

man pages section 3: Basic Library Functions

Sun Microsystems, Inc.
4150 Network Circle
Santa Clara, CA 95054
U.S.A.

Part No: 817-0662-10
April 2003

Copyright 2003 Sun Microsystems, Inc. 4150 Network Circle, Santa Clara, CA 95054 U.S.A. All rights reserved.

This product or document is protected by copyright and distributed under licenses restricting its use, copying, distribution, and decompilation. No part of this product or document may be reproduced in any form by any means without prior written authorization of Sun and its licensors, if any. Third-party software, including font technology, is copyrighted and licensed from Sun suppliers.

Parts of the product may be derived from Berkeley BSD systems, licensed from the University of California. UNIX is a registered trademark in the U.S. and other countries, exclusively licensed through X/Open Company, Ltd.

Sun, Sun Microsystems, the Sun logo, docs.sun.com, AnswerBook, AnswerBook2, and Solaris are trademarks, registered trademarks, or service marks of Sun Microsystems, Inc. in the U.S. and other countries. All SPARC trademarks are used under license and are trademarks or registered trademarks of SPARC International, Inc. in the U.S. and other countries. Products bearing SPARC trademarks are based upon an architecture developed by Sun Microsystems, Inc.

The OPEN LOOK and Sun™ Graphical User Interface was developed by Sun Microsystems, Inc. for its users and licensees. Sun acknowledges the pioneering efforts of Xerox in researching and developing the concept of visual or graphical user interfaces for the computer industry. Sun holds a non-exclusive license from Xerox to the Xerox Graphical User Interface, which license also covers Sun's licensees who implement OPEN LOOK GUIs and otherwise comply with Sun's written license agreements.

Federal Acquisitions: Commercial Software—Government Users Subject to Standard License Terms and Conditions.

DOCUMENTATION IS PROVIDED "AS IS" AND ALL EXPRESS OR IMPLIED CONDITIONS, REPRESENTATIONS AND WARRANTIES, INCLUDING ANY IMPLIED WARRANTY OF MERCHANTABILITY, FITNESS FOR A PARTICULAR PURPOSE OR NON-INFRINGEMENT, ARE DISCLAIMED, EXCEPT TO THE EXTENT THAT SUCH DISCLAIMERS ARE HELD TO BE LEGALLY INVALID.

Copyright 2003 Sun Microsystems, Inc. 4150 Network Circle, Santa Clara, CA 95054 U.S.A. Tous droits réservés

Ce produit ou document est protégé par un copyright et distribué avec des licences qui en restreignent l'utilisation, la copie, la distribution, et la décompilation. Aucune partie de ce produit ou document ne peut être reproduite sous aucune forme, par quelque moyen que ce soit, sans l'autorisation préalable et écrite de Sun et de ses bailleurs de licence, s'il y en a. Le logiciel détenu par des tiers, et qui comprend la technologie relative aux polices de caractères, est protégé par un copyright et licencié par des fournisseurs de Sun.

Des parties de ce produit pourront être dérivées du système Berkeley BSD licenciés par l'Université de Californie. UNIX est une marque déposée aux Etats-Unis et dans d'autres pays et licenciée exclusivement par X/Open Company, Ltd.

Sun, Sun Microsystems, le logo Sun, docs.sun.com, AnswerBook, AnswerBook2, et Solaris sont des marques de fabrique ou des marques déposées, ou marques de service, de Sun Microsystems, Inc. aux Etats-Unis et dans d'autres pays. Toutes les marques SPARC sont utilisées sous licence et sont des marques de fabrique ou des marques déposées de SPARC International, Inc. aux Etats-Unis et dans d'autres pays. Les produits portant les marques SPARC sont basés sur une architecture développée par Sun Microsystems, Inc.

L'interface d'utilisation graphique OPEN LOOK et Sun™ a été développée par Sun Microsystems, Inc. pour ses utilisateurs et licenciés. Sun reconnaît les efforts de pionniers de Xerox pour la recherche et le développement du concept des interfaces d'utilisation visuelle ou graphique pour l'industrie de l'informatique. Sun détient une licence non exclusive de Xerox sur l'interface d'utilisation graphique Xerox, cette licence couvrant également les licenciés de Sun qui mettent en place l'interface d'utilisation graphique OPEN LOOK et qui en outre se conforment aux licences écrites de Sun.

CETTE PUBLICATION EST FOURNIE "EN L'ETAT" ET AUCUNE GARANTIE, EXPRESSE OU IMPLICITE, N'EST ACCORDEE, Y COMPRIS DES GARANTIES CONCERNANT LA VALEUR MARCHANDE, L'APTITUDE DE LA PUBLICATION A REpondre A UNE UTILISATION PARTICULIERE, OU LE FAIT QU'ELLE NE SOIT PAS CONTREFAISANTE DE PRODUIT DE TIERS. CE DENI DE GARANTIE NE S'APPLIQUERAIT PAS, DANS LA MESURE OU IL SERAIT TENU JURIDIQUEMENT NUL ET NON AVENU.

Index 2005

Preface

Both novice users and those familiar with the SunOS operating system can use online man pages to obtain information about the system and its features. A man page is intended to answer concisely the question “What does it do?” The man pages in general comprise a reference manual. They are not intended to be a tutorial.

Overview

The following contains a brief description of each man page section and the information it references:

- Section 1 describes, in alphabetical order, commands available with the operating system.
- Section 1M describes, in alphabetical order, commands that are used chiefly for system maintenance and administration purposes.
- Section 2 describes all of the system calls. Most of these calls have one or more error returns. An error condition is indicated by an otherwise impossible returned value.
- Section 3 describes functions found in various libraries, other than those functions that directly invoke UNIX system primitives, which are described in Section 2.
- Section 4 outlines the formats of various files. The C structure declarations for the file formats are given where applicable.
- Section 5 contains miscellaneous documentation such as character-set tables.
- Section 6 contains available games and demos.
- Section 7 describes various special files that refer to specific hardware peripherals and device drivers. STREAMS software drivers, modules and the STREAMS-generic set of system calls are also described.

- Section 9 provides reference information needed to write device drivers in the kernel environment. It describes two device driver interface specifications: the Device Driver Interface (DDI) and the Driver/Kernel Interface (DKI).
- Section 9E describes the DDI/DKI, DDI-only, and DKI-only entry-point routines a developer can include in a device driver.
- Section 9F describes the kernel functions available for use by device drivers.
- Section 9S describes the data structures used by drivers to share information between the driver and the kernel.

Below is a generic format for man pages. The man pages of each manual section generally follow this order, but include only needed headings. For example, if there are no bugs to report, there is no BUGS section. See the `intro` pages for more information and detail about each section, and `man(1)` for more information about man pages in general.

NAME	This section gives the names of the commands or functions documented, followed by a brief description of what they do.								
SYNOPSIS	<p>This section shows the syntax of commands or functions. When a command or file does not exist in the standard path, its full path name is shown. Options and arguments are alphabetized, with single letter arguments first, and options with arguments next, unless a different argument order is required.</p> <p>The following special characters are used in this section:</p> <table border="0" style="margin-left: 20px;"> <tr> <td style="padding-right: 10px;">[]</td> <td>Brackets. The option or argument enclosed in these brackets is optional. If the brackets are omitted, the argument must be specified.</td> </tr> <tr> <td style="padding-right: 10px;">. . .</td> <td>Ellipses. Several values can be provided for the previous argument, or the previous argument can be specified multiple times, for example, "filename . . .".</td> </tr> <tr> <td style="padding-right: 10px;"> </td> <td>Separator. Only one of the arguments separated by this character can be specified at a time.</td> </tr> <tr> <td style="padding-right: 10px;">{ }</td> <td>Braces. The options and/or arguments enclosed within braces are interdependent, such that everything enclosed must be treated as a unit.</td> </tr> </table>	[]	Brackets. The option or argument enclosed in these brackets is optional. If the brackets are omitted, the argument must be specified.	. . .	Ellipses. Several values can be provided for the previous argument, or the previous argument can be specified multiple times, for example, "filename . . .".		Separator. Only one of the arguments separated by this character can be specified at a time.	{ }	Braces. The options and/or arguments enclosed within braces are interdependent, such that everything enclosed must be treated as a unit.
[]	Brackets. The option or argument enclosed in these brackets is optional. If the brackets are omitted, the argument must be specified.								
. . .	Ellipses. Several values can be provided for the previous argument, or the previous argument can be specified multiple times, for example, "filename . . .".								
	Separator. Only one of the arguments separated by this character can be specified at a time.								
{ }	Braces. The options and/or arguments enclosed within braces are interdependent, such that everything enclosed must be treated as a unit.								

PROTOCOL	This section occurs only in subsection 3R to indicate the protocol description file.
DESCRIPTION	This section defines the functionality and behavior of the service. Thus it describes concisely what the command does. It does not discuss OPTIONS or cite EXAMPLES. Interactive commands, subcommands, requests, macros, and functions are described under USAGE.
IOCTL	This section appears on pages in Section 7 only. Only the device class that supplies appropriate parameters to the <code>ioctl(2)</code> system call is called <code>ioctl</code> and generates its own heading. <code>ioctl</code> calls for a specific device are listed alphabetically (on the man page for that specific device). <code>ioctl</code> calls are used for a particular class of devices all of which have an <code>io</code> ending, such as <code>mtio(7I)</code> .
OPTIONS	This section lists the command options with a concise summary of what each option does. The options are listed literally and in the order they appear in the SYNOPSIS section. Possible arguments to options are discussed under the option, and where appropriate, default values are supplied.
OPERANDS	This section lists the command operands and describes how they affect the actions of the command.
OUTPUT	This section describes the output – standard output, standard error, or output files – generated by the command.
RETURN VALUES	If the man page documents functions that return values, this section lists these values and describes the conditions under which they are returned. If a function can return only constant values, such as 0 or -1, these values are listed in tagged paragraphs. Otherwise, a single paragraph describes the return values of each function. Functions declared void do not return values, so they are not discussed in RETURN VALUES.
ERRORS	On failure, most functions place an error code in the global variable <code>errno</code> indicating why they failed. This section lists alphabetically all error codes a function can generate and describes the conditions that cause each error. When more than

	one condition can cause the same error, each condition is described in a separate paragraph under the error code.
USAGE	This section lists special rules, features, and commands that require in-depth explanations. The subsections listed here are used to explain built-in functionality: Commands Modifiers Variables Expressions Input Grammar
EXAMPLES	This section provides examples of usage or of how to use a command or function. Wherever possible a complete example including command-line entry and machine response is shown. Whenever an example is given, the prompt is shown as <code>example%</code> , or if the user must be superuser, <code>example#</code> . Examples are followed by explanations, variable substitution rules, or returned values. Most examples illustrate concepts from the SYNOPSIS, DESCRIPTION, OPTIONS, and USAGE sections.
ENVIRONMENT VARIABLES	This section lists any environment variables that the command or function affects, followed by a brief description of the effect.
EXIT STATUS	This section lists the values the command returns to the calling program or shell and the conditions that cause these values to be returned. Usually, zero is returned for successful completion, and values other than zero for various error conditions.
FILES	This section lists all file names referred to by the man page, files of interest, and files created or required by commands. Each is followed by a descriptive summary or explanation.
ATTRIBUTES	This section lists characteristics of commands, utilities, and device drivers by defining the attribute type and its corresponding value. See <code>attributes(5)</code> for more information.
SEE ALSO	This section lists references to other man pages, in-house documentation, and outside publications.

DIAGNOSTICS	This section lists diagnostic messages with a brief explanation of the condition causing the error.
WARNINGS	This section lists warnings about special conditions which could seriously affect your working conditions. This is not a list of diagnostics.
NOTES	This section lists additional information that does not belong anywhere else on the page. It takes the form of an aside to the user, covering points of special interest. Critical information is never covered here.
BUGS	This section describes known bugs and, wherever possible, suggests workarounds.

Basic Library Functions

a64l(3C)

NAME a64l, l64a – convert between long integer and base-64 ASCII string

SYNOPSIS

```
#include <stdlib.h>

long a64l(const char *s);
char *l64a(long l);
```

DESCRIPTION These functions maintain numbers stored in base-64 ASCII characters that define a notation by which long integers can be represented by up to six characters. Each character represents a “digit” in a radix-64 notation.

The characters used to represent “digits” are as follows:

Character	Digit
.	0
/	1
0-9	2-11
A-Z	12-37
a-z	38-63

The a64l () function takes a pointer to a null-terminated base-64 representation and returns a corresponding long value. If the string pointed to by s contains more than six characters, a64l () uses the first six.

The a64l () function scans the character string from left to right with the least significant digit on the left, decoding each character as a 6-bit radix-64 number.

The l64a () function takes a long argument and returns a pointer to the corresponding base-64 representation. If the argument is 0, l64a () returns a pointer to a null string.

The value returned by l64a () is a pointer into a static buffer, the contents of which are overwritten by each call. In the case of multithreaded applications, the return value is a pointer to thread specific data.

ATTRIBUTES See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
MT-Level	MT-Safe

SEE ALSO attributes(5)

NAME	abort – terminate the process abnormally				
SYNOPSIS	<pre>#include <stdlib.h> void abort(void);</pre>				
DESCRIPTION	<p>The <code>abort()</code> function causes abnormal process termination to occur, unless the signal <code>SIGABRT</code> is being caught and the signal handler does not return. The abnormal termination processing includes at least the effect of <code>fclose(3C)</code> on all open streams and message catalogue descriptors, and the default actions defined for <code>SIGABRT</code>. The <code>SIGABRT</code> signal is sent to the calling process as if by means of the <code>raise(3C)</code> function with the argument <code>SIGABRT</code>.</p> <p>The status made available to <code>wait(2)</code> or <code>waitpid(2)</code> by <code>abort</code> will be that of a process terminated by the <code>SIGABRT</code> signal. <code>abort</code> will override blocking or ignoring the <code>SIGABRT</code> signal.</p>				
RETURN VALUES	The <code>abort()</code> function does not return.				
ERRORS	No errors are defined.				
USAGE	Catching the signal is intended to provide the application writer with a portable means to abort processing, free from possible interference from any implementation-provided library functions. If <code>SIGABRT</code> is neither caught nor ignored, and the current directory is writable, a core dump may be produced.				
ATTRIBUTES	See <code>attributes(5)</code> for descriptions of the following attributes:				
	<table border="1" style="width: 100%; border-collapse: collapse;"> <thead> <tr> <th style="text-align: center;">ATTRIBUTE TYPE</th> <th style="text-align: center;">ATTRIBUTE VALUE</th> </tr> </thead> <tbody> <tr> <td>MT-Level</td> <td>Safe</td> </tr> </tbody> </table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	MT-Level	Safe
ATTRIBUTE TYPE	ATTRIBUTE VALUE				
MT-Level	Safe				
SEE ALSO	<code>exit(2)</code> , <code>getrlimit(2)</code> , <code>kill(2)</code> , <code>wait(2)</code> , <code>waitpid(2)</code> , <code>fclose(3C)</code> , <code>raise(3C)</code> , <code>signal(3C)</code> , <code>attributes(5)</code>				

abs(3C)

NAME abs, labs, llabs – return absolute value of integer

SYNOPSIS

```
#include <stdlib.h>
int abs(int val);
long labs(long lval);
long long llabs(long long llval);
```

DESCRIPTION The `abs()` function returns the absolute value of its `int` operand.
The `labs()` function returns the absolute value of its `long` operand.
The `llabs()` function returns the absolute value of its `long long` operand.

USAGE In 2's-complement representation, the absolute value of the largest magnitude negative integral value is undefined.

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
MT-Level	MT-Safe

SEE ALSO `attributes(5)`

NAME	addsev – define additional severities				
SYNOPSIS	<pre>#include <pfmt.h> int addsev(int <i>int_val</i>, const char *<i>string</i>);</pre>				
DESCRIPTION	<p>The <code>addsev()</code> function defines additional severities for use in subsequent calls to <code>pfmt(3C)</code> or <code>lfmt(3C)</code>. It associates an integer value <code>int_val</code> in the range [5-255] with a character <code>string</code>, overwriting any previous string association between <code>int_val</code> and <code>string</code>.</p> <p>If <code>int_val</code> is OR-ed with the <code>flags</code> argument passed to subsequent calls to <code>pfmt()</code> or <code>lfmt()</code>, <code>string</code> will be used as severity. Passing a null <code>string</code> removes the severity.</p>				
RETURN VALUES	Upon successful completion, <code>addsev()</code> returns 0. Otherwise it returns -1.				
USAGE	Only the standard severities are automatically displayed for the locale in effect at runtime. An application must provide the means for displaying locale-specific versions of add-on severities. Add-on severities are only effective within the applications defining them.				
EXAMPLES	<p>EXAMPLE 1 Example of <code>addsev()</code> function.</p> <p>The following example</p> <pre>#define Panic 5 setlabel("APPL"); setcat("my_appl"); addsev(Panic, gettext(":26", "PANIC")); /* . . . */ lfmt(stderr, MM_SOFT MM_APPL PANIC, ":12:Cannot locate database\n");</pre> <p>will display the message to <code>stderr</code> and forward to the logging service</p> <pre>APPL: PANIC: Cannot locate database</pre>				
ATTRIBUTES	See <code>attributes(5)</code> for descriptions of the following attributes:				
	<table border="1" style="width: 100%; border-collapse: collapse;"> <thead> <tr> <th style="text-align: center;">ATTRIBUTE TYPE</th> <th style="text-align: center;">ATTRIBUTE VALUE</th> </tr> </thead> <tbody> <tr> <td style="text-align: center;">MT-Level</td> <td style="text-align: center;">MT-safe</td> </tr> </tbody> </table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	MT-Level	MT-safe
ATTRIBUTE TYPE	ATTRIBUTE VALUE				
MT-Level	MT-safe				
SEE ALSO	<code>gettext(3C)</code> , <code>lfmt(3C)</code> , <code>pfmt(3C)</code> , <code>attributes(5)</code>				

addseverity(3C)

NAME	addseverity – build a list of severity levels for an application for use with <code>fmtmsg</code>										
SYNOPSIS	<pre>#include <fmtmsg.h> int addseverity(int <i>severity</i>, const char *<i>string</i>);</pre>										
DESCRIPTION	<p>The <code>addseverity()</code> function builds a list of severity levels for an application to be used with the message formatting facility <code>fmtmsg()</code>. The <i>severity</i> argument is an integer value indicating the seriousness of the condition. The <i>string</i> argument is a pointer to a string describing the condition (string is not limited to a specific size).</p> <p>If <code>addseverity()</code> is called with an integer value that has not been previously defined, the function adds that new severity value and print string to the existing set of standard severity levels.</p> <p>If <code>addseverity()</code> is called with an integer value that has been previously defined, the function redefines that value with the new print string. Previously defined severity levels may be removed by supplying the null string. If <code>addseverity()</code> is called with a negative number or an integer value of 0, 1, 2, 3, or 4, the function fails and returns -1. The values 0–4 are reserved for the standard severity levels and cannot be modified. Identifiers for the standard levels of severity are:</p> <table><tr><td><code>MM_HALT</code></td><td>Indicates that the application has encountered a severe fault and is halting. Produces the print string <code>HALT</code>.</td></tr><tr><td><code>MM_ERROR</code></td><td>Indicates that the application has detected a fault. Produces the print string <code>ERROR</code>.</td></tr><tr><td><code>MM_WARNING</code></td><td>Indicates a condition that is out of the ordinary, that might be a problem, and should be watched. Produces the print string <code>WARNING</code>.</td></tr><tr><td><code>MM_INFO</code></td><td>Provides information about a condition that is not in error. Produces the print string <code>INFO</code>.</td></tr><tr><td><code>MM_NOSEV</code></td><td>Indicates that no severity level is supplied for the message.</td></tr></table> <p>Severity levels may also be defined at run time using the <code>SEV_LEVEL</code> environment variable (see <code>fmtmsg(3C)</code>).</p>	<code>MM_HALT</code>	Indicates that the application has encountered a severe fault and is halting. Produces the print string <code>HALT</code> .	<code>MM_ERROR</code>	Indicates that the application has detected a fault. Produces the print string <code>ERROR</code> .	<code>MM_WARNING</code>	Indicates a condition that is out of the ordinary, that might be a problem, and should be watched. Produces the print string <code>WARNING</code> .	<code>MM_INFO</code>	Provides information about a condition that is not in error. Produces the print string <code>INFO</code> .	<code>MM_NOSEV</code>	Indicates that no severity level is supplied for the message.
<code>MM_HALT</code>	Indicates that the application has encountered a severe fault and is halting. Produces the print string <code>HALT</code> .										
<code>MM_ERROR</code>	Indicates that the application has detected a fault. Produces the print string <code>ERROR</code> .										
<code>MM_WARNING</code>	Indicates a condition that is out of the ordinary, that might be a problem, and should be watched. Produces the print string <code>WARNING</code> .										
<code>MM_INFO</code>	Provides information about a condition that is not in error. Produces the print string <code>INFO</code> .										
<code>MM_NOSEV</code>	Indicates that no severity level is supplied for the message.										
RETURN VALUES	Upon successful completion, <code>addseverity()</code> returns <code>MM_OK</code> . Otherwise it returns <code>MM_NOTOK</code> .										
EXAMPLES	<p>EXAMPLE 1 Example of <code>addseverity()</code> function.</p> <p>When the function call</p> <pre>addseverity(7, "ALERT")</pre> <p>is followed by the call</p> <pre>fmtmsg(MM_PRINT, "UX:cat", 7, "invalid syntax", "refer to manual", "UX:cat:001")</pre>										

EXAMPLE 1 Example of addseverity() function. (Continued)

the resulting output is

```
UX:cat: ALERT: invalid syntax
TO FIX: refer to manual   UX:cat:001
```

ATTRIBUTES See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
MT-Level	Safe

SEE ALSO fmtmsg(1), fmtmsg(3C), gettxt(3C), printf(3C), attributes(5)

alloca(3C)

NAME	malloc, calloc, free, memalign, realloc, valloc, alloca – memory allocator
SYNOPSIS	<pre>#include <stdlib.h> void *malloc(size_t size); void *calloc(size_t nelem, size_t elsize); void free(void *ptr); void *memalign(size_t alignment, size_t size); void *realloc(void *ptr, size_t size); void *valloc(size_t size); #include <alloca.h> void *alloca(size_t size);</pre>
DESCRIPTION	<p>The <code>malloc()</code> and <code>free()</code> functions provide a simple, general-purpose memory allocation package. The <code>malloc()</code> function returns a pointer to a block of at least <i>size</i> bytes suitably aligned for any use. If the space assigned by <code>malloc()</code> is overrun, the results are undefined.</p> <p>The argument to <code>free()</code> is a pointer to a block previously allocated by <code>malloc()</code>, <code>calloc()</code>, or <code>realloc()</code>. After <code>free()</code> is executed, this space is made available for further allocation by the application, though not returned to the system. Memory is returned to the system only upon termination of the application. If <i>ptr</i> is a null pointer, no action occurs. If a random number is passed to <code>free()</code>, the results are undefined.</p> <p>The <code>calloc()</code> function allocates space for an array of <i>nelem</i> elements of size <i>elsize</i>. The space is initialized to zeros.</p> <p>The <code>memalign()</code> function allocates <i>size</i> bytes on a specified alignment boundary and returns a pointer to the allocated block. The value of the returned address is guaranteed to be an even multiple of <i>alignment</i>. The value of <i>alignment</i> must be a power of two and must be greater than or equal to the size of a word.</p> <p>The <code>realloc()</code> function changes the size of the block pointed to by <i>ptr</i> to <i>size</i> bytes and returns a pointer to the (possibly moved) block. The contents will be unchanged up to the lesser of the new and old sizes. If <i>ptr</i> is NULL, <code>realloc()</code> behaves like <code>malloc()</code> for the specified size. If <i>size</i> is 0 and <i>ptr</i> is not a null pointer, the space pointed to is made available for further allocation by the application, though not returned to the system. Memory is returned to the system only upon termination of the application.</p> <p>The <code>valloc()</code> function has the same effect as <code>malloc()</code>, except that the allocated memory will be aligned to a multiple of the value returned by <code>sysconf(_SC_PAGESIZE)</code>.</p>

The `alloca()` function allocates *size* bytes of space in the stack frame of the caller, and returns a pointer to the allocated block. This temporary space is automatically freed when the caller returns. If the allocated block is beyond the current stack limit, the resulting behavior is undefined.

RETURN VALUES Upon successful completion, each of the allocation functions returns a pointer to space suitably aligned (after possible pointer coercion) for storage of any type of object.

If there is no available memory, `malloc()`, `realloc()`, `memalign()`, `valloc()`, and `calloc()` return a null pointer. When `realloc()` is called with *size* > 0 and returns `NULL`, the block pointed to by *ptr* is left intact. If *size*, *nelem*, or *elsize* is 0, either a null pointer or a unique pointer that can be passed to `free()` is returned.

If `malloc()`, `calloc()`, or `realloc()` returns unsuccessfully, `errno` will be set to indicate the error. The `free()` function does not set `errno`.

ERRORS The `malloc()`, `calloc()`, and `realloc()` functions will fail if:

- `ENOMEM` The physical limits of the system are exceeded by *size* bytes of memory which cannot be allocated.
- `EAGAIN` There is not enough memory available to allocate *size* bytes of memory; but the application could try again later.

USAGE Portable applications should avoid using `valloc()` but should instead use `malloc()` or `mmap(2)`. On systems with a large page size, the number of successful `valloc()` operations might be 0.

Comparative features of `malloc(3C)`, `bsdmalloc(3MALLOC)`, and `malloc(3MALLOC)` are as follows:

- The `bsdmalloc(3MALLOC)` routines afford better performance, but are space-inefficient.
- The `malloc(3MALLOC)` routines are space-efficient, but have slower performance.
- The standard, fully SCD-compliant `malloc` routines are a trade-off between performance and space-efficiency.

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Interface Stability	<code>malloc()</code> , <code>calloc()</code> , <code>free()</code> , <code>realloc()</code> , <code>valloc()</code> are Standard; <code>memalign()</code> and <code>alloca()</code> are Stable.
MT-Level	Safe

SEE ALSO `brk(2)`, `getrlimit(2)`, `bsdmalloc(3MALLOC)`, `malloc(3MALLOC)`, `mapmalloc(3MALLOC)`, `watchmalloc(3MALLOC)`, `attributes(5)`

alloca(3C)

WARNINGS Undefined results will occur if the size requested for a block of memory exceeds the maximum size of a process's heap, which can be obtained with `getrlimit(2)`

The `alloca()` function is machine-, compiler-, and most of all, system-dependent. Its use is strongly discouraged.

NAME	scandir, alphasort – scan a directory
SYNOPSIS	<pre> /usr/ucb/cc [flag...] file... #include <sys/types.h> #include <sys/dir.h> int scandir(dirname, namelist, select, dcomp); char *dirname; struct direct *(*namelist[]); int (*select(.), (*dcomp)()); int alphasort(d1, d2); struct direct **d1, **d2; </pre>
DESCRIPTION	<p>The <code>scandir()</code> function reads the directory <i>dirname</i> and builds an array of pointers to directory entries using <code>malloc(3C)</code>. The second parameter is a pointer to an array of structure pointers. The third parameter is a pointer to a routine which is called with a pointer to a directory entry and should return a non zero value if the directory entry should be included in the array. If this pointer is <code>NULL</code>, then all the directory entries will be included. The last argument is a pointer to a routine which is passed to <code>qsort(3C)</code>, which sorts the completed array. If this pointer is <code>NULL</code>, the array is not sorted.</p> <p>The <code>alphasort()</code> function sorts the array alphabetically.</p>
RETURN VALUES	<p>The <code>scandir()</code> function returns the number of entries in the array and a pointer to the array through the parameter <i>namelist</i>. The <code>scandir()</code> function returns <code>-1</code> if the directory cannot be opened for reading or if <code>malloc(3C)</code> cannot allocate enough memory to hold all the data structures.</p> <p>The <code>alphasort()</code> function returns an integer greater than, equal to, or less than 0 if the directory entry name pointed to by <i>d1</i> is greater than, equal to, or less than the directory entry name pointed to by <i>d2</i>.</p>
USAGE	The <code>scandir()</code> and <code>alphasort()</code> functions have transitional interfaces for 64-bit file offsets. See <code>lf64(5)</code> .
SEE ALSO	<code>getdents(2)</code> , <code>malloc(3C)</code> , <code>qsort(3C)</code> , <code>readdir(3UCB)</code> , <code>readdir(3C)</code> , <code>lf64(5)</code>
NOTES	Use of these functions should be restricted to applications written on BSD platforms. Use of these functions with any of the system libraries or in multithreaded applications is unsupported.

asctime(3C)

NAME	strftime, cftime, asctime – convert date and time to string																						
SYNOPSIS	<pre>#include <time.h> size_t strftime(char *s, size_t <i>maxsize</i>, const char *<i>format</i>, const struct tm *<i>timeptr</i>); int cftime(char *s, char *<i>format</i>, const time_t *<i>clock</i>); int asctime(char *s, const char *<i>format</i>, const struct tm *<i>timeptr</i>);</pre>																						
DESCRIPTION	<p>The <code>strftime()</code>, <code>asctime()</code>, and <code>cftime()</code> functions place bytes into the array pointed to by <i>s</i> as controlled by the string pointed to by <i>format</i>. The <i>format</i> string consists of zero or more conversion specifications and ordinary characters. A conversion specification consists of a '%' (percent) character and one or two terminating conversion characters that determine the conversion specification's behavior. All ordinary characters (including the terminating null byte) are copied unchanged into the array pointed to by <i>s</i>. If copying takes place between objects that overlap, the behavior is undefined. For <code>strftime()</code>, no more than <i>maxsize</i> bytes are placed into the array.</p> <p>If <i>format</i> is <code>(char *)0</code>, then the locale's default format is used. For <code>strftime()</code> the default format is the same as <code>%c</code>; for <code>cftime()</code> and <code>asctime()</code> the default format is the same as <code>%C</code>. <code>cftime()</code> and <code>asctime()</code> first try to use the value of the environment variable <code>CFTIME</code>, and if that is undefined or empty, the default format is used.</p> <p>Each conversion specification is replaced by appropriate characters as described in the following list. The appropriate characters are determined by the <code>LC_TIME</code> category of the program's locale and by the values contained in the structure pointed to by <i>timeptr</i> for <code>strftime()</code> and <code>asctime()</code>, and by the time represented by <i>clock</i> for <code>cftime()</code>.</p> <table border="0" style="width: 100%;"> <tr> <td style="padding-right: 20px;">%%</td> <td>Same as %.</td> </tr> <tr> <td>%a</td> <td>Locale's abbreviated weekday name.</td> </tr> <tr> <td>%A</td> <td>Locale's full weekday name.</td> </tr> <tr> <td>%b</td> <td>Locale's abbreviated month name.</td> </tr> <tr> <td>%B</td> <td>Locale's full month name.</td> </tr> <tr> <td>%c</td> <td>Locale's appropriate date and time representation.</td> </tr> <tr> <td>Default %C</td> <td>Locale's date and time representation as produced by <code>date(1)</code>.</td> </tr> <tr> <td>Standard conforming %C</td> <td>Century number (the year divided by 100 and truncated to an integer as a decimal number [1,99]); single digits are preceded by 0; see <code>standards(5)</code>.</td> </tr> <tr> <td>%d</td> <td>Day of month [1,31]; single digits are preceded by 0.</td> </tr> <tr> <td>%D</td> <td>Date as <code>%m/%d/%y</code>.</td> </tr> <tr> <td>%e</td> <td>Day of month [1,31]; single digits are preceded by a space.</td> </tr> </table>	%%	Same as %.	%a	Locale's abbreviated weekday name.	%A	Locale's full weekday name.	%b	Locale's abbreviated month name.	%B	Locale's full month name.	%c	Locale's appropriate date and time representation.	Default %C	Locale's date and time representation as produced by <code>date(1)</code> .	Standard conforming %C	Century number (the year divided by 100 and truncated to an integer as a decimal number [1,99]); single digits are preceded by 0; see <code>standards(5)</code> .	%d	Day of month [1,31]; single digits are preceded by 0.	%D	Date as <code>%m/%d/%y</code> .	%e	Day of month [1,31]; single digits are preceded by a space.
%%	Same as %.																						
%a	Locale's abbreviated weekday name.																						
%A	Locale's full weekday name.																						
%b	Locale's abbreviated month name.																						
%B	Locale's full month name.																						
%c	Locale's appropriate date and time representation.																						
Default %C	Locale's date and time representation as produced by <code>date(1)</code> .																						
Standard conforming %C	Century number (the year divided by 100 and truncated to an integer as a decimal number [1,99]); single digits are preceded by 0; see <code>standards(5)</code> .																						
%d	Day of month [1,31]; single digits are preceded by 0.																						
%D	Date as <code>%m/%d/%y</code> .																						
%e	Day of month [1,31]; single digits are preceded by a space.																						

%g	Week-based year within century [00,99].
%G	Week-based year, including the century [0000,9999].
%h	Locale's abbreviated month name.
%H	Hour (24-hour clock) [0,23]; single digits are preceded by 0.
%I	Hour (12-hour clock) [1,12]; single digits are preceded by 0.
%j	Day number of year [1,366]; single digits are preceded by 0.
%k	Hour (24-hour clock) [0,23]; single digits are preceded by a blank.
%l	Hour (12-hour clock) [1,12]; single digits are preceded by a blank.
%m	Month number [1,12]; single digits are preceded by 0.
%M	Minute [00,59]; leading 0 is permitted but not required.
%n	Insert a NEWLINE.
%p	Locale's equivalent of either a.m. or p.m.
%r	Appropriate time representation in 12-hour clock format with %p.
%R	Time as %H:%M.
%S	Seconds [00,61]; the range of values is [00,61] rather than [00,59] to allow for the occasional leap second and even more occasional double leap second.
%t	Insert a TAB.
%T	Time as %H:%M:%S.
%u	Weekday as a decimal number [1,7], with 1 representing Monday. See NOTES below.
%U	Week number of year as a decimal number [00,53], with Sunday as the first day of week 1.
%V	The ISO 8601 week number as a decimal number [01,53]. In the ISO 8601 week-based system, weeks begin on a Monday and week 1 of the year is the week that includes both January 4th and the first Thursday of the year. If the first Monday of January is the 2nd, 3rd, or 4th, the preceding days are part of the last week of the preceding year. See NOTES below.
%w	Weekday as a decimal number [0,6], with 0 representing Sunday.
%W	Week number of year as a decimal number [00,53], with Monday as the first day of week 1.
%x	Locale's appropriate date representation.
%X	Locale's appropriate time representation.
%y	Year within century [00,99].

asctime(3C)

%Y Year, including the century (for example 1993).
%Z Time zone name or abbreviation, or no bytes if no time zone information exists.

If a conversion specification does not correspond to any of the above or to any of the modified conversion specifications listed below, the behavior is undefined and 0 is returned.

The difference between %U and %W (and also between modified conversion specifications %OU and %OW) lies in which day is counted as the first of the week. Week number 1 is the first week in January starting with a Sunday for %U or a Monday for %W. Week number 0 contains those days before the first Sunday or Monday in January for %U and %W, respectively.

Modified Conversion Specifications

Some conversion specifications can be modified by the E and O modifiers to indicate that an alternate format or specification should be used rather than the one normally used by the unmodified conversion specification. If the alternate format or specification does not exist in the current locale, the behavior will be as if the unmodified specification were used.

%Ec Locale's alternate appropriate date and time representation.
%EC Name of the base year (period) in the locale's alternate representation.
%Eg Offset from %EC of the week-based year in the locale's alternative representation.
%EG Full alternative representation of the week-based year.
%Ex Locale's alternate date representation.
%EX Locale's alternate time representation.
%Ey Offset from %EC (year only) in the locale's alternate representation.
%EY Full alternate year representation.
%Od Day of the month using the locale's alternate numeric symbols.
%Oe Same as %Od.
%Og Week-based year (offset from %C) in the locale's alternate representation and using the locale's alternate numeric symbols.
%OH Hour (24-hour clock) using the locale's alternate numeric symbols.
%OI Hour (12-hour clock) using the locale's alternate numeric symbols.
%Om Month using the locale's alternate numeric symbols.
%OM Minutes using the locale's alternate numeric symbols.
%OS Seconds using the locale's alternate numeric symbols.
%Ou Weekday as a number in the locale's alternate numeric symbols.

%OU	Week number of the year (Sunday as the first day of the week) using the locale's alternate numeric symbols.
%Ow	Number of the weekday (Sunday=0) using the locale's alternate numeric symbols.
%OW	Week number of the year (Monday as the first day of the week) using the locale's alternate numeric symbols.
%Oy	Year (offset from %C) in the locale's alternate representation and using the locale's alternate numeric symbols.

Selecting the Output Language

By default, the output of `strftime()`, `cftime()`, and `ascftime()` appear in U.S. English. The user can request that the output of `strftime()`, `cftime()`, or `ascftime()` be in a specific language by setting the `LC_TIME` category using `setlocale()`.

Time Zone

Local time zone information is used as though `tzset(3C)` were called.

RETURN VALUES

The `strftime()`, `cftime()`, and `ascftime()` functions return the number of characters placed into the array pointed to by `s`, not including the terminating null character. If the total number of resulting characters including the terminating null character is more than `maxsize`, `strftime()` returns 0 and the contents of the array are indeterminate.

EXAMPLES

EXAMPLE 1 An example of the `strftime()` function.

The following example illustrates the use of `strftime()` for the POSIX locale. It shows what the string in `str` would look like if the structure pointed to by `tmpr` contains the values corresponding to Thursday, August 28, 1986 at 12:44:36.

```
strftime (str, strsize, "%A %b %d %j", tmpr)
```

This results in `str` containing "Thursday Aug 28 240".

asctime(3C)

NOTES | The conversion specification for %V was changed in the Solaris 7 release. This change was based on the public review draft of the ISO C9x standard at that time. Previously, the specification stated that if the week containing 1 January had fewer than four days in the new year, it became week 53 of the previous year. The ISO C9x standard committee subsequently recognized that that specification had been incorrect.

The conversion specifications for %g, %G, %Eg, %EG, and %Og were added in the Solaris 7 release. This change was based on the public review draft of the ISO C9x standard at that time. These specifications are evolving. If the ISO C9x standard is finalized with a different conclusion, these specifications will change to conform to the ISO C9x standard decision.

The conversion specification for %u was changed in the Solaris 8 release. This change was based on the XPG4 specification.

If using the %Z specifier and `zoneinfo` timezones and if the input date is outside the range 20:45:52 UTC, December 13, 1901 to 03:14:07 UTC, January 19, 2038, the timezone name may not be correct.

NAME	ctime, ctime_r, localtime, localtime_r, gmtime, gmtime_r, asctime, asctime_r, tzset – convert date and time to string
SYNOPSIS	<pre>#include <time.h> char *ctime(const time_t *clock); struct tm *localtime(const time_t *clock); struct tm *gmtime(const time_t *clock); char *asctime(const struct tm *tm); extern time_t timezone, altzone; extern int daylight; extern char *tzname[2]; void tzset(void); char *ctime_r(const time_t *clock, char *buf, int buflen); struct tm *localtime_r(const time_t *clock, struct tm *res); struct tm *gmtime_r(const time_t *clock, struct tm *res); char *asctime_r(const struct tm *tm, char *buf, int buflen);</pre>
POSIX	<pre>cc [flag...] file... -D_POSIX_PTHREAD_SEMANTICS [library...] char *ctime_r(const time_t *clock, char *buf); char *asctime_r(const struct tm *tm, char *buf);</pre>
DESCRIPTION	<p>The <code>ctime()</code> function converts the time pointed to by <code>clock</code>, representing the time in seconds since the Epoch (00:00:00 UTC, January 1, 1970), to local time in the form of a 26-character string, as shown below. Time zone and daylight savings corrections are made before string generation. The fields are in constant width:</p> <pre>Fri Sep 13 00:00:00 1986\n\0</pre> <p>The <code>ctime()</code> function is equivalent to:</p> <pre>asctime(localtime(clock))</pre> <p>The <code>ctime()</code>, <code>asctime()</code>, <code>gmtime()</code>, and <code>localtime()</code> functions return values in one of two static objects: a broken-down time structure and an array of <code>char</code>. Execution of any of the functions can overwrite the information returned in either of these objects by any of the other functions.</p> <p>The <code>ctime_r()</code> function has the same functionality as <code>ctime()</code> except that the caller must supply a buffer <code>buf</code> with length <code>buflen</code> to store the result; <code>buf</code> must be at least 26 bytes. The POSIX <code>ctime_r()</code> function does not take a <code>buflen</code> parameter.</p>

asctime(3C)

The `localtime()` and `gmtime()` functions return pointers to `tm` structures (see below). The `localtime()` function corrects for the main time zone and possible alternate (“daylight savings”) time zone; the `gmtime()` function converts directly to Coordinated Universal Time (UTC), which is what the UNIX system uses internally.

The `localtime_r()` and `gmtime_r()` functions have the same functionality as `localtime()` and `gmtime()` respectively, except that the caller must supply a buffer *res* to store the result.

The `asctime()` function converts a `tm` structure to a 26-character string, as shown in the previous example, and returns a pointer to the string.

The `asctime_r()` function has the same functionality as `asctime()` except that the caller must supply a buffer *buf* with length *buflen* for the result to be stored. The *buf* argument must be at least 26 bytes. The POSIX `asctime_r()` function does not take a *buflen* parameter. The `asctime_r()` function returns a pointer to *buf* upon success. In case of failure, `NULL` is returned and `errno` is set.

Declarations of all the functions and externals, and the `tm` structure, are in the `<time.h>` header. The members of the `tm` structure are:

```
int    tm_sec;    /* seconds after the minute - [0, 61] */
        /* for leap seconds */
int    tm_min;    /* minutes after the hour - [0, 59] */
int    tm_hour;   /* hour since midnight - [0, 23] */
int    tm_mday;   /* day of the month - [1, 31] */
int    tm_mon;    /* months since January - [0, 11] */
int    tm_year;   /* years since 1900 */
int    tm_wday;   /* days since Sunday - [0, 6] */
int    tm_yday;   /* days since January 1 - [0, 365] */
int    tm_isdst;  /* flag for alternate daylight savings time */
```

The value of `tm_isdst` is positive if daylight savings time is in effect, zero if daylight savings time is not in effect, and negative if the information is not available. Previously, the value of `tm_isdst` was defined as non-zero if daylight savings was in effect.

The external `time_t` variable `altzone` contains the difference, in seconds, between Coordinated Universal Time and the alternate time zone. The external variable `timezone` contains the difference, in seconds, between UTC and local standard time. The external variable `daylight` indicates whether time should reflect daylight savings time. Both `timezone` and `altzone` default to 0 (UTC). The external variable `daylight` is non-zero if an alternate time zone exists. The time zone names are contained in the external variable `tzname`, which by default is set to:

```
char *tzname[2] = { "GMT", "" };
```

These functions know about the peculiarities of this conversion for various time periods for the U.S. (specifically, the years 1974, 1975, and 1987). They start handling the new daylight savings time starting with the first Sunday in April, 1987.

The `tzset()` function uses the contents of the environment variable `TZ` to override the value of the different external variables. It is called by `asctime()` and can also be called by the user. See `environ(5)` for a description of the `TZ` environment variable.

Starting and ending times are relative to the current local time zone. If the alternate time zone start and end dates and the time are not provided, the days for the United States that year will be used and the time will be 2 AM. If the start and end dates are provided but the time is not provided, the time will be 2 AM. The effects of `tzset()` change the values of the external variables `timezone`, `altzone`, `daylight`, and `tzname`.

Note that in most installations, `TZ` is set to the correct value by default when the user logs on, using the local `/etc/default/init` file (see `TIMEZONE(4)`).

ERRORS The `ctime_r()` and `asctime_r()` functions will fail if:

ERANGE The length of the buffer supplied by the caller is not large enough to store the result.

USAGE These functions do not support localized date and time formats. The `strftime(3C)` function can be used when localization is required.

The `localtime()`, `localtime_r()`, `gmtime()`, `gmtime_r()`, `ctime()`, and `ctime_r()` functions assume Gregorian dates. Times before the adoption of the Gregorian calendar will not match historical records.

EXAMPLES **EXAMPLE 1** Examples of the `tzset()` function.

