which status is requested.
- If `pid` is equal to zero, status is requested for any child process whose process group ID is equal to that of the calling process.
- If `pid` is less than `-1`, status is requested for any child process whose process group ID is equal to the absolute value of `pid`.

`options` is constructed from the bitwise inclusive OR of zero or more of the following flags, defined in the header `<sys/wait.h>`:

WNOHANG	<code>waitpid()</code> does not suspend execution of the calling process if status is not immediately available for one of the child processes specified by <code>pid</code> .
WUNTRACED	The status of any child processes specified by <code>pid</code> that are stopped, and whose status has not yet been reported since they stopped, are also reported to the requesting process.

`wait3()` is an alternate interface that allows both non-blocking status collection and the collection of the status of children stopped by any means. The `status` parameter is defined as above. The `options` parameter is used to indicate the call should not block if there are no processes that have status to report (WNOHANG), and/or that children of the current process that are stopped due to a SIGTTIN, SIGTTOU, SIGTSTP, or SIGSTOP signal are eligible to have their status reported as well (WUNTRACED). A terminated child is discarded after it reports status, and a stopped process will not

WIFSIGNALED(3UCB)

report its status more than once. If *rusage* is not a NULL pointer, a summary of the resources used by the terminated process and all its children is returned. Only the user time used and the system time used are currently available. They are returned in `rusage.ru_utime` and `rusage.ru_stime`, respectively.

When the `WNOHANG` option is specified and no processes have status to report, `wait3()` returns 0. The `WNOHANG` and `WUNTRACED` options may be combined by ORing the two values.

`wait4()` is another alternate interface. With a *pid* argument of 0, it is equivalent to `wait3()`. If *pid* has a nonzero value, then `wait4()` returns status only for the indicated process ID, but not for any other child processes.

`WIFSTOPPED`, `WIFSIGNALED`, `WIFEXITED`, are macros that take an argument *status*, of type `int`, as returned by `wait()`, or `wait3()`, or `wait4()`. `WIFSTOPPED` evaluates to true (1) when the process for which the `wait()` call was made is stopped, or to false (0) otherwise. `WIFSIGNALED` evaluates to true when the process was terminated with a signal. `WIFEXITED` evaluates to true when the process exited by using an `exit(2)` call.

RETURN VALUES

If `wait()` or `waitpid()` returns due to a stopped or terminated child process, the process ID of the child is returned to the calling process. Otherwise, a value of -1 is returned and `errno` is set to indicate the error.

If `wait()` or `waitpid()` return due to the delivery of a signal to the calling process, a value of -1 is returned and `errno` is set to `EINTR`. If `waitpid()` function was invoked with `WNOHANG` set in *options*, it has at least one child process specified by *pid* for which status is not available, and status is not available for any process specified by *pid*, a value of zero is returned. Otherwise, a value of -1 is returned, and `errno` is set to indicate the error.

`wait3()` and `wait4()` returns 0 if `WNOHANG` is specified and there are no stopped or exited children, and returns the process ID of the child process if it returns due to a stopped or terminated child process. Otherwise, they returns a value of -1 and sets `errno` to indicate the error.

ERRORS

`wait()`, `wait3()` or `wait4()` will fail and return immediately if one or more of the following are true:

<code>ECHILD</code>	The calling process has no existing unwaited-for child processes.
<code>EFAULT</code>	The <i>status</i> or <i>rusage</i> arguments point to an illegal address.

`waitpid()` may set `errno` to:

<code>ECHILD</code>	The process or process group specified by <i>pid</i> does not exist or is not a child of the calling process.
<code>EINTR</code>	The function was interrupted by a signal. The value of the location pointed to by <i>statusp</i> is undefined.

EINVAL The value of *options* is not valid.

`wait()`, and `wait3()`, and `wait4()` will terminate prematurely, return `-1`, and set `errno` to `EINTR` upon the arrival of a signal whose `SV_INTERRUPT` bit in its flags field is set (see `sigvec(3UCB)` and `siginterrupt(3UCB)`). `signal(3UCB)`, sets this bit for any signal it catches.

SEE ALSO `exit(2)`, `ptrace(2)`, `wait(2)`, `waitpid(2)`, `getrusage(3C)`, `siginterrupt(3UCB)`, `signal(3UCB)`, `sigvec(3UCB)`, `signal(3C)`

NOTES Use of these interfaces should be restricted to only applications written on BSD platforms. Use of these interfaces with any of the system libraries or in multi-thread applications is unsupported.

If a parent process terminates without waiting on its children, the initialization process (process ID = 1) inherits the children.

`wait()`, and `wait3()`, and `wait4()` are automatically restarted when a process receives a signal while awaiting termination of a child process, unless the `SV_INTERRUPT` bit is set in the flags for that signal.

Calls to `wait()` with an argument of 0 should be cast to type `'int *'`, as in:

```
wait((int *)0)
```

Previous SunOS releases used union `wait*statusp` and union `wait status` in place of `int *statusp` and `int status`. The union contained a member `w_status` that could be treated in the same way as `status`.

Other members of the `wait` union could be used to extract this information more conveniently:

- If the `w_stopval` member had the value `WSTOPPED`, the child process had stopped; the value of the `w_stopsig` member was the signal that stopped the process.
- If the `w_termsig` member was non-zero, the child process terminated due to a signal; the value of the `w_termsig` member was the number of the signal that terminated the process. If the `w_coredump` member was non-zero, a core dump was produced.
- Otherwise, the child process terminated due to a call to `exit()`. The value of the `w_retcode` member was the low-order 8 bits of the argument that the child process passed to `exit()`.

union `wait` is obsolete in light of the new specifications provided by *IEEE Std 1003.1-1988* and endorsed by *SVID89* and *XPG3*. SunOS Release 4.1 supports `unionwait` for backward compatibility, but it will disappear in a future release.

WIFSTOPPED(3UCB)

NAME	<code>wait, wait3, wait4, waitpid, WIFSTOPPED, WIFSIGNALED, WIFEXITED</code> – wait for process to terminate or stop
SYNOPSIS	<pre><code>/usr/ucb/cc [flag ...] file ... #include <sys/wait.h> int wait(statusp); int *statusp; int waitpid(pid, statusp, options); int pid; int *statusp; int options; #include <sys/time.h> #include <sys/resource.h> int wait3(statusp, options, rusage); int *statusp; int options; struct rusage *rusage; int wait4(pid, statusp, options, rusage); int pid; int *statusp; int options; struct rusage *rusage; WIFSTOPPED(status); int status; WIFSIGNALED(status); int status; WIFEXITED(status); int status;</code></pre>
DESCRIPTION	<p><code>wait()</code> delays its caller until a signal is received or one of its child processes terminates or stops due to tracing. If any child process has died or stopped due to tracing and this has not been reported using <code>wait()</code>, return is immediate, returning the process ID and exit status of one of those children. If that child process has died, it is discarded. If there are no children, return is immediate with the value <code>-1</code> returned. If there are only running or stopped but reported children, the calling process is blocked.</p> <p>If <code>status</code> is not a <code>NULL</code> pointer, then on return from a successful <code>wait()</code> call the status of the child process whose process ID is the return value of <code>wait()</code> is stored in the <code>wait()</code> union pointed to by <code>status</code>. The <code>w_status</code> member of that union is an <code>int</code>; it indicates the cause of termination and other information about the terminated process in the following manner:</p>

- If the low-order 8 bits of `w_status` are equal to 0177, the child process has stopped; the 8 bits higher up from the low-order 8 bits of `w_status` contain the number of the signal that caused the process to stop. See `ptrace(2)` and `sigvec(3UCB)`.
- If the low-order 8 bits of `w_status` are non-zero and are not equal to 0177, the child process terminated due to a signal; the low-order 7 bits of `w_status` contain the number of the signal that terminated the process. In addition, if the low-order seventh bit of `w_status` (that is, bit 0200) is set, a “core image” of the process was produced; see `sigvec(3UCB)`.
- Otherwise, the child process terminated due to an `exit()` call; the 8 bits higher up from the low-order 8 bits of `w_status` contain the low-order 8 bits of the argument that the child process passed to `exit()`; see `exit(2)`.

`waitpid()` behaves identically to `wait()` if `pid` has a value of `-1` and `options` has a value of zero. Otherwise, the behavior of `waitpid()` is modified by the values of `pid` and `options` as follows:

`pid` specifies a set of child processes for which status is requested. `waitpid()` only returns the status of a child process from this set.

- If `pid` is equal to `-1`, status is requested for any child process. In this respect, `waitpid()` is then equivalent to `wait()`.
- If `pid` is greater than zero, it specifies the process ID of a single child process for which status is requested.
- If `pid` is equal to zero, status is requested for any child process whose process group ID is equal to that of the calling process.
- If `pid` is less than `-1`, status is requested for any child process whose process group ID is equal to the absolute value of `pid`.

`options` is constructed from the bitwise inclusive OR of zero or more of the following flags, defined in the header `<sys/wait.h>`:

WNOHANG	<code>waitpid()</code> does not suspend execution of the calling process if status is not immediately available for one of the child processes specified by <code>pid</code> .
WUNTRACED	The status of any child processes specified by <code>pid</code> that are stopped, and whose status has not yet been reported since they stopped, are also reported to the requesting process.

`wait3()` is an alternate interface that allows both non-blocking status collection and the collection of the status of children stopped by any means. The `status` parameter is defined as above. The `options` parameter is used to indicate the call should not block if there are no processes that have status to report (WNOHANG), and/or that children of the current process that are stopped due to a SIGTTIN, SIGTTOU, SIGTSTP, or SIGSTOP signal are eligible to have their status reported as well (WUNTRACED). A terminated child is discarded after it reports status, and a stopped process will not

WIFSTOPPED(3UCB)

report its status more than once. If *rusage* is not a NULL pointer, a summary of the resources used by the terminated process and all its children is returned. Only the user time used and the system time used are currently available. They are returned in `rusage.ru_utime` and `rusage.ru_stime`, respectively.

When the `WNOHANG` option is specified and no processes have status to report, `wait3()` returns 0. The `WNOHANG` and `WUNTRACED` options may be combined by ORing the two values.

`wait4()` is another alternate interface. With a *pid* argument of 0, it is equivalent to `wait3()`. If *pid* has a nonzero value, then `wait4()` returns status only for the indicated process ID, but not for any other child processes.

`WIFSTOPPED`, `WIFSIGNALED`, `WIFEXITED`, are macros that take an argument *status*, of type `int`, as returned by `wait()`, or `wait3()`, or `wait4()`. `WIFSTOPPED` evaluates to true (1) when the process for which the `wait()` call was made is stopped, or to false (0) otherwise. `WIFSIGNALED` evaluates to true when the process was terminated with a signal. `WIFEXITED` evaluates to true when the process exited by using an `exit(2)` call.

RETURN VALUES

If `wait()` or `waitpid()` returns due to a stopped or terminated child process, the process ID of the child is returned to the calling process. Otherwise, a value of -1 is returned and `errno` is set to indicate the error.

If `wait()` or `waitpid()` return due to the delivery of a signal to the calling process, a value of -1 is returned and `errno` is set to `EINTR`. If `waitpid()` function was invoked with `WNOHANG` set in *options*, it has at least one child process specified by *pid* for which status is not available, and status is not available for any process specified by *pid*, a value of zero is returned. Otherwise, a value of -1 is returned, and `errno` is set to indicate the error.

`wait3()` and `wait4()` returns 0 if `WNOHANG` is specified and there are no stopped or exited children, and returns the process ID of the child process if it returns due to a stopped or terminated child process. Otherwise, they returns a value of -1 and sets `errno` to indicate the error.

ERRORS

`wait()`, `wait3()` or `wait4()` will fail and return immediately if one or more of the following are true:

<code>ECHILD</code>	The calling process has no existing unwaited-for child processes.
<code>EFAULT</code>	The <i>status</i> or <i>rusage</i> arguments point to an illegal address.

`waitpid()` may set `errno` to:

<code>ECHILD</code>	The process or process group specified by <i>pid</i> does not exist or is not a child of the calling process.
<code>EINTR</code>	The function was interrupted by a signal. The value of the location pointed to by <i>statusp</i> is undefined.

EINVAL The value of *options* is not valid.

`wait()`, `wait3()`, and `wait4()` will terminate prematurely, return `-1`, and set `errno` to `EINTR` upon the arrival of a signal whose `SV_INTERRUPT` bit in its flags field is set (see `sigvec(3UCB)` and `siginterrupt(3UCB)`). `signal(3UCB)`, sets this bit for any signal it catches.

SEE ALSO `exit(2)`, `ptrace(2)`, `wait(2)`, `waitpid(2)`, `getrusage(3C)`, `siginterrupt(3UCB)`, `signal(3UCB)`, `sigvec(3UCB)`, `signal(3C)`

NOTES Use of these interfaces should be restricted to only applications written on BSD platforms. Use of these interfaces with any of the system libraries or in multi-thread applications is unsupported.

If a parent process terminates without waiting on its children, the initialization process (process ID = 1) inherits the children.

`wait()`, `wait3()`, and `wait4()` are automatically restarted when a process receives a signal while awaiting termination of a child process, unless the `SV_INTERRUPT` bit is set in the flags for that signal.

Calls to `wait()` with an argument of 0 should be cast to type `'int *'`, as in:

```
wait((int *)0)
```

Previous SunOS releases used union `wait*statusp` and union `wait status` in place of `int *statusp` and `int status`. The union contained a member `w_status` that could be treated in the same way as `status`.

Other members of the `wait` union could be used to extract this information more conveniently:

- If the `w_stopval` member had the value `WSTOPPED`, the child process had stopped; the value of the `w_stopsig` member was the signal that stopped the process.
- If the `w_termsig` member was non-zero, the child process terminated due to a signal; the value of the `w_termsig` member was the number of the signal that terminated the process. If the `w_coredump` member was non-zero, a core dump was produced.
- Otherwise, the child process terminated due to a call to `exit()`. The value of the `w_retcode` member was the low-order 8 bits of the argument that the child process passed to `exit()`.

union `wait` is obsolete in light of the new specifications provided by *IEEE Std 1003.1-1988* and endorsed by *SVID89* and *XPG3*. SunOS Release 4.1 supports `unionwait` for backward compatibility, but it will disappear in a future release.

	<pre> size_t wcspn(const wchar_t *ws1, const wchar_t *ws2); wchar_t *wstok(wchar_t *ws1, const wchar_t *ws2); wchar_t *windex(const wchar_t *ws, wchar_t wc); wchar_t *wrindex(const wchar_t *ws, wchar_t wc); </pre>
ISO C++	<pre> #include <wchar.h> const wchar_t *wcschr(const wchar_t *ws, wchar_t wc); const wchar_t *wcspbrk(const wchar_t *ws1, const wchar_t *ws2); const wchar_t *wcsrchr(const wchar_t *ws, wchar_t wc); #include <cwchar> wchar_t *std::wcschr(wchar_t *ws, wchar_t wc); wchar_t *std::wcspbrk(wchar_t *ws1, const wchar_t *ws2); wchar_t *std::wcsrchr(wchar_t *ws, wchar_t wc); </pre>
DESCRIPTION	<p>These functions operate on wide-character strings terminated by <code>wchar_t</code> NULL characters. During appending or copying, these routines do not check for an overflow condition of the receiving string. In the following, <i>ws</i>, <i>ws1</i>, and <i>ws2</i> point to wide-character strings terminated by a <code>wchar_t</code> NULL.</p>
wcscat() , wscat()	<p>The <code>wcscat()</code> and <code>wscat()</code> functions append a copy of the wide-character string pointed to by <i>ws2</i> (including the terminating null wide-character code) to the end of the wide-character string pointed to by <i>ws1</i>. The initial wide-character code of <i>ws2</i> overwrites the null wide-character code at the end of <i>ws1</i>. If copying takes place between objects that overlap, the behavior is undefined. Both functions return <i>s1</i>; no return value is reserved to indicate an error.</p>
wcsncat() , wsncat()	<p>The <code>wcsncat()</code> and <code>wsncat()</code> functions append not more than <i>n</i> wide-character codes (a null wide-character code and wide-character codes that follow it are not appended) from the array pointed to by <i>ws2</i> to the end of the wide-character string pointed to by <i>ws1</i>. The initial wide-character code of <i>ws2</i> overwrites the null wide-character code at the end of <i>ws1</i>. A terminating null wide-character code is always appended to the result. Both functions return <i>ws1</i>; no return value is reserved to indicate an error.</p>
wcscmp() , wscmp()	<p>The <code>wcscmp()</code> and <code>wscmp()</code> functions compare the wide-character string pointed to by <i>ws1</i> to the wide-character string pointed to by <i>ws2</i>. The sign of a non-zero return value is determined by the sign of the difference between the values of the first pair of wide-character codes that differ in the objects being compared. Upon completion, both functions return an integer greater than, equal to, or less than zero, if the wide-character string pointed to by <i>ws1</i> is greater than, equal to, or less than the wide-character string pointed to by <i>ws2</i>.</p>

windex(3C)

wcsncmp() , wsncmp()	The <code>wcsncmp()</code> and <code>wsncmp()</code> functions compare not more than <i>n</i> wide-character codes (wide-character codes that follow a null wide character code are not compared) from the array pointed to by <i>ws1</i> to the array pointed to by <i>ws2</i> . The sign of a non-zero return value is determined by the sign of the difference between the values of the first pair of wide-character codes that differ in the objects being compared. Upon successful completion, both functions return an integer greater than, equal to, or less than zero, if the possibly null-terminated array pointed to by <i>ws1</i> is greater than, equal to, or less than the possibly null-terminated array pointed to by <i>ws2</i> .
wscpy() , wscopy()	The <code>wscopy()</code> and <code>wscpy()</code> functions copy the wide-character string pointed to by <i>ws2</i> (including the terminating null wide-character code) into the array pointed to by <i>ws1</i> . If copying takes place between objects that overlap, the behavior is undefined. Both functions return <i>ws1</i> ; no return value is reserved to indicate an error.
wcsncpy() , wsncpy()	The <code>wcsncpy()</code> and <code>wsncpy()</code> functions copy not more than <i>n</i> wide-character codes (wide-character codes that follow a null wide character code are not copied) from the array pointed to by <i>ws2</i> to the array pointed to by <i>ws1</i> . If copying takes place between objects that overlap, the behavior is undefined. If the array pointed to by <i>ws2</i> is a wide-character string that is shorter than <i>n</i> wide-character codes, null wide-character codes are appended to the copy in the array pointed to by <i>ws1</i> , until a total <i>n</i> wide-character codes are written. Both functions return <i>ws1</i> ; no return value is reserved to indicate an error.
wcslen() , wslen()	The <code>wcslen()</code> and <code>wslen()</code> functions compute the number of wide-character codes in the wide-character string to which <i>ws</i> points, not including the terminating null wide-character code. Both functions return <i>ws</i> ; no return value is reserved to indicate an error.
wcschr() , wschr()	The <code>wcschr()</code> and <code>wschr()</code> functions locate the first occurrence of <i>wc</i> in the wide-character string pointed to by <i>ws</i> . The value of <i>wc</i> must be a character representable as a type <code>wchar_t</code> and must be a wide-character code corresponding to a valid character in the current locale. The terminating null wide-character code is considered to be part of the wide-character string. Upon completion, both functions return a pointer to the wide-character code, or a null pointer if the wide-character code is not found.
wcsrchr() , wsrchr()	The <code>wcsrchr()</code> and <code>wsrchr()</code> functions locate the last occurrence of <i>wc</i> in the wide-character string pointed to by <i>ws</i> . The value of <i>wc</i> must be a character representable as a type <code>wchar_t</code> and must be a wide-character code corresponding to a valid character in the current locale. The terminating null wide-character code is considered to be part of the wide-character string. Upon successful completion, both functions return a pointer to the wide-character code, or a null pointer if <i>wc</i> does not occur in the wide-character string.
windex() , wrindex()	The <code>windex()</code> and <code>wrindex()</code> functions behave the same as <code>wschr()</code> and <code>wsrchr()</code> , respectively.

wcspbrk(), wspbrk()	The <code>wcspbrk()</code> and <code>wspbrk()</code> functions locate the first occurrence in the wide character string pointed to by <i>ws1</i> of any wide-character code from the wide-character string pointed to by <i>ws2</i> . Upon successful completion, the function returns a pointer to the wide-character code, or a null pointer if no wide-character code from <i>ws2</i> occurs in <i>ws1</i> .
wcswcs()	The <code>wcswcs()</code> function locates the first occurrence in the wide-character string pointed to by <i>ws1</i> of the sequence of wide-character codes (excluding the terminating null wide-character code) in the wide-character string pointed to by <i>ws2</i> . Upon successful completion, the function returns a pointer to the located wide-character string, or a null pointer if the wide-character string is not found. If <i>ws2</i> points to a wide-character string with zero length, the function returns <i>ws1</i> .
wcsspn(), wsspnl()	The <code>wcsspn()</code> and <code>wsspnl()</code> functions compute the length of the maximum initial segment of the wide-character string pointed to by <i>ws1</i> which consists entirely of wide-character codes from the wide-character string pointed to by <i>ws2</i> . Both functions return the length <i>ws1</i> ; no return value is reserved to indicate an error.
wcscspnl(), wscspnl()	The <code>wcscspnl()</code> and <code>wscspnl()</code> functions compute the length of the maximum initial segment of the wide-character string pointed to by <i>ws1</i> which consists entirely of wide-character codes <i>not</i> from the wide-character string pointed to by <i>ws2</i> . Both functions return the length of the initial substring of <i>ws1</i> ; no return value is reserved to indicate an error.
wcstok(), wstok()	A sequence of calls to the <code>wcstok()</code> and <code>wstok()</code> functions break the wide-character string pointed to by <i>ws1</i> into a sequence of tokens, each of which is delimited by a wide-character code from the wide-character string pointed to by <i>ws2</i> .
Default and other standards	<p>The third argument points to a caller-provided <code>wchar_t</code> pointer into which the <code>wcstok()</code> function stores information necessary for it to continue scanning the same wide-character string. This argument is not available with the XPG4 and SUS versions of <code>wcstok()</code>, nor is it available with the <code>wstok()</code> function. See <code>standards(5)</code>.</p> <p>The first call in the sequence has <i>ws1</i> as its first argument, and is followed by calls with a null pointer as their first argument. The separator string pointed to by <i>ws2</i> may be different from call to call.</p> <p>The first call in the sequence searches the wide-character string pointed to by <i>ws1</i> for the first wide-character code that is <i>not</i> contained in the current separator string pointed to by <i>ws2</i>. If no such wide-character code is found, then there are no tokens in the wide-character string pointed to by <i>ws1</i>, and <code>wcstok()</code> and <code>wstok()</code> return a null pointer. If such a wide-character code is found, it is the start of the first token.</p> <p>The <code>wcstok()</code> and <code>wstok()</code> functions then search from that point for a wide-character code that <i>is</i> contained in the current separator string. If no such wide-character code is found, the current token extends to the end of the wide-character string pointed to by <i>ws1</i>, and subsequent searches for a token will</p>

windex(3C)

return a null pointer. If such a wide-character code is found, it is overwritten by a null wide character, which terminates the current token. The `wcstok()` and `wstok()` functions save a pointer to the following wide-character code, from which the next search for a token will start.

Each subsequent call, with a null pointer as the value of the first argument, starts searching from the saved pointer and behaves as described above.

Upon successful completion, both functions return a pointer to the first wide-character code of a token. Otherwise, if there is no token, a null pointer is returned.

NAME | wmemchr – find a wide-character in memory

SYNOPSIS | #include <wchar.h>
 wchar_t *wmemchr(const wchar_t *ws, wchar_t wc, size_t n);

ISO C++ | #include <wchar.h>
 const wchar_t *wmemchr(const wchar_t *ws, wchar_t wc, size_t n);
 #include <cwchar>
 wchar_t *std::wmemchr(wchar_t *ws, wchar_t wc, size_t n);

DESCRIPTION | The wmemchr() function locates the first occurrence of *wc* in the initial *n* wide-characters of the object pointed to be *ws*. This function is not affected by locale and all wchar_t values are treated identically. The null wide-character and wchar_t values not corresponding to valid characters are not treated specially.

If *n* is 0, *ws* must be a valid pointer and the function behaves as if no valid occurrence of *wc* is found.

RETURN VALUES | The wmemchr() function returns a pointer to the located wide-character, or a null pointer if the wide-character does not occur in the object.

ERRORS | No errors are defined.

ATTRIBUTES | See attributes(5) for descriptions of the following attributes:

wmemmove(3C)

NAME	wmemmove – copy wide-characters in memory with overlapping areas				
SYNOPSIS	<pre>#include <wchar.h> wchar_t *wmemmove(wchar_t *ws1, const wchar_t *ws2, size_t n);</pre>				
DESCRIPTION	<p>The <code>wmemmove()</code> function copies n wide-characters from the object pointed to by <code>ws2</code> to the object pointed to by <code>ws1</code>. Copying takes place as if the n wide-characters from the object pointed to by <code>ws2</code> are first copied into a temporary array of n wide-characters that does not overlap the objects pointed to by <code>ws1</code> or <code>ws2</code>, and then the n wide-characters from the temporary array are copied into the object pointed to by <code>ws1</code>.</p> <p>This function is not affected by locale and all <code>wchar_t</code> values are treated identically. The null wide-character and <code>wchar_t</code> values not corresponding to valid characters are not treated specially.</p> <p>If n is 0, <code>ws1</code> and <code>ws2</code> must be a valid pointers, and the function copies zero wide-characters.</p>				
RETURN VALUES	The <code>wmemmove()</code> function returns the value of <code>ws1</code> .				
ERRORS	No errors are defined.				
ATTRIBUTES	See <code>attributes(5)</code> for descriptions of the following attributes:

wordexp(3C)

NAME	wordexp, wordfree – perform word expansions						
SYNOPSIS	<pre>#include <wordexp.h> int wordexp(const char *words, wordexp_t *pwordexp, int flags); void wordfree(wordexp_t *pwordexp);</pre>						
DESCRIPTION	<p>The <code>wordexp()</code> function performs word expansions, subject to quoting, and places the list of expanded words into the structure pointed to by <code>pwordexp</code>.</p> <p>The <code>wordfree()</code> function frees any memory allocated by <code>wordexp()</code> associated with <code>pwordexp</code>.</p>						
<i>words</i> Argument	<p>The <i>words</i> argument is a pointer to a string containing one or more words to be expanded. The expansions will be the same as would be performed by the shell if <i>words</i> were the part of a command line representing the arguments to a utility. Therefore, <i>words</i> must not contain an unquoted NEWLINE or any of the unquoted shell special characters:</p> <p> & ; < ></p> <p>except in the context of command substitution. It also must not contain unquoted parentheses or braces, except in the context of command or variable substitution. If the argument <i>words</i> contains an unquoted comment character (number sign) that is the beginning of a token, <code>wordexp()</code> may treat the comment character as a regular character, or may interpret it as a comment indicator and ignore the remainder of <i>words</i>.</p>						
<i>pwordexp</i> Argument	<p>The structure type <code>wordexp_t</code> is defined in the header <code><wordexp.h></code> and includes at least the following members:</p> <table><tr><td><code>size_t we_wordc</code></td><td>Count of words matched by <i>words</i>.</td></tr><tr><td><code>char **we_wordv</code></td><td>Pointer to list of expanded words.</td></tr><tr><td><code>size_t we_offs</code></td><td>Slots to reserve at the beginning of <code>pwordexp->we_wordv</code>.</td></tr></table> <p>The <code>wordexp()</code> function stores the number of generated words into <code>pwordexp->we_wordc</code> and a pointer to a list of pointers to words in <code>pwordexp->we_wordv</code>. Each individual field created during field splitting is a separate word in the <code>pwordexp->we_wordv</code> list. The words are in order. The first pointer after the last word pointer will be a null pointer.</p> <p>It is the caller's responsibility to allocate the storage pointed to by <code>pwordexp</code>. The <code>wordexp()</code> function allocates other space as needed, including memory pointed to by <code>pwordexp->we_wordv</code>. The <code>wordfree()</code> function frees any memory associated with <code>pwordexp</code> from a previous call to <code>wordexp()</code>.</p>	<code>size_t we_wordc</code>	Count of words matched by <i>words</i> .	<code>char **we_wordv</code>	Pointer to list of expanded words.	<code>size_t we_offs</code>	Slots to reserve at the beginning of <code>pwordexp->we_wordv</code> .
<code>size_t we_wordc</code>	Count of words matched by <i>words</i> .						
<code>char **we_wordv</code>	Pointer to list of expanded words.						
<code>size_t we_offs</code>	Slots to reserve at the beginning of <code>pwordexp->we_wordv</code> .						

flags Argument

The *flags* argument is used to control the behavior of `wordexp()`. The value of *flags* is the bitwise inclusive OR of zero or more of the following constants, which are defined in `<wordexp.h>`:

<code>WRDE_APPEND</code>	Append words generated to the ones from a previous call to <code>wordexp()</code> .
<code>WRDE_DOOFFS</code>	Make use of <code>pwordexp->we_offs</code> . If this flag is set, <code>pwordexp->we_offs</code> is used to specify how many NULL pointers to add to the beginning of <code>pwordexp->we_wordv</code> . In other words, <code>pwordexp->we_wordv</code> will point to <code>pwordexp->we_offs</code> NULL pointers, followed by <code>pwordexp->we_wordc</code> word pointers, followed by a NULL pointer.
<code>WRDE_NOCMD</code>	Fail if command substitution is requested.
<code>WRDE_REUSE</code>	The <code>pwordexp</code> argument was passed to a previous successful call to <code>wordexp()</code> , and has not been passed to <code>wordfree()</code> . The result will be the same as if the application had called <code>wordfree()</code> and then called <code>wordexp()</code> without <code>WRDE_REUSE</code> .
<code>WRDE_SHOWERR</code>	Do not redirect <code>stderr</code> to <code>/dev/null</code> .
<code>WRDE_UNDEF</code>	Report error on an attempt to expand an undefined shell variable.

The `WRDE_APPEND` flag can be used to append a new set of words to those generated by a previous call to `wordexp()`. The following rules apply when two or more calls to `wordexp()` are made with the same value of `pwordexp` and without intervening calls to `wordfree()`:

1. The first such call must not set `WRDE_APPEND`. All subsequent calls must set it.
2. All of the calls must set `WRDE_DOOFFS`, or all must not set it.
3. After the second and each subsequent call, `pwordexp->we_wordv` will point to a list containing the following:
 - a. zero or more NULL pointers, as specified by `WRDE_DOOFFS` and `pwordexp->we_offs`.
 - b. pointers to the words that were in the `pwordexp->we_wordv` list before the call, in the same order as before.
 - c. pointers to the new words generated by the latest call, in the specified order.
4. The count returned in `pwordexp->we_wordc` will be the total number of words from all of the calls.
5. The application can change any of the fields after a call to `wordexp()`, but if it does it must reset them to the original value before a subsequent call, using the same `pwordexp` value, to `wordfree()` or `wordexp()` with the `WRDE_APPEND` or `WRDE_REUSE` flag.

If *words* contains an unquoted:

wordexp(3C)

NEWLINE | & ; < > () { } in an inappropriate context, `wordexp()` will fail, and the number of expanded words will be zero.

Unless `WRDE_SHOWERR` is set in *flags*, `wordexp()` will redirect `stderr` to `/dev/null` for any utilities executed as a result of command substitution while expanding *words*.

If `WRDE_SHOWERR` is set, `wordexp()` may write messages to *stderr* if syntax errors are detected while expanding *words*. If `WRDE_DOOFFS` is set, then `pwordexp->we_offs` must have the same value for each `wordexp()` call and `wordfree()` call using a given *pwordexp*.

The following constants are defined as error return values:

<code>WRDE_BADCHAR</code>	One of the unquoted characters: NEWLINE & ; < > () { } appears in <i>words</i> in an inappropriate context.
<code>WRDE_BADVAL</code>	Reference to undefined shell variable when <code>WRDE_UNDEF</code> is set in <i>flags</i> .
<code>WRDE_CMDSUB</code>	Command substitution requested when <code>WRDE_NOCMD</code> was set in <i>flags</i> .
<code>WRDE_NOSPACE</code>	Attempt to allocate memory failed.
<code>WRDE_SYNTAX</code>	Shell syntax error, such as unbalanced parentheses or unterminated string.

RETURN VALUES On successful completion, `wordexp()` returns 0.

Otherwise, a non-zero value as described in `<wordexp.h>` is returned to indicate an error. If `wordexp()` returns the value `WRDE_NOSPACE`, then `pwordexp->we_wordc` and `pwordexp->we_wordv` will be updated to reflect any words that were successfully expanded. In other cases, they will not be modified.

The `wordfree()` function returns no value.

ERRORS No errors are defined.

USAGE This function is intended to be used by an application that wants to do all of the shell's expansions on a word or words obtained from a user. For example, if the application prompts for a filename (or list of filenames) and then uses `wordexp()` to process the input, the user could respond with anything that would be valid as input to the shell.

The `WRDE_NOCMD` flag is provided for applications that, for security or other reasons, want to prevent a user from executing shell command. Disallowing unquoted shell special characters also prevents unwanted side effects such as executing a command or writing a file.

wordfree(3C)

NAME	wordexp, wordfree – perform word expansions						
SYNOPSIS	<pre>#include <wordexp.h> int wordexp(const char *words, wordexp_t *pwordexp, int flags); void wordfree(wordexp_t *pwordexp);</pre>						
DESCRIPTION	<p>The <code>wordexp()</code> function performs word expansions, subject to quoting, and places the list of expanded words into the structure pointed to by <code>pwordexp</code>.</p> <p>The <code>wordfree()</code> function frees any memory allocated by <code>wordexp()</code> associated with <code>pwordexp</code>.</p>						
<i>words</i> Argument	<p>The <i>words</i> argument is a pointer to a string containing one or more words to be expanded. The expansions will be the same as would be performed by the shell if <i>words</i> were the part of a command line representing the arguments to a utility. Therefore, <i>words</i> must not contain an unquoted NEWLINE or any of the unquoted shell special characters:</p> <pre> & ; < ></pre> <p>except in the context of command substitution. It also must not contain unquoted parentheses or braces, except in the context of command or variable substitution. If the argument <i>words</i> contains an unquoted comment character (number sign) that is the beginning of a token, <code>wordexp()</code> may treat the comment character as a regular character, or may interpret it as a comment indicator and ignore the remainder of <i>words</i>.</p>						
<i>pwordexp</i> Argument	<p>The structure type <code>wordexp_t</code> is defined in the header <code><wordexp.h></code> and includes at least the following members:</p> <table><tr><td><code>size_t we_wordc</code></td><td>Count of words matched by <i>words</i>.</td></tr><tr><td><code>char **we_wordv</code></td><td>Pointer to list of expanded words.</td></tr><tr><td><code>size_t we_offs</code></td><td>Slots to reserve at the beginning of <code>pwordexp->we_wordv</code>.</td></tr></table> <p>The <code>wordexp()</code> function stores the number of generated words into <code>pwordexp->we_wordc</code> and a pointer to a list of pointers to words in <code>pwordexp->we_wordv</code>. Each individual field created during field splitting is a separate word in the <code>pwordexp->we_wordv</code> list. The words are in order. The first pointer after the last word pointer will be a null pointer.</p> <p>It is the caller's responsibility to allocate the storage pointed to by <code>pwordexp</code>. The <code>wordexp()</code> function allocates other space as needed, including memory pointed to by <code>pwordexp->we_wordv</code>. The <code>wordfree()</code> function frees any memory associated with <code>pwordexp</code> from a previous call to <code>wordexp()</code>.</p>	<code>size_t we_wordc</code>	Count of words matched by <i>words</i> .	<code>char **we_wordv</code>	Pointer to list of expanded words.	<code>size_t we_offs</code>	Slots to reserve at the beginning of <code>pwordexp->we_wordv</code> .
<code>size_t we_wordc</code>	Count of words matched by <i>words</i> .						
<code>char **we_wordv</code>	Pointer to list of expanded words.						
<code>size_t we_offs</code>	Slots to reserve at the beginning of <code>pwordexp->we_wordv</code> .						

flags Argument

The *flags* argument is used to control the behavior of `wordexp()`. The value of *flags* is the bitwise inclusive OR of zero or more of the following constants, which are defined in `<wordexp.h>`:

<code>WRDE_APPEND</code>	Append words generated to the ones from a previous call to <code>wordexp()</code> .
<code>WRDE_DOOFFS</code>	Make use of <code>pwordexp->we_offs</code> . If this flag is set, <code>pwordexp->we_offs</code> is used to specify how many NULL pointers to add to the beginning of <code>pwordexp->we_wordv</code> . In other words, <code>pwordexp->we_wordv</code> will point to <code>pwordexp->we_offs</code> NULL pointers, followed by <code>pwordexp->we_wordc</code> word pointers, followed by a NULL pointer.
<code>WRDE_NOCMD</code>	Fail if command substitution is requested.
<code>WRDE_REUSE</code>	The <code>pwordexp</code> argument was passed to a previous successful call to <code>wordexp()</code> , and has not been passed to <code>wordfree()</code> . The result will be the same as if the application had called <code>wordfree()</code> and then called <code>wordexp()</code> without <code>WRDE_REUSE</code> .
<code>WRDE_SHOWERR</code>	Do not redirect <code>stderr</code> to <code>/dev/null</code> .
<code>WRDE_UNDEF</code>	Report error on an attempt to expand an undefined shell variable.

The `WRDE_APPEND` flag can be used to append a new set of words to those generated by a previous call to `wordexp()`. The following rules apply when two or more calls to `wordexp()` are made with the same value of `pwordexp` and without intervening calls to `wordfree()`:

1. The first such call must not set `WRDE_APPEND`. All subsequent calls must set it.
2. All of the calls must set `WRDE_DOOFFS`, or all must not set it.
3. After the second and each subsequent call, `pwordexp->we_wordv` will point to a list containing the following:
 - a. zero or more NULL pointers, as specified by `WRDE_DOOFFS` and `pwordexp->we_offs`.
 - b. pointers to the words that were in the `pwordexp->we_wordv` list before the call, in the same order as before.
 - c. pointers to the new words generated by the latest call, in the specified order.
4. The count returned in `pwordexp->we_wordc` will be the total number of words from all of the calls.
5. The application can change any of the fields after a call to `wordexp()`, but if it does it must reset them to the original value before a subsequent call, using the same `pwordexp` value, to `wordfree()` or `wordexp()` with the `WRDE_APPEND` or `WRDE_REUSE` flag.

If *words* contains an unquoted:

wordfree(3C)

NEWLINE | & ; < > () { } in an inappropriate context, `wordexp()` will fail, and the number of expanded words will be zero.

Unless `WRDE_SHOWERR` is set in *flags*, `wordexp()` will redirect `stderr` to `/dev/null` for any utilities executed as a result of command substitution while expanding *words*.

If `WRDE_SHOWERR` is set, `wordexp()` may write messages to *stderr* if syntax errors are detected while expanding *words*. If `WRDE_DOOFFS` is set, then `pwordexp->we_offs` must have the same value for each `wordexp()` call and `wordfree()` call using a given *pwordexp*.

The following constants are defined as error return values:

<code>WRDE_BADCHAR</code>	One of the unquoted characters: NEWLINE & ; < > () { } appears in <i>words</i> in an inappropriate context.
<code>WRDE_BADVAL</code>	Reference to undefined shell variable when <code>WRDE_UNDEF</code> is set in <i>flags</i> .
<code>WRDE_CMDSUB</code>	Command substitution requested when <code>WRDE_NOCMD</code> was set in <i>flags</i> .
<code>WRDE_NOSPACE</code>	Attempt to allocate memory failed.
<code>WRDE_SYNTAX</code>	Shell syntax error, such as unbalanced parentheses or unterminated string.

RETURN VALUES On successful completion, `wordexp()` returns 0.

Otherwise, a non-zero value as described in `<wordexp.h>` is returned to indicate an error. If `wordexp()` returns the value `WRDE_NOSPACE`, then `pwordexp->we_wordc` and `pwordexp->we_wordv` will be updated to reflect any words that were successfully expanded. In other cases, they will not be modified.

The `wordfree()` function returns no value.

ERRORS No errors are defined.

USAGE This function is intended to be used by an application that wants to do all of the shell's expansions on a word or words obtained from a user. For example, if the application prompts for a filename (or list of filenames) and then uses `wordexp()` to process the input, the user could respond with anything that would be valid as input to the shell.

The `WRDE_NOCMD` flag is provided for applications that, for security or other reasons, want to prevent a user from executing shell command. Disallowing unquoted shell special characters also prevents unwanted side effects such as executing a command or writing a file.

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
MT-Level	MT-Safe

SEE ALSO `fnmatch(3C)`, `glob(3C)`, `attributes(5)`

wprintf(3C)

NAME	<code>fwprintf</code> , <code>wprintf</code> , <code>swprintf</code> – print formatted wide-character output
SYNOPSIS	<pre>#include <stdio.h> #include <wchar.h> int fwprintf(FILE *<i>stream</i>, const wchar_t *<i>format</i>, ...); int wprintf(const wchar_t *<i>format</i>, <...>); int swprintf(wchar_t *<i>s</i>, size_t <i>n</i>, const wchar_t *<i>format</i>, ...);</pre>
DESCRIPTION	<p>The <code>fwprintf()</code> function places output on the named output <i>stream</i>. The <code>wprintf()</code> function places output on the standard output stream <code>stdout</code>. The <code>swprintf()</code> function places output followed by the null wide-character in consecutive wide-characters starting at <i>*s</i>; no more than <i>n</i> wide-characters are written, including a terminating null wide-character, which is always added (unless <i>n</i> is zero).</p> <p>Each of these functions converts, formats and prints its arguments under control of the <i>format</i> wide-character string. The <i>format</i> is composed of zero or more directives: <i>ordinary wide-characters</i>, which are simply copied to the output stream and <i>conversion specifications</i>, each of which results in the fetching of zero or more arguments. The results are undefined if there are insufficient arguments for the <i>format</i>. If the <i>format</i> is exhausted while arguments remain, the excess arguments are evaluated but are otherwise ignored.</p> <p>Conversions can be applied to the <i>n</i>th argument after the <i>format</i> in the argument list, rather than to the next unused argument. In this case, the conversion wide-character <code>%</code> (see below) is replaced by the sequence <code>%n\$</code>, where <i>n</i> is a decimal integer in the range <code>[1, NL_ARGMAX]</code>, giving the position of the argument in the argument list. This feature provides for the definition of format wide-character strings that select arguments in an order appropriate to specific languages (see the <code>EXAMPLES</code> section).</p> <p>In format wide-character strings containing the <code>%n\$</code> form of conversion specifications, numbered arguments in the argument list can be referenced from the format wide-character string as many times as required.</p> <p>In format wide-character strings containing the <code>%</code> form of conversion specifications, each argument in the argument list is used exactly once.</p> <p>All forms of the <code>fwprintf()</code> functions allow for the insertion of a language-dependent radix character in the output string, output as a wide-character value. The radix character is defined in the program's locale (category <code>LC_NUMERIC</code>). In the POSIX locale, or in a locale where the radix character is not defined, the radix character defaults to a period (<code>.</code>).</p> <p>Each conversion specification is introduced by the <code>%</code> wide-character or by the wide-character sequence <code>%n\$</code>, after which the following appear in sequence:</p> <ul style="list-style-type: none">■ Zero or more <i>flags</i> (in any order), which modify the meaning of the conversion specification.

- An optional minimum *field width*. If the converted value has fewer wide-characters than the field width, it will be padded with spaces by default on the left; it will be padded on the right, if the left-adjustment flag (-), described below, is given to the field width. The field width takes the form of an asterisk (*), described below, or a decimal integer.
- An optional *precision* that gives the minimum number of digits to appear for the d, i, o, u, x, and X conversions; the number of digits to appear after the radix character for the e, E, and f conversions; the maximum number of significant digits for the g and G conversions; or the maximum number of wide-characters to be printed from a string in s conversions. The precision takes the form of a period (.) followed by either an asterisk (*), described below, or an optional decimal digit string, where a null digit string is treated as 0. If a precision appears with any other conversion wide-character, the behavior is undefined.
- An optional l (ell) specifying that a following c conversion wide-character applies to a `wint_t` argument; an optional l specifying that a following s conversion wide-character applies to a `wchar_t` argument; an optional h specifying that a following d, i, o, u, x, and X conversion wide-character applies to a type `short int` or type `unsigned short int` argument (the argument will have been promoted according to the integral promotions, and its value will be converted to type `short int` or `unsigned short int` before printing); an optional h specifying that a following n conversion wide-character applies to a pointer to a type `short int` argument; an optional l (ell) specifying that a following d, i, o, u, x, and X conversion wide-character applies to a type `long int` or `unsigned long int` argument; an optional l (ell) specifying that a following n conversion wide-character applies to a pointer to a type `long int` argument; or an optional L specifying that a following e, E, f, g, or G conversion wide-character applies to a type `long double` argument. If an h, l, or L appears with any other conversion wide-character, the behavior is undefined.
- A *conversion wide-character* that indicates the type of conversion to be applied.

A field width, or precision, or both, may be indicated by an asterisk (*). In this case an argument of type `int` supplies the field width or precision. Arguments specifying field width, or precision, or both must appear in that order before the argument, if any, to be converted. A negative field width is taken as a - flag followed by a positive field width. A negative precision is taken as if the precision were omitted. In format wide-character strings containing the `%n$` form of a conversion specification, a field width or precision may be indicated by the sequence `*m$`, where *m* is a decimal integer in the range [1, `NL_ARGMAX`] giving the position in the argument list (after the format argument) of an integer argument containing the field width or precision, for example:

```
wprintf(L"%1$d:%2$.*3$d:%4$.*3$d\n", hour, min, precision, sec);
```

The *format* can contain either numbered argument specifications (that is, `%n$` and `*m$`), or unnumbered argument specifications (that is, `%` and `*`), but normally not both. The only exception to this is that `%%` can be mixed with the `%n$` form. The results of mixing numbered and unnumbered argument specifications in a *format*

wprintf(3C)

wide-character string are undefined. When numbered argument specifications are used, specifying the N th argument requires that all the leading arguments, from the first to the $(N-1)$ th, are specified in the format wide-character string.

The flag wide-characters and their meanings are:

'	The integer portion of the result of a decimal conversion (<code>%i</code> , <code>%d</code> , <code>%u</code> , <code>%f</code> , <code>%g</code> , or <code>%G</code>) will be formatted with thousands' grouping wide-characters. For other conversions the behavior is undefined. The non-monetary grouping wide-character is used.
–	The result of the conversion will be left-justified within the field. The conversion will be right-justified if this flag is not specified.
+	The result of a signed conversion will always begin with a sign (+ or –). The conversion will begin with a sign only when a negative value is converted if this flag is not specified.
space	If the first wide-character of a signed conversion is not a sign or if a signed conversion results in no wide-characters, a space will be prefixed to the result. This means that if the space and + flags both appear, the space flag will be ignored.
#	This flag specifies that the value is to be converted to an alternative form. For <code>o</code> conversion, it increases the precision (if necessary) to force the first digit of the result to be 0. For <code>x</code> or <code>X</code> conversions, a non-zero result will have <code>0x</code> (or <code>0X</code>) prefixed to it. For <code>e</code> , <code>E</code> , <code>f</code> , <code>g</code> , or <code>G</code> conversions, the result will always contain a radix character, even if no digits follow it. Without this flag, a radix character appears in the result of these conversions only if a digit follows it. For <code>g</code> and <code>G</code> conversions, trailing zeros will <i>not</i> be removed from the result as they normally are. For other conversions, the behavior is undefined.
0	For <code>d</code> , <code>i</code> , <code>o</code> , <code>u</code> , <code>x</code> , <code>X</code> , <code>e</code> , <code>E</code> , <code>f</code> , <code>g</code> , and <code>G</code> conversions, leading zeros (following any indication of sign or base) are used to pad to the field width; no space padding is performed. If the <code>0</code> and <code>–</code> flags both appear, the <code>0</code> flag will be ignored. For <code>d</code> , <code>i</code> , <code>o</code> , <code>u</code> , <code>x</code> , and <code>X</code> conversions, if a precision is specified, the <code>0</code> flag will be ignored. If the <code>0</code> and <code>'</code> flags both appear, the grouping wide-characters are inserted before zero padding. For other conversions, the behavior is undefined.

The conversion wide-characters and their meanings are:

<code>d</code> , <code>i</code>	The <code>int</code> argument is converted to a signed decimal in the style <code>[-] dddd</code> . The precision specifies the minimum number of digits to appear; if the value being converted can be represented in fewer digits, it will be expanded with leading zeros. The default precision is 1. The result of converting 0 with an explicit precision of 0 is no wide-characters.
---------------------------------	--

- o The `unsigned int` argument is converted to unsigned octal format in the style *dddd*. The precision specifies the minimum number of digits to appear; if the value being converted can be represented in fewer digits, it will be expanded with leading zeros. The default precision is 1. The result of converting 0 with an explicit precision of 0 is no wide-characters.
- u The `unsigned int` argument is converted to unsigned decimal format in the style *dddd*. The precision specifies the minimum number of digits to appear; if the value being converted can be represented in fewer digits, it will be expanded with leading zeros. The default precision is 1. The result of converting 0 with an explicit precision of 0 is no wide-characters.
- x The `unsigned int` argument is converted to unsigned hexadecimal format in the style *dddd*; the letters abcdef are used. The precision specifies the minimum number of digits to appear; if the value being converted can be represented in fewer digits, it will be expanded with leading zeros. The default precision is 1. The result of converting 0 with an explicit precision of 0 is no wide-characters.
- X Behaves the same as the x conversion wide-character except that letters ABCDEF are used instead of abcdef.
- f The `double` argument is converted to decimal notation in the style *[-]ddd.ddd*, where the number of digits after the radix character is equal to the precision specification. If the precision is missing, it is taken as 6; if the precision is explicitly 0 and no # flag is present, no radix character appears. If a radix character appears, at least one digit appears before it. The value is rounded to the appropriate number of digits.

The `fwprintf()` family of functions may make available wide-character string representations for infinity and NaN.
- e, E The `double` argument is converted in the style *[-]d.ddde ± dd*, where there is one digit before the radix character (which is non-zero if the argument is non-zero) and the number of digits after it is equal to the precision; if the precision is missing, it is taken as 6; if the precision is 0 and no # flag is present, no radix character appears. The value is rounded to the appropriate number of digits. The E conversion wide-character will produce a number with E instead of e introducing the exponent. The exponent always contains at least two digits. If the value is 0, the exponent is 0.

The `fwprintf()` family of functions may make available wide-character string representations for infinity and NaN.
- g, G The `double` argument is converted in the style *f* or *e* (or in the style *E* in the case of a G conversion wide-character), with the precision specifying the number of significant digits. If an explicit precision is 0, it is taken as 1. The style used depends on the value converted; style *e* (or *E*) will be used only if the exponent resulting from such a conversion is less than -4 or

wprintf(3C)

greater than or equal to the precision. Trailing zeros are removed from the fractional portion of the result; a radix character appears only if it is followed by a digit.

The `fwprintf()` family of functions may make available wide-character string representations for infinity and NaN.

- c If no `l` (ell) qualifier is present, the `int` argument is converted to a wide-character as if by calling the `btowc(3C)` function and the resulting wide-character is written. Otherwise the `wint_t` argument is converted to `wchar_t`, and written.
- s If no `l` (ell) qualifier is present, the argument must be a pointer to a character array containing a character sequence beginning in the initial shift state. Characters from the array are converted as if by repeated calls to the `mbrtowc(3C)` function, with the conversion state described by an `mbstate_t` object initialized to zero before the first character is converted, and written up to (but not including) the terminating null wide-character. If the precision is specified, no more than that many wide-characters are written. If the precision is not specified or is greater than the size of the array, the array must contain a null wide-character.

If an `l` (ell) qualifier is present, the argument must be a pointer to an array of type `wchar_t`. Wide characters from the array are written up to (but not including) a terminating null wide-character. If no precision is specified or is greater than the size of the array, the array must contain a null wide-character. If a precision is specified, no more than that many wide-characters are written.
- p The argument must be a pointer to `void`. The value of the pointer is converted to a sequence of printable wide-characters.
- n The argument must be a pointer to an integer into which is written the number of wide-characters written to the output so far by this call to one of the `fwprintf()` functions. No argument is converted.
- C Same as `lc`.
- S Same as `ls`.
- % Output a `%` wide-character; no argument is converted. The entire conversion specification must be `%%`.

If a conversion specification does not match one of the above forms, the behavior is undefined.

In no case does a non-existent or small field width cause truncation of a field; if the result of a conversion is wider than the field width, the field is simply expanded to contain the conversion result. Characters generated by `fwprintf()` and `wprintf()` are printed as if `fputwc(3C)` had been called.

The `st_ctime` and `st_mtime` fields of the file will be marked for update between the call to a successful execution of `fwprintf()` or `wprintf()` and the next successful completion of a call to `fflush(3C)` or `fclose(3C)` on the same stream or a call to `exit(3C)` or `abort(3C)`.

RETURN VALUES Upon successful completion, these functions return the number of wide-characters transmitted excluding the terminating null wide-character in the case of `swprintf()` or a negative value if an output error was encountered.

ERRORS For the conditions under which `fwprintf()` and `wprintf()` will fail and may fail, refer to `fputwc(3C)`.

In addition, all forms of `fwprintf()` may fail if:

`EILSEQ` A wide-character code that does not correspond to a valid character has been detected.

`EINVAL` There are insufficient arguments.

In addition, `wprintf()` and `fwprintf()` may fail if:

`ENOMEM` Insufficient storage space is available.

EXAMPLES **EXAMPLE 1** Print language-dependent date and time format.

To print the language-independent date and time format, the following statement could be used:

```
wprintf(format, weekday, month, day, hour, min);
```

For American usage, *format* could be a pointer to the wide-character string:

```
L"%s, %s %d, %d:%.2d\n"
```

producing the message:

```
Sunday, July 3, 10:02
```

whereas for German usage, *format* could be a pointer to the wide-character string:

```
L"%1$s, %3$d. %2$s, %4$d:%5$.2d\n"
```

producing the message:

```
Sonntag, 3. Juli, 10:02
```

DESCRIPTION	<p>These functions operate on wide-character strings terminated by <code>wchar_t</code> <code>NULL</code> characters. During appending or copying, these routines do not check for an overflow condition of the receiving string. In the following, <i>ws</i>, <i>ws1</i>, and <i>ws2</i> point to wide-character strings terminated by a <code>wchar_t</code> <code>NULL</code>.</p>
wscat(), wscat()	<p>The <code>wscat()</code> and <code>wscat()</code> functions append a copy of the wide-character string pointed to by <i>ws2</i> (including the terminating null wide-character code) to the end of the wide-character string pointed to by <i>ws1</i>. The initial wide-character code of <i>ws2</i> overwrites the null wide-character code at the end of <i>ws1</i>. If copying takes place between objects that overlap, the behavior is undefined. Both functions return <i>s1</i>; no return value is reserved to indicate an error.</p>
wcsncat(), wsncat()	<p>The <code>wcsncat()</code> and <code>wsncat()</code> functions append not more than <i>n</i> wide-character codes (a null wide-character code and wide-character codes that follow it are not appended) from the array pointed to by <i>ws2</i> to the end of the wide-character string pointed to by <i>ws1</i>. The initial wide-character code of <i>ws2</i> overwrites the null wide-character code at the end of <i>ws1</i>. A terminating null wide-character code is always appended to the result. Both functions return <i>ws1</i>; no return value is reserved to indicate an error.</p>
wscmp(), wscmp()	<p>The <code>wscmp()</code> and <code>wscmp()</code> functions compare the wide-character string pointed to by <i>ws1</i> to the wide-character string pointed to by <i>ws2</i>. The sign of a non-zero return value is determined by the sign of the difference between the values of the first pair of wide-character codes that differ in the objects being compared. Upon completion, both functions return an integer greater than, equal to, or less than zero, if the wide-character string pointed to by <i>ws1</i> is greater than, equal to, or less than the wide-character string pointed to by <i>ws2</i>.</p>

wcsncmp() , wsncmp()	The <code>wcsncmp()</code> and <code>wsncmp()</code> functions compare not more than <i>n</i> wide-character codes (wide-character codes that follow a null wide character code are not compared) from the array pointed to by <i>ws1</i> to the array pointed to by <i>ws2</i> . The sign of a non-zero return value is determined by the sign of the difference between the values of the first pair of wide-character codes that differ in the objects being compared. Upon successful completion, both functions return an integer greater than, equal to, or less than zero, if the possibly null-terminated array pointed to by <i>ws1</i> is greater than, equal to, or less than the possibly null-terminated array pointed to by <i>ws2</i> .
wscpy() , wscopy()	The <code>wscpy()</code> and <code>wscopy()</code> functions copy the wide-character string pointed to by <i>ws2</i> (including the terminating null wide-character code) into the array pointed to by <i>ws1</i> . If copying takes place between objects that overlap, the behavior is undefined. Both functions return <i>ws1</i> ; no return value is reserved to indicate an error.
wcsncpy() , wsncpy()	The <code>wcsncpy()</code> and <code>wsncpy()</code> functions copy not more than <i>n</i> wide-character codes (wide-character codes that follow a null wide character code are not copied) from the array pointed to by <i>ws2</i> to the array pointed to by <i>ws1</i> . If copying takes place between objects that overlap, the behavior is undefined. If the array pointed to by <i>ws2</i> is a wide-character string that is shorter than <i>n</i> wide-character codes, null wide-character codes are appended to the copy in the array pointed to by <i>ws1</i> , until a total <i>n</i> wide-character codes are written. Both functions return <i>ws1</i> ; no return value is reserved to indicate an error.
wcslen() , wslen()	The <code>wcslen()</code> and <code>wslen()</code> functions compute the number of wide-character codes in the wide-character string to which <i>ws</i> points, not including the terminating null wide-character code. Both functions return <i>ws</i> ; no return value is reserved to indicate an error.
wcschr() , wschr()	The <code>wcschr()</code> and <code>wschr()</code> functions locate the first occurrence of <i>wc</i> in the wide-character string pointed to by <i>ws</i> . The value of <i>wc</i> must be a character representable as a type <code>wchar_t</code> and must be a wide-character code corresponding to a valid character in the current locale. The terminating null wide-character code is considered to be part of the wide-character string. Upon completion, both functions return a pointer to the wide-character code, or a null pointer if the wide-character code is not found.
wcsrchr() , wsrchr()	The <code>wcsrchr()</code> and <code>wsrchr()</code> functions locate the last occurrence of <i>wc</i> in the wide-character string pointed to by <i>ws</i> . The value of <i>wc</i> must be a character representable as a type <code>wchar_t</code> and must be a wide-character code corresponding to a valid character in the current locale. The terminating null wide-character code is considered to be part of the wide-character string. Upon successful completion, both functions return a pointer to the wide-character code, or a null pointer if <i>wc</i> does not occur in the wide-character string.
windex() , wrintdex()	The <code>windex()</code> and <code>wrintdex()</code> functions behave the same as <code>wschr()</code> and <code>wsrchr()</code> , respectively.

wrindex(3C)

wcspbrk() , wspbrk()	The <code>wcspbrk()</code> and <code>wspbrk()</code> functions locate the first occurrence in the wide character string pointed to by <code>ws1</code> of any wide-character code from the wide-character string pointed to by <code>ws2</code> . Upon successful completion, the function returns a pointer to the wide-character code, or a null pointer if no wide-character code from <code>ws2</code> occurs in <code>ws1</code> .
wcswcs()	The <code>wcswcs()</code> function locates the first occurrence in the wide-character string pointed to by <code>ws1</code> of the sequence of wide-character codes (excluding the terminating null wide-character code) in the wide-character string pointed to by <code>ws2</code> . Upon successful completion, the function returns a pointer to the located wide-character string, or a null pointer if the wide-character string is not found. If <code>ws2</code> points to a wide-character string with zero length, the function returns <code>ws1</code> .
wcsspn() , wsspnl()	The <code>wcsspn()</code> and <code>wsspnl()</code> functions compute the length of the maximum initial segment of the wide-character string pointed to by <code>ws1</code> which consists entirely of wide-character codes from the wide-character string pointed to by <code>ws2</code> . Both functions return the length <code>ws1</code> ; no return value is reserved to indicate an error.
wcscspn() , wscspnl()	The <code>wcscspn()</code> and <code>wscspnl()</code> functions compute the length of the maximum initial segment of the wide-character string pointed to by <code>ws1</code> which consists entirely of wide-character codes <i>not</i> from the wide-character string pointed to by <code>ws2</code> . Both functions return the length of the initial substring of <code>ws1</code> ; no return value is reserved to indicate an error.
wcstok() , wstok()	A sequence of calls to the <code>wcstok()</code> and <code>wstok()</code> functions break the wide-character string pointed to by <code>ws1</code> into a sequence of tokens, each of which is delimited by a wide-character code from the wide-character string pointed to by <code>ws2</code> .
Default and other standards	<p>The third argument points to a caller-provided <code>wchar_t</code> pointer into which the <code>wcstok()</code> function stores information necessary for it to continue scanning the same wide-character string. This argument is not available with the XPG4 and SUS versions of <code>wcstok()</code>, nor is it available with the <code>wstok()</code> function. See <code>standards(5)</code>.</p> <p>The first call in the sequence has <code>ws1</code> as its first argument, and is followed by calls with a null pointer as their first argument. The separator string pointed to by <code>ws2</code> may be different from call to call.</p> <p>The first call in the sequence searches the wide-character string pointed to by <code>ws1</code> for the first wide-character code that is <i>not</i> contained in the current separator string pointed to by <code>ws2</code>. If no such wide-character code is found, then there are no tokens in the wide-character string pointed to by <code>ws1</code>, and <code>wcstok()</code> and <code>wstok()</code> return a null pointer. If such a wide-character code is found, it is the start of the first token.</p> <p>The <code>wcstok()</code> and <code>wstok()</code> functions then search from that point for a wide-character code that <i>is</i> contained in the current separator string. If no such wide-character code is found, the current token extends to the end of the wide-character string pointed to by <code>ws1</code>, and subsequent searches for a token will</p>

wrindex(3C)

return a null pointer. If such a wide-character code is found, it is overwritten by a null wide character, which terminates the current token. The `wcstok()` and `wstok()` functions save a pointer to the following wide-character code, from which the next search for a token will start.

Each subsequent call, with a null pointer as the value of the first argument, starts searching from the saved pointer and behaves as described above.

Upon successful completion, both functions return a pointer to the first wide-character code of a token. Otherwise, if there is no token, a null pointer is returned.

wscanf(3C)

NAME	<code>fwscanf</code> , <code>wscanf</code> , <code>swscanf</code> , <code>vfwscanf</code> , <code>vswscanf</code> , <code>vswscanf</code> – convert formatted wide-character input
SYNOPSIS	<pre>#include <stdio.h> #include <wchar.h> int fwscanf(FILE *stream, const wchar_t *format, ...); int wscanf(const wchar_t *format, ...); int swscanf(const wchar_t *s, const wchar_t *format, ...); #include <stdarg.h> #include <stdio.h> #include <wchar.h> int vfwscanf(FILE *stream, const wchar_t *format, va_list arg); int vswscanf(const wchar_t *ws, const wchar_t *format, va_list arg); int vswscanf(const wchar_t *format, va_list arg);</pre>
DESCRIPTION	<p>The <code>fwscanf()</code> function reads from the named input <i>stream</i>.</p> <p>The <code>wscanf()</code> function reads from the standard input stream <code>stdin</code>.</p> <p>The <code>swscanf()</code> function reads from the wide-character string <i>s</i>.</p> <p>The <code>vfwscanf()</code>, <code>vswscanf()</code>, and <code>vswscanf()</code> functions are equivalent to the <code>fwscanf()</code>, <code>swscanf()</code>, and <code>wscanf()</code> functions, respectively, except that instead of being called with a variable number of arguments, they are called with an argument list as defined by the <code><stdarg.h></code> header (see <code>stdarg(3HEAD)</code>). These functions do not invoke the <code>va_end()</code> macro. Applications using these functions should call <code>va_end(ap)</code> afterwards to clean up.</p> <p>Each function reads wide-characters, interprets them according to a format, and stores the results in its arguments. Each expects, as arguments, a control wide-character string <i>format</i> described below, and a set of <i>pointer</i> arguments indicating where the converted input should be stored. The result is undefined if there are insufficient arguments for the format. If the format is exhausted while arguments remain, the excess arguments are evaluated but are otherwise ignored.</p> <p>Conversions can be applied to the <i>n</i>th argument after the <i>format</i> in the argument list, rather than to the next unused argument. In this case, the conversion wide-character <code>%</code> (see below) is replaced by the sequence <code>%n\$</code>, where <i>n</i> is a decimal integer in the range <code>[1, NL_ARGMAX]</code>. This feature provides for the definition of format wide-character strings that select arguments in an order appropriate to specific languages. In format wide-character strings containing the <code>%n\$</code> form of conversion specifications, it is unspecified whether numbered arguments in the argument list can be referenced from the format wide-character string more than once.</p>

The *format* can contain either form of a conversion specification, that is, % or %n\$, but the two forms cannot normally be mixed within a single *format* wide-character string. The only exception to this is that %% or %* can be mixed with the %n\$ form.

The `fwscanf()` function in all its forms allows for detection of a language-dependent radix character in the input string, encoded as a wide-character value. The radix character is defined in the program's locale (category `LC_NUMERIC`). In the POSIX locale, or in a locale where the radix character is not defined, the radix character defaults to a period (.).

The format is a wide-character string composed of zero or more directives. Each directive is composed of one of the following: one or more white-space wide-characters (space, tab, newline, vertical-tab or form-feed characters); an ordinary wide-character (neither % nor a white-space character); or a conversion specification. Each conversion specification is introduced by a % or the sequence %n\$ after which the following appear in sequence:

- An optional assignment-suppressing character *.
- An optional non-zero decimal integer that specifies the maximum field width.
- An optional size modifier h, l(ell), or L indicating the size of the receiving object. The conversion wide-characters c, s, and [must be preceded by l(ell) if the corresponding argument is a pointer to `wchar_t` rather than a pointer to a character type. The conversion wide-characters d, i, and n must be preceded by h if the corresponding argument is a pointer to `short int` rather than a pointer to `int`, or by l(ell) if it is a pointer to `long int`. Similarly, the conversion wide-characters o, u, and x must be preceded by h if the corresponding argument is a pointer to `unsigned short int` rather than a pointer to `unsigned int`, or by l(ell) if it is a pointer to `unsigned long int`. The conversion wide-characters e, f, and g must be preceded by l(ell) if the corresponding argument is a pointer to `double` rather than a pointer to `float`, or by L if it is a pointer to `long double`. If an h, l(ell), or L appears with any other conversion wide-character, the behavior is undefined.
- A conversion wide-character that specifies the type of conversion to be applied. The valid conversion wide-characters are described below.

The `fwscanf()` functions execute each directive of the format in turn. If a directive fails, as detailed below, the function returns. Failures are described as input failures (due to the unavailability of input bytes) or matching failures (due to inappropriate input).

A directive composed of one or more white-space wide-characters is executed by reading input until no more valid input can be read, or up to the first wide-character which is not a white-space wide-character, which remains unread.

A directive that is an ordinary wide-character is executed as follows. The next wide-character is read from the input and compared with the wide-character that comprises the directive; if the comparison shows that they are not equivalent, the directive fails, and the differing and subsequent wide-characters remain unread.

wscanf(3C)

A directive that is a conversion specification defines a set of matching input sequences, as described below for each conversion wide-character. A conversion specification is executed in the following steps:

Input white-space wide-characters (as specified by `isspace(3C)`) are skipped, unless the conversion specification includes a `l`, `c`, or `n` conversion character.

An item is read from the input, unless the conversion specification includes an `n` conversion wide-character. An input item is defined as the longest sequence of input wide-characters, not exceeding any specified field width, which is an initial subsequence of a matching sequence. The first wide-character, if any, after the input item remains unread. If the length of the input item is 0, the execution of the conversion specification fails; this condition is a matching failure, unless end-of-file, an encoding error, or a read error prevented input from the stream, in which case it is an input failure.

Except in the case of a `%` conversion wide-character, the input item (or, in the case of a `%n` conversion specification, the count of input wide-characters) is converted to a type appropriate to the conversion wide-character. If the input item is not a matching sequence, the execution of the conversion specification fails; this condition is a matching failure. Unless assignment suppression was indicated by a `*`, the result of the conversion is placed in the object pointed to by the first argument following the *format* argument that has not already received a conversion result if the conversion specification is introduced by `%`, or in the *n*th argument if introduced by the wide-character sequence `%n$`. If this object does not have an appropriate type, or if the result of the conversion cannot be represented in the space provided, the behavior is undefined.