The `tzset()` function scans the contents of the environment variable and assigns the different fields to the respective variable. For example, the most complete setting for New Jersey in 1986 could be:

```
EST5EDT4,116/2:00:00,298/2:00:00
```

or simply

```
EST5EDT
```

An example of a southern hemisphere setting such as the Cook Islands could be

```
KDT9:30KST10:00,63/5:00,302/20:00
```

In the longer version of the New Jersey example of `TZ`, `tzname[0]` is `EST`, `timezone` is set to `5*60*60`, `tzname[1]` is `EDT`, `altzone` is set to `4*60*60`, the starting date of the alternate time zone is the 117th day at 2 AM, the ending date of the alternate time zone is the 299th day at 2 AM (using zero-based Julian days), and `daylight` is set positive. Starting and ending times are relative to the current local time zone. If the alternate time zone start and end dates and the time are not provided, the days for the United States that year will be used and the time will be 2 AM. If the start and end dates are provided but the time is not provided, the time will be 2 AM. The effects of `tzset()` are thus to change the values of the external variables `timezone`, `altzone`, `daylight`, and `tzname`. The `ctime()`, `localtime()`, `mktime()`, and `strftime()` functions also update these external variables as if they had called `tzset()` at the

asctime(3C)

EXAMPLE 1 Examples of the `tzset()` function. (Continued)

time specified by the `time_t` or `struct tm` value that they are converting.

BUGS The `zoneinfo` timezone data files do not transition past Tue Jan 19 03:14:07 2038 UTC. Therefore for 64-bit applications using `zoneinfo` timezones, calculations beyond this date might not use the correct offset from standard time, and could return incorrect values. This affects the 64-bit version of `localtime()`, `localtime_r()`, `ctime()`, and `ctime_r()`.

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
MT-Level	MT-Safe with exceptions
CSI	Enabled

SEE ALSO `time(2)`, `Intro(3)`, `getenv(3C)`, `mktime(3C)`, `printf(3C)`, `putenv(3C)`, `setlocale(3C)`, `strftime(3C)`, `TIMEZONE(4)`, `attributes(5)`, `environ(5)`

NOTES When compiling multithreaded programs, see `Intro(3)`, *Notes On Multithreaded Applications*.

The return values for `ctime()`, `localtime()`, and `gmtime()` point to static data whose content is overwritten by each call.

Setting the time during the interval of change from `timezone` to `altzone` or vice versa can produce unpredictable results. The system administrator must change the Julian start and end days annually.

The `asctime()`, `ctime()`, `gmtime()`, and `localtime()` functions are unsafe in multithread applications. The `asctime_r()` and `gmtime_r()` functions are MT-Safe. The `ctime_r()`, `localtime_r()`, and `tzset()` functions are MT-Safe in multithread applications, as long as no user-defined function directly modifies one of the following variables: `timezone`, `altzone`, `daylight`, and `tzname`. These four variables are not MT-Safe to access. They are modified by the `tzset()` function in an MT-Safe manner. The `mktime()`, `localtime_r()`, and `ctime_r()` functions call `tzset()`.

Solaris 2.4 and earlier releases provided definitions of the `ctime_r()`, `localtime_r()`, `gmtime_r()`, and `asctime_r()` functions as specified in POSIX.1c Draft 6. The final POSIX.1c standard changed the interface for `ctime_r()` and `asctime_r()`. Support for the Draft 6 interface is provided for compatibility only and might not be supported in future releases. New applications and libraries should use the POSIX standard interface.

asctime(3C)

For POSIX.1c-compliant applications, the `_POSIX_PTHREAD_SEMANTICS` and `_REENTRANT` flags are automatically turned on by defining the `_POSIX_C_SOURCE` flag with a value `>= 199506L`.

asctime_r(3C)

NAME	ctime, ctime_r, localtime, localtime_r, gmtime, gmtime_r, asctime, asctime_r, tzset – convert date and time to string
SYNOPSIS	<pre>#include <time.h> char *ctime(const time_t *clock); struct tm *localtime(const time_t *clock); struct tm *gmtime(const time_t *clock); char *asctime(const struct tm *tm); extern time_t timezone, altzone; extern int daylight; extern char *tzname[2]; void tzset(void); char *ctime_r(const time_t *clock, char *buf, int buflen); struct tm *localtime_r(const time_t *clock, struct tm *res); struct tm *gmtime_r(const time_t *clock, struct tm *res); char *asctime_r(const struct tm *tm, char *buf, int buflen);</pre>
POSIX	<pre>cc [flag...] file... -D_POSIX_THREAD_SEMANTICS [library...] char *ctime_r(const time_t *clock, char *buf); char *asctime_r(const struct tm *tm, char *buf);</pre>
DESCRIPTION	<p>The <code>ctime()</code> function converts the time pointed to by <code>clock</code>, representing the time in seconds since the Epoch (00:00:00 UTC, January 1, 1970), to local time in the form of a 26-character string, as shown below. Time zone and daylight savings corrections are made before string generation. The fields are in constant width:</p> <pre>Fri Sep 13 00:00:00 1986\n\0</pre> <p>The <code>ctime()</code> function is equivalent to:</p> <pre>asctime(localtime(clock))</pre> <p>The <code>ctime()</code>, <code>asctime()</code>, <code>gmtime()</code>, and <code>localtime()</code> functions return values in one of two static objects: a broken-down time structure and an array of <code>char</code>. Execution of any of the functions can overwrite the information returned in either of these objects by any of the other functions.</p> <p>The <code>ctime_r()</code> function has the same functionality as <code>ctime()</code> except that the caller must supply a buffer <code>buf</code> with length <code>buflen</code> to store the result; <code>buf</code> must be at least 26 bytes. The POSIX <code>ctime_r()</code> function does not take a <code>buflen</code> parameter.</p>

The `localtime()` and `gmtime()` functions return pointers to `tm` structures (see below). The `localtime()` function corrects for the main time zone and possible alternate (“daylight savings”) time zone; the `gmtime()` function converts directly to Coordinated Universal Time (UTC), which is what the UNIX system uses internally.

The `localtime_r()` and `gmtime_r()` functions have the same functionality as `localtime()` and `gmtime()` respectively, except that the caller must supply a buffer *res* to store the result.

The `asctime()` function converts a `tm` structure to a 26-character string, as shown in the previous example, and returns a pointer to the string.

The `asctime_r()` function has the same functionality as `asctime()` except that the caller must supply a buffer *buf* with length *buflen* for the result to be stored. The *buf* argument must be at least 26 bytes. The POSIX `asctime_r()` function does not take a *buflen* parameter. The `asctime_r()` function returns a pointer to *buf* upon success. In case of failure, `NULL` is returned and `errno` is set.

Declarations of all the functions and externals, and the `tm` structure, are in the `<time.h>` header. The members of the `tm` structure are:

```
int    tm_sec;    /* seconds after the minute - [0, 61] */
        /* for leap seconds */
int    tm_min;    /* minutes after the hour - [0, 59] */
int    tm_hour;   /* hour since midnight - [0, 23] */
int    tm_mday;   /* day of the month - [1, 31] */
int    tm_mon;    /* months since January - [0, 11] */
int    tm_year;   /* years since 1900 */
int    tm_wday;   /* days since Sunday - [0, 6] */
int    tm_yday;   /* days since January 1 - [0, 365] */
int    tm_isdst;  /* flag for alternate daylight savings time */
```

The value of `tm_isdst` is positive if daylight savings time is in effect, zero if daylight savings time is not in effect, and negative if the information is not available.

Previously, the value of `tm_isdst` was defined as non-zero if daylight savings was in effect.

The external `time_t` variable `altzone` contains the difference, in seconds, between Coordinated Universal Time and the alternate time zone. The external variable `timezone` contains the difference, in seconds, between UTC and local standard time. The external variable `daylight` indicates whether time should reflect daylight savings time. Both `timezone` and `altzone` default to 0 (UTC). The external variable `daylight` is non-zero if an alternate time zone exists. The time zone names are contained in the external variable `tzname`, which by default is set to:

```
char *tzname[2] = { "GMT", "" };
```

These functions know about the peculiarities of this conversion for various time periods for the U.S. (specifically, the years 1974, 1975, and 1987). They start handling the new daylight savings time starting with the first Sunday in April, 1987.

asctime_r(3C)

The `tzset()` function uses the contents of the environment variable `TZ` to override the value of the different external variables. It is called by `asctime()` and can also be called by the user. See `environ(5)` for a description of the `TZ` environment variable.

Starting and ending times are relative to the current local time zone. If the alternate time zone start and end dates and the time are not provided, the days for the United States that year will be used and the time will be 2 AM. If the start and end dates are provided but the time is not provided, the time will be 2 AM. The effects of `tzset()` change the values of the external variables `timezone`, `altzone`, `daylight`, and `tzname`.

Note that in most installations, `TZ` is set to the correct value by default when the user logs on, using the local `/etc/default/init` file (see `TIMEZONE(4)`).

ERRORS The `ctime_r()` and `asctime_r()` functions will fail if:

ERANGE The length of the buffer supplied by the caller is not large enough to store the result.

USAGE These functions do not support localized date and time formats. The `strftime(3C)` function can be used when localization is required.

The `localtime()`, `localtime_r()`, `gmtime()`, `gmtime_r()`, `ctime()`, and `ctime_r()` functions assume Gregorian dates. Times before the adoption of the Gregorian calendar will not match historical records.

EXAMPLES **EXAMPLE 1** Examples of the `tzset()` function.

The `tzset()` function scans the contents of the environment variable and assigns the different fields to the respective variable. For example, the most complete setting for New Jersey in 1986 could be:

```
EST5EDT4,116/2:00:00,298/2:00:00
```

or simply

```
EST5EDT
```

An example of a southern hemisphere setting such as the Cook Islands could be

```
KDT9:30KST10:00,63/5:00,302/20:00
```

In the longer version of the New Jersey example of `TZ`, `tzname[0]` is `EST`, `timezone` is set to `5*60*60`, `tzname[1]` is `EDT`, `altzone` is set to `4*60*60`, the starting date of the alternate time zone is the 117th day at 2 AM, the ending date of the alternate time zone is the 299th day at 2 AM (using zero-based Julian days), and `daylight` is set positive. Starting and ending times are relative to the current local time zone. If the alternate time zone start and end dates and the time are not provided, the days for the United States that year will be used and the time will be 2 AM. If the start and end dates are provided but the time is not provided, the time will be 2 AM. The effects of `tzset()` are thus to change the values of the external variables `timezone`, `altzone`, `daylight`, and `tzname`. The `ctime()`, `localtime()`, `mktime()`, and `strftime()` functions also update these external variables as if they had called `tzset()` at the

EXAMPLE 1 Examples of the `tzset()` function. (Continued)

time specified by the `time_t` or `struct tm` value that they are converting.

BUGS The `zoneinfo` timezone data files do not transition past Tue Jan 19 03:14:07 2038 UTC. Therefore for 64-bit applications using `zoneinfo` timezones, calculations beyond this date might not use the correct offset from standard time, and could return incorrect values. This affects the 64-bit version of `localtime()`, `localtime_r()`, `ctime()`, and `ctime_r()`.

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
MT-Level	MT-Safe with exceptions
CSI	Enabled

SEE ALSO `time(2)`, `Intro(3)`, `getenv(3C)`, `mktime(3C)`, `printf(3C)`, `putenv(3C)`, `setlocale(3C)`, `strftime(3C)`, `TIMEZONE(4)`, `attributes(5)`, `environ(5)`

NOTES When compiling multithreaded programs, see `Intro(3)`, *Notes On Multithreaded Applications*.

The return values for `ctime()`, `localtime()`, and `gmtime()` point to static data whose content is overwritten by each call.

Setting the time during the interval of change from `timezone` to `altzone` or vice versa can produce unpredictable results. The system administrator must change the Julian start and end days annually.

The `asctime()`, `ctime()`, `gmtime()`, and `localtime()` functions are unsafe in multithread applications. The `asctime_r()` and `gmtime_r()` functions are MT-Safe. The `ctime_r()`, `localtime_r()`, and `tzset()` functions are MT-Safe in multithread applications, as long as no user-defined function directly modifies one of the following variables: `timezone`, `altzone`, `daylight`, and `tzname`. These four variables are not MT-Safe to access. They are modified by the `tzset()` function in an MT-Safe manner. The `mktime()`, `localtime_r()`, and `ctime_r()` functions call `tzset()`.

Solaris 2.4 and earlier releases provided definitions of the `ctime_r()`, `localtime_r()`, `gmtime_r()`, and `asctime_r()` functions as specified in POSIX.1c Draft 6. The final POSIX.1c standard changed the interface for `ctime_r()` and `asctime_r()`. Support for the Draft 6 interface is provided for compatibility only and might not be supported in future releases. New applications and libraries should use the POSIX standard interface.

asctime_r(3C)

For POSIX.1c-compliant applications, the `_POSIX_PTHREAD_SEMANTICS` and `_REENTRANT` flags are automatically turned on by defining the `_POSIX_C_SOURCE` flag with a value `>= 199506L`.

NAME	assert – verify program assertion				
SYNOPSIS	<pre>#include <assert.h> void assert(int <i>expression</i>);</pre>				
DESCRIPTION	<p>The <code>assert()</code> macro inserts diagnostics into applications. When executed, if <i>expression</i> is FALSE (zero), <code>assert()</code> prints the error message</p> <pre>Assertion failed: <i>expression</i>, file <i>xyz</i>, line <i>nnn</i></pre> <p>on the standard error output and aborts. In the error message, <i>xyz</i> is the name of the source file and <i>nnn</i> the source line number of the <code>assert()</code> statement. These are respectively the values of the preprocessor macros <code>__FILE__</code> and <code>__LINE__</code>.</p> <p>Since <code>assert()</code> is implemented as a macro, the <i>expression</i> may not contain any string literals.</p> <p>Compiling with the preprocessor option <code>-DNDEBUG</code> (see <code>cc(1B)</code>), or with the preprocessor control statement <code>#define NDEBUG</code> ahead of the <code>#include <assert.h></code> statement, will stop assertions from being compiled into the program.</p> <p>If the application is linked with <code>-lintl</code>, messages printed from this function are in the native language specified by the <code>LC_MESSAGES</code> locale category; see <code>setlocale(3C)</code>.</p>				
ATTRIBUTES	<p>See <code>attributes(5)</code> for descriptions of the following attributes:</p> <table border="1" style="width: 100%; border-collapse: collapse;"> <thead> <tr> <th style="text-align: center;">ATTRIBUTE TYPE</th> <th style="text-align: center;">ATTRIBUTE VALUE</th> </tr> </thead> <tbody> <tr> <td>MT-Level</td> <td>Safe</td> </tr> </tbody> </table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	MT-Level	Safe

atexit(3C)

NAME	atexit – register a function to run at process termination or object unloading						
SYNOPSIS	<pre>#include <stdlib.h> int atexit(void (*<i>func</i>)(void));</pre>						
DESCRIPTION	<p>The <code>atexit()</code> function registers the function pointed to by <i>func</i> to be called without arguments on normal termination of the program or when the object defining the function is unloaded.</p> <p>Normal termination occurs by either a call to the <code>exit(3C)</code> function or a return from <code>main()</code>. Object unloading occurs when a call to <code>dldclose(3DL)</code> results in the object becoming unreferenced.</p> <p>The number of functions that may be registered with <code>atexit()</code> is limited only by available memory (refer to the <code>_SC_ATEXIT_MAX</code> argument of <code>sysconf(3C)</code>).</p> <p>After a successful call to any of the <code>exec(2)</code> functions, any functions previously registered by <code>atexit()</code> are no longer registered.</p> <p>On process exit, functions are called in the reverse order of their registration. On object unloading, any functions belonging to an unloadable object are called in the reverse order of their registration.</p>						
RETURN VALUES	Upon successful completion, the <code>atexit()</code> function returns 0. Otherwise, it returns a non-zero value.						
ERRORS	The <code>atexit()</code> function may fail if: ENOMEM Insufficient storage space is available.						
USAGE	<p>The functions registered by a call to <code>atexit()</code> must return to ensure that all registered functions are called.</p> <p>There is no way for an application to tell how many functions have already been registered with <code>atexit()</code>.</p>						
ATTRIBUTES	See <code>attributes(5)</code> for descriptions of the following attributes:

NAME	strtod, atof – convert string to double-precision number
SYNOPSIS	<pre>#include <stdlib.h> double strtod(const char *str, char **endptr); double atof(const char *str);</pre>
DESCRIPTION	<p>The <code>strtod()</code> function converts the initial portion of the string pointed to by <code>str</code> to type <code>double</code> representation. First it decomposes the input string into three parts: an initial, possibly empty, sequence of white-space characters (as specified by <code>isspace(3C)</code>); a subject sequence interpreted as a floating-point constant; and a final string of one or more unrecognized characters, including the terminating null byte of the input string. Then it attempts to convert the subject sequence to a floating-point number, and returns the result.</p> <p>The expected form of the subject sequence is an optional <code>+</code> or <code>-</code> sign, then a non-empty sequence of digits optionally containing a radix character, then an optional exponent part. An exponent part consists of <code>e</code> or <code>E</code>, followed by an optional sign, followed by one or more decimal digits. The subject sequence is defined as the longest initial subsequence of the input string, starting with the first non-white-space character, that is of the expected form. The subject sequence is empty if the input string is empty or consists entirely of white-space characters, or if the first character that is not white space is other than a sign, a digit or a radix character.</p> <p>If the subject sequence has the expected form, the sequence starting with the first digit or the radix character (whichever occurs first) is interpreted as a floating constant of the C language, except that the radix character is used in place of a period, and that if neither an exponent part nor a radix character appears, a radix character is assumed to follow the last digit in the string. If the subject sequence begins with a minus sign, the value resulting from the conversion is negated. A pointer to the final string is stored in the object pointed to by <code>endptr</code>, provided that <code>endptr</code> is not a null pointer.</p> <p>The radix character is defined in the program's locale (category <code>LC_NUMERIC</code>). In the POSIX locale, or in a locale where the radix character is not defined, the radix character defaults to a period (<code>.</code>).</p> <p>In other than the POSIX locale, other implementation-dependent subject sequence forms may be accepted.</p> <p>If the subject sequence is empty or does not have the expected form, no conversion is performed; the value of <code>str</code> is stored in the object pointed to by <code>endptr</code>, provided that <code>endptr</code> is not a null pointer.</p>
atof()	The <code>atof(str)</code> function call is equivalent to <code>strtod(str, (char **)NULL)</code> .
RETURN VALUES	Upon successful completion, <code>strtod()</code> returns the converted value. If no conversion could be performed, 0 is returned and <code>errno</code> may be set to <code>EINVAL</code> .

atof(3C)

If the correct value is outside the range of representable values, \pm HUGE is returned (according to the sign of the value), and `errno` is set to `ERANGE`. When the `-Xc` or `-Xa` compilation options are used, `HUGE_VAL` is returned instead of `HUGE`.

If the correct value would cause an underflow, 0 is returned and `errno` is set to `ERANGE`.

If `str` is NaN, then `atof()` returns NaN.

ERRORS The `strtod()` function will fail if:

`ERANGE` The value to be returned would cause overflow or underflow. The `strtod()` function may fail if:

`EINVAL` No conversion could be performed.

USAGE Because 0 is returned on error and is also a valid return on success, an application wishing to check for error situations should set `errno` to 0, then call `strtod()`, then check `errno` and if it is non-zero, assume an error has occurred.

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
MT-Level	MT-Safe with exceptions
CSI	Enabled

SEE ALSO `isspace(3C)`, `localeconv(3C)`, `scanf(3C)`, `setlocale(3C)`, `strtol(3C)`, `attributes(5)`, `standards(5)`

NOTES The `strtod()` and `atof()` functions can be used safely in multithreaded applications, as long as `setlocale(3C)` is not called to change the locale.

The DESCRIPTION and RETURN VALUES sections above are very similar to the wording used by the Single UNIX Specification version 2 and the 1989 C Standard to describe the behavior of the `strtod()` function. Since some users have reported that they find the description confusing, the following notes may be helpful.

1. The `strtod()` function does not modify the string pointed to by `str` and does not `malloc()` space to hold the decomposed portions of the input string.
2. If `endptr` is not `(char **)NULL`, `strtod()` will set the pointer pointed to by `endptr` to the first byte of the "final string of unrecognized characters". (If all input characters were processed, the pointer pointed to by `endptr` will be set to point to the null character at the end of the input string.)
3. If `strtod()` returns 0.0, one of the following occurred:
 - a. The "subject sequence" was not an empty string, but evaluated to 0.0. (In this case, `errno` will be left unchanged.)

- b. The "subject sequence" was an empty string. (In this case, the Single UNIX Specification version 2 allows `errno` to be set to `EINVAL` or to be left unchanged. The C Standard does not specify any specific behavior in this case.)
 - c. The "subject sequence" specified a numeric value that would cause a floating point underflow. (In this case, `errno` may be set to `ERANGE` or may be left unchanged.) Note that the standards do not require that implementations distinguish between these three cases. An application can determine case (b) by making sure that there are no leading white-space characters in the string pointed to by `str` and giving `strtod()` an `endptr` that is not `(char **)NULL`. If `endptr` points to the first character of `str` when `strtod()` returns, you have detected case (b). Case (c) can be detected by looking for a non-zero digit before the exponent part of the "subject sequence". Note, however, that the decimal-point character is locale-dependent.
4. If `strtod()` returns `+HUGE_VAL` or `-HUGE_VAL`, one of the following occurred:
- a. If `+HUGE_VAL` is returned and `errno` is set to `ERANGE`, a floating point overflow occurred while processing a positive value.
 - b. If `-HUGE_VAL` is returned and `errno` is set to `ERANGE`, a floating point overflow occurred while processing a negative value.
 - c. If `strtod()` does not set `errno` to `ERANGE`, the value specified by the "subject string" converted to `+HUGE_VAL` or `-HUGE_VAL`, respectively. Note that if `errno` is set to `ERANGE` when `strtod()` is called, case (c) is indistinguishable from cases (a) and (b).

atoi(3C)

NAME	<code>strtol, strtoll, atol, atoll, atoi, lltostr, ulltostr</code> – string conversion routines
SYNOPSIS	<pre>#include <stdlib.h> long strtol(const char *str, char **endptr, int base); long long strtoll(const char *str, char **endptr, int base); long atol(const char *str); long long atoll(const char *str); int atoi(const char *str); char *lltostr(long long value, char *endptr); char *ulltostr(unsigned long long value, char *endptr);</pre>
strtol() and strtoll()	<p>The <code>strtol()</code> function converts the initial portion of the string pointed to by <code>str</code> to a type long int representation.</p> <p>The <code>strtoll()</code> function converts the initial portion of the string pointed to by <code>str</code> to a type long long representation.</p> <p>Both functions first decompose the input string into three parts: an initial, possibly empty, sequence of white-space characters (as specified by <code>isspace(3C)</code>); a subject sequence interpreted as an integer represented in some radix determined by the value of <code>base</code>; and a final string of one or more unrecognized characters, including the terminating null byte of the input string. They then attempt to convert the subject sequence to an integer and return the result.</p> <p>If the value of <code>base</code> is 0, the expected form of the subject sequence is that of a decimal constant, octal constant or hexadecimal constant, any of which may be preceded by a + or – sign. A decimal constant begins with a non-zero digit, and consists of a sequence of decimal digits. An octal constant consists of the prefix 0 optionally followed by a sequence of the digits 0 to 7 only. A hexadecimal constant consists of the prefix 0x or 0X followed by a sequence of the decimal digits and letters a (or A) to f (or F) with values 10 to 15 respectively.</p> <p>If the value of <code>base</code> is between 2 and 36, the expected form of the subject sequence is a sequence of letters and digits representing an integer with the radix specified by <code>base</code>, optionally preceded by a + or – sign. The letters from a (or A) to z (or Z) inclusive are ascribed the values 10 to 35; only letters whose ascribed values are less than that of <code>base</code> are permitted. If the value of <code>base</code> is 16, the characters 0x or 0X may optionally precede the sequence of letters and digits, following the sign if present.</p> <p>The subject sequence is defined as the longest initial subsequence of the input string, starting with the first non-white-space character, that is of the expected form. The subject sequence contains no characters if the input string is empty or consists entirely of white-space characters, or if the first non-white-space character is other than a sign or a permissible letter or digit.</p>

If the subject sequence has the expected form and the value of *base* is 0, the sequence of characters starting with the first digit is interpreted as an integer constant. If the subject sequence has the expected form and the value of *base* is between 2 and 36, it is used as the base for conversion, ascribing to each letter its value as given above. If the subject sequence begins with a minus sign, the value resulting from the conversion is negated. A pointer to the final string is stored in the object pointed to by *endptr*, provided that *endptr* is not a null pointer.

In other than the POSIX locale, additional implementation-dependent subject sequence forms may be accepted.

If the subject sequence is empty or does not have the expected form, no conversion is performed; the value of *str* is stored in the object pointed to by *endptr*, provided that *endptr* is not a null pointer.

`atol()`, `atoll()`
and `atoi()`

Except for behavior on error, `atol()` is equivalent to: `strtol(str, (char **)NULL, 10)`.

Except for behavior on error, `atoll()` is equivalent to: `strtoll(str, (char **)NULL, 10)`.

Except for behavior on error, `atoi()` is equivalent to: `(int) strtol(str, (char **)NULL, 10)`.

`lltostr()` **and**
`ulltostr()`

The `lltostr()` function returns a pointer to the string represented by the long long *value*. The *endptr* argument is assumed to point to the byte following a storage area into which the decimal representation of *value* is to be placed as a string. The `lltostr()` function converts *value* to decimal and produces the string, and returns a pointer to the beginning of the string. No leading zeros are produced, and no terminating null is produced. The low-order digit of the result always occupies memory position *endptr*-1. The behavior of `lltostr()` is undefined if *value* is negative. A single zero digit is produced if *value* is 0.

The `ulltostr()` function is similar to `lltostr()` except that *value* is an unsigned long long.

RETURN VALUES

Upon successful completion, `strtol()`, `strtoll()`, `atol()`, `atoll()`, and `atoi()` return the converted value, if any. If no conversion could be performed, `strtol()` and `strtoll()` return 0 and `errno` may be set to `EINVAL`.

If the correct value is outside the range of representable values, `strtol()` returns `LONG_MAX` or `LONG_MIN` and `strtoll()` returns `LLONG_MAX` or `LLONG_MIN` (according to the sign of the value), and `errno` is set to `ERANGE`.

Upon successful completion, `lltostr()` and `ulltostr()` return a pointer to the converted string.

ERRORS

The `strtol()` and `strtoll()` functions will fail if:

`ERANGE` The value to be returned is not representable. The `strtol()` and `strtoll()` functions may fail if:

atoi(3C)

EINVAL The value of *base* is not supported.

USAGE Because 0, LONG_MIN, LONG_MAX, LLONG_MIN, and LLONG_MAX are returned on error and are also valid returns on success, an application wishing to check for error situations should set `errno` to 0, call the function, then check `errno` and if it is non-zero, assume an error has occurred.

The `strtol()` function no longer accepts values greater than LONG_MAX or LLONG_MAX as valid input. Use `strtoul(3C)` instead.

The subject sequence contains no characters if the input string is empty or consists entirely of white-space characters, or if the first non-white-space character is other than a sign or a permissible letter or digit.</p>

atol(3C)

If the subject sequence has the expected form and the value of *base* is 0, the sequence of characters starting with the first digit is interpreted as an integer constant. If the subject sequence has the expected form and the value of *base* is between 2 and 36, it is used as the base for conversion, ascribing to each letter its value as given above. If the subject sequence begins with a minus sign, the value resulting from the conversion is negated. A pointer to the final string is stored in the object pointed to by *endptr*, provided that *endptr* is not a null pointer.

In other than the POSIX locale, additional implementation-dependent subject sequence forms may be accepted.

If the subject sequence is empty or does not have the expected form, no conversion is performed; the value of *str* is stored in the object pointed to by *endptr*, provided that *endptr* is not a null pointer.

atol(), atoll()
and atoi()

Except for behavior on error, `atol()` is equivalent to: `strtol(str, (char **)NULL, 10)`.

Except for behavior on error, `atoll()` is equivalent to: `strtoll(str, (char **)NULL, 10)`.

Except for behavior on error, `atoi()` is equivalent to: `(int) strtol(str, (char **)NULL, 10)`.

lltostr() and
ulltostr()

The `lltostr()` function returns a pointer to the string represented by the long long *value*. The *endptr* argument is assumed to point to the byte following a storage area into which the decimal representation of *value* is to be placed as a string. The `lltostr()` function converts *value* to decimal and produces the string, and returns a pointer to the beginning of the string. No leading zeros are produced, and no terminating null is produced. The low-order digit of the result always occupies memory position *endptr*-1. The behavior of `lltostr()` is undefined if *value* is negative. A single zero digit is produced if *value* is 0.

The `ulltostr()` function is similar to `lltostr()` except that *value* is an unsigned long long.

RETURN VALUES

Upon successful completion, `strtol()`, `strtoll()`, `atol()`, `atoll()`, and `atoi()` return the converted value, if any. If no conversion could be performed, `strtol()` and `strtoll()` return 0 and `errno` may be set to `EINVAL`.

If the correct value is outside the range of representable values, `strtol()` returns `LONG_MAX` or `LONG_MIN` and `strtoll()` returns `LLONG_MAX` or `LLONG_MIN` (according to the sign of the value), and `errno` is set to `ERANGE`.

Upon successful completion, `lltostr()` and `ulltostr()` return a pointer to the converted string.

ERRORS

The `strtol()` and `strtoll()` functions will fail if:

`ERANGE` The value to be returned is not representable. The `strtol()` and `strtoll()` functions may fail if:

EINVAL The value of *base* is not supported.

USAGE Because 0, LONG_MIN, LONG_MAX, LLONG_MIN, and LLONG_MAX are returned on error and are also valid returns on success, an application wishing to check for error situations should set `errno` to 0, call the function, then check `errno` and if it is non-zero, assume an error has occurred.

The `strtol()` function no longer accepts values greater than LONG_MAX or LLONG_MAX as valid input. Use `strtoul(3C)` instead.

atoll(3C)

NAME	strtol, strtoll, atol, atoll, atoi, lltostr, ulltostr – string conversion routines
SYNOPSIS	<pre>#include <stdlib.h> long strtol(const char *str, char **endptr, int base); long long strtoll(const char *str, char **endptr, int base); long atol(const char *str); long long atoll(const char *str); int atoi(const char *str); char *lltostr(long long value, char *endptr); char *ulltostr(unsigned long long value, char *endptr);</pre>
strtol() and strtoll()	<p>The <code>strtol()</code> function converts the initial portion of the string pointed to by <code>str</code> to a type long int representation.</p> <p>The <code>strtoll()</code> function converts the initial portion of the string pointed to by <code>str</code> to a type long long representation.</p> <p>Both functions first decompose the input string into three parts: an initial, possibly empty, sequence of white-space characters (as specified by <code>isspace(3C)</code>); a subject sequence interpreted as an integer represented in some radix determined by the value of <code>base</code>; and a final string of one or more unrecognized characters, including the terminating null byte of the input string. They then attempt to convert the subject sequence to an integer and return the result.</p> <p>If the value of <code>base</code> is 0, the expected form of the subject sequence is that of a decimal constant, octal constant or hexadecimal constant, any of which may be preceded by a + or – sign. A decimal constant begins with a non-zero digit, and consists of a sequence of decimal digits. An octal constant consists of the prefix 0 optionally followed by a sequence of the digits 0 to 7 only. A hexadecimal constant consists of the prefix 0x or 0X followed by a sequence of the decimal digits and letters a (or A) to f (or F) with values 10 to 15 respectively.</p> <p>If the value of <code>base</code> is between 2 and 36, the expected form of the subject sequence is a sequence of letters and digits representing an integer with the radix specified by <code>base</code>, optionally preceded by a + or – sign. The letters from a (or A) to z (or Z) inclusive are ascribed the values 10 to 35; only letters whose ascribed values are less than that of <code>base</code> are permitted. If the value of <code>base</code> is 16, the characters 0x or 0X may optionally precede the sequence of letters and digits, following the sign if present.</p> <p>The subject sequence is defined as the longest initial subsequence of the input string, starting with the first non-white-space character, that is of the expected form. The subject sequence contains no characters if the input string is empty or consists entirely of white-space characters, or if the first non-white-space character is other than a sign or a permissible letter or digit.</p>

If the subject sequence has the expected form and the value of *base* is 0, the sequence of characters starting with the first digit is interpreted as an integer constant. If the subject sequence has the expected form and the value of *base* is between 2 and 36, it is used as the base for conversion, ascribing to each letter its value as given above. If the subject sequence begins with a minus sign, the value resulting from the conversion is negated. A pointer to the final string is stored in the object pointed to by *endptr*, provided that *endptr* is not a null pointer.

In other than the POSIX locale, additional implementation-dependent subject sequence forms may be accepted.

If the subject sequence is empty or does not have the expected form, no conversion is performed; the value of *str* is stored in the object pointed to by *endptr*, provided that *endptr* is not a null pointer.

`atol()`, `atoll()`
and `atoi()`

Except for behavior on error, `atol()` is equivalent to: `strtol(str, (char **)NULL, 10)`.

Except for behavior on error, `atoll()` is equivalent to: `strtoll(str, (char **)NULL, 10)`.

Except for behavior on error, `atoi()` is equivalent to: `(int) strtol(str, (char **)NULL, 10)`.

`lltostr()` **and**
`ulltostr()`

The `lltostr()` function returns a pointer to the string represented by the long long *value*. The *endptr* argument is assumed to point to the byte following a storage area into which the decimal representation of *value* is to be placed as a string. The `lltostr()` function converts *value* to decimal and produces the string, and returns a pointer to the beginning of the string. No leading zeros are produced, and no terminating null is produced. The low-order digit of the result always occupies memory position *endptr*-1. The behavior of `lltostr()` is undefined if *value* is negative. A single zero digit is produced if *value* is 0.

The `ulltostr()` function is similar to `lltostr()` except that *value* is an unsigned long long.

RETURN VALUES

Upon successful completion, `strtol()`, `strtoll()`, `atol()`, `atoll()`, and `atoi()` return the converted value, if any. If no conversion could be performed, `strtol()` and `strtoll()` return 0 and `errno` may be set to `EINVAL`.

If the correct value is outside the range of representable values, `strtol()` returns `LONG_MAX` or `LONG_MIN` and `strtoll()` returns `LLONG_MAX` or `LLONG_MIN` (according to the sign of the value), and `errno` is set to `ERANGE`.

Upon successful completion, `lltostr()` and `ulltostr()` return a pointer to the converted string.

ERRORS

The `strtol()` and `strtoll()` functions will fail if:

`ERANGE` The value to be returned is not representable. The `strtol()` and `strtoll()` functions may fail if:

atoll(3C)

EINVAL The value of *base* is not supported.

USAGE Because 0, LONG_MIN, LONG_MAX, LLONG_MIN, and LLONG_MAX are returned on error and are also valid returns on success, an application wishing to check for error situations should set `errno` to 0, call the function, then check `errno` and if it is non-zero, assume an error has occurred.

The `strtol()` function no longer accepts values greater than LONG_MAX or LLONG_MAX as valid input. Use `strtoul(3C)` instead.

NAME	attropen – open a file						
SYNOPSIS	<pre>#include <sys/types.h> #include <sys/stat.h> #include <fcntl.h> int attropen(const char *path, const char *attrpath, int oflag, /* mode_t mode */...);</pre>						
DESCRIPTION	<p>The <code>attropen()</code> function is similar to the <code>open(2)</code> function except that it takes a second path argument, <code>attrpath</code>, that identifies an extended attribute file associated with the first <code>path</code> argument. This function returns a file descriptor for the extended attribute rather than the file named by the initial argument.</p> <p>The <code>O_XATTR</code> flag is set by default for <code>attropen()</code> and the <code>attrpath</code> argument is always interpreted as a reference to an extended attribute. Extended attributes must be referenced with a relative path; providing an absolute path results in a normal file reference.</p>

NAME	gettext, dgettext, dcgettext, ngettext, dngettext, dcngettext, textdomain, bindtextdomain, bind_textdomain_codeset – message handling functions
Solaris and GNU-compatible	<pre>#include <libintl.h> char *gettext(const char *msgid); char *dgettext(const char *domainname, const char *msgid); char *textdomain(const char *domainname); char *bindtextdomain(const char *domainname, const char *dirname); #include <libintl.h> #include <locale.h> char *dcgettext(const char *domainname, const char *msgid, int category);</pre>
GNU-compatible	<pre>#include <libintl.h> char *ngettext(const char *msgid1, const char *msgid2, unsigned long int n); char *dngettext(const char *domainname, const char *msgid1, const char *msgid2, unsigned long int n); char *bind_textdomain_codeset(const char *domainname, const char *codeset); #include <libintl.h> #include <locale.h> char *dcngettext(const char *domainname, const char *msgid1, const char *msgid2, unsigned long int n, int category);</pre>
DESCRIPTION	<p>The <code>gettext()</code>, <code>dgettext()</code>, and <code>dcgettext()</code> functions attempt to retrieve a target string based on the specified <code>msgid</code> argument within the context of a specific domain and the current locale. The length of strings returned by <code>gettext()</code>, <code>dgettext()</code>, and <code>dcgettext()</code> is undetermined until the function is called. The <code>msgid</code> argument is a null-terminated string.</p> <p>The <code>ngettext()</code>, <code>dngettext()</code>, and <code>dcngettext()</code> functions are equivalent to <code>gettext()</code>, <code>dgettext()</code>, and <code>dcgettext()</code>, respectively, except for the handling of plural forms. These functions work only with GNU-compatible message catalogues. The <code>ngettext()</code>, <code>dngettext()</code>, and <code>dcngettext()</code> functions search for the message string using the <code>msgid1</code> argument as the key and the <code>n</code> argument to determine the plural form. If no message catalogues are found, <code>msgid1</code> is returned if <code>n == 1</code>, otherwise <code>msgid2</code> is returned.</p> <p>The <code>NLSPATH</code> environment variable (see <code>environ(5)</code>) is searched first for the location of the <code>LC_MESSAGES</code> catalogue. The setting of the <code>LC_MESSAGES</code> category of the current locale determines the locale used by <code>gettext()</code> and <code>dgettext()</code> for string retrieval. The <code>category</code> argument determines the locale used by <code>dcgettext()</code>. If <code>NLSPATH</code> is not defined and the current locale is "C", <code>gettext()</code>, <code>dgettext()</code>, and</p>

bindtextdomain(3C)

`dcgettext()` simply return the message string that was passed. In a locale other than "C", if `NLSPATH` is not defined or if a message catalogue is not found in any of the components specified by `NLSPATH`, the routines search for the message catalogue using the scheme described in the following paragraph.

The `LANGUAGE` environment variable is examined to determine the GNU-compatible message catalogues to be used. The value of `LANGUAGE` is a list of locale names separated by a colon (':') character. If `LANGUAGE` is defined, each locale name is tried in the specified order and if a GNU-compatible message catalogue is found, the message is returned. If a GNU-compatible message catalogue is found but failed to find a corresponding *msgid*, the *msgid* string is return. If `LANGUAGE` is not defined or if a Solaris message catalogue is found or no GNU-compatible message catalogue is found in processing `LANGUAGE`, the pathname used to locate the message catalogue is *dirname/locale/category/domainname.mo*, where *dirname* is the directory specified by `bindtextdomain()`, *locale* is a locale name, and *category* is either `LC_MESSAGES` if `gettext()`, `dgettext()`, `ngettext()`, or `dngettext()` is called, or `LC_XXX` where the name is the same as the locale category name specified by the *category* argument to `dcgettext()` or `dcngettext()`.

For `gettext()` and `ngettext()`, the domain used is set by the last valid call to `textdomain()`. If a valid call to `textdomain()` has not been made, the default domain (called `messages`) is used.

For `dgettext()`, `dcgettext()`, `dngettext()`, and `dcngettext()`, the domain used is specified by the *domainname* argument. The *domainname* argument is equivalent in syntax and meaning to the *domainname* argument to `textdomain()`, except that the selection of the domain is valid only for the duration of the `dgettext()`, `dcgettext()`, `dngettext()`, or `dcngettext()` function call.

The `textdomain()` function sets or queries the name of the current domain of the active `LC_MESSAGES` locale category. The *domainname* argument is a null-terminated string that can contain only the characters allowed in legal filenames.

The *domainname* argument is the unique name of a domain on the system. If there are multiple versions of the same domain on one system, namespace collisions can be avoided by using `bindtextdomain()`. If `textdomain()` is not called, a default domain is selected. The setting of domain made by the last valid call to `textdomain()` remains valid across subsequent calls to `setlocale(3C)`, and `gettext()`.

The *domainname* argument is applied to the currently active `LC_MESSAGES` locale.

The current setting of the domain can be queried without affecting the current state of the domain by calling `textdomain()` with *domainname* set to the null pointer. Calling `textdomain()` with a *domainname* argument of a null string sets the domain to the default domain (`messages`).

The `bindtextdomain()` function binds the path predicate for a message domain *domainname* to the value contained in *dirname*. If *domainname* is a non-empty string and has not been bound previously, `bindtextdomain()` binds *domainname* with *dirname*.

If *domainname* is a non-empty string and has been bound previously, `bindtextdomain()` replaces the old binding with *dirname*. The *dirname* argument can be an absolute or relative pathname being resolved when `gettext()`, `dgettext()`, or `dcgettext()` are called. If *domainname* is a null pointer or an empty string, `bindtextdomain()` returns NULL. User defined domain names cannot begin with the string `SYS_`. Domain names beginning with this string are reserved for system use.

The `bind_textdomain_codeset()` function can be used to specify the output codeset for message catalogues for domain *domainname*. The *codeset* argument must be a valid codeset name that can be used for the `iconv_open(3C)` function, or a null pointer. If the *codeset* argument is the null pointer, `bind_textdomain_codeset()` returns the currently selected codeset for the domain with the name *domainname*. It returns a null pointer if a codeset has not yet been selected. The `bind_textdomain_codeset()` function can be used multiple times. If used multiple times with the same *domainname* argument, the later call overrides the settings made by the earlier one. The `bind_textdomain_codeset()` function returns a pointer to a string containing the name of the selected codeset. The string is allocated internally in the function and must not be changed by the user.

RETURN VALUES

The `gettext()`, `dgettext()`, and `dcgettext()` functions return the message string if the search succeeds. Otherwise they return the *msgid* string.

The `ngettext()`, `dngettext()`, and `dcngettext()` functions return the message string if the search succeeds. If the search fails, *msgid1* is returned if *n* == 1. Otherwise *msgid2* is returned.

The individual bytes of the string returned by `gettext()`, `dgettext()`, `dcgettext()`, `ngettext()`, `dngettext()`, or `dcngettext()` can contain any value other than NULL. If *msgid* is a null pointer, the return value is undefined. The string returned must not be modified by the program and can be invalidated by a subsequent call to `bind_textdomain_codeset()` or `setlocale(3C)`. If the *domainname* argument to `dgettext()`, `dcgettext()`, `dngettext()`, or `dcngettext()` is a null pointer, the the domain currently bound by `textdomain()` is used.

The normal return value from `textdomain()` is a pointer to a string containing the current setting of the domain. If *domainname* is a null pointer, `textdomain()` returns a pointer to the string containing the current domain. If `textdomain()` was not previously called and *domainname* is a null string, the name of the default domain is returned. The name of the default domain is `messages`. If `textdomain()` fails, a null pointer is returned.

The return value from `bindtextdomain()` is a null-terminated string containing *dirname* or the directory binding associated with *domainname* if *dirname* is NULL. If no binding is found, the default return value is `/usr/lib/locale`. If *domainname* is a null pointer or an empty string, `bindtextdomain()` takes no action and returns a null pointer. The string returned must not be modified by the caller. If `bindtextdomain()` fails, a null pointer is returned.

bindtextdomain(3C)

USAGE These functions impose no limit on message length. However, a text *domainname* is limited to TEXTDOMAINMAX (256) bytes.

The `gettext()`, `dgettext()`, `dcgettext()`, `ngettext()`, `dngettext()`, `dcngettext()`, `textdomain()`, and `bindtextdomain()` functions can be used safely in multithreaded applications, as long as `setlocale(3C)` is not being called to change the locale.

The `gettext()`, `dgettext()`, `dcgettext()`, `textdomain()`, and `bindtextdomain()` functions work with both Solaris message catalogues and GNU-compatible message catalogues. The `ngettext()`, `dngettext()`, `dcngettext()`, and `bind_textdomain_codeset()` functions work only with GNU-compatible message catalogues. See `msgfmt(1)` for information about Solaris message catalogues and GNU-compatible message catalogues.