The following conversion wide-characters are valid:

- d Matches an optionally signed decimal integer, whose format is the same as expected for the subject sequence of `wcstol(3C)` with the value 10 for the *base* argument. In the absence of a size modifier, the corresponding argument must be a pointer to `int`.
- i Matches an optionally signed integer, whose format is the same as expected for the subject sequence of `wcstol(3C)` with 0 for the *base* argument. In the absence of a size modifier, the corresponding argument must be a pointer to `int`.
- o Matches an optionally signed octal integer, whose format is the same as expected for the subject sequence of `wcstoul(3C)` with the value 8 for the *base* argument. In the absence of a size modifier, the corresponding argument must be a pointer to `unsigned int`.
- u Matches an optionally signed decimal integer, whose format is the same as expected for the subject sequence of `wcstoul(3C)` with the value 10 for the *base* argument. In the absence of a size modifier, the corresponding argument must be a pointer to `unsigned int`.

- x Matches an optionally signed hexadecimal integer, whose format is the same as expected for the subject sequence of `wcstoul(3C)` with the value 16 for the *base* argument. In the absence of a size modifier, the corresponding argument must be a pointer to `unsigned int`.
- e,f,g Matches an optionally signed floating-point number, whose format is the same as expected for the subject sequence of `wcstod(3C)`. In the absence of a size modifier, the corresponding argument must be a pointer to `float`.
- If the `fwprintf()` family of functions generates character string representations for infinity and NaN (a 7858 symbolic entity encoded in floating-point format) to support the ANSI/IEEE Std 754:1985 standard, the `wscanf()` family of functions will recognize them as input.
- s Matches a sequence of non white-space wide-characters. If no `l` (`ell`) qualifier is present, characters from the input field are converted as if by repeated calls to the `wcrtomb(3C)` function, with the conversion state described by an `mbstate_t` object initialized to zero before the first wide-character is converted. The corresponding argument must be a pointer to a character array large enough to accept the sequence and the terminating null character, which will be added automatically.
- Otherwise, the corresponding argument must be a pointer to an array of `wchar_t` large enough to accept the sequence and the terminating null wide-character, which will be added automatically.
- [Matches a non-empty sequence of wide-characters from a set of expected wide-characters (the *scanset*). If no `l` (`ell`) qualifier is present, wide-characters from the input field are converted as if by repeated calls to the `wcrtomb()` function, with the conversion state described by an `mbstate_t` object initialized to zero before the first wide-character is converted. The corresponding argument must be a pointer to a character array large enough to accept the sequence and the terminating null character, which will be added automatically.
- If an `l` (`ell`) qualifier is present, the corresponding argument must be a pointer to an array of `wchar_t` large enough to accept the sequence and the terminating null wide-character, which will be added automatically.
- The conversion specification includes all subsequent `widw` characters in the *format* string up to and including the matching right square bracket (`]`). The wide-characters between the square brackets (the *scanlist*) comprise the *scanset*, unless the wide-character after the left square bracket is a circumflex (`^`), in which case the *scanset* contains all wide-characters that do not appear in the *scanlist* between the circumflex and the right square bracket. If the conversion specification begins with `[]` or `[^]`, the right square bracket is included in the *scanlist* and the next right square bracket is the matching right square bracket that ends the conversion specification; otherwise the first right square bracket is the one that ends the conversion

wscanf(3C)

	specification. If a minus-sign (-) is in the scanlist and is not the first wide-character, nor the second where the first wide-character is a ^, nor the last wide-character, it indicates a range of characters to be matched.
c	Matches a sequence of wide-characters of the number specified by the field width (1 if no field width is present in the conversion specification). If no l (ell) qualifier is present, wide-characters from the input field are converted as if by repeated calls to the <code>wcrtomb()</code> function, with the conversion state described by an <code>mbstate_t</code> object initialized to zero before the first wide-character is converted. The corresponding argument must be a pointer to a character array large enough to accept the sequence. No null character is added. Otherwise, the corresponding argument must be a pointer to an array of <code>wchar_t</code> large enough to accept the sequence. No null wide-character is added.
p	Matches the set of sequences that is the same as the set of sequences that is produced by the %p conversion of the corresponding <code>fwprintf(3C)</code> functions. The corresponding argument must be a pointer to a pointer to <code>void</code> . If the input item is a value converted earlier during the same program execution, the pointer that results will compare equal to that value; otherwise the behavior of the %p conversion is undefined.
n	No input is consumed. The corresponding argument must be a pointer to the integer into which is to be written the number of wide-characters read from the input so far by this call to the <code>fwscanf()</code> functions. Execution of a %n conversion specification does not increment the assignment count returned at the completion of execution of the function.
C	Same as lc.
S	Same as ls.
%	Matches a single %; no conversion or assignment occurs. The complete conversion specification must be %%.

If a conversion specification is invalid, the behavior is undefined.

The conversion characters E, G, and X are also valid and behave the same as, respectively, e, g, and x.

If end-of-file is encountered during input, conversion is terminated. If end-of-file occurs before any wide-characters matching the current conversion specification (except for %n) have been read (other than leading white-space, where permitted), execution of the current conversion specification terminates with an input failure. Otherwise, unless execution of the current conversion specification is terminated with a matching failure, execution of the following conversion specification (if any) is terminated with an input failure.

Reaching the end of the string in `swscanf()` is equivalent to encountering end-of-file for `fwscanf()`.

If conversion terminates on a conflicting input, the offending input is left unread in the input. Any trailing white space (including newline) is left unread unless matched by a conversion specification. The success of literal matches and suppressed assignments is only directly determinable via the `%n` conversion specification.

The `fwscanf()` and `wscanf()` functions may mark the `st_atime` field of the file associated with *stream* for update. The `st_atime` field will be marked for update by the first successful execution of `fgetc(3C)`, `fgetwc(3C)`, `fgets(3C)`, `fgetws(3C)`, `fread(3C)`, `getc(3C)`, `getwc(3C)`, `getchar(3C)`, `getwchar(3C)`, `gets(3C)`, `fscanf(3C)` or `fwscanf()` using *stream* that returns data not supplied by a prior call to `ungetc(3C)`.

RETURN VALUES Upon successful completion, these functions return the number of successfully matched and assigned input items; this number can be 0 in the event of an early matching failure. If the input ends before the first matching failure or conversion, EOF is returned. If a read error occurs the error indicator for the stream is set, EOF is returned, and `errno` is set to indicate the error.

ERRORS For the conditions under which the `fwscanf()` functions will fail and may fail, refer to `fgetwc(3C)`.

In addition, `fwscanf()` may fail if:

`EILSEQ` Input byte sequence does not form a valid character.

`EINVAL` There are insufficient arguments.

USAGE In format strings containing the `%` form of conversion specifications, each argument in the argument list is used exactly once.

EXAMPLES **EXAMPLE 1** `wscanf()` example

The call:

```
int i, n; float x; char name[50];
n = wscanf(L"%d%f%s", &i, &x, name);
```

with the input line:

```
25 54.32E-1 Hamster
```

will assign to *n* the value 3, to *i* the value 25, to *x* the value 5.432, and *name* will contain the string Hamster.

The call:

```
int i; float x; char name[50];
(void) wscanf(L"%2d%f*d %[0123456789]", &i, &x, name);
```

with input:

wscanf(3C)

EXAMPLE 1 wscanf () example (Continued)

56789 0123 56a72

will assign 56 to *i*, 789.0 to *x*, skip 0123, and place the string 56\0 in *name*. The next call to `getchar(3C)` will return the character *a*.

NAME	wstring, wscasecmp, wscasecmp, wsdup, wscol – Process Code string operations				
SYNOPSIS	<pre>#include <wchar.h> int wscasecmp(const wchar_t *s1, const wchar_t *s2); int wscasecmp(const wchar_t *s1, const wchar_t *s2, int n); wchar_t *wsdup(const wchar_t *s); int wscol(const wchar_t *s);</pre>				
DESCRIPTION	<p>These functions operate on Process Code strings terminated by <code>wchar_t</code> null characters. During appending or copying, these routines do not check for an overflow condition of the receiving string. In the following, <i>s</i>, <i>s1</i>, and <i>s2</i> point to Process Code strings terminated by a <code>wchar_t</code> null.</p> <p>wscasecmp(), wscasecmp() The <code>wscasecmp()</code> function compares its arguments, ignoring case, and returns an integer greater than, equal to, or less than 0, depending upon whether <i>s1</i> is lexicographically greater than, equal to, or less than <i>s2</i>. It makes the same comparison but compares at most <i>n</i> Process Code characters. The four Extended Unix Code (EUC) codesets are ordered from lowest to highest as 0, 2, 3, 1 when characters from different codesets are compared.</p> <p>wsdup() The <code>wsdup()</code> function returns a pointer to a new Process Code string, which is a duplicate of the string pointed to by <i>s</i>. The space for the new string is obtained using <code>malloc(3C)</code>. If the new string cannot be created, a null pointer is returned.</p> <p>wscol() The <code>wscol()</code> function returns the screen display width (in columns) of the Process Code string <i>s</i>.</p>

wscat(3C)

NAME	wcstring, wscat, wscat, wcsncat, wsncat, wscmp, wscmp, wcsncmp, wsncmp, wcsncpy, wcsncpy, wcsncpy, wsncpy, wcslen, wslen, wcschr, wschr, wcsrchr, wsrchr, windex, wrindex, wcsprk, wspbrk, wcsvcs, wcsspn, wssp, wcspspn, wscpspn, wscpspn, wstok, wstok – wide-character string operations
SYNOPSIS	<pre>#include <wchar.h> wchar_t *wscat(wchar_t *ws1, const wchar_t *ws2); wchar_t *wcsncat(wchar_t *ws1, const wchar_t *ws2, size_t n); int wscmp(const wchar_t *ws1, const wchar_t *ws2); int wcsncmp(const wchar_t *ws1, const wchar_t *ws2, size_t n); wchar_t *wcsncpy(wchar_t *ws1, const wchar_t *ws2); wchar_t *wcsncpy(wchar_t *ws1, const wchar_t *ws2, size_t n); size_t wcslen(const wchar_t *ws); wchar_t *wcschr(const wchar_t *ws, wchar_t wc); wchar_t *wcsrchr(const wchar_t *ws, wchar_t wc); wchar_t *wcpbrk(const wchar_t *ws1, const wchar_t *ws2); wchar_t *wcsvcs(const wchar_t *ws1, const wchar_t *ws2); size_t wcsspn(const wchar_t *ws1, const wchar_t *ws2); size_t wcspspn(const wchar_t *ws1, const wchar_t *ws2); wchar_t *wstok(wchar_t *ws1, const wchar_t *ws2); wchar_t *wstok(wchar_t *ws1, const wchar_t *ws2, wchar_t **ptr); #include <widec.h> wchar_t *wscat(wchar_t *ws1, const wchar_t *ws2); wchar_t *wsncat(wchar_t *ws1, const wchar_t *ws2, size_t n); int wscmp(const wchar_t *ws1, const wchar_t *ws2); int wsncmp(const wchar_t *ws1, const wchar_t *ws2, size_t n); wchar_t *wscpy(wchar_t *ws1, const wchar_t *ws2); wchar_t *wsncpy(wchar_t *ws1, const wchar_t *ws2, size_t n); size_t wslen(const wchar_t *ws); wchar_t *wschr(const wchar_t *ws, wchar_t wc); wchar_t *wsrchr(const wchar_t *ws, wchar_t wc); wchar_t *wspbrk(const wchar_t *ws1, const wchar_t *ws2); size_t wssp(const wchar_t *ws1, const wchar_t *ws2);</pre>
XPG4 and SUS Default and other standards	

	<pre> size_t wscspn(const wchar_t *ws1, const wchar_t *ws2); wchar_t *wstok(wchar_t *ws1, const wchar_t *ws2); wchar_t *windex(const wchar_t *ws, wchar_t wc); wchar_t *wrindex(const wchar_t *ws, wchar_t wc); </pre>
ISO C++	<pre> #include <wchar.h> const wchar_t *wcschr(const wchar_t *ws, wchar_t wc); const wchar_t *wcspbrk(const wchar_t *ws1, const wchar_t *ws2); const wchar_t *wcsrchr(const wchar_t *ws, wchar_t wc); #include <cwchar> wchar_t *std::wcschr(wchar_t *ws, wchar_t wc); wchar_t *std::wcspbrk(wchar_t *ws1, const wchar_t *ws2); wchar_t *std::wcsrchr(wchar_t *ws, wchar_t wc); </pre>
DESCRIPTION	<p>These functions operate on wide-character strings terminated by <code>wchar_t</code> <code>NULL</code> characters. During appending or copying, these routines do not check for an overflow condition of the receiving string. In the following, <i>ws</i>, <i>ws1</i>, and <i>ws2</i> point to wide-character strings terminated by a <code>wchar_t</code> <code>NULL</code>.</p>
wscat() , wscat()	<p>The <code>wscat()</code> and <code>wscat()</code> functions append a copy of the wide-character string pointed to by <i>ws2</i> (including the terminating null wide-character code) to the end of the wide-character string pointed to by <i>ws1</i>. The initial wide-character code of <i>ws2</i> overwrites the null wide-character code at the end of <i>ws1</i>. If copying takes place between objects that overlap, the behavior is undefined. Both functions return <i>s1</i>; no return value is reserved to indicate an error.</p>
wcsncat() , wsncat()	<p>The <code>wcsncat()</code> and <code>wsncat()</code> functions append not more than <i>n</i> wide-character codes (a null wide-character code and wide-character codes that follow it are not appended) from the array pointed to by <i>ws2</i> to the end of the wide-character string pointed to by <i>ws1</i>. The initial wide-character code of <i>ws2</i> overwrites the null wide-character code at the end of <i>ws1</i>. A terminating null wide-character code is always appended to the result. Both functions return <i>ws1</i>; no return value is reserved to indicate an error.</p>
wcscmp() , wscmp()	<p>The <code>wcscmp()</code> and <code>wscmp()</code> functions compare the wide-character string pointed to by <i>ws1</i> to the wide-character string pointed to by <i>ws2</i>. The sign of a non-zero return value is determined by the sign of the difference between the values of the first pair of wide-character codes that differ in the objects being compared. Upon completion, both functions return an integer greater than, equal to, or less than zero, if the wide-character string pointed to by <i>ws1</i> is greater than, equal to, or less than the wide-character string pointed to by <i>ws2</i>.</p>

wscat(3C)

wcsncmp() , wsncmp()	The <code>wcsncmp()</code> and <code>wsncmp()</code> functions compare not more than <i>n</i> wide-character codes (wide-character codes that follow a null wide character code are not compared) from the array pointed to by <i>ws1</i> to the array pointed to by <i>ws2</i> . The sign of a non-zero return value is determined by the sign of the difference between the values of the first pair of wide-character codes that differ in the objects being compared. Upon successful completion, both functions return an integer greater than, equal to, or less than zero, if the possibly null-terminated array pointed to by <i>ws1</i> is greater than, equal to, or less than the possibly null-terminated array pointed to by <i>ws2</i> .
wcscpy() , wscpy()	The <code>wcscpy()</code> and <code>wscpy()</code> functions copy the wide-character string pointed to by <i>ws2</i> (including the terminating null wide-character code) into the array pointed to by <i>ws1</i> . If copying takes place between objects that overlap, the behavior is undefined. Both functions return <i>ws1</i> ; no return value is reserved to indicate an error.
wcsncpy() , wsncpy()	The <code>wcsncpy()</code> and <code>wsncpy()</code> functions copy not more than <i>n</i> wide-character codes (wide-character codes that follow a null wide character code are not copied) from the array pointed to by <i>ws2</i> to the array pointed to by <i>ws1</i> . If copying takes place between objects that overlap, the behavior is undefined. If the array pointed to by <i>ws2</i> is a wide-character string that is shorter than <i>n</i> wide-character codes, null wide-character codes are appended to the copy in the array pointed to by <i>ws1</i> , until a total <i>n</i> wide-character codes are written. Both functions return <i>ws1</i> ; no return value is reserved to indicate an error.
wcslen() , wslen()	The <code>wcslen()</code> and <code>wslen()</code> functions compute the number of wide-character codes in the wide-character string to which <i>ws</i> points, not including the terminating null wide-character code. Both functions return <i>ws</i> ; no return value is reserved to indicate an error.
wcschr() , wschr()	The <code>wcschr()</code> and <code>wschr()</code> functions locate the first occurrence of <i>wc</i> in the wide-character string pointed to by <i>ws</i> . The value of <i>wc</i> must be a character representable as a type <code>wchar_t</code> and must be a wide-character code corresponding to a valid character in the current locale. The terminating null wide-character code is considered to be part of the wide-character string. Upon completion, both functions return a pointer to the wide-character code, or a null pointer if the wide-character code is not found.
wcsrchr() , wsrchr()	The <code>wcsrchr()</code> and <code>wsrchr()</code> functions locate the last occurrence of <i>wc</i> in the wide-character string pointed to by <i>ws</i> . The value of <i>wc</i> must be a character representable as a type <code>wchar_t</code> and must be a wide-character code corresponding to a valid character in the current locale. The terminating null wide-character code is considered to be part of the wide-character string. Upon successful completion, both functions return a pointer to the wide-character code, or a null pointer if <i>wc</i> does not occur in the wide-character string.
windex() , wrindex()	The <code>windex()</code> and <code>wrindex()</code> functions behave the same as <code>wschr()</code> and <code>wsrchr()</code> , respectively.

wcspbrk() , wspbrk()	The <code>wcspbrk()</code> and <code>wspbrk()</code> functions locate the first occurrence in the wide character string pointed to by <code>ws1</code> of any wide-character code from the wide-character string pointed to by <code>ws2</code> . Upon successful completion, the function returns a pointer to the wide-character code, or a null pointer if no wide-character code from <code>ws2</code> occurs in <code>ws1</code> .
wcswcs()	The <code>wcswcs()</code> function locates the first occurrence in the wide-character string pointed to by <code>ws1</code> of the sequence of wide-character codes (excluding the terminating null wide-character code) in the wide-character string pointed to by <code>ws2</code> . Upon successful completion, the function returns a pointer to the located wide-character string, or a null pointer if the wide-character string is not found. If <code>ws2</code> points to a wide-character string with zero length, the function returns <code>ws1</code> .
wcsspn() , wsspnl()	The <code>wcsspn()</code> and <code>wsspnl()</code> functions compute the length of the maximum initial segment of the wide-character string pointed to by <code>ws1</code> which consists entirely of wide-character codes from the wide-character string pointed to by <code>ws2</code> . Both functions return the length <code>ws1</code> ; no return value is reserved to indicate an error.
wcscspn() , wscspnl()	The <code>wcscspn()</code> and <code>wscspnl()</code> functions compute the length of the maximum initial segment of the wide-character string pointed to by <code>ws1</code> which consists entirely of wide-character codes <i>not</i> from the wide-character string pointed to by <code>ws2</code> . Both functions return the length of the initial substring of <code>ws1</code> ; no return value is reserved to indicate an error.
wcstok() , wstok()	A sequence of calls to the <code>wcstok()</code> and <code>wstok()</code> functions break the wide-character string pointed to by <code>ws1</code> into a sequence of tokens, each of which is delimited by a wide-character code from the wide-character string pointed to by <code>ws2</code> .
Default and other standards	<p>The third argument points to a caller-provided <code>wchar_t</code> pointer into which the <code>wcstok()</code> function stores information necessary for it to continue scanning the same wide-character string. This argument is not available with the XPG4 and SUS versions of <code>wcstok()</code>, nor is it available with the <code>wstok()</code> function. See <code>standards(5)</code>.</p> <p>The first call in the sequence has <code>ws1</code> as its first argument, and is followed by calls with a null pointer as their first argument. The separator string pointed to by <code>ws2</code> may be different from call to call.</p> <p>The first call in the sequence searches the wide-character string pointed to by <code>ws1</code> for the first wide-character code that is <i>not</i> contained in the current separator string pointed to by <code>ws2</code>. If no such wide-character code is found, then there are no tokens in the wide-character string pointed to by <code>ws1</code>, and <code>wcstok()</code> and <code>wstok()</code> return a null pointer. If such a wide-character code is found, it is the start of the first token.</p> <p>The <code>wcstok()</code> and <code>wstok()</code> functions then search from that point for a wide-character code that <i>is</i> contained in the current separator string. If no such wide-character code is found, the current token extends to the end of the wide-character string pointed to by <code>ws1</code>, and subsequent searches for a token will</p>

wscat(3C)

return a null pointer. If such a wide-character code is found, it is overwritten by a null wide character, which terminates the current token. The `wcstok()` and `wstok()` functions save a pointer to the following wide-character code, from which the next search for a token will start.

Each subsequent call, with a null pointer as the value of the first argument, starts searching from the saved pointer and behaves as described above.

Upon successful completion, both functions return a pointer to the first wide-character code of a token. Otherwise, if there is no token, a null pointer is returned.

The initial wide-character code of <i>ws2</i> overwrites the null wide-character code at the end of <i>ws1</i>. A terminating null wide-character code is always appended to the result. Both functions return <i>ws1</i>; no return value is reserved to indicate an error.</p>
wcscmp(), wcscmp()	<p>The <code>wcscmp()</code> and <code>wcscmp()</code> functions compare the wide-character string pointed to by <i>ws1</i> to the wide-character string pointed to by <i>ws2</i>. The sign of a non-zero return value is determined by the sign of the difference between the values of the first pair of wide-character codes that differ in the objects being compared. Upon completion, both functions return an integer greater than, equal to, or less than zero, if the wide-character string pointed to by <i>ws1</i> is greater than, equal to, or less than the wide-character string pointed to by <i>ws2</i>.</p>

wcsncmp() , wsncmp()	The <code>wcsncmp()</code> and <code>wsncmp()</code> functions compare not more than <i>n</i> wide-character codes (wide-character codes that follow a null wide character code are not compared) from the array pointed to by <i>ws1</i> to the array pointed to by <i>ws2</i> . The sign of a non-zero return value is determined by the sign of the difference between the values of the first pair of wide-character codes that differ in the objects being compared. Upon successful completion, both functions return an integer greater than, equal to, or less than zero, if the possibly null-terminated array pointed to by <i>ws1</i> is greater than, equal to, or less than the possibly null-terminated array pointed to by <i>ws2</i> .
wscpy() , wscopy()	The <code>wscpy()</code> and <code>wscopy()</code> functions copy the wide-character string pointed to by <i>ws2</i> (including the terminating null wide-character code) into the array pointed to by <i>ws1</i> . If copying takes place between objects that overlap, the behavior is undefined. Both functions return <i>ws1</i> ; no return value is reserved to indicate an error.
wcsncpy() , wsncpy()	The <code>wcsncpy()</code> and <code>wsncpy()</code> functions copy not more than <i>n</i> wide-character codes (wide-character codes that follow a null wide character code are not copied) from the array pointed to by <i>ws2</i> to the array pointed to by <i>ws1</i> . If copying takes place between objects that overlap, the behavior is undefined. If the array pointed to by <i>ws2</i> is a wide-character string that is shorter than <i>n</i> wide-character codes, null wide-character codes are appended to the copy in the array pointed to by <i>ws1</i> , until a total <i>n</i> wide-character codes are written. Both functions return <i>ws1</i> ; no return value is reserved to indicate an error.
wcslen() , wslen()	The <code>wcslen()</code> and <code>wslen()</code> functions compute the number of wide-character codes in the wide-character string to which <i>ws</i> points, not including the terminating null wide-character code. Both functions return <i>ws</i> ; no return value is reserved to indicate an error.
wcschr() , wschr()	The <code>wcschr()</code> and <code>wschr()</code> functions locate the first occurrence of <i>wc</i> in the wide-character string pointed to by <i>ws</i> . The value of <i>wc</i> must be a character representable as a type <code>wchar_t</code> and must be a wide-character code corresponding to a valid character in the current locale. The terminating null wide-character code is considered to be part of the wide-character string. Upon completion, both functions return a pointer to the wide-character code, or a null pointer if the wide-character code is not found.
wcsrchr() , wsrchr()	The <code>wcsrchr()</code> and <code>wsrchr()</code> functions locate the last occurrence of <i>wc</i> in the wide-character string pointed to by <i>ws</i> . The value of <i>wc</i> must be a character representable as a type <code>wchar_t</code> and must be a wide-character code corresponding to a valid character in the current locale. The terminating null wide-character code is considered to be part of the wide-character string. Upon successful completion, both functions return a pointer to the wide-character code, or a null pointer if <i>wc</i> does not occur in the wide-character string.
windex() , wrindex()	The <code>windex()</code> and <code>wrindex()</code> functions behave the same as <code>wschr()</code> and <code>wsrchr()</code> , respectively.

wchr(3C)

wcspbrk() , wspbrk()	The <code>wcspbrk()</code> and <code>wspbrk()</code> functions locate the first occurrence in the wide character string pointed to by <code>ws1</code> of any wide-character code from the wide-character string pointed to by <code>ws2</code> . Upon successful completion, the function returns a pointer to the wide-character code, or a null pointer if no wide-character code from <code>ws2</code> occurs in <code>ws1</code> .
wcswcs()	The <code>wcswcs()</code> function locates the first occurrence in the wide-character string pointed to by <code>ws1</code> of the sequence of wide-character codes (excluding the terminating null wide-character code) in the wide-character string pointed to by <code>ws2</code> . Upon successful completion, the function returns a pointer to the located wide-character string, or a null pointer if the wide-character string is not found. If <code>ws2</code> points to a wide-character string with zero length, the function returns <code>ws1</code> .
wcsspn() , wsspnl()	The <code>wcsspn()</code> and <code>wsspnl()</code> functions compute the length of the maximum initial segment of the wide-character string pointed to by <code>ws1</code> which consists entirely of wide-character codes from the wide-character string pointed to by <code>ws2</code> . Both functions return the length <code>ws1</code> ; no return value is reserved to indicate an error.
wcscspn() , wscspnl()	The <code>wcscspn()</code> and <code>wscspnl()</code> functions compute the length of the maximum initial segment of the wide-character string pointed to by <code>ws1</code> which consists entirely of wide-character codes <i>not</i> from the wide-character string pointed to by <code>ws2</code> . Both functions return the length of the initial substring of <code>ws1</code> ; no return value is reserved to indicate an error.
wcstok() , wstok()	A sequence of calls to the <code>wcstok()</code> and <code>wstok()</code> functions break the wide-character string pointed to by <code>ws1</code> into a sequence of tokens, each of which is delimited by a wide-character code from the wide-character string pointed to by <code>ws2</code> .
Default and other standards	<p>The third argument points to a caller-provided <code>wchar_t</code> pointer into which the <code>wcstok()</code> function stores information necessary for it to continue scanning the same wide-character string. This argument is not available with the XPG4 and SUS versions of <code>wcstok()</code>, nor is it available with the <code>wstok()</code> function. See <code>standards(5)</code>.</p> <p>The first call in the sequence has <code>ws1</code> as its first argument, and is followed by calls with a null pointer as their first argument. The separator string pointed to by <code>ws2</code> may be different from call to call.</p> <p>The first call in the sequence searches the wide-character string pointed to by <code>ws1</code> for the first wide-character code that is <i>not</i> contained in the current separator string pointed to by <code>ws2</code>. If no such wide-character code is found, then there are no tokens in the wide-character string pointed to by <code>ws1</code>, and <code>wcstok()</code> and <code>wstok()</code> return a null pointer. If such a wide-character code is found, it is the start of the first token.</p> <p>The <code>wcstok()</code> and <code>wstok()</code> functions then search from that point for a wide-character code that <i>is</i> contained in the current separator string. If no such wide-character code is found, the current token extends to the end of the wide-character string pointed to by <code>ws1</code>, and subsequent searches for a token will</p>

wchr(3C)

return a null pointer. If such a wide-character code is found, it is overwritten by a null wide character, which terminates the current token. The `wcstok()` and `wstok()` functions save a pointer to the following wide-character code, from which the next search for a token will start.

Each subsequent call, with a null pointer as the value of the first argument, starts searching from the saved pointer and behaves as described above.

Upon successful completion, both functions return a pointer to the first wide-character code of a token. Otherwise, if there is no token, a null pointer is returned.

	<pre> size_t wscspn(const wchar_t *ws1, const wchar_t *ws2); wchar_t *wstok(wchar_t *ws1, const wchar_t *ws2); wchar_t *windex(const wchar_t *ws, wchar_t wc); wchar_t *wrindex(const wchar_t *ws, wchar_t wc); </pre>
ISO C++	<pre> #include <wchar.h> const wchar_t *wcschr(const wchar_t *ws, wchar_t wc); const wchar_t *wcspbrk(const wchar_t *ws1, const wchar_t *ws2); const wchar_t *wcsrchr(const wchar_t *ws, wchar_t wc); #include <cwchar> wchar_t *std::wcschr(wchar_t *ws, wchar_t wc); wchar_t *std::wcspbrk(wchar_t *ws1, const wchar_t *ws2); wchar_t *std::wcsrchr(wchar_t *ws, wchar_t wc); </pre>
DESCRIPTION	<p>These functions operate on wide-character strings terminated by <code>wchar_t NULL</code> characters. During appending or copying, these routines do not check for an overflow condition of the receiving string. In the following, <i>ws</i>, <i>ws1</i>, and <i>ws2</i> point to wide-character strings terminated by a <code>wchar_t NULL</code>.</p>
wscat(), wscat()	<p>The <code>wscat()</code> and <code>wscat()</code> functions append a copy of the wide-character string pointed to by <i>ws2</i> (including the terminating null wide-character code) to the end of the wide-character string pointed to by <i>ws1</i>. The initial wide-character code of <i>ws2</i> overwrites the null wide-character code at the end of <i>ws1</i>. If copying takes place between objects that overlap, the behavior is undefined. Both functions return <i>s1</i>; no return value is reserved to indicate an error.</p>
wcsncat(), wsncat()	<p>The <code>wcsncat()</code> and <code>wsncat()</code> functions append not more than <i>n</i> wide-character codes (a null wide-character code and wide-character codes that follow it are not appended) from the array pointed to by <i>ws2</i> to the end of the wide-character string pointed to by <i>ws1</i>. The initial wide-character code of <i>ws2</i> overwrites the null wide-character code at the end of <i>ws1</i>. A terminating null wide-character code is always appended to the result. Both functions return <i>ws1</i>; no return value is reserved to indicate an error.</p>
wscmp(), wscmp()	<p>The <code>wscmp()</code> and <code>wscmp()</code> functions compare the wide-character string pointed to by <i>ws1</i> to the wide-character string pointed to by <i>ws2</i>. The sign of a non-zero return value is determined by the sign of the difference between the values of the first pair of wide-character codes that differ in the objects being compared. Upon completion, both functions return an integer greater than, equal to, or less than zero, if the wide-character string pointed to by <i>ws1</i> is greater than, equal to, or less than the wide-character string pointed to by <i>ws2</i>.</p>

wscmp(3C)

wcsncmp(), wsncmp()	The <code>wcsncmp()</code> and <code>wsncmp()</code> functions compare not more than <i>n</i> wide-character codes (wide-character codes that follow a null wide character code are not compared) from the array pointed to by <i>ws1</i> to the array pointed to by <i>ws2</i> . The sign of a non-zero return value is determined by the sign of the difference between the values of the first pair of wide-character codes that differ in the objects being compared. Upon successful completion, both functions return an integer greater than, equal to, or less than zero, if the possibly null-terminated array pointed to by <i>ws1</i> is greater than, equal to, or less than the possibly null-terminated array pointed to by <i>ws2</i> .
wcscpy(), wscpy()	The <code>wcscpy()</code> and <code>wscpy()</code> functions copy the wide-character string pointed to by <i>ws2</i> (including the terminating null wide-character code) into the array pointed to by <i>ws1</i> . If copying takes place between objects that overlap, the behavior is undefined. Both functions return <i>ws1</i> ; no return value is reserved to indicate an error.
wcsncpy(), wsncpy()	The <code>wcsncpy()</code> and <code>wsncpy()</code> functions copy not more than <i>n</i> wide-character codes (wide-character codes that follow a null wide character code are not copied) from the array pointed to by <i>ws2</i> to the array pointed to by <i>ws1</i> . If copying takes place between objects that overlap, the behavior is undefined. If the array pointed to by <i>ws2</i> is a wide-character string that is shorter than <i>n</i> wide-character codes, null wide-character codes are appended to the copy in the array pointed to by <i>ws1</i> , until a total <i>n</i> wide-character codes are written. Both functions return <i>ws1</i> ; no return value is reserved to indicate an error.
wcslen(), wslen()	The <code>wcslen()</code> and <code>wslen()</code> functions compute the number of wide-character codes in the wide-character string to which <i>ws</i> points, not including the terminating null wide-character code. Both functions return <i>ws</i> ; no return value is reserved to indicate an error.
wcschr(), wschr()	The <code>wcschr()</code> and <code>wschr()</code> functions locate the first occurrence of <i>wc</i> in the wide-character string pointed to by <i>ws</i> . The value of <i>wc</i> must be a character representable as a type <code>wchar_t</code> and must be a wide-character code corresponding to a valid character in the current locale. The terminating null wide-character code is considered to be part of the wide-character string. Upon completion, both functions return a pointer to the wide-character code, or a null pointer if the wide-character code is not found.
wcsrchr(), wsrchr()	The <code>wcsrchr()</code> and <code>wsrchr()</code> functions locate the last occurrence of <i>wc</i> in the wide-character string pointed to by <i>ws</i> . The value of <i>wc</i> must be a character representable as a type <code>wchar_t</code> and must be a wide-character code corresponding to a valid character in the current locale. The terminating null wide-character code is considered to be part of the wide-character string. Upon successful completion, both functions return a pointer to the wide-character code, or a null pointer if <i>wc</i> does not occur in the wide-character string.
windex(), wrintdex()	The <code>windex()</code> and <code>wrintdex()</code> functions behave the same as <code>wschr()</code> and <code>wsrchr()</code> , respectively.

wcspbrk() , wspbrk()	The <code>wcspbrk()</code> and <code>wspbrk()</code> functions locate the first occurrence in the wide character string pointed to by <code>ws1</code> of any wide-character code from the wide-character string pointed to by <code>ws2</code> . Upon successful completion, the function returns a pointer to the wide-character code, or a null pointer if no wide-character code from <code>ws2</code> occurs in <code>ws1</code> .
wcswcs()	The <code>wcswcs()</code> function locates the first occurrence in the wide-character string pointed to by <code>ws1</code> of the sequence of wide-character codes (excluding the terminating null wide-character code) in the wide-character string pointed to by <code>ws2</code> . Upon successful completion, the function returns a pointer to the located wide-character string, or a null pointer if the wide-character string is not found. If <code>ws2</code> points to a wide-character string with zero length, the function returns <code>ws1</code> .
wcsspn() , wsspnl()	The <code>wcsspn()</code> and <code>wsspnl()</code> functions compute the length of the maximum initial segment of the wide-character string pointed to by <code>ws1</code> which consists entirely of wide-character codes from the wide-character string pointed to by <code>ws2</code> . Both functions return the length <code>ws1</code> ; no return value is reserved to indicate an error.
wcscspn() , wscspnl()	The <code>wcscspn()</code> and <code>wscspnl()</code> functions compute the length of the maximum initial segment of the wide-character string pointed to by <code>ws1</code> which consists entirely of wide-character codes <i>not</i> from the wide-character string pointed to by <code>ws2</code> . Both functions return the length of the initial substring of <code>ws1</code> ; no return value is reserved to indicate an error.
wcstok() , wstok()	A sequence of calls to the <code>wcstok()</code> and <code>wstok()</code> functions break the wide-character string pointed to by <code>ws1</code> into a sequence of tokens, each of which is delimited by a wide-character code from the wide-character string pointed to by <code>ws2</code> .
Default and other standards	<p>The third argument points to a caller-provided <code>wchar_t</code> pointer into which the <code>wcstok()</code> function stores information necessary for it to continue scanning the same wide-character string. This argument is not available with the XPG4 and SUS versions of <code>wcstok()</code>, nor is it available with the <code>wstok()</code> function. See <code>standards(5)</code>.</p> <p>The first call in the sequence has <code>ws1</code> as its first argument, and is followed by calls with a null pointer as their first argument. The separator string pointed to by <code>ws2</code> may be different from call to call.</p> <p>The first call in the sequence searches the wide-character string pointed to by <code>ws1</code> for the first wide-character code that is <i>not</i> contained in the current separator string pointed to by <code>ws2</code>. If no such wide-character code is found, then there are no tokens in the wide-character string pointed to by <code>ws1</code>, and <code>wcstok()</code> and <code>wstok()</code> return a null pointer. If such a wide-character code is found, it is the start of the first token.</p> <p>The <code>wcstok()</code> and <code>wstok()</code> functions then search from that point for a wide-character code that <i>is</i> contained in the current separator string. If no such wide-character code is found, the current token extends to the end of the wide-character string pointed to by <code>ws1</code>, and subsequent searches for a token will</p>

wscmp(3C)

return a null pointer. If such a wide-character code is found, it is overwritten by a null wide character, which terminates the current token. The `wcstok()` and `wstok()` functions save a pointer to the following wide-character code, from which the next search for a token will start.