FILES `/usr/lib/locale`
default path predicate for message domain files

`/usr/lib/locale/locale/LC_MESSAGES/domainname.mo`
system default location for file containing messages for language *locale* and *domainname*

`/usr/lib/locale/locale/LC_XXX/domainname.mo`
system default location for file containing messages for language *locale* and *domainname* for `dcgettext()` calls where `LC_XXX` is `LC_CTYPE`, `LC_NUMERIC`, `LC_TIME`, `LC_COLLATE`, `LC_MONETARY`, or `LC_MESSAGES`

`dirname/locale/LC_MESSAGES/domainname.mo`
location for file containing messages for domain *domainname* and path predicate *dirname* after a successful call to `bindtextdomain()`

`dirname/locale/LC_XXX/domainname.mo`
location for files containing messages for domain *domainname*, language *locale*, and path predicate *dirname* after a successful call to `bindtextdomain()` for `dcgettext()` calls where `LC_XXX` is one of `LC_CTYPE`, `LC_NUMERIC`, `LC_TIME`, `LC_COLLATE`, `LC_MONETARY`, or `LC_MESSAGES`

The <code>ngettext()</code>, <code>dngettext()</code>, and <code>dcngettext()</code> functions search for the message string using the <code>msgid1</code> argument as the key and the <code>n</code> argument to determine the plural form. If no message catalogues are found, <code>msgid1</code> is returned if <code>n == 1</code>, otherwise <code>msgid2</code> is returned.</p> <p>The <code>NLSPATH</code> environment variable (see <code>environ(5)</code>) is searched first for the location of the <code>LC_MESSAGES</code> catalogue. The setting of the <code>LC_MESSAGES</code> category of the current locale determines the locale used by <code>gettext()</code> and <code>dgettext()</code> for string retrieval. The <code>category</code> argument determines the locale used by <code>dcgettext()</code>. If <code>NLSPATH</code> is not defined and the current locale is "C", <code>gettext()</code>, <code>dgettext()</code>, and</p>

bind_textdomain_codeset(3C)

`dcgettext()` simply return the message string that was passed. In a locale other than "C", if `NLSPATH` is not defined or if a message catalogue is not found in any of the components specified by `NLSPATH`, the routines search for the message catalogue using the scheme described in the following paragraph.

The `LANGUAGE` environment variable is examined to determine the GNU-compatible message catalogues to be used. The value of `LANGUAGE` is a list of locale names separated by a colon (':') character. If `LANGUAGE` is defined, each locale name is tried in the specified order and if a GNU-compatible message catalogue is found, the message is returned. If a GNU-compatible message catalogue is found but failed to find a corresponding *msgid*, the *msgid* string is return. If `LANGUAGE` is not defined or if a Solaris message catalogue is found or no GNU-compatible message catalogue is found in processing `LANGUAGE`, the pathname used to locate the message catalogue is *dirname/locale/category/domainname.mo*, where *dirname* is the directory specified by `bindtextdomain()`, *locale* is a locale name, and *category* is either `LC_MESSAGES` if `gettext()`, `dgettext()`, `ngettext()`, or `dngettext()` is called, or `LC_XXX` where the name is the same as the locale category name specified by the *category* argument to `dcgettext()` or `dcngettext()`.

For `gettext()` and `ngettext()`, the domain used is set by the last valid call to `textdomain()`. If a valid call to `textdomain()` has not been made, the default domain (called `messages`) is used.

For `dgettext()`, `dcgettext()`, `dngettext()`, and `dcngettext()`, the domain used is specified by the *domainname* argument. The *domainname* argument is equivalent in syntax and meaning to the *domainname* argument to `textdomain()`, except that the selection of the domain is valid only for the duration of the `dgettext()`, `dcgettext()`, `dngettext()`, or `dcngettext()` function call.

The `textdomain()` function sets or queries the name of the current domain of the active `LC_MESSAGES` locale category. The *domainname* argument is a null-terminated string that can contain only the characters allowed in legal filenames.

The *domainname* argument is the unique name of a domain on the system. If there are multiple versions of the same domain on one system, namespace collisions can be avoided by using `bindtextdomain()`. If `textdomain()` is not called, a default domain is selected. The setting of domain made by the last valid call to `textdomain()` remains valid across subsequent calls to `setlocale(3C)`, and `gettext()`.

The *domainname* argument is applied to the currently active `LC_MESSAGES` locale.

The current setting of the domain can be queried without affecting the current state of the domain by calling `textdomain()` with *domainname* set to the null pointer. Calling `textdomain()` with a *domainname* argument of a null string sets the domain to the default domain (`messages`).

The `bindtextdomain()` function binds the path predicate for a message domain *domainname* to the value contained in *dirname*. If *domainname* is a non-empty string and has not been bound previously, `bindtextdomain()` binds *domainname* with *dirname*.

If *domainname* is a non-empty string and has been bound previously, `bindtextdomain()` replaces the old binding with *dirname*. The *dirname* argument can be an absolute or relative pathname being resolved when `gettext()`, `dgettext()`, or `dcgettext()` are called. If *domainname* is a null pointer or an empty string, `bindtextdomain()` returns NULL. User defined domain names cannot begin with the string `SYS_`. Domain names beginning with this string are reserved for system use.

The `bind_textdomain_codeset()` function can be used to specify the output codeset for message catalogues for domain *domainname*. The *codeset* argument must be a valid codeset name that can be used for the `iconv_open(3C)` function, or a null pointer. If the *codeset* argument is the null pointer, `bind_textdomain_codeset()` returns the currently selected codeset for the domain with the name *domainname*. It returns a null pointer if a codeset has not yet been selected. The `bind_textdomain_codeset()` function can be used multiple times. If used multiple times with the same *domainname* argument, the later call overrides the settings made by the earlier one. The `bind_textdomain_codeset()` function returns a pointer to a string containing the name of the selected codeset. The string is allocated internally in the function and must not be changed by the user.

RETURN VALUES

The `gettext()`, `dgettext()`, and `dcgettext()` functions return the message string if the search succeeds. Otherwise they return the *msgid* string.

The `ngettext()`, `dngettext()`, and `dcngettext()` functions return the message string if the search succeeds. If the search fails, *msgid1* is returned if *n* == 1. Otherwise *msgid2* is returned.

The individual bytes of the string returned by `gettext()`, `dgettext()`, `dcgettext()`, `ngettext()`, `dngettext()`, or `dcngettext()` can contain any value other than NULL. If *msgid* is a null pointer, the return value is undefined. The string returned must not be modified by the program and can be invalidated by a subsequent call to `bind_textdomain_codeset()` or `setlocale(3C)`. If the *domainname* argument to `dgettext()`, `dcgettext()`, `dngettext()`, or `dcngettext()` is a null pointer, the the domain currently bound by `textdomain()` is used.

The normal return value from `textdomain()` is a pointer to a string containing the current setting of the domain. If *domainname* is a null pointer, `textdomain()` returns a pointer to the string containing the current domain. If `textdomain()` was not previously called and *domainname* is a null string, the name of the default domain is returned. The name of the default domain is `messages`. If `textdomain()` fails, a null pointer is returned.

The return value from `bindtextdomain()` is a null-terminated string containing *dirname* or the directory binding associated with *domainname* if *dirname* is NULL. If no binding is found, the default return value is `/usr/lib/locale`. If *domainname* is a null pointer or an empty string, `bindtextdomain()` takes no action and returns a null pointer. The string returned must not be modified by the caller. If `bindtextdomain()` fails, a null pointer is returned.

bind_textdomain_codeset(3C)

USAGE These functions impose no limit on message length. However, a text *domainname* is limited to TEXTDOMAINMAX (256) bytes.

The `gettext()`, `dgettext()`, `dcgettext()`, `ngettext()`, `dngettext()`, `dcngettext()`, `textdomain()`, and `bindtextdomain()` functions can be used safely in multithreaded applications, as long as `setlocale(3C)` is not being called to change the locale.

The `gettext()`, `dgettext()`, `dcgettext()`, `textdomain()`, and `bindtextdomain()` functions work with both Solaris message catalogues and GNU-compatible message catalogues. The `ngettext()`, `dngettext()`, `dcngettext()`, and `bind_textdomain_codeset()` functions work only with GNU-compatible message catalogues. See `msgfmt(1)` for information about Solaris message catalogues and GNU-compatible message catalogues.

FILES `/usr/lib/locale`
default path predicate for message domain files

`/usr/lib/locale/locale/LC_MESSAGES/domainname.mo`
system default location for file containing messages for language *locale* and *domainname*

`/usr/lib/locale/locale/LC_XXX/domainname.mo`
system default location for file containing messages for language *locale* and *domainname* for `dcgettext()` calls where `LC_XXX` is `LC_CTYPE`, `LC_NUMERIC`, `LC_TIME`, `LC_COLLATE`, `LC_MONETARY`, or `LC_MESSAGES`

`dirname/locale/LC_MESSAGES/domainname.mo`
location for file containing messages for domain *domainname* and path predicate *dirname* after a successful call to `bindtextdomain()`

`dirname/locale/LC_XXX/domainname.mo`
location for files containing messages for domain *domainname*, language *locale*, and path predicate *dirname* after a successful call to `bindtextdomain()` for `dcgettext()` calls where `LC_XXX` is one of `LC_CTYPE`, `LC_NUMERIC`, `LC_TIME`, `LC_COLLATE`, `LC_MONETARY`, or `LC_MESSAGES`

NAME	bsdmalloc – memory allocator				
SYNOPSIS	<pre>cc [<i>flag ...</i>] <i>file ...</i> -lbsdmalloc [<i>library ...</i>] char *malloc (<i>size</i>) ; unsigned <i>size</i> ; int free (<i>ptr</i>) ; char *<i>ptr</i> ; char *realloc (<i>ptr</i>, <i>size</i>) ; char *<i>ptr</i> ; unsigned <i>size</i> ;</pre>				
DESCRIPTION	<p>These routines provide a general-purpose memory allocation package. They maintain a table of free blocks for efficient allocation and coalescing of free storage. When there is no suitable space already free, the allocation routines call <code>sbrk(2)</code> to get more memory from the system. Each of the allocation routines returns a pointer to space suitably aligned for storage of any type of object. Each returns a null pointer if the request cannot be completed.</p> <p>The <code>malloc()</code> function returns a pointer to a block of at least <i>size</i> bytes, which is appropriately aligned.</p> <p>The <code>free()</code> function releases a previously allocated block. Its argument is a pointer to a block previously allocated by <code>malloc()</code> or <code>realloc()</code>.</p> <p>The <code>realloc()</code> function changes the size of the block referenced by <i>ptr</i> to <i>size</i> bytes and returns a pointer to the (possibly moved) block. The contents will be unchanged up to the lesser of the new and old sizes. If unable to honor a reallocation request, <code>realloc()</code> leaves its first argument unaltered. For backwards compatibility, <code>realloc()</code> accepts a pointer to a block freed since the most recent call to <code>malloc()</code> or <code>realloc()</code>.</p>				
RETURN VALUES	The <code>malloc()</code> and <code>realloc()</code> functions return a null pointer if there is not enough available memory. When <code>realloc()</code> returns <code>NULL</code> , the block pointed to by <i>ptr</i> is left intact.				
ERRORS	<p>If <code>malloc()</code> or <code>realloc()</code> returns unsuccessfully, <code>errno</code> will be set to indicate the following:</p> <table border="0"> <tr> <td style="padding-right: 20px;">ENOMEM</td> <td><i>size</i> bytes of memory cannot be allocated because it exceeds the physical limits of the system.</td> </tr> <tr> <td>EAGAIN</td> <td>There is not enough memory available at this point in time to allocate <i>size</i> bytes of memory; but the application could try again later.</td> </tr> </table>	ENOMEM	<i>size</i> bytes of memory cannot be allocated because it exceeds the physical limits of the system.	EAGAIN	There is not enough memory available at this point in time to allocate <i>size</i> bytes of memory; but the application could try again later.
ENOMEM	<i>size</i> bytes of memory cannot be allocated because it exceeds the physical limits of the system.				
EAGAIN	There is not enough memory available at this point in time to allocate <i>size</i> bytes of memory; but the application could try again later.				
SEE ALSO	<code>brk(2)</code> , <code>malloc(3C)</code> , <code>malloc(3MALLOC)</code> , <code>mapmalloc(3MALLOC)</code>				
WARNINGS	Use of <code>libbsdmalloc</code> renders an application non-SCD compliant.				

bsdmalloc(3MALLOC)

The libbsdmalloc routines are incompatible with the memory allocation routines in the standard C-library (libc): `malloc(3C)`, `alloca(3C)`, `calloc(3C)`, `free(3C)`, `memalign(3C)`, `realloc(3C)`, and `valloc(3C)`.

NOTES Using `realloc()` with a block freed before the most recent call to `malloc()` or `realloc()` results in an error.

The `malloc()` and `realloc()` functions return a non-null pointer if *size* is 0. These pointers should not be dereferenced.

Always cast the value returned by `malloc()` and `realloc()`.

Comparative features of `bsdmalloc`, `malloc(3MALLOC)`, and `malloc(3C)`:

- The `bsdmalloc()` routines afford better performance but are space-inefficient.
- The `malloc(3MALLOC)` routines are space-efficient but have slower performance.
- The standard, fully SCD-compliant `malloc(3C)` routines are a trade-off between performance and space-efficiency.

The `free()` function does not set `errno`.

NAME	bsd_signal – simplified signal facilities
SYNOPSIS	<pre>#include <signal.h> void (*bsd_signal(int sig, void (*func) (int))) (int);</pre>
DESCRIPTION	<p>The <code>bsd_signal()</code> function provides a partially compatible interface for programs written to historical system interfaces (see <code>USAGE</code> below).</p> <p>The function call <code>bsd_signal(sig, func)</code> has an effect as if implemented as:</p> <pre>void (*bsd_signal(int sig, void (*func) (int))) (int) { struct sigaction act, oact; act.sa_handler = func; act.sa_flags = SA_RESTART; sigemptyset(&act.sa_mask); sigaddset(&act.sa_mask, sig); if (sigaction(sig, &act, &oact) == -1) return(SIG_ERR); return(oact.sa_handler); }</pre> <p>The handler function should be declared:</p> <pre>void handler(int sig);</pre> <p>where <code>sig</code> is the signal number. The behavior is undefined if <code>func</code> is a function that takes more than one argument, or an argument of a different type.</p>
RETURN VALUES	Upon successful completion, <code>bsd_signal()</code> returns the previous action for <code>sig</code> . Otherwise, <code>SIG_ERR</code> is returned and <code>errno</code> is set to indicate the error.
ERRORS	Refer to <code>sigaction(2)</code> .
USAGE	This function is a direct replacement for the BSD <code>signal(3UCB)</code> function for simple applications that are installing a single-argument signal handler function. If a BSD signal handler function is being installed that expects more than one argument, the application has to be modified to use <code>sigaction(2)</code> . The <code>bsd_signal()</code> function differs from <code>signal(3UCB)</code> in that the <code>SA_RESTART</code> flag is set and the <code>SA_RESETHAND</code> will be clear when <code>bsd_signal()</code> is used. The state of these flags is not specified for <code>signal(3UCB)</code> .
SEE ALSO	<code>sigaction(2)</code> , <code>sigaddset(3C)</code> , <code>sigemptyset(3C)</code> , <code>signal(3UCB)</code>

bsearch(3C)

NAME	bsearch – binary search a sorted table
SYNOPSIS	<pre>#include <stdlib.h> void *bsearch(const void *key, const void *base, size_t nel, size_t size, int (*compar)(const void *,const void *));</pre>
DESCRIPTION	<p>The <code>bsearch()</code> function is a binary search routine generalized from Knuth (6.2.1) Algorithm B. It returns a pointer into a table (an array) indicating where a datum may be found or a null pointer if the datum cannot be found. The table must be previously sorted in increasing order according to a comparison function pointed to by <code>compar</code>.</p> <p>The <code>key</code> argument points to a datum instance to be sought in the table. The <code>base</code> argument points to the element at the base of the table. The <code>nel</code> argument is the number of elements in the table. The <code>size</code> argument is the number of bytes in each element.</p> <p>The comparison function pointed to by <code>compar</code> is called with two arguments that point to the <code>key</code> object and to an array element, in that order. The function must return an integer less than, equal to, or greater than 0 if the <code>key</code> object is considered, respectively, to be less than, equal to, or greater than the array element.</p>
RETURN VALUES	The <code>bsearch()</code> function returns a pointer to a matching member of the array, or a null pointer if no match is found. If two or more members compare equal, which member is returned is unspecified.
USAGE	<p>The pointers to the key and the element at the base of the table should be of type pointer-to-element.</p> <p>The comparison function need not compare every byte, so arbitrary data may be contained in the elements in addition to the values being compared.</p> <p>If the number of elements in the table is less than the size reserved for the table, <code>nel</code> should be the lower number.</p>
EXAMPLES	<p>EXAMPLE 1 Examples for searching a table containing pointers to nodes.</p> <p>The example below searches a table containing pointers to nodes consisting of a string and its length. The table is ordered alphabetically on the string in the node pointed to by each entry.</p> <p>This program reads in strings and either finds the corresponding node and prints out the string and its length, or prints an error message.</p> <pre>#include <stdio.h> #include <stdlib.h> #include <string.h> struct node { /* these are stored in the table */ char *string; int length; }; static struct node table[] = { /* table to be searched */</pre>

NAME	malloc, calloc, free, memalign, realloc, valloc, alloca – memory allocator
SYNOPSIS	<pre>#include <stdlib.h> void *malloc(size_t size); void *calloc(size_t nelem, size_t elsize); void free(void *ptr); void *memalign(size_t alignment, size_t size); void *realloc(void *ptr, size_t size); void *valloc(size_t size); #include <alloca.h> void *alloca(size_t size);</pre>
DESCRIPTION	<p>The <code>malloc()</code> and <code>free()</code> functions provide a simple, general-purpose memory allocation package. The <code>malloc()</code> function returns a pointer to a block of at least <i>size</i> bytes suitably aligned for any use. If the space assigned by <code>malloc()</code> is overrun, the results are undefined.</p> <p>The argument to <code>free()</code> is a pointer to a block previously allocated by <code>malloc()</code>, <code>calloc()</code>, or <code>realloc()</code>. After <code>free()</code> is executed, this space is made available for further allocation by the application, though not returned to the system. Memory is returned to the system only upon termination of the application. If <i>ptr</i> is a null pointer, no action occurs. If a random number is passed to <code>free()</code>, the results are undefined.</p> <p>The <code>calloc()</code> function allocates space for an array of <i>nelem</i> elements of size <i>elsize</i>. The space is initialized to zeros.</p> <p>The <code>memalign()</code> function allocates <i>size</i> bytes on a specified alignment boundary and returns a pointer to the allocated block. The value of the returned address is guaranteed to be an even multiple of <i>alignment</i>. The value of <i>alignment</i> must be a power of two and must be greater than or equal to the size of a word.</p> <p>The <code>realloc()</code> function changes the size of the block pointed to by <i>ptr</i> to <i>size</i> bytes and returns a pointer to the (possibly moved) block. The contents will be unchanged up to the lesser of the new and old sizes. If <i>ptr</i> is NULL, <code>realloc()</code> behaves like <code>malloc()</code> for the specified size. If <i>size</i> is 0 and <i>ptr</i> is not a null pointer, the space pointed to is made available for further allocation by the application, though not returned to the system. Memory is returned to the system only upon termination of the application.</p> <p>The <code>valloc()</code> function has the same effect as <code>malloc()</code>, except that the allocated memory will be aligned to a multiple of the value returned by <code>sysconf(_SC_PAGESIZE)</code>.</p>

calloc(3C)

The `alloca()` function allocates *size* bytes of space in the stack frame of the caller, and returns a pointer to the allocated block. This temporary space is automatically freed when the caller returns. If the allocated block is beyond the current stack limit, the resulting behavior is undefined.

RETURN VALUES Upon successful completion, each of the allocation functions returns a pointer to space suitably aligned (after possible pointer coercion) for storage of any type of object.

If there is no available memory, `malloc()`, `realloc()`, `memalign()`, `valloc()`, and `calloc()` return a null pointer. When `realloc()` is called with *size* > 0 and returns `NULL`, the block pointed to by *ptr* is left intact. If *size*, *nelem*, or *elsize* is 0, either a null pointer or a unique pointer that can be passed to `free()` is returned.

If `malloc()`, `calloc()`, or `realloc()` returns unsuccessfully, `errno` will be set to indicate the error. The `free()` function does not set `errno`.

ERRORS The `malloc()`, `calloc()`, and `realloc()` functions will fail if:

`ENOMEM` The physical limits of the system are exceeded by *size* bytes of memory which cannot be allocated.

`EAGAIN` There is not enough memory available to allocate *size* bytes of memory; but the application could try again later.

USAGE Portable applications should avoid using `valloc()` but should instead use `malloc()` or `mmap(2)`. On systems with a large page size, the number of successful `valloc()` operations might be 0.

Comparative features of `malloc(3C)`, `bsdmalloc(3MALLOC)`, and `malloc(3MALLOC)` are as follows:

- The `bsdmalloc(3MALLOC)` routines afford better performance, but are space-inefficient.
- The `malloc(3MALLOC)` routines are space-efficient, but have slower performance.
- The standard, fully SCD-compliant `malloc` routines are a trade-off between performance and space-efficiency.

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Interface Stability	<code>malloc()</code> , <code>calloc()</code> , <code>free()</code> , <code>realloc()</code> , <code>valloc()</code> are Standard; <code>memalign()</code> and <code>alloca()</code> are Stable.
MT-Level	Safe

SEE ALSO `brk(2)`, `getrlimit(2)`, `bsdmalloc(3MALLOC)`, `malloc(3MALLOC)`, `mapmalloc(3MALLOC)`, `watchmalloc(3MALLOC)`, `attributes(5)`

WARNINGS Undefined results will occur if the size requested for a block of memory exceeds the maximum size of a process's heap, which can be obtained with `getrlimit(2)`

The `alloca()` function is machine-, compiler-, and most of all, system-dependent. Its use is strongly discouraged.

calloc(3MALLOC)

NAME	malloc, free, realloc, calloc, malloc, mallinfo – memory allocator				
SYNOPSIS	<pre>cc [<i>flag</i> ...] <i>file</i> ... -lmalloc [<i>library</i> ...] #include <stdlib.h> void *malloc(size_t <i>size</i>); void free(void *<i>ptr</i>); void *realloc(void *<i>ptr</i>, size_t <i>size</i>); void *calloc(size_t <i>nelem</i>, size_t <i>elsize</i>); #include <malloc.h> int malloc(int <i>cmd</i>, int <i>value</i>); struct mallinfo mallinfo(void);</pre>				
DESCRIPTION	<p>The malloc() and free() functins provide a simple general-purpose memory allocation package.</p> <p>The malloc() function returns a pointer to a block of at least <i>size</i> bytes suitably aligned for any use.</p> <p>The argument to free() is a pointer to a block previously allocated by malloc(). After free() is performed, this space is made available for further allocation, and its contents have been destroyed See malloc() below for a way to change this behavior. If <i>ptr</i> is a null pointer, no action occurs.</p> <p>Undefined results occur if the space assigned by malloc() is overrun or if some random number is handed to free().</p> <p>The realloc() function changes the size of the block pointed to by <i>ptr</i> to <i>size</i> bytes and returns a pointer to the (possibly moved) block. The contents are unchanged up to the lesser of the new and old sizes. If <i>ptr</i> is a null pointer, realloc() behaves like malloc() for the specified size. If <i>size</i> is 0 and <i>ptr</i> is not a null pointer, the object it points to is freed.</p> <p>The calloc() function allocates space for an array of <i>nelem</i> elements of size <i>elsize</i>. The space is initialized to zeros.</p> <p>The malloc() function provides for control over the allocation algorithm. The available values for <i>cmd</i> are:</p> <table><tr><td>M_MXFAST</td><td>Set <i>maxfast</i> to <i>value</i>. The algorithm allocates all blocks below the size of <i>maxfast</i> in large groups and then doles them out very quickly. The default value for <i>maxfast</i> is 24.</td></tr><tr><td>M_NLBLKS</td><td>Set <i>numlblks</i> to <i>value</i>. The above mentioned “large groups” each contain <i>numlblks</i> blocks. <i>numlblks</i> must be greater than 0. The default value for <i>numlblks</i> is 100.</td></tr></table>	M_MXFAST	Set <i>maxfast</i> to <i>value</i> . The algorithm allocates all blocks below the size of <i>maxfast</i> in large groups and then doles them out very quickly. The default value for <i>maxfast</i> is 24.	M_NLBLKS	Set <i>numlblks</i> to <i>value</i> . The above mentioned “large groups” each contain <i>numlblks</i> blocks. <i>numlblks</i> must be greater than 0. The default value for <i>numlblks</i> is 100.
M_MXFAST	Set <i>maxfast</i> to <i>value</i> . The algorithm allocates all blocks below the size of <i>maxfast</i> in large groups and then doles them out very quickly. The default value for <i>maxfast</i> is 24.				
M_NLBLKS	Set <i>numlblks</i> to <i>value</i> . The above mentioned “large groups” each contain <i>numlblks</i> blocks. <i>numlblks</i> must be greater than 0. The default value for <i>numlblks</i> is 100.				

M_GRAIN	Set <i>grain</i> to <i>value</i> . The sizes of all blocks smaller than <i>maxfast</i> are considered to be rounded up to the nearest multiple of <i>grain</i> . <i>grain</i> must be greater than 0. The default value of <i>grain</i> is the smallest number of bytes that will allow alignment of any data type. Value will be rounded up to a multiple of the default when <i>grain</i> is set.
M_KEEP	Preserve data in a freed block until the next <code>malloc()</code> , <code>realloc()</code> , or <code>calloc()</code> . This option is provided only for compatibility with the old version of <code>malloc()</code> , and it is not recommended.

These values are defined in the `<malloc.h>` header.

The `mallot()` function can be called repeatedly, but cannot be called after the first small block is allocated.

The `mallinfo()` function provides instrumentation describing space usage. It returns the `mallinfo` structure with the following members:

```

unsigned long arena;      /* total space in arena */
unsigned long ordblks;    /* number of ordinary blocks */
unsigned long smlbks;    /* number of small blocks */
unsigned long hblkhd;    /* space in holding block headers */
unsigned long hblks;     /* number of holding blocks */
unsigned long usmlbks;   /* space in small blocks in use */
unsigned long fsmblks;   /* space in free small blocks */
unsigned long uordblks;  /* space in ordinary blocks in use */
unsigned long fordblks;  /* space in free ordinary blocks */
unsigned long keepcost;  /* space penalty if keep option */
                        /* is used */

```

The `mallinfo` structure is defined in the `<malloc.h>` header.

Each of the allocation routines returns a pointer to space suitably aligned (after possible pointer coercion) for storage of any type of object.

RETURN VALUES

The `malloc()`, `realloc()`, and `calloc()` functions return a null pointer if there is not enough available memory. When `realloc()` returns `NULL`, the block pointed to by *ptr* is left intact. If `mallot()` is called after any allocation or if *cmd* or *value* are invalid, a non-zero value is returned. Otherwise, it returns 0.

ERRORS

If `malloc()`, `calloc()`, or `realloc()` returns unsuccessfully, `errno` is set to indicate the error:

ENOMEM	<i>size</i> bytes of memory exceeds the physical limits of your system, and cannot be allocated.
EAGAIN	There is not enough memory available at this point in time to allocate <i>size</i> bytes of memory; but the application could try again later.

calloc(3MALLOC)

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
MT-Level	Safe

SEE ALSO `brk(2)`, `bsdmalloc(3MALLOC)`, `libmtmalloc(3LIB)`, `malloc(3C)`, `mapmalloc(3MALLOC)`, `mtmalloc(3MALLOC)`, `watchmalloc(3MALLOC)`, `attributes(5)`

NOTES Note that unlike `malloc(3C)`, this package does not preserve the contents of a block when it is freed, unless the `M_KEEP` option of `mallopt()` is used.

Undocumented features of `malloc(3C)` have not been duplicated.

Function prototypes for `malloc()`, `realloc()`, `calloc()`, and `free()` are also defined in the `<malloc.h>` header for compatibility with old applications. New applications should include `<stdlib.h>` to access the prototypes for these functions. Comparative Features of these `malloc` routines, `bsdmalloc(3MALLOC)`, and `malloc(3C)`

- These `malloc` routines are space-efficient but have slower performance.
- The `bsdmalloc(3MALLOC)` routines afford better performance but are space-inefficient.
- The standard, fully SCD-compliant `malloc(3C)` routines are a trade-off between performance and space-efficiency.

The `free()` function does not set `errno`.

NAME	catopen, catclose – open/close a message catalog												
SYNOPSIS	<pre>#include <nl_types.h> nl_catd catopen(const char *name, int oflag); int catclose(nl_catd catd);</pre>												
DESCRIPTION	<p>The <code>catopen()</code> function opens a message catalog and returns a message catalog descriptor. <i>name</i> specifies the name of the message catalog to be opened. If <i>name</i> contains a <code>"/</code>, then <i>name</i> specifies a complete pathname for the message catalog; otherwise, the environment variable <code>NLSPATH</code> is used and <code>/usr/lib/locale/locale/LC_MESSAGES</code> must exist. If <code>NLSPATH</code> does not exist in the environment, or if a message catalog cannot be opened in any of the paths specified by <code>NLSPATH</code>, then the default path <code>/usr/lib/locale/locale/LC_MESSAGES</code> is used. In the "C" locale, <code>catopen()</code> will always succeed without checking the default search path.</p> <p>The names of message catalogs and their location in the filesystem can vary from one system to another. Individual applications can choose to name or locate message catalogs according to their own special needs. A mechanism is therefore required to specify where the catalog resides.</p> <p>The <code>NLSPATH</code> variable provides both the location of message catalogs, in the form of a search path, and the naming conventions associated with message catalog files. For example:</p> <pre>NLSPATH=/nlslib/%L/%N.cat:/nlslib/%N/%L</pre> <p>The metacharacter <code>%</code> introduces a substitution field, where <code>%L</code> substitutes the current setting of either the <code>LANG</code> environment variable, if the value of <i>oflag</i> is 0, or the <code>LC_MESSAGES</code> category, if the value of <i>oflag</i> is <code>NL_CAT_LOCALE</code>, and <code>%N</code> substitutes the value of the <i>name</i> parameter passed to <code>catopen()</code>. Thus, in the above example, <code>catopen()</code> will search in <code>/nlslib/\$LANG/name.cat</code>, if <i>oflag</i> is 0, or in <code>/nlslib/{LC_MESSAGES}/name.cat</code>, if <i>oflag</i> is <code>NL_CAT_LOCALE</code>.</p> <p>The <code>NLSPATH</code> variable will normally be set up on a system wide basis (in <code>/etc/profile</code>) and thus makes the location and naming conventions associated with message catalogs transparent to both programs and users.</p> <p>The full set of metacharacters is:</p> <table border="0"> <tr> <td style="padding-right: 20px;"><code>%N</code></td> <td>The value of the name parameter passed to <code>catopen()</code>.</td> </tr> <tr> <td><code>%L</code></td> <td>The value of <code>LANG</code> or <code>LC_MESSAGES</code>.</td> </tr> <tr> <td><code>%l</code></td> <td>The value of the <i>language</i> element of <code>LANG</code> or <code>LC_MESSAGES</code>.</td> </tr> <tr> <td><code>%t</code></td> <td>The value of the <i>territory</i> element of <code>LANG</code> or <code>LC_MESSAGES</code>.</td> </tr> <tr> <td><code>%c</code></td> <td>The value of the <i>codeset</i> element of <code>LANG</code> or <code>LC_MESSAGES</code>.</td> </tr> <tr> <td><code>%%</code></td> <td>A single <code>%</code>.</td> </tr> </table>	<code>%N</code>	The value of the name parameter passed to <code>catopen()</code> .	<code>%L</code>	The value of <code>LANG</code> or <code>LC_MESSAGES</code> .	<code>%l</code>	The value of the <i>language</i> element of <code>LANG</code> or <code>LC_MESSAGES</code> .	<code>%t</code>	The value of the <i>territory</i> element of <code>LANG</code> or <code>LC_MESSAGES</code> .	<code>%c</code>	The value of the <i>codeset</i> element of <code>LANG</code> or <code>LC_MESSAGES</code> .	<code>%%</code>	A single <code>%</code> .
<code>%N</code>	The value of the name parameter passed to <code>catopen()</code> .												
<code>%L</code>	The value of <code>LANG</code> or <code>LC_MESSAGES</code> .												
<code>%l</code>	The value of the <i>language</i> element of <code>LANG</code> or <code>LC_MESSAGES</code> .												
<code>%t</code>	The value of the <i>territory</i> element of <code>LANG</code> or <code>LC_MESSAGES</code> .												
<code>%c</code>	The value of the <i>codeset</i> element of <code>LANG</code> or <code>LC_MESSAGES</code> .												
<code>%%</code>	A single <code>%</code> .												

catclose(3C)

The LANG environment variable provides the ability to specify the user's requirements for native languages, local customs and character set, as an ASCII string in the form

```
LANG=language[_territory[.codeset]]
```

A user who speaks German as it is spoken in Austria and has a terminal which operates in ISO 8859/1 codeset, would want the setting of the LANG variable to be

```
LANG=De_A.88591
```

With this setting it should be possible for that user to find any relevant catalogs should they exist.

Should the LANG variable not be set, the value of LC_MESSAGES as returned by `setlocale()` is used. If this is NULL, the default path as defined in `<nl_types.h>` is used.

A message catalogue descriptor remains valid in a process until that process closes it, or a successful call to one of the `exec` functions. A change in the setting of the LC_MESSAGES category may invalidate existing open catalogues.

If a file descriptor is used to implement message catalogue descriptors, the FD_CLOEXEC flag will be set; see `<fcntl.h>`.

If the value of *oflag* argument is 0, the LANG environment variable is used to locate the catalogue without regard to the LC_MESSAGES category. If the *oflag* argument is NL_CAT_LOCALE, the LC_MESSAGES category is used to locate the message catalogue.

The `catclose()` function closes the message catalog identified by *catd*. If a file descriptor is used to implement the type `nl_catd`, that file descriptor will be closed.

RETURN VALUES

Upon successful completion, `catopen()` returns a message catalog descriptor for use on subsequent calls to `catgets()` and `catclose()`. Otherwise it returns `(nl_catd) -1`.

Upon successful completion, `catclose()` returns 0. Otherwise it returns `-1` and sets `errno` to indicate the error.

ERRORS

The `catopen()` function may fail if:

EACCES	Search permission is denied for the component of the path prefix of the message catalogue or read permission is denied for the message catalogue.
EMFILE	There are OPEN_MAX file descriptors currently open in the calling process.
ENAMETOOLONG	The length of the pathname of the message catalogue exceeds PATH_MAX, or a pathname component is longer than NAME_MAX.
ENAMETOOLONG	Pathname resolution of a symbolic link produced an intermediate result whose length exceeds PATH_MAX.

ENFILE	Too many files are currently open in the system.
ENOENT	The message catalogue does not exist or the <i>name</i> argument points to an empty string.
ENOMEM	Insufficient storage space is available.
ENOTDIR	A component of the path prefix of the message catalogue is not a directory.

The `catclose()` function may fail if:

EBADF	The catalogue descriptor is not valid.
EINTR	The <code>catclose()</code> function was interrupted by a signal.

USAGE The `catopen()` and `catclose()` functions can be used safely in multithreaded applications, as long as `setlocale(3C)` is not being called to change the locale.

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

catgets(3C)

NAME	catgets – read a program message				
SYNOPSIS	<pre>#include <nl_types.h> char *catgets (nl_catd catd, int set_num, int msg_num, const char *s);</pre>				
DESCRIPTION	The <code>catgets()</code> function attempts to read message <code>msg_num</code> , in set <code>set_num</code> , from the message catalog identified by <code>catd</code> . The <code>catd</code> argument is a catalog descriptor returned from an earlier call to <code>catopen()</code> . The <code>s</code> argument points to a default message string which will be returned by <code>catgets()</code> if the identified message catalog is not currently available.				
RETURN VALUES	If the identified message is retrieved successfully, <code>catgets()</code> returns a pointer to an internal buffer area containing the null terminated message string. If the call is unsuccessful for any reason, <code>catgets()</code> returns a pointer to <code>s</code> and <code>errno</code> may be set to indicate the error.				
ERRORS	The <code>catgets()</code> function may fail if: EBADF The <code>catd</code> argument is not a valid message catalogue descriptor open for reading. EINTR The read operation was terminated due to the receipt of a signal, and no data was transferred. EINVAL The message catalog identified by <code>catd</code> is corrupted. ENOMSG The message identified by <code>set_id</code> and <code>msg_id</code> is not in the message catalog.				
USAGE	The <code>catgets()</code> function can be used safely in multithreaded applications, as long as <code>setlocale(3C)</code> is not being called to change the locale.

NAME	catopen, catclose – open/close a message catalog												
SYNOPSIS	<pre>#include <nl_types.h> nl_catd catopen(const char *name, int oflag); int catclose(nl_catd catd);</pre>												
DESCRIPTION	<p>The <code>catopen()</code> function opens a message catalog and returns a message catalog descriptor. <i>name</i> specifies the name of the message catalog to be opened. If <i>name</i> contains a <code>"/"</code>, then <i>name</i> specifies a complete pathname for the message catalog; otherwise, the environment variable <code>NLSPATH</code> is used and <code>/usr/lib/locale/locale/LC_MESSAGES</code> must exist. If <code>NLSPATH</code> does not exist in the environment, or if a message catalog cannot be opened in any of the paths specified by <code>NLSPATH</code>, then the default path <code>/usr/lib/locale/locale/LC_MESSAGES</code> is used. In the "C" locale, <code>catopen()</code> will always succeed without checking the default search path.</p> <p>The names of message catalogs and their location in the filesystem can vary from one system to another. Individual applications can choose to name or locate message catalogs according to their own special needs. A mechanism is therefore required to specify where the catalog resides.</p> <p>The <code>NLSPATH</code> variable provides both the location of message catalogs, in the form of a search path, and the naming conventions associated with message catalog files. For example:</p> <pre>NLSPATH=/nlslib/%L/%N.cat:/nlslib/%N/%L</pre> <p>The metacharacter <code>%</code> introduces a substitution field, where <code>%L</code> substitutes the current setting of either the <code>LANG</code> environment variable, if the value of <i>oflag</i> is 0, or the <code>LC_MESSAGES</code> category, if the value of <i>oflag</i> is <code>NL_CAT_LOCALE</code>, and <code>%N</code> substitutes the value of the <i>name</i> parameter passed to <code>catopen()</code>. Thus, in the above example, <code>catopen()</code> will search in <code>/nlslib/\$LANG/name.cat</code>, if <i>oflag</i> is 0, or in <code>/nlslib/{LC_MESSAGES}/name.cat</code>, if <i>oflag</i> is <code>NL_CAT_LOCALE</code>.</p> <p>The <code>NLSPATH</code> variable will normally be set up on a system wide basis (in <code>/etc/profile</code>) and thus makes the location and naming conventions associated with message catalogs transparent to both programs and users.</p> <p>The full set of metacharacters is:</p> <table border="0"> <tr> <td style="padding-right: 20px;"><code>%N</code></td> <td>The value of the name parameter passed to <code>catopen()</code>.</td> </tr> <tr> <td><code>%L</code></td> <td>The value of <code>LANG</code> or <code>LC_MESSAGES</code>.</td> </tr> <tr> <td><code>%l</code></td> <td>The value of the <i>language</i> element of <code>LANG</code> or <code>LC_MESSAGES</code>.</td> </tr> <tr> <td><code>%t</code></td> <td>The value of the <i>territory</i> element of <code>LANG</code> or <code>LC_MESSAGES</code>.</td> </tr> <tr> <td><code>%c</code></td> <td>The value of the <i>codeset</i> element of <code>LANG</code> or <code>LC_MESSAGES</code>.</td> </tr> <tr> <td><code>%%</code></td> <td>A single <code>%</code>.</td> </tr> </table>	<code>%N</code>	The value of the name parameter passed to <code>catopen()</code> .	<code>%L</code>	The value of <code>LANG</code> or <code>LC_MESSAGES</code> .	<code>%l</code>	The value of the <i>language</i> element of <code>LANG</code> or <code>LC_MESSAGES</code> .	<code>%t</code>	The value of the <i>territory</i> element of <code>LANG</code> or <code>LC_MESSAGES</code> .	<code>%c</code>	The value of the <i>codeset</i> element of <code>LANG</code> or <code>LC_MESSAGES</code> .	<code>%%</code>	A single <code>%</code> .
<code>%N</code>	The value of the name parameter passed to <code>catopen()</code> .												
<code>%L</code>	The value of <code>LANG</code> or <code>LC_MESSAGES</code> .												
<code>%l</code>	The value of the <i>language</i> element of <code>LANG</code> or <code>LC_MESSAGES</code> .												
<code>%t</code>	The value of the <i>territory</i> element of <code>LANG</code> or <code>LC_MESSAGES</code> .												
<code>%c</code>	The value of the <i>codeset</i> element of <code>LANG</code> or <code>LC_MESSAGES</code> .												
<code>%%</code>	A single <code>%</code> .												

catopen(3C)

The LANG environment variable provides the ability to specify the user's requirements for native languages, local customs and character set, as an ASCII string in the form

```
LANG=language[_territory[.codeset]]
```

A user who speaks German as it is spoken in Austria and has a terminal which operates in ISO 8859/1 codeset, would want the setting of the LANG variable to be

```
LANG=De_A.88591
```

With this setting it should be possible for that user to find any relevant catalogs should they exist.

Should the LANG variable not be set, the value of LC_MESSAGES as returned by `setlocale()` is used. If this is NULL, the default path as defined in `<nl_types.h>` is used.

A message catalogue descriptor remains valid in a process until that process closes it, or a successful call to one of the `exec` functions. A change in the setting of the LC_MESSAGES category may invalidate existing open catalogues.

If a file descriptor is used to implement message catalogue descriptors, the FD_CLOEXEC flag will be set; see `<fcntl.h>`.

If the value of *oflag* argument is 0, the LANG environment variable is used to locate the catalogue without regard to the LC_MESSAGES category. If the *oflag* argument is NL_CAT_LOCALE, the LC_MESSAGES category is used to locate the message catalogue.

The `catclose()` function closes the message catalog identified by *catd*. If a file descriptor is used to implement the type `nl_catd`, that file descriptor will be closed.

RETURN VALUES

Upon successful completion, `catopen()` returns a message catalog descriptor for use on subsequent calls to `catgets()` and `catclose()`. Otherwise it returns `(nl_catd) -1`.

Upon successful completion, `catclose()` returns 0. Otherwise it returns `-1` and sets `errno` to indicate the error.

ERRORS

The `catopen()` function may fail if:

EACCES	Search permission is denied for the component of the path prefix of the message catalogue or read permission is denied for the message catalogue.
EMFILE	There are OPEN_MAX file descriptors currently open in the calling process.
ENAMETOOLONG	The length of the pathname of the message catalogue exceeds PATH_MAX, or a pathname component is longer than NAME_MAX.
ENAMETOOLONG	Pathname resolution of a symbolic link produced an intermediate result whose length exceeds PATH_MAX.

ENFILE Too many files are currently open in the system.

ENOENT The message catalogue does not exist or the *name* argument points to an empty string.

ENOMEM Insufficient storage space is available.

ENOTDIR A component of the path prefix of the message catalogue is not a directory.

The `catclose()` function may fail if:

EBADF The catalogue descriptor is not valid.

EINTR The `catclose()` function was interrupted by a signal.

USAGE The `catopen()` and `catclose()` functions can be used safely in multithreaded applications, as long as `setlocale(3C)` is not being called to change the locale.

cfgetispeed(3C)

NAME cfgetispeed, cfgetospeed – get input and output baud rate

SYNOPSIS `#include <termios.h>`
`speed_t cfgetispeed(const struct termios *termios_p);`
`speed_t cfgetospeed(const struct termios *termios_p);`

DESCRIPTION The `cfgetispeed()` function extracts the input baud rate from the `termios` structure to which the `termios_p` argument points.

The `cfgetospeed()` function extracts the output baud rate from the `termios` structure to which the `termios_p` argument points.

These functions returns exactly the value in the `termios` data structure, without interpretation.

RETURN VALUES Upon successful completion, `cfgetispeed()` returns a value of type `speed_t` representing the input baud rate.

Upon successful completion, `cfgetospeed()` returns a value of type `speed_t` representing the output baud rate.

ERRORS No errors are defined.

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

cfree(3MALLOC)

NAME	watchmalloc, cfree, memalign, valloc – debugging memory allocator
SYNOPSIS	<pre>#include <stdlib.h> void *malloc(size_t size); void free(void *ptr); void *realloc(void *ptr, size_t size); void *memalign(size_t alignment, size_t size); void *valloc(size_t size); void *calloc(size_t nelem, size_t elsize); void cfree(void *ptr, size_t nelem, size_t elsize); #include <malloc.h> int mallopt(int cmd, int value); struct mallinfo mallinfo(void);</pre>
DESCRIPTION	<p>The collection of <code>malloc()</code> functions in this shared object are an optional replacement for the standard versions of the same functions in the system C library. See <code>malloc(3C)</code>. They provide a more strict interface than the standard versions and enable enforcement of the interface through the watchpoint facility of <code>/proc</code>. See <code>proc(4)</code>.</p> <p>Any dynamically linked application can be run with these functions in place of the standard functions if the following string is present in the environment (see <code>ld.so.1(1)</code>):</p> <pre>LD_PRELOAD=watchmalloc.so.1</pre> <p>The individual function interfaces are identical to the standard ones as described in <code>malloc(3C)</code>. However, laxities provided in the standard versions are not permitted when the watchpoint facility is enabled (see <code>WATCHPOINTS</code> below):</p> <ul style="list-style-type: none">■ Memory may not be freed more than once.■ A pointer to freed memory may not be used in a call to <code>realloc()</code>.■ A call to <code>malloc()</code> immediately following a call to <code>free()</code> will not return the same space.■ Any reference to memory that has been freed yields undefined results. <p>To enforce these restrictions partially, without great loss in speed as compared to the watchpoint facility described below, a freed block of memory is overwritten with the pattern <code>0xdeadbeef</code> before returning from <code>free()</code>. The <code>malloc()</code> function returns with the allocated memory filled with the pattern <code>0xbaddcafe</code> as a precaution against applications incorrectly expecting to receive back unmodified memory from the last <code>free()</code>. The <code>calloc()</code> function always returns with the memory zero-filled.</p>

WATCHPOINTS

Entry points for `malloc()` and `mallinfo()` are provided as empty routines, and are present only because some `malloc()` implementations provide them.

The watchpoint facility of `/proc` can be applied by a process to itself. The functions in `watchmalloc.so.1` use this feature if the following string is present in the environment:

```
MALLOC_DEBUG=WATCH
```

This causes every block of freed memory to be covered with `WA_WRITE` watched areas. If the application attempts to write any part of freed memory, it will trigger a watchpoint trap, resulting in a `SIGTRAP` signal, which normally produces an application core dump.

A header is maintained before each block of allocated memory. Each header is covered with a watched area, thereby providing a red zone before and after each block of allocated memory (the header for the subsequent memory block serves as the trailing red zone for its preceding memory block). Writing just before or just after a memory block returned by `malloc()` will trigger a watchpoint trap.

Watchpoints incur a large performance penalty. Requesting `MALLOC_DEBUG=WATCH` can cause the application to run 10 to 100 times slower, depending on the use made of allocated memory.

Further options are enabled by specifying a comma-separated string of options:

```
MALLOC_DEBUG=WATCH,RW,STOP
```

<code>WATCH</code>	Enables <code>WA_WRITE</code> watched areas as described above.
<code>RW</code>	Enables both <code>WA_READ</code> and <code>WA_WRITE</code> watched areas. An attempt either to read or write freed memory or the red zones will trigger a watchpoint trap. This incurs even more overhead and can cause the application to run up to 1000 times slower.
<code>STOP</code>	The process will stop showing a <code>FLTWATCH</code> machine fault if it triggers a watchpoint trap, rather than dumping core with a <code>SIGTRAP</code> signal. This allows a debugger to be attached to the live process at the point where it underwent the watchpoint trap. Also, the various <code>/proc</code> tools described in <code>proc(1)</code> can be used to examine the stopped process.

One of `WATCH` or `RW` must be specified, else the watchpoint facility is not engaged. `RW` overrides `WATCH`. Unrecognized options are silently ignored.

`cfree(3MALLOC)`

LIMITATIONS Sizes of memory blocks allocated by `malloc()` are rounded up to the the worst-case alignment size, 8 bytes for 32-bit processes and 16 bytes for 64-bit processes. Accessing the extra space allocated for a memory block is technically a memory violation but is in fact innocuous. Such accesses are not detected by the watchpoint facility of `watchmalloc`.

Interposition of `watchmalloc.so.1` fails innocuously if the target application is statically linked with respect to its `malloc()` functions.

NAME	strftime, cftime, ascftime – convert date and time to string																						
SYNOPSIS	<pre>#include <time.h> size_t strftime(char *s, size_t <i>maxsize</i>, const char *<i>format</i>, const struct tm *<i>timeptr</i>); int cftime(char *s, char *<i>format</i>, const time_t *<i>clock</i>); int ascftime(char *s, const char *<i>format</i>, const struct tm *<i>timeptr</i>);</pre>																						
DESCRIPTION	<p>The <code>strftime()</code>, <code>ascftime()</code>, and <code>cftime()</code> functions place bytes into the array pointed to by <code>s</code> as controlled by the string pointed to by <code>format</code>. The <code>format</code> string consists of zero or more conversion specifications and ordinary characters. A conversion specification consists of a '%' (percent) character and one or two terminating conversion characters that determine the conversion specification's behavior. All ordinary characters (including the terminating null byte) are copied unchanged into the array pointed to by <code>s</code>. If copying takes place between objects that overlap, the behavior is undefined. For <code>strftime()</code>, no more than <code>maxsize</code> bytes are placed into the array.</p> <p>If <code>format</code> is <code>(char *)0</code>, then the locale's default format is used. For <code>strftime()</code> the default format is the same as <code>%c</code>; for <code>cftime()</code> and <code>ascftime()</code> the default format is the same as <code>%C</code>. <code>cftime()</code> and <code>ascftime()</code> first try to use the value of the environment variable <code>CFTIME</code>, and if that is undefined or empty, the default format is used.</p> <p>Each conversion specification is replaced by appropriate characters as described in the following list. The appropriate characters are determined by the <code>LC_TIME</code> category of the program's locale and by the values contained in the structure pointed to by <code>timeptr</code> for <code>strftime()</code> and <code>ascftime()</code>, and by the time represented by <code>clock</code> for <code>cftime()</code>.</p> <table border="0"> <tr> <td style="padding-right: 20px;">%%</td> <td>Same as %.</td> </tr> <tr> <td>%a</td> <td>Locale's abbreviated weekday name.</td> </tr> <tr> <td>%A</td> <td>Locale's full weekday name.</td> </tr> <tr> <td>%b</td> <td>Locale's abbreviated month name.</td> </tr> <tr> <td>%B</td> <td>Locale's full month name.</td> </tr> <tr> <td>%c</td> <td>Locale's appropriate date and time representation.</td> </tr> <tr> <td>Default %C</td> <td>Locale's date and time representation as produced by <code>date(1)</code>.</td> </tr> <tr> <td>Standard conforming %C</td> <td>Century number (the year divided by 100 and truncated to an integer as a decimal number [1,99]); single digits are preceded by 0; see <code>standards(5)</code>.</td> </tr> <tr> <td>%d</td> <td>Day of month [1,31]; single digits are preceded by 0.</td> </tr> <tr> <td>%D</td> <td>Date as <code>%m/%d/%y</code>.</td> </tr> <tr> <td>%e</td> <td>Day of month [1,31]; single digits are preceded by a space.</td> </tr> </table>	%%	Same as %.	%a	Locale's abbreviated weekday name.	%A	Locale's full weekday name.	%b	Locale's abbreviated month name.	%B	Locale's full month name.	%c	Locale's appropriate date and time representation.	Default %C	Locale's date and time representation as produced by <code>date(1)</code> .	Standard conforming %C	Century number (the year divided by 100 and truncated to an integer as a decimal number [1,99]); single digits are preceded by 0; see <code>standards(5)</code> .	%d	Day of month [1,31]; single digits are preceded by 0.	%D	Date as <code>%m/%d/%y</code> .	%e	Day of month [1,31]; single digits are preceded by a space.
%%	Same as %.																						
%a	Locale's abbreviated weekday name.																						
%A	Locale's full weekday name.																						
%b	Locale's abbreviated month name.																						
%B	Locale's full month name.																						
%c	Locale's appropriate date and time representation.																						
Default %C	Locale's date and time representation as produced by <code>date(1)</code> .																						
Standard conforming %C	Century number (the year divided by 100 and truncated to an integer as a decimal number [1,99]); single digits are preceded by 0; see <code>standards(5)</code> .																						
%d	Day of month [1,31]; single digits are preceded by 0.																						
%D	Date as <code>%m/%d/%y</code> .																						
%e	Day of month [1,31]; single digits are preceded by a space.																						

cftime(3C)

%g	Week-based year within century [00,99].
%G	Week-based year, including the century [0000,9999].
%h	Locale's abbreviated month name.
%H	Hour (24-hour clock) [0,23]; single digits are preceded by 0.
%I	Hour (12-hour clock) [1,12]; single digits are preceded by 0.
%j	Day number of year [1,366]; single digits are preceded by 0.
%k	Hour (24-hour clock) [0,23]; single digits are preceded by a blank.
%l	Hour (12-hour clock) [1,12]; single digits are preceded by a blank.
%m	Month number [1,12]; single digits are preceded by 0.
%M	Minute [00,59]; leading 0 is permitted but not required.
%n	Insert a NEWLINE.
%p	Locale's equivalent of either a.m. or p.m.
%r	Appropriate time representation in 12-hour clock format with %p.
%R	Time as %H:%M.
%S	Seconds [00,61]; the range of values is [00,61] rather than [00,59] to allow for the occasional leap second and even more occasional double leap second.
%t	Insert a TAB.
%T	Time as %H:%M:%S.
%u	Weekday as a decimal number [1,7], with 1 representing Monday. See NOTES below.
%U	Week number of year as a decimal number [00,53], with Sunday as the first day of week 1.
%V	The ISO 8601 week number as a decimal number [01,53]. In the ISO 8601 week-based system, weeks begin on a Monday and week 1 of the year is the week that includes both January 4th and the first Thursday of the year. If the first Monday of January is the 2nd, 3rd, or 4th, the preceding days are part of the last week of the preceding year. See NOTES below.
%w	Weekday as a decimal number [0,6], with 0 representing Sunday.
%W	Week number of year as a decimal number [00,53], with Monday as the first day of week 1.
%x	Locale's appropriate date representation.
%X	Locale's appropriate time representation.
%y	Year within century [00,99].

%Y	Year, including the century (for example 1993).
%Z	Time zone name or abbreviation, or no bytes if no time zone information exists.

If a conversion specification does not correspond to any of the above or to any of the modified conversion specifications listed below, the behavior is undefined and 0 is returned.

The difference between %U and %W (and also between modified conversion specifications %OU and %OW) lies in which day is counted as the first of the week. Week number 1 is the first week in January starting with a Sunday for %U or a Monday for %W. Week number 0 contains those days before the first Sunday or Monday in January for %U and %W, respectively.

Modified Conversion Specifications

Some conversion specifications can be modified by the E and O modifiers to indicate that an alternate format or specification should be used rather than the one normally used by the unmodified conversion specification. If the alternate format or specification does not exist in the current locale, the behavior will be as if the unmodified specification were used.

%Ec	Locale's alternate appropriate date and time representation.
%EC	Name of the base year (period) in the locale's alternate representation.
%Eg	Offset from %EC of the week-based year in the locale's alternative representation.
%EG	Full alternative representation of the week-based year.
%Ex	Locale's alternate date representation.
%EX	Locale's alternate time representation.
%Ey	Offset from %EC (year only) in the locale's alternate representation.
%EY	Full alternate year representation.
%Od	Day of the month using the locale's alternate numeric symbols.
%Oe	Same as %Od.
%Og	Week-based year (offset from %C) in the locale's alternate representation and using the locale's alternate numeric symbols.
%OH	Hour (24-hour clock) using the locale's alternate numeric symbols.
%OI	Hour (12-hour clock) using the locale's alternate numeric symbols.
%Om	Month using the locale's alternate numeric symbols.
%OM	Minutes using the locale's alternate numeric symbols.
%OS	Seconds using the locale's alternate numeric symbols.
%Ou	Weekday as a number in the locale's alternate numeric symbols.

cftime(3C)

%OU	Week number of the year (Sunday as the first day of the week) using the locale's alternate numeric symbols.
%Ow	Number of the weekday (Sunday=0) using the locale's alternate numeric symbols.
%OW	Week number of the year (Monday as the first day of the week) using the locale's alternate numeric symbols.
%Oy	Year (offset from %C) in the locale's alternate representation and using the locale's alternate numeric symbols.

Selecting the Output Language

By default, the output of `strftime()`, `cftime()`, and `ascftime()` appear in U.S. English. The user can request that the output of `strftime()`, `cftime()`, or `ascftime()` be in a specific language by setting the `LC_TIME` category using `setlocale()`.

Time Zone

Local time zone information is used as though `tzset(3C)` were called.

RETURN VALUES

The `strftime()`, `cftime()`, and `ascftime()` functions return the number of characters placed into the array pointed to by `s`, not including the terminating null character. If the total number of resulting characters including the terminating null character is more than `maxsize`, `strftime()` returns 0 and the contents of the array are indeterminate.

EXAMPLES

EXAMPLE 1 An example of the `strftime()` function.

The following example illustrates the use of `strftime()` for the POSIX locale. It shows what the string in `str` would look like if the structure pointed to by `tmpr` contains the values corresponding to Thursday, August 28, 1986 at 12:44:36.

```
strftime (str, strsize, "%A %b %d %j", tmpr)
```

This results in `str` containing "Thursday Aug 28 240".

ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
MT-Level	MT-Safe
CSI	Enabled

SEE ALSO

`date(1)`, `ctime(3C)`, `mktime(3C)`, `setlocale(3C)`, `strptime(3C)`, `tzset(3C)`, `TIMEZONE(4)`, `zoneinfo(4)`, `attributes(5)`, `environ(5)`, `standards(5)`

NOTES The conversion specification for %V was changed in the Solaris 7 release. This change was based on the public review draft of the ISO C9x standard at that time. Previously, the specification stated that if the week containing 1 January had fewer than four days in the new year, it became week 53 of the previous year. The ISO C9x standard committee subsequently recognized that that specification had been incorrect.

The conversion specifications for %g, %G, %Eg, %EG, and %Og were added in the Solaris 7 release. This change was based on the public review draft of the ISO C9x standard at that time. These specifications are evolving. If the ISO C9x standard is finalized with a different conclusion, these specifications will change to conform to the ISO C9x standard decision.

The conversion specification for %u was changed in the Solaris 8 release. This change was based on the XPG4 specification.

If using the %Z specifier and `zoneinfo` timezones and if the input date is outside the range 20:45:52 UTC, December 13, 1901 to 03:14:07 UTC, January 19, 2038, the timezone name may not be correct.

clearerr(3C)

NAME | `error, feof, clearerr, fileno` – stream status inquiries

SYNOPSIS | `#include <stdio.h>`
`int error(FILE *stream);`
`int feof(FILE *stream);`
`void clearerr(FILE *stream);`
`int fileno(FILE *stream);`

DESCRIPTION | The `error()` function returns a non-zero value when an error has previously occurred reading from or writing to the named *stream* (see `intro(3)`). It returns 0 otherwise.

The `feof()` function returns a non-zero value when EOF has previously been detected reading the named input *stream*. It returns 0 otherwise.

The `clearerr()` function resets the error indicator and EOF indicator to 0 on the named *stream*.

The `fileno()` function returns the integer file descriptor associated with the named *stream*; see `open(2)`.

ATTRIBUTES | See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
MT-Level	MT-Safe

SEE ALSO | `open(2), intro(3), fopen(3C), stdio(3C), attributes(5)`

NAME clock – report CPU time used

SYNOPSIS `#include <time.h>`
`clock_t clock(void);`

DESCRIPTION The `clock()` function returns the amount of CPU time (in microseconds) used since the first call to `clock()` in the calling process. The time reported is the sum of the user and system times of the calling process and its terminated child processes for which it has executed the `wait(2)` function, the `pclose(3C)` function, or the `system(3C)` function.

RETURN VALUES Dividing the value returned by `clock()` by the constant `CLOCKS_PER_SEC`, defined in the `<time.h>` header, will give the time in seconds. If the process time used is not available or cannot be represented, `clock` returns the value `(clock_t) -1`.

USAGE The value returned by `clock()` is defined in microseconds for compatibility with systems that have CPU clocks with much higher resolution. Because of this, the value returned will wrap around after accumulating only 2147 seconds of CPU time (about 36 minutes).

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
MT-Level	MT-Safe

SEE ALSO `times(2)`, `wait(2)`, `popen(3C)`, `system(3C)`, `attributes(5)`

closedir(3C)

NAME | closedir – close a directory stream

SYNOPSIS | #include <sys/types.h>
| #include <dirent.h>
|
| int **closedir**(DIR **dirp*) ;

DESCRIPTION | The `closedir()` function closes the directory stream referred to by the argument *dirp*. Upon return, the value of *dirp* may no longer point to an accessible object of the type DIR. If a file descriptor is used to implement type DIR, that file descriptor will be closed.

RETURN VALUES | Upon successful completion, `closedir()` returns 0. Otherwise, -1 is returned and `errno` is set to indicate the error.

ERRORS | The `closedir()` function may fail if:
| EBADF The *dirp* argument does not refer to an open directory stream.
| EINTR The `closedir()` function was interrupted by a signal.

ATTRIBUTES | See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
MT-Level	Safe

SEE ALSO | `opendir(3C)`, `attributes(5)`

NAME	closefrom, fdwalk – close or iterate over open file descriptors
SYNOPSIS	<pre>#include <stdlib.h> void closefrom(int <i>lowfd</i>); int fdwalk(int (*<i>func</i>)(void *, int), void *<i>cd</i>);</pre>
DESCRIPTION	<p>The <code>closefrom()</code> function calls <code>close(2)</code> on all open file descriptors greater than or equal to <i>lowfd</i>.</p> <p>The effect of <code>closefrom(<i>lowfd</i>)</code> is the same as the code</p> <pre>#include <sys/resource.h> struct rlimit rl; int i; getrlimit(RLIMIT_NOFILE, &rl); for (i = lowfd; i < rl.rlim_max; i++) (void) close(i);</pre> <p>except that <code>close()</code> is called only on file descriptors that are actually open, not on every possible file descriptor greater than or equal to <i>lowfd</i>, and <code>close()</code> is also called on any open file descriptors greater than or equal to <code>rl.rlim_max</code> (and <i>lowfd</i>), should any exist.</p> <p>The <code>fdwalk()</code> function first makes a list of all currently open file descriptors. Then for each file descriptor in the list, it calls the user-defined function, <code>func(<i>cd</i>, <i>fd</i>)</code>, passing it the pointer to the callback data, <i>cd</i>, and the value of the file descriptor from the list, <i>fd</i>. The list is processed in file descriptor value order, lowest numeric value first.</p> <p>If <code>func()</code> returns a non-zero value, the iteration over the list is terminated and <code>fdwalk()</code> returns the non-zero value returned by <code>func()</code>. Otherwise, <code>fdwalk()</code> returns 0 after having called <code>func()</code> for every file descriptor in the list.</p> <p>The <code>fdwalk()</code> function can be used for fine-grained control over the closing of file descriptors. For example, the <code>closefrom()</code> function can be implemented as:</p> <pre>static int close_func(void *lowfdp, int fd) { if (fd >= *(int *)lowfdp) (void) close(fd); return (0); } void closefrom(int lowfd) { (void) fdwalk(close_func, &lowfd); }</pre> <p>The <code>fdwalk()</code> function can then be used to count the number of open files in the process.</p>

closefrom(3C)

RETURN VALUES No return value is defined for `closefrom()`. If `close()` fails for any of the open file descriptors, the error is ignored and the file descriptors whose `close()` operation failed might remain open on return from `closefrom()`.

The `fdwalk()` function returns the return value of the last call to the callback function `func()`, or 0 if `func()` is never called (no open files).

ERRORS No errors are defined. The `closefrom()` and `fdwalk()` functions do not set `errno` but `errno` can be set by `close()` or by another function called by the callback function, `func()`.

FILES `/proc/self/fd` directory (list of open files)

USAGE The act of closing all open file descriptors should be performed only as the first action of a daemon process. Closing file descriptors that are in use elsewhere in the current process normally leads to disastrous results.

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
MT-Level	Unsafe

SEE ALSO `close(2)`, `getrlimit(2)`, `proc(4)`, `attributes(5)`

NAME	syslog, openlog, closelog, setlogmask – control system log																
SYNOPSIS	<pre>#include <syslog.h> void openlog(const char *ident, int logopt, int facility); void syslog(int priority, const char *message, .../* arguments */); void closelog(void); int setlogmask(int maskpri);</pre>																
DESCRIPTION	<p>The <code>syslog()</code> function sends a message to <code>syslogd(1M)</code>, which, depending on the configuration of <code>/etc/syslog.conf</code>, logs it in an appropriate system log, writes it to the system console, forwards it to a list of users, or forwards it to <code>syslogd</code> on another host over the network. The logged message includes a message header and a message body. The message header consists of a facility indicator, a severity level indicator, a timestamp, a tag string, and optionally the process ID.</p> <p>The message body is generated from the <i>message</i> and following arguments in the same manner as if these were arguments to <code>printf(3UCB)</code>, except that occurrences of <code>%m</code> in the format string pointed to by the <i>message</i> argument are replaced by the error message string associated with the current value of <code>errno</code>. A trailing <code>NEWLINE</code> character is added if needed.</p> <p>Values of the <i>priority</i> argument are formed by ORing together a <i>severity level</i> value and an optional <i>facility</i> value. If no facility value is specified, the current default facility value is used.</p> <p>Possible values of severity level include:</p> <table border="0"> <tr> <td style="padding-right: 20px;"><code>LOG_EMERG</code></td> <td>A panic condition. This is normally broadcast to all users.</td> </tr> <tr> <td><code>LOG_ALERT</code></td> <td>A condition that should be corrected immediately, such as a corrupted system database.</td> </tr> <tr> <td><code>LOG_CRIT</code></td> <td>Critical conditions, such as hard device errors.</td> </tr> <tr> <td><code>LOG_ERR</code></td> <td>Errors.</td> </tr> <tr> <td><code>LOG_WARNING</code></td> <td>Warning messages.</td> </tr> <tr> <td><code>LOG_NOTICE</code></td> <td>Conditions that are not error conditions, but that may require special handling.</td> </tr> <tr> <td><code>LOG_INFO</code></td> <td>Informational messages.</td> </tr> <tr> <td><code>LOG_DEBUG</code></td> <td>Messages that contain information normally of use only when debugging a program.</td> </tr> </table> <p>The facility indicates the application or system component generating the message. Possible facility values include:</p>	<code>LOG_EMERG</code>	A panic condition. This is normally broadcast to all users.	<code>LOG_ALERT</code>	A condition that should be corrected immediately, such as a corrupted system database.	<code>LOG_CRIT</code>	Critical conditions, such as hard device errors.	<code>LOG_ERR</code>	Errors.	<code>LOG_WARNING</code>	Warning messages.	<code>LOG_NOTICE</code>	Conditions that are not error conditions, but that may require special handling.	<code>LOG_INFO</code>	Informational messages.	<code>LOG_DEBUG</code>	Messages that contain information normally of use only when debugging a program.
<code>LOG_EMERG</code>	A panic condition. This is normally broadcast to all users.																
<code>LOG_ALERT</code>	A condition that should be corrected immediately, such as a corrupted system database.																
<code>LOG_CRIT</code>	Critical conditions, such as hard device errors.																
<code>LOG_ERR</code>	Errors.																
<code>LOG_WARNING</code>	Warning messages.																
<code>LOG_NOTICE</code>	Conditions that are not error conditions, but that may require special handling.																
<code>LOG_INFO</code>	Informational messages.																
<code>LOG_DEBUG</code>	Messages that contain information normally of use only when debugging a program.																

closelog(3C)

LOG_KERN	Messages generated by the kernel. These cannot be generated by any user processes.
LOG_USER	Messages generated by random user processes. This is the default facility identifier if none is specified.
LOG_MAIL	The mail system.
LOG_DAEMON	System daemons, such as <code>in.ftpd(1M)</code> .
LOG_AUTH	The authorization system: <code>login(1)</code> , <code>su(1M)</code> , <code>getty(1M)</code> .
LOG_LPR	The line printer spooling system: <code>lpr(1B)</code> , <code>lpc(1B)</code> .
LOG_NEWS	Reserved for the USENET network news system.
LOG_UUCP	Reserved for the UUCP system; it does not currently use <code>syslog</code> .
LOG_CRON	The <code>cron/at</code> facility; <code>crontab(1)</code> , <code>at(1)</code> , <code>cron(1M)</code> .
LOG_LOCAL0	Reserved for local use.
LOG_LOCAL1	Reserved for local use.
LOG_LOCAL2	Reserved for local use.
LOG_LOCAL3	Reserved for local use.
LOG_LOCAL4	Reserved for local use.
LOG_LOCAL5	Reserved for local use.
LOG_LOCAL6	Reserved for local use.
LOG_LOCAL7	Reserved for local use.

The `openlog()` function sets process attributes that affect subsequent calls to `syslog()`. The *ident* argument is a string that is prepended to every message. The *logopt* argument indicates logging options. Values for *logopt* are constructed by a bitwise-inclusive OR of zero or more of the following:

LOG_PID	Log the process ID with each message. This is useful for identifying specific daemon processes (for daemons that fork).
LOG_CONS	Write messages to the system console if they cannot be sent to <code>syslogd(1M)</code> . This option is safe to use in daemon processes that have no controlling terminal, since <code>syslog()</code> forks before opening the console.
LOG_NDELAY	Open the connection to <code>syslogd(1M)</code> immediately. Normally the open is delayed until the first message is

logged. This is useful for programs that need to manage the order in which file descriptors are allocated.

LOG_ODELAY

Delay open until `syslog()` is called.

LOG_NOWAIT

Do not wait for child processes that have been forked to log messages onto the console. This option should be used by processes that enable notification of child termination using `SIGCHLD`, since `syslog()` may otherwise block waiting for a child whose exit status has already been collected.

The *facility* argument encodes a default facility to be assigned to all messages that do not have an explicit facility already encoded. The initial default facility is `LOG_USER`.

The `openlog()` and `syslog()` functions may allocate a file descriptor. It is not necessary to call `openlog()` prior to calling `syslog()`.

The `closelog()` function closes any open file descriptors allocated by previous calls to `openlog()` or `syslog()`.

The `setlogmask()` function sets the log priority mask for the current process to *maskpri* and returns the previous mask. If the *maskpri* argument is 0, the current log mask is not modified. Calls by the current process to `syslog()` with a priority not set in *maskpri* are rejected. The mask for an individual priority *pri* is calculated by the macro `LOG_MASK(pri)`; the mask for all priorities up to and including *toppri* is given by the macro `LOG_UPT(toppri)`. The default log mask allows all priorities to be logged.

Symbolic constants for use as values of the *logopt*, *facility*, *priority*, and *maskpri* arguments are defined in the `<syslog.h>` header.

RETURN VALUES

The `setlogmask()` function returns the previous log priority mask. The `closelog()`, `openlog()` and `syslog()` functions return no value.

ERRORS

No errors are defined.

EXAMPLES

EXAMPLE 1 Example of `LOG_ALERT` message.

This call logs a message at priority `LOG_ALERT`:

```
syslog(LOG_ALERT, "who: internal error 23");
```

The FTP daemon `ftpd` would make this call to `openlog()` to indicate that all messages it logs should have an identifying string of `ftpd`, should be treated by `syslogd(1M)` as other messages from system daemons are, should include the process ID of the process logging the message:

```
openlog("ftpd", LOG_PID, LOG_DAEMON);
```

closelog(3C)

EXAMPLE 1 Example of LOG_ALERT message. (Continued)

Then it would make the following call to `setlogmask()` to indicate that messages at priorities from LOG_EMERG through LOG_ERR should be logged, but that no messages at any other priority should be logged:

```
setlogmask(LOG_UPTO(LOG_ERR));
```

Then, to log a message at priority LOG_INFO, it would make the following call to `syslog`:

```
syslog(LOG_INFO, "Connection from host %d", CallingHost);
```

A locally-written utility could use the following call to `syslog()` to log a message at priority LOG_INFO to be treated by `syslogd(1M)` as other messages to the facility LOG_LOCAL2 are:

```
syslog(LOG_INFO|LOG_LOCAL2, "error: %m");
```

NAME	confstr – get configurable variables
SYNOPSIS	<pre>#include <unistd.h> size_t confstr(int <i>name</i>, char *<i>buf</i>, size_t <i>len</i>);</pre>
DESCRIPTION	<p>The <code>confstr()</code> function provides a method for applications to get configuration-defined string values. Its use and purpose are similar to the <code>sysconf(3C)</code> function, but it is used where string values rather than numeric values are returned.</p> <p>The <i>name</i> argument represents the system variable to be queried.</p> <p>If <i>len</i> is not 0, and if <i>name</i> has a configuration-defined value, <code>confstr()</code> copies that value into the <i>len</i>-byte buffer pointed to by <i>buf</i>. If the string to be returned is longer than <i>len</i> bytes, including the terminating null, then <code>confstr()</code> truncates the string to <i>len</i>–1 bytes and null-terminates the result. The application can detect that the string was truncated by comparing the value returned by <code>confstr()</code> with <i>len</i>.</p> <p>If <i>len</i> is 0, and <i>buf</i> is a null pointer, then <code>confstr()</code> still returns the integer value as defined below, but does not return the string. If <i>len</i> is 0 but <i>buf</i> is not a null pointer, the result is unspecified.</p> <p>The <code>confstr()</code> function supports the following values for <i>name</i>, defined in <code><unistd.h></code>, for both SPARC and IA:</p> <p><code>_CS_LFS64_CFLAGS</code> If <code>_LFS64_LARGEFILE</code> is defined in <code><unistd.h></code>, this value is the set of initial options to be given to the <code>cc</code> and <code>c89</code> utilities to build an application using the Large File Summit transitional compilation environment (see <code>lfcompile64(5)</code>).</p> <p><code>_CS_LFS64_LDFLAGS</code> If <code>_LFS64_LARGEFILE</code> is defined in <code><unistd.h></code>, this value is the set of final options to be given to the <code>cc</code> and <code>c89</code> utilities to build an application using the Large File Summit transitional compilation environment (see <code>lfcompile64(5)</code>).</p> <p><code>_CS_LFS64_LIBS</code> If <code>_LFS64_LARGEFILE</code> is defined in <code><unistd.h></code>, this value is the set of libraries to be given to the <code>cc</code> and <code>c89</code> utilities to build an application using the Large File Summit transitional compilation environment (see <code>lfcompile64(5)</code>).</p> <p><code>_CS_LFS64_LINTFLAGS</code> If <code>_LFS64_LARGEFILE</code> is defined in <code><unistd.h></code>, this value is the set of options to be given to the <code>lint</code> utility to check application source using the Large File Summit transitional compilation environment (see <code>lfcompile64(5)</code>).</p> <p><code>_CS_LFS_CFLAGS</code> If <code>_LFS_LARGEFILE</code> is defined in <code><unistd.h></code>, this value is the set of initial options to be given to the <code>cc</code> and <code>c89</code> utilities to build an application using the Large File Summit large file compilation environment for 32-bit applications (see <code>lfcompile(5)</code>).</p>

confstr(3C)

`_CS_LFS_LDFLAGS`

If `_LFS_LARGEFILE` is defined in `<unistd.h>`, this value is the set of final options to be given to the `cc` and `c89` utilities to build an application using the Large File Summit large file compilation environment for 32-bit applications (see `lfcompile(5)`).

`_CS_LFS_LIBS`

If `_LFS_LARGEFILE` is defined in `<unistd.h>`, this value is the set of libraries to be given to the `cc` and `c89` utilities to build an application using the Large File Summit large file compilation environment for 32-bit applications (see `lfcompile(5)`).

`_CS_LFS_LINTFLAGS`

If `_LFS_LARGEFILE` is defined in `<unistd.h>`, this value is the set of options to be given to the `lint` utility to check application source using the Large File Summit large file compilation environment for 32-bit applications (see `lfcompile(5)`).

`_CS_PATH`

If the ISO POSIX.2 standard is supported, this is the value for the `PATH` environment variable that finds all standard utilities. Otherwise the meaning of this value is unspecified.

`_CS_XBS5_ILP32_OFF32_CFLAGS`

If `sysconf(_SC_XBS5_ILP32_OFF32)` returns `-1` the meaning of this value is unspecified. Otherwise, this value is the set of initial options to be given to the `cc` and `c89` utilities to build an application using a programming model with 32-bit `int`, `long`, `pointer`, and `off_t` types.

`_CS_XBS5_ILP32_OFF32_LDFLAGS`

If `sysconf(_SC_XBS5_ILP32_OFF32)` returns `-1` the meaning of this value is unspecified. Otherwise, this value is the set of final options to be given to the `cc` and `c89` utilities to build an application using a programming model with 32-bit `int`, `long`, `pointer`, and `off_t` types.

`_CS_XBS5_ILP32_OFF32_LIBS`

If `sysconf(_SC_XBS5_ILP32_OFF32)` returns `-1` the meaning of this value is unspecified. Otherwise, this value is the set of libraries to be given to the `cc` and `c89` utilities to build an application using a programming model with 32-bit `int`, `long`, `pointer`, and `off_t` types.

`_CS_XBS5_ILP32_OFF32_LINTFLAGS`

If `sysconf(_SC_XBS5_ILP32_OFF32)` returns `-1` the meaning of this value is unspecified. Otherwise, this value is the set of options to be given to the `lint` utility to check application source using a programming model with 32-bit `int`, `long`, `pointer`, and `off_t` types.

`_CS_XBS5_ILP32_OFFBIG_CFLAGS`

If `sysconf(_SC_XBS5_ILP32_OFFBIG)` returns `-1` the meaning of this value is unspecified. Otherwise, this value is the set of initial options to be given to the `cc` and `c89` utilities to build an application using a programming model with 32-bit `int`, `long`, and `pointer` types, and an `off_t` type using at least 64 bits.

`_CS_XBS5_ILP32_OFFBIG_LDFLAGS`

If `sysconf(SC_XBS5_ILP32_OFFBIG)` returns `-1` the meaning of this value is unspecified. Otherwise, this value is the set of final options to be given to the `cc` and `c89` utilities to build an application using a programming model with 32-bit `int`, `long`, and `pointer` types, and an `off_t` type using at least 64 bits.

`_CS_XBS5_ILP32_OFFBIG_LIBS`

If `sysconf(_SC_XBS5_ILP32_OFFBIG)` returns `-1` the meaning of this value is unspecified. Otherwise, this value is the set of libraries to be given to the `cc` and `c89` utilities to build an application using a programming model with 32-bit `int`, `long`, and `pointer` types, and an `off_t` type using at least 64 bits.

`_CS_XBS5_ILP32_OFFBIG_LINTFLAGS`

If `sysconf(_SC_XBS5_ILP32_OFFBIG)` returns `-1` the meaning of this value is unspecified. Otherwise, this value is the set of options to be given to the `lint` utility to check an application using a programming model with 32-bit `int`, `long`, and `pointer` types, and an `off_t` type using at least 64 bits.

The `confstr()` function supports the following values for *name*, defined in `<unistd.h>`, for SPARC only:

`_CS_XBS5_LP64_OFF64_CFLAGS`

If `sysconf(_SC_XBS5_LP64_OFF64)` returns `-1` the meaning of this value is unspecified. Otherwise, this value is the set of initial options to be given to the `cc` and `c89` utilities to build an application using a programming model with 64-bit `int`, `long`, `pointer`, and `off_t` types.

`_CS_XBS5_LP64_OFF64_LDFLAGS`

If `sysconf(_SC_XBS5_LP64_OFF64)` returns `-1` the meaning of this value is unspecified. Otherwise, this value is the set of final options to be given to the `cc` and `c89` utilities to build an application using a programming model with 64-bit `int`, `long`, `pointer`, and `off_t` types.

`_CS_XBS5_LP64_OFF64_LIBS`

If `sysconf(_SC_XBS5_LP64_OFF64)` returns `-1` the meaning of this value is unspecified. Otherwise, this value is the set of libraries to be given to the `cc` and `c89` utilities to build an application using a programming model with 64-bit `int`, `long`, `pointer`, and `off_t` types.

`_CS_XBS5_LP64_OFF64_LINTFLAGS`

If `sysconf(_SC_XBS5_LP64_OFF64)` returns `-1` the meaning of this value is unspecified. Otherwise, this value is the set of options to be given to the `lint` utility to check application source using a programming model with 64-bit `int`, `long`, `pointer`, and `off_t` types.

`_CS_XBS5_LPBIG_OFFBIG_CFLAGS`

If `sysconf(_SC_XBS5_LPBIG_OFFBIG)` returns `-1` the meaning of this value is unspecified. Otherwise, this value is the set of initial options to be given to the `cc` and `c89` utilities to build an application using a programming model with an `int` type using at least 32 bits and `long`, `pointer`, and `off_t` types using at least 64 bits.

confstr(3C)

`_CS_XBS5_LPBIG_OFFBIG_LDFLAGS`

If `sysconf(_SC_XBS5_LPBIG_OFFBIG)` returns `-1` the meaning of this value is unspecified. Otherwise, this value is the set of final options to be given to the `cc` and `c89` utilities to build an application using a programming model with an `int` type using at least 32 bits and `long`, `pointer`, and `off_t` types using at least 64 bits.

`_CS_XBS5_LPBIG_OFFBIG_LIBS`

If `sysconf(_SC_XBS5_LPBIG_OFFBIG)` returns `-1` the meaning of this value is unspecified. Otherwise, this value is the set of libraries to be given to the `cc` and `c89` utilities to build an application using a programming model with an `int` type using at least 32 bits and `long`, `pointer`, and `off_t` types using at least 64 bits.

`_CS_XBS5_LPBIG_OFFBIG_LINTFLAGS`

If `sysconf(_SC_XBS5_LPBIG_OFFBIG)` returns `-1` the meaning of this value is unspecified. Otherwise, this value is the set of options to be given to the `lint` utility to check application source using a programming model with an `int` type using at least 32 bits and `long`, `pointer`, and `off_t` types using at least 64 bits.

RETURN VALUES

If *name* has a configuration-defined value, the `confstr()` function returns the size of buffer that would be needed to hold the entire configuration-defined value. If this return value is greater than *len*, the string returned in *buf* is truncated.

If *name* is invalid, `confstr()` returns 0 and sets `errno` to indicate the error.

If *name* does not have a configuration-defined value, `confstr()` returns 0 and leaves `errno` unchanged.

ERRORS

The `confstr()` function will fail if:

`EINVAL` The value of the *name* argument is invalid.

NAME	crypt – string encoding function								
SYNOPSIS	<pre>#include <crypt.h> char *crypt(const char *key, const char *salt);</pre>								
Standard conforming	<pre>#include <unistd.h> char *crypt(const char *key, const char *salt);</pre>								
DESCRIPTION	<p>The <code>crypt()</code> function encodes strings suitable for secure storage as passwords. It generates the password hash given the <i>key</i> and <i>salt</i>.</p> <p>The <i>key</i> argument is the plain text password to be encrypted.</p> <p>The <code>crypt()</code> function calls <code>crypt_gensalt(3C)</code> to generate the <i>salt</i>. If the first character of <i>salt</i> is "\$", <code>crypt()</code> uses <code>crypt.conf(4)</code> to determine which shared module to load for the encryption algorithm. If the first character of <i>salt</i> is not "\$", the algorithm described on <code>crypt_unix(5)</code> is used.</p>								
RETURN VALUES	<p>Upon successful completion, <code>crypt()</code> returns a pointer to the encoded string. Otherwise it returns a null pointer and sets <code>errno</code> to indicate the error.</p> <p>The return value points to static data that is overwritten by each call.</p>								
ERRORS	<p>The <code>crypt()</code> function will fail if:</p> <table border="0"> <tr> <td style="padding-right: 20px;">EINVAL</td> <td>An entry in <code>crypt.conf</code> is invalid.</td> </tr> <tr> <td>ELIBACC</td> <td>The required shared library was not found.</td> </tr> <tr> <td>ENOMEM</td> <td>There is insufficient memory to generate the hash.</td> </tr> <tr> <td>ENOSYS</td> <td>The functionality is not supported on this system.</td> </tr> </table>	EINVAL	An entry in <code>crypt.conf</code> is invalid.	ELIBACC	The required shared library was not found.	ENOMEM	There is insufficient memory to generate the hash.	ENOSYS	The functionality is not supported on this system.
EINVAL	An entry in <code>crypt.conf</code> is invalid.								
ELIBACC	The required shared library was not found.								
ENOMEM	There is insufficient memory to generate the hash.								
ENOSYS	The functionality is not supported on this system.								
USAGE	<p>The values returned by this function might not be portable among standard-conforming systems. See <code>standards(5)</code>.</p> <p>Applications should not use <code>crypt()</code> to store or verify user passwords but should use the functions described on <code>pam(3PAM)</code> instead.</p>

crypt_genhash_impl(3C)

NAME	crypt_genhash_impl – generate encrypted password						
SYNOPSIS	<pre>#include <crypt.h> char *crypt_genhash_impl(char *ctbuffer, size_t ctbuflen, const char *plaintext, const char *salt, const char **params);</pre>						
DESCRIPTION	<p>The <code>crypt_genhash_impl()</code> function is called by <code>crypt(3C)</code> to generate the encrypted password <i>plaintext</i>.</p> <p>The <i>ctbuffer</i> argument is a pointer to an MT-safe buffer of <i>ctbuflen</i> size that is used to return the result.</p> <p>The <i>salt</i> argument is the salt used in encoding.</p> <p>The <i>params</i> argument is an <i>argv</i>-like null-terminated vector of type <code>char *</code>. The first element of <i>params</i> represents the mechanism token name from <code>crypt.conf(4)</code>. The remaining elements of <i>params</i> represent strings of the form <code><parameter>[=<value>]</code> to allow passing in additional information from the <code>crypt.conf</code> entry, such as specifying rounds information "rounds=4096".</p> <p>The <code>crypt_genhash_impl()</code> function must not <code>free(3C)</code> <i>ctbuflen</i> on error.</p>						
RETURN VALUES	Upon successful completion, <code>crypt_genhash_impl()</code> returns a pointer to the encoded version of <i>plaintext</i> . Otherwise a null pointer is returned and <code>errno</code> is set to indicate the error.						
ERRORS	The <code>crypt_genhash_impl()</code> function will fail if: <table><tr><td><code>EINVAL</code></td><td>The configuration file <code>crypt.conf</code> contains an invalid entry.</td></tr><tr><td><code>ELIBACC</code></td><td>The required shared library was not found.</td></tr><tr><td><code>ENOMEM</code></td><td>There is insufficient memory to perform hashing.</td></tr></table>	<code>EINVAL</code>	The configuration file <code>crypt.conf</code> contains an invalid entry.	<code>ELIBACC</code>	The required shared library was not found.	<code>ENOMEM</code>	There is insufficient memory to perform hashing.
<code>EINVAL</code>	The configuration file <code>crypt.conf</code> contains an invalid entry.						
<code>ELIBACC</code>	The required shared library was not found.						
<code>ENOMEM</code>	There is insufficient memory to perform hashing.						
ATTRIBUTES	See <code>attributes(5)</code> for descriptions of the following attributes:

SEE ALSO	<code>passwd(1)</code> , <code>crypt(3C)</code> , <code>crypt_gensalt_impl(3C)</code> , <code>free(3C)</code> , <code>getpassphrase(3C)</code> , <code>crypt.conf(4)</code> , <code>passwd(4)</code> , <code>attributes(5)</code>						

NAME	crypt_gensalt – generate salt string for string encoding						
SYNOPSIS	<pre>#include <crypt.h> char *crypt_gensalt(const char *oldsalt, const struct passwd *userinfo);</pre>						
DESCRIPTION	<p>The <code>crypt_gensalt()</code> function generates the salt string required by <code>crypt(3C)</code>.</p> <p>If <code>oldsalt</code> is <code>NULL</code>, <code>crypt_gensalt()</code> uses the algorithm defined by <code>CRYPT_DEFAULT</code> in <code>/etc/security/policy.conf</code>. See <code>policy.conf(4)</code>.</p> <p>If <code>oldsalt</code> is non-null, <code>crypt_gensalt()</code> determines if the algorithm specified by <code>oldsalt</code> is allowable by checking the <code>CRYPT_ALGORITHMS_ALLOW</code> and <code>CRYPT_ALGORITHMS_DEPRECATED</code> variables in <code>/etc/security/policy.conf</code>. If the algorithm is allowed, <code>crypt_gensalt()</code> loads the appropriate shared library and calls <code>crypt_gensalt_impl(3C)</code>. If the algorithm is not allowed or there is no entry for it in <code>crypt.conf</code>, <code>crypt_gensalt()</code> uses the default algorithm.</p> <p>The mechanism just described provides a means to migrate users to new password hashing algorithms when the password is changed.</p>						
RETURN VALUES	Upon successful completion, <code>crypt_gensalt()</code> returns a pointer to the new salt. Otherwise a null pointer is returned and <code>errno</code> is set to indicate the error.						
ERRORS	<p>The <code>crypt_gensalt()</code> function will fail if:</p> <table border="0"> <tr> <td style="padding-right: 20px;"><code>EINVAL</code></td> <td>The configuration file <code>crypt.conf</code> contains an invalid entry.</td> </tr> <tr> <td><code>ELIBACC</code></td> <td>The required shared library was not found.</td> </tr> <tr> <td><code>ENOMEM</code></td> <td>There is insufficient memory to perform hashing.</td> </tr> </table>	<code>EINVAL</code>	The configuration file <code>crypt.conf</code> contains an invalid entry.	<code>ELIBACC</code>	The required shared library was not found.	<code>ENOMEM</code>	There is insufficient memory to perform hashing.
<code>EINVAL</code>	The configuration file <code>crypt.conf</code> contains an invalid entry.						
<code>ELIBACC</code>	The required shared library was not found.						
<code>ENOMEM</code>	There is insufficient memory to perform hashing.						
USAGE	<p>The value returned by <code>crypt_gensalt()</code> points to a null-terminated string. The caller of <code>crypt_gensalt()</code> is responsible for calling <code>free(3C)</code>.</p> <p>Applications dealing with user authentication and password changing should not call <code>crypt_gensalt()</code> directly but should instead call the appropriate <code>pam(3PAM)</code> functions.</p>						
ATTRIBUTES	See <code>attributes(5)</code> for descriptions of the following attributes:						
	<table border="1" style="width: 100%; border-collapse: collapse;"> <thead> <tr> <th style="text-align: center;">ATTRIBUTE TYPE</th> <th style="text-align: center;">ATTRIBUTE VALUE</th> </tr> </thead> <tbody> <tr> <td>Interface Stability</td> <td>Evolving</td> </tr> <tr> <td>MT-Level</td> <td>MT-Safe</td> </tr> </tbody> </table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	Interface Stability	Evolving	MT-Level	MT-Safe

NAME	cset, csetlen, csetcol, csetno, wcsetno – get information on EUC codesets				
SYNOPSIS	<pre>#include <euc.h> int csetlen(int codeset); int csetcol(int codeset); int csetno(unsigned char c); #include <widec.h> int wcsetno(wchar_t pc);</pre>				
DESCRIPTION	<p>Both <code>csetlen()</code> and <code>csetcol()</code> take a code set number <i>codeset</i>, which must be 0, 1, 2, or 3. The <code>csetlen()</code> function returns the number of bytes needed to represent a character of the given Extended Unix Code (EUC) code set, excluding the single-shift characters SS2 and SS3 for codesets 2 and 3. The <code>csetcol()</code> function returns the number of columns a character in the given EUC code set would take on the display.</p> <p>The <code>csetno()</code> function is implemented as a macro that returns a codeset number (0, 1, 2, or 3) for the EUC character whose first byte is <i>c</i>. For example,</p> <pre>#include<euc.h> . . . x+=csetcol(csetno(c));</pre> <p>increments a counter “<i>x</i>” (such as the cursor position) by the width of the character whose first byte is <i>c</i>.</p> <p>The <code>wcsetno()</code> function is implemented as a macro that returns a codeset number (0, 1, 2, or 3) for the given process code character <i>pc</i>. For example,</p> <pre>#include<euc.h> #include<widec.h> . . . x+=csetcol(wcsetno(pc));</pre> <p>increments a counter “<i>x</i>” (such as the cursor position) by the width of the Process Code character <i>pc</i>.</p>				
USAGE	The <code>cset()</code> , <code>csetlen()</code> , <code>csetcol()</code> , <code>csetno()</code> , and <code>wcsetno()</code> functions can be used safely in multithreaded applications, as long as <code>setlocale(3C)</code> is not being called to change the locale.				
ATTRIBUTES	See <code>attributes(5)</code> for descriptions of the following attributes:

NAME	ctime, ctime_r, localtime, localtime_r, gmtime, gmtime_r, asctime, asctime_r, tzset – convert date and time to string
SYNOPSIS	<pre>#include <time.h> char *ctime(const time_t *clock); struct tm *localtime(const time_t *clock); struct tm *gmtime(const time_t *clock); char *asctime(const struct tm *tm); extern time_t timezone, altzone; extern int daylight; extern char *tzname[2]; void tzset(void); char *ctime_r(const time_t *clock, char *buf, int buflen); struct tm *localtime_r(const time_t *clock, struct tm *res); struct tm *gmtime_r(const time_t *clock, struct tm *res); char *asctime_r(const struct tm *tm, char *buf, int buflen);</pre>
POSIX	<pre>cc [flag...] file... -D_POSIX_PTHREAD_SEMANTICS [library...] char *ctime_r(const time_t *clock, char *buf); char *asctime_r(const struct tm *tm, char *buf);</pre>
DESCRIPTION	<p>The <code>ctime()</code> function converts the time pointed to by <code>clock</code>, representing the time in seconds since the Epoch (00:00:00 UTC, January 1, 1970), to local time in the form of a 26-character string, as shown below. Time zone and daylight savings corrections are made before string generation. The fields are in constant width:</p> <pre>Fri Sep 13 00:00:00 1986\n\0</pre> <p>The <code>ctime()</code> function is equivalent to:</p> <pre>asctime(localtime(clock))</pre> <p>The <code>ctime()</code>, <code>asctime()</code>, <code>gmtime()</code>, and <code>localtime()</code> functions return values in one of two static objects: a broken-down time structure and an array of <code>char</code>. Execution of any of the functions can overwrite the information returned in either of these objects by any of the other functions.</p> <p>The <code>ctime_r()</code> function has the same functionality as <code>ctime()</code> except that the caller must supply a buffer <code>buf</code> with length <code>buflen</code> to store the result; <code>buf</code> must be at least 26 bytes. The POSIX <code>ctime_r()</code> function does not take a <code>buflen</code> parameter.</p>

ctime(3C)

The `localtime()` and `gmtime()` functions return pointers to `tm` structures (see below). The `localtime()` function corrects for the main time zone and possible alternate (“daylight savings”) time zone; the `gmtime()` function converts directly to Coordinated Universal Time (UTC), which is what the UNIX system uses internally.