Each subsequent call, with a null pointer as the value of the first argument, starts searching from the saved pointer and behaves as described above.

Upon successful completion, both functions return a pointer to the first wide-character code of a token. Otherwise, if there is no token, a null pointer is returned.

NAME	wstring, wscasecmp, wsnccasecmp, wsdup, wscol – Process Code string operations				
SYNOPSIS	<pre>#include <widec.h> int wscasecmp(const wchar_t *s1, const wchar_t *s2); int wsnccasecmp(const wchar_t *s1, const wchar_t *s2, int n); wchar_t *wsdup(const wchar_t *s); int wscol(const wchar_t *s);</pre>				
DESCRIPTION	<p>These functions operate on Process Code strings terminated by <code>wchar_t</code> null characters. During appending or copying, these routines do not check for an overflow condition of the receiving string. In the following, <i>s</i>, <i>s1</i>, and <i>s2</i> point to Process Code strings terminated by a <code>wchar_t</code> null.</p> <p>wscasecmp(), wsnccasecmp() The <code>wscasecmp()</code> function compares its arguments, ignoring case, and returns an integer greater than, equal to, or less than 0, depending upon whether <i>s1</i> is lexicographically greater than, equal to, or less than <i>s2</i>. It makes the same comparison but compares at most <i>n</i> Process Code characters. The four Extended Unix Code (EUC) codesets are ordered from lowest to highest as 0, 2, 3, 1 when characters from different codesets are compared.</p> <p>wsdup() The <code>wsdup()</code> function returns a pointer to a new Process Code string, which is a duplicate of the string pointed to by <i>s</i>. The space for the new string is obtained using <code>malloc(3C)</code>. If the new string cannot be created, a null pointer is returned.</p> <p>wscol() The <code>wscol()</code> function returns the screen display width (in columns) of the Process Code string <i>s</i>.</p>				
ATTRIBUTES	<p>See <code>attributes(5)</code> for descriptions of the following attributes:</p> <table border="1" style="width: 100%; border-collapse: collapse;"> <thead> <tr> <th style="text-align: left;">ATTRIBUTE TYPE</th> <th style="text-align: left;">ATTRIBUTE VALUE</th> </tr> </thead> <tbody> <tr> <td>MT-Level</td> <td>MT-Safe</td> </tr> </tbody> </table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	MT-Level	MT-Safe

wscoll(3C)

NAME	wscoll, wscoll – wide character string comparison using collating information						
SYNOPSIS	<pre>#include <wchar.h> int wcscoll(const wchar_t *ws1, const wchar_t *ws2); int wscoll(const wchar_t *ws1, const wchar_t *ws2);</pre>						
DESCRIPTION	The <code>wcscoll()</code> and <code>wscoll()</code> functions compare the wide character string pointed to by <code>ws1</code> to the wide character string pointed to by <code>ws2</code> , both interpreted as appropriate to the <code>LC_COLLATE</code> category of the current locale.						
RETURN VALUES	Upon successful completion, <code>wcscoll()</code> and <code>wscoll()</code> return an integer greater than, equal to, or less than 0, depending upon whether the wide character string pointed to by <code>ws1</code> is greater than, equal to, or less than the wide character string pointed to by <code>ws2</code> , when both are interpreted as appropriate to the current locale. On error, <code>wcscoll()</code> and <code>wscoll()</code> may set <code>errno</code> , but no return value is reserved to indicate an error.						
ERRORS	The <code>wcscoll()</code> and <code>wscoll()</code> functions may fail if: EINVAL The <code>ws1</code> or <code>ws2</code> arguments contain wide character codes outside the domain of the collating sequence. ENOSYS The function is not supported.						
USAGE	Because no return value is reserved to indicate an error, an application wishing to check for error situations should set <code>errno</code> to 0, call either <code>wcscoll()</code> or <code>wscoll()</code> , then check <code>errno</code> and if it is non-zero, assume an error has occurred. The <code>wcsxfrm(3C)</code> and <code>wcscmp(3C)</code> functions should be used for sorting large lists. The <code>wcscoll()</code> and <code>wscoll()</code> functions can be used safely in multithreaded applications as long as <code>setlocale(3C)</code> is not being called to change the locale.						
ATTRIBUTES	See <code>attributes(5)</code> for descriptions of the following attributes: <table border="1"><thead><tr><th>ATTRIBUTE TYPE</th><th>ATTRIBUTE VALUE</th></tr></thead><tbody><tr><td>MT-Level</td><td>MT-Safe with exceptions</td></tr><tr><td>CSI</td><td>Enabled</td></tr></tbody></table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	MT-Level	MT-Safe with exceptions	CSI	Enabled

wscopy(3C)

	<pre> size_t wscspn(const wchar_t *ws1, const wchar_t *ws2); wchar_t *wstok(wchar_t *ws1, const wchar_t *ws2); wchar_t *windex(const wchar_t *ws, wchar_t wc); wchar_t *wrindex(const wchar_t *ws, wchar_t wc); </pre>
ISO C++	<pre> #include <wchar.h> const wchar_t *wcschr(const wchar_t *ws, wchar_t wc); const wchar_t *wcspbrk(const wchar_t *ws1, const wchar_t *ws2); const wchar_t *wcsrchr(const wchar_t *ws, wchar_t wc); #include <cwchar> wchar_t *std::wcschr(wchar_t *ws, wchar_t wc); wchar_t *std::wcspbrk(wchar_t *ws1, const wchar_t *ws2); wchar_t *std::wcsrchr(wchar_t *ws, wchar_t wc); </pre>
DESCRIPTION	<p>These functions operate on wide-character strings terminated by <code>wchar_t NULL</code> characters. During appending or copying, these routines do not check for an overflow condition of the receiving string. In the following, <i>ws</i>, <i>ws1</i>, and <i>ws2</i> point to wide-character strings terminated by a <code>wchar_t NULL</code>.</p>
wscat(), wscat()	<p>The <code>wscat()</code> and <code>wscat()</code> functions append a copy of the wide-character string pointed to by <i>ws2</i> (including the terminating null wide-character code) to the end of the wide-character string pointed to by <i>ws1</i>. The initial wide-character code of <i>ws2</i> overwrites the null wide-character code at the end of <i>ws1</i>. If copying takes place between objects that overlap, the behavior is undefined. Both functions return <i>s1</i>; no return value is reserved to indicate an error.</p>
wcsncat(), wsncat()	<p>The <code>wcsncat()</code> and <code>wsncat()</code> functions append not more than <i>n</i> wide-character codes (a null wide-character code and wide-character codes that follow it are not appended) from the array pointed to by <i>ws2</i> to the end of the wide-character string pointed to by <i>ws1</i>. The initial wide-character code of <i>ws2</i> overwrites the null wide-character code at the end of <i>ws1</i>. A terminating null wide-character code is always appended to the result. Both functions return <i>ws1</i>; no return value is reserved to indicate an error.</p>
wscmp(), wscmp()	<p>The <code>wscmp()</code> and <code>wscmp()</code> functions compare the wide-character string pointed to by <i>ws1</i> to the wide-character string pointed to by <i>ws2</i>. The sign of a non-zero return value is determined by the sign of the difference between the values of the first pair of wide-character codes that differ in the objects being compared. Upon completion, both functions return an integer greater than, equal to, or less than zero, if the wide-character string pointed to by <i>ws1</i> is greater than, equal to, or less than the wide-character string pointed to by <i>ws2</i>.</p>

wcsncmp() , wsncmp()	The <code>wcsncmp()</code> and <code>wsncmp()</code> functions compare not more than <i>n</i> wide-character codes (wide-character codes that follow a null wide character code are not compared) from the array pointed to by <i>ws1</i> to the array pointed to by <i>ws2</i> . The sign of a non-zero return value is determined by the sign of the difference between the values of the first pair of wide-character codes that differ in the objects being compared. Upon successful completion, both functions return an integer greater than, equal to, or less than zero, if the possibly null-terminated array pointed to by <i>ws1</i> is greater than, equal to, or less than the possibly null-terminated array pointed to by <i>ws2</i> .
wscpy() , wscopy()	The <code>wscpy()</code> and <code>wscopy()</code> functions copy the wide-character string pointed to by <i>ws2</i> (including the terminating null wide-character code) into the array pointed to by <i>ws1</i> . If copying takes place between objects that overlap, the behavior is undefined. Both functions return <i>ws1</i> ; no return value is reserved to indicate an error.
wcsncpy() , wsncpy()	The <code>wcsncpy()</code> and <code>wsncpy()</code> functions copy not more than <i>n</i> wide-character codes (wide-character codes that follow a null wide character code are not copied) from the array pointed to by <i>ws2</i> to the array pointed to by <i>ws1</i> . If copying takes place between objects that overlap, the behavior is undefined. If the array pointed to by <i>ws2</i> is a wide-character string that is shorter than <i>n</i> wide-character codes, null wide-character codes are appended to the copy in the array pointed to by <i>ws1</i> , until a total <i>n</i> wide-character codes are written. Both functions return <i>ws1</i> ; no return value is reserved to indicate an error.
wcslen() , wslen()	The <code>wcslen()</code> and <code>wslen()</code> functions compute the number of wide-character codes in the wide-character string to which <i>ws</i> points, not including the terminating null wide-character code. Both functions return <i>ws</i> ; no return value is reserved to indicate an error.
wcschr() , wschr()	The <code>wcschr()</code> and <code>wschr()</code> functions locate the first occurrence of <i>wc</i> in the wide-character string pointed to by <i>ws</i> . The value of <i>wc</i> must be a character representable as a type <code>wchar_t</code> and must be a wide-character code corresponding to a valid character in the current locale. The terminating null wide-character code is considered to be part of the wide-character string. Upon completion, both functions return a pointer to the wide-character code, or a null pointer if the wide-character code is not found.
wcsrchr() , wsrchr()	The <code>wcsrchr()</code> and <code>wsrchr()</code> functions locate the last occurrence of <i>wc</i> in the wide-character string pointed to by <i>ws</i> . The value of <i>wc</i> must be a character representable as a type <code>wchar_t</code> and must be a wide-character code corresponding to a valid character in the current locale. The terminating null wide-character code is considered to be part of the wide-character string. Upon successful completion, both functions return a pointer to the wide-character code, or a null pointer if <i>wc</i> does not occur in the wide-character string.
windex() , wrindex()	The <code>windex()</code> and <code>wrindex()</code> functions behave the same as <code>wschr()</code> and <code>wsrchr()</code> , respectively.

wscopy(3C)

wcspbrk() , wspbrk()	The <code>wcspbrk()</code> and <code>wspbrk()</code> functions locate the first occurrence in the wide character string pointed to by <code>ws1</code> of any wide-character code from the wide-character string pointed to by <code>ws2</code> . Upon successful completion, the function returns a pointer to the wide-character code, or a null pointer if no wide-character code from <code>ws2</code> occurs in <code>ws1</code> .
wcswcs()	The <code>wcswcs()</code> function locates the first occurrence in the wide-character string pointed to by <code>ws1</code> of the sequence of wide-character codes (excluding the terminating null wide-character code) in the wide-character string pointed to by <code>ws2</code> . Upon successful completion, the function returns a pointer to the located wide-character string, or a null pointer if the wide-character string is not found. If <code>ws2</code> points to a wide-character string with zero length, the function returns <code>ws1</code> .
wcsspn() , wsspnl()	The <code>wcsspn()</code> and <code>wsspnl()</code> functions compute the length of the maximum initial segment of the wide-character string pointed to by <code>ws1</code> which consists entirely of wide-character codes from the wide-character string pointed to by <code>ws2</code> . Both functions return the length <code>ws1</code> ; no return value is reserved to indicate an error.
wcscspn() , wscspnl()	The <code>wcscspn()</code> and <code>wscspnl()</code> functions compute the length of the maximum initial segment of the wide-character string pointed to by <code>ws1</code> which consists entirely of wide-character codes <i>not</i> from the wide-character string pointed to by <code>ws2</code> . Both functions return the length of the initial substring of <code>ws1</code> ; no return value is reserved to indicate an error.
wcstok() , wstok()	A sequence of calls to the <code>wcstok()</code> and <code>wstok()</code> functions break the wide-character string pointed to by <code>ws1</code> into a sequence of tokens, each of which is delimited by a wide-character code from the wide-character string pointed to by <code>ws2</code> .
Default and other standards	<p>The third argument points to a caller-provided <code>wchar_t</code> pointer into which the <code>wcstok()</code> function stores information necessary for it to continue scanning the same wide-character string. This argument is not available with the XPG4 and SUS versions of <code>wcstok()</code>, nor is it available with the <code>wstok()</code> function. See <code>standards(5)</code>.</p> <p>The first call in the sequence has <code>ws1</code> as its first argument, and is followed by calls with a null pointer as their first argument. The separator string pointed to by <code>ws2</code> may be different from call to call.</p> <p>The first call in the sequence searches the wide-character string pointed to by <code>ws1</code> for the first wide-character code that is <i>not</i> contained in the current separator string pointed to by <code>ws2</code>. If no such wide-character code is found, then there are no tokens in the wide-character string pointed to by <code>ws1</code>, and <code>wcstok()</code> and <code>wstok()</code> return a null pointer. If such a wide-character code is found, it is the start of the first token.</p> <p>The <code>wcstok()</code> and <code>wstok()</code> functions then search from that point for a wide-character code that <i>is</i> contained in the current separator string. If no such wide-character code is found, the current token extends to the end of the wide-character string pointed to by <code>ws1</code>, and subsequent searches for a token will</p>

wscopy(3C)

return a null pointer. If such a wide-character code is found, it is overwritten by a null wide character, which terminates the current token. The `wcstok()` and `wstok()` functions save a pointer to the following wide-character code, from which the next search for a token will start.

Each subsequent call, with a null pointer as the value of the first argument, starts searching from the saved pointer and behaves as described above.

Upon successful completion, both functions return a pointer to the first wide-character code of a token. Otherwise, if there is no token, a null pointer is returned.

DESCRIPTION	<p>These functions operate on wide-character strings terminated by <code>wchar_t</code> <code>NULL</code> characters. During appending or copying, these routines do not check for an overflow condition of the receiving string. In the following, <i>ws</i>, <i>ws1</i>, and <i>ws2</i> point to wide-character strings terminated by a <code>wchar_t</code> <code>NULL</code>.</p>
wscat(), wscat()	<p>The <code>wscat()</code> and <code>wscat()</code> functions append a copy of the wide-character string pointed to by <i>ws2</i> (including the terminating null wide-character code) to the end of the wide-character string pointed to by <i>ws1</i>. The initial wide-character code of <i>ws2</i> overwrites the null wide-character code at the end of <i>ws1</i>. If copying takes place between objects that overlap, the behavior is undefined. Both functions return <i>s1</i>; no return value is reserved to indicate an error.</p>
wcsncat(), wsncat()	<p>The <code>wcsncat()</code> and <code>wsncat()</code> functions append not more than <i>n</i> wide-character codes (a null wide-character code and wide-character codes that follow it are not appended) from the array pointed to by <i>ws2</i> to the end of the wide-character string pointed to by <i>ws1</i>. The initial wide-character code of <i>ws2</i> overwrites the null wide-character code at the end of <i>ws1</i>. A terminating null wide-character code is always appended to the result. Both functions return <i>ws1</i>; no return value is reserved to indicate an error.</p>
wscmp(), wscmp()	<p>The <code>wscmp()</code> and <code>wscmp()</code> functions compare the wide-character string pointed to by <i>ws1</i> to the wide-character string pointed to by <i>ws2</i>. The sign of a non-zero return value is determined by the sign of the difference between the values of the first pair of wide-character codes that differ in the objects being compared. Upon completion, both functions return an integer greater than, equal to, or less than zero, if the wide-character string pointed to by <i>ws1</i> is greater than, equal to, or less than the wide-character string pointed to by <i>ws2</i>.</p>

wcspn(3C)

wcsncmp(), wsncmp()	The <code>wcsncmp()</code> and <code>wsncmp()</code> functions compare not more than <i>n</i> wide-character codes (wide-character codes that follow a null wide character code are not compared) from the array pointed to by <i>ws1</i> to the array pointed to by <i>ws2</i> . The sign of a non-zero return value is determined by the sign of the difference between the values of the first pair of wide-character codes that differ in the objects being compared. Upon successful completion, both functions return an integer greater than, equal to, or less than zero, if the possibly null-terminated array pointed to by <i>ws1</i> is greater than, equal to, or less than the possibly null-terminated array pointed to by <i>ws2</i> .
wcscpy(), wscpy()	The <code>wcscpy()</code> and <code>wscpy()</code> functions copy the wide-character string pointed to by <i>ws2</i> (including the terminating null wide-character code) into the array pointed to by <i>ws1</i> . If copying takes place between objects that overlap, the behavior is undefined. Both functions return <i>ws1</i> ; no return value is reserved to indicate an error.
wcsncpy(), wsncpy()	The <code>wcsncpy()</code> and <code>wsncpy()</code> functions copy not more than <i>n</i> wide-character codes (wide-character codes that follow a null wide character code are not copied) from the array pointed to by <i>ws2</i> to the array pointed to by <i>ws1</i> . If copying takes place between objects that overlap, the behavior is undefined. If the array pointed to by <i>ws2</i> is a wide-character string that is shorter than <i>n</i> wide-character codes, null wide-character codes are appended to the copy in the array pointed to by <i>ws1</i> , until a total <i>n</i> wide-character codes are written. Both functions return <i>ws1</i> ; no return value is reserved to indicate an error.
wcslen(), wslen()	The <code>wcslen()</code> and <code>wslen()</code> functions compute the number of wide-character codes in the wide-character string to which <i>ws</i> points, not including the terminating null wide-character code. Both functions return <i>ws</i> ; no return value is reserved to indicate an error.
wcschr(), wschr()	The <code>wcschr()</code> and <code>wschr()</code> functions locate the first occurrence of <i>wc</i> in the wide-character string pointed to by <i>ws</i> . The value of <i>wc</i> must be a character representable as a type <code>wchar_t</code> and must be a wide-character code corresponding to a valid character in the current locale. The terminating null wide-character code is considered to be part of the wide-character string. Upon completion, both functions return a pointer to the wide-character code, or a null pointer if the wide-character code is not found.
wcsrchr(), wsrchr()	The <code>wcsrchr()</code> and <code>wsrchr()</code> functions locate the last occurrence of <i>wc</i> in the wide-character string pointed to by <i>ws</i> . The value of <i>wc</i> must be a character representable as a type <code>wchar_t</code> and must be a wide-character code corresponding to a valid character in the current locale. The terminating null wide-character code is considered to be part of the wide-character string. Upon successful completion, both functions return a pointer to the wide-character code, or a null pointer if <i>wc</i> does not occur in the wide-character string.
windex(), wrindex()	The <code>windex()</code> and <code>wrindex()</code> functions behave the same as <code>wschr()</code> and <code>wsrchr()</code> , respectively.

wcspbrk() , wspbrk()	The <code>wcspbrk()</code> and <code>wspbrk()</code> functions locate the first occurrence in the wide character string pointed to by <code>ws1</code> of any wide-character code from the wide-character string pointed to by <code>ws2</code> . Upon successful completion, the function returns a pointer to the wide-character code, or a null pointer if no wide-character code from <code>ws2</code> occurs in <code>ws1</code> .
wcswcs()	The <code>wcswcs()</code> function locates the first occurrence in the wide-character string pointed to by <code>ws1</code> of the sequence of wide-character codes (excluding the terminating null wide-character code) in the wide-character string pointed to by <code>ws2</code> . Upon successful completion, the function returns a pointer to the located wide-character string, or a null pointer if the wide-character string is not found. If <code>ws2</code> points to a wide-character string with zero length, the function returns <code>ws1</code> .
wcsspn() , wsspnl()	The <code>wcsspn()</code> and <code>wsspnl()</code> functions compute the length of the maximum initial segment of the wide-character string pointed to by <code>ws1</code> which consists entirely of wide-character codes from the wide-character string pointed to by <code>ws2</code> . Both functions return the length <code>ws1</code> ; no return value is reserved to indicate an error.
wcscspn() , wscspn()	The <code>wcscspn()</code> and <code>wscspn()</code> functions compute the length of the maximum initial segment of the wide-character string pointed to by <code>ws1</code> which consists entirely of wide-character codes <i>not</i> from the wide-character string pointed to by <code>ws2</code> . Both functions return the length of the initial substring of <code>ws1</code> ; no return value is reserved to indicate an error.
wcstok() , wstok()	A sequence of calls to the <code>wcstok()</code> and <code>wstok()</code> functions break the wide-character string pointed to by <code>ws1</code> into a sequence of tokens, each of which is delimited by a wide-character code from the wide-character string pointed to by <code>ws2</code> .
Default and other standards	<p>The third argument points to a caller-provided <code>wchar_t</code> pointer into which the <code>wcstok()</code> function stores information necessary for it to continue scanning the same wide-character string. This argument is not available with the XPG4 and SUS versions of <code>wcstok()</code>, nor is it available with the <code>wstok()</code> function. See <code>standards(5)</code>.</p> <p>The first call in the sequence has <code>ws1</code> as its first argument, and is followed by calls with a null pointer as their first argument. The separator string pointed to by <code>ws2</code> may be different from call to call.</p> <p>The first call in the sequence searches the wide-character string pointed to by <code>ws1</code> for the first wide-character code that is <i>not</i> contained in the current separator string pointed to by <code>ws2</code>. If no such wide-character code is found, then there are no tokens in the wide-character string pointed to by <code>ws1</code>, and <code>wcstok()</code> and <code>wstok()</code> return a null pointer. If such a wide-character code is found, it is the start of the first token.</p> <p>The <code>wcstok()</code> and <code>wstok()</code> functions then search from that point for a wide-character code that <i>is</i> contained in the current separator string. If no such wide-character code is found, the current token extends to the end of the wide-character string pointed to by <code>ws1</code>, and subsequent searches for a token will</p>

wscspn(3C)

return a null pointer. If such a wide-character code is found, it is overwritten by a null wide character, which terminates the current token. The `wcstok()` and `wstok()` functions save a pointer to the following wide-character code, from which the next search for a token will start.

Each subsequent call, with a null pointer as the value of the first argument, starts searching from the saved pointer and behaves as described above.

Upon successful completion, both functions return a pointer to the first wide-character code of a token. Otherwise, if there is no token, a null pointer is returned.

NAME	wstring, wscasecmp, wsnccasecmp, wsdup, wscol – Process Code string operations				
SYNOPSIS	<pre>#include <widec.h> int wscasecmp(const wchar_t *s1, const wchar_t *s2); int wsnccasecmp(const wchar_t *s1, const wchar_t *s2, int n); wchar_t *wsdup(const wchar_t *s); int wscol(const wchar_t *s);</pre>				
DESCRIPTION	<p>These functions operate on Process Code strings terminated by <code>wchar_t</code> null characters. During appending or copying, these routines do not check for an overflow condition of the receiving string. In the following, <i>s</i>, <i>s1</i>, and <i>s2</i> point to Process Code strings terminated by a <code>wchar_t</code> null.</p> <p>wscasecmp(), wsnccasecmp() The <code>wscasecmp()</code> function compares its arguments, ignoring case, and returns an integer greater than, equal to, or less than 0, depending upon whether <i>s1</i> is lexicographically greater than, equal to, or less than <i>s2</i>. It makes the same comparison but compares at most <i>n</i> Process Code characters. The four Extended Unix Code (EUC) codesets are ordered from lowest to highest as 0, 2, 3, 1 when characters from different codesets are compared.</p> <p>wsdup() The <code>wsdup()</code> function returns a pointer to a new Process Code string, which is a duplicate of the string pointed to by <i>s</i>. The space for the new string is obtained using <code>malloc(3C)</code>. If the new string cannot be created, a null pointer is returned.</p> <p>wscol() The <code>wscol()</code> function returns the screen display width (in columns) of the Process Code string <i>s</i>.</p>

DESCRIPTION	<p>These functions operate on wide-character strings terminated by <code>wchar_t</code> <code>NULL</code> characters. During appending or copying, these routines do not check for an overflow condition of the receiving string. In the following, <i>ws</i>, <i>ws1</i>, and <i>ws2</i> point to wide-character strings terminated by a <code>wchar_t</code> <code>NULL</code>.</p>
wscat() , wscat()	<p>The <code>wscat()</code> and <code>wscat()</code> functions append a copy of the wide-character string pointed to by <i>ws2</i> (including the terminating null wide-character code) to the end of the wide-character string pointed to by <i>ws1</i>. The initial wide-character code of <i>ws2</i> overwrites the null wide-character code at the end of <i>ws1</i>. If copying takes place between objects that overlap, the behavior is undefined. Both functions return <i>s1</i>; no return value is reserved to indicate an error.</p>
wcsncat() , wsncat()	<p>The <code>wcsncat()</code> and <code>wsncat()</code> functions append not more than <i>n</i> wide-character codes (a null wide-character code and wide-character codes that follow it are not appended) from the array pointed to by <i>ws2</i> to the end of the wide-character string pointed to by <i>ws1</i>. The initial wide-character code of <i>ws2</i> overwrites the null wide-character code at the end of <i>ws1</i>. A terminating null wide-character code is always appended to the result. Both functions return <i>ws1</i>; no return value is reserved to indicate an error.</p>
wscmp() , wscmp()	<p>The <code>wscmp()</code> and <code>wscmp()</code> functions compare the wide-character string pointed to by <i>ws1</i> to the wide-character string pointed to by <i>ws2</i>. The sign of a non-zero return value is determined by the sign of the difference between the values of the first pair of wide-character codes that differ in the objects being compared. Upon completion, both functions return an integer greater than, equal to, or less than zero, if the wide-character string pointed to by <i>ws1</i> is greater than, equal to, or less than the wide-character string pointed to by <i>ws2</i>.</p>

wslen(3C)

wcsncmp(), wsncmp()	The <code>wcsncmp()</code> and <code>wsncmp()</code> functions compare not more than <i>n</i> wide-character codes (wide-character codes that follow a null wide character code are not compared) from the array pointed to by <i>ws1</i> to the array pointed to by <i>ws2</i> . The sign of a non-zero return value is determined by the sign of the difference between the values of the first pair of wide-character codes that differ in the objects being compared. Upon successful completion, both functions return an integer greater than, equal to, or less than zero, if the possibly null-terminated array pointed to by <i>ws1</i> is greater than, equal to, or less than the possibly null-terminated array pointed to by <i>ws2</i> .
wcscpy(), wscpy()	The <code>wcscpy()</code> and <code>wscpy()</code> functions copy the wide-character string pointed to by <i>ws2</i> (including the terminating null wide-character code) into the array pointed to by <i>ws1</i> . If copying takes place between objects that overlap, the behavior is undefined. Both functions return <i>ws1</i> ; no return value is reserved to indicate an error.
wcsncpy(), wsncpy()	The <code>wcsncpy()</code> and <code>wsncpy()</code> functions copy not more than <i>n</i> wide-character codes (wide-character codes that follow a null wide character code are not copied) from the array pointed to by <i>ws2</i> to the array pointed to by <i>ws1</i> . If copying takes place between objects that overlap, the behavior is undefined. If the array pointed to by <i>ws2</i> is a wide-character string that is shorter than <i>n</i> wide-character codes, null wide-character codes are appended to the copy in the array pointed to by <i>ws1</i> , until a total <i>n</i> wide-character codes are written. Both functions return <i>ws1</i> ; no return value is reserved to indicate an error.
wcslen(), wslen()	The <code>wcslen()</code> and <code>wslen()</code> functions compute the number of wide-character codes in the wide-character string to which <i>ws</i> points, not including the terminating null wide-character code. Both functions return <i>ws</i> ; no return value is reserved to indicate an error.
wcschr(), wschr()	The <code>wcschr()</code> and <code>wschr()</code> functions locate the first occurrence of <i>wc</i> in the wide-character string pointed to by <i>ws</i> . The value of <i>wc</i> must be a character representable as a type <code>wchar_t</code> and must be a wide-character code corresponding to a valid character in the current locale. The terminating null wide-character code is considered to be part of the wide-character string. Upon completion, both functions return a pointer to the wide-character code, or a null pointer if the wide-character code is not found.
wcsrchr(), wsrchr()	The <code>wcsrchr()</code> and <code>wsrchr()</code> functions locate the last occurrence of <i>wc</i> in the wide-character string pointed to by <i>ws</i> . The value of <i>wc</i> must be a character representable as a type <code>wchar_t</code> and must be a wide-character code corresponding to a valid character in the current locale. The terminating null wide-character code is considered to be part of the wide-character string. Upon successful completion, both functions return a pointer to the wide-character code, or a null pointer if <i>wc</i> does not occur in the wide-character string.
windex(), wrindex()	The <code>windex()</code> and <code>wrindex()</code> functions behave the same as <code>wschr()</code> and <code>wsrchr()</code> , respectively.

wcspbrk(), wspbrk()	The <code>wcspbrk()</code> and <code>wspbrk()</code> functions locate the first occurrence in the wide character string pointed to by <code>ws1</code> of any wide-character code from the wide-character string pointed to by <code>ws2</code> . Upon successful completion, the function returns a pointer to the wide-character code, or a null pointer if no wide-character code from <code>ws2</code> occurs in <code>ws1</code> .
wcswcs()	The <code>wcswcs()</code> function locates the first occurrence in the wide-character string pointed to by <code>ws1</code> of the sequence of wide-character codes (excluding the terminating null wide-character code) in the wide-character string pointed to by <code>ws2</code> . Upon successful completion, the function returns a pointer to the located wide-character string, or a null pointer if the wide-character string is not found. If <code>ws2</code> points to a wide-character string with zero length, the function returns <code>ws1</code> .
wcsspn(), wsspnl()	The <code>wcsspn()</code> and <code>wsspnl()</code> functions compute the length of the maximum initial segment of the wide-character string pointed to by <code>ws1</code> which consists entirely of wide-character codes from the wide-character string pointed to by <code>ws2</code> . Both functions return the length <code>ws1</code> ; no return value is reserved to indicate an error.
wcscspn(), wscspnl()	The <code>wcscspn()</code> and <code>wscspnl()</code> functions compute the length of the maximum initial segment of the wide-character string pointed to by <code>ws1</code> which consists entirely of wide-character codes <i>not</i> from the wide-character string pointed to by <code>ws2</code> . Both functions return the length of the initial substring of <code>ws1</code> ; no return value is reserved to indicate an error.
wcstok(), wstok()	A sequence of calls to the <code>wcstok()</code> and <code>wstok()</code> functions break the wide-character string pointed to by <code>ws1</code> into a sequence of tokens, each of which is delimited by a wide-character code from the wide-character string pointed to by <code>ws2</code> .
Default and other standards	<p>The third argument points to a caller-provided <code>wchar_t</code> pointer into which the <code>wcstok()</code> function stores information necessary for it to continue scanning the same wide-character string. This argument is not available with the XPG4 and SUS versions of <code>wcstok()</code>, nor is it available with the <code>wstok()</code> function. See <code>standards(5)</code>.</p> <p>The first call in the sequence has <code>ws1</code> as its first argument, and is followed by calls with a null pointer as their first argument. The separator string pointed to by <code>ws2</code> may be different from call to call.</p> <p>The first call in the sequence searches the wide-character string pointed to by <code>ws1</code> for the first wide-character code that is <i>not</i> contained in the current separator string pointed to by <code>ws2</code>. If no such wide-character code is found, then there are no tokens in the wide-character string pointed to by <code>ws1</code>, and <code>wcstok()</code> and <code>wstok()</code> return a null pointer. If such a wide-character code is found, it is the start of the first token.</p> <p>The <code>wcstok()</code> and <code>wstok()</code> functions then search from that point for a wide-character code that <i>is</i> contained in the current separator string. If no such wide-character code is found, the current token extends to the end of the wide-character string pointed to by <code>ws1</code>, and subsequent searches for a token will</p>

wslen(3C)

return a null pointer. If such a wide-character code is found, it is overwritten by a null wide character, which terminates the current token. The `wcstok()` and `wstok()` functions save a pointer to the following wide-character code, from which the next search for a token will start.

Each subsequent call, with a null pointer as the value of the first argument, starts searching from the saved pointer and behaves as described above.

Upon successful completion, both functions return a pointer to the first wide-character code of a token. Otherwise, if there is no token, a null pointer is returned.

NAME	wstring, wscasecmp, wscasecmp, wsdup, wscol – Process Code string operations				
SYNOPSIS	<pre>#include <wchar.h> int wscasecmp(const wchar_t *s1, const wchar_t *s2); int wscasecmp(const wchar_t *s1, const wchar_t *s2, int n); wchar_t *wsdup(const wchar_t *s); int wscol(const wchar_t *s);</pre>				
DESCRIPTION	<p>These functions operate on Process Code strings terminated by <code>wchar_t</code> null characters. During appending or copying, these routines do not check for an overflow condition of the receiving string. In the following, <i>s</i>, <i>s1</i>, and <i>s2</i> point to Process Code strings terminated by a <code>wchar_t</code> null.</p> <p>wscasecmp(), wscasecmp() The <code>wscasecmp()</code> function compares its arguments, ignoring case, and returns an integer greater than, equal to, or less than 0, depending upon whether <i>s1</i> is lexicographically greater than, equal to, or less than <i>s2</i>. It makes the same comparison but compares at most <i>n</i> Process Code characters. The four Extended Unix Code (EUC) codesets are ordered from lowest to highest as 0, 2, 3, 1 when characters from different codesets are compared.</p> <p>wsdup() The <code>wsdup()</code> function returns a pointer to a new Process Code string, which is a duplicate of the string pointed to by <i>s</i>. The space for the new string is obtained using <code>malloc(3C)</code>. If the new string cannot be created, a null pointer is returned.</p> <p>wscol() The <code>wscol()</code> function returns the screen display width (in columns) of the Process Code string <i>s</i>.</p>

	<pre> size_t wscspn(const wchar_t *ws1, const wchar_t *ws2); wchar_t *wstok(wchar_t *ws1, const wchar_t *ws2); wchar_t *windex(const wchar_t *ws, wchar_t wc); wchar_t *wrindex(const wchar_t *ws, wchar_t wc); </pre>
ISO C++	<pre> #include <wchar.h> const wchar_t *wcschr(const wchar_t *ws, wchar_t wc); const wchar_t *wcspbrk(const wchar_t *ws1, const wchar_t *ws2); const wchar_t *wcsrchr(const wchar_t *ws, wchar_t wc); #include <cwchar> wchar_t *std::wcschr(wchar_t *ws, wchar_t wc); wchar_t *std::wcspbrk(wchar_t *ws1, const wchar_t *ws2); wchar_t *std::wcsrchr(wchar_t *ws, wchar_t wc); </pre>
DESCRIPTION	<p>These functions operate on wide-character strings terminated by <code>wchar_t</code> <code>NULL</code> characters. During appending or copying, these routines do not check for an overflow condition of the receiving string. In the following, <i>ws</i>, <i>ws1</i>, and <i>ws2</i> point to wide-character strings terminated by a <code>wchar_t</code> <code>NULL</code>.</p>
wscat() , wscat()	<p>The <code>wscat()</code> and <code>wscat()</code> functions append a copy of the wide-character string pointed to by <i>ws2</i> (including the terminating null wide-character code) to the end of the wide-character string pointed to by <i>ws1</i>. The initial wide-character code of <i>ws2</i> overwrites the null wide-character code at the end of <i>ws1</i>. If copying takes place between objects that overlap, the behavior is undefined. Both functions return <i>s1</i>; no return value is reserved to indicate an error.</p>
wcsncat() , wsncat()	<p>The <code>wcsncat()</code> and <code>wsncat()</code> functions append not more than <i>n</i> wide-character codes (a null wide-character code and wide-character codes that follow it are not appended) from the array pointed to by <i>ws2</i> to the end of the wide-character string pointed to by <i>ws1</i>. The initial wide-character code of <i>ws2</i> overwrites the null wide-character code at the end of <i>ws1</i>. A terminating null wide-character code is always appended to the result. Both functions return <i>ws1</i>; no return value is reserved to indicate an error.</p>
wscmp() , wscmp()	<p>The <code>wscmp()</code> and <code>wscmp()</code> functions compare the wide-character string pointed to by <i>ws1</i> to the wide-character string pointed to by <i>ws2</i>. The sign of a non-zero return value is determined by the sign of the difference between the values of the first pair of wide-character codes that differ in the objects being compared. Upon completion, both functions return an integer greater than, equal to, or less than zero, if the wide-character string pointed to by <i>ws1</i> is greater than, equal to, or less than the wide-character string pointed to by <i>ws2</i>.</p>

wsncat(3C)

wcsncmp() , wsncmp()	The <code>wcsncmp()</code> and <code>wsncmp()</code> functions compare not more than <i>n</i> wide-character codes (wide-character codes that follow a null wide character code are not compared) from the array pointed to by <i>ws1</i> to the array pointed to by <i>ws2</i> . The sign of a non-zero return value is determined by the sign of the difference between the values of the first pair of wide-character codes that differ in the objects being compared. Upon successful completion, both functions return an integer greater than, equal to, or less than zero, if the possibly null-terminated array pointed to by <i>ws1</i> is greater than, equal to, or less than the possibly null-terminated array pointed to by <i>ws2</i> .
wcscpy() , wscpy()	The <code>wcscpy()</code> and <code>wscpy()</code> functions copy the wide-character string pointed to by <i>ws2</i> (including the terminating null wide-character code) into the array pointed to by <i>ws1</i> . If copying takes place between objects that overlap, the behavior is undefined. Both functions return <i>ws1</i> ; no return value is reserved to indicate an error.
wcsncpy() , wsncpy()	The <code>wcsncpy()</code> and <code>wsncpy()</code> functions copy not more than <i>n</i> wide-character codes (wide-character codes that follow a null wide character code are not copied) from the array pointed to by <i>ws2</i> to the array pointed to by <i>ws1</i> . If copying takes place between objects that overlap, the behavior is undefined. If the array pointed to by <i>ws2</i> is a wide-character string that is shorter than <i>n</i> wide-character codes, null wide-character codes are appended to the copy in the array pointed to by <i>ws1</i> , until a total <i>n</i> wide-character codes are written. Both functions return <i>ws1</i> ; no return value is reserved to indicate an error.
wcslen() , wslen()	The <code>wcslen()</code> and <code>wslen()</code> functions compute the number of wide-character codes in the wide-character string to which <i>ws</i> points, not including the terminating null wide-character code. Both functions return <i>ws</i> ; no return value is reserved to indicate an error.
wcschr() , wschr()	The <code>wcschr()</code> and <code>wschr()</code> functions locate the first occurrence of <i>wc</i> in the wide-character string pointed to by <i>ws</i> . The value of <i>wc</i> must be a character representable as a type <code>wchar_t</code> and must be a wide-character code corresponding to a valid character in the current locale. The terminating null wide-character code is considered to be part of the wide-character string. Upon completion, both functions return a pointer to the wide-character code, or a null pointer if the wide-character code is not found.
wcsrchr() , wsrchr()	The <code>wcsrchr()</code> and <code>wsrchr()</code> functions locate the last occurrence of <i>wc</i> in the wide-character string pointed to by <i>ws</i> . The value of <i>wc</i> must be a character representable as a type <code>wchar_t</code> and must be a wide-character code corresponding to a valid character in the current locale. The terminating null wide-character code is considered to be part of the wide-character string. Upon successful completion, both functions return a pointer to the wide-character code, or a null pointer if <i>wc</i> does not occur in the wide-character string.
windex() , wrindex()	The <code>windex()</code> and <code>wrindex()</code> functions behave the same as <code>wschr()</code> and <code>wsrchr()</code> , respectively.

wcspbrk() , wspbrk()	The <code>wcspbrk()</code> and <code>wspbrk()</code> functions locate the first occurrence in the wide character string pointed to by <code>ws1</code> of any wide-character code from the wide-character string pointed to by <code>ws2</code> . Upon successful completion, the function returns a pointer to the wide-character code, or a null pointer if no wide-character code from <code>ws2</code> occurs in <code>ws1</code> .
wcswcs()	The <code>wcswcs()</code> function locates the first occurrence in the wide-character string pointed to by <code>ws1</code> of the sequence of wide-character codes (excluding the terminating null wide-character code) in the wide-character string pointed to by <code>ws2</code> . Upon successful completion, the function returns a pointer to the located wide-character string, or a null pointer if the wide-character string is not found. If <code>ws2</code> points to a wide-character string with zero length, the function returns <code>ws1</code> .
wcsspn() , wsspnl()	The <code>wcsspn()</code> and <code>wsspnl()</code> functions compute the length of the maximum initial segment of the wide-character string pointed to by <code>ws1</code> which consists entirely of wide-character codes from the wide-character string pointed to by <code>ws2</code> . Both functions return the length <code>ws1</code> ; no return value is reserved to indicate an error.
wcscspnl() , wscspnl()	The <code>wcscspnl()</code> and <code>wscspnl()</code> functions compute the length of the maximum initial segment of the wide-character string pointed to by <code>ws1</code> which consists entirely of wide-character codes <i>not</i> from the wide-character string pointed to by <code>ws2</code> . Both functions return the length of the initial substring of <code>ws1</code> ; no return value is reserved to indicate an error.
wcstok() , wstok()	A sequence of calls to the <code>wcstok()</code> and <code>wstok()</code> functions break the wide-character string pointed to by <code>ws1</code> into a sequence of tokens, each of which is delimited by a wide-character code from the wide-character string pointed to by <code>ws2</code> .
Default and other standards	<p>The third argument points to a caller-provided <code>wchar_t</code> pointer into which the <code>wcstok()</code> function stores information necessary for it to continue scanning the same wide-character string. This argument is not available with the XPG4 and SUS versions of <code>wcstok()</code>, nor is it available with the <code>wstok()</code> function. See <code>standards(5)</code>.</p> <p>The first call in the sequence has <code>ws1</code> as its first argument, and is followed by calls with a null pointer as their first argument. The separator string pointed to by <code>ws2</code> may be different from call to call.</p> <p>The first call in the sequence searches the wide-character string pointed to by <code>ws1</code> for the first wide-character code that is <i>not</i> contained in the current separator string pointed to by <code>ws2</code>. If no such wide-character code is found, then there are no tokens in the wide-character string pointed to by <code>ws1</code>, and <code>wcstok()</code> and <code>wstok()</code> return a null pointer. If such a wide-character code is found, it is the start of the first token.</p> <p>The <code>wcstok()</code> and <code>wstok()</code> functions then search from that point for a wide-character code that <i>is</i> contained in the current separator string. If no such wide-character code is found, the current token extends to the end of the wide-character string pointed to by <code>ws1</code>, and subsequent searches for a token will</p>

wsnecat(3C)

return a null pointer. If such a wide-character code is found, it is overwritten by a null wide character, which terminates the current token. The `wcstok()` and `wstok()` functions save a pointer to the following wide-character code, from which the next search for a token will start.

Each subsequent call, with a null pointer as the value of the first argument, starts searching from the saved pointer and behaves as described above.

Upon successful completion, both functions return a pointer to the first wide-character code of a token. Otherwise, if there is no token, a null pointer is returned.

wscat(), wscat()	<p>The <code>wscat()</code> and <code>wscat()</code> functions append a copy of the wide-character string pointed to by <i>ws2</i> (including the terminating null wide-character code) to the end of the wide-character string pointed to by <i>ws1</i>. The initial wide-character code of <i>ws2</i> overwrites the null wide-character code at the end of <i>ws1</i>. If copying takes place between objects that overlap, the behavior is undefined. Both functions return <i>s1</i>; no return value is reserved to indicate an error.</p>
wcsncat(), wsncat()	<p>The <code>wcsncat()</code> and <code>wsncat()</code> functions append not more than <i>n</i> wide-character codes (a null wide-character code and wide-character codes that follow it are not appended) from the array pointed to by <i>ws2</i> to the end of the wide-character string pointed to by <i>ws1</i>. The initial wide-character code of <i>ws2</i> overwrites the null wide-character code at the end of <i>ws1</i>. A terminating null wide-character code is always appended to the result. Both functions return <i>ws1</i>; no return value is reserved to indicate an error.</p>
wscmp(), wscmp()	<p>The <code>wscmp()</code> and <code>wscmp()</code> functions compare the wide-character string pointed to by <i>ws1</i> to the wide-character string pointed to by <i>ws2</i>. The sign of a non-zero return value is determined by the sign of the difference between the values of the first pair of wide-character codes that differ in the objects being compared. Upon completion, both functions return an integer greater than, equal to, or less than zero, if the wide-character string pointed to by <i>ws1</i> is greater than, equal to, or less than the wide-character string pointed to by <i>ws2</i>.</p>

wcsncmp() , wscnmp()	The <code>wcsncmp()</code> and <code>wscnmp()</code> functions compare not more than <i>n</i> wide-character codes (wide-character codes that follow a null wide character code are not compared) from the array pointed to by <i>ws1</i> to the array pointed to by <i>ws2</i> . The sign of a non-zero return value is determined by the sign of the difference between the values of the first pair of wide-character codes that differ in the objects being compared. Upon successful completion, both functions return an integer greater than, equal to, or less than zero, if the possibly null-terminated array pointed to by <i>ws1</i> is greater than, equal to, or less than the possibly null-terminated array pointed to by <i>ws2</i> .
wscpy() , wscopy()	The <code>wscopy()</code> and <code>wscpy()</code> functions copy the wide-character string pointed to by <i>ws2</i> (including the terminating null wide-character code) into the array pointed to by <i>ws1</i> . If copying takes place between objects that overlap, the behavior is undefined. Both functions return <i>ws1</i> ; no return value is reserved to indicate an error.
wcsncpy() , wscncpy()	The <code>wscncpy()</code> and <code>wcsncpy()</code> functions copy not more than <i>n</i> wide-character codes (wide-character codes that follow a null wide character code are not copied) from the array pointed to by <i>ws2</i> to the array pointed to by <i>ws1</i> . If copying takes place between objects that overlap, the behavior is undefined. If the array pointed to by <i>ws2</i> is a wide-character string that is shorter than <i>n</i> wide-character codes, null wide-character codes are appended to the copy in the array pointed to by <i>ws1</i> , until a total <i>n</i> wide-character codes are written. Both functions return <i>ws1</i> ; no return value is reserved to indicate an error.
wcslen() , wslen()	The <code>wcslen()</code> and <code>wslen()</code> functions compute the number of wide-character codes in the wide-character string to which <i>ws</i> points, not including the terminating null wide-character code. Both functions return <i>ws</i> ; no return value is reserved to indicate an error.
wcschr() , wchr()	The <code>wcschr()</code> and <code>wchr()</code> functions locate the first occurrence of <i>wc</i> in the wide-character string pointed to by <i>ws</i> . The value of <i>wc</i> must be a character representable as a type <code>wchar_t</code> and must be a wide-character code corresponding to a valid character in the current locale. The terminating null wide-character code is considered to be part of the wide-character string. Upon completion, both functions return a pointer to the wide-character code, or a null pointer if the wide-character code is not found.
wcsrchr() , wsrchr()	The <code>wcsrchr()</code> and <code>wsrchr()</code> functions locate the last occurrence of <i>wc</i> in the wide-character string pointed to by <i>ws</i> . The value of <i>wc</i> must be a character representable as a type <code>wchar_t</code> and must be a wide-character code corresponding to a valid character in the current locale. The terminating null wide-character code is considered to be part of the wide-character string. Upon successful completion, both functions return a pointer to the wide-character code, or a null pointer if <i>wc</i> does not occur in the wide-character string.
windex() , wrindex()	The <code>windex()</code> and <code>wrindex()</code> functions behave the same as <code>wchr()</code> and <code>wsrchr()</code> , respectively.

wsncmp(3C)

wcspbrk() , wspbrk()	The <code>wcspbrk()</code> and <code>wspbrk()</code> functions locate the first occurrence in the wide character string pointed to by <code>ws1</code> of any wide-character code from the wide-character string pointed to by <code>ws2</code> . Upon successful completion, the function returns a pointer to the wide-character code, or a null pointer if no wide-character code from <code>ws2</code> occurs in <code>ws1</code> .
wcswcs()	The <code>wcswcs()</code> function locates the first occurrence in the wide-character string pointed to by <code>ws1</code> of the sequence of wide-character codes (excluding the terminating null wide-character code) in the wide-character string pointed to by <code>ws2</code> . Upon successful completion, the function returns a pointer to the located wide-character string, or a null pointer if the wide-character string is not found. If <code>ws2</code> points to a wide-character string with zero length, the function returns <code>ws1</code> .
wcsspn() , wsspnl()	The <code>wcsspn()</code> and <code>wsspnl()</code> functions compute the length of the maximum initial segment of the wide-character string pointed to by <code>ws1</code> which consists entirely of wide-character codes from the wide-character string pointed to by <code>ws2</code> . Both functions return the length <code>ws1</code> ; no return value is reserved to indicate an error.
wcscspn() , wscspnl()	The <code>wcscspn()</code> and <code>wscspnl()</code> functions compute the length of the maximum initial segment of the wide-character string pointed to by <code>ws1</code> which consists entirely of wide-character codes <i>not</i> from the wide-character string pointed to by <code>ws2</code> . Both functions return the length of the initial substring of <code>ws1</code> ; no return value is reserved to indicate an error.
wcstok() , wstok()	A sequence of calls to the <code>wcstok()</code> and <code>wstok()</code> functions break the wide-character string pointed to by <code>ws1</code> into a sequence of tokens, each of which is delimited by a wide-character code from the wide-character string pointed to by <code>ws2</code> .
Default and other standards	<p>The third argument points to a caller-provided <code>wchar_t</code> pointer into which the <code>wcstok()</code> function stores information necessary for it to continue scanning the same wide-character string. This argument is not available with the XPG4 and SUS versions of <code>wcstok()</code>, nor is it available with the <code>wstok()</code> function. See <code>standards(5)</code>.</p> <p>The first call in the sequence has <code>ws1</code> as its first argument, and is followed by calls with a null pointer as their first argument. The separator string pointed to by <code>ws2</code> may be different from call to call.</p> <p>The first call in the sequence searches the wide-character string pointed to by <code>ws1</code> for the first wide-character code that is <i>not</i> contained in the current separator string pointed to by <code>ws2</code>. If no such wide-character code is found, then there are no tokens in the wide-character string pointed to by <code>ws1</code>, and <code>wcstok()</code> and <code>wstok()</code> return a null pointer. If such a wide-character code is found, it is the start of the first token.</p> <p>The <code>wcstok()</code> and <code>wstok()</code> functions then search from that point for a wide-character code that <i>is</i> contained in the current separator string. If no such wide-character code is found, the current token extends to the end of the wide-character string pointed to by <code>ws1</code>, and subsequent searches for a token will</p>

return a null pointer. If such a wide-character code is found, it is overwritten by a null wide character, which terminates the current token. The `wcstok()` and `wstok()` functions save a pointer to the following wide-character code, from which the next search for a token will start.

Each subsequent call, with a null pointer as the value of the first argument, starts searching from the saved pointer and behaves as described above.

Upon successful completion, both functions return a pointer to the first wide-character code of a token. Otherwise, if there is no token, a null pointer is returned.

	<pre> size_t wscspn(const wchar_t *ws1, const wchar_t *ws2); wchar_t *wstok(wchar_t *ws1, const wchar_t *ws2); wchar_t *windex(const wchar_t *ws, wchar_t wc); wchar_t *wrindex(const wchar_t *ws, wchar_t wc); </pre>
ISO C++	<pre> #include <wchar.h> const wchar_t *wcschr(const wchar_t *ws, wchar_t wc); const wchar_t *wcspbrk(const wchar_t *ws1, const wchar_t *ws2); const wchar_t *wcsrchr(const wchar_t *ws, wchar_t wc); #include <cwchar> wchar_t *std::wcschr(wchar_t *ws, wchar_t wc); wchar_t *std::wcspbrk(wchar_t *ws1, const wchar_t *ws2); wchar_t *std::wcsrchr(wchar_t *ws, wchar_t wc); </pre>
DESCRIPTION	<p>These functions operate on wide-character strings terminated by <code>wchar_t NULL</code> characters. During appending or copying, these routines do not check for an overflow condition of the receiving string. In the following, <i>ws</i>, <i>ws1</i>, and <i>ws2</i> point to wide-character strings terminated by a <code>wchar_t NULL</code>.</p>
wscat(), wscat()	<p>The <code>wscat()</code> and <code>wscat()</code> functions append a copy of the wide-character string pointed to by <i>ws2</i> (including the terminating null wide-character code) to the end of the wide-character string pointed to by <i>ws1</i>. The initial wide-character code of <i>ws2</i> overwrites the null wide-character code at the end of <i>ws1</i>. If copying takes place between objects that overlap, the behavior is undefined. Both functions return <i>s1</i>; no return value is reserved to indicate an error.</p>
wcsncat(), wsncat()	<p>The <code>wcsncat()</code> and <code>wsncat()</code> functions append not more than <i>n</i> wide-character codes (a null wide-character code and wide-character codes that follow it are not appended) from the array pointed to by <i>ws2</i> to the end of the wide-character string pointed to by <i>ws1</i>. The initial wide-character code of <i>ws2</i> overwrites the null wide-character code at the end of <i>ws1</i>. A terminating null wide-character code is always appended to the result. Both functions return <i>ws1</i>; no return value is reserved to indicate an error.</p>
wscmp(), wscmp()	<p>The <code>wscmp()</code> and <code>wscmp()</code> functions compare the wide-character string pointed to by <i>ws1</i> to the wide-character string pointed to by <i>ws2</i>. The sign of a non-zero return value is determined by the sign of the difference between the values of the first pair of wide-character codes that differ in the objects being compared. Upon completion, both functions return an integer greater than, equal to, or less than zero, if the wide-character string pointed to by <i>ws1</i> is greater than, equal to, or less than the wide-character string pointed to by <i>ws2</i>.</p>

wcscpy(3C)

wcsncmp(), wsncmp()	The <code>wcsncmp()</code> and <code>wsncmp()</code> functions compare not more than <i>n</i> wide-character codes (wide-character codes that follow a null wide character code are not compared) from the array pointed to by <i>ws1</i> to the array pointed to by <i>ws2</i> . The sign of a non-zero return value is determined by the sign of the difference between the values of the first pair of wide-character codes that differ in the objects being compared. Upon successful completion, both functions return an integer greater than, equal to, or less than zero, if the possibly null-terminated array pointed to by <i>ws1</i> is greater than, equal to, or less than the possibly null-terminated array pointed to by <i>ws2</i> .
wcscpy(), wscopy()	The <code>wcscpy()</code> and <code>wscopy()</code> functions copy the wide-character string pointed to by <i>ws2</i> (including the terminating null wide-character code) into the array pointed to by <i>ws1</i> . If copying takes place between objects that overlap, the behavior is undefined. Both functions return <i>ws1</i> ; no return value is reserved to indicate an error.
wcsncpy(), wsncpy()	The <code>wcsncpy()</code> and <code>wsncpy()</code> functions copy not more than <i>n</i> wide-character codes (wide-character codes that follow a null wide character code are not copied) from the array pointed to by <i>ws2</i> to the array pointed to by <i>ws1</i> . If copying takes place between objects that overlap, the behavior is undefined. If the array pointed to by <i>ws2</i> is a wide-character string that is shorter than <i>n</i> wide-character codes, null wide-character codes are appended to the copy in the array pointed to by <i>ws1</i> , until a total <i>n</i> wide-character codes are written. Both functions return <i>ws1</i> ; no return value is reserved to indicate an error.
wcslen(), wslen()	The <code>wcslen()</code> and <code>wslen()</code> functions compute the number of wide-character codes in the wide-character string to which <i>ws</i> points, not including the terminating null wide-character code. Both functions return <i>ws</i> ; no return value is reserved to indicate an error.
wcschr(), wschr()	The <code>wcschr()</code> and <code>wschr()</code> functions locate the first occurrence of <i>wc</i> in the wide-character string pointed to by <i>ws</i> . The value of <i>wc</i> must be a character representable as a type <code>wchar_t</code> and must be a wide-character code corresponding to a valid character in the current locale. The terminating null wide-character code is considered to be part of the wide-character string. Upon completion, both functions return a pointer to the wide-character code, or a null pointer if the wide-character code is not found.
wcsrchr(), wsrchr()	The <code>wcsrchr()</code> and <code>wsrchr()</code> functions locate the last occurrence of <i>wc</i> in the wide-character string pointed to by <i>ws</i> . The value of <i>wc</i> must be a character representable as a type <code>wchar_t</code> and must be a wide-character code corresponding to a valid character in the current locale. The terminating null wide-character code is considered to be part of the wide-character string. Upon successful completion, both functions return a pointer to the wide-character code, or a null pointer if <i>wc</i> does not occur in the wide-character string.
windex(), wrindex()	The <code>windex()</code> and <code>wrindex()</code> functions behave the same as <code>wschr()</code> and <code>wsrchr()</code> , respectively.

wcspbrk() , wspbrk()	The <code>wcspbrk()</code> and <code>wspbrk()</code> functions locate the first occurrence in the wide character string pointed to by <code>ws1</code> of any wide-character code from the wide-character string pointed to by <code>ws2</code> . Upon successful completion, the function returns a pointer to the wide-character code, or a null pointer if no wide-character code from <code>ws2</code> occurs in <code>ws1</code> .
wcswcs()	The <code>wcswcs()</code> function locates the first occurrence in the wide-character string pointed to by <code>ws1</code> of the sequence of wide-character codes (excluding the terminating null wide-character code) in the wide-character string pointed to by <code>ws2</code> . Upon successful completion, the function returns a pointer to the located wide-character string, or a null pointer if the wide-character string is not found. If <code>ws2</code> points to a wide-character string with zero length, the function returns <code>ws1</code> .
wcsspn() , wsspnl()	The <code>wcsspn()</code> and <code>wsspnl()</code> functions compute the length of the maximum initial segment of the wide-character string pointed to by <code>ws1</code> which consists entirely of wide-character codes from the wide-character string pointed to by <code>ws2</code> . Both functions return the length <code>ws1</code> ; no return value is reserved to indicate an error.
wcscspn() , wscspnl()	The <code>wcscspn()</code> and <code>wscspnl()</code> functions compute the length of the maximum initial segment of the wide-character string pointed to by <code>ws1</code> which consists entirely of wide-character codes <i>not</i> from the wide-character string pointed to by <code>ws2</code> . Both functions return the length of the initial substring of <code>ws1</code> ; no return value is reserved to indicate an error.
wcstok() , wstok()	A sequence of calls to the <code>wcstok()</code> and <code>wstok()</code> functions break the wide-character string pointed to by <code>ws1</code> into a sequence of tokens, each of which is delimited by a wide-character code from the wide-character string pointed to by <code>ws2</code> .
Default and other standards	<p>The third argument points to a caller-provided <code>wchar_t</code> pointer into which the <code>wcstok()</code> function stores information necessary for it to continue scanning the same wide-character string. This argument is not available with the XPG4 and SUS versions of <code>wcstok()</code>, nor is it available with the <code>wstok()</code> function. See <code>standards(5)</code>.</p> <p>The first call in the sequence has <code>ws1</code> as its first argument, and is followed by calls with a null pointer as their first argument. The separator string pointed to by <code>ws2</code> may be different from call to call.</p> <p>The first call in the sequence searches the wide-character string pointed to by <code>ws1</code> for the first wide-character code that is <i>not</i> contained in the current separator string pointed to by <code>ws2</code>. If no such wide-character code is found, then there are no tokens in the wide-character string pointed to by <code>ws1</code>, and <code>wcstok()</code> and <code>wstok()</code> return a null pointer. If such a wide-character code is found, it is the start of the first token.</p> <p>The <code>wcstok()</code> and <code>wstok()</code> functions then search from that point for a wide-character code that <i>is</i> contained in the current separator string. If no such wide-character code is found, the current token extends to the end of the wide-character string pointed to by <code>ws1</code>, and subsequent searches for a token will</p>

wsncpy(3C)

return a null pointer. If such a wide-character code is found, it is overwritten by a null wide character, which terminates the current token. The `wcstok()` and `wstok()` functions save a pointer to the following wide-character code, from which the next search for a token will start.

Each subsequent call, with a null pointer as the value of the first argument, starts searching from the saved pointer and behaves as described above.

Upon successful completion, both functions return a pointer to the first wide-character code of a token. Otherwise, if there is no token, a null pointer is returned.

The initial wide-character code of <i>ws2</i> overwrites the null wide-character code at the end of <i>ws1</i>. If copying takes place between objects that overlap, the behavior is undefined. Both functions return <i>s1</i>; no return value is reserved to indicate an error.</p>
wcsncat(), wsncat()	<p>The <code>wcsncat()</code> and <code>wsncat()</code> functions append not more than <i>n</i> wide-character codes (a null wide-character code and wide-character codes that follow it are not appended) from the array pointed to by <i>ws2</i> to the end of the wide-character string pointed to by <i>ws1</i>. The initial wide-character code of <i>ws2</i> overwrites the null wide-character code at the end of <i>ws1</i>. A terminating null wide-character code is always appended to the result. Both functions return <i>ws1</i>; no return value is reserved to indicate an error.</p>
wscmp(), wscmp()	<p>The <code>wscmp()</code> and <code>wscmp()</code> functions compare the wide-character string pointed to by <i>ws1</i> to the wide-character string pointed to by <i>ws2</i>. The sign of a non-zero return value is determined by the sign of the difference between the values of the first pair of wide-character codes that differ in the objects being compared. Upon completion, both functions return an integer greater than, equal to, or less than zero, if the wide-character string pointed to by <i>ws1</i> is greater than, equal to, or less than the wide-character string pointed to by <i>ws2</i>.</p>

wcsncmp() , wsncmp()	The <code>wcsncmp()</code> and <code>wsncmp()</code> functions compare not more than <i>n</i> wide-character codes (wide-character codes that follow a null wide character code are not compared) from the array pointed to by <i>ws1</i> to the array pointed to by <i>ws2</i> . The sign of a non-zero return value is determined by the sign of the difference between the values of the first pair of wide-character codes that differ in the objects being compared. Upon successful completion, both functions return an integer greater than, equal to, or less than zero, if the possibly null-terminated array pointed to by <i>ws1</i> is greater than, equal to, or less than the possibly null-terminated array pointed to by <i>ws2</i> .
wcscpy() , wscpy()	The <code>wcscpy()</code> and <code>wscpy()</code> functions copy the wide-character string pointed to by <i>ws2</i> (including the terminating null wide-character code) into the array pointed to by <i>ws1</i> . If copying takes place between objects that overlap, the behavior is undefined. Both functions return <i>ws1</i> ; no return value is reserved to indicate an error.
wcsncpy() , wsncpy()	The <code>wcsncpy()</code> and <code>wsncpy()</code> functions copy not more than <i>n</i> wide-character codes (wide-character codes that follow a null wide character code are not copied) from the array pointed to by <i>ws2</i> to the array pointed to by <i>ws1</i> . If copying takes place between objects that overlap, the behavior is undefined. If the array pointed to by <i>ws2</i> is a wide-character string that is shorter than <i>n</i> wide-character codes, null wide-character codes are appended to the copy in the array pointed to by <i>ws1</i> , until a total <i>n</i> wide-character codes are written. Both functions return <i>ws1</i> ; no return value is reserved to indicate an error.
wcslen() , wslen()	The <code>wcslen()</code> and <code>wslen()</code> functions compute the number of wide-character codes in the wide-character string to which <i>ws</i> points, not including the terminating null wide-character code. Both functions return <i>ws</i> ; no return value is reserved to indicate an error.
wcschr() , wschr()	The <code>wcschr()</code> and <code>wschr()</code> functions locate the first occurrence of <i>wc</i> in the wide-character string pointed to by <i>ws</i> . The value of <i>wc</i> must be a character representable as a type <code>wchar_t</code> and must be a wide-character code corresponding to a valid character in the current locale. The terminating null wide-character code is considered to be part of the wide-character string. Upon completion, both functions return a pointer to the wide-character code, or a null pointer if the wide-character code is not found.
wcsrchr() , wsrchr()	The <code>wcsrchr()</code> and <code>wsrchr()</code> functions locate the last occurrence of <i>wc</i> in the wide-character string pointed to by <i>ws</i> . The value of <i>wc</i> must be a character representable as a type <code>wchar_t</code> and must be a wide-character code corresponding to a valid character in the current locale. The terminating null wide-character code is considered to be part of the wide-character string. Upon successful completion, both functions return a pointer to the wide-character code, or a null pointer if <i>wc</i> does not occur in the wide-character string.
windex() , wrindex()	The <code>windex()</code> and <code>wrindex()</code> functions behave the same as <code>wschr()</code> and <code>wsrchr()</code> , respectively.

wspbrk(3C)

wcspbrk(), wspbrk()	The <code>wcspbrk()</code> and <code>wspbrk()</code> functions locate the first occurrence in the wide character string pointed to by <code>ws1</code> of any wide-character code from the wide-character string pointed to by <code>ws2</code> . Upon successful completion, the function returns a pointer to the wide-character code, or a null pointer if no wide-character code from <code>ws2</code> occurs in <code>ws1</code> .
wcswcs()	The <code>wcswcs()</code> function locates the first occurrence in the wide-character string pointed to by <code>ws1</code> of the sequence of wide-character codes (excluding the terminating null wide-character code) in the wide-character string pointed to by <code>ws2</code> . Upon successful completion, the function returns a pointer to the located wide-character string, or a null pointer if the wide-character string is not found. If <code>ws2</code> points to a wide-character string with zero length, the function returns <code>ws1</code> .
wcsspn(), wsspnl()	The <code>wcsspn()</code> and <code>wsspnl()</code> functions compute the length of the maximum initial segment of the wide-character string pointed to by <code>ws1</code> which consists entirely of wide-character codes from the wide-character string pointed to by <code>ws2</code> . Both functions return the length <code>ws1</code> ; no return value is reserved to indicate an error.
wcscspn(), wscspnl()	The <code>wcscspn()</code> and <code>wscspnl()</code> functions compute the length of the maximum initial segment of the wide-character string pointed to by <code>ws1</code> which consists entirely of wide-character codes <i>not</i> from the wide-character string pointed to by <code>ws2</code> . Both functions return the length of the initial substring of <code>ws1</code> ; no return value is reserved to indicate an error.
wcstok(), wstok()	A sequence of calls to the <code>wcstok()</code> and <code>wstok()</code> functions break the wide-character string pointed to by <code>ws1</code> into a sequence of tokens, each of which is delimited by a wide-character code from the wide-character string pointed to by <code>ws2</code> .
Default and other standards	<p>The third argument points to a caller-provided <code>wchar_t</code> pointer into which the <code>wcstok()</code> function stores information necessary for it to continue scanning the same wide-character string. This argument is not available with the XPG4 and SUS versions of <code>wcstok()</code>, nor is it available with the <code>wstok()</code> function. See <code>standards(5)</code>.</p> <p>The first call in the sequence has <code>ws1</code> as its first argument, and is followed by calls with a null pointer as their first argument. The separator string pointed to by <code>ws2</code> may be different from call to call.</p> <p>The first call in the sequence searches the wide-character string pointed to by <code>ws1</code> for the first wide-character code that is <i>not</i> contained in the current separator string pointed to by <code>ws2</code>. If no such wide-character code is found, then there are no tokens in the wide-character string pointed to by <code>ws1</code>, and <code>wcstok()</code> and <code>wstok()</code> return a null pointer. If such a wide-character code is found, it is the start of the first token.</p> <p>The <code>wcstok()</code> and <code>wstok()</code> functions then search from that point for a wide-character code that <i>is</i> contained in the current separator string. If no such wide-character code is found, the current token extends to the end of the wide-character string pointed to by <code>ws1</code>, and subsequent searches for a token will</p>

wspbrk(3C)

return a null pointer. If such a wide-character code is found, it is overwritten by a null wide character, which terminates the current token. The `wcstok()` and `wstok()` functions save a pointer to the following wide-character code, from which the next search for a token will start.