The `localtime_r()` and `gmtime_r()` functions have the same functionality as `localtime()` and `gmtime()` respectively, except that the caller must supply a buffer *res* to store the result.

The `asctime()` function converts a `tm` structure to a 26-character string, as shown in the previous example, and returns a pointer to the string.

The `asctime_r()` function has the same functionality as `asctime()` except that the caller must supply a buffer *buf* with length *buflen* for the result to be stored. The *buf* argument must be at least 26 bytes. The POSIX `asctime_r()` function does not take a *buflen* parameter. The `asctime_r()` function returns a pointer to *buf* upon success. In case of failure, `NULL` is returned and `errno` is set.

Declarations of all the functions and externals, and the `tm` structure, are in the `<time.h>` header. The members of the `tm` structure are:

```
int    tm_sec;    /* seconds after the minute - [0, 61] */
        /* for leap seconds */
int    tm_min;    /* minutes after the hour - [0, 59] */
int    tm_hour;   /* hour since midnight - [0, 23] */
int    tm_mday;   /* day of the month - [1, 31] */
int    tm_mon;    /* months since January - [0, 11] */
int    tm_year;   /* years since 1900 */
int    tm_wday;   /* days since Sunday - [0, 6] */
int    tm_yday;   /* days since January 1 - [0, 365] */
int    tm_isdst;  /* flag for alternate daylight savings time */
```

The value of `tm_isdst` is positive if daylight savings time is in effect, zero if daylight savings time is not in effect, and negative if the information is not available. Previously, the value of `tm_isdst` was defined as non-zero if daylight savings was in effect.

The external `time_t` variable `altzone` contains the difference, in seconds, between Coordinated Universal Time and the alternate time zone. The external variable `timezone` contains the difference, in seconds, between UTC and local standard time. The external variable `daylight` indicates whether time should reflect daylight savings time. Both `timezone` and `altzone` default to 0 (UTC). The external variable `daylight` is non-zero if an alternate time zone exists. The time zone names are contained in the external variable `tzname`, which by default is set to:

```
char *tzname[2] = { "GMT", "" };
```

These functions know about the peculiarities of this conversion for various time periods for the U.S. (specifically, the years 1974, 1975, and 1987). They start handling the new daylight savings time starting with the first Sunday in April, 1987.

The `tzset()` function uses the contents of the environment variable `TZ` to override the value of the different external variables. It is called by `asctime()` and can also be called by the user. See `environ(5)` for a description of the `TZ` environment variable.

Starting and ending times are relative to the current local time zone. If the alternate time zone start and end dates and the time are not provided, the days for the United States that year will be used and the time will be 2 AM. If the start and end dates are provided but the time is not provided, the time will be 2 AM. The effects of `tzset()` change the values of the external variables `timezone`, `altzone`, `daylight`, and `tzname`.

Note that in most installations, `TZ` is set to the correct value by default when the user logs on, using the local `/etc/default/init` file (see `TIMEZONE(4)`).

ERRORS The `ctime_r()` and `asctime_r()` functions will fail if:

ERANGE The length of the buffer supplied by the caller is not large enough to store the result.

USAGE These functions do not support localized date and time formats. The `strftime(3C)` function can be used when localization is required.

The `localtime()`, `localtime_r()`, `gmtime()`, `gmtime_r()`, `ctime()`, and `ctime_r()` functions assume Gregorian dates. Times before the adoption of the Gregorian calendar will not match historical records.

EXAMPLES **EXAMPLE 1** Examples of the `tzset()` function.

The `tzset()` function scans the contents of the environment variable and assigns the different fields to the respective variable. For example, the most complete setting for New Jersey in 1986 could be:

```
EST5EDT4,116/2:00:00,298/2:00:00
```

or simply

```
EST5EDT
```

An example of a southern hemisphere setting such as the Cook Islands could be

```
KDT9:30KST10:00,63/5:00,302/20:00
```

In the longer version of the New Jersey example of `TZ`, `tzname[0]` is `EST`, `timezone` is set to `5*60*60`, `tzname[1]` is `EDT`, `altzone` is set to `4*60*60`, the starting date of the alternate time zone is the 117th day at 2 AM, the ending date of the alternate time zone is the 299th day at 2 AM (using zero-based Julian days), and `daylight` is set positive. Starting and ending times are relative to the current local time zone. If the alternate time zone start and end dates and the time are not provided, the days for the United States that year will be used and the time will be 2 AM. If the start and end dates are provided but the time is not provided, the time will be 2 AM. The effects of `tzset()` are thus to change the values of the external variables `timezone`, `altzone`, `daylight`, and `tzname`. The `ctime()`, `localtime()`, `mktime()`, and `strftime()` functions also update these external variables as if they had called `tzset()` at the

ctime(3C)

EXAMPLE 1 Examples of the `tzset()` function. (Continued)

time specified by the `time_t` or `struct tm` value that they are converting.

BUGS The `zoneinfo` timezone data files do not transition past Tue Jan 19 03:14:07 2038 UTC. Therefore for 64-bit applications using `zoneinfo` timezones, calculations beyond this date might not use the correct offset from standard time, and could return incorrect values. This affects the 64-bit version of `localtime()`, `localtime_r()`, `ctime()`, and `ctime_r()`.

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
MT-Level	MT-Safe with exceptions
CSI	Enabled

SEE ALSO `time(2)`, `Intro(3)`, `getenv(3C)`, `mktime(3C)`, `printf(3C)`, `putenv(3C)`, `setlocale(3C)`, `strftime(3C)`, `TIMEZONE(4)`, `attributes(5)`, `environ(5)`

NOTES When compiling multithreaded programs, see `Intro(3)`, *Notes On Multithreaded Applications*.

The return values for `ctime()`, `localtime()`, and `gmtime()` point to static data whose content is overwritten by each call.

Setting the time during the interval of change from `timezone` to `altzone` or vice versa can produce unpredictable results. The system administrator must change the Julian start and end days annually.

The `asctime()`, `ctime()`, `gmtime()`, and `localtime()` functions are unsafe in multithread applications. The `asctime_r()` and `gmtime_r()` functions are MT-Safe. The `ctime_r()`, `localtime_r()`, and `tzset()` functions are MT-Safe in multithread applications, as long as no user-defined function directly modifies one of the following variables: `timezone`, `altzone`, `daylight`, and `tzname`. These four variables are not MT-Safe to access. They are modified by the `tzset()` function in an MT-Safe manner. The `mktime()`, `localtime_r()`, and `ctime_r()` functions call `tzset()`.

Solaris 2.4 and earlier releases provided definitions of the `ctime_r()`, `localtime_r()`, `gmtime_r()`, and `asctime_r()` functions as specified in POSIX.1c Draft 6. The final POSIX.1c standard changed the interface for `ctime_r()` and `asctime_r()`. Support for the Draft 6 interface is provided for compatibility only and might not be supported in future releases. New applications and libraries should use the POSIX standard interface.

ctime(3C)

For POSIX.1c-compliant applications, the `_POSIX_PTHREAD_SEMANTICS` and `_REENTRANT` flags are automatically turned on by defining the `_POSIX_C_SOURCE` flag with a value `>= 199506L`.

ctime_r(3C)

NAME	ctime, ctime_r, localtime, localtime_r, gmtime, gmtime_r, asctime, asctime_r, tzset – convert date and time to string
SYNOPSIS	<pre>#include <time.h> char *ctime(const time_t *clock); struct tm *localtime(const time_t *clock); struct tm *gmtime(const time_t *clock); char *asctime(const struct tm *tm); extern time_t timezone, altzone; extern int daylight; extern char *tzname[2]; void tzset(void); char *ctime_r(const time_t *clock, char *buf, int buflen); struct tm *localtime_r(const time_t *clock, struct tm *res); struct tm *gmtime_r(const time_t *clock, struct tm *res); char *asctime_r(const struct tm *tm, char *buf, int buflen);</pre>
POSIX	<pre>cc [flag...] file... -D_POSIX_THREAD_SEMANTICS [library...] char *ctime_r(const time_t *clock, char *buf); char *asctime_r(const struct tm *tm, char *buf);</pre>
DESCRIPTION	<p>The <code>ctime()</code> function converts the time pointed to by <code>clock</code>, representing the time in seconds since the Epoch (00:00:00 UTC, January 1, 1970), to local time in the form of a 26-character string, as shown below. Time zone and daylight savings corrections are made before string generation. The fields are in constant width:</p> <pre>Fri Sep 13 00:00:00 1986\n\0</pre> <p>The <code>ctime()</code> function is equivalent to:</p> <pre>asctime(localtime(clock))</pre> <p>The <code>ctime()</code>, <code>asctime()</code>, <code>gmtime()</code>, and <code>localtime()</code> functions return values in one of two static objects: a broken-down time structure and an array of <code>char</code>. Execution of any of the functions can overwrite the information returned in either of these objects by any of the other functions.</p> <p>The <code>ctime_r()</code> function has the same functionality as <code>ctime()</code> except that the caller must supply a buffer <code>buf</code> with length <code>buflen</code> to store the result; <code>buf</code> must be at least 26 bytes. The POSIX <code>ctime_r()</code> function does not take a <code>buflen</code> parameter.</p>

The `localtime()` and `gmtime()` functions return pointers to `tm` structures (see below). The `localtime()` function corrects for the main time zone and possible alternate (“daylight savings”) time zone; the `gmtime()` function converts directly to Coordinated Universal Time (UTC), which is what the UNIX system uses internally.

The `localtime_r()` and `gmtime_r()` functions have the same functionality as `localtime()` and `gmtime()` respectively, except that the caller must supply a buffer *res* to store the result.

The `asctime()` function converts a `tm` structure to a 26-character string, as shown in the previous example, and returns a pointer to the string.

The `asctime_r()` function has the same functionality as `asctime()` except that the caller must supply a buffer *buf* with length *buflen* for the result to be stored. The *buf* argument must be at least 26 bytes. The POSIX `asctime_r()` function does not take a *buflen* parameter. The `asctime_r()` function returns a pointer to *buf* upon success. In case of failure, `NULL` is returned and `errno` is set.

Declarations of all the functions and externals, and the `tm` structure, are in the `<time.h>` header. The members of the `tm` structure are:

```
int    tm_sec;    /* seconds after the minute - [0, 61] */
        /* for leap seconds */
int    tm_min;    /* minutes after the hour - [0, 59] */
int    tm_hour;   /* hour since midnight - [0, 23] */
int    tm_mday;   /* day of the month - [1, 31] */
int    tm_mon;    /* months since January - [0, 11] */
int    tm_year;   /* years since 1900 */
int    tm_wday;   /* days since Sunday - [0, 6] */
int    tm_yday;   /* days since January 1 - [0, 365] */
int    tm_isdst;  /* flag for alternate daylight savings time */
```

The value of `tm_isdst` is positive if daylight savings time is in effect, zero if daylight savings time is not in effect, and negative if the information is not available. Previously, the value of `tm_isdst` was defined as non-zero if daylight savings was in effect.

The external `time_t` variable `altzone` contains the difference, in seconds, between Coordinated Universal Time and the alternate time zone. The external variable `timezone` contains the difference, in seconds, between UTC and local standard time. The external variable `daylight` indicates whether time should reflect daylight savings time. Both `timezone` and `altzone` default to 0 (UTC). The external variable `daylight` is non-zero if an alternate time zone exists. The time zone names are contained in the external variable `tzname`, which by default is set to:

```
char *tzname[2] = { "GMT", "" };
```

These functions know about the peculiarities of this conversion for various time periods for the U.S. (specifically, the years 1974, 1975, and 1987). They start handling the new daylight savings time starting with the first Sunday in April, 1987.

ctime_r(3C)

The `tzset()` function uses the contents of the environment variable `TZ` to override the value of the different external variables. It is called by `asctime()` and can also be called by the user. See `environ(5)` for a description of the `TZ` environment variable.

Starting and ending times are relative to the current local time zone. If the alternate time zone start and end dates and the time are not provided, the days for the United States that year will be used and the time will be 2 AM. If the start and end dates are provided but the time is not provided, the time will be 2 AM. The effects of `tzset()` change the values of the external variables `timezone`, `altzone`, `daylight`, and `tzname`.

Note that in most installations, `TZ` is set to the correct value by default when the user logs on, using the local `/etc/default/init` file (see `TIMEZONE(4)`).

ERRORS The `ctime_r()` and `asctime_r()` functions will fail if:

ERANGE The length of the buffer supplied by the caller is not large enough to store the result.

USAGE These functions do not support localized date and time formats. The `strftime(3C)` function can be used when localization is required.

The `localtime()`, `localtime_r()`, `gmtime()`, `gmtime_r()`, `ctime()`, and `ctime_r()` functions assume Gregorian dates. Times before the adoption of the Gregorian calendar will not match historical records.

EXAMPLES **EXAMPLE 1** Examples of the `tzset()` function.

The `tzset()` function scans the contents of the environment variable and assigns the different fields to the respective variable. For example, the most complete setting for New Jersey in 1986 could be:

```
EST5EDT4,116/2:00:00,298/2:00:00
```

or simply

```

In the longer version of the New Jersey example of `TZ`, `tzname[0]` is `EST`, `timezone` is set to `5*60*60`, `tzname[1]` is `EDT`, `altzone` is set to `4*60*60`, the starting date of the alternate time zone is the 117th day at 2 AM, the ending date of the alternate time zone is the 299th day at 2 AM (using zero-based Julian days), and `daylight` is set positive. Starting and ending times are relative to the current local time zone. If the alternate time zone start and end dates and the time are not provided, the days for the United States that year will be used and the time will be 2 AM. If the start and end dates are provided but the time is not provided, the time will be 2 AM. The effects of `tzset()` are thus to change the values of the external variables `timezone`, `altzone`, `daylight`, and `tzname`. The `ctime()`, `localtime()`, `mktime()`, and `strftime()` functions also update these external variables as if they had called `tzset()` at the

EXAMPLE 1 Examples of the tzset () function. (Continued)

time specified by the time_t or struct tm value that they are converting.

BUGS The zoneinfo timezone data files do not transition past Tue Jan 19 03:14:07 2038 UTC. Therefore for 64-bit applications using zoneinfo timezones, calculations beyond this date might not use the correct offset from standard time, and could return incorrect values. This affects the 64-bit version of localtime (), localtime_r (), ctime (), and ctime_r ().

ATTRIBUTES See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
MT-Level	MT-Safe with exceptions
CSI	Enabled

SEE ALSO time(2), Intro(3), getenv(3C), mktime(3C), printf(3C), putenv(3C), setlocale(3C), strftime(3C), TIMEZONE(4), attributes(5), environ(5)

NOTES When compiling multithreaded programs, see Intro(3), *Notes On Multithreaded Applications*.

The return values for ctime (), localtime (), and gmtime () point to static data whose content is overwritten by each call.

Setting the time during the interval of change from timezone to altzone or vice versa can produce unpredictable results. The system administrator must change the Julian start and end days annually.

The asctime (), ctime (), gmtime (), and localtime () functions are unsafe in multithread applications. The asctime_r () and gmtime_r () functions are MT-Safe. The ctime_r (), localtime_r (), and tzset () functions are MT-Safe in multithread applications, as long as no user-defined function directly modifies one of the following variables: timezone, altzone, daylight, and tzname. These four variables are not MT-Safe to access. They are modified by the tzset () function in an MT-Safe manner. The mktime (), localtime_r (), and ctime_r () functions call tzset ().

Solaris 2.4 and earlier releases provided definitions of the ctime_r (), localtime_r (), gmtime_r (), and asctime_r () functions as specified in POSIX.1c Draft 6. The final POSIX.1c standard changed the interface for ctime_r () and asctime_r (). Support for the Draft 6 interface is provided for compatibility only and might not be supported in future releases. New applications and libraries should use the POSIX standard interface.

ctime_r(3C)

For POSIX.1c-compliant applications, the `_POSIX_PTHREAD_SEMANTICS` and `_REENTRANT` flags are automatically turned on by defining the `_POSIX_C_SOURCE` flag with a value `>= 199506L`.

NAME	ctype, isdigit, isxdigit, islower, isupper, isalpha, isalnum, isspace, iscntrl, ispunct, isprint, isgraph, isascii – character handling		
SYNOPSIS	<pre>#include <ctype.h> int isalpha(int c); int isupper(int c); int islower(int c); int isdigit(int c); int isxdigit(int c); int isalnum(int c); int isspace(int c); int ispunct(int c); int isprint(int c); int isgraph(int c); int iscntrl(int c); int isascii(int c);</pre>		
DESCRIPTION	<p>These macros classify character-coded integer values. Each is a predicate returning non-zero for true, 0 for false. The behavior of these macros, except <code>isascii()</code>, is affected by the current locale (see <code>setlocale(3C)</code>). To modify the behavior, change the <code>LC_TYPE</code> category in <code>setlocale()</code>, that is, <code>setlocale(LC_TYPE, newlocale)</code>. In the "C" locale, or in a locale where character type information is not defined, characters are classified according to the rules of the US-ASCII 7-bit coded character set.</p> <p>The macro <code>isascii()</code> is defined on all integer values; the rest are defined only where the argument is an <code>int</code>, the value of which is representable as an unsigned <code>char</code>, or <code>EOF</code>, which is defined by the <code><stdio.h></code> header and represents end-of-file.</p> <p>Functions exist for all the macros defined below. To get the function form, the macro name must be undefined (for example, <code>#undef isdigit</code>).</p> <p>For macros described with Default and Standard conforming versions, standard-conforming behavior will be provided for standard-conforming applications (see <code>standards(5)</code>) and for applications that define <code>__XPG4_CHAR_CLASS__</code> before including <code><ctype.h></code>.</p>		
Default	<table border="0"> <tr> <td style="padding-right: 20px;"><code>isalpha()</code></td> <td>Tests for any character for which <code>isupper()</code> or <code>islower()</code> is true.</td> </tr> </table>	<code>isalpha()</code>	Tests for any character for which <code>isupper()</code> or <code>islower()</code> is true.
<code>isalpha()</code>	Tests for any character for which <code>isupper()</code> or <code>islower()</code> is true.		
Standard conforming	<table border="0"> <tr> <td style="padding-right: 20px;"><code>isalpha()</code></td> <td>Tests for any character for which <code>isupper()</code> or <code>islower()</code> is true, or any character that is one of the current locale-defined set of characters for which none of <code>iscntrl()</code>, <code>isdigit()</code>,</td> </tr> </table>	<code>isalpha()</code>	Tests for any character for which <code>isupper()</code> or <code>islower()</code> is true, or any character that is one of the current locale-defined set of characters for which none of <code>iscntrl()</code> , <code>isdigit()</code> ,
<code>isalpha()</code>	Tests for any character for which <code>isupper()</code> or <code>islower()</code> is true, or any character that is one of the current locale-defined set of characters for which none of <code>iscntrl()</code> , <code>isdigit()</code> ,		

ctype(3C)

		ispunct(), or isspace() is true. In "C" locale, isalpha() returns true only for the characters for which isupper() or islower() is true.
	isupper()	Tests for any character that is an upper-case letter or is one of the current locale-defined set of characters for which none of iscntrl(), isdigit(), ispunct(), isspace(), or islower() is true. In the "C" locale, isupper() returns true only for the characters defined as upper-case ASCII characters.
	islower()	Tests for any character that is a lower-case letter or is one of the current locale-defined set of characters for which none of iscntrl(), isdigit(), ispunct(), isspace(), or isupper() is true. In the "C" locale, islower() returns true only for the characters defined as lower-case ASCII characters.
	isdigit()	Tests for any decimal-digit character.
Default	isxdigit()	Tests for any hexadecimal-digit character ([0-9], [A-F], or [a-f]).
Standard conforming	isxdigit()	Tests for any hexadecimal-digit character ([0-9], [A-F], or [a-f] or the current locale-defined sets of characters representing the hexadecimal digits 10 to 15 inclusive). In the "C" locale, only 0 1 2 3 4 5 6 7 8 9 A B C D E F a b c d e f are included.
	isalnum()	Tests for any character for which isalpha() or isdigit() is true (letter or digit).
	isspace()	Tests for any space, tab, carriage-return, newline, vertical-tab or form-feed (standard white-space characters) or for one of the current locale-defined set of characters for which isalnum() is false. In the C locale, isspace() returns true only for the standard white-space characters.
	ispunct()	Tests for any printing character which is neither a space (" ") nor a character for which isalnum() or iscntrl() is true.
Default	isprint()	Tests for any character for which ispunct(), isupper(), islower(), isdigit(), and the space character (" ") is true.
Standard conforming	isprint()	Tests for any character for which iscntrl() is false, and isalnum(), isgraph(), ispunct(), the space character (" "), and the characters in the current locale-defined "print" class are true.
Default	isgraph()	Tests for any character for which ispunct(), isupper(), islower(), and isdigit() is true.

Standard conforming

`isgraph()` Tests for any character for which `isalnum()` and `ispunct()` are true, or any character in the current locale-defined "graph" class which is neither a space (" ") nor a character for which `iscntrl()` is true.

`iscntrl()` Tests for any "control character" as defined by the character set.

`isascii()` Tests for any ASCII character, code between 0 and 0177 inclusive.

RETURN VALUES

If the argument to any of the character handling macros is not in the domain of the function, the result is undefined. Otherwise, the macro/function will return non-zero if the classification is TRUE, and 0 for FALSE.

USAGE

The `isdigit()`, `isxdigit()`, `islower()`, `isupper()`, `isalpha()`, `isalnum()`, `isspace()`, `iscntrl()`, `ispunct()`, `isprint()`, `isgraph()`, and `isascii()` macros can be used safely in multithreaded applications, as long as `setlocale(3C)` is not being called to change the locale.

cuserid(3C)

- NAME** cuserid – get character login name of the user
- SYNOPSIS**

```
#include <stdio.h>

char *cuserid(char *s);
```
- DESCRIPTION** The `cuserid()` function generates a character-string representation of the login name under which the owner of the current process is logged in. If `s` is a null pointer, this representation is generated in an internal static area whose address is returned. Otherwise, `s` is assumed to point to an array of at least `L_cuserid` characters; the representation is left in this array. The constant `L_cuserid` is defined in the `<stdio.h>` header.
- In multithreaded applications, the caller must always supply an array `s` for the return value.
- RETURN VALUES** If the login name cannot be found, `cuserid()` returns a null pointer. If `s` is not a null pointer, the null character `'\0'` will be placed at `s[0]`.
- ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
MT-Level	MT-Safe

SEE ALSO `getlogin(3C)`, `getpwnam(3C)`, `attributes(5)`

NAME	dbm, dbm _{init} , dbm _{close} , fetch, store, delete, firstkey, nextkey – data base subroutines
SYNOPSIS	<pre> /usr/ucb/cc [flag ...] file ... -ldb_m #include <dbm.h> typedef struct { char *dp_{tr}; int dsize; }datum; int dbm_{init} (file); char *file; int dbm_{close} (); datum fetch (key); datum key; int store (key, dat); datum key, dat; int delete (key); datum key; datum firstkey() datum nextkey (key); datum key; </pre>
DESCRIPTION	<p>The dbm() library has been superseded by ndbm (see ndbm(3C)).</p> <p>These functions maintain key/content pairs in a data base. The functions will handle very large (a billion blocks) databases and will access a keyed item in one or two file system accesses.</p> <p><i>key/dat</i> and their content are described by the datum typedef. A datum specifies a string of <i>dsize</i> bytes pointed to by <i>dptr</i>. Arbitrary binary data, as well as normal ASCII strings, are allowed. The data base is stored in two files. One file is a directory containing a bit map and has <i>.dir</i> as its suffix. The second file contains all data and has <i>.pag</i> as its suffix.</p> <p>Before a database can be accessed, it must be opened by dbm_{init} (). At the time of this call, the files <i>file.dir</i> and <i>file.pag</i> must exist. An empty database is created by creating zero-length <i>.dir</i> and <i>.pag</i> files.</p> <p>A database may be closed by calling dbm_{close} (). You must close a database before opening a new one.</p>

dbm(3UCB)

Once open, the data stored under a key is accessed by `fetch()` and data is placed under a key by `store`. A key (and its associated contents) is deleted by `delete()`. A linear pass through all keys in a database may be made, in an (apparently) random order, by use of `firstkey()` and `nextkey()`. `firstkey()` will return the first key in the database. With any key `nextkey()` will return the next key in the database. This code will traverse the data base:

```
for (key = firstkey; key.dptr != NULL; key = nextkey(key))
```

RETURN VALUES All functions that return an `int` indicate errors with negative values. A zero return indicates no error. Routines that return a datum indicate errors with a `NULL (0) dptr`.

SEE ALSO `ar(1)`, `cat(1)`, `cp(1)`, `tar(1)`, `ndbm(3C)`

NOTES Use of these interfaces should be restricted to only applications written on BSD platforms. Use of these interfaces with any of the system libraries or in multi-thread applications is unsupported.

The `.pag` file will contain holes so that its apparent size may be larger than its actual content. Older versions of the UNIX operating system may create real file blocks for these holes when touched. These files cannot be copied by normal means (`cp(1)`, `cat(1)`, `tar(1)`, `ar(1)`) without filling in the holes.

`dptr` pointers returned by these subroutines point into static storage that is changed by subsequent calls.

The sum of the sizes of a key/content pair must not exceed the internal block size (currently 1024 bytes). Moreover all key/content pairs that hash together must fit on a single block. `store` will return an error in the event that a disk block fills with inseparable data.

`delete()` does not physically reclaim file space, although it does make it available for reuse.

The order of keys presented by `firstkey()` and `nextkey()` depends on a hashing function, not on anything interesting.

There are no interlocks and no reliable cache flushing; thus concurrent updating and reading is risky.

The database files (`file.dir` and `file.pag`) are binary and are architecture-specific (for example, they depend on the architecture's byte order.) These files are not guaranteed to be portable across architectures.

NAME	ndbm, dbm_clearerr, dbm_close, dbm_delete, dbm_error, dbm_fetch, dbm_firstkey, dbm_nextkey, dbm_open, dbm_store – database functions
SYNOPSIS	<pre>#include <ndbm.h> int dbm_clearerr (DBM *db) ; void dbm_close (DBM *db) ; int dbm_delete (DBM *db, datum key) ; int dbm_error (DBM *db) ; datum dbm_fetch (DBM *db, datum key) ; datum dbm_firstkey (DBM *db) ; datum dbm_nextkey (DBM *db) ; DBM *dbm_open (const char *file, int open_flags, mode_t file_mode) ; int dbm_store (DBM *db, datum key, datum content, int store_mode) ;</pre>
DESCRIPTION	<p>These functions create, access and modify a database. They maintain <i>key/content</i> pairs in a database. The functions will handle large databases (up to a billion blocks) and will access a keyed item in one or two file system accesses. This package replaces the earlier dbm(3UCB) library, which managed only a single database.</p> <p><i>keys</i> and <i>contents</i> are described by the datum typedef. A datum consists of at least two members, <i>dptr</i> and <i>dsize</i>. The <i>dptr</i> member points to an object that is <i>dsize</i> bytes in length. Arbitrary binary data, as well as ASCII character strings, may be stored in the object pointed to by <i>dptr</i>.</p> <p>The database is stored in two files. One file is a directory containing a bit map of keys and has <i>.dir</i> as its suffix. The second file contains all data and has <i>.pag</i> as its suffix.</p> <p>The <code>dbm_open()</code> function opens a database. The <i>file</i> argument to the function is the pathname of the database. The function opens two files named <i>file.dir</i> and <i>file.pag</i>. The <i>open_flags</i> argument has the same meaning as the <i>flags</i> argument of <code>open(2)</code> except that a database opened for write-only access opens the files for read and write access. The <i>file_mode</i> argument has the same meaning as the third argument of <code>open(2)</code>.</p> <p>The <code>dbm_close()</code> function closes a database. The argument <i>db</i> must be a pointer to a dbm structure that has been returned from a call to <code>dbm_open()</code>.</p> <p>The <code>dbm_fetch()</code> function reads a record from a database. The argument <i>db</i> is a pointer to a database structure that has been returned from a call to <code>dbm_open()</code>. The argument <i>key</i> is a datum that has been initialized by the application program to the value of the key that matches the key of the record the program is fetching.</p> <p>The <code>dbm_store()</code> function writes a record to a database. The argument <i>db</i> is a pointer to a database structure that has been returned from a call to <code>dbm_open()</code>. The argument <i>key</i> is a datum that has been initialized by the application program to the</p>

dbm_clearerr(3C)

value of the key that identifies (for subsequent reading, writing or deleting) the record the program is writing. The argument *content* is a datum that has been initialized by the application program to the value of the record the program is writing. The argument *store_mode* controls whether `dbm_store()` replaces any pre-existing record that has the same key that is specified by the *key* argument. The application program must set *store_mode* to either `DBM_INSERT` or `DBM_REPLACE`. If the database contains a record that matches the *key* argument and *store_mode* is `DBM_REPLACE`, the existing record is replaced with the new record. If the database contains a record that matches the *key* argument and *store_mode* is `DBM_INSERT`, the existing record is not replaced with the new record. If the database does not contain a record that matches the *key* argument and *store_mode* is either `DBM_INSERT` or `DBM_REPLACE`, the new record is inserted in the database.

The `dbm_delete()` function deletes a record and its key from the database. The argument *db* is a pointer to a database structure that has been returned from a call to `dbm_open()`. The argument *key* is a datum that has been initialized by the application program to the value of the key that identifies the record the program is deleting.

The `dbm_firstkey()` function returns the first key in the database. The argument *db* is a pointer to a database structure that has been returned from a call to `dbm_open()`.

The `dbm_nextkey()` function returns the next key in the database. The argument *db* is a pointer to a database structure that has been returned from a call to `dbm_open()`. The `dbm_firstkey()` function must be called before calling `dbm_nextkey()`. Subsequent calls to `dbm_nextkey()` return the next key until all of the keys in the database have been returned.

The `dbm_error()` function returns the error condition of the database. The argument *db* is a pointer to a database structure that has been returned from a call to `dbm_open()`.

The `dbm_clearerr()` function clears the error condition of the database. The argument *db* is a pointer to a database structure that has been returned from a call to `dbm_open()`.

These database functions support key/content pairs of at least 1024 bytes.

RETURN VALUES

The `dbm_store()` and `dbm_delete()` functions return 0 when they succeed and a negative value when they fail.

The `dbm_store()` function returns 1 if it is called with a *flags* value of `DBM_INSERT` and the function finds an existing record with the same key.

The `dbm_error()` function returns 0 if the error condition is not set and returns a non-zero value if the error condition is set.

The return value of `dbm_clearerr()` is unspecified.

The `dbm_firstkey()` and `dbm_nextkey()` functions return a key datum. When the end of the database is reached, the `dptr` member of the key is a null pointer. If an error is detected, the `dptr` member of the key is a null pointer and the error condition of the database is set.

The `dbm_fetch()` function returns a content datum. If no record in the database matches the key or if an error condition has been detected in the database, the `dptr` member of the content is a null pointer.

The `dbm_open()` function returns a pointer to a database structure. If an error is detected during the operation, `dbm_open()` returns a `(DBM *)0`.

ERRORS No errors are defined.

USAGE The following code can be used to traverse the database:

```
for(key = dbm_firstkey(db); key.dptr != NULL; key = dbm_nextkey(db))
```

The `dbm_*` functions provided in this library should not be confused in any way with those of a general-purpose database management system. These functions do not provide for multiple search keys per entry, they do not protect against multi-user access (in other words they do not lock records or files), and they do not provide the many other useful database functions that are found in more robust database management systems. Creating and updating databases by use of these functions is relatively slow because of data copies that occur upon hash collisions. These functions are useful for applications requiring fast lookup of relatively static information that is to be indexed by a single key.

The `dptr` pointers returned by these functions may point into static storage that may be changed by subsequent calls.

The `dbm_delete()` function does not physically reclaim file space, although it does make it available for reuse.

After calling `dbm_store()` or `dbm_delete()` during a pass through the keys by `dbm_firstkey()` and `dbm_nextkey()`, the application should reset the database by calling `dbm_firstkey()` before again calling `dbm_nextkey()`.

EXAMPLES **EXAMPLE 1** Using the Database Functions

The following example stores and retrieves a phone number, using the name as the key. Note that this example does not include error checking.

```
#include <ndbm.h>
#include <stdio.h>
#include <fcntl.h>
#define NAME "Bill"
#define PHONE_NO "123-4567"
#define DB_NAME "phones"
main()
{
    DBM *db;
    datum name = {NAME, sizeof (NAME)};
```

dbm_clearerr(3C)

EXAMPLE 1 Using the Database Functions (Continued)

```
datum put_phone_no = {PHONE_NO, sizeof (PHONE_NO)};
datum get_phone_no;
/* Open the database and store the record */
db = dbm_open(DB_NAME, O_RDWR | O_CREAT, 0660);
(void) dbm_store(db, name, put_phone_no, DBM_INSERT);
/* Retrieve the record */
get_phone_no = dbm_fetch(db, name);
(void) printf("Name: %s, Phone Number: %s\n", name.dptr,
get_phone_no.dptr);
/* Close the database */
dbm_close(db);
return (0);
}
```

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
MT-Level	Unsafe

SEE ALSO `ar(1)`, `cat(1)`, `cp(1)`, `tar(1)`, `open(2)`, `dbm(3UCB)`, `netconfig(4)`, `attributes(5)`

NOTES The `.pag` file will contain holes so that its apparent size may be larger than its actual content. Older versions of the UNIX operating system may create real file blocks for these holes when touched. These files cannot be copied by normal means (`cp(1)`, `cat(1)`, `tar(1)`, `ar(1)`) without filling in the holes.

The sum of the sizes of a *key/content* pair must not exceed the internal block size (currently 1024 bytes). Moreover all *key/content* pairs that hash together must fit on a single block. `dbm_store()` will return an error in the event that a disk block fills with inseparable data.

The order of keys presented by `dbm_firstkey()` and `dbm_nextkey()` depends on a hashing function.

There are no interlocks and no reliable cache flushing; thus concurrent updating and reading is risky.

The database files (`file.dir` and `file.pag`) are binary and are architecture-specific (for example, they depend on the architecture's byte order.) These files are not guaranteed to be portable across architectures.

NAME	ndbm, dbm_clearerr, dbm_close, dbm_delete, dbm_error, dbm_fetch, dbm_firstkey, dbm_nextkey, dbm_open, dbm_store – database functions
SYNOPSIS	<pre>#include <ndbm.h> int dbm_clearerr (DBM *db) ; void dbm_close (DBM *db) ; int dbm_delete (DBM *db, datum key) ; int dbm_error (DBM *db) ; datum dbm_fetch (DBM *db, datum key) ; datum dbm_firstkey (DBM *db) ; datum dbm_nextkey (DBM *db) ; DBM *dbm_open (const char *file, int open_flags, mode_t file_mode) ; int dbm_store (DBM *db, datum key, datum content, int store_mode) ;</pre>
DESCRIPTION	<p>These functions create, access and modify a database. They maintain <i>key/content</i> pairs in a database. The functions will handle large databases (up to a billion blocks) and will access a keyed item in one or two file system accesses. This package replaces the earlier dbm(3UCB) library, which managed only a single database.</p> <p><i>keys</i> and <i>contents</i> are described by the datum typedef. A datum consists of at least two members, <i>dptr</i> and <i>dsize</i>. The <i>dptr</i> member points to an object that is <i>dsize</i> bytes in length. Arbitrary binary data, as well as ASCII character strings, may be stored in the object pointed to by <i>dptr</i>.</p> <p>The database is stored in two files. One file is a directory containing a bit map of keys and has <i>.dir</i> as its suffix. The second file contains all data and has <i>.pag</i> as its suffix.</p> <p>The <code>dbm_open()</code> function opens a database. The <i>file</i> argument to the function is the pathname of the database. The function opens two files named <i>file.dir</i> and <i>file.pag</i>. The <i>open_flags</i> argument has the same meaning as the <i>flags</i> argument of <code>open(2)</code> except that a database opened for write-only access opens the files for read and write access. The <i>file_mode</i> argument has the same meaning as the third argument of <code>open(2)</code>.</p> <p>The <code>dbm_close()</code> function closes a database. The argument <i>db</i> must be a pointer to a dbm structure that has been returned from a call to <code>dbm_open()</code>.</p> <p>The <code>dbm_fetch()</code> function reads a record from a database. The argument <i>db</i> is a pointer to a database structure that has been returned from a call to <code>dbm_open()</code>. The argument <i>key</i> is a datum that has been initialized by the application program to the value of the key that matches the key of the record the program is fetching.</p> <p>The <code>dbm_store()</code> function writes a record to a database. The argument <i>db</i> is a pointer to a database structure that has been returned from a call to <code>dbm_open()</code>. The argument <i>key</i> is a datum that has been initialized by the application program to the</p>

dbm_close(3C)

value of the key that identifies (for subsequent reading, writing or deleting) the record the program is writing. The argument *content* is a datum that has been initialized by the application program to the value of the record the program is writing. The argument *store_mode* controls whether `dbm_store()` replaces any pre-existing record that has the same key that is specified by the *key* argument. The application program must set *store_mode* to either `DBM_INSERT` or `DBM_REPLACE`. If the database contains a record that matches the *key* argument and *store_mode* is `DBM_REPLACE`, the existing record is replaced with the new record. If the database contains a record that matches the *key* argument and *store_mode* is `DBM_INSERT`, the existing record is not replaced with the new record. If the database does not contain a record that matches the *key* argument and *store_mode* is either `DBM_INSERT` or `DBM_REPLACE`, the new record is inserted in the database.

The `dbm_delete()` function deletes a record and its key from the database. The argument *db* is a pointer to a database structure that has been returned from a call to `dbm_open()`. The argument *key* is a datum that has been initialized by the application program to the value of the key that identifies the record the program is deleting.

The `dbm_firstkey()` function returns the first key in the database. The argument *db* is a pointer to a database structure that has been returned from a call to `dbm_open()`.

The `dbm_nextkey()` function returns the next key in the database. The argument *db* is a pointer to a database structure that has been returned from a call to `dbm_open()`. The `dbm_firstkey()` function must be called before calling `dbm_nextkey()`. Subsequent calls to `dbm_nextkey()` return the next key until all of the keys in the database have been returned.

The `dbm_error()` function returns the error condition of the database. The argument *db* is a pointer to a database structure that has been returned from a call to `dbm_open()`.

The `dbm_clearerr()` function clears the error condition of the database. The argument *db* is a pointer to a database structure that has been returned from a call to `dbm_open()`.

These database functions support key/content pairs of at least 1024 bytes.

RETURN VALUES

The `dbm_store()` and `dbm_delete()` functions return 0 when they succeed and a negative value when they fail.

The `dbm_store()` function returns 1 if it is called with a *flags* value of `DBM_INSERT` and the function finds an existing record with the same key.

The `dbm_error()` function returns 0 if the error condition is not set and returns a non-zero value if the error condition is set.

The return value of `dbm_clearerr()` is unspecified.

The `dbm_firstkey()` and `dbm_nextkey()` functions return a key datum. When the end of the database is reached, the `dptr` member of the key is a null pointer. If an error is detected, the `dptr` member of the key is a null pointer and the error condition of the database is set.

The `dbm_fetch()` function returns a content datum. If no record in the database matches the key or if an error condition has been detected in the database, the `dptr` member of the content is a null pointer.

The `dbm_open()` function returns a pointer to a database structure. If an error is detected during the operation, `dbm_open()` returns a `(DBM *)0`.

ERRORS No errors are defined.

USAGE The following code can be used to traverse the database:

```
for(key = dbm_firstkey(db); key.dptr != NULL; key = dbm_nextkey(db))
```

The `dbm_*` functions provided in this library should not be confused in any way with those of a general-purpose database management system. These functions do not provide for multiple search keys per entry, they do not protect against multi-user access (in other words they do not lock records or files), and they do not provide the many other useful database functions that are found in more robust database management systems. Creating and updating databases by use of these functions is relatively slow because of data copies that occur upon hash collisions. These functions are useful for applications requiring fast lookup of relatively static information that is to be indexed by a single key.

The `dptr` pointers returned by these functions may point into static storage that may be changed by subsequent calls.

The `dbm_delete()` function does not physically reclaim file space, although it does make it available for reuse.

After calling `dbm_store()` or `dbm_delete()` during a pass through the keys by `dbm_firstkey()` and `dbm_nextkey()`, the application should reset the database by calling `dbm_firstkey()` before again calling `dbm_nextkey()`.

EXAMPLES **EXAMPLE 1** Using the Database Functions

The following example stores and retrieves a phone number, using the name as the key. Note that this example does not include error checking.

```
#include <ndbm.h>
#include <stdio.h>
#include <fcntl.h>
#define NAME "Bill"
#define PHONE_NO "123-4567"
#define DB_NAME "phones"
main()
{
    DBM *db;
    datum name = {NAME, sizeof (NAME)};
```

dbm_close(3C)

EXAMPLE 1 Using the Database Functions (Continued)

```
datum put_phone_no = {PHONE_NO, sizeof (PHONE_NO)};
datum get_phone_no;
/* Open the database and store the record */
db = dbm_open(DB_NAME, O_RDWR | O_CREAT, 0660);
(void) dbm_store(db, name, put_phone_no, DBM_INSERT);
/* Retrieve the record */
get_phone_no = dbm_fetch(db, name);
(void) printf("Name: %s, Phone Number: %s\n", name.dptr,
get_phone_no.dptr);
/* Close the database */
dbm_close(db);
return (0);
}
```

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
MT-Level	Unsafe

SEE ALSO `ar(1)`, `cat(1)`, `cp(1)`, `tar(1)`, `open(2)`, `dbm(3UCB)`, `netconfig(4)`, `attributes(5)`

NOTES The `.pag` file will contain holes so that its apparent size may be larger than its actual content. Older versions of the UNIX operating system may create real file blocks for these holes when touched. These files cannot be copied by normal means (`cp(1)`, `cat(1)`, `tar(1)`, `ar(1)`) without filling in the holes.

The sum of the sizes of a *key/content* pair must not exceed the internal block size (currently 1024 bytes). Moreover all *key/content* pairs that hash together must fit on a single block. `dbm_store()` will return an error in the event that a disk block fills with inseparable data.

The order of keys presented by `dbm_firstkey()` and `dbm_nextkey()` depends on a hashing function.

There are no interlocks and no reliable cache flushing; thus concurrent updating and reading is risky.

The database files (`file.dir` and `file.pag`) are binary and are architecture-specific (for example, they depend on the architecture's byte order.) These files are not guaranteed to be portable across architectures.

NAME	dbm, dbmopen, dbmclose, fetch, store, delete, firstkey, nextkey – data base subroutines
SYNOPSIS	<pre> /usr/ucb/cc [flag ...] file ... -ldb #include <dbm.h> typedef struct { char *dptr; int dsize; } datum; int dbmopen (file); char *file; int dbmclose (); datum fetch (key); datum key; int store (key, dat); datum key, dat; int delete (key); datum key; datum firstkey() datum nextkey (key); datum key; </pre>
DESCRIPTION	<p>The dbm() library has been superseded by ndbm (see ndbm(3C)).</p> <p>These functions maintain key/content pairs in a data base. The functions will handle very large (a billion blocks) databases and will access a keyed item in one or two file system accesses.</p> <p><i>key/dat</i> and their content are described by the datum typedef. A datum specifies a string of <i>dsize</i> bytes pointed to by <i>dptr</i>. Arbitrary binary data, as well as normal ASCII strings, are allowed. The data base is stored in two files. One file is a directory containing a bit map and has <i>.dir</i> as its suffix. The second file contains all data and has <i>.pag</i> as its suffix.</p> <p>Before a database can be accessed, it must be opened by dbmopen(). At the time of this call, the files <i>file.dir</i> and <i>file.pag</i> must exist. An empty database is created by creating zero-length <i>.dir</i> and <i>.pag</i> files.</p> <p>A database may be closed by calling dbmclose(). You must close a database before opening a new one.</p>

dbmclose(3UCB)

Once open, the data stored under a key is accessed by `fetch()` and data is placed under a key by `store`. A key (and its associated contents) is deleted by `delete()`. A linear pass through all keys in a database may be made, in an (apparently) random order, by use of `firstkey()` and `nextkey()`. `firstkey()` will return the first key in the database. With any key `nextkey()` will return the next key in the database. This code will traverse the data base:

```
for (key = firstkey; key.dptr != NULL; key = nextkey(key))
```

RETURN VALUES All functions that return an `int` indicate errors with negative values. A zero return indicates no error. Routines that return a datum indicate errors with a `NULL (0) dptr`.

SEE ALSO `ar(1)`, `cat(1)`, `cp(1)`, `tar(1)`, `ndbm(3C)`

NOTES Use of these interfaces should be restricted to only applications written on BSD platforms. Use of these interfaces with any of the system libraries or in multi-thread applications is unsupported.

The `.pag` file will contain holes so that its apparent size may be larger than its actual content. Older versions of the UNIX operating system may create real file blocks for these holes when touched. These files cannot be copied by normal means (`cp(1)`, `cat(1)`, `tar(1)`, `ar(1)`) without filling in the holes.

`dptr` pointers returned by these subroutines point into static storage that is changed by subsequent calls.

The sum of the sizes of a key/content pair must not exceed the internal block size (currently 1024 bytes). Moreover all key/content pairs that hash together must fit on a single block. `store` will return an error in the event that a disk block fills with inseparable data.

`delete()` does not physically reclaim file space, although it does make it available for reuse.

The order of keys presented by `firstkey()` and `nextkey()` depends on a hashing function, not on anything interesting.

There are no interlocks and no reliable cache flushing; thus concurrent updating and reading is risky.

The database files (`file.dir` and `file.pag`) are binary and are architecture-specific (for example, they depend on the architecture's byte order.) These files are not guaranteed to be portable across architectures.

NAME	ndbm, dbm_clearerr, dbm_close, dbm_delete, dbm_error, dbm_fetch, dbm_firstkey, dbm_nextkey, dbm_open, dbm_store – database functions
SYNOPSIS	<pre>#include <ndbm.h> int dbm_clearerr (DBM *db) ; void dbm_close (DBM *db) ; int dbm_delete (DBM *db, datum key) ; int dbm_error (DBM *db) ; datum dbm_fetch (DBM *db, datum key) ; datum dbm_firstkey (DBM *db) ; datum dbm_nextkey (DBM *db) ; DBM *dbm_open (const char *file, int open_flags, mode_t file_mode) ; int dbm_store (DBM *db, datum key, datum content, int store_mode) ;</pre>
DESCRIPTION	<p>These functions create, access and modify a database. They maintain <i>key/content</i> pairs in a database. The functions will handle large databases (up to a billion blocks) and will access a keyed item in one or two file system accesses. This package replaces the earlier dbm(3UCB) library, which managed only a single database.</p> <p><i>keys</i> and <i>contents</i> are described by the datum typedef. A datum consists of at least two members, <i>dptr</i> and <i>dsize</i>. The <i>dptr</i> member points to an object that is <i>dsize</i> bytes in length. Arbitrary binary data, as well as ASCII character strings, may be stored in the object pointed to by <i>dptr</i>.</p> <p>The database is stored in two files. One file is a directory containing a bit map of keys and has <i>.dir</i> as its suffix. The second file contains all data and has <i>.pag</i> as its suffix.</p> <p>The <code>dbm_open()</code> function opens a database. The <i>file</i> argument to the function is the pathname of the database. The function opens two files named <i>file.dir</i> and <i>file.pag</i>. The <i>open_flags</i> argument has the same meaning as the <i>flags</i> argument of <code>open(2)</code> except that a database opened for write-only access opens the files for read and write access. The <i>file_mode</i> argument has the same meaning as the third argument of <code>open(2)</code>.</p> <p>The <code>dbm_close()</code> function closes a database. The argument <i>db</i> must be a pointer to a dbm structure that has been returned from a call to <code>dbm_open()</code>.</p> <p>The <code>dbm_fetch()</code> function reads a record from a database. The argument <i>db</i> is a pointer to a database structure that has been returned from a call to <code>dbm_open()</code>. The argument <i>key</i> is a datum that has been initialized by the application program to the value of the key that matches the key of the record the program is fetching.</p> <p>The <code>dbm_store()</code> function writes a record to a database. The argument <i>db</i> is a pointer to a database structure that has been returned from a call to <code>dbm_open()</code>. The argument <i>key</i> is a datum that has been initialized by the application program to the</p>

dbm_delete(3C)

value of the key that identifies (for subsequent reading, writing or deleting) the record the program is writing. The argument *content* is a datum that has been initialized by the application program to the value of the record the program is writing. The argument *store_mode* controls whether `dbm_store()` replaces any pre-existing record that has the same key that is specified by the *key* argument. The application program must set *store_mode* to either `DBM_INSERT` or `DBM_REPLACE`. If the database contains a record that matches the *key* argument and *store_mode* is `DBM_REPLACE`, the existing record is replaced with the new record. If the database contains a record that matches the *key* argument and *store_mode* is `DBM_INSERT`, the existing record is not replaced with the new record. If the database does not contain a record that matches the *key* argument and *store_mode* is either `DBM_INSERT` or `DBM_REPLACE`, the new record is inserted in the database.

The `dbm_delete()` function deletes a record and its key from the database. The argument *db* is a pointer to a database structure that has been returned from a call to `dbm_open()`. The argument *key* is a datum that has been initialized by the application program to the value of the key that identifies the record the program is deleting.

The `dbm_firstkey()` function returns the first key in the database. The argument *db* is a pointer to a database structure that has been returned from a call to `dbm_open()`.

The `dbm_nextkey()` function returns the next key in the database. The argument *db* is a pointer to a database structure that has been returned from a call to `dbm_open()`. The `dbm_firstkey()` function must be called before calling `dbm_nextkey()`. Subsequent calls to `dbm_nextkey()` return the next key until all of the keys in the database have been returned.

The `dbm_error()` function returns the error condition of the database. The argument *db* is a pointer to a database structure that has been returned from a call to `dbm_open()`.

The `dbm_clearerr()` function clears the error condition of the database. The argument *db* is a pointer to a database structure that has been returned from a call to `dbm_open()`.

These database functions support key/content pairs of at least 1024 bytes.

RETURN VALUES

The `dbm_store()` and `dbm_delete()` functions return 0 when they succeed and a negative value when they fail.

The `dbm_store()` function returns 1 if it is called with a *flags* value of `DBM_INSERT` and the function finds an existing record with the same key.

The `dbm_error()` function returns 0 if the error condition is not set and returns a non-zero value if the error condition is set.

The return value of `dbm_clearerr()` is unspecified.

The `dbm_firstkey()` and `dbm_nextkey()` functions return a key datum. When the end of the database is reached, the `dptr` member of the key is a null pointer. If an error is detected, the `dptr` member of the key is a null pointer and the error condition of the database is set.

The `dbm_fetch()` function returns a content datum. If no record in the database matches the key or if an error condition has been detected in the database, the `dptr` member of the content is a null pointer.

The `dbm_open()` function returns a pointer to a database structure. If an error is detected during the operation, `dbm_open()` returns a `(DBM *)0`.

ERRORS No errors are defined.

USAGE The following code can be used to traverse the database:

```
for(key = dbm_firstkey(db); key.dptr != NULL; key = dbm_nextkey(db))
```

The `dbm_` functions provided in this library should not be confused in any way with those of a general-purpose database management system. These functions do not provide for multiple search keys per entry, they do not protect against multi-user access (in other words they do not lock records or files), and they do not provide the many other useful database functions that are found in more robust database management systems. Creating and updating databases by use of these functions is relatively slow because of data copies that occur upon hash collisions. These functions are useful for applications requiring fast lookup of relatively static information that is to be indexed by a single key.

The `dptr` pointers returned by these functions may point into static storage that may be changed by subsequent calls.

The `dbm_delete()` function does not physically reclaim file space, although it does make it available for reuse.

After calling `dbm_store()` or `dbm_delete()` during a pass through the keys by `dbm_firstkey()` and `dbm_nextkey()`, the application should reset the database by calling `dbm_firstkey()` before again calling `dbm_nextkey()`.

EXAMPLES **EXAMPLE 1** Using the Database Functions

The following example stores and retrieves a phone number, using the name as the key. Note that this example does not include error checking.

```
#include <ndbm.h>
#include <stdio.h>
#include <fcntl.h>
#define NAME "Bill"
#define PHONE_NO "123-4567"
#define DB_NAME "phones"
main()
{
    DBM *db;
    datum name = {NAME, sizeof (NAME)};
```

dbm_delete(3C)

EXAMPLE 1 Using the Database Functions (Continued)

```
datum put_phone_no = {PHONE_NO, sizeof (PHONE_NO)};
datum get_phone_no;
/* Open the database and store the record */
db = dbm_open(DB_NAME, O_RDWR | O_CREAT, 0660);
(void) dbm_store(db, name, put_phone_no, DBM_INSERT);
/* Retrieve the record */
get_phone_no = dbm_fetch(db, name);
(void) printf("Name: %s, Phone Number: %s\n", name.dptr,
get_phone_no.dptr);
/* Close the database */
dbm_close(db);
return (0);
}
```

ATTRIBUTES See [attributes\(5\)](#) for descriptions of the following attributes:

The argument <i>key</i> is a datum that has been initialized by the application program to the</p>

dbm_error(3C)

value of the key that identifies (for subsequent reading, writing or deleting) the record the program is writing. The argument *content* is a datum that has been initialized by the application program to the value of the record the program is writing. The argument *store_mode* controls whether `dbm_store()` replaces any pre-existing record that has the same key that is specified by the *key* argument. The application program must set *store_mode* to either `DBM_INSERT` or `DBM_REPLACE`. If the database contains a record that matches the *key* argument and *store_mode* is `DBM_REPLACE`, the existing record is replaced with the new record. If the database contains a record that matches the *key* argument and *store_mode* is `DBM_INSERT`, the existing record is not replaced with the new record. If the database does not contain a record that matches the *key* argument and *store_mode* is either `DBM_INSERT` or `DBM_REPLACE`, the new record is inserted in the database.

The `dbm_delete()` function deletes a record and its key from the database. The argument *db* is a pointer to a database structure that has been returned from a call to `dbm_open()`. The argument *key* is a datum that has been initialized by the application program to the value of the key that identifies the record the program is deleting.

The `dbm_firstkey()` function returns the first key in the database. The argument *db* is a pointer to a database structure that has been returned from a call to `dbm_open()`.

The `dbm_nextkey()` function returns the next key in the database. The argument *db* is a pointer to a database structure that has been returned from a call to `dbm_open()`. The `dbm_firstkey()` function must be called before calling `dbm_nextkey()`. Subsequent calls to `dbm_nextkey()` return the next key until all of the keys in the database have been returned.

The `dbm_error()` function returns the error condition of the database. The argument *db* is a pointer to a database structure that has been returned from a call to `dbm_open()`.

The `dbm_clearerr()` function clears the error condition of the database. The argument *db* is a pointer to a database structure that has been returned from a call to `dbm_open()`.

These database functions support key/content pairs of at least 1024 bytes.

RETURN VALUES

The `dbm_store()` and `dbm_delete()` functions return 0 when they succeed and a negative value when they fail.

The `dbm_store()` function returns 1 if it is called with a *flags* value of `DBM_INSERT` and the function finds an existing record with the same key.

The `dbm_error()` function returns 0 if the error condition is not set and returns a non-zero value if the error condition is set.

The return value of `dbm_clearerr()` is unspecified.

The `dbm_firstkey()` and `dbm_nextkey()` functions return a key datum. When the end of the database is reached, the `dptr` member of the key is a null pointer. If an error is detected, the `dptr` member of the key is a null pointer and the error condition of the database is set.

The `dbm_fetch()` function returns a content datum. If no record in the database matches the key or if an error condition has been detected in the database, the `dptr` member of the content is a null pointer.

The `dbm_open()` function returns a pointer to a database structure. If an error is detected during the operation, `dbm_open()` returns a `(DBM *)0`.

ERRORS No errors are defined.

USAGE The following code can be used to traverse the database:

```
for(key = dbm_firstkey(db); key.dptr != NULL; key = dbm_nextkey(db))
```

The `dbm_*` functions provided in this library should not be confused in any way with those of a general-purpose database management system. These functions do not provide for multiple search keys per entry, they do not protect against multi-user access (in other words they do not lock records or files), and they do not provide the many other useful database functions that are found in more robust database management systems. Creating and updating databases by use of these functions is relatively slow because of data copies that occur upon hash collisions. These functions are useful for applications requiring fast lookup of relatively static information that is to be indexed by a single key.

The `dptr` pointers returned by these functions may point into static storage that may be changed by subsequent calls.

The `dbm_delete()` function does not physically reclaim file space, although it does make it available for reuse.

After calling `dbm_store()` or `dbm_delete()` during a pass through the keys by `dbm_firstkey()` and `dbm_nextkey()`, the application should reset the database by calling `dbm_firstkey()` before again calling `dbm_nextkey()`.

EXAMPLES **EXAMPLE 1** Using the Database Functions

The following example stores and retrieves a phone number, using the name as the key. Note that this example does not include error checking.

```
#include <ndbm.h>
#include <stdio.h>
#include <fcntl.h>
#define NAME "Bill"
#define PHONE_NO "123-4567"
#define DB_NAME "phones"
main()
{
    DBM *db;
    datum name = {NAME, sizeof (NAME)};
```

dbm_error(3C)

EXAMPLE 1 Using the Database Functions (Continued)

```
datum put_phone_no = {PHONE_NO, sizeof (PHONE_NO)};
datum get_phone_no;
/* Open the database and store the record */
db = dbm_open(DB_NAME, O_RDWR | O_CREAT, 0660);
(void) dbm_store(db, name, put_phone_no, DBM_INSERT);
/* Retrieve the record */
get_phone_no = dbm_fetch(db, name);
(void) printf("Name: %s, Phone Number: %s\n", name.dptr,
get_phone_no.dptr);
/* Close the database */
dbm_close(db);
return (0);
}
```

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
MT-Level	Unsafe

SEE ALSO `ar(1)`, `cat(1)`, `cp(1)`, `tar(1)`, `open(2)`, `dbm(3UCB)`, `netconfig(4)`, `attributes(5)`

The second file contains all data and has <i>.pag</i> as its suffix.</p> <p>The <code>dbm_open()</code> function opens a database. The <i>file</i> argument to the function is the pathname of the database. The function opens two files named <i>file.dir</i> and <i>file.pag</i>. The <i>open_flags</i> argument has the same meaning as the <i>flags</i> argument of <code>open(2)</code> except that a database opened for write-only access opens the files for read and write access. The <i>file_mode</i> argument has the same meaning as the third argument of <code>open(2)</code>.</p> <p>The <code>dbm_close()</code> function closes a database. The argument <i>db</i> must be a pointer to a dbm structure that has been returned from a call to <code>dbm_open()</code>.</p> <p>The <code>dbm_fetch()</code> function reads a record from a database. The argument <i>db</i> is a pointer to a database structure that has been returned from a call to <code>dbm_open()</code>. The argument <i>key</i> is a datum that has been initialized by the application program to the value of the key that matches the key of the record the program is fetching.</p> <p>The <code>dbm_store()</code> function writes a record to a database. The argument <i>db</i> is a pointer to a database structure that has been returned from a call to <code>dbm_open()</code>. The argument <i>key</i> is a datum that has been initialized by the application program to the</p>

dbm_fetch(3C)

value of the key that identifies (for subsequent reading, writing or deleting) the record the program is writing. The argument *content* is a datum that has been initialized by the application program to the value of the record the program is writing. The argument *store_mode* controls whether `dbm_store()` replaces any pre-existing record that has the same key that is specified by the *key* argument. The application program must set *store_mode* to either `DBM_INSERT` or `DBM_REPLACE`. If the database contains a record that matches the *key* argument and *store_mode* is `DBM_REPLACE`, the existing record is replaced with the new record. If the database contains a record that matches the *key* argument and *store_mode* is `DBM_INSERT`, the existing record is not replaced with the new record. If the database does not contain a record that matches the *key* argument and *store_mode* is either `DBM_INSERT` or `DBM_REPLACE`, the new record is inserted in the database.

The `dbm_delete()` function deletes a record and its key from the database. The argument *db* is a pointer to a database structure that has been returned from a call to `dbm_open()`. The argument *key* is a datum that has been initialized by the application program to the value of the key that identifies the record the program is deleting.

The `dbm_firstkey()` function returns the first key in the database. The argument *db* is a pointer to a database structure that has been returned from a call to `dbm_open()`.

The `dbm_nextkey()` function returns the next key in the database. The argument *db* is a pointer to a database structure that has been returned from a call to `dbm_open()`. The `dbm_firstkey()` function must be called before calling `dbm_nextkey()`. Subsequent calls to `dbm_nextkey()` return the next key until all of the keys in the database have been returned.

The `dbm_error()` function returns the error condition of the database. The argument *db* is a pointer to a database structure that has been returned from a call to `dbm_open()`.

The `dbm_clearerr()` function clears the error condition of the database. The argument *db* is a pointer to a database structure that has been returned from a call to `dbm_open()`.

These database functions support key/content pairs of at least 1024 bytes.

RETURN VALUES

The `dbm_store()` and `dbm_delete()` functions return 0 when they succeed and a negative value when they fail.

The `dbm_store()` function returns 1 if it is called with a *flags* value of `DBM_INSERT` and the function finds an existing record with the same key.

The `dbm_error()` function returns 0 if the error condition is not set and returns a non-zero value if the error condition is set.

The return value of `dbm_clearerr()` is unspecified.

The `dbm_firstkey()` and `dbm_nextkey()` functions return a key datum. When the end of the database is reached, the `dptr` member of the key is a null pointer. If an error is detected, the `dptr` member of the key is a null pointer and the error condition of the database is set.

The `dbm_fetch()` function returns a content datum. If no record in the database matches the key or if an error condition has been detected in the database, the `dptr` member of the content is a null pointer.

The `dbm_open()` function returns a pointer to a database structure. If an error is detected during the operation, `dbm_open()` returns a `(DBM *)0`.

ERRORS No errors are defined.

USAGE The following code can be used to traverse the database:

```
for(key = dbm_firstkey(db); key.dptr != NULL; key = dbm_nextkey(db))
```

The `dbm_*` functions provided in this library should not be confused in any way with those of a general-purpose database management system. These functions do not provide for multiple search keys per entry, they do not protect against multi-user access (in other words they do not lock records or files), and they do not provide the many other useful database functions that are found in more robust database management systems. Creating and updating databases by use of these functions is relatively slow because of data copies that occur upon hash collisions. These functions are useful for applications requiring fast lookup of relatively static information that is to be indexed by a single key.

The `dptr` pointers returned by these functions may point into static storage that may be changed by subsequent calls.

The `dbm_delete()` function does not physically reclaim file space, although it does make it available for reuse.

After calling `dbm_store()` or `dbm_delete()` during a pass through the keys by `dbm_firstkey()` and `dbm_nextkey()`, the application should reset the database by calling `dbm_firstkey()` before again calling `dbm_nextkey()`.

EXAMPLES **EXAMPLE 1** Using the Database Functions

The following example stores and retrieves a phone number, using the name as the key. Note that this example does not include error checking.

```
#include <ndbm.h>
#include <stdio.h>
#include <fcntl.h>
#define NAME "Bill"
#define PHONE_NO "123-4567"
#define DB_NAME "phones"
main()
{
    DBM *db;
    datum name = {NAME, sizeof (NAME)};
```

dbm_fetch(3C)

EXAMPLE 1 Using the Database Functions (Continued)

```
datum put_phone_no = {PHONE_NO, sizeof (PHONE_NO)};
datum get_phone_no;
/* Open the database and store the record */
db = dbm_open(DB_NAME, O_RDWR | O_CREAT, 0660);
(void) dbm_store(db, name, put_phone_no, DBM_INSERT);
/* Retrieve the record */
get_phone_no = dbm_fetch(db, name);
(void) printf("Name: %s, Phone Number: %s\n", name.dptr,
get_phone_no.dptr);
/* Close the database */
dbm_close(db);
return (0);
}
```

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
MT-Level	Unsafe

SEE ALSO `ar(1)`, `cat(1)`, `cp(1)`, `tar(1)`, `open(2)`, `dbm(3UCB)`, `netconfig(4)`, `attributes(5)`

NOTES The `.pag` file will contain holes so that its apparent size may be larger than its actual content. Older versions of the UNIX operating system may create real file blocks for these holes when touched. These files cannot be copied by normal means (`cp(1)`, `cat(1)`, `tar(1)`, `ar(1)`) without filling in the holes.

The sum of the sizes of a *key/content* pair must not exceed the internal block size (currently 1024 bytes). Moreover all *key/content* pairs that hash together must fit on a single block. `dbm_store()` will return an error in the event that a disk block fills with inseparable data.

The order of keys presented by `dbm_firstkey()` and `dbm_nextkey()` depends on a hashing function.

There are no interlocks and no reliable cache flushing; thus concurrent updating and reading is risky.

The database files (`file.dir` and `file.pag`) are binary and are architecture-specific (for example, they depend on the architecture's byte order.) These files are not guaranteed to be portable across architectures.

NAME	ndbm, dbm_clearerr, dbm_close, dbm_delete, dbm_error, dbm_fetch, dbm_firstkey, dbm_nextkey, dbm_open, dbm_store – database functions
SYNOPSIS	<pre>#include <ndbm.h> int dbm_clearerr (DBM *db) ; void dbm_close (DBM *db) ; int dbm_delete (DBM *db, datum key) ; int dbm_error (DBM *db) ; datum dbm_fetch (DBM *db, datum key) ; datum dbm_firstkey (DBM *db) ; datum dbm_nextkey (DBM *db) ; DBM *dbm_open (const char *file, int open_flags, mode_t file_mode) ; int dbm_store (DBM *db, datum key, datum content, int store_mode) ;</pre>
DESCRIPTION	<p>These functions create, access and modify a database. They maintain <i>key/content</i> pairs in a database. The functions will handle large databases (up to a billion blocks) and will access a keyed item in one or two file system accesses. This package replaces the earlier dbm(3UCB) library, which managed only a single database.</p> <p><i>keys</i> and <i>contents</i> are described by the datum typedef. A datum consists of at least two members, <i>dptr</i> and <i>dsize</i>. The <i>dptr</i> member points to an object that is <i>dsize</i> bytes in length. Arbitrary binary data, as well as ASCII character strings, may be stored in the object pointed to by <i>dptr</i>.</p> <p>The database is stored in two files. One file is a directory containing a bit map of keys and has <i>.dir</i> as its suffix. The second file contains all data and has <i>.pag</i> as its suffix.</p> <p>The <code>dbm_open()</code> function opens a database. The <i>file</i> argument to the function is the pathname of the database. The function opens two files named <i>file.dir</i> and <i>file.pag</i>. The <i>open_flags</i> argument has the same meaning as the <i>flags</i> argument of <code>open(2)</code> except that a database opened for write-only access opens the files for read and write access. The <i>file_mode</i> argument has the same meaning as the third argument of <code>open(2)</code>.</p> <p>The <code>dbm_close()</code> function closes a database. The argument <i>db</i> must be a pointer to a dbm structure that has been returned from a call to <code>dbm_open()</code>.</p> <p>The <code>dbm_fetch()</code> function reads a record from a database. The argument <i>db</i> is a pointer to a database structure that has been returned from a call to <code>dbm_open()</code>. The argument <i>key</i> is a datum that has been initialized by the application program to the value of the key that matches the key of the record the program is fetching.</p> <p>The <code>dbm_store()</code> function writes a record to a database. The argument <i>db</i> is a pointer to a database structure that has been returned from a call to <code>dbm_open()</code>. The argument <i>key</i> is a datum that has been initialized by the application program to the</p>

dbm_firstkey(3C)

value of the key that identifies (for subsequent reading, writing or deleting) the record the program is writing. The argument *content* is a datum that has been initialized by the application program to the value of the record the program is writing. The argument *store_mode* controls whether `dbm_store()` replaces any pre-existing record that has the same key that is specified by the *key* argument. The application program must set *store_mode* to either `DBM_INSERT` or `DBM_REPLACE`. If the database contains a record that matches the *key* argument and *store_mode* is `DBM_REPLACE`, the existing record is replaced with the new record. If the database contains a record that matches the *key* argument and *store_mode* is `DBM_INSERT`, the existing record is not replaced with the new record. If the database does not contain a record that matches the *key* argument and *store_mode* is either `DBM_INSERT` or `DBM_REPLACE`, the new record is inserted in the database.

The `dbm_delete()` function deletes a record and its key from the database. The argument *db* is a pointer to a database structure that has been returned from a call to `dbm_open()`. The argument *key* is a datum that has been initialized by the application program to the value of the key that identifies the record the program is deleting.

The `dbm_firstkey()` function returns the first key in the database. The argument *db* is a pointer to a database structure that has been returned from a call to `dbm_open()`.

The `dbm_nextkey()` function returns the next key in the database. The argument *db* is a pointer to a database structure that has been returned from a call to `dbm_open()`. The `dbm_firstkey()` function must be called before calling `dbm_nextkey()`. Subsequent calls to `dbm_nextkey()` return the next key until all of the keys in the database have been returned.

The `dbm_error()` function returns the error condition of the database. The argument *db* is a pointer to a database structure that has been returned from a call to `dbm_open()`.

The `dbm_clearerr()` function clears the error condition of the database. The argument *db* is a pointer to a database structure that has been returned from a call to `dbm_open()`.

These database functions support key/content pairs of at least 1024 bytes.

RETURN VALUES

The `dbm_store()` and `dbm_delete()` functions return 0 when they succeed and a negative value when they fail.

The `dbm_store()` function returns 1 if it is called with a *flags* value of `DBM_INSERT` and the function finds an existing record with the same key.

The `dbm_error()` function returns 0 if the error condition is not set and returns a non-zero value if the error condition is set.

The return value of `dbm_clearerr()` is unspecified.

The `dbm_firstkey()` and `dbm_nextkey()` functions return a key datum. When the end of the database is reached, the `dptr` member of the key is a null pointer. If an error is detected, the `dptr` member of the key is a null pointer and the error condition of the database is set.

The `dbm_fetch()` function returns a content datum. If no record in the database matches the key or if an error condition has been detected in the database, the `dptr` member of the content is a null pointer.

The `dbm_open()` function returns a pointer to a database structure. If an error is detected during the operation, `dbm_open()` returns a `(DBM *)0`.

ERRORS No errors are defined.

USAGE The following code can be used to traverse the database:

```
for(key = dbm_firstkey(db); key.dptr != NULL; key = dbm_nextkey(db))
```

The `dbm_*` functions provided in this library should not be confused in any way with those of a general-purpose database management system. These functions do not provide for multiple search keys per entry, they do not protect against multi-user access (in other words they do not lock records or files), and they do not provide the many other useful database functions that are found in more robust database management systems. Creating and updating databases by use of these functions is relatively slow because of data copies that occur upon hash collisions. These functions are useful for applications requiring fast lookup of relatively static information that is to be indexed by a single key.

The `dptr` pointers returned by these functions may point into static storage that may be changed by subsequent calls.

The `dbm_delete()` function does not physically reclaim file space, although it does make it available for reuse.

After calling `dbm_store()` or `dbm_delete()` during a pass through the keys by `dbm_firstkey()` and `dbm_nextkey()`, the application should reset the database by calling `dbm_firstkey()` before again calling `dbm_nextkey()`.

EXAMPLES **EXAMPLE 1** Using the Database Functions

The following example stores and retrieves a phone number, using the name as the key. Note that this example does not include error checking.

```
#include <ndbm.h>
#include <stdio.h>
#include <fcntl.h>
#define NAME "Bill"
#define PHONE_NO "123-4567"
#define DB_NAME "phones"
main()
{
    DBM *db;
    datum name = {NAME, sizeof (NAME)};
```

dbm_firstkey(3C)

EXAMPLE 1 Using the Database Functions (Continued)

```
datum put_phone_no = {PHONE_NO, sizeof (PHONE_NO)};
datum get_phone_no;
/* Open the database and store the record */
db = dbm_open(DB_NAME, O_RDWR | O_CREAT, 0660);
(void) dbm_store(db, name, put_phone_no, DBM_INSERT);
/* Retrieve the record */
get_phone_no = dbm_fetch(db, name);
(void) printf("Name: %s, Phone Number: %s\n", name.dptr,
get_phone_no.dptr);
/* Close the database */
dbm_close(db);
return (0);
}
```

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
MT-Level	Unsafe

SEE ALSO `ar(1)`, `cat(1)`, `cp(1)`, `tar(1)`, `open(2)`, `dbm(3UCB)`, `netconfig(4)`, `attributes(5)`

NOTES The `.pag` file will contain holes so that its apparent size may be larger than its actual content. Older versions of the UNIX operating system may create real file blocks for these holes when touched. These files cannot be copied by normal means (`cp(1)`, `cat(1)`, `tar(1)`, `ar(1)`) without filling in the holes.

The sum of the sizes of a *key/content* pair must not exceed the internal block size (currently 1024 bytes). Moreover all *key/content* pairs that hash together must fit on a single block. `dbm_store()` will return an error in the event that a disk block fills with inseparable data.

The order of keys presented by `dbm_firstkey()` and `dbm_nextkey()` depends on a hashing function.

There are no interlocks and no reliable cache flushing; thus concurrent updating and reading is risky.

The database files (`file.dir` and `file.pag`) are binary and are architecture-specific (for example, they depend on the architecture's byte order.) These files are not guaranteed to be portable across architectures.

NAME	dbm, dbminit, dbmclose, fetch, store, delete, firstkey, nextkey – data base subroutines
SYNOPSIS	<pre> /usr/ucb/cc [flag ...] file ... -ldb #include <dbm.h> typedef struct { char *dptr; int dsize; } datum; int dbminit (file) ; char *file; int dbmclose () ; datum fetch (key) ; datum key; int store (key, dat) ; datum key, dat; int delete (key) ; datum key; datum firstkey() datum nextkey (key) ; datum key; </pre>
DESCRIPTION	<p>The dbm() library has been superseded by ndbm (see ndbm(3C)).</p> <p>These functions maintain key/content pairs in a data base. The functions will handle very large (a billion blocks) databases and will access a keyed item in one or two file system accesses.</p> <p><i>key/dat</i> and their content are described by the datum typedef. A datum specifies a string of <i>dsize</i> bytes pointed to by <i>dptr</i>. Arbitrary binary data, as well as normal ASCII strings, are allowed. The data base is stored in two files. One file is a directory containing a bit map and has <i>.dir</i> as its suffix. The second file contains all data and has <i>.pag</i> as its suffix.</p> <p>Before a database can be accessed, it must be opened by dbminit(). At the time of this call, the files <i>file.dir</i> and <i>file.pag</i> must exist. An empty database is created by creating zero-length <i>.dir</i> and <i>.pag</i> files.</p> <p>A database may be closed by calling dbmclose(). You must close a database before opening a new one.</p>

dbmopen(3UCB)

Once open, the data stored under a key is accessed by `fetch()` and data is placed under a key by `store`. A key (and its associated contents) is deleted by `delete()`. A linear pass through all keys in a database may be made, in an (apparently) random order, by use of `firstkey()` and `nextkey()`. `firstkey()` will return the first key in the database. With any key `nextkey()` will return the next key in the database. This code will traverse the data base:

```
for (key = firstkey; key.dptr != NULL; key = nextkey(key))
```

RETURN VALUES All functions that return an `int` indicate errors with negative values. A zero return indicates no error. Routines that return a `datum` indicate errors with a `NULL (0) dptr`.

SEE ALSO `ar(1)`, `cat(1)`, `cp(1)`, `tar(1)`, `ndbm(3C)`

NOTES Use of these interfaces should be restricted to only applications written on BSD platforms. Use of these interfaces with any of the system libraries or in multi-thread applications is unsupported.

The `.pag` file will contain holes so that its apparent size may be larger than its actual content. Older versions of the UNIX operating system may create real file blocks for these holes when touched. These files cannot be copied by normal means (`cp(1)`, `cat(1)`, `tar(1)`, `ar(1)`) without filling in the holes.

`dptr` pointers returned by these subroutines point into static storage that is changed by subsequent calls.

The sum of the sizes of a key/content pair must not exceed the internal block size (currently 1024 bytes). Moreover all key/content pairs that hash together must fit on a single block. `store` will return an error in the event that a disk block fills with inseparable data.

`delete()` does not physically reclaim file space, although it does make it available for reuse.

The order of keys presented by `firstkey()` and `nextkey()` depends on a hashing function, not on anything interesting.

There are no interlocks and no reliable cache flushing; thus concurrent updating and reading is risky.

The database files (`file.dir` and `file.pag`) are binary and are architecture-specific (for example, they depend on the architecture's byte order.) These files are not guaranteed to be portable across architectures.

NAME	ndbm, dbm_clearerr, dbm_close, dbm_delete, dbm_error, dbm_fetch, dbm_firstkey, dbm_nextkey, dbm_open, dbm_store – database functions
SYNOPSIS	<pre>#include <ndbm.h> int dbm_clearerr (DBM *db) ; void dbm_close (DBM *db) ; int dbm_delete (DBM *db, datum key) ; int dbm_error (DBM *db) ; datum dbm_fetch (DBM *db, datum key) ; datum dbm_firstkey (DBM *db) ; datum dbm_nextkey (DBM *db) ; DBM *dbm_open (const char *file, int open_flags, mode_t file_mode) ; int dbm_store (DBM *db, datum key, datum content, int store_mode) ;</pre>
DESCRIPTION	<p>These functions create, access and modify a database. They maintain <i>key/content</i> pairs in a database. The functions will handle large databases (up to a billion blocks) and will access a keyed item in one or two file system accesses. This package replaces the earlier dbm(3UCB) library, which managed only a single database.</p> <p><i>keys</i> and <i>contents</i> are described by the datum typedef. A datum consists of at least two members, <i>dptr</i> and <i>dsize</i>. The <i>dptr</i> member points to an object that is <i>dsize</i> bytes in length. Arbitrary binary data, as well as ASCII character strings, may be stored in the object pointed to by <i>dptr</i>.</p> <p>The database is stored in two files. One file is a directory containing a bit map of keys and has <i>.dir</i> as its suffix. The second file contains all data and has <i>.pag</i> as its suffix.</p> <p>The <code>dbm_open()</code> function opens a database. The <code>file</code> argument to the function is the pathname of the database. The function opens two files named <code>file.dir</code> and <code>file.pag</code>. The <code>open_flags</code> argument has the same meaning as the <code>flags</code> argument of <code>open(2)</code> except that a database opened for write-only access opens the files for read and write access. The <code>file_mode</code> argument has the same meaning as the third argument of <code>open(2)</code>.</p> <p>The <code>dbm_close()</code> function closes a database. The argument <code>db</code> must be a pointer to a <code>dbm</code> structure that has been returned from a call to <code>dbm_open()</code>.</p> <p>The <code>dbm_fetch()</code> function reads a record from a database. The argument <code>key</code> is a datum that has been initialized by the application program to the value of the key that matches the key of the record the program is fetching.</p> <p>The <code>dbm_store()</code> function writes a record to a database. The argument <code>db</code> is a pointer to a database structure that has been returned from a call to <code>dbm_open()</code>. The argument <code>key</code> is a datum that has been initialized by the application program to the</p>

dbm_nextkey(3C)

value of the key that identifies (for subsequent reading, writing or deleting) the record the program is writing. The argument *content* is a datum that has been initialized by the application program to the value of the record the program is writing. The argument *store_mode* controls whether `dbm_store()` replaces any pre-existing record that has the same key that is specified by the *key* argument. The application program must set *store_mode* to either `DBM_INSERT` or `DBM_REPLACE`. If the database contains a record that matches the *key* argument and *store_mode* is `DBM_REPLACE`, the existing record is replaced with the new record. If the database contains a record that matches the *key* argument and *store_mode* is `DBM_INSERT`, the existing record is not replaced with the new record. If the database does not contain a record that matches the *key* argument and *store_mode* is either `DBM_INSERT` or `DBM_REPLACE`, the new record is inserted in the database.

The `dbm_delete()` function deletes a record and its key from the database. The argument *db* is a pointer to a database structure that has been returned from a call to `dbm_open()`. The argument *key* is a datum that has been initialized by the application program to the value of the key that identifies the record the program is deleting.

The `dbm_firstkey()` function returns the first key in the database. The argument *db* is a pointer to a database structure that has been returned from a call to `dbm_open()`.

The `dbm_nextkey()` function returns the next key in the database. The argument *db* is a pointer to a database structure that has been returned from a call to `dbm_open()`. The `dbm_firstkey()` function must be called before calling `dbm_nextkey()`. Subsequent calls to `dbm_nextkey()` return the next key until all of the keys in the database have been returned.

The `dbm_error()` function returns the error condition of the database. The argument *db* is a pointer to a database structure that has been returned from a call to `dbm_open()`.

The `dbm_clearerr()` function clears the error condition of the database. The argument *db* is a pointer to a database structure that has been returned from a call to `dbm_open()`.

These database functions support key/content pairs of at least 1024 bytes.

RETURN VALUES

The `dbm_store()` and `dbm_delete()` functions return 0 when they succeed and a negative value when they fail.

The `dbm_store()` function returns 1 if it is called with a *flags* value of `DBM_INSERT` and the function finds an existing record with the same key.

The `dbm_error()` function returns 0 if the error condition is not set and returns a non-zero value if the error condition is set.

The return value of `dbm_clearerr()` is unspecified.

The `dbm_firstkey()` and `dbm_nextkey()` functions return a key datum. When the end of the database is reached, the `dptr` member of the key is a null pointer. If an error is detected, the `dptr` member of the key is a null pointer and the error condition of the database is set.

The `dbm_fetch()` function returns a content datum. If no record in the database matches the key or if an error condition has been detected in the database, the `dptr` member of the content is a null pointer.

The `dbm_open()` function returns a pointer to a database structure. If an error is detected during the operation, `dbm_open()` returns a `(DBM *)0`.

ERRORS No errors are defined.

USAGE The following code can be used to traverse the database:

```
for(key = dbm_firstkey(db); key.dptr != NULL; key = dbm_nextkey(db))
```

The `dbm_*` functions provided in this library should not be confused in any way with those of a general-purpose database management system. These functions do not provide for multiple search keys per entry, they do not protect against multi-user access (in other words they do not lock records or files), and they do not provide the many other useful database functions that are found in more robust database management systems. Creating and updating databases by use of these functions is relatively slow because of data copies that occur upon hash collisions. These functions are useful for applications requiring fast lookup of relatively static information that is to be indexed by a single key.

The `dptr` pointers returned by these functions may point into static storage that may be changed by subsequent calls.

The `dbm_delete()` function does not physically reclaim file space, although it does make it available for reuse.

After calling `dbm_store()` or `dbm_delete()` during a pass through the keys by `dbm_firstkey()` and `dbm_nextkey()`, the application should reset the database by calling `dbm_firstkey()` before again calling `dbm_nextkey()`.

EXAMPLES **EXAMPLE 1** Using the Database Functions

The following example stores and retrieves a phone number, using the name as the key. Note that this example does not include error checking.