Each subsequent call, with a null pointer as the value of the first argument, starts searching from the saved pointer and behaves as described above.

Upon successful completion, both functions return a pointer to the first wide-character code of a token. Otherwise, if there is no token, a null pointer is returned.

wsprintf(3C)

NAME	wsprintf – formatted output conversion				
SYNOPSIS	<pre>#include <stdio.h> #include <wchar.h> int wsprintf(wchar_t *s, const char *format, /* arg */ ...);</pre>				
DESCRIPTION	<p>The <code>wsprintf()</code> function outputs a Process Code string ending with a Process Code (<code>wchar_t</code>) null character. It is the user's responsibility to allocate enough space for this <code>wchar_t</code> string.</p> <p>This returns the number of Process Code characters (excluding the null terminator) that have been written. The conversion specifications and behavior of <code>wsprintf()</code> are the same as the regular <code>sprintf(3C)</code> function except that the result is a Process Code string for <code>wsprintf()</code>, and on Extended Unix Code (EUC) character string for <code>sprintf()</code>.</p>				
RETURN VALUES	Upon successful completion, <code>wsprintf()</code> returns the number of characters printed. Otherwise, a negative value is returned.				
ATTRIBUTES	See <code>attributes(5)</code> for descriptions of the following attributes:

wsrchr(3C)

	<pre> size_t wscspn(const wchar_t *ws1, const wchar_t *ws2); wchar_t *wstok(wchar_t *ws1, const wchar_t *ws2); wchar_t *windex(const wchar_t *ws, wchar_t wc); wchar_t *wrindex(const wchar_t *ws, wchar_t wc); </pre>
ISO C++	<pre> #include <wchar.h> const wchar_t *wcschr(const wchar_t *ws, wchar_t wc); const wchar_t *wcspbrk(const wchar_t *ws1, const wchar_t *ws2); const wchar_t *wcsrchr(const wchar_t *ws, wchar_t wc); #include <cwchar> wchar_t *std::wcschr(wchar_t *ws, wchar_t wc); wchar_t *std::wcspbrk(wchar_t *ws1, const wchar_t *ws2); wchar_t *std::wcsrchr(wchar_t *ws, wchar_t wc); </pre>
DESCRIPTION	<p>These functions operate on wide-character strings terminated by <code>wchar_t NULL</code> characters. During appending or copying, these routines do not check for an overflow condition of the receiving string. In the following, <i>ws</i>, <i>ws1</i>, and <i>ws2</i> point to wide-character strings terminated by a <code>wchar_t NULL</code>.</p>
wscat(), wscat()	<p>The <code>wscat()</code> and <code>wscat()</code> functions append a copy of the wide-character string pointed to by <i>ws2</i> (including the terminating null wide-character code) to the end of the wide-character string pointed to by <i>ws1</i>. The initial wide-character code of <i>ws2</i> overwrites the null wide-character code at the end of <i>ws1</i>. If copying takes place between objects that overlap, the behavior is undefined. Both functions return <i>s1</i>; no return value is reserved to indicate an error.</p>
wcsncat(), wsncat()	<p>The <code>wcsncat()</code> and <code>wsncat()</code> functions append not more than <i>n</i> wide-character codes (a null wide-character code and wide-character codes that follow it are not appended) from the array pointed to by <i>ws2</i> to the end of the wide-character string pointed to by <i>ws1</i>. The initial wide-character code of <i>ws2</i> overwrites the null wide-character code at the end of <i>ws1</i>. A terminating null wide-character code is always appended to the result. Both functions return <i>ws1</i>; no return value is reserved to indicate an error.</p>
wscmp(), wscmp()	<p>The <code>wscmp()</code> and <code>wscmp()</code> functions compare the wide-character string pointed to by <i>ws1</i> to the wide-character string pointed to by <i>ws2</i>. The sign of a non-zero return value is determined by the sign of the difference between the values of the first pair of wide-character codes that differ in the objects being compared. Upon completion, both functions return an integer greater than, equal to, or less than zero, if the wide-character string pointed to by <i>ws1</i> is greater than, equal to, or less than the wide-character string pointed to by <i>ws2</i>.</p>

wcsncmp() , wsncmp()	The <code>wcsncmp()</code> and <code>wsncmp()</code> functions compare not more than <i>n</i> wide-character codes (wide-character codes that follow a null wide character code are not compared) from the array pointed to by <i>ws1</i> to the array pointed to by <i>ws2</i> . The sign of a non-zero return value is determined by the sign of the difference between the values of the first pair of wide-character codes that differ in the objects being compared. Upon successful completion, both functions return an integer greater than, equal to, or less than zero, if the possibly null-terminated array pointed to by <i>ws1</i> is greater than, equal to, or less than the possibly null-terminated array pointed to by <i>ws2</i> .
wscpy() , wscopy()	The <code>wscpy()</code> and <code>wscopy()</code> functions copy the wide-character string pointed to by <i>ws2</i> (including the terminating null wide-character code) into the array pointed to by <i>ws1</i> . If copying takes place between objects that overlap, the behavior is undefined. Both functions return <i>ws1</i> ; no return value is reserved to indicate an error.
wcsncpy() , wsncpy()	The <code>wcsncpy()</code> and <code>wsncpy()</code> functions copy not more than <i>n</i> wide-character codes (wide-character codes that follow a null wide character code are not copied) from the array pointed to by <i>ws2</i> to the array pointed to by <i>ws1</i> . If copying takes place between objects that overlap, the behavior is undefined. If the array pointed to by <i>ws2</i> is a wide-character string that is shorter than <i>n</i> wide-character codes, null wide-character codes are appended to the copy in the array pointed to by <i>ws1</i> , until a total <i>n</i> wide-character codes are written. Both functions return <i>ws1</i> ; no return value is reserved to indicate an error.
wcslen() , wslen()	The <code>wcslen()</code> and <code>wslen()</code> functions compute the number of wide-character codes in the wide-character string to which <i>ws</i> points, not including the terminating null wide-character code. Both functions return <i>ws</i> ; no return value is reserved to indicate an error.
wcschr() , wschr()	The <code>wcschr()</code> and <code>wschr()</code> functions locate the first occurrence of <i>wc</i> in the wide-character string pointed to by <i>ws</i> . The value of <i>wc</i> must be a character representable as a type <code>wchar_t</code> and must be a wide-character code corresponding to a valid character in the current locale. The terminating null wide-character code is considered to be part of the wide-character string. Upon completion, both functions return a pointer to the wide-character code, or a null pointer if the wide-character code is not found.
wcsrchr() , wsrcchr()	The <code>wcsrchr()</code> and <code>wsrcchr()</code> functions locate the last occurrence of <i>wc</i> in the wide-character string pointed to by <i>ws</i> . The value of <i>wc</i> must be a character representable as a type <code>wchar_t</code> and must be a wide-character code corresponding to a valid character in the current locale. The terminating null wide-character code is considered to be part of the wide-character string. Upon successful completion, both functions return a pointer to the wide-character code, or a null pointer if <i>wc</i> does not occur in the wide-character string.
windex() , wrindex()	The <code>windex()</code> and <code>wrindex()</code> functions behave the same as <code>wschr()</code> and <code>wsrcchr()</code> , respectively.

wsrchr(3C)

wcspbrk() , wspbrk()	The <code>wcspbrk()</code> and <code>wspbrk()</code> functions locate the first occurrence in the wide character string pointed to by <code>ws1</code> of any wide-character code from the wide-character string pointed to by <code>ws2</code> . Upon successful completion, the function returns a pointer to the wide-character code, or a null pointer if no wide-character code from <code>ws2</code> occurs in <code>ws1</code> .
wcswcs()	The <code>wcswcs()</code> function locates the first occurrence in the wide-character string pointed to by <code>ws1</code> of the sequence of wide-character codes (excluding the terminating null wide-character code) in the wide-character string pointed to by <code>ws2</code> . Upon successful completion, the function returns a pointer to the located wide-character string, or a null pointer if the wide-character string is not found. If <code>ws2</code> points to a wide-character string with zero length, the function returns <code>ws1</code> .
wcsspn() , wsspnl()	The <code>wcsspn()</code> and <code>wsspnl()</code> functions compute the length of the maximum initial segment of the wide-character string pointed to by <code>ws1</code> which consists entirely of wide-character codes from the wide-character string pointed to by <code>ws2</code> . Both functions return the length <code>ws1</code> ; no return value is reserved to indicate an error.
wcscspn() , wscspnl()	The <code>wcscspn()</code> and <code>wscspnl()</code> functions compute the length of the maximum initial segment of the wide-character string pointed to by <code>ws1</code> which consists entirely of wide-character codes <i>not</i> from the wide-character string pointed to by <code>ws2</code> . Both functions return the length of the initial substring of <code>ws1</code> ; no return value is reserved to indicate an error.
wcstok() , wstok()	A sequence of calls to the <code>wcstok()</code> and <code>wstok()</code> functions break the wide-character string pointed to by <code>ws1</code> into a sequence of tokens, each of which is delimited by a wide-character code from the wide-character string pointed to by <code>ws2</code> .
Default and other standards	<p>The third argument points to a caller-provided <code>wchar_t</code> pointer into which the <code>wcstok()</code> function stores information necessary for it to continue scanning the same wide-character string. This argument is not available with the XPG4 and SUS versions of <code>wcstok()</code>, nor is it available with the <code>wstok()</code> function. See <code>standards(5)</code>.</p> <p>The first call in the sequence has <code>ws1</code> as its first argument, and is followed by calls with a null pointer as their first argument. The separator string pointed to by <code>ws2</code> may be different from call to call.</p> <p>The first call in the sequence searches the wide-character string pointed to by <code>ws1</code> for the first wide-character code that is <i>not</i> contained in the current separator string pointed to by <code>ws2</code>. If no such wide-character code is found, then there are no tokens in the wide-character string pointed to by <code>ws1</code>, and <code>wcstok()</code> and <code>wstok()</code> return a null pointer. If such a wide-character code is found, it is the start of the first token.</p> <p>The <code>wcstok()</code> and <code>wstok()</code> functions then search from that point for a wide-character code that <i>is</i> contained in the current separator string. If no such wide-character code is found, the current token extends to the end of the wide-character string pointed to by <code>ws1</code>, and subsequent searches for a token will</p>

wsrchr(3C)

return a null pointer. If such a wide-character code is found, it is overwritten by a null wide character, which terminates the current token. The `wcstok()` and `wstok()` functions save a pointer to the following wide-character code, from which the next search for a token will start.

Each subsequent call, with a null pointer as the value of the first argument, starts searching from the saved pointer and behaves as described above.

Upon successful completion, both functions return a pointer to the first wide-character code of a token. Otherwise, if there is no token, a null pointer is returned.

wsscanf(3C)

NAME	wsscanf – formatted input conversion				
SYNOPSIS	<pre>#include<stdio.h> #include <wchar.h> int wsscanf(wchar_t *s, const char *format, /* pointer */ ...);</pre>				
DESCRIPTION	<p>The <code>wsscanf()</code> function reads Process Code characters from the Process Code string <code>s</code>, interprets them according to the <code>format</code>, and stores the results in its arguments. It expects, as arguments, a control string <code>format</code>, and a set of <code>pointer</code> arguments indicating where the converted input should be stored. The results are undefined if there are insufficient <code>args</code> for the format. If the format is exhausted while <code>args</code> remain, the excess <code>args</code> are simply ignored.</p> <p>The conversion specifications and behavior of <code>wsscanf()</code> are the same as the regular <code>sscanf(3C)</code> function except that the source is a Process Code string for <code>wsscanf()</code> and on Extended Unix Code (EUC) character string for <code>sscanf(3C)</code>.</p>				
RETURN VALUES	Upon successful completion, <code>wsscanf()</code> returns the number of characters matched. Otherwise, it returns a negative value.

wcslen() , wslen()	The <code>wcslen()</code> and <code>wslen()</code> functions compute the number of wide-character codes in the wide-character string to which <i>ws</i> points, not including the terminating null wide-character code. Both functions return <i>ws</i> ; no return value is reserved to indicate an error.
wcschr() , wschr()	The <code>wcschr()</code> and <code>wschr()</code> functions locate the first occurrence of <i>wc</i> in the wide-character string pointed to by <i>ws</i> . The value of <i>wc</i> must be a character representable as a type <code>wchar_t</code> and must be a wide-character code corresponding to a valid character in the current locale. The terminating null wide-character code is considered to be part of the wide-character string. Upon completion, both functions return a pointer to the wide-character code, or a null pointer if the wide-character code is not found.
wcsrchr() , wsrchr()	The <code>wcsrchr()</code> and <code>wsrchr()</code> functions locate the last occurrence of <i>wc</i> in the wide-character string pointed to by <i>ws</i> . The value of <i>wc</i> must be a character representable as a type <code>wchar_t</code> and must be a wide-character code corresponding to a valid character in the current locale. The terminating null wide-character code is considered to be part of the wide-character string. Upon successful completion, both functions return a pointer to the wide-character code, or a null pointer if <i>wc</i> does not occur in the wide-character string.
windex() , wrindex()	The <code>windex()</code> and <code>wrindex()</code> functions behave the same as <code>wschr()</code> and <code>wsrchr()</code> , respectively.

wsspn(3C)

wcspbrk() , wspbrk()	The <code>wcspbrk()</code> and <code>wspbrk()</code> functions locate the first occurrence in the wide character string pointed to by <code>ws1</code> of any wide-character code from the wide-character string pointed to by <code>ws2</code> . Upon successful completion, the function returns a pointer to the wide-character code, or a null pointer if no wide-character code from <code>ws2</code> occurs in <code>ws1</code> .
wcswcs()	The <code>wcswcs()</code> function locates the first occurrence in the wide-character string pointed to by <code>ws1</code> of the sequence of wide-character codes (excluding the terminating null wide-character code) in the wide-character string pointed to by <code>ws2</code> . Upon successful completion, the function returns a pointer to the located wide-character string, or a null pointer if the wide-character string is not found. If <code>ws2</code> points to a wide-character string with zero length, the function returns <code>ws1</code> .
wcsspn() , wsspn()	The <code>wcsspn()</code> and <code>wsspn()</code> functions compute the length of the maximum initial segment of the wide-character string pointed to by <code>ws1</code> which consists entirely of wide-character codes from the wide-character string pointed to by <code>ws2</code> . Both functions return the length <code>ws1</code> ; no return value is reserved to indicate an error.
wcscspn() , wscspn()	The <code>wcscspn()</code> and <code>wscspn()</code> functions compute the length of the maximum initial segment of the wide-character string pointed to by <code>ws1</code> which consists entirely of wide-character codes <i>not</i> from the wide-character string pointed to by <code>ws2</code> . Both functions return the length of the initial substring of <code>ws1</code> ; no return value is reserved to indicate an error.
wcstok() , wstok()	A sequence of calls to the <code>wcstok()</code> and <code>wstok()</code> functions break the wide-character string pointed to by <code>ws1</code> into a sequence of tokens, each of which is delimited by a wide-character code from the wide-character string pointed to by <code>ws2</code> .
Default and other standards	<p>The third argument points to a caller-provided <code>wchar_t</code> pointer into which the <code>wcstok()</code> function stores information necessary for it to continue scanning the same wide-character string. This argument is not available with the XPG4 and SUS versions of <code>wcstok()</code>, nor is it available with the <code>wstok()</code> function. See <code>standards(5)</code>.</p> <p>The first call in the sequence has <code>ws1</code> as its first argument, and is followed by calls with a null pointer as their first argument. The separator string pointed to by <code>ws2</code> may be different from call to call.</p> <p>The first call in the sequence searches the wide-character string pointed to by <code>ws1</code> for the first wide-character code that is <i>not</i> contained in the current separator string pointed to by <code>ws2</code>. If no such wide-character code is found, then there are no tokens in the wide-character string pointed to by <code>ws1</code>, and <code>wcstok()</code> and <code>wstok()</code> return a null pointer. If such a wide-character code is found, it is the start of the first token.</p> <p>The <code>wcstok()</code> and <code>wstok()</code> functions then search from that point for a wide-character code that <i>is</i> contained in the current separator string. If no such wide-character code is found, the current token extends to the end of the wide-character string pointed to by <code>ws1</code>, and subsequent searches for a token will</p>

wsspn(3C)

return a null pointer. If such a wide-character code is found, it is overwritten by a null wide character, which terminates the current token. The `wcstok()` and `wstok()` functions save a pointer to the following wide-character code, from which the next search for a token will start.

Each subsequent call, with a null pointer as the value of the first argument, starts searching from the saved pointer and behaves as described above.

Upon successful completion, both functions return a pointer to the first wide-character code of a token. Otherwise, if there is no token, a null pointer is returned.

wstod(3C)

NAME	<code>wcstod</code> , <code>wstod</code> , <code>watof</code> – convert wide character string to double-precision number
SYNOPSIS	<pre>#include <wchar.h> double wcstod(const wchar_t *nptr, wchar_t **endptr); double wstod(const wchar_t *nptr, wchar_t **endptr); double watof(wchar_t *nptr);</pre>
DESCRIPTION	<p>The <code>wcstod()</code> and <code>wstod()</code> functions convert the initial portion of the wide character string pointed to by <code>nptr</code> to double representation. They first decompose the input wide character string into three parts: an initial, possibly empty, sequence of white-space wide character codes (as specified by <code>iswspace(3C)</code>); a subject sequence interpreted as a floating-point constant; and a final wide-character string of one or more unrecognised wide-character codes, including the terminating null wide character code of the input wide character string. They then attempt to convert the subject sequence to a floating-point number, and return the result.</p> <p>The expected form of the subject sequence is an optional '+' or '-' sign, then a non-empty sequence of digits optionally containing a radix, then an optional exponent part. An exponent part consists of 'e' or 'E', followed by an optional sign, followed by one or more decimal digits. The subject sequence is defined as the longest initial subsequence of the input wide character string, starting with the first non-white-space wide-character code, that is of the expected form. The subject sequence contains no wide-character codes if the input wide character string is empty or consists entirely of white-space wide-character codes, or if the first wide-character code that is not white space other than a sign, a digit or a radix.</p> <p>If the subject sequence has the expected form, the sequence of wide-character codes starting with the first digit or the radix (whichever occurs first) is interpreted as a floating constant as defined in the C language, except that the radix is used in place of a period, and that if neither an exponent part nor a radix appears, a radix is assumed to follow the last digit in the wide character string. If the subject sequence begins with a minus sign (-), the value resulting from the conversion is negated. A pointer to the final wide character string is stored in the object pointed to by <code>endptr</code>, provided that <code>endptr</code> is not a null pointer.</p> <p>The radix is defined in the program's locale (category <code>LC_NUMERIC</code>). In the POSIX locale, or in a locale where the radix is not defined, the radix defaults to a period (.).</p> <p>In other than the POSIX locale, other implementation-dependent subject sequence forms may be accepted.</p> <p>If the subject sequence is empty or does not have the expected form, no conversion is performed; the value of <code>nptr</code> is stored in the object pointed to by <code>endptr</code>, provided that <code>endptr</code> is not a null pointer.</p> <p>The <code>watof(str)</code> function is equivalent to <code>wstod(str, (wchar_t **)NULL)</code>.</p>

RETURN VALUES The `wcstod()` and `wstod()` functions return the converted value, if any. If no conversion could be performed, 0 is returned and `errno` may be set to `EINVAL`.

If the correct value is outside the range of representable values, `±HUGE_VAL` is returned (according to the sign of the value), and `errno` is set to `ERANGE`.

If the correct value would cause underflow, 0 is returned, and `errno` is set to `ERANGE`.

ERRORS The `wcstod()` and `wstod()` functions will fail if:

`ERANGE` The value to be returned would cause overflow or underflow.

The `wcstod()` and `wcstod()` functions may fail if:

`EINVAL` No conversion could be performed.

USAGE Because 0 is returned on error and is also a valid return on success, an application wishing to check for error situations should set `errno` to 0 call `wcstod()` or `wstod()`, then check `errno` and if it is non-zero, assume an error has occurred.

ISO C++	<pre> #include <wchar.h> const wchar_t *wcschr(const wchar_t *ws, wchar_t wc); const wchar_t *wcspbrk(const wchar_t *ws1, const wchar_t *ws2); const wchar_t *wcsrchr(const wchar_t *ws, wchar_t wc); #include <cwchar> wchar_t *std::wcschr(wchar_t *ws, wchar_t wc); wchar_t *std::wcspbrk(wchar_t *ws1, const wchar_t *ws2); wchar_t *std::wcsrchr(wchar_t *ws, wchar_t wc); </pre>
DESCRIPTION	<p>These functions operate on wide-character strings terminated by <code>wchar_t</code> NULL characters. During appending or copying, these routines do not check for an overflow condition of the receiving string. In the following, <i>ws</i>, <i>ws1</i>, and <i>ws2</i> point to wide-character strings terminated by a <code>wchar_t</code> NULL.</p>
wscat(), wscat()	<p>The <code>wscat()</code> and <code>wscat()</code> functions append a copy of the wide-character string pointed to by <i>ws2</i> (including the terminating null wide-character code) to the end of the wide-character string pointed to by <i>ws1</i>. The initial wide-character code of <i>ws2</i> overwrites the null wide-character code at the end of <i>ws1</i>. If copying takes place between objects that overlap, the behavior is undefined. Both functions return <i>s1</i>; no return value is reserved to indicate an error.</p>
wcsncat(), wsncat()	<p>The <code>wcsncat()</code> and <code>wsncat()</code> functions append not more than <i>n</i> wide-character codes (a null wide-character code and wide-character codes that follow it are not appended) from the array pointed to by <i>ws2</i> to the end of the wide-character string pointed to by <i>ws1</i>. The initial wide-character code of <i>ws2</i> overwrites the null wide-character code at the end of <i>ws1</i>. A terminating null wide-character code is always appended to the result. Both functions return <i>ws1</i>; no return value is reserved to indicate an error.</p>
wscmp(), wscmp()	<p>The <code>wscmp()</code> and <code>wscmp()</code> functions compare the wide-character string pointed to by <i>ws1</i> to the wide-character string pointed to by <i>ws2</i>. The sign of a non-zero return value is determined by the sign of the difference between the values of the first pair of wide-character codes that differ in the objects being compared. Upon completion, both functions return an integer greater than, equal to, or less than zero, if the wide-character string pointed to by <i>ws1</i> is greater than, equal to, or less than the wide-character string pointed to by <i>ws2</i>.</p>

wstok(3C)

wcsncmp() , wsncmp()	The <code>wcsncmp()</code> and <code>wsncmp()</code> functions compare not more than <i>n</i> wide-character codes (wide-character codes that follow a null wide character code are not compared) from the array pointed to by <i>ws1</i> to the array pointed to by <i>ws2</i> . The sign of a non-zero return value is determined by the sign of the difference between the values of the first pair of wide-character codes that differ in the objects being compared. Upon successful completion, both functions return an integer greater than, equal to, or less than zero, if the possibly null-terminated array pointed to by <i>ws1</i> is greater than, equal to, or less than the possibly null-terminated array pointed to by <i>ws2</i> .
wcscpy() , wscpy()	The <code>wcscpy()</code> and <code>wscpy()</code> functions copy the wide-character string pointed to by <i>ws2</i> (including the terminating null wide-character code) into the array pointed to by <i>ws1</i> . If copying takes place between objects that overlap, the behavior is undefined. Both functions return <i>ws1</i> ; no return value is reserved to indicate an error.
wcsncpy() , wsncpy()	The <code>wcsncpy()</code> and <code>wsncpy()</code> functions copy not more than <i>n</i> wide-character codes (wide-character codes that follow a null wide character code are not copied) from the array pointed to by <i>ws2</i> to the array pointed to by <i>ws1</i> . If copying takes place between objects that overlap, the behavior is undefined. If the array pointed to by <i>ws2</i> is a wide-character string that is shorter than <i>n</i> wide-character codes, null wide-character codes are appended to the copy in the array pointed to by <i>ws1</i> , until a total <i>n</i> wide-character codes are written. Both functions return <i>ws1</i> ; no return value is reserved to indicate an error.
wcslen() , wslen()	The <code>wcslen()</code> and <code>wslen()</code> functions compute the number of wide-character codes in the wide-character string to which <i>ws</i> points, not including the terminating null wide-character code. Both functions return <i>ws</i> ; no return value is reserved to indicate an error.
wcschr() , wschr()	The <code>wcschr()</code> and <code>wschr()</code> functions locate the first occurrence of <i>wc</i> in the wide-character string pointed to by <i>ws</i> . The value of <i>wc</i> must be a character representable as a type <code>wchar_t</code> and must be a wide-character code corresponding to a valid character in the current locale. The terminating null wide-character code is considered to be part of the wide-character string. Upon completion, both functions return a pointer to the wide-character code, or a null pointer if the wide-character code is not found.
wcsrchr() , wsrchr()	The <code>wcsrchr()</code> and <code>wsrchr()</code> functions locate the last occurrence of <i>wc</i> in the wide-character string pointed to by <i>ws</i> . The value of <i>wc</i> must be a character representable as a type <code>wchar_t</code> and must be a wide-character code corresponding to a valid character in the current locale. The terminating null wide-character code is considered to be part of the wide-character string. Upon successful completion, both functions return a pointer to the wide-character code, or a null pointer if <i>wc</i> does not occur in the wide-character string.
windex() , wrindex()	The <code>windex()</code> and <code>wrindex()</code> functions behave the same as <code>wschr()</code> and <code>wsrchr()</code> , respectively.

wcspbrk(), wspbrk()	The <code>wcspbrk()</code> and <code>wspbrk()</code> functions locate the first occurrence in the wide character string pointed to by <code>ws1</code> of any wide-character code from the wide-character string pointed to by <code>ws2</code> . Upon successful completion, the function returns a pointer to the wide-character code, or a null pointer if no wide-character code from <code>ws2</code> occurs in <code>ws1</code> .
wcswcs()	The <code>wcswcs()</code> function locates the first occurrence in the wide-character string pointed to by <code>ws1</code> of the sequence of wide-character codes (excluding the terminating null wide-character code) in the wide-character string pointed to by <code>ws2</code> . Upon successful completion, the function returns a pointer to the located wide-character string, or a null pointer if the wide-character string is not found. If <code>ws2</code> points to a wide-character string with zero length, the function returns <code>ws1</code> .
wcsspn(), wsspn()	The <code>wcsspn()</code> and <code>wsspn()</code> functions compute the length of the maximum initial segment of the wide-character string pointed to by <code>ws1</code> which consists entirely of wide-character codes from the wide-character string pointed to by <code>ws2</code> . Both functions return the length <code>ws1</code> ; no return value is reserved to indicate an error.
wcscspn(), wscspn()	The <code>wcscspn()</code> and <code>wscspn()</code> functions compute the length of the maximum initial segment of the wide-character string pointed to by <code>ws1</code> which consists entirely of wide-character codes <i>not</i> from the wide-character string pointed to by <code>ws2</code> . Both functions return the length of the initial substring of <code>ws1</code> ; no return value is reserved to indicate an error.
wcstok(), wstok()	A sequence of calls to the <code>wcstok()</code> and <code>wstok()</code> functions break the wide-character string pointed to by <code>ws1</code> into a sequence of tokens, each of which is delimited by a wide-character code from the wide-character string pointed to by <code>ws2</code> .
Default and other standards	<p>The third argument points to a caller-provided <code>wchar_t</code> pointer into which the <code>wcstok()</code> function stores information necessary for it to continue scanning the same wide-character string. This argument is not available with the XPG4 and SUS versions of <code>wcstok()</code>, nor is it available with the <code>wstok()</code> function. See <code>standards(5)</code>.</p> <p>The first call in the sequence has <code>ws1</code> as its first argument, and is followed by calls with a null pointer as their first argument. The separator string pointed to by <code>ws2</code> may be different from call to call.</p> <p>The first call in the sequence searches the wide-character string pointed to by <code>ws1</code> for the first wide-character code that is <i>not</i> contained in the current separator string pointed to by <code>ws2</code>. If no such wide-character code is found, then there are no tokens in the wide-character string pointed to by <code>ws1</code>, and <code>wcstok()</code> and <code>wstok()</code> return a null pointer. If such a wide-character code is found, it is the start of the first token.</p> <p>The <code>wcstok()</code> and <code>wstok()</code> functions then search from that point for a wide-character code that <i>is</i> contained in the current separator string. If no such wide-character code is found, the current token extends to the end of the wide-character string pointed to by <code>ws1</code>, and subsequent searches for a token will</p>

wstok(3C)

return a null pointer. If such a wide-character code is found, it is overwritten by a null wide character, which terminates the current token. The `wcstok()` and `wstok()` functions save a pointer to the following wide-character code, from which the next search for a token will start.

Each subsequent call, with a null pointer as the value of the first argument, starts searching from the saved pointer and behaves as described above.

Upon successful completion, both functions return a pointer to the first wide-character code of a token. Otherwise, if there is no token, a null pointer is returned.

NAME	wcstol, wstol, watol, watoll, watoi – convert wide character string to long integer
SYNOPSIS	<pre>#include <wchar.h> long int wcstol(const wchar_t *nptr, wchar_t **endptr, int base); #include <widec.h> long int wstol(const wchar_t *nptr, wchar_t **endptr, int base); long watol(wchar_t *nptr); long long watoll(wchar_t *nptr); int watoi(wchar_t *nptr);</pre>
DESCRIPTION	<p>The <code>wcstol()</code> and <code>wstol()</code> functions convert the initial portion of the wide character string pointed to by <code>nptr</code> to long int representation. They first decompose the input wide character string into three parts: an initial, possibly empty, sequence of white-space wide-character codes (as specified by <code>iswspace(3C)</code>), a subject sequence interpreted as an integer represented in some radix determined by the value of <code>base</code>; and a final wide character string of one or more unrecognised wide character codes, including the terminating null wide-character code of the input wide character string. They then attempt to convert the subject sequence to an integer, and return the result.</p> <p>If the value of <code>base</code> is 0, the expected form of the subject sequence is that of a decimal constant, octal constant or hexadecimal constant, any of which may be preceded by a '+' or '-' sign. A decimal constant begins with a non-zero digit, and consists of a sequence of decimal digits. An octal constant consists of the prefix '0' optionally followed by a sequence of the digits '0' to '7' only. A hexadecimal constant consists of the prefix '0x' or '0X' followed by a sequence of the decimal digits and letters 'a' (or 'A') to 'f' (or 'F') with values 10 to 15 respectively.</p> <p>If the value of <code>base</code> is between 2 and 36, the expected form of the subject sequence is a sequence of letters and digits representing an integer with the radix specified by <code>base</code>, optionally preceded by a '+' or '-' sign, but not including an integer suffix. The letters from 'a' (or 'A') to 'z' (or 'Z') inclusive are ascribed the values 10 to 35; only letters whose ascribed values are less than that of <code>base</code> are permitted. If the value of <code>base</code> is 16, the wide-character code representations of '0x' or '0X' may optionally precede the sequence of letters and digits, following the sign if present.</p> <p>The subject sequence is defined as the longest initial subsequence of the input wide character string, starting with the first non-white-space wide-character code, that is of the expected form. The subject sequence contains no wide-character codes if the input wide character string is empty or consists entirely of white-space wide-character code, or if the first non-white-space wide-character code is other than a sign or a permissible letter or digit.</p> <p>If the subject sequence has the expected form and the value of <code>base</code> is 0, the sequence of wide-character codes starting with the first digit is interpreted as an integer constant. If the subject sequence has the expected form and the value of <code>base</code> is between 2 and 36, it is used as the base for conversion, ascribing to each letter its</p>

wstol(3C)

value as given above. If the subject sequence begins with a minus sign (-), the value resulting from the conversion is negated. A pointer to the final wide character string is stored in the object pointed to by *endptr*, provided that *endptr* is not a null pointer.

In other than the POSIX locale, additional implementation-dependent subject sequence forms may be accepted.

If the subject sequence is empty or does not have the expected form, no conversion is performed; the value of *nptr* is stored in the object pointed to by *endptr*, provided that *endptr* is not a null pointer.

The `watol()` function is equivalent to `wstol(str, (wchar_t **)NULL, 10)`.

The `watoll()` function is the long-long (double long) version of `watol()`.

The `watoi()` function is equivalent to `(int)watol()`.

RETURN VALUES

Upon successful completion, `wcstol()` and `wstol()` return the converted value, if any. If no conversion could be performed, 0 is returned, and `errno` may be set to indicate the error. If the correct value is outside the range of representable values, `{LONG_MAX}` or `{LONG_MIN}` is returned (according to the sign of the value), and `errno` is set to `ERANGE`.

ERRORS

The `wcstol()` and `wstol()` functions will fail if:

`EINVAL` The value of *base* is not supported.

`ERANGE` The value to be returned is not representable.

The `wcstol()` and `wstol()` functions may fail if:

`EINVAL` No conversion could be performed.

ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
MT-Level	MT-Safe

SEE ALSO

`iswalphabet(3C)`, `iswspace(3C)`, `scanf(3C)`, `wcstod(3C)`, `attributes(5)`

NOTES

Because 0, `{LONG_MIN}`, and `{LONG_MAX}` are returned on error and are also valid returns on success, an application wishing to check for error situations should set `errno` to 0, call `wcstol()` or `wstol()`, then check `errno` and if it is non-zero assume an error has occurred.

Truncation from long long to long can take place upon assignment or by an explicit cast.

NAME	strtows, wstostr – code conversion for Process Code and File Code
SYNOPSIS	<pre>#include <wchar.h> wchar_t *strtows(wchar_t *dst, const char *src); char *wstostr(char *dst, const wchar_t *src);</pre>
DESCRIPTION	<p>The <code>strtows()</code> and <code>wstostr()</code> functions convert strings back and forth between File Code representation and Process Code.</p> <p>The <code>strtows()</code> function takes a character string <i>src</i>, converts it to a Process Code string, terminated by a Process Code null, and places the result into <i>dst</i>.</p> <p>The <code>wstostr()</code> function takes the Process Code string pointed to by <i>src</i>, converts it to a character string, and places the result into <i>dst</i>.</p>
RETURN VALUES	<p>The <code>strtows()</code> function returns the Process Code string if it completes successfully. Otherwise, a null pointer will be returned and <code>errno</code> will be set to <code>EILSEQ</code>.</p> <p>The <code>wstostr()</code> function returns the File Code string if it completes successfully. Otherwise, a null pointer will be returned and <code>errno</code> will be set to <code>EILSEQ</code>.</p>
SEE ALSO	wstring(3C)

wstring(3C)

NAME	wstring, wscasecmp, wsnccasecmp, wsdup, wscol – Process Code string operations				
SYNOPSIS	<pre>#include <wchar.h> int wscasecmp(const wchar_t *s1, const wchar_t *s2); int wsnccasecmp(const wchar_t *s1, const wchar_t *s2, int n); wchar_t *wsdup(const wchar_t *s); int wscol(const wchar_t *s);</pre>				
DESCRIPTION	<p>These functions operate on Process Code strings terminated by <code>wchar_t</code> null characters. During appending or copying, these routines do not check for an overflow condition of the receiving string. In the following, <code>s</code>, <code>s1</code>, and <code>s2</code> point to Process Code strings terminated by a <code>wchar_t</code> null.</p> <p>wscasecmp(), wsnccasecmp() The <code>wscasecmp()</code> function compares its arguments, ignoring case, and returns an integer greater than, equal to, or less than 0, depending upon whether <code>s1</code> is lexicographically greater than, equal to, or less than <code>s2</code>. It makes the same comparison but compares at most <code>n</code> Process Code characters. The four Extended Unix Code (EUC) codesets are ordered from lowest to highest as 0, 2, 3, 1 when characters from different codesets are compared.</p> <p>wsdup() The <code>wsdup()</code> function returns a pointer to a new Process Code string, which is a duplicate of the string pointed to by <code>s</code>. The space for the new string is obtained using <code>malloc(3C)</code>. If the new string cannot be created, a null pointer is returned.</p> <p>wscol() The <code>wscol()</code> function returns the screen display width (in columns) of the Process Code string <code>s</code>.</p>

NAME	wcsxfrm, wsxfrm – wide character string transformation				
SYNOPSIS	<pre>#include <wchar.h> size_t wcsxfrm(wchar_t *ws1, const wchar_t *ws2, size_t n); size_t wsxfrm(wchar_t *ws1, const wchar_t *ws2, size_t n);</pre>				
DESCRIPTION	<p>The <code>wcsxfrm()</code> and <code>wsxfrm()</code> functions transform the wide character string pointed to by <code>ws2</code> and place the resulting wide character string into the array pointed to by <code>ws1</code>. The transformation is such that if either the <code>wcscmp(3C)</code> or <code>wscmp(3C)</code> functions are applied to two transformed wide strings, they return a value greater than, equal to, or less than 0, corresponding to the result of the <code>wscoll(3C)</code> or <code>wscoll(3C)</code> function applied to the same two original wide character strings. No more than <code>n</code> wide-character codes are placed into the resulting array pointed to by <code>ws1</code>, including the terminating null wide-character code. If <code>n</code> is 0, <code>ws1</code> is permitted to be a null pointer. If copying takes place between objects that overlap, the behavior is undefined.</p>				
RETURN VALUES	<p>The <code>wcsxfrm()</code> and <code>wsxfrm()</code> functions return the length of the transformed wide character string (not including the terminating null wide-character code). If the value returned is <code>n</code> or more, the contents of the array pointed to by <code>ws1</code> are indeterminate.</p> <p>On error, <code>wcsxfrm()</code> and <code>wsxfrm()</code> return <code>(size_t)-1</code> and set <code>errno</code> to indicate the error.</p>				
ERRORS	<p>The <code>wcsxfrm()</code> and <code>wsxfrm()</code> functions may fail if:</p> <table border="0"> <tr> <td style="padding-right: 20px;">EINVAL</td> <td>The wide character string pointed to by <code>ws2</code> contains wide-character codes outside the domain of the collating sequence.</td> </tr> <tr> <td>ENOSYS</td> <td>The function is not supported.</td> </tr> </table>	EINVAL	The wide character string pointed to by <code>ws2</code> contains wide-character codes outside the domain of the collating sequence.	ENOSYS	The function is not supported.
EINVAL	The wide character string pointed to by <code>ws2</code> contains wide-character codes outside the domain of the collating sequence.				
ENOSYS	The function is not supported.				
USAGE	<p>The transformation function is such that two transformed wide character strings can be ordered by the <code>wcscmp()</code> or <code>wscmp()</code> functions as appropriate to collating sequence information in the program's locale (category <code>LC_COLLATE</code>).</p> <p>The fact that when <code>n</code> is 0, <code>ws1</code> is permitted to be a null pointer, is useful to determine the size of the <code>ws1</code> array prior to making the transformation.</p> <p>Because no return value is reserved to indicate an error, an application wishing to check for error situations should set <code>errno</code> to 0, call <code>wcsxfrm()</code> or <code>wsxfrm()</code>, then check <code>errno</code> and if it is non-zero, assume an error has occurred.</p> <p>The <code>wcsxfrm()</code> and <code>wsxfrm()</code> functions can be used safely in multithreaded applications as long as <code>setlocale(3C)</code> is not being called to change the locale.</p>				
ATTRIBUTES	See <code>attributes(5)</code> for descriptions of the following attributes:				

ATTRIBUTE TYPE	ATTRIBUTE VALUE
----------------	-----------------

wsxfrm(3C)

MT-Level	MT-Safe with exceptions
CSI	Enabled

b

binary output — `fwrite`, 510

Numbers and Symbols

`__fbufsize` — interfaces to `stdio FILE` structure, 306
`__filbf` — interfaces to `stdio FILE` structure, 306
`__fpending` — interfaces to `stdio FILE` structure, 306
`__fpurge` — interfaces to `stdio FILE` structure, 306
`__freadable` — interfaces to `stdio FILE` structure, 306
`__freading` — interfaces to `stdio FILE` structure, 306
`__fsetlocking` — interfaces to `stdio FILE` structure, 306
`__fwritable` — interfaces to `stdio FILE` structure, 306
`__fwriting` — interfaces to `stdio FILE` structure, 306

A

`abort` — terminate the process abnormally, 33
`abs` — return absolute value of integer, 34
accounting, time accounting for current process — `times`, 1553
acquire and release stream lock — `flockfile`, 391
`funlockfile`, 391

additional severities, define — `addsev`, 35
address of symbol, get address in shared object or executable — `dlsym`, 249
`addsev` — define additional severities, 35
`addseverity` — build a list of severity levels for an application for use with `fmtmsg`, 36
alarm, schedule signal after interval in microseconds — `ualarm`, 1586
allocation cache manipulation — `umem_cache_alloc`, 1604
allocation cache manipulation — `umem_cache_create`, 1604
allocation cache manipulation — `umem_cache_destroy`, 1604
allocation cache manipulation — `umem_cache_free`, 1604
`alphasort` — scan a directory, 1194
applications
 build a list of severity levels for use with `fmtmsg` — `addseverity`, 36
 display a message on `stderr` or system console — `fmtmsg`, 395
 get entries from symbol table — `nlist`, 988
arithmetic, compute the quotient and remainder — `div`, 224
arithmetic, 48-bit integer, generate uniformly distributed pseudo-random numbers — `drand48`, 257
`asctime` — convert date and time to string, 1409
`assert` — verify program assertion, 57
associate a stream with a file descriptor — `fdopen`, 324

atexit — register a function to run at process termination or object unloading, 58
atof — convert string to double-precision number, 1471
atoi — string conversion routines, 1482
atol — string conversion routines, 1482
atoll — string conversion routines, 1482
attopen — open a file, 71

B

base-64 ASCII characters
 convert from long integer — l64a, 32
 convert to long integer — a64l, 32
basename — return the last element of path name, 72
bcmp — operates on variable length strings of bytes, 88
bcopy — operates on variable length strings of bytes, 88
binary input — fread, 445
binary search of sorted table, — bsearch, 86
binary search trees, manage
 — tdelete, 1570
 — tfind, 1570
 — tsearch, 1570
 — twalk, 1570
bind_textdomain_codeset — message handling functions, 652
bindtextdomain — message handling functions, 652
bit and byte operations, find first set bit — ffs, 344
bsd_signal — simplified signal facilities, 85
bsdmalloc — memory allocator, 83
bsearch — binary search a sorted table, 86
bstring — bit and byte string operations, 88
btowc — single-byte to wide-character conversion, 89
buffering, assign to stream
 — setbuffer, 1213
 — setlinebuf, 1213
byte swap — swab, 1495
bzero — operates on variable length strings of bytes, 88

C

C Compilation
 close a shared object — dlclose, 229
 create new file from dynamic object component — dldump, 230
 get address of symbol in shared object or executable — dlsym, 249
 get diagnostic information — dlerror, 236
 open a shared object — dlopen, 245
catclose — close a message catalog, 101
catgets — read a program message, 100
catopen — open a message catalog, 101
cfgetispeed — get input baud rate, 104
cfgetospeed — get output baud rate, 104
cfsetispeed — set input baud rate, 109
cfsetospeed — set output baud rate, 109
ctime — convert date and time to string, 1409
character handling
 — ctype, 149
 — isalnum, 149
 — isalpha, 149
 — isascii, 149
 — iscntrl, 149
 — isdigit, 149
 — isgraph, 149
 — islower, 149
 — isprint, 149
 — ispunct, 149
 — isspace, 149
 — isupper, 149
 — isxdigit, 149
clock — report CPU time used, 117
close or iterate over open file descriptors — closefrom, 119
close or iterate over open file descriptors — fdwalk, 119
close a directory stream — closedir, 118
close a shared object — dlclose, 229
close a stream — fclose, 308
closedir — close a directory stream, 118
closefrom — close or iterate over open file descriptors, 119
closelog — control system log, 1522
code conversion allocation function — iconv_open, 744
code conversion deallocation function — iconv_close, 743

- code conversion for Process Code and File Code
 - strtows, 1492
 - wstostr, 1492
- code conversion function — iconv, 738
- column positions of a wide-character code —
 - wcwidth, 1875
- column positions of a wide-character string —
 - wcswidth, 1868
- command options, get option letter from
 - argument vector — getopt, 594
- command suboptions, parse suboptions from a
 - string — getsubopt, 649
- compare wide-characters in memory —
 - wmemcmp, 1894
- compile and execute regular expressions
 - re_comp, 1157
 - re_exec, 1157
- confstr — get configurable variables, 125
- control system log
 - closelog, 1522
 - openlog, 1522
 - setlogmask, 1522
 - syslog, 1522
- convert date and time to string —
 - strftime, 1409
- convert formatted input — fscanf, 1195
- convert formatted input — scanf, 1195
- convert formatted input — sscanf, 1195
- convert formatted input — vfscanf, 1195
- convert formatted input — vscanf, 1195
- convert formatted input — vsscanf, 1195
- convert formatted wide-character input —
 - fwscanf, 513
- convert formatted wide-character input —
 - swscanf, 513
- convert formatted wide-character input —
 - vwscanf, 513
- convert formatted wide-character input —
 - vswscanf, 513
- convert formatted wide-character input —
 - vwsscanf, 513
- convert formatted wide-character input —
 - wscanf, 513
- convert string to unsigned long — strtoul, 1488
- convert wide character string to
 - double-precision number — wcstod, 1846
- convert date and time to string — strftime
 - asctime, 1409
- convert date and time to string — strftime
 - (Continued)
 - cftime, 1409
- convert wide character string to
 - double-precision number — watof,
 - watof, 1846
- convert wide character string to
 - double-precision number — wstod,
 - wstod, 1846
- convert a character string to a wide-character
 - string — mbstowcs, 921
- convert a character string to a wide-character
 - string (restartable) — mbsrtowcs, 919
- convert a character to a wide-character code —
 - mbtowl, 922
- convert a character to a wide-character code
 - (restartable) — mbrtowl, 916
- convert a wide-character code to a character —
 - wctomb, 1872
- convert a wide-character code to a character
 - (restartable) — wcrctomb, 1778
- convert a wide-character string to a character
 - string — wcstombs, 1855
- convert a wide-character string to a character
 - string (restartable) — wcsrtombs, 1838
- convert date and time to wide character string
 - wcsftime, 1807
- convert floating-point number to string
 - ecvt, 262
 - fcvt, 262
 - gcvt, 262
- convert monetary value to string
 - strfmon, 1405
- convert numbers to strings
 - econvert, 260
 - fconvert, 260
 - fprintf, 1017
 - gconvert, 260
 - printf, 1017
 - qconvert, 260
 - qfconvert, 260
 - qgconvert, 260
 - seconvert, 260
 - sfconvert, 260
 - sgconvert, 260
 - sprintf, 1017
 - vfprintf, 1017
 - vprintf, 1017

- convert string to double-precision number
 - `atof`, 1471
 - `strtod`, 1471
- convert to `wchar_t` strings, `wsprintf`, 1980
- convert wide character string to unsigned long
 - `wcstoul`, 1856
- copy wide-characters in memory — `wmemcpy`, 1895
- copy wide-characters in memory with overlapping areas — `wmemmove`, 1896
- CPU time, report for calling process — `clock`, 117
- CPU-use, prepare execution profile — `monitor`, 959
- create a temporary file — `tmpfile`, 1554
- create new file from dynamic object component — `dldump`, 230
- `crypt` — string encoding function, 129
- `cset` — get information on EUC codesets, 133
- `csetcol` — get information on EUC codesets, 133
- `csetlen` — get information on EUC codesets, 133
- `csetno` — get information on EUC codesets, 133
- `ctermid` — generate path name for controlling terminal, 137
- `ctermid_r` — generate path name for controlling terminal, 137
- `ctype` — character handling, 149
- current location of a named directory stream — `telldir`, 1542
- current working directory, get pathname — `getcwd`, 537
- `cuserid` — get character-string representation of login name of user, 152

D

- data base subroutines — `dbm`, 153
 - `dbmclose`, 153
 - `dbmopen`, 153
 - `delete`, 153
 - `fetch`, 153
 - `firstkey`, 153
 - `nextkey`, 153
 - `store`, 153
- database functions — `dbm_clearerr`, 972

- `dbm_store` — database functions, 972
- `dbmclose` — data base subroutines, 153
- `dbmopen` — data base subroutines, 153
- `dcgettext` — message handling functions, 652
- `dcngettext` — message handling functions, 652
- debugging features of the `umem` library — `umem_debug`, 1628
- debugging memory allocator
 - `calloc`, 1767
 - `cfree`, 1767
 - `free`, 1767
 - `mallinfo`, 1767
 - `malloc`, 1767
 - `mallopt`, 1767
 - `memalign`, 1767
 - `realloc`, 1767

debugging memory allocator (Continued)
 — `valloc`, 1767

decimal record from double-precision floating
 — `double_to_decimal`, 387

decimal record from extended-precision floating
 — `extended_to_decimal`, 387

decimal record from quadruple-precision
 floating — `quadruple_to_decimal`, 387

decimal record from single-precision floating —
 `single_to_decimal`, 387

decimal record to double-precision floating —
 `decimal_to_double`, 207

decimal record to extended-precision floating —
 `decimal_to_extended`, 207

decimal record to quadruple-precision floating
 — `decimal_to_quadruple`, 207

decimal record to single-precision floating —
 `decimal_to_single`, 207

`decimal_to_double` — decimal record to
 double-precision floating, 207

`decimal_to_extended` — decimal record to
 extended-precision floating, 207

`decimal_to_quadruple` — decimal record to
 quadruple-precision floating, 207

`decimal_to_single` — decimal record to
 single-precision floating, 207

decompose floating-point number
 — `modf`, 957
 — `modff`, 957

define character class — `wctype`, 1874

define character mapping — `wctrans`, 1873

define default catalog — `setcat`, 1214

define the label for `pfmt()` and `lfmt()`. —
 `setlabel`, 1231

delete — data base subroutines, 153

detach a name from a STREAMS-based file
 descriptor — `fdetach`, 318

determine conversion object status —
 `mbsinit`, 918

determine if address is within stack boundaries
 — `stack_inbounds`, 1364

determine stack boundary violation event —
 `stack_violation`, 1366

device number, manage — `makedev`, major,
 minor, 895

`dgettext` — message handling functions, 652

`difftime` — computes the difference between
 two calendar times, 219

`directio` — provide advice to file system, 220

directories
 get current working directory pathname —
 `getwd`, 704
 get pathname of current working directory
 — `getcwd`, 537

directory operations
 — `alphasort`, 1194
 — `scandir`, 1194

`dirname` — report parent directory name of file
 path name, 222

`display error message in standard format` —
 `pfmt`, 1002

`display error message in standard format and
 pass to logging and monitoring services` —
 `lfmt`, 848

`display error message in standard format and
 pass to logging and monitoring services` —
 `vlfmt`, 1694

`display error message in standard format and
 pass to logging and monitoring services` —
 `vpfmt`, 1696

`div` — compute quotient and remainder, 224

division and remainder operations
 — `div`, 224
 — `ldiv`, 224

`dladdr` — translate address to symbolic
 information, 227

`dladdr1` — translate address to symbolic
 information, 227

`dlclose` — close a shared object, 229

`dldump` — create new file from dynamic object
 component of calling process, 230

`dlerror` — get diagnostic information, 236

`dlinfo` — dynamic load information, 237

`dlopen` — open a shared object, 245

`dlsym` — get address of symbol in shared object
 or executable, 249

`dngettext` — message handling functions, 652

`double_to_decimal` — decimal record from
 double-precision floating, 387

`dup2` — duplicate an open file descriptor, 259

duplicate an open file descriptor — `dup2`, 259

dynamic linking
 close a shared object — `dlclose`, 229
 create new file from dynamic object
 component — `dldump`, 230

dynamic linking (Continued)
 get address of symbol in shared object or
 executable — `dlsym`, 249
 get diagnostic information — `dlderror`, 236
 open a shared object — `dlopen`, 245
dynamic load information — `dldinfo`, 237

E

`econvert` — convert number to ASCII, 260
`edata` — last location in program, 268
`end` — last location in program, 268
`endgrent` — group database entry
 functions, 566
`endpwent` — get password entry from user
 database, 613
`endspent` — get shadow password database
 entry, 641
`endusershell()` — function, 661
`endutent` — user accounting database
 functions, 662
`endutxent` — user accounting database
 functions, 679
environment name, return value — `getenv`, 546
environment variables, change or add value —
 `putenv`, 1042
error messages, get string — `strerror`, 1404
error messages, system, print — `perror`, 1001
`etext` — last location in program, 268
EUC character bytes, — `euclen`, 298
EUC characters, convert a string of Process
 Code characters to EUC characters and put it
 on a stream — `putws`, 1062
EUC codeset, get information, — `getwidth`, 705
EUC codesets, get information
 — `cset`, 133
 — `csetcol`, 133
 — `csetlen`, 133
 — `csetno`, 133
 — `wcsetno`, 133
EUC display width
 — `euccol`, 298
 — `eukscol`, 298
`euccol` — get EUC character display width, 298
`euclen` — get EUC byte length, 298
`eukscol` — get EUC string display width, 298
`exit` — terminate process, 300

express an intention to extend the stack —
 `_stack_grow`, 1363
`extended_to_decimal` — decimal record from
 extended-precision floating, 387
Extended Unix Code
 See EUC
extract mantissa and exponent from double
 precision number — `frexp`, 461

F

fast, scalable memory allocation —
 `umem_alloc`, 1591
fast, scalable memory allocation —
 `umem_free`, 1591
fast, scalable memory allocation —
 `umem_nofail_callback`, 1591
fast, scalable memory allocation —
 `umem_zalloc`, 1591
`fattach` — attach a STREAMS-based file
 descriptor to an object in the file system
 name space, 304
`fclose` — close a stream, 308
`fconvert` — convert number to ASCII, 260
`FD_CLR` — synchronous I/O
 multiplexing, 1207
`FD_ISSET` — synchronous I/O
 multiplexing, 1207
`FD_SET` — synchronous I/O
 multiplexing, 1207
`FD_ZERO` — synchronous I/O
 multiplexing, 1207
`fdetach` — detach a name from a
 STREAMS-based file descriptor, 318
`fdopen` — associate a stream with a file
 descriptor, 324
`fdopendir` — open directory, 993
`fdwalk` — close or iterate over open file
 descriptors, 119
`fetch` — data base subroutines, 153
`fflush` — flush a stream, 342
`ffs` — find first set bit, 344
`fgetc` — get a byte from a stream, 345
`fgetgrent` — group database entry
 functions, 566
`fgetgrent_r` — group database entry
 functions, 566

fgetpos — get current file position information, 356
 fgetpwent — get password entry from a file, 613
 fgetpwent_r — get password entry from a file, 613
 fgetspent — get shadow password database entry, 641
 fgetspent_r — get shadow password database entry(reentrant), 641
 fgetwc — get a wide-character code from a stream, 374
 fgetws — get a wide-character string from a stream, 706
 file descriptor
 duplicate an open one — dup2, 259
 STREAMS-based, attach to an object in file system name space — fattach, 304
 test for a STREAMS file — isastream, 765
 file descriptors, apply or remove advisory lock on open file — flock, 389
 file name, make a unique one — mktemp, 949
 make a unique file name — mkstemp, 948
 file pointer in a stream, reposition — fsetpos, fgetpos, 477
 file_to_decimal — decimal record from character stream, 1418
 file tree
 recursively descend — ftw, 490
 recursively descend — nftw, 490
 files
 allows sections of file to be locked — lockf, 871
 optimizing usage of files — directio, 220
 — remove, 1187
 report parent directory of file path name — dirname, 222
 set a file to a specified length — truncate, 1567
 find a wide-character in memory — wmemchr, 1893
 find a wide-character substring — wcsstr, 1845
 find pathname of a terminal
 — ttyname, 1573
 — ttyname_r, 1573
 firstkey — data base subroutines, 153
 floating-point number, convert to string — ecvt, 262
 floating-point number, determine type
 — finite, 783
 — fpclass, 783
 — isnan, 783
 — isnand, 783
 — isnanf, 783
 — unordered, 783
 flock — apply or remove an advisory lock on an open file, 389
 flockfile — acquire and release stream lock, 391
 flush a stream — fflush, 342
 flush non-transmitted output data, non-read input data or both — tcflush, 1530
 _flushlbf — interfaces to stdio FILE structure, 306
 fmtmsg — display a message on stderr or system console, 395
 fnmatch — match filename or path name, 400
 fopen — open a stream, 402
 fopen — open stream, 405
 formatted input conversion — wscanf, 1986
 formatted output conversion
 — fprintf, 1017
 — printf, 1017
 — sprintf, 1017
 — vfprintf, 1017
 — vprintf, 1017
 — vsprintf, 1017
 fpgetmask — IEEE floating-point environment control, 413
 fpgetround — IEEE floating-point environment control, 413
 fpgetsticky — IEEE floating-point environment control, 413
 fprintf — formatted output conversion, 1017
 fprintf — print formatted output, 1008
 fpsetmask — IEEE floating-point environment control, 413
 fpsetround — IEEE floating-point environment control, 413
 fpsetsticky — IEEE floating-point environment control, 413
 fputc — put a byte on a stream, 438
 fputwc — put wide-character code on a stream, 442
 fputws — put wide character string on a stream, 444
 fread — binary input, 445

free — memory allocator, 83
 freopen — open a stream, 457
 freopen — open stream, 405
 frexp — extract mantissa and exponent from
 double precision number, 461
 fscanf — convert formatted input, 1195
 fseek — reposition a file-position indicator in a
 stream, 469
 fseeko — reposition a file-position indicator in a
 stream, 469
 fsetpos — reposition a file pointer in a
 stream, 477
 fsync — synchronize changes to a file, 478
 ftell — return a file offset in a stream, 480
 ftello — return a file offset in a stream, 480
 ftime — get date and time, 482
 ftruncate — set a file to a specified length, 1567
 ftw — walk a file tree, 490
 func_to_decimal — decimal record from
 character function, 1418
 funlockfile — acquire and release stream
 lock, 391
 fwide — set stream orientation, 500
 fwprintf — print formatted wide-character
 output, 501
 fwrite — binary output, 510
 fwscanf — convert formatted wide-character
 input, 513

G

gconvert — convert number to ASCII, 260
 general terminal interface, — `termios`, 1545
 generate path name for controlling terminal
 — `ctermid`, 137
 — `ctermid_r`, 137
 generate path names matching a pattern
 — `glob`, 707
 — `globfree`, 707
 get a wide-character string from a stream —
 `fgetws`, 706
 get a wide-character string from a stream —
 `getws`, 706
 get mnttab file information —
 `getextmntent`, 586
 get mnttab file information — `getmntany`, 586
 get mnttab file information — `getmntent`, 586

get mnttab file information — `hasmntopt`, 586
 get mnttab file information — `putmntent`, 586
 get mnttab file information — `resetmnttab`, 586
 get a byte from a stream
 — `fgetc`, 345
 — `getc`, 345
 — `getc_unlocked`, 345
 — `getchar`, 345
 — `getchar_unlocked`, 345
 — `getw`, 345
 get a wide-character code from a stream —
 `fgetwc`, 374
 get address of symbol in shared object or
 executable — `dlsym`, 249
 get an identifier for the current host —
 `gethostid`, 575
 get configurable variables — `confstr`, 125
 get current file position information —
 `fgetpos`, 356
 get diagnostic information — `dlderror`, 236
 get foreground process group ID —
 `tcgetpgrp`, 1532
 get input baud rate, — `cfgetispeed`, 104
 get name of signal — `strsignal`, 1462
 get number of bytes in a character —
 `mblen`, 913
 get number of bytes in a character (restartable)
 — `mbrlen`, 914
 get or set process scheduling priority
 — `getpriority`, 602
 — `setpriority`, 602
 get output baud rate, — `cfgetospeed`, 104
 get process group ID for session leader for
 controlling terminal — `tcgetsid`, 1533
 get system load averages — `getloadavg`, 579
 get system load averages for a processor set —
 `pset_getloadavg`, 1023
 get the parameters associated with the terminal
 — `tcgetattr`, 1531
 get wide character from a stream — `getwc`, 702
 get wide character from stdin stream —
 `getwchar`, 703
 getc — get a byte from a stream, 345
 getc_unlocked — get a byte from a stream, 345
 getchar — get a byte from a stream, 345
 getchar_unlocked — get a byte from a
 stream, 345

getcpuid — obtain information on scheduling decisions, 533
 getcwd — get pathname of current working directory, 537
 getdate — convert user format date and time, 539
 General Specifications, 541
 Internal Format Conversion, 541
 Modified Conversion Specifications, 540
 getenv — return value for environment name, 546
 getexecname — return pathname of executable, 547
 getextmntent — get mnttab file information, 586
 getgrent — group database entry functions, 566
 getgrent_r — group database entry functions, 566
 getgrgid — group database entry functions, 566
 getgrgid_r — group database entry functions, 566
 getgrnam — group database entry functions, 566
 getgrnam_r — group database entry functions, 566
 gethomegroup — obtain information on scheduling decisions, 533
 gethostid — get an identifier for the current host, 575
 gethostname — get name of current host, 576
 gethrtime — get high resolution real time, 577
 gethrvtime — get high resolution virtual time, 577
 getloadavg — get system load averages, 579
 getlogin — get login name, 580
 getlogin_r — get login name, 580
 getmntany — get mnttab file information, 586
 getmntent — get mnttab file information, 586
 getopt — get option letter from argument vector, 594
 getpagesize — get system page size, 598
 getpass — read a string of characters without echo, 600
 getpassphrase — read a string of characters without echo, 600
 getpriority — get or set process scheduling priority, 602
 getpw — get passwd entry from UID, 604
 getpwent — get password entry from user database, 613
 getpwent_r — get password entry from user database, 613
 getpwnam — get password entry from user database, 613
 getpwnam_r — get password entry from user database, 613
 getpwuid — get password entry from user database, 613
 getpwuid_r — get password entry from user database, 613
 getrusage — get information about resource utilization, 629
 getspent — get shadow password database entry, 641
 getspent_r — get shadow password database entry (reentrant), 641
 getspnam — get shadow password database entry, 641
 getspnam_r — get shadow password database entry (reentrant), 641
 getsubopt — parse suboptions from a string, 649
 gettext — message handling functions, 652
 gettimeofday — get date and time, 656
 gettimeofday — get system's notion of current Greenwich time, 658
 gettxt — retrieve a text string, 659
 getusershell() — get legal user shells, 661
 getutent — user accounting database functions, 662
 getutid — user accounting database functions, 662
 getutline — user accounting database functions, 662
 getutmp — user accounting database functions, 679
 getutmpx — user accounting database functions, 679
 getutxent — user accounting database functions, 679
 getutxid — user accounting database functions, 679
 getutxline — user accounting database functions, 679
 getvfsany — get vfstab file entry, 693

getvfsent — get vfstab file entry, 693
 getvfsfile — get vfstab file entry, 693
 getvfsspec — get vfstab file entry, 693
 getw — get a byte from a stream, 345
 getwc — get wide character from a stream, 702
 getwchar — get wide character from stdin stream, 703
 getwd — get current working directory pathname, 704
 getwidth — get codeset information, 705
 getws — get a wide-character string from a stream, 706
 glob — generate path names matching a pattern, 707
 globfree — generate path names matching a pattern, 707
 grantpt — grant access to the slave pseudo-terminal device, 725
 group database entry functions —
 endgrent, 566
 group database entry functions —
 fgetgrent, 566
 group database entry functions —
 fgetgrent_r, 566
 group database entry functions — getgrent, 566
 group database entry functions —
 getgrent_r, 566
 group database entry functions —
 getgrgid, 566
 group database entry functions —
 getgrgid_r, 566
 group database entry functions —
 getgrnam, 566
 group database entry functions —
 getgrnam_r, 566
 group database entry functions — setgrent, 566
 group IDs, supplementary, initialize —
 initgroups, 747

H

halt system processor, — reboot, 1156
 hash-table search routine, — hsearch, 735
 hasmntopt — get mnttab file information, 586
 hcreate — create hash table, 735
 hdestroy — destroy hash table, 735

host name
 get name of current host —
 gethostname, 576
 set name of current host — sethostname, 576
 hsearch — hash-table search routine, 735

I

I/O multiplexing, synchronous, — select, 1207
 I/O package, standard buffered I/O —
 stdio, 1368
 iconv — code conversion function, 738
 iconv_close — code conversion deallocation function, 743
 iconv_open — code conversion allocation function, 744
 IEEE arithmetic, convert floating-point number to string — ecvt, 262
 IEEE floating-point environment control
 — fpgetmasks, 413
 — fpgetround, 413
 — fpgetsticky, 413
 — fpsetmask, 413
 — fpsetround, 413
 — fpsetsticky, 413
 index — string operations, 746
 initgroups — initialize the supplementary group access list, 747
 initstate — pseudorandom number functions, 1076
 input conversion, convert from wchar_t string — wscanf, 1986
 input/output package, standard buffered I/O —
 stdio, 1368
 insque — insert element to a queue, 754
 interfaces to stdio FILE structure —
 __flushbuf, 306
 interfaces to stdio FILE structure —
 __fbufsize, 306
 interfaces to stdio FILE structure —
 __flbf, 306
 interfaces to stdio FILE structure —
 __fpending, 306
 interfaces to stdio FILE structure —
 __fpurge, 306
 interfaces to stdio FILE structure —
 __freadable, 306

interfaces to stdio FILE structure —
 __freading, 306
 interfaces to stdio FILE structure —
 __fsetlocking, 306
 interfaces to stdio FILE structure —
 __fwritable, 306
 interfaces to stdio FILE structure —
 __fwriting, 306
 invoke isa-specific executable — isaexec, 755
 isaexec — invoke isa-specific executable, 755
 isalnum — character handling, 149
 isalpha — character handling, 149
 isascii — character handling, 149
 isatty — test for a terminal device, 766
 isdigit — character handling, 149
 isenglish — wide-character code classification
 functions, 809
 isgraph — character handling, 149
 isideogram — wide-character code classification
 functions, 809
 islower — character handling, 149
 isnumber — wide-character code classification
 functions, 809
 isphonogram — wide-character code
 classification functions, 809
 isprint — character handling, 149
 ispunct — character handling, 149
 isspace — character handling, 149
 isspecial — wide-character code classification
 functions, 809
 isupper — character handling, 149
 iswalnum — wide-character code classification
 functions, 809
 iswalpha — wide-character code classification
 functions, 809
 iswascii — wide-character code classification
 functions, 809
 iswcntrl — wide-character code classification
 functions, 809
 iswctype — test character for specified
 class, 815
 iswdigit — wide-character code classification
 functions, 809
 iswgraph — wide-character code classification
 functions, 809
 iswlower — wide-character code classification
 functions, 809

iswprint — wide-character code classification
 functions, 809
 iswpunct — wide-character code classification
 functions, 809
 iswspace — wide-character code classification
 functions, 809
 iswupper — wide-character code classification
 functions, 809
 iswxdigit — wide-character code classification
 functions, 809
 isxdigit — character handling, 149