```
#include <ndbm.h>
#include <stdio.h>
#include <fcntl.h>
#define NAME "Bill"
#define PHONE_NO "123-4567"
#define DB_NAME "phones"
main()
{
    DBM *db;
    datum name = {NAME, sizeof (NAME)};
```

dbm_nextkey(3C)

EXAMPLE 1 Using the Database Functions (Continued)

```
datum put_phone_no = {PHONE_NO, sizeof (PHONE_NO)};
datum get_phone_no;
/* Open the database and store the record */
db = dbm_open(DB_NAME, O_RDWR | O_CREAT, 0660);
(void) dbm_store(db, name, put_phone_no, DBM_INSERT);
/* Retrieve the record */
get_phone_no = dbm_fetch(db, name);
(void) printf("Name: %s, Phone Number: %s\n", name.dptr,
get_phone_no.dptr);
/* Close the database */
dbm_close(db);
return (0);
}
```

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
MT-Level	Unsafe

SEE ALSO `ar(1)`, `cat(1)`, `cp(1)`, `tar(1)`, `open(2)`, `dbm(3UCB)`, `netconfig(4)`, `attributes(5)`

NOTES The `.pag` file will contain holes so that its apparent size may be larger than its actual content. Older versions of the UNIX operating system may create real file blocks for these holes when touched. These files cannot be copied by normal means (`cp(1)`, `cat(1)`, `tar(1)`, `ar(1)`) without filling in the holes.

The sum of the sizes of a *key/content* pair must not exceed the internal block size (currently 1024 bytes). Moreover all *key/content* pairs that hash together must fit on a single block. `dbm_store()` will return an error in the event that a disk block fills with inseparable data.

The order of keys presented by `dbm_firstkey()` and `dbm_nextkey()` depends on a hashing function.

There are no interlocks and no reliable cache flushing; thus concurrent updating and reading is risky.

The database files (`file.dir` and `file.pag`) are binary and are architecture-specific (for example, they depend on the architecture's byte order.) These files are not guaranteed to be portable across architectures.

NAME	ndbm, dbm_clearerr, dbm_close, dbm_delete, dbm_error, dbm_fetch, dbm_firstkey, dbm_nextkey, dbm_open, dbm_store – database functions
SYNOPSIS	<pre>#include <ndbm.h> int dbm_clearerr (DBM *db) ; void dbm_close (DBM *db) ; int dbm_delete (DBM *db, datum key) ; int dbm_error (DBM *db) ; datum dbm_fetch (DBM *db, datum key) ; datum dbm_firstkey (DBM *db) ; datum dbm_nextkey (DBM *db) ; DBM *dbm_open (const char *file, int open_flags, mode_t file_mode) ; int dbm_store (DBM *db, datum key, datum content, int store_mode) ;</pre>
DESCRIPTION	<p>These functions create, access and modify a database. They maintain <i>key/content</i> pairs in a database. The functions will handle large databases (up to a billion blocks) and will access a keyed item in one or two file system accesses. This package replaces the earlier dbm(3UCB) library, which managed only a single database.</p> <p><i>keys</i> and <i>contents</i> are described by the datum typedef. A datum consists of at least two members, <i>dptr</i> and <i>dsize</i>. The <i>dptr</i> member points to an object that is <i>dsize</i> bytes in length. Arbitrary binary data, as well as ASCII character strings, may be stored in the object pointed to by <i>dptr</i>.</p> <p>The database is stored in two files. One file is a directory containing a bit map of keys and has <i>.dir</i> as its suffix. The second file contains all data and has <i>.pag</i> as its suffix.</p> <p>The <code>dbm_open()</code> function opens a database. The <i>file</i> argument to the function is the pathname of the database. The function opens two files named <i>file.dir</i> and <i>file.pag</i>. The <i>open_flags</i> argument has the same meaning as the <i>flags</i> argument of <code>open(2)</code> except that a database opened for write-only access opens the files for read and write access. The <i>file_mode</i> argument has the same meaning as the third argument of <code>open(2)</code>.</p> <p>The <code>dbm_close()</code> function closes a database. The argument <i>db</i> must be a pointer to a <code>dbm</code> structure that has been returned from a call to <code>dbm_open()</code>.</p> <p>The <code>dbm_fetch()</code> function reads a record from a database. The argument <i>db</i> is a pointer to a database structure that has been returned from a call to <code>dbm_open()</code>. The argument <i>key</i> is a datum that has been initialized by the application program to the value of the key that matches the key of the record the program is fetching.</p> <p>The <code>dbm_store()</code> function writes a record to a database. The argument <i>db</i> is a pointer to a database structure that has been returned from a call to <code>dbm_open()</code>. The argument <i>key</i> is a datum that has been initialized by the application program to the</p>

dbm_open(3C)

value of the key that identifies (for subsequent reading, writing or deleting) the record the program is writing. The argument *content* is a datum that has been initialized by the application program to the value of the record the program is writing. The argument *store_mode* controls whether `dbm_store()` replaces any pre-existing record that has the same key that is specified by the *key* argument. The application program must set *store_mode* to either `DBM_INSERT` or `DBM_REPLACE`. If the database contains a record that matches the *key* argument and *store_mode* is `DBM_REPLACE`, the existing record is replaced with the new record. If the database contains a record that matches the *key* argument and *store_mode* is `DBM_INSERT`, the existing record is not replaced with the new record. If the database does not contain a record that matches the *key* argument and *store_mode* is either `DBM_INSERT` or `DBM_REPLACE`, the new record is inserted in the database.

The `dbm_delete()` function deletes a record and its key from the database. The argument *db* is a pointer to a database structure that has been returned from a call to `dbm_open()`. The argument *key* is a datum that has been initialized by the application program to the value of the key that identifies the record the program is deleting.

The `dbm_firstkey()` function returns the first key in the database. The argument *db* is a pointer to a database structure that has been returned from a call to `dbm_open()`.

The `dbm_nextkey()` function returns the next key in the database. The argument *db* is a pointer to a database structure that has been returned from a call to `dbm_open()`. The `dbm_firstkey()` function must be called before calling `dbm_nextkey()`. Subsequent calls to `dbm_nextkey()` return the next key until all of the keys in the database have been returned.

The `dbm_error()` function returns the error condition of the database. The argument *db* is a pointer to a database structure that has been returned from a call to `dbm_open()`.

The `dbm_clearerr()` function clears the error condition of the database. The argument *db* is a pointer to a database structure that has been returned from a call to `dbm_open()`.

These database functions support key/content pairs of at least 1024 bytes.

RETURN VALUES

The `dbm_store()` and `dbm_delete()` functions return 0 when they succeed and a negative value when they fail.

The `dbm_store()` function returns 1 if it is called with a *flags* value of `DBM_INSERT` and the function finds an existing record with the same key.

The `dbm_error()` function returns 0 if the error condition is not set and returns a non-zero value if the error condition is set.

The return value of `dbm_clearerr()` is unspecified.

The `dbm_firstkey()` and `dbm_nextkey()` functions return a key datum. When the end of the database is reached, the `dptr` member of the key is a null pointer. If an error is detected, the `dptr` member of the key is a null pointer and the error condition of the database is set.

The `dbm_fetch()` function returns a content datum. If no record in the database matches the key or if an error condition has been detected in the database, the `dptr` member of the content is a null pointer.

The `dbm_open()` function returns a pointer to a database structure. If an error is detected during the operation, `dbm_open()` returns a `(DBM *)0`.

ERRORS No errors are defined.

USAGE The following code can be used to traverse the database:

```
for(key = dbm_firstkey(db); key.dptr != NULL; key = dbm_nextkey(db))
```

The `dbm_*` functions provided in this library should not be confused in any way with those of a general-purpose database management system. These functions do not provide for multiple search keys per entry, they do not protect against multi-user access (in other words they do not lock records or files), and they do not provide the many other useful database functions that are found in more robust database management systems. Creating and updating databases by use of these functions is relatively slow because of data copies that occur upon hash collisions. These functions are useful for applications requiring fast lookup of relatively static information that is to be indexed by a single key.

The `dptr` pointers returned by these functions may point into static storage that may be changed by subsequent calls.

The `dbm_delete()` function does not physically reclaim file space, although it does make it available for reuse.

After calling `dbm_store()` or `dbm_delete()` during a pass through the keys by `dbm_firstkey()` and `dbm_nextkey()`, the application should reset the database by calling `dbm_firstkey()` before again calling `dbm_nextkey()`.

EXAMPLES **EXAMPLE 1** Using the Database Functions

The following example stores and retrieves a phone number, using the name as the key. Note that this example does not include error checking.

```
#include <ndbm.h>
#include <stdio.h>
#include <fcntl.h>
#define NAME "Bill"
#define PHONE_NO "123-4567"
#define DB_NAME "phones"
main()
{
    DBM *db;
    datum name = {NAME, sizeof (NAME)};
```

dbm_open(3C)

EXAMPLE 1 Using the Database Functions (Continued)

```
datum put_phone_no = {PHONE_NO, sizeof (PHONE_NO)};
datum get_phone_no;
/* Open the database and store the record */
db = dbm_open(DB_NAME, O_RDWR | O_CREAT, 0660);
(void) dbm_store(db, name, put_phone_no, DBM_INSERT);
/* Retrieve the record */
get_phone_no = dbm_fetch(db, name);
(void) printf("Name: %s, Phone Number: %s\n", name.dptr,
get_phone_no.dptr);
/* Close the database */
dbm_close(db);
return (0);
}
```

The argument <i>db</i> is a pointer to a database structure that has been returned from a call to <code>dbm_open()</code>. The argument <i>key</i> is a datum that has been initialized by the application program to the</p>

dbm_store(3C)

value of the key that identifies (for subsequent reading, writing or deleting) the record the program is writing. The argument *content* is a datum that has been initialized by the application program to the value of the record the program is writing. The argument *store_mode* controls whether `dbm_store()` replaces any pre-existing record that has the same key that is specified by the *key* argument. The application program must set *store_mode* to either `DBM_INSERT` or `DBM_REPLACE`. If the database contains a record that matches the *key* argument and *store_mode* is `DBM_REPLACE`, the existing record is replaced with the new record. If the database contains a record that matches the *key* argument and *store_mode* is `DBM_INSERT`, the existing record is not replaced with the new record. If the database does not contain a record that matches the *key* argument and *store_mode* is either `DBM_INSERT` or `DBM_REPLACE`, the new record is inserted in the database.

The `dbm_delete()` function deletes a record and its key from the database. The argument *db* is a pointer to a database structure that has been returned from a call to `dbm_open()`. The argument *key* is a datum that has been initialized by the application program to the value of the key that identifies the record the program is deleting.

The `dbm_firstkey()` function returns the first key in the database. The argument *db* is a pointer to a database structure that has been returned from a call to `dbm_open()`.

The `dbm_nextkey()` function returns the next key in the database. The argument *db* is a pointer to a database structure that has been returned from a call to `dbm_open()`. The `dbm_firstkey()` function must be called before calling `dbm_nextkey()`. Subsequent calls to `dbm_nextkey()` return the next key until all of the keys in the database have been returned.

The `dbm_error()` function returns the error condition of the database. The argument *db* is a pointer to a database structure that has been returned from a call to `dbm_open()`.

The `dbm_clearerr()` function clears the error condition of the database. The argument *db* is a pointer to a database structure that has been returned from a call to `dbm_open()`.

These database functions support key/content pairs of at least 1024 bytes.

RETURN VALUES

The `dbm_store()` and `dbm_delete()` functions return 0 when they succeed and a negative value when they fail.

The `dbm_store()` function returns 1 if it is called with a *flags* value of `DBM_INSERT` and the function finds an existing record with the same key.

The `dbm_error()` function returns 0 if the error condition is not set and returns a non-zero value if the error condition is set.

The return value of `dbm_clearerr()` is unspecified.

The `dbm_firstkey()` and `dbm_nextkey()` functions return a key datum. When the end of the database is reached, the `dptr` member of the key is a null pointer. If an error is detected, the `dptr` member of the key is a null pointer and the error condition of the database is set.

The `dbm_fetch()` function returns a content datum. If no record in the database matches the key or if an error condition has been detected in the database, the `dptr` member of the content is a null pointer.

The `dbm_open()` function returns a pointer to a database structure. If an error is detected during the operation, `dbm_open()` returns a `(DBM *)0`.

ERRORS No errors are defined.

USAGE The following code can be used to traverse the database:

```
for(key = dbm_firstkey(db); key.dptr != NULL; key = dbm_nextkey(db))
```

The `dbm_*` functions provided in this library should not be confused in any way with those of a general-purpose database management system. These functions do not provide for multiple search keys per entry, they do not protect against multi-user access (in other words they do not lock records or files), and they do not provide the many other useful database functions that are found in more robust database management systems. Creating and updating databases by use of these functions is relatively slow because of data copies that occur upon hash collisions. These functions are useful for applications requiring fast lookup of relatively static information that is to be indexed by a single key.

The `dptr` pointers returned by these functions may point into static storage that may be changed by subsequent calls.

The `dbm_delete()` function does not physically reclaim file space, although it does make it available for reuse.

After calling `dbm_store()` or `dbm_delete()` during a pass through the keys by `dbm_firstkey()` and `dbm_nextkey()`, the application should reset the database by calling `dbm_firstkey()` before again calling `dbm_nextkey()`.

EXAMPLES **EXAMPLE 1** Using the Database Functions

The following example stores and retrieves a phone number, using the name as the key. Note that this example does not include error checking.

```
#include <ndbm.h>
#include <stdio.h>
#include <fcntl.h>
#define NAME "Bill"
#define PHONE_NO "123-4567"
#define DB_NAME "phones"
main()
{
    DBM *db;
    datum name = {NAME, sizeof (NAME)};
```

dbm_store(3C)

EXAMPLE 1 Using the Database Functions (Continued)

```
datum put_phone_no = {PHONE_NO, sizeof (PHONE_NO)};
datum get_phone_no;
/* Open the database and store the record */
db = dbm_open(DB_NAME, O_RDWR | O_CREAT, 0660);
(void) dbm_store(db, name, put_phone_no, DBM_INSERT);
/* Retrieve the record */
get_phone_no = dbm_fetch(db, name);
(void) printf("Name: %s, Phone Number: %s\n", name.dptr,
get_phone_no.dptr);
/* Close the database */
dbm_close(db);
return (0);
}
```

NAME	gettext, dgettext, dcgettext, ngettext, dngettext, dcngettext, textdomain, bindtextdomain, bind_textdomain_codeset – message handling functions
Solaris and GNU-compatible	<pre>#include <libintl.h> char *gettext(const char *msgid); char *dgettext(const char *domainname, const char *msgid); char *textdomain(const char *domainname); char *bindtextdomain(const char *domainname, const char *dirname); #include <libintl.h> #include <locale.h> char *dcgettext(const char *domainname, const char *msgid, int category);</pre>
GNU-compatible	<pre>#include <libintl.h> char *ngettext(const char *msgid1, const char *msgid2, unsigned long int n); char *dngettext(const char *domainname, const char *msgid1, const char *msgid2, unsigned long int n); char *bind_textdomain_codeset(const char *domainname, const char *codeset); #include <libintl.h> #include <locale.h> char *dcngettext(const char *domainname, const char *msgid1, const char *msgid2, unsigned long int n, int category);</pre>
DESCRIPTION	<p>The <code>gettext()</code>, <code>dgettext()</code>, and <code>dcgettext()</code> functions attempt to retrieve a target string based on the specified <code>msgid</code> argument within the context of a specific domain and the current locale. The length of strings returned by <code>gettext()</code>, <code>dgettext()</code>, and <code>dcgettext()</code> is undetermined until the function is called. The <code>msgid</code> argument is a null-terminated string.</p> <p>The <code>ngettext()</code>, <code>dngettext()</code>, and <code>dcngettext()</code> functions are equivalent to <code>gettext()</code>, <code>dgettext()</code>, and <code>dcgettext()</code>, respectively, except for the handling of plural forms. These functions work only with GNU-compatible message catalogues. The <code>ngettext()</code>, <code>dngettext()</code>, and <code>dcngettext()</code> functions search for the message string using the <code>msgid1</code> argument as the key and the <code>n</code> argument to determine the plural form. If no message catalogues are found, <code>msgid1</code> is returned if <code>n == 1</code>, otherwise <code>msgid2</code> is returned.</p> <p>The <code>NLSPATH</code> environment variable (see <code>environ(5)</code>) is searched first for the location of the <code>LC_MESSAGES</code> catalogue. The setting of the <code>LC_MESSAGES</code> category of the current locale determines the locale used by <code>gettext()</code> and <code>dgettext()</code> for string retrieval. The <code>category</code> argument determines the locale used by <code>dcgettext()</code>. If <code>NLSPATH</code> is not defined and the current locale is "C", <code>gettext()</code>, <code>dgettext()</code>, and</p>

dcgettext(3C)

`dcgettext()` simply return the message string that was passed. In a locale other than "C", if `NLSPATH` is not defined or if a message catalogue is not found in any of the components specified by `NLSPATH`, the routines search for the message catalogue using the scheme described in the following paragraph.

The `LANGUAGE` environment variable is examined to determine the GNU-compatible message catalogues to be used. The value of `LANGUAGE` is a list of locale names separated by a colon (':') character. If `LANGUAGE` is defined, each locale name is tried in the specified order and if a GNU-compatible message catalogue is found, the message is returned. If a GNU-compatible message catalogue is found but failed to find a corresponding *msgid*, the *msgid* string is return. If `LANGUAGE` is not defined or if a Solaris message catalogue is found or no GNU-compatible message catalogue is found in processing `LANGUAGE`, the pathname used to locate the message catalogue is *dirname/locale/category/domainname.mo*, where *dirname* is the directory specified by `bindtextdomain()`, *locale* is a locale name, and *category* is either `LC_MESSAGES` if `gettext()`, `dgettext()`, `ngettext()`, or `dcgettext()` is called, or `LC_XXX` where the name is the same as the locale category name specified by the *category* argument to `dcgettext()` or `dcngettext()`.

For `gettext()` and `ngettext()`, the domain used is set by the last valid call to `textdomain()`. If a valid call to `textdomain()` has not been made, the default domain (called `messages`) is used.

For `dgettext()`, `dcgettext()`, `dngettext()`, and `dcngettext()`, the domain used is specified by the *domainname* argument. The *domainname* argument is equivalent in syntax and meaning to the *domainname* argument to `textdomain()`, except that the selection of the domain is valid only for the duration of the `dgettext()`, `dcgettext()`, `dngettext()`, or `dcngettext()` function call.

The `textdomain()` function sets or queries the name of the current domain of the active `LC_MESSAGES` locale category. The *domainname* argument is a null-terminated string that can contain only the characters allowed in legal filenames.

The *domainname* argument is the unique name of a domain on the system. If there are multiple versions of the same domain on one system, namespace collisions can be avoided by using `bindtextdomain()`. If `textdomain()` is not called, a default domain is selected. The setting of domain made by the last valid call to `textdomain()` remains valid across subsequent calls to `setlocale(3C)`, and `gettext()`.

The *domainname* argument is applied to the currently active `LC_MESSAGES` locale.

The current setting of the domain can be queried without affecting the current state of the domain by calling `textdomain()` with *domainname* set to the null pointer. Calling `textdomain()` with a *domainname* argument of a null string sets the domain to the default domain (`messages`).

The `bindtextdomain()` function binds the path predicate for a message domain *domainname* to the value contained in *dirname*. If *domainname* is a non-empty string and has not been bound previously, `bindtextdomain()` binds *domainname* with *dirname*.

If *domainname* is a non-empty string and has been bound previously, `bindtextdomain()` replaces the old binding with *dirname*. The *dirname* argument can be an absolute or relative pathname being resolved when `gettext()`, `dgettext()`, or `dcgettext()` are called. If *domainname* is a null pointer or an empty string, `bindtextdomain()` returns NULL. User defined domain names cannot begin with the string `SYS_`. Domain names beginning with this string are reserved for system use.

The `bind_textdomain_codeset()` function can be used to specify the output codeset for message catalogues for domain *domainname*. The *codeset* argument must be a valid codeset name that can be used for the `iconv_open(3C)` function, or a null pointer. If the *codeset* argument is the null pointer, `bind_textdomain_codeset()` returns the currently selected codeset for the domain with the name *domainname*. It returns a null pointer if a codeset has not yet been selected. The `bind_textdomain_codeset()` function can be used multiple times. If used multiple times with the same *domainname* argument, the later call overrides the settings made by the earlier one. The `bind_textdomain_codeset()` function returns a pointer to a string containing the name of the selected codeset. The string is allocated internally in the function and must not be changed by the user.

RETURN VALUES

The `gettext()`, `dgettext()`, and `dcgettext()` functions return the message string if the search succeeds. Otherwise they return the *msgid* string.

The `ngettext()`, `dngettext()`, and `dcngettext()` functions return the message string if the search succeeds. If the search fails, *msgid1* is returned if *n* == 1. Otherwise *msgid2* is returned.

The individual bytes of the string returned by `gettext()`, `dgettext()`, `dcgettext()`, `ngettext()`, `dngettext()`, or `dcngettext()` can contain any value other than NULL. If *msgid* is a null pointer, the return value is undefined. The string returned must not be modified by the program and can be invalidated by a subsequent call to `bind_textdomain_codeset()` or `setlocale(3C)`. If the *domainname* argument to `dgettext()`, `dcgettext()`, `dngettext()`, or `dcngettext()` is a null pointer, the the domain currently bound by `textdomain()` is used.

The normal return value from `textdomain()` is a pointer to a string containing the current setting of the domain. If *domainname* is a null pointer, `textdomain()` returns a pointer to the string containing the current domain. If `textdomain()` was not previously called and *domainname* is a null string, the name of the default domain is returned. The name of the default domain is `messages`. If `textdomain()` fails, a null pointer is returned.

The return value from `bindtextdomain()` is a null-terminated string containing *dirname* or the directory binding associated with *domainname* if *dirname* is NULL. If no binding is found, the default return value is `/usr/lib/locale`. If *domainname* is a null pointer or an empty string, `bindtextdomain()` takes no action and returns a null pointer. The string returned must not be modified by the caller. If `bindtextdomain()` fails, a null pointer is returned.

dcgettext(3C)

USAGE These functions impose no limit on message length. However, a text *domainname* is limited to TEXTDOMAINMAX (256) bytes.

The `gettext()`, `dgettext()`, `dcgettext()`, `ngettext()`, `dngettext()`, `dcngettext()`, `textdomain()`, and `bindtextdomain()` functions can be used safely in multithreaded applications, as long as `setlocale(3C)` is not being called to change the locale.

The `gettext()`, `dgettext()`, `dcgettext()`, `textdomain()`, and `bindtextdomain()` functions work with both Solaris message catalogues and GNU-compatible message catalogues. The `ngettext()`, `dngettext()`, `dcngettext()`, and `bind_textdomain_codeset()` functions work only with GNU-compatible message catalogues. See `msgfmt(1)` for information about Solaris message catalogues and GNU-compatible message catalogues.

FILES `/usr/lib/locale`

default path predicate for message domain files

`/usr/lib/locale/locale/LC_MESSAGES/domainname.mo`

system default location for file containing messages for language *locale* and *domainname*

`/usr/lib/locale/locale/LC_XXX/domainname.mo`

system default location for file containing messages for language *locale* and *domainname* for `dcgettext()` calls where `LC_XXX` is `LC_CTYPE`, `LC_NUMERIC`, `LC_TIME`, `LC_COLLATE`, `LC_MONETARY`, or `LC_MESSAGES`

`dirname/locale/LC_MESSAGES/domainname.mo`

location for file containing messages for domain *domainname* and path predicate *dirname* after a successful call to `bindtextdomain()`

`dirname/locale/LC_XXX/domainname.mo`

location for files containing messages for domain *domainname*, language *locale*, and path predicate *dirname* after a successful call to `bindtextdomain()` for `dcgettext()` calls where `LC_XXX` is one of `LC_CTYPE`, `LC_NUMERIC`, `LC_TIME`, `LC_COLLATE`, `LC_MONETARY`, or `LC_MESSAGES`

NAME	gettext, dgettext, dcgettext, ngettext, dngettext, dcngettext, textdomain, bindtextdomain, bind_textdomain_codeset – message handling functions
Solaris and GNU-compatible	<pre>#include <libintl.h> char *gettext(const char *msgid); char *dgettext(const char *domainname, const char *msgid); char *textdomain(const char *domainname); char *bindtextdomain(const char *domainname, const char *dirname); #include <libintl.h> #include <locale.h> char *dcgettext(const char *domainname, const char *msgid, int category);</pre>
GNU-compatible	<pre>#include <libintl.h> char *ngettext(const char *msgid1, const char *msgid2, unsigned long int n); char *dngettext(const char *domainname, const char *msgid1, const char *msgid2, unsigned long int n); char *bind_textdomain_codeset(const char *domainname, const char *codeset); #include <libintl.h> #include <locale.h> char *dcngettext(const char *domainname, const char *msgid1, const char *msgid2, unsigned long int n, int category);</pre>
DESCRIPTION	<p>The <code>gettext()</code>, <code>dgettext()</code>, and <code>dcgettext()</code> functions attempt to retrieve a target string based on the specified <code>msgid</code> argument within the context of a specific domain and the current locale. The length of strings returned by <code>gettext()</code>, <code>dgettext()</code>, and <code>dcgettext()</code> is undetermined until the function is called. The <code>msgid</code> argument is a null-terminated string.</p> <p>The <code>ngettext()</code>, <code>dngettext()</code>, and <code>dcngettext()</code> functions are equivalent to <code>gettext()</code>, <code>dgettext()</code>, and <code>dcgettext()</code>, respectively, except for the handling of plural forms. These functions work only with GNU-compatible message catalogues. The <code>ngettext()</code>, <code>dngettext()</code>, and <code>dcngettext()</code> functions search for the message string using the <code>msgid1</code> argument as the key and the <code>n</code> argument to determine the plural form. If no message catalogues are found, <code>msgid1</code> is returned if <code>n == 1</code>, otherwise <code>msgid2</code> is returned.</p> <p>The <code>NLSPATH</code> environment variable (see <code>environ(5)</code>) is searched first for the location of the <code>LC_MESSAGES</code> catalogue. The setting of the <code>LC_MESSAGES</code> category of the current locale determines the locale used by <code>gettext()</code> and <code>dgettext()</code> for string retrieval. The <code>category</code> argument determines the locale used by <code>dcgettext()</code>. If <code>NLSPATH</code> is not defined and the current locale is "C", <code>gettext()</code>, <code>dgettext()</code>, and</p>

dcngettext(3C)

`dcgettext()` simply return the message string that was passed. In a locale other than "C", if `NLSPATH` is not defined or if a message catalogue is not found in any of the components specified by `NLSPATH`, the routines search for the message catalogue using the scheme described in the following paragraph.

The `LANGUAGE` environment variable is examined to determine the GNU-compatible message catalogues to be used. The value of `LANGUAGE` is a list of locale names separated by a colon (':') character. If `LANGUAGE` is defined, each locale name is tried in the specified order and if a GNU-compatible message catalogue is found, the message is returned. If a GNU-compatible message catalogue is found but failed to find a corresponding *msgid*, the *msgid* string is return. If `LANGUAGE` is not defined or if a Solaris message catalogue is found or no GNU-compatible message catalogue is found in processing `LANGUAGE`, the pathname used to locate the message catalogue is *dirname/locale/category/domainname.mo*, where *dirname* is the directory specified by `bindtextdomain()`, *locale* is a locale name, and *category* is either `LC_MESSAGES` if `gettext()`, `dgettext()`, `ngettext()`, or `dcgettext()` is called, or `LC_XXX` where the name is the same as the locale category name specified by the *category* argument to `dcgettext()` or `dcngettext()`.

For `gettext()` and `ngettext()`, the domain used is set by the last valid call to `textdomain()`. If a valid call to `textdomain()` has not been made, the default domain (called `messages`) is used.

For `dgettext()`, `dcgettext()`, `dngettext()`, and `dcngettext()`, the domain used is specified by the *domainname* argument. The *domainname* argument is equivalent in syntax and meaning to the *domainname* argument to `textdomain()`, except that the selection of the domain is valid only for the duration of the `dgettext()`, `dcgettext()`, `dngettext()`, or `dcngettext()` function call.

The `textdomain()` function sets or queries the name of the current domain of the active `LC_MESSAGES` locale category. The *domainname* argument is a null-terminated string that can contain only the characters allowed in legal filenames.

The *domainname* argument is the unique name of a domain on the system. If there are multiple versions of the same domain on one system, namespace collisions can be avoided by using `bindtextdomain()`. If `textdomain()` is not called, a default domain is selected. The setting of domain made by the last valid call to `textdomain()` remains valid across subsequent calls to `setlocale(3C)`, and `gettext()`.

The *domainname* argument is applied to the currently active `LC_MESSAGES` locale.

The current setting of the domain can be queried without affecting the current state of the domain by calling `textdomain()` with *domainname* set to the null pointer. Calling `textdomain()` with a *domainname* argument of a null string sets the domain to the default domain (`messages`).

The `bindtextdomain()` function binds the path predicate for a message domain *domainname* to the value contained in *dirname*. If *domainname* is a non-empty string and has not been bound previously, `bindtextdomain()` binds *domainname* with *dirname*.

If *domainname* is a non-empty string and has been bound previously, `bindtextdomain()` replaces the old binding with *dirname*. The *dirname* argument can be an absolute or relative pathname being resolved when `gettext()`, `dgettext()`, or `dcgettext()` are called. If *domainname* is a null pointer or an empty string, `bindtextdomain()` returns NULL. User defined domain names cannot begin with the string `SYS_`. Domain names beginning with this string are reserved for system use.

The `bind_textdomain_codeset()` function can be used to specify the output codeset for message catalogues for domain *domainname*. The *codeset* argument must be a valid codeset name that can be used for the `iconv_open(3C)` function, or a null pointer. If the *codeset* argument is the null pointer, `bind_textdomain_codeset()` returns the currently selected codeset for the domain with the name *domainname*. It returns a null pointer if a codeset has not yet been selected. The `bind_textdomain_codeset()` function can be used multiple times. If used multiple times with the same *domainname* argument, the later call overrides the settings made by the earlier one. The `bind_textdomain_codeset()` function returns a pointer to a string containing the name of the selected codeset. The string is allocated internally in the function and must not be changed by the user.

RETURN VALUES

The `gettext()`, `dgettext()`, and `dcgettext()` functions return the message string if the search succeeds. Otherwise they return the *msgid* string.

The `ngettext()`, `dngettext()`, and `dcngettext()` functions return the message string if the search succeeds. If the search fails, *msgid1* is returned if *n* == 1. Otherwise *msgid2* is returned.

The individual bytes of the string returned by `gettext()`, `dgettext()`, `dcgettext()`, `ngettext()`, `dngettext()`, or `dcngettext()` can contain any value other than NULL. If *msgid* is a null pointer, the return value is undefined. The string returned must not be modified by the program and can be invalidated by a subsequent call to `bind_textdomain_codeset()` or `setlocale(3C)`. If the *domainname* argument to `dgettext()`, `dcgettext()`, `dngettext()`, or `dcngettext()` is a null pointer, the the domain currently bound by `textdomain()` is used.

The normal return value from `textdomain()` is a pointer to a string containing the current setting of the domain. If *domainname* is a null pointer, `textdomain()` returns a pointer to the string containing the current domain. If `textdomain()` was not previously called and *domainname* is a null string, the name of the default domain is returned. The name of the default domain is `messages`. If `textdomain()` fails, a null pointer is returned.

The return value from `bindtextdomain()` is a null-terminated string containing *dirname* or the directory binding associated with *domainname* if *dirname* is NULL. If no binding is found, the default return value is `/usr/lib/locale`. If *domainname* is a null pointer or an empty string, `bindtextdomain()` takes no action and returns a null pointer. The string returned must not be modified by the caller. If `bindtextdomain()` fails, a null pointer is returned.

dcgettext(3C)

USAGE These functions impose no limit on message length. However, a text *domainname* is limited to TEXTDOMAINMAX (256) bytes.

The `gettext()`, `dgettext()`, `dcgettext()`, `ngettext()`, `dngettext()`, `dcngettext()`, `textdomain()`, and `bindtextdomain()` functions can be used safely in multithreaded applications, as long as `setlocale(3C)` is not being called to change the locale.

The `gettext()`, `dgettext()`, `dcgettext()`, `textdomain()`, and `bindtextdomain()` functions work with both Solaris message catalogues and GNU-compatible message catalogues. The `ngettext()`, `dngettext()`, `dcngettext()`, and `bind_textdomain_codeset()` functions work only with GNU-compatible message catalogues. See `msgfmt(1)` for information about Solaris message catalogues and GNU-compatible message catalogues.

NAME decimal_to_floating, decimal_to_single, decimal_to_double, decimal_to_extended, decimal_to_quadruple – convert decimal record to floating-point value

SYNOPSIS

```
#include <floatingpoint.h>

void decimal_to_single(single *px, decimal_mode *pm,
    decimal_record *pd, fp_exception_field_type *ps);

void decimal_to_double(double *px, decimal_mode *pm,
    decimal_record *pd, fp_exception_field_type *ps);

void decimal_to_extended(extended *px, decimal_mode *pm,
    decimal_record *pd, fp_exception_field_type *ps);

void decimal_to_quadruple(quadruple *px, decimal_mode *pm,
    decimal_record *pd, fp_exception_field_type *ps);
```

DESCRIPTION

The `decimal_to_floating()` functions convert the decimal record at `*pd` into a floating-point value at `*px`, observing the modes specified in `*pm` and setting exceptions in `*ps`. If there are no IEEE exceptions, `*ps` will be zero.

`pd->sign` and `pd->fpclass` are always taken into account. `pd->exponent`, `pd->ds` and `pd->ndigits` are used when `pd->fpclass` is `fp_normal` or `fp_subnormal`. In these cases `pd->ds` must contain one or more ascii digits followed by a NULL and `pd->ndigits` is assumed to be the length of the string `pd->ds`. Notice that for efficiency reasons, the assumption that `pd->ndigits == strlen(pd->ds)` is NEVER verified.

On output, `*px` is set to a correctly rounded approximation to

$$(pd->sign)*(pd->ds)*10^{(pd->exponent)}$$

Thus if `pd->exponent == -2` and `pd->ds == "1234"`, `*px` will get 12.34 rounded to storage precision. `pd->ds` cannot have more than `DECIMAL_STRING_LENGTH-1` significant digits because one character is used to terminate the string with a NULL. If `pd->more != 0` on input then additional nonzero digits follow those in `pd->ds`; `fp_inexact` is set accordingly on output in `*ps`.

`*px` is correctly rounded according to the IEEE rounding modes in `pm->rd`. `*ps` is set to contain `fp_inexact`, `fp_underflow`, or `fp_overflow` if any of these arise.

`pm->df` and `pm->ndigits` are not used.

`strtod(3C)`, `scanf(3C)`, `fscanf(3C)`, and `sscanf(3C)` all use `decimal_to_double()`.

NAME	dbm, dbm _{init} , dbm _{close} , fetch, store, delete, firstkey, nextkey – data base subroutines
SYNOPSIS	<pre> /usr/ucb/cc [flag ...] file ... -ldb_m #include <dbm.h> typedef struct { char *dp_{tr}; int dsize; }datum; int dbm_{init} (file); char *file; int dbm_{close} (); datum fetch (key); datum key; int store (key, dat); datum key, dat; int delete (key); datum key; datum firstkey() datum nextkey (key); datum key; </pre>
DESCRIPTION	<p>The dbm() library has been superseded by ndbm (see ndbm(3C)).</p> <p>These functions maintain key/content pairs in a data base. The functions will handle very large (a billion blocks) databases and will access a keyed item in one or two file system accesses.</p> <p><i>key/dat</i> and their content are described by the datum typedef. A datum specifies a string of <i>dsize</i> bytes pointed to by <i>dptr</i>. Arbitrary binary data, as well as normal ASCII strings, are allowed. The data base is stored in two files. One file is a directory containing a bit map and has <i>.dir</i> as its suffix. The second file contains all data and has <i>.pag</i> as its suffix.</p> <p>Before a database can be accessed, it must be opened by dbm_{init} (). At the time of this call, the files <i>file.dir</i> and <i>file.pag</i> must exist. An empty database is created by creating zero-length <i>.dir</i> and <i>.pag</i> files.</p> <p>A database may be closed by calling dbm_{close} (). You must close a database before opening a new one.</p>

delete(3UCB)

Once open, the data stored under a key is accessed by `fetch()` and data is placed under a key by `store`. A key (and its associated contents) is deleted by `delete()`. A linear pass through all keys in a database may be made, in an (apparently) random order, by use of `firstkey()` and `nextkey()`. `firstkey()` will return the first key in the database. With any key `nextkey()` will return the next key in the database. This code will traverse the data base:

```
for (key = firstkey; key.dptr != NULL; key = nextkey(key))
```

RETURN VALUES All functions that return an `int` indicate errors with negative values. A zero return indicates no error. Routines that return a `datum` indicate errors with a `NULL (0) dptr`.

SEE ALSO `ar(1)`, `cat(1)`, `cp(1)`, `tar(1)`, `ndbm(3C)`

NOTES Use of these interfaces should be restricted to only applications written on BSD platforms. Use of these interfaces with any of the system libraries or in multi-thread applications is unsupported.

The `.pag` file will contain holes so that its apparent size may be larger than its actual content. Older versions of the UNIX operating system may create real file blocks for these holes when touched. These files cannot be copied by normal means (`cp(1)`, `cat(1)`, `tar(1)`, `ar(1)`) without filling in the holes.

`dptr` pointers returned by these subroutines point into static storage that is changed by subsequent calls.

The sum of the sizes of a key/content pair must not exceed the internal block size (currently 1024 bytes). Moreover all key/content pairs that hash together must fit on a single block. `store` will return an error in the event that a disk block fills with inseparable data.

`delete()` does not physically reclaim file space, although it does make it available for reuse.

The order of keys presented by `firstkey()` and `nextkey()` depends on a hashing function, not on anything interesting.

There are no interlocks and no reliable cache flushing; thus concurrent updating and reading is risky.

The database files (`file.dir` and `file.pag`) are binary and are architecture-specific (for example, they depend on the architecture's byte order.) These files are not guaranteed to be portable across architectures.

NAME	gettext, dgettext, dcgettext, ngettext, dngettext, dcngettext, textdomain, bindtextdomain, bind_textdomain_codeset – message handling functions
Solaris and GNU-compatible	<pre>#include <libintl.h> char *gettext(const char *msgid); char *dgettext(const char *domainname, const char *msgid); char *textdomain(const char *domainname); char *bindtextdomain(const char *domainname, const char *dirname); #include <libintl.h> #include <locale.h> char *dcgettext(const char *domainname, const char *msgid, int category);</pre>
GNU-compatible	<pre>#include <libintl.h> char *ngettext(const char *msgid1, const char *msgid2, unsigned long int n); char *dngettext(const char *domainname, const char *msgid1, const char *msgid2, unsigned long int n); char *bind_textdomain_codeset(const char *domainname, const char *codeset); #include <libintl.h> #include <locale.h> char *dcngettext(const char *domainname, const char *msgid1, const char *msgid2, unsigned long int n, int category);</pre>
DESCRIPTION	<p>The <code>gettext()</code>, <code>dgettext()</code>, and <code>dcgettext()</code> functions attempt to retrieve a target string based on the specified <code>msgid</code> argument within the context of a specific domain and the current locale. The length of strings returned by <code>gettext()</code>, <code>dgettext()</code>, and <code>dcgettext()</code> is undetermined until the function is called. The <code>msgid</code> argument is a null-terminated string.</p> <p>The <code>ngettext()</code>, <code>dngettext()</code>, and <code>dcngettext()</code> functions are equivalent to <code>gettext()</code>, <code>dgettext()</code>, and <code>dcgettext()</code>, respectively, except for the handling of plural forms. These functions work only with GNU-compatible message catalogues. The <code>ngettext()</code>, <code>dngettext()</code>, and <code>dcngettext()</code> functions search for the message string using the <code>msgid1</code> argument as the key and the <code>n</code> argument to determine the plural form. If no message catalogues are found, <code>msgid1</code> is returned if <code>n == 1</code>, otherwise <code>msgid2</code> is returned.</p> <p>The <code>NLSPATH</code> environment variable (see <code>environ(5)</code>) is searched first for the location of the <code>LC_MESSAGES</code> catalogue. The setting of the <code>LC_MESSAGES</code> category of the current locale determines the locale used by <code>gettext()</code> and <code>dgettext()</code> for string retrieval. The <code>category</code> argument determines the locale used by <code>dcgettext()</code>. If <code>NLSPATH</code> is not defined and the current locale is "C", <code>gettext()</code>, <code>dgettext()</code>, and</p>

dgettext(3C)

`dcgettext()` simply return the message string that was passed. In a locale other than "C", if `NLSPATH` is not defined or if a message catalogue is not found in any of the components specified by `NLSPATH`, the routines search for the message catalogue using the scheme described in the following paragraph.

The `LANGUAGE` environment variable is examined to determine the GNU-compatible message catalogues to be used. The value of `LANGUAGE` is a list of locale names separated by a colon (':') character. If `LANGUAGE` is defined, each locale name is tried in the specified order and if a GNU-compatible message catalogue is found, the message is returned. If a GNU-compatible message catalogue is found but failed to find a corresponding *msgid*, the *msgid* string is return. If `LANGUAGE` is not defined or if a Solaris message catalogue is found or no GNU-compatible message catalogue is found in processing `LANGUAGE`, the pathname used to locate the message catalogue is *dirname/locale/category/domainname.mo*, where *dirname* is the directory specified by `bindtextdomain()`, *locale* is a locale name, and *category* is either `LC_MESSAGES` if `gettext()`, `dgettext()`, `ngettext()`, or `dcgettext()` is called, or `LC_XXX` where the name is the same as the locale category name specified by the *category* argument to `dcgettext()` or `dcngettext()`.

For `gettext()` and `ngettext()`, the domain used is set by the last valid call to `textdomain()`. If a valid call to `textdomain()` has not been made, the default domain (called `messages`) is used.

For `dgettext()`, `dcgettext()`, `dcngettext()`, and `dcngettext()`, the domain used is specified by the *domainname* argument. The *domainname* argument is equivalent in syntax and meaning to the *domainname* argument to `textdomain()`, except that the selection of the domain is valid only for the duration of the `dgettext()`, `dcgettext()`, `dcngettext()`, or `dcngettext()` function call.

The `textdomain()` function sets or queries the name of the current domain of the active `LC_MESSAGES` locale category. The *domainname* argument is a null-terminated string that can contain only the characters allowed in legal filenames.

The *domainname* argument is the unique name of a domain on the system. If there are multiple versions of the same domain on one system, namespace collisions can be avoided by using `bindtextdomain()`. If `textdomain()` is not called, a default domain is selected. The setting of domain made by the last valid call to `textdomain()` remains valid across subsequent calls to `setlocale(3C)`, and `gettext()`.

The *domainname* argument is applied to the currently active `LC_MESSAGES` locale.

The current setting of the domain can be queried without affecting the current state of the domain by calling `textdomain()` with *domainname* set to the null pointer. Calling `textdomain()` with a *domainname* argument of a null string sets the domain to the default domain (`messages`).

The `bindtextdomain()` function binds the path predicate for a message domain *domainname* to the value contained in *dirname*. If *domainname* is a non-empty string and has not been bound previously, `bindtextdomain()` binds *domainname* with *dirname*.

If *domainname* is a non-empty string and has been bound previously, `bindtextdomain()` replaces the old binding with *dirname*. The *dirname* argument can be an absolute or relative pathname being resolved when `gettext()`, `dgettext()`, or `dcgettext()` are called. If *domainname* is a null pointer or an empty string, `bindtextdomain()` returns NULL. User defined domain names cannot begin with the string `SYS_`. Domain names beginning with this string are reserved for system use.

The `bind_textdomain_codeset()` function can be used to specify the output codeset for message catalogues for domain *domainname*. The *codeset* argument must be a valid codeset name that can be used for the `iconv_open(3C)` function, or a null pointer. If the *codeset* argument is the null pointer, `bind_textdomain_codeset()` returns the currently selected codeset for the domain with the name *domainname*. It returns a null pointer if a codeset has not yet been selected. The `bind_textdomain_codeset()` function can be used multiple times. If used multiple times with the same *domainname* argument, the later call overrides the settings made by the earlier one. The `bind_textdomain_codeset()` function returns a pointer to a string containing the name of the selected codeset. The string is allocated internally in the function and must not be changed by the user.

RETURN VALUES

The `gettext()`, `dgettext()`, and `dcgettext()` functions return the message string if the search succeeds. Otherwise they return the *msgid* string.

The `ngettext()`, `dngettext()`, and `dcngettext()` functions return the message string if the search succeeds. If the search fails, *msgid1* is returned if *n* == 1. Otherwise *msgid2* is returned.

The individual bytes of the string returned by `gettext()`, `dgettext()`, `dcgettext()`, `ngettext()`, `dngettext()`, or `dcngettext()` can contain any value other than NULL. If *msgid* is a null pointer, the return value is undefined. The string returned must not be modified by the program and can be invalidated by a subsequent call to `bind_textdomain_codeset()` or `setlocale(3C)`. If the *domainname* argument to `dgettext()`, `dcgettext()`, `dngettext()`, or `dcngettext()` is a null pointer, the the domain currently bound by `textdomain()` is used.

The normal return value from `textdomain()` is a pointer to a string containing the current setting of the domain. If *domainname* is a null pointer, `textdomain()` returns a pointer to the string containing the current domain. If `textdomain()` was not previously called and *domainname* is a null string, the name of the default domain is returned. The name of the default domain is `messages`. If `textdomain()` fails, a null pointer is returned.

The return value from `bindtextdomain()` is a null-terminated string containing *dirname* or the directory binding associated with *domainname* if *dirname* is NULL. If no binding is found, the default return value is `/usr/lib/locale`. If *domainname* is a null pointer or an empty string, `bindtextdomain()` takes no action and returns a null pointer. The string returned must not be modified by the caller. If `bindtextdomain()` fails, a null pointer is returned.

dgettext(3C)

USAGE These functions impose no limit on message length. However, a text *domainname* is limited to TEXTDOMAINMAX (256) bytes.

The `gettext()`, `dgettext()`, `dcgettext()`, `ngettext()`, `dngettext()`, `dcngettext()`, `textdomain()`, and `bindtextdomain()` functions can be used safely in multithreaded applications, as long as `setlocale(3C)` is not being called to change the locale.

The `gettext()`, `dgettext()`, `dcgettext()`, `textdomain()`, and `bindtextdomain()` functions work with both Solaris message catalogues and GNU-compatible message catalogues. The `ngettext()`, `dngettext()`, `dcngettext()`, and `bind_textdomain_codeset()` functions work only with GNU-compatible message catalogues. See `msgfmt(1)` for information about Solaris message catalogues and GNU-compatible message catalogues.

FILES `/usr/lib/locale`
default path predicate for message domain files

`/usr/lib/locale/locale/LC_MESSAGES/domainname.mo`
system default location for file containing messages for language *locale* and *domainname*

`/usr/lib/locale/locale/LC_XXX/domainname.mo`
system default location for file containing messages for language *locale* and *domainname* for `dcgettext()` calls where `LC_XXX` is `LC_CTYPE`, `LC_NUMERIC`, `LC_TIME`, `LC_COLLATE`, `LC_MONETARY`, or `LC_MESSAGES`

`dirname/locale/LC_MESSAGES/domainname.mo`
location for file containing messages for domain *domainname* and path predicate *dirname* after a successful call to `bindtextdomain()`

`dirname/locale/LC_XXX/domainname.mo`
location for files containing messages for domain *domainname*, language *locale*, and path predicate *dirname* after a successful call to `bindtextdomain()` for `dcgettext()` calls where `LC_XXX` is one of `LC_CTYPE`, `LC_NUMERIC`, `LC_TIME`, `LC_COLLATE`, `LC_MONETARY`, or `LC_MESSAGES`

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE

SEE ALSO `msgfmt(1)`, `xgettext(1)`, `iconv_open(3C)`, `setlocale(3C)`, `attributes(5)`, `environ(5)`

NAME difftime – computes the difference between two calendar times

SYNOPSIS