K

killpg — send signal to a process group, 838

L

labs — return absolute value of long integer, 34
 language information — nl_langinfo, 989
 ldexp — load exponent of a floating point
 number, 844
 ldiv — compute quotient and remainder, 224
 lfmt — display error message in standard
 format and pass to logging and monitoring
 services, 848
 linear search and update routine
 — lfind, 886
 — lsearch, 886
 llabs — return absolute value of long long
 integer, 34
 lldiv — compute quotient and remainder, 224
 lltostr — string conversion routines, 1482
 load exponent of a floating point number —
 ldexp, 844
 locale, modify and query a program's locale —
 setlocale, 1233
 localeconv — get numeric formatting
 information, 857
 lock, apply or remove advisory lock on open file
 — flock, 389
 lock address space, — mlockall, 955
 lock memory pages, — mlock, 953
 lockf — allows sections of file to be locked, 871
 log message with a stdarg argument list —
 vsyslog, 1734

login name
— getlogin, 580
— getlogin_r, 580
longjmp — non-local goto, 1221, 1227
_longjmp — non-local goto, 874, 1227

M

madvise — provide advice to VM system, 888
make a FIFO special file — mkfifo, 946
make modified instructions executable —
sync_instruction_memory, 1513
makecontext — manipulate user contexts, 892
malloc — memory allocator, 83
mallocctl — MT hot memory allocator, 965
manipulate resource control blocks —
rctlblk_get_enforced_value, 1128
manipulate resource control blocks —
rctlblk_get_firing_time, 1128
manipulate resource control blocks —
rctlblk_get_global_action, 1128
manipulate resource control blocks —
rctlblk_get_global_flags, 1128
manipulate resource control blocks —
rctlblk_get_local_action, 1128
manipulate resource control blocks —
rctlblk_get_local_flags, 1128
manipulate resource control blocks —
rctlblk_get_privilege, 1128
manipulate resource control blocks —
rctlblk_get_recipient_pid, 1128
manipulate resource control blocks —
rctlblk_get_value, 1128
manipulate resource control blocks —
rctlblk_set_local_action, 1128
manipulate resource control blocks —
rctlblk_set_local_flags, 1128
manipulate resource control blocks —
rctlblk_set_privilege, 1128
manipulate resource control blocks —
rctlblk_set_value, 1128
manipulate resource control blocks —
rctlblk_size, 1128
manipulate sets of signals — sigsetops, 1311
sigaddset, 1311
sigdelset, 1311
sigemptyset, 1311

manipulate sets of signals — sigsetops
(Continued)
sigfillset, 1311
sigismember, 1311
match filename or path name — fnmatch, 400
mblen — get number of bytes in a
character, 913
mbrlen — get number of bytes in a character
(restartable), 914
mbrtowc — convert a character to a
wide-character code (restartable), 916
mbsinit — determine conversion object
status, 918
mbsrtowcs — convert a character string to a
wide-character string (restartable), 919
mbstowcs — convert a character string to a
wide-character string, 921
mbtowlc — convert a character to a
wide-character code, 922
mctl — memory management control, 923
memory — memory operations, 941
memory, optimizing usage of user mapped
memory — madvise, 888
memory allocator — bsdmalloc, 83
memory allocator
— alloca, 899
— calloc, 899, 902, 911
memory allocator — bsdmalloc
free, 83
memory allocator
— free, 899, 902, 911
— mallinfo, 902
memory allocator — bsdmalloc
malloc, 83
memory allocator
— malloc, 899, 902, 911
— mallopt, 902
— memalign, 899
memory allocator — bsdmalloc
realloc, 83
memory allocator
— realloc, 899, 902, 911
— valloc, 899
memory lock or unlock, calling process —
plock, 1005
memory management — mctl, 923
memory management
get system page size — getpagesize, 598

- memory management (Continued)
 - lock address space — `mlockall`, 955
 - lock pages in memory — `mlock`, 953
 - synchronize memory with physical storage
 - `msync`, 963
 - unlock address space — `munlockall`, 955
 - unlock pages in memory — `munlock`, 953
- memory operations
 - `memccpy`, 941
 - `memchr`, 941
 - `memcmp`, 941
 - `memcpy`, 941
 - `memmove`, 941
 - `memory`, 941
 - `memset`, 941
- message handling functions —
 - `bindtextdomain`, 652
- message handling functions —
 - `bind_textdomain_codeset`, 652
- message handling functions — `dcgettext`, 652
- message handling functions — `dcngettext`, 652
- message handling functions — `dgettext`, 652
- message handling functions — `dngettext`, 652
- message handling functions — `gettext`, 652
- message handling functions — `ngettext`, 652
- message handling functions — `textdomain`, 652
- message catalog
 - `open/catalog` — `catopen`, `catclose`, 101
 - read a program message — `catgets`, 100
- messages
 - display a message on `stderr` or system console — `fmtmsg`, 395
 - print system error messages — `perror`, 1001
 - system signal messages — `psignal`, 1025
- `mkfifo` — make a FIFO special file, 946
- `mkstemp` — make a unique file name, 948
- `mktemp` — make a unique file name, 949
- `mktime` — converts a `tm` structure to a calendar time, 950
- `modf` — decompose floating-point number, 957
- `modff` — decompose floating-point number, 957
- `monitor` — prepare process execution profile, 959
- `msync` — synchronize memory with physical storage, 963
- MT hot memory allocator — `mallocctl`, 965
- MT hot memory allocator — `mtmalloc`, 965
- `mtmalloc` — MT hot memory allocator, 965

N

- `ndbm` — database functions, 972
- network group entry
 - `endnetgrent`, 588
 - `getnetgrent`, 588
 - `getnetgrent_r`, 588
 - `innetgr`, 588
 - `setnetgrent`, 588
- `nextkey` — data base subroutines, 153
- `nftw` — walk a file tree, 490
- `ngettext` — message handling functions, 652
- `nice` — change priority of a process, 987
- `nl_langinfo` — language information, 989
- `nlist` — get entries from symbol table, 988
- non-local goto — `setjmp`, 1221, 1227
 - `_longjmp`, 1227
 - `longjmp`, 1221, 1227
 - `_setjmp`, 1227
 - `siglongjmp`, 1221
 - `sigsetjmp`, 1221
- non-local goto
 - `_longjmp`, 874
 - `_setjmp`, 874
- numbers, convert to strings — `econvert`, 260

O

- obtain information on scheduling decisions —
 - `getcpuid`, 533
- obtain information on scheduling decisions —
 - `gethomeigroup`, 533
- `offsetof` — offset of structure member, 992
- open a shared object — `dlopen`, 245
- open directory — `fdopendir`, 993
- open directory — `opendir`, 993
- open a file — `attropen`, 71
- open a stream — `fopen`, 402
- open a stream — `freopen`, 457
- `opendir` — open directory, 993
- `openlog` — control system log, 1522
- output conversion, `wsprintf` — convert to `wchar_t` string, 1980

output conversion, formatted

- fprintf, 1017
- printf, 1017
- sprintf, 1017
- vfprintf, 1017
- vprintf, 1017
- vsprintf, 1017

P

page size, system, get — getpagesize, 598

password databases

- lock the lock file — lckpwwdf, 841
- unlock the lock file — ulckpwwdf, 841

passwords

- get password entry from a file —
fgetpwent, 613
- get password entry from a file —
fgetpwent_r, 613
- get password entry in user database —
endpwent, 613
- get password entry in user database —
getpwent, 613
- get password entry in user database —
getpwent_r, 613
- get password entry in user database —
getpwnam, 613
- get password entry in user database —
getpwnam_r, 613
- get password entry in user database —
getpwuid, 613
- get password entry in user database —
getpwuid_r, 613
- get password entry in user database —
setpwent, 613
- get passwd entry from UID — getpw, 604
- write password file entry — putpwent, 1045

passwords, shadow

- get shadow password database entry —
endspent, 641
- get shadow password database entry —
fgetspent, 641
- get shadow password database entry —
getspent, 641
- get shadow password database entry —
getspnam, 641

passwords, shadow (Continued)

- get shadow password database entry —
setspent, 641
 - get shadow password database entry
(reentrant) — fgetspent_r, 641
 - get shadow password database entry
(reentrant) — getspent_r, 641
 - get shadow password database entry
(reentrant) — getspnam_r, 641
 - write shadow password file entry —
putspent, 1047
- path name, return last element — path
name, 72
- pclose — initiate pipe to/from a process, 1006
- perform word expansions
- wordexp, 1898
 - wordfree, 1898
- perror — print system error messages, 1001
- pfmt — display error message in standard
format, 1002
- pipes
- initiate to/from a process — pclose, 1006
 - initiate to/from a process — popen, 1006
- plock — lock or unlock into memory process,
text, or data, 1005
- popen — initiate pipe to/from a process, 1006
- print formatted output
- fprintf, 1008
 - printf, 1008
 - snprintf, 1008
 - sprintf, 1008
- print formatted output of a variable argument
list
- vfprintf, 1698
 - vprintf, 1698
 - vsnprintf, 1698
 - vsprintf, 1698
- print formatted wide-character output
- fwprintf, 501
 - swprintf, 501
 - wprintf, 501
- printf — formatted output conversion, 1017
- printf — print formatted output, 1008
- printstack — walk stack pointed to by
ucontext, 1765
- Process Code string operations —
wstring, 2002

Process Code string operations — wscasecmp, wscasecmp, 2002
 Process Code string operations — wscol, wscol, 2002
 Process Code string operations — wsdup, wsdup, 2002
 Process Code string operations — wsncasecmp, wsncasecmp, 2002
 process statistics, prepare execution profile — monitor, 959
 processes
 change priority — nice, 987
 duplicate an open file descriptor — dup2, 259
 generate path name for controlling terminal — ctermid, ctermid_r, 137
 get character-string representation — cuserid, 152
 initiate pipe to/from a process — popen, pclose, 1006
 manipulate user contexts — makecontext, swapcontext, 892
 memory lock or unlock — plock, 1005
 prepare execution profile — monitor, 959
 report CPU time used — clock, 117
 send signal to a process group — killpg, 838
 send signal to program — raise, 1073
 suspend execution for interval — sleep, 1324
 terminate process — exit, 300
 terminate the process abnormally — abort, 33
 wait for process to terminate or stop — WIFEXITED, 1750
 wait for process to terminate or stop — WIFSIGNALED, 1750
 wait for process to terminate or stop — WIFSTOPPED, 1750
 wait for process to terminate or stop — wait, 1750
 profiling utilities, prepare process execution profile — monitor, 959
 program assertion, verify — assert, 57
 program messages
 open/close a message catalog — catopen, catclose, 101
 read — catgets, 100
 programs, last locations — end, etext, edata, 268
 pset_getloadavg — get system load averages for a processor set, 1023
 pseudo-terminal device
 get name of the slave pseudo-terminal device — ptsname, 1029
 grant access to the slave pseudo-terminal device — grantpt, 725
 pseudorandom number functions
 — initstate, 1076
 — random, 1076
 — setstate, 1076
 — srandom, 1076
 psiginfo — system signal messages, 1025
 psignal — system signal messages, 1025, 1026
 pthread_atfork — register fork handlers, 1027
 ptsname — get name of the slave pseudo-terminal device, 1029
 push byte back into input stream — ungetc, 1646
 push wide-character code back into input stream — ungetwc, 1647
 put wide-character code on a stream — fputwc, 442
 put wide-character code on a stream — putwc, 442
 put wide-character code on a stream — putwchar, 442
 put a byte on a stream
 — fputc, 438
 — putc, 438
 — putc_unlocked, 438
 — putchar, 438
 — putchar_unlocked, 438
 — putw, 438
 put wide character string on a stream — fputws, 444
 putc — put a byte on a stream, 438
 putc_unlocked — put a byte on a stream, 438
 putchar — put a byte on a stream, 438
 putchar_unlocked — put a byte on a stream, 438
 putenv — change or add value to environment, 1042
 putmntent — get mnttab file information, 586
 putpwent — write password file entry, 1045
 putspent — write shadow password file entry, 1047

pututline — user accounting database functions, 662
pututxline — user accounting database functions, 679
putw — put a byte on a stream, 438
putwc — put wide-character code on a stream, 442
putwchar — put wide-character code on a stream, 442
putws — convert a string of Process Code characters to EUC characters and put it on a stream, 1062

Q

qconvert — convert number to ASCII, 260
qfconvert — convert number to ASCII, 260
qgconvert — convert number to ASCII, 260
qsort — quick sort, 1069
quadruple_to_decimal — decimal record from quadruple-precision floating, 387
queues, insert/remove element from a queue — insque, remque, 754

R

raise — send signal to program, 1073
rand — simple random number generator, 1075
rand — simple random-number generator, 1074
random — pseudorandom number functions, 1076
random number generator
— drand48, 257
— erand48, 257
— jrand48, 257
— lcong48, 257
— lrand48, 257
— mrand48, 257
— nrand48, 257
— rand, 1075
— seed48, 257
— srand48, 257
random number generator, simple
— rand, 1074
— srand, 1074

rctl_walk — visit registered rctls on current system, 1136
rctlblk_get_enforced_value — manipulate resource control blocks, 1128
rctlblk_get_firing_time — manipulate resource control blocks, 1128
rctlblk_get_global_action — manipulate resource control blocks, 1128
rctlblk_get_global_flags — manipulate resource control blocks, 1128
rctlblk_get_local_action — manipulate resource control blocks, 1128
rctlblk_get_local_flags — manipulate resource control blocks, 1128
rctlblk_get_privilege — manipulate resource control blocks, 1128
rctlblk_get_recipient_pid — manipulate resource control blocks, 1128
rctlblk_get_value — manipulate resource control blocks, 1128
rctlblk_set_local_action — manipulate resource control blocks, 1128
rctlblk_set_local_flags — manipulate resource control blocks, 1128
rctlblk_set_privilege — manipulate resource control blocks, 1128
rctlblk_set_value — manipulate resource control blocks, 1128
rctlblk_size — manipulate resource control blocks, 1128
re_comp — compile and execute regular expressions, 1157
re_exec — compile and execute regular expressions, 1157
read a string of characters without echo — getpass, 600
read a directory entry — readdir, 1142
read a string of characters without echo, — getpassphrase, 600
read directory
— readdir, 1138
— readdir_r, 1138
readdir — read a directory entry, 1142
readdir — read directory, 1138
POSIX, 1138
readdir_r — read directory, 1138
realloc — memory allocator, 83
realpath — resolve pathname, 1154

reboot — reboot system or halt processor, 1156
 regcmp — compile regular expression, 1159
 regcomp — regular expression matching, 1161
 regerror — regular expression matching, 1161
 regex — execute regular expression, 1159
 regexec — regular expression matching, 1161
 regfree — regular expression matching, 1161
 register a function to run at process termination
 or object unloading— atexit, 58
 register fork handlers — pthread_atfork, 1027
 regular expression matching
 — regcomp, 1161
 — regerror, 1161
 — regexec, 1161
 — regfree, 1161
 regular expressions, compile and execute —
 regcmp, regex, 1159
 remove — remove file, 1187
 remque — remove element from a queue, 754
 reposition a file-position indicator in a stream
 — fseek, 469
 — fseeko, 469
 reset file position indicator in a stream —
 rewind, 1191
 reset position of directory stream to the
 beginning of a directory — rewinddir, 1192
 resetmnttab — get mnttab file information, 586
 resolve pathname — realpath, 1154
 resource utilization, get information —
 getrusage, 629
 retrieve stack boundaries —
 stack_getbounds, 1362
 return a file offset for a file descriptor —
 tell, 1541
 return a file offset in a stream
 — ftell, 480
 — ftello, 480
 return pathname of executable —
 getexecname, 547
 rewind — reset file position indicator in a
 stream, 1191
 rewinddir — reset position of directory stream
 to the beginning of a directory, 1192
 rindex — string operations, 746

S

scan a directory
 — alphasort, 1194
 — scandir, 1194
 scandir — scan a directory, 1194
 scanf — convert formatted input, 1195
 Conversion Characters, 1197
 Conversion Specifications, 1196
 scheduling priority, change priority of a process
 — nice, 987
 search functions
 binary search a sorted table — bsearch, 86
 linear search and update routine — lsearch,
 lfind, 886
 manage hash search tables — hsearch, 735
 seconvert — convert number to ASCII, 260
 seekdir — set position of directory stream, 1206
 select — synchronous I/O multiplexing, 1207
 send a “break” for a specific duration —
 tcsendbreak, 1534
 set and/or get alternate signal stack context —
 sigstack, 1313
 set and/or get signal stack context —
 sigstack, 1315
 set encoding key — setkey, 1230
 set foreground process group ID —
 tcsetpgrp, 1537
 set input baud rate, — cfsetispeed, 109
 set output baud rate, — cfsetospeed, 109
 set position of directory stream — seekdir, 1206
 set stream orientation — fwide, 500
 set the parameters associated with the terminal
 — tcsetattr, 1535
 set wide-characters in memory —
 wmemset, 1897
 setcat — define default catalog, 1214
 setgrent — group database entry functions, 566
 sethostname — set name of current host, 576
 setjmp — non-local goto, 1221, 1227
 _setjmp — non-local goto, 874, 1227
 setkey — set encoding key, 1230
 setlabel — define the label for pfmt() and
 lfmt()., 1231
 setlocale — modify and query a program’s
 locale, 1233
 setlogmask — control system log, 1522
 setpriority — get or set process scheduling
 priority, 602

setpwnam — get password entry from user database, 613
 setspent — get shadow password database entry, 641
 setstate — pseudorandom number functions, 1076
 settimeofday — set date and time, 656
 settimeofday — set system's notion of current Greenwich time, 658
 setusershell() — function, 661
 setutent — user accounting database functions, 662
 setutxent — user accounting database functions, 679
 severity levels, applications, build a list for use with fmtmsg — addseverity, 36
 sfconvert — convert number to ASCII, 260
 sgconvert — convert number to ASCII, 260
 shared object
 close — dlclose, 229
 get address of symbol — dlsym, 249
 get diagnostic information — dlerror, 236
 open — dlopen, 245
 shell command, issue one — system, 1527
 sig2str — translation between signal name and signal number, 1374
 sigaddset — manipulate sets of signals, 1311
 sigdelset — manipulate sets of signals, 1311
 sigemptyset — manipulate sets of signals, 1311
 sigfillset — manipulate sets of signals, 1311
 sigfpe() function, 1283
 sighold — adds sig to the calling process's signal mask, 1296
 sigignore — sets the disposition of sig to SIG_IGN, 1296
 siginterrupt — allow signals to interrupt functions, 1289
 sigismember — manipulate sets of signals, 1311
 siglongjmp — non-local goto, 1221
 signal — modify signal disposition, 1296
 signal — simplified software signal facilities, 1298
 signal
 schedule after interval in microseconds — ualarm, 1586
 suspend execution for interval in microseconds — usleep, 1659
 simplified signal facilities — `bsd_signal`, 85
 signal management, simplified, for application processes — signal, 1296
 signal messages, system
 — `psignal`, 1025, 1026
 signals, block
 — `sigblock`, 1276
 — `sigmask`, 1276
 — `sigpause`, 1276
 — `sigsetmask`, 1276
 signals, software
 — `gsignal`, 1361
 — `ssignal`, 1361
 sigpause — removes sig from the calling process's signal mask and suspends the calling process until a signal is received, 1296
 sigrelse — removes sig from the calling process's signal mask, 1296
 sigset — modify signal disposition, 1296
 sigsetjmp — non-local goto, 1221
 sigsetops — manipulate sets of signals, 1311
 sigstack — set and/or get alternate signal stack context, 1313
 sigstack — set and/or get signal stack context, 1315
 sigvec — software signal facilities, 1316
 single-byte to wide-character conversion — `btowc`, 89
 single_to_decimal — decimal record from single-precision floating, 387
 sleep — suspend execution for interval, 1324
 sleep, suspend execution for interval in microseconds — `usleep`, 1659
 snprintf — print formatted output, 1008
 software signals
 — `gsignal`, 1361
 — `ssignal`, 1361
 sort, quick — `qsort`, 1069
 sprintf — formatted output conversion, 1017
 printf — print formatted output, 1008
 srand — reset simple random number generator, 1075
 srandom — pseudorandom number functions, 1076
 sscanf — convert formatted input, 1195
 stack_getbounds — retrieve stack boundaries, 1362

_stack_grow — express an intention to extend the stack, 1363
 stack_inbounds — determine if address is within stack boundaries, 1364
 stack_setbounds — update stack boundaries, 1365
 stack_violation — determine stack boundary violation event, 1366
 stdio — standard buffered input/output package, 1368
 sting collation, — strcoll, 1391
 store — data base subroutines, 153
 str2sig — translation between signal name and signal number, 1374
 strcasecmp — string operations, 1415
 strcat — string operations, 1415
 strchr — string operations, 1415
 strcmp — string operations, 1415
 strcpy — string operations, 1415
 strcspn — string operations, 1415
 strdup — string operations, 1415
 stream
 convert a string of Process Code characters to EUC characters and put it on a stream — putws, 1062
 open — fopen, 405
 stream, assign buffering
 — setbuf, 1211
 — setvbuf, 1211
 stream, get string
 — fgets, 632
 — gets, 632
 stream, put a string
 — fputs, 1046
 — puts, 1046
 stream status inquiries
 — clearerr, 339
 — feof, 339
 — ferror, 339
 — fileno, 339
 STREAMS
 attach a STREAMS-based file descriptor to an object in the file system name space — fattach, 304
 test file descriptor for a STREAMS file — isastream, 765
 strfmon — convert monetary value to string, 1405
 strftime — convert date and time to string, 1409
 string — string operations, 1415
 string operations — strcasecmp, 1415
 string operations — strcat, 1415
 string operations — strchr, 1415
 string operations — strcmp, 1415
 string operations — strcpy, 1415
 string operations — strcspn, 1415
 string operations — strdup, 1415
 string operations — string, 1415
 string operations — strlcat, 1415
 string operations — strlcpy, 1415
 string operations — strlen, 1415
 string operations — strncasecmp, 1415
 string operations — strncat, 1415
 string operations — strncmp, 1415
 string operations — strncpy, 1415
 string operations — strpbrk, 1415
 string operations — strchr, 1415
 string operations — strspn, 1415
 string operations — strstr, 1415
 string operations — strtok, 1415
 string operations — strtok_r, 1415
 string conversion routines
 — atoi, 1482
 — atol, 1482
 — atoll, 1482
 — lltostr, 1482
 — strtol, 1482
 — strtoll, 1482
 — ulltostr, 1482
 string encoding function — crypt, 129
 string operation, get error message string — strerror, 1404
 string operations
 bit and byte — bstring, 88
 — index, 746
 — rindex, 746
 string_to_decimal — decimal record from character string, 1418
 string transformation — strxfrm, 1493
 strings, convert from numbers — econvert, 260
 strlcat — string operations, 1415
 strlcpy — string operations, 1415
 strlen — string operations, 1415
 strncasecmp — string operations, 1415
 strncat — string operations, 1415

strncmp — string operations, 1415
 strncpy — string operations, 1415
 strpbrk — string operations, 1415
 strptime — date and time conversion, 1453
 strrchr — string operations, 1415
 strsignal — get name of signal, 1462
 strspn — string operations, 1415
 strstr — string operations, 1415
 strtod — convert string to double-precision number, 1471
 strtok — string operations, 1415
 strtok_r — string operations, 1415
 strtol — string conversion routines, 1482
 strtoll — string conversion routines, 1482
 strtoul — convert string to unsigned long, 1488
 strtows — code conversion for Process Code and File Code, 1492
 strxfrm — string transformation, 1493
 suspend or restart the transmission or reception of data — tcfLOW, 1529
 swab — swap bytes, 1495
 swap bytes — swab, 1495
 swapcontext — manipulate user contexts, 892
 swprintf — print formatted wide-character output, 501
 swscanf — convert formatted wide-character input, 513
 symbol address, get address in shared object or executable — dlsym, 249
 symbol table, get entries — nlist, 988
 sync_instruction_memory — make modified instructions executable, 1513
 synchronize changes to a file — fsync, 478
 synchronous I/O multiplexing
 — FD_CLR, 1207
 — FD_ISSET, 1207
 — FD_SET, 1207
 — select, 1207
 sys_siglist — system signal messages list, 1026
 syscall — indirect system call, 1514
 sysconf — get configurable system variables, 1515
 syslog — control system log, 1522
 system — issue shell command, 1527
 system error messages, print — perror, 1001
 system signal messages, — psignal, 1025
 system variables, get configurable ones — sysconf, 1515

T

tcdrain — wait for transmission of output, 1528
 tcfLOW — suspend or restart the transmission or reception of data, 1529
 tcfLush — flush non-transmitted output data, non-read input data or both, 1530
 tcgetattr — get the parameters associated with the terminal, 1531
 tcgetpgrp — get foreground process group ID, 1532
 tcgetsid — get process group ID for session leader for controlling terminal, 1533
 tcsendbreak — send a “break” for a specific duration, 1534
 tcsetattr — set the parameters associated with the terminal, 1535
 tcsetpgrp — set foreground process group ID, 1537
 tdelete — manage binary search trees, 1570
 tell — return a file offset for a file descriptor, 1541
 telldir — current location of a named directory stream, 1542
 tempnam — create a name for a temporary file, 1555
 terminal, find the slot of the current user in the user accounting database — ttyslot, 1577
 terminal device, slave pseudo
 get name — ptsname, 1029
 grant access — grantpt, 725
 terminal ID, generate path name for controlling terminal — ctermid, ctermid_r, 137
 termios — general terminal interface, 1545
 test character for specified class — iswctype, 815
 test for a terminal device — isatty, 766
 text processing utilities
 compile and execute regular expressions — regcmp, regex, 1159
 quick sort — qsort, 1069
 text string, — gettext, 659
 textdomain — message handling functions, 652
 tfind — manage binary search trees, 1570
 time, computes the difference between two calendar times — difftime, 219
 time, calendar, convert from a tm structure — mktime, 950

time accounting, for current process — times, 1553

time and date

- convert to string — asctime, 139
- convert to string — ctime, 139
- convert to string — gmtime, 139
- convert to string — localtime, 139
- convert to string — tzset, 139
- convert user format date and time — getdate, 539
- get — ftime, 482
- settimeofday, 656

time of day, get and set — gettimeofday, settimeofday, 658

times — get process times, 1553

tmpfile — create a temporary file, 1554

tmpnam — create a name for a temporary file, 1555

toascii — translate integer to a 7-bit ASCII character, 1559

tolower — transliterate upper-case characters to lower-case, 1561

_tolower — transliterate upper-case characters to lower-case, 1560

toupper — transliterate lower-case characters to upper-case, 1563

_toupper — transliterate lower-case characters to upper-case, 1562

towctrans — wide-character mapping, 1564

towlower — transliterate upper-case wide-character code to lower-case, 1565

towupper — transliterate lower-case wide-character code to upper-case, 1566

translate address to symbolic information — dladdr1, 227

translate address to symbolic information — dladdr, 227

translate integer to a 7-bit ASCII character — toascii, 1559

translation between signal name and signal number — str2sig, 1374

sig2str, 1374

transliterate lower-case characters to upper-case — toupper, 1563

transliterate lower-case characters to upper-case — _toupper, 1562

transliterate lower-case wide-character code to upper-case — towupper, 1566

transliterate upper-case characters to lower-case — tolower, 1561

transliterate upper-case characters to lower-case — _tolower, 1560

transliterate upper-case wide-character code to lower-case — towlower, 1565

truncate — set a file to a specified length, 1567

tsearch — manage binary search trees, 1570

ttyname — find pathname of a terminal, 1573

POSIX, 1573

ttyname_r — find pathname of a terminal, 1573

ttyslot — find the slot of the current user in the user accounting database, 1577

twalk — manage binary search trees, 1570

U

ualarm — schedule signal after interval in microseconds, 1586

ulltostr — string conversion routines, 1482

umem_alloc — fast, scalable memory allocation, 1591

umem_cache_alloc — allocation cache manipulation, 1604

umem_cache_create — allocation cache manipulation, 1604

umem_cache_destroy — allocation cache manipulation, 1604

umem_cache_free — allocation cache manipulation, 1604

umem_debug — debugging features of the umem library, 1628

umem_free — fast, scalable memory allocation, 1591

umem_nofail_callback — fast, scalable memory allocation, 1591

umem_zalloc — fast, scalable memory allocation, 1591

ungetc — push byte back into input stream, 1646

ungetwc — push wide-character code back into input stream, 1647

unlock a pseudo-terminal master/slave pair — unlockpt, 1648

unlock address space, — munlockall, 955

unlock memory pages, — munlock, 953

- unlockpt — unlock a pseudo-terminal master/slave pair, 1648
- update stack boundaries — stack_setbounds, 1365
- updwtmp — user accounting database functions, 679
- updwtmpx — user accounting database functions, 679
- user accounting database functions — endutent, 662
- user accounting database functions — endutxent, 679
- user accounting database functions — getutent, 662
- user accounting database functions — getutid, 662
- user accounting database functions — getutline, 662
- user accounting database functions — getutmp, 679
- user accounting database functions — getutmpx, 679
- user accounting database functions — getutxent, 679
- user accounting database functions — getutxid, 679
- user accounting database functions — getutxline, 679
- user accounting database functions — pututline, 662
- user accounting database functions — pututxline, 679
- user accounting database functions — setutent, 662
- user accounting database functions — setutxent, 679
- user accounting database functions — updwtmp, 679
- user accounting database functions — updwtmpx, 679
- user accounting database functions — utmpname, 662
- user accounting database functions — utmpxname, 679
- user context
 - makecontext, 892
 - swapcontext, 892

- user IDs, get character-string representation — cuserid, 152
- usleep — suspend execution for interval in microseconds, 1659
- utmpname — user accounting database functions, 662
- utmpx file, find the slot of current user — tty slot, 1577
- utmpxname — user accounting database functions, 679

V

- vfprintf — formatted output conversion, 1017
- vfscanf — convert formatted input, 1195
- vfstab file, — getvfsent, 693
- vwprintf — wide-character formatted output of a stdarg argument list, 1686
- vwscanf — convert formatted wide-character input, 513
- virtual memory, optimizing usage of user mapped memory — madvise, 888
- visit registered rctls on current system — rctl_walk, 1136
- vlfmt — display error message in standard format and pass to logging and monitoring services, 1694
- vpfmt — display error message in standard format and pass to logging and monitoring services, 1696
- vprintf — formatted output conversion, 1017
- vscanf — convert formatted input, 1195
- vsprintf — formatted output conversion, 1017
- vsscanf — convert formatted input, 1195
- vswprintf — wide-character formatted output of a stdarg argument list, 1686
- vswscanf — convert formatted wide-character input, 513
- vsyslog — log message with a stdarg argument list, 1734
- vwprintf — wide-character formatted output of a stdarg argument list, 1686
- vwsscanf — convert formatted wide-character input, 513

W

- wait — wait for process to terminate or stop, 1750
- waitpid — wait for process to terminate or stop, 1750
- wait for process to terminate or stop
 - wait3, 1743
 - wait4, 1743
- wait for transmission of output — `tcdrain`, 1528
- wait3 — wait for process to terminate or stop, 1743, 1750
- wait4 — wait for process to terminate or stop, 1743, 1750
- walk stack pointed to by `ucontext` — `printstack`, 1765
- walk stack pointed to by `ucontext` — `walkcontext`, 1765
- walkcontext — walk stack pointed to by `ucontext`, 1765
- watof — convert wide character string to double-precision number, 1846
- watoi — convert wide character string to long integer, 1853
- watol — convert wide character string to long integer, 1853
- watoll — convert wide character string to long integer, 1853
- wchar_t string, number conversion — `wscanf`, 1986
- wcrtomb — convert a wide-character code to a character (restartable), 1778
- wcscat — wide-character string operations, 1859
- wcschr — wide-character string operations, 1860
- wcscmp — wide-character string operations, 1859
- wcscoll — wide character string comparison using collating information, 1795
- wcscpy — wide-character string operations, 1860
- wcscspn — wide-character string operations, 1861
- wcsetno — get information on EUC codesets, 133
- wcsftime — convert date and time to wide character string, 1807
- wcslen — wide-character string operations, 1860
- wcsncat — wide-character string operations, 1859
- wcsncmp — wide-character string operations, 1860
- wcsncpy — wide-character string operations, 1860
- wcspbrk — wide-character string operations, 1861
- wcsrchr — wide-character string operations, 1860
- wcsrtombs — convert a wide-character string to a character string (restartable), 1838
- wcsspn — wide-character string operations, 1861
- wcsstr — find a wide-character substring, 1845
- wcstod — convert wide character string to double-precision number, 1846
- wcstok — wide-character string operations, 1861
- wcstol — convert wide character string to long integer, 1853
- wcstombs — convert a wide-character string to a character string, 1855
- wcstoul — convert wide character string to unsigned long, 1856
- wcstring — wide-character string operations, 1859
- wcswcs — wide-character string operations, 1861
- wcswidth — number of column positions of a wide-character string, 1868
- wcsxfrm — wide character string transformation, 1869
- wctob — wide-character to single-byte conversion, 1871
- wctomb — convert a wide-character code to a character, 1872
- wctrans — define character mapping, 1873
- wctype — define character class, 1874
- wcwidth — number of column positions of a wide-character code, 1875
- wide character string to long integer, convert
 - watoi, 1853
 - watol, 1853
 - watoll, 1853
 - wcstol, 1853

wide character string to long integer, convert (Continued)

— `wstol`, 1853

wide-character code classification functions

— `isenglish`, 809
— `isideogram`, 809

wide-character string operations (Continued)

— `wrindex`, 1860

wide character string transformation

— `wcsxfrm`, 1869
— `wsxfrm`, 1869

wide-character to single-byte conversion —

`wctob`, 1871

`windex` — wide-character string

operations, 1860

`wmemchr` — find a wide-character in

memory, 1893

`wmemcmp` — compare wide-characters in

memory, 1894

`wmemcpy` — copy wide-characters in

memory, 1895

`wmemmove` — copy wide-characters in

memory with overlapping areas, 1896

`wmemset` — set wide-characters in

memory, 1897

`wordexp` — perform word expansions, 1898

`wordfree` — perform word expansions, 1898

working directory, get pathname — `getwd`, 704

`wprintf` — print formatted wide-character output, 501

`wrindex` — wide-character string

operations, 1860

`wscanf` — convert formatted wide-character input, 513

`wscasecmp` — Process Code string

operations, 2002

`wscol` — Process Code string operations, 2002

`wscoll` — wide character string comparison

using collating information, 1795

`wsdup` — Process Code string operations, 2002

`wscasecmp` — Process Code string

operations, 2002

`wsprintf` — formatted output conversion, 1980

`wscanf` — formatted input conversion, 1986

`wstod` — convert wide character string to

double-precision number, 1846

`wstol` — convert wide character string to long integer, 1853

`wstostr` — code conversion for Process Code and File Code, 1492

`wsxfrm` — wide character string transformation, 1869