```
#include <time.h>
double difftime(time_t time1, time_t time0);
```

DESCRIPTION The `difftime()` function computes the difference between two calendar times.

RETURN VALUES The `difftime()` functions returns the difference (*time1-time0*) expressed in seconds as a double.

USAGE The `difftime()` function is provided because there are no general arithmetic properties defined for type `time_t`.

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
MT-Level	MT-Safe

directio(3C)

NAME	directio – provide advice to file system
SYNOPSIS	<pre>#include <sys/types.h> #include <sys/fcntl.h> int directio(int <i>fildev</i>, int <i>advice</i>);</pre>
DESCRIPTION	<p>The <code>directio()</code> function provides advice to the system about the expected behavior of the application when accessing the data in the file associated with the open file descriptor <i>fildev</i>. The system uses this information to help optimize accesses to the file's data. The <code>directio()</code> function has no effect on the semantics of the other operations on the data, though it may affect the performance of other operations.</p> <p>The <i>advice</i> argument is kept per file; the last caller of <code>directio()</code> sets the <i>advice</i> for all applications using the file associated with <i>fildev</i>.</p> <p>Values for <i>advice</i> are defined in <code><sys/fcntl.h></code>.</p> <p>DIRECTIO_OFF Applications get the default system behavior when accessing file data.</p> <p>When an application reads data from a file, the data is first cached in system memory and then copied into the application's buffer (see <code>read(2)</code>). If the system detects that the application is reading sequentially from a file, the system will asynchronously "read ahead" from the file into system memory so the data is immediately available for the next <code>read(2)</code> operation.</p> <p>When an application writes data into a file, the data is first cached in system memory and is written to the device at a later time (see <code>write(2)</code>). When possible, the system increases the performance of <code>write(2)</code> operations by caching the data in memory pages. The data is copied into system memory and the <code>write(2)</code> operation returns immediately to the application. The data is later written asynchronously to the device. When possible, the cached data is "clustered" into large chunks and written to the device in a single write operation.</p> <p>The system behavior for <code>DIRECTIO_OFF</code> can change without notice.</p> <p>DIRECTIO_ON The system behaves as though the application is not going to reuse the file data in the near future. In other words, the file data is not cached in the system's memory pages.</p> <p>When possible, data is read or written directly between the application's memory and the device when the data is accessed with <code>read(2)</code> and <code>write(2)</code> operations. When such transfers are not possible, the system switches back to the default behavior, but just for that operation. In general, the transfer is possible when the</p>

application's buffer is aligned on a two-byte (short) boundary, the offset into the file is on a device sector boundary, and the size of the operation is a multiple of device sectors.

This advisory is ignored while the file associated with *fildev* is mapped (see `mmap(2)`).

The system behavior for `DIRECTIO_ON` can change without notice.

RETURN VALUES Upon successful completion, `directio()` returns 0. Otherwise, it returns -1 and sets `errno` to indicate the error.

ERRORS The `directio()` function will fail if:

<code>EBADF</code>	The <i>fildev</i> argument is not a valid open file descriptor.
<code>ENOTTY</code>	The <i>fildev</i> argument is not associated with a file system that accepts advisory functions.
<code>EINVAL</code>	The value in <i>advise</i> is invalid.

USAGE Small sequential I/O generally performs best with `DIRECTIO_OFF`.

Large sequential I/O generally performs best with `DIRECTIO_ON`, except when a file is sparse or is being extended and is opened with `O_SYNC` or `O_DSYNC` (see `open(2)`).

The `directio()` function is supported for the `ufs` file system type (see `fstyp(1M)`).

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
MT-Level	MT-Safe

SEE ALSO `fstyp(1M)`, `mmap(2)`, `open(2)`, `read(2)`, `write(2)`, `attributes(5)`, `fcntl(3HEAD)`

WARNINGS Switching between `DIRECTIO_OFF` and `DIRECTIO_ON` can slow the system because each switch to `DIRECTIO_ON` might entail flushing the file's data from the system's memory.

dirname(3C)

NAME | dirname – report the parent directory name of a file path name

SYNOPSIS | #include <libgen.h>
char ***dirname** (char **path*);

DESCRIPTION | The `dirname()` function takes a pointer to a character string that contains a pathname, and returns a pointer to a string that is a pathname of the parent directory of that file. Trailing '/' characters in the path are not counted as part of the path.
If *path* does not contain a '/', then `dirname()` returns a pointer to the string ".". If *path* is a null pointer or points to an empty string, `dirname()` returns a pointer to the string ".".

RETURN VALUES | The `dirname()` function returns a pointer to a string that is the parent directory of *path*. If *path* is a null pointer or points to an empty string, a pointer to a string "." is returned.

ERRORS | No errors are defined.

EXAMPLES | **EXAMPLE 1** A sample code using the `dirname()` function.

Input String	Output String
"/usr/lib"	"/usr"
"/usr/"	"/"
"usr"	"/"
"/"	"/"
."	."
.."	.."

The following code fragment reads a path name, changes directory to the parent directory of the named file (see `chdir(2)`), and opens the file.

```
char path[100], *pathcopy;
int fd;
gets (path);
pathcopy = strdup (path);
chdir (dirname (pathcopy) );
free (pathcopy);
fd = open (basename (path), O_RDONLY);
```

USAGE | The `dirname()` function may modify the string pointed to by *path*, and may return a pointer to static storage that may then be overwritten by subsequent calls to `dirname()`.

dirname(3C)

The `dirname()` and `basename(3C)` functions together yield a complete pathname. The expression `dirname(path)` obtains the pathname of the directory where `basename(path)` is found.

When compiling multithreaded applications, the `_REENTRANT` flag must be defined on the compile line. This flag should only be used in multithreaded applications.

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
MT-Level	MT-Safe

SEE ALSO `basename(1)`, `chdir(2)`, `basename(3C)`, `attributes(5)`

div(3C)

NAME	div, ldiv, lldiv – compute the quotient and remainder				
SYNOPSIS	<pre>#include <stdlib.h> div_t div(int numer, int denom); ldiv_t ldiv(long int numer, long int denom); lldiv_t lldiv(long long numer, long long denom);</pre>				
DESCRIPTION	<p>The <code>div()</code> function computes the quotient and remainder of the division of the numerator <i>numer</i> by the denominator <i>denom</i>. It provides a well-defined semantics for the signed integral division and remainder operations, unlike the implementation-defined semantics of the built-in operations. The sign of the resulting quotient is that of the algebraic quotient, and if the division is inexact, the magnitude of the resulting quotient is the largest integer less than the magnitude of the algebraic quotient. If the result cannot be represented, the behavior is undefined; otherwise, <i>quotient * denom + remainder</i> will equal <i>numer</i>.</p> <p>The <code>ldiv()</code> and <code>lldiv()</code> functions are similar to <code>div()</code>, except that the arguments and the members of the returned structure are different. The <code>ldiv()</code> function returns a structure of type <code>ldiv_t</code> and has type <code>long int</code>. The <code>lldiv()</code> function returns a structure of type <code>lldiv_t</code> and has type <code>long long</code>.</p>				
RETURN VALUES	<p>The <code>div()</code> function returns a structure of type <code>div_t</code>, comprising both the quotient and remainder:</p> <pre>int quot; /*quotient*/ int rem; /*remainder*/</pre> <p>The <code>ldiv()</code> function returns a structure of type <code>ldiv_t</code> and <code>lldiv()</code> returns a structure of type <code>lldiv_t</code>, comprising both the quotient and remainder:</p> <pre>long int quot; /*quotient*/ long int rem; /*remainder*/</pre>

NAME	dladdr, dladdr1 – translate address to symbolic information												
SYNOPSIS	<pre>cc [flag ...] file... -ldl [library ...] #include <dlfcn.h> int dladdr(void *address, Dl_info *dlip); int dladdr1(void *address, Dl_info *dlip, void **info, int flags);</pre>												
DESCRIPTION	<p>The <code>dladdr()</code> and <code>dladdr1()</code> functions determine if the specified <i>address</i> is located within one of the mapped objects that make up the current applications address space. An address is deemed to fall within a mapped object when it is between the base address, and the <code>_end</code> address of that object. If a mapped object fits this criteria, the symbol table made available to the runtime linker is searched to locate the nearest symbol to the specified address. The nearest symbol is one that has a value less than or equal to the required address.</p> <p>The <code>Dl_info</code> structure must be preallocated by the user. The structure members are filled in by <code>dladdr()</code> based on the specified <i>address</i>. The <code>Dl_info</code> structure includes the following members:</p> <pre>const char * dli_fname; void * dli_fbase; const char * dli_sname; void * dli_saddr;</pre> <p>Descriptions of these members appear below.</p> <table border="0" style="margin-left: 20px;"> <tr> <td style="padding-right: 20px;"><code>dli_fname</code></td> <td>Contains a pointer to the filename of the containing object.</td> </tr> <tr> <td><code>dli_fbase</code></td> <td>Contains the base address of the containing object.</td> </tr> <tr> <td><code>dli_sname</code></td> <td>Contains a pointer to the symbol name nearest to the specified address. This symbol either has the same address, or is the nearest symbol with a lower address.</td> </tr> <tr> <td><code>dli_saddr</code></td> <td>Contains the actual address of the above symbol.</td> </tr> </table> <p>The <code>dladdr1()</code> function provides for addition information to be returned as specified by the <i>flags</i> argument:</p> <table border="0" style="margin-left: 20px;"> <tr> <td style="padding-right: 20px;"><code>RTLD_DL_SYMENT</code></td> <td>Obtain the ELF symbol table entry for the matched symbol. The <i>info</i> argument points to a symbol pointer as defined in <code><sys/elf.h></code> (<code>Elf32_Sym **info</code> or <code>Elf64_Sym **info</code>).</td> </tr> <tr> <td><code>RTLD_DL_LINKMAP</code></td> <td>Obtain the <code>Link_map</code> for the matched file. The <i>info</i> argument points to a <code>Link_map</code> pointer as defined in <code><sys/link.h></code> (<code>Link_map **info</code>).</td> </tr> </table>	<code>dli_fname</code>	Contains a pointer to the filename of the containing object.	<code>dli_fbase</code>	Contains the base address of the containing object.	<code>dli_sname</code>	Contains a pointer to the symbol name nearest to the specified address. This symbol either has the same address, or is the nearest symbol with a lower address.	<code>dli_saddr</code>	Contains the actual address of the above symbol.	<code>RTLD_DL_SYMENT</code>	Obtain the ELF symbol table entry for the matched symbol. The <i>info</i> argument points to a symbol pointer as defined in <code><sys/elf.h></code> (<code>Elf32_Sym **info</code> or <code>Elf64_Sym **info</code>).	<code>RTLD_DL_LINKMAP</code>	Obtain the <code>Link_map</code> for the matched file. The <i>info</i> argument points to a <code>Link_map</code> pointer as defined in <code><sys/link.h></code> (<code>Link_map **info</code>).
<code>dli_fname</code>	Contains a pointer to the filename of the containing object.												
<code>dli_fbase</code>	Contains the base address of the containing object.												
<code>dli_sname</code>	Contains a pointer to the symbol name nearest to the specified address. This symbol either has the same address, or is the nearest symbol with a lower address.												
<code>dli_saddr</code>	Contains the actual address of the above symbol.												
<code>RTLD_DL_SYMENT</code>	Obtain the ELF symbol table entry for the matched symbol. The <i>info</i> argument points to a symbol pointer as defined in <code><sys/elf.h></code> (<code>Elf32_Sym **info</code> or <code>Elf64_Sym **info</code>).												
<code>RTLD_DL_LINKMAP</code>	Obtain the <code>Link_map</code> for the matched file. The <i>info</i> argument points to a <code>Link_map</code> pointer as defined in <code><sys/link.h></code> (<code>Link_map **info</code>).												
RETURN VALUES	If the specified <i>address</i> cannot be matched to a mapped object, a 0 is returned. Otherwise, a non-zero return is made and the associated <code>Dl_info</code> elements are filled.												

dladdr1(3DL)

USAGE The `dladdr()` and `dladdr1()` functions are one of a family of functions that give the user direct access to the dynamic linking facilities (see *Linker and Libraries Guide*) and are available to dynamically-linked processes only.

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
MT-Level	MT-Safe

SEE ALSO `ld(1)`, `dlclose(3DL)`, `dldump(3DL)`, `dlerror(3DL)`, `dlopen(3DL)`, `dlsym(3DL)`, `attributes(5)`

Linker and Libraries Guide

NOTES The `Dl_info` pointer elements point to addresses within the mapped objects. These may become invalid if objects are removed prior to these elements being used (see `dlclose()`).

If no symbol is found to describe the specified address, both the `dli_sname` and `dli_saddr` members are set to 0.

NAME	dladdr, dladdr1 – translate address to symbolic information												
SYNOPSIS	<pre>cc [flag ...] file... -ldl [library ...] #include <dlfcn.h> int dladdr(void *address, Dl_info *dlip); int dladdr1(void *address, Dl_info *dlip, void **info, int flags);</pre>												
DESCRIPTION	<p>The <code>dladdr()</code> and <code>dladdr1()</code> functions determine if the specified <i>address</i> is located within one of the mapped objects that make up the current applications address space. An address is deemed to fall within a mapped object when it is between the base address, and the <code>_end</code> address of that object. If a mapped object fits this criteria, the symbol table made available to the runtime linker is searched to locate the nearest symbol to the specified address. The nearest symbol is one that has a value less than or equal to the required address.</p> <p>The <code>Dl_info</code> structure must be preallocated by the user. The structure members are filled in by <code>dladdr()</code> based on the specified <i>address</i>. The <code>Dl_info</code> structure includes the following members:</p> <pre>const char * dli_fname; void * dli_fbase; const char * dli_sname; void * dli_saddr;</pre> <p>Descriptions of these members appear below.</p> <table border="0" style="margin-left: 20px;"> <tr> <td style="padding-right: 20px;"><code>dli_fname</code></td> <td>Contains a pointer to the filename of the containing object.</td> </tr> <tr> <td><code>dli_fbase</code></td> <td>Contains the base address of the containing object.</td> </tr> <tr> <td><code>dli_sname</code></td> <td>Contains a pointer to the symbol name nearest to the specified address. <code>dli_fname</code>	Contains a pointer to the filename of the containing object.												
<code>dli_fbase</code>	Contains the base address of the containing object.												
<code>dli_sname</code>	Contains a pointer to the symbol name nearest to the specified address. This symbol either has the same address, or is the nearest symbol with a lower address.												
<code>dli_saddr</code>	Contains the actual address of the above symbol.												
<code>RTLD_DL_SYMENT</code>	Obtain the ELF symbol table entry for the matched symbol. The <i>info</i> argument points to a symbol pointer as defined in <code><sys/elf.h></code> (<code>Elf32_Sym **info</code> or <code>Elf64_Sym **info</code>).												
<code>RTLD_DL_LINKMAP</code>	Obtain the <code>Link_map</code> for the matched file. The <i>info</i> argument points to a <code>Link_map</code> pointer as defined in <code><sys/link.h></code> (<code>Link_map **info</code>).												
RETURN VALUES	If the specified <i>address</i> cannot be matched to a mapped object, a 0 is returned. Otherwise, a non-zero return is made and the associated <code>Dl_info</code> elements are filled.												

dladdr(3DL)

USAGE The `dladdr()` and `dladdr1()` functions are one of a family of functions that give the user direct access to the dynamic linking facilities (see *Linker and Libraries Guide*) and are available to dynamically-linked processes only.

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
MT-Level	MT-Safe

SEE ALSO `ld(1)`, `dlclose(3DL)`, `dldump(3DL)`, `dlerror(3DL)`, `dlopen(3DL)`, `dlsym(3DL)`, `attributes(5)`

Linker and Libraries Guide

NOTES The `Dl_info` pointer elements point to addresses within the mapped objects. These may become invalid if objects are removed prior to these elements being used (see `dlclose()`).

If no symbol is found to describe the specified address, both the `dli_sname` and `dli_saddr` members are set to 0.

NAME	dldclose – close a shared object				
SYNOPSIS	<pre>cc [flag ...] file ... -ldl [library ...] #include <dldfcn.h> int dldclose(void *handle);</pre>				
DESCRIPTION	The <code>dldclose()</code> function disassociates a shared object previously opened by <code>dldlopen()</code> from the current process. Once an object has been closed using <code>dldclose()</code> , its symbols are no longer available to <code>dldsym()</code> . All objects loaded automatically as a result of invoking <code>dldlopen()</code> on the referenced object are also closed. <i>handle</i> is the value returned by a previous invocation of <code>dldlopen()</code> .				
RETURN VALUES	If the referenced object was successfully closed, <code>dldclose()</code> returns 0. If the object could not be closed, or if <i>handle</i> does not refer to an open object, <code>dldclose()</code> returns a non-zero value. More detailed diagnostic information will be available through <code>dlderror()</code> .				
USAGE	The <code>dldclose()</code> function is one of a family of functions that give the user direct access to the dynamic linking facilities (see <i>Linker and Libraries Guide</i>) and are available to dynamically-linked processes only.				
ATTRIBUTES	See <code>attributes(5)</code> for descriptions of the following attributes:				
	<table border="1" style="width: 100%; border-collapse: collapse;"> <thead> <tr> <th style="text-align: center;">ATTRIBUTE TYPE</th> <th style="text-align: center;">ATTRIBUTE VALUE</th> </tr> </thead> <tbody> <tr> <td style="text-align: center;">MT-Level</td> <td style="text-align: center;">MT-Safe</td> </tr> </tbody> </table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	MT-Level	MT-Safe
ATTRIBUTE TYPE	ATTRIBUTE VALUE				
MT-Level	MT-Safe				
SEE ALSO	<code>ld(1)</code> , <code>dldaddr(3DL)</code> , <code>dlddump(3DL)</code> , <code>dlderror(3DL)</code> , <code>dldlopen(3DL)</code> , <code>dldsym(3DL)</code> , <code>attributes(5)</code> <i>Linker and Libraries Guide</i>				
NOTES	<p>A successful invocation of <code>dldclose()</code> does not guarantee that the objects associated with <i>handle</i> will actually be removed from the address space of the process. Objects loaded by one invocation of <code>dldlopen()</code> may also be loaded by another invocation of <code>dldlopen()</code>. The same object may also be opened multiple times. An object will not be removed from the address space until all references to that object through an explicit <code>dldlopen()</code> invocation have been closed and all other objects implicitly referencing that object have also been closed.</p> <p>Once an object has been closed by <code>dldclose()</code>, referencing symbols contained in that object can cause undefined behavior.</p>				

dldump(3DL)

NAME	dldump – create a new file from a dynamic object component of the calling process		
SYNOPSIS	<pre>cc [flag ...] file ... -ldl [library ...] #include <dlfcn.h> int dldump(const char * ipath, const char * opath, int flags);</pre>		
DESCRIPTION	<p>The <code>dldump()</code> function creates a new dynamic object <i>opath</i> from an existing dynamic object <i>ipath</i> that is bound to the current process. An <i>ipath</i> value of 0 is interpreted as the dynamic object that started the process. The new object is constructed from the existing objects' disc file. Relocations can be applied to the new object to pre-bind it to other dynamic objects, or fix the object to a specific memory location. In addition, data elements within the new object may be obtained from the objects' memory image as it exists in the calling process.</p> <p>These techniques allow the new object to be executed with a lower startup cost, either because there are less relocations required to load the object, or because of a reduction in the data processing requirements of the object. However, it is important to note that limitations may exist in using these techniques. Applying relocations to the new dynamic object <i>opath</i> may restrict its flexibility within a dynamically changing environment. In addition, limitations regarding data usage may make dumping a memory image impractical (see EXAMPLES).</p> <p>The runtime linker verifies that the dynamic object <i>ipath</i> is mapped as part of the current process. Thus, the object must either be the dynamic object that started the process (see <code>exec(2)</code>), one of the process's dependencies, or an object that has been preloaded (see <code>ld.so.1(1)</code>).</p> <p>As part of the runtime processing of a dynamic object, <i>relocation</i> records within the object are interpreted and applied to offsets within the object. These offsets are said to be <i>relocated</i>. Relocations can be categorized into two basic types: <i>non-symbolic</i> and <i>symbolic</i>.</p> <p>The <i>non-symbolic</i> relocation is a simple <i>relative</i> relocation that requires the base address at which the object is mapped to perform the relocation. The <i>symbolic</i> relocation requires the address of an associated symbol, and results in a <i>binding</i> to the dynamic object that defines this symbol. This symbol definition may originate from any of the dynamic objects that make up the process, that is, the object that started the process, one of the process's dependencies, an object that has been preloaded, or the dynamic object being relocated.</p> <p>The <i>flags</i> parameter controls the relocation processing and other attributes of producing the new dynamic object <i>opath</i>. Without any <i>flags</i>, the new object is constructed solely from the contents of the <i>ipath</i> disc file without any relocations applied.</p> <p>Various relocation flags may be <i>or'ed</i> into the <i>flags</i> parameter to affect the relocations applied to the new object. <i>Non-symbolic</i> relocations can be applied using the following:</p> <table><tr><td>RTLD_REL_RELATIVE</td><td>Relocation records from the object <i>ipath</i>, that define <i>relative</i> relocations, are applied to the object <i>opath</i>.</td></tr></table>	RTLD_REL_RELATIVE	Relocation records from the object <i>ipath</i> , that define <i>relative</i> relocations, are applied to the object <i>opath</i> .
RTLD_REL_RELATIVE	Relocation records from the object <i>ipath</i> , that define <i>relative</i> relocations, are applied to the object <i>opath</i> .		

A variety of *symbolic* relocations can be applied using the following flags (each of these flags also implies `RTLTD_REL_RELATIVE` is in effect):

<code>RTLTD_REL_EXEC</code>	Symbolic relocations that result in binding <i>ipath</i> to the dynamic object that started the process (commonly a dynamic executable) are applied to the object <i>opath</i> .
<code>RTLTD_REL_DEPENDS</code>	Symbolic relocations that result in binding <i>ipath</i> to any of the dynamic dependencies of the process are applied to the object <i>opath</i> .
<code>RTLTD_REL_PRELOAD</code>	Symbolic relocations that result in binding <i>ipath</i> to any objects preloaded with the process are applied to the object <i>opath</i> . (See <code>LD_PRELOAD</code> in <code>ld.so.1(1)</code>).
<code>RTLTD_REL_SELF</code>	Symbolic relocations that result in binding <i>ipath</i> to itself are applied to the object <i>opath</i> .
<code>RTLTD_REL_WEAK</code>	Weak relocations that remain unresolved are applied to the object <i>opath</i> as 0.
<code>RTLTD_REL_ALL</code>	All relocation records defined in the object <i>ipath</i> are applied to the new object <i>opath</i> (this is basically a concatenation of all the above relocation flags).

Note that for dynamic executables, `RTLTD_REL_RELATIVE`, `RTLTD_REL_EXEC`, and `RTLTD_REL_SELF` have no effect (see `EXAMPLES`).

If relocations, knowledgeable of the base address of the mapped object, are applied to the new object *opath*, then the new object will become fixed to the location that the *ipath* image is mapped within the current process.

Any relocations applied to the new object *opath* will have the original relocation record removed so that the relocation will not be applied more than once. Otherwise, the new object *opath* will retain the relocation records as they exist in the *ipath* disc file.

The following additional attributes for creating the new dynamic object *opath* can be specified using the *flags* parameter:

<code>RTLTD_MEMORY</code>	The new object <i>opath</i> is constructed from the current memory contents of the <i>ipath</i> image as it exists in the calling process. This option allows data modified by the calling process to be captured in the new object. Note that not all data modifications may be applicable for capture; significant restrictions exist in using this technique (see <code>EXAMPLES</code>). By default, when processing a dynamic executable, any allocated memory that follows the end of the data segment is captured in the new object (see <code>malloc(3C)</code> and <code>brk(2)</code>). This data, which represents the process heap, is saved as a new <code>.SUNW_heap</code> section in the object
---------------------------	---

dldump(3DL)

	<p><i>opath</i>. The objects' program headers and symbol entries, such as <code>_end</code>, are adjusted accordingly. See also <code>RTLD_NOHEAP</code>. When using this attribute, any relocations that have been applied to the <i>ipath</i> memory image that do not fall into one of the requested relocation categories are undone, that is, the relocated element is returned to the value as it existed in the <i>ipath</i> disc file.</p>
<code>RTLD_STRIP</code>	<p>Only collect allocatable sections within the object <i>opath</i>; sections that are not part of the dynamic objects' memory image are removed. This parameter reduces the size of the <i>opath</i> disc file and is comparable to having run the new object through <code>strip(1)</code>.</p>
<code>RTLD_NOHEAP</code>	<p>Do not save any heap to the new object. This option is only meaningful when processing a dynamic executable with the <code>RTLD_MEMORY</code> attribute and allows for reducing the size of the <i>opath</i> disc file. In this case, the executable must confine its data initialization to data elements within its data segment and must not use any allocated data elements that comprise the heap.</p>

It should be emphasized that an object created by `dldump()` is simply an updated ELF object file. No additional state regarding the process at the time `dldump()` is called is maintained in the new object. `dldump()` does not provide a panacea for checkpoint/resume. A new dynamic executable, for example, will not start where the original executable called `dldump()`; it will gain control at the executable's normal entry point (see `EXAMPLES`).

RETURN VALUES

On successful creation of the new object, `dldump()` returns 0. Otherwise, a non-zero value is returned and more detailed diagnostic information is available through `dlerror()`.

EXAMPLES

EXAMPLE 1 Sample code using `dldump()`.

The following code fragment, which can be part of a dynamic executable `a.out`, can be used to create a new shared object from one of the dynamic executables' dependencies `libfoo.so.1`:

```
const char *   ipath = "libfoo.so.1";
const char *   opath = "./tmp/libfoo.so.1";
...
if (dldump(ipath, opath, RTLD_REL_RELATIVE) != 0)
    (void) printf("dldump failed: %s\n", dlerror());
```

The new shared object *opath* is fixed to the address of the mapped *ipath* bound to the dynamic executable `a.out`. All relative relocations are applied to this new shared object, which will reduce its relocation overhead when it is used as part of another process.

EXAMPLE 1 Sample code using `dldump()`. (Continued)

By performing only relative relocations, any symbolic relocation records remain defined within the new object, and thus the dynamic binding to external symbols will be preserved when the new object is used.

Use of the other relocation flags can fix specific relocations in the new object and thus can reduce even more the runtime relocation startup cost of the new object. However, this will also restrict the flexibility of using the new object within a dynamically changing environment, as it will bind the new object to some or all of the dynamic objects presently mapped as part of the process.

For example, the use of `RTLD_REL_SELF` will cause any references to symbols from *ipath* to be bound to definitions within itself if no other preceding object defined the same symbol. In other words, a call to *foo()* within *ipath* will bind to the definition *foo* within the same object. Therefore, *opath* will have one less binding that must be computed at runtime. This reduces the startup cost of using *opath* by other applications; however, interposition of the symbol *foo* will no longer be possible.

Using a dumped shared object with applied relocations as an applications dependency normally requires that the application have the same dependencies as the application that produced the dumped image. Dumping shared objects, and the various flags associated with relocation processing, have some specialized uses. However, the technique is intended as a building block for future technology.

The following code fragment, which is part of the dynamic executable *a.out*, can be used to create a new version of the dynamic executable:

```
static char *    dumped = 0;
const char *    opath = "./a.out.new";
...
if (dumped == 0) {
    char        buffer[100];
    int         size;
    time_t      seconds;
    ...
    /* Perform data initialization */
    seconds = time((time_t *)0);
    size = cftime(buffer, (char *)0, &seconds);
    if ((dumped = (char *)malloc(size + 1)) == 0) {
        (void) printf("malloc failed: %s\n", strerror(errno));
        return (1);
    }
    (void) strcpy(dumped, buffer);
    ...
    /*
     * Tear down any undesirable data initializations and
     * dump the dynamic executables memory image.
     */
    _exithandle( );
    _exit(dldump(0, opath, RTLD_MEMORY));
}
```

dldump(3DL)

EXAMPLE 1 Sample code using `dldump()`. (Continued)

```
(void) printf("Dumped: %s\n", dumped);
```

Any modifications made to the dynamic executable, up to the point the `dldump()` call is made, are saved in the new object `a.out.new`. This mechanism allows the executable to update parts of its data segment and heap prior to creating the new object. In this case, the date the executable is dumped is saved in the new object. The new object can then be executed without having to carry out the same (presumably expensive) initialization.

For greatest flexibility, this example does not save *any* relocated information. The elements of the dynamic executable *ipath* that have been modified by relocations at process startup, that is, references to external functions, are returned to the values of these elements as they existed in the *ipath* disc file. This preservation of relocation records allows the new dynamic executable to be flexible, and correctly bind and initialize to its dependencies when executed on the same or newer upgrades of the OS.

Fixing relocations by applying some of the relocation flags would bind the new object to the dependencies presently mapped as part of the process calling `dldump()`. It may also remove necessary copy relocation processing required for the correct initialization of its shared object dependencies. Therefore, if the new dynamic executables' dependencies have no specialized initialization requirements, the executable may still only interact correctly with the dependencies to which it binds if they were mapped to the same locations as they were when `dldump()` was called.

Note that for dynamic executables, `RTLD_REL_RELATIVE`, `RTLD_REL_EXEC`, and `RTLD_REL_SELF` have no effect, as relocations within the dynamic executable will have been fixed when it was created by `ld(1)`.

When `RTLD_MEMORY` is used, care should be taken to insure that dumped data sections that reference external objects are not reused without appropriate re-initialization. For example, if a data item contains a file descriptor, a variable returned from a shared object, or some other external data, and this data item has been initialized prior to the `dldump()` call, its value will have no meaning in the new dumped image.

When `RTLD_MEMORY` is used, any modification to a data item that is initialized via a relocation whose relocation record will be retained in the new image will effectively be lost or invalidated within the new image. For example, if a pointer to an external object is incremented prior to the `dldump()` call, this data item will be reset to its disc file contents so that it can be relocated when the new image is used; hence, the previous increment is lost.

Non-idempotent data initializations may prevent the use of `RTLD_MEMORY`. For example, the addition of elements to a linked-list via `init` sections can result in the linked-list data being captured in the new image. Running this new image may result in `init` sections continuing to add new elements to the list without the prerequisite

EXAMPLE 1 Sample code using `dldump()`. (Continued)

initialization of the list head. It is recommended that `_exithandle(3C)` be called before `dldump()` to tear down any data initializations established via initialization code. Note that this may invalidate the calling image; thus, following the call to `dldump()`, only a call to `_exit(2)` should be made.

USAGE The `dldump()` function is one of a family of functions that give the user direct access to the dynamic linking facilities (see *Linker and Libraries Guide*) and are available to dynamically-linked processes only.

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu
MT-Level	MT-Safe

SEE ALSO `ld(1)`, `ld.so.1(1)`, `strip(1)`, `_exit(2)`, `brk(2)`, `exec(2)`, `_exithandle(3C)`, `dladdr(3DL)`, `dlclose(3DL)`, `dLError(3DL)`, `dlopen(3DL)`, `dlsym(3DL)`, `end(3C)`, `malloc(3C)`, `attributes(5)`

Linker and Libraries Guide

NOTES These functions are available to dynamically-linked processes only.

Any NOBITS sections within the *ipath* are expanded to PROGBITS sections within the *opath*. NOBITS sections occupy no space within an ELF file image. They declare memory that must be created and zero-filled when the object is mapped into the runtime environment. *.bss* is a typical example of this section type. PROGBITS sections, on the other hand, hold information defined by the object within the ELF file image. This section conversion reduces the runtime initialization cost of the new dumped object but increases the objects' disc space requirement.

When a shared object is dumped, and relocations are applied which are knowledgeable of the base address of the mapped object, the new object is fixed to this new base address and thus its ELF type is reclassified to be a dynamic executable. This new object can be processed by the runtime linker, but is not valid as input to the link-editor.

If relocations are applied to the new object, any remaining relocation records will be reorganized for better locality of reference. The relocation sections are renamed to *.SUNW_reloc* and the association to the section they were to relocate is lost. Only the offset of the relocation record itself is meaningful. This change does not make the new object invalid to either the runtime linker or link-editor, but may reduce the objects analysis with some ELF readers.

dlerror(3DL)

- NAME** dlerror – get diagnostic information
- SYNOPSIS**

```
cc [ flag ... ] file ... -ldl [ library ... ]
#include <dlfcn.h>

char *dlerror(void);
```
- DESCRIPTION** The `dlerror()` function returns a null-terminated character string (with no trailing newline) that describes the last error that occurred during dynamic linking processing. If no dynamic linking errors have occurred since the last invocation of `dlerror()`, `dlerror()` returns `NULL`. Thus, invoking `dlerror()` a second time, immediately following a prior invocation, will result in `NULL` being returned.
- USAGE** The `dlerror()` function is one of a family of functions that give the user direct access to the dynamic linking facilities (see *Linker and Libraries Guide*) and are available to dynamically-linked processes only.
- ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
MT-Level	MT-Safe

- SEE ALSO** `ld(1)`, `dladdr(3DL)`, `dlclose(3DL)`, `dlDump(3DL)`, `dlopen(3DL)`, `dlSym(3DL)`, `attributes(5)`

Linker and Libraries Guide

- NOTES** The messages returned by `dlerror()` may reside in a static buffer that is overwritten on each call to `dlerror()`. Application code should not write to this buffer. Programs wishing to preserve an error message should make their own copies of that message.

NAME	dldlfo – dynamic load information										
SYNOPSIS	<pre>cc [flag ...] file ... -ldl [library ...] #include <dldfcn.h> #include <link.h> #include <limits.h> int dldlfo(void *handle, int request, void *p);</pre>										
DESCRIPTION	<p>The dldlfo() function extracts information about a dynamically-loaded object. This function is loosely modeled after the ioctl() function. The request argument and a third argument of varying type are passed to dldlfo(). The action taken by dldlfo() depends on the value of the request provided.</p> <p>A handle argument, required for all requests except RTLD_DI_CONFIGADDR, is either the value returned from a dlopen() or dlmopen() call, or the special handle RTLD_SELF. If handle is the value returned from a dlopen() or dlmopen() call, the information returned by the dldlfo() call pertains to the specified object. If handle is the special handle RTLD_SELF, the information returned by the dldlfo() call pertains to the caller itself.</p> <p>The following are possible values for request to be passed into dldlfo():</p> <table border="0" style="width: 100%;"> <tr> <td style="vertical-align: top; padding-right: 20px;">RTLD_DI_CONFIGADDR</td> <td> <p>Obtain the configuration file name and the address at which it has been loaded. The p argument is a Dl_info pointer (Dl_info *p). The following elements from this structure are initialized:</p> <table border="0" style="width: 100%;"> <tr> <td style="padding-right: 20px;">dli_fname</td> <td>The full name of the configuration file.</td> </tr> <tr> <td style="padding-right: 20px;">dli_fbase</td> <td>The base address of the configuration file loaded into memory.</td> </tr> </table> </td> </tr> <tr> <td style="vertical-align: top; padding-right: 20px;">RTLD_DI_LINKMAP</td> <td> <p>Obtain the Link_map for the handle specified. The p argument points to a Link_map pointer (Link_map **p). The actual storage for the Link_map structure is maintained by ld.so.1.</p> <p>The Link_map structure includes the following members:</p> <pre>unsigned long l_addr; /* base address */ char *l_name; /* object name */ Elf32_Dyn *l_ld; /* .dynamic section */ Link_map *l_next; /* next link object */ Link_map *l_prev; /* previous link object */ char *l_refname; /* filter reference name */</pre> <table border="0" style="width: 100%;"> <tr> <td style="padding-right: 20px;">l_addr</td> <td>The base address of the object loaded into memory.</td> </tr> </table> </td> </tr> </table>	RTLD_DI_CONFIGADDR	<p>Obtain the configuration file name and the address at which it has been loaded. The p argument is a Dl_info pointer (Dl_info *p). The following elements from this structure are initialized:</p> <table border="0" style="width: 100%;"> <tr> <td style="padding-right: 20px;">dli_fname</td> <td>The full name of the configuration file.</td> </tr> <tr> <td style="padding-right: 20px;">dli_fbase</td> <td>The base address of the configuration file loaded into memory.</td> </tr> </table>	dli_fname	The full name of the configuration file.	dli_fbase	The base address of the configuration file loaded into memory.	RTLD_DI_LINKMAP	<p>Obtain the Link_map for the handle specified. The p argument points to a Link_map pointer (Link_map **p). The actual storage for the Link_map structure is maintained by ld.so.1.</p> <p>The Link_map structure includes the following members:</p> <pre>unsigned long l_addr; /* base address */ char *l_name; /* object name */ Elf32_Dyn *l_ld; /* .dynamic section */ Link_map *l_next; /* next link object */ Link_map *l_prev; /* previous link object */ char *l_refname; /* filter reference name */</pre> <table border="0" style="width: 100%;"> <tr> <td style="padding-right: 20px;">l_addr</td> <td>The base address of the object loaded into memory.</td> </tr> </table>	l_addr	The base address of the object loaded into memory.
RTLD_DI_CONFIGADDR	<p>Obtain the configuration file name and the address at which it has been loaded. The p argument is a Dl_info pointer (Dl_info *p). The following elements from this structure are initialized:</p> <table border="0" style="width: 100%;"> <tr> <td style="padding-right: 20px;">dli_fname</td> <td>The full name of the configuration file.</td> </tr> <tr> <td style="padding-right: 20px;">dli_fbase</td> <td>The base address of the configuration file loaded into memory.</td> </tr> </table>	dli_fname	The full name of the configuration file.	dli_fbase	The base address of the configuration file loaded into memory.						
dli_fname	The full name of the configuration file.										
dli_fbase	The base address of the configuration file loaded into memory.										
RTLD_DI_LINKMAP	<p>Obtain the Link_map for the handle specified. The p argument points to a Link_map pointer (Link_map **p). The actual storage for the Link_map structure is maintained by ld.so.1.</p> <p>The Link_map structure includes the following members:</p> <pre>unsigned long l_addr; /* base address */ char *l_name; /* object name */ Elf32_Dyn *l_ld; /* .dynamic section */ Link_map *l_next; /* next link object */ Link_map *l_prev; /* previous link object */ char *l_refname; /* filter reference name */</pre> <table border="0" style="width: 100%;"> <tr> <td style="padding-right: 20px;">l_addr</td> <td>The base address of the object loaded into memory.</td> </tr> </table>	l_addr	The base address of the object loaded into memory.								
l_addr	The base address of the object loaded into memory.										

dldlfo(3DL)

	<code>l_name</code>	The full name of the loaded object. This is the filename of the object as referenced by <code>ld.so.1</code> .
	<code>l_ld</code>	Points to the <code>SHT_DYNAMIC</code> structure.
	<code>l_next</code>	The next <code>Link_map</code> on the link-map list, other objects on the same link-map list as the current object may be examined by following the and <code>l_prev</code> fields.
	<code>l_prev</code>	The previous <code>Link_map</code> on the link-map list.
	<code>l_refname</code>	If the object referenced is a <i>filter</i> this field points to the name of the object being filtered. If the object is not a <i>filter</i> , this field will be 0. See <i>Linker and Libraries Guide</i> .
<code>RTLD_DI_LMID</code>		Obtain the ID for the link-map list upon which the <i>handle</i> is loaded. The <i>p</i> argument is a <code>Lmid_t</code> pointer (<code>Lmid_t *p</code>).
<code>RTLD_DI_SERINFO</code>		Obtain the library search paths for the <i>handle</i> specified. The <i>p</i> argument is a <code>Dl_serinfo</code> pointer (<code>Dl_serinfo *p</code>). A user must first initialize the <code>Dl_serinfo</code> structure with a <code>RTLD_DI_SERINFO</code> request. See <code>EXAMPLES</code> . The returned <code>Dl_serinfo</code> structure contains <code>dls_cnt</code> <code>Dl_serpath</code> entries. Each entry's <code>dlp_name</code> field points to the search path. The corresponding <code>dlp_info</code> field contains one of more flags indicating the origin of the path (see the <code>LA_SER_*</code> flags defined in <code><link.h></code>).
<code>RTLD_DI_SERINFO</code>		Initialize a <code>Dl_serinfo</code> structure for use in a <code>RTLD_DI_SERINFO</code> request. Both the <code>dls_cnt</code> and <code>dls_size</code> fields are returned to indicate the number of search paths applicable to the <i>handle</i> , and the total size of a <code>Dl_serinfo</code> buffer required to hold <code>dls_cnt</code> <code>Dl_serpath</code> entries and the associated search path strings.

To obtain the complete path information, a new `Dl_serinfo` buffer of size `dls_size` should be allocated, initialized with the `dls_cnt` and `dls_size` entries, and passed to a `RTLD_DI_SERINFO` request. See `EXAMPLES`.

`RTLD_DI_ORIGIN` Obtain the origin of the dynamic object associated with the *handle*. The *p* argument is a char pointer (char **p*). The `dirname(3C)` of the associated object's `realpath(3C)`, which can be no bigger than `PATH_MAX`, is copied to the pointer *p*.

RETURN VALUES If the *request* is invalid, the parameter *p* is null, *handle* does not refer to a valid object opened by `dlopen()` or is not the special handle `RTLD_SELF`, or the `Dl_serinfo` structure is uninitialized for a `RTLD_DI_SERINFO` request, then `dldlfo()` returns `-1`. More detailed diagnostic information is available through `dldlerror(3DL)`.

EXAMPLES **EXAMPLE 1** Using `dldlfo()` to obtain the library search paths

The following example shows how a dynamic object can inspect the library search paths that would be used to locate a simple filename with `dlopen()`. For simplicity, error checking has been omitted.

```
Dl_serinfo    _info, *info = &_info;
Dl_serpath    *path;
uint_t        cnt;

/* determine search path count and required buffer size */
dldlfo(RTLD_SELF, RTLD_DI_SERINFO, (void *)info);

/* allocate new buffer and initialize */
info = malloc(_info.dls_size);
info->dls_size = _info.dls_size;
info->dls_cnt = _info.dls_cnt;

/* obtain search path information */
dldlfo(RTLD_SELF, RTLD_DI_SERINFO, (void *)info);

path = &info->dls_serpath[0];

for (cnt = 1; cnt <= info->dls_cnt; cnt++, path++) {
    (void) printf("%2d: %s\n", cnt, path->dls_name);
}
```

USAGE The `dldlfo()` function is one of a family of functions that give the user direct access to the dynamic linking facilities (see *Linker and Libraries Guide*) and are available to dynamically-linked processes only.

dlinfo(3DL)

Linker and Libraries Guide

NAME	dlopen, dlmopen – gain access to an executable object file
SYNOPSIS	<pre>cc [flag...] file... -ldl [library...] #include <dlfcn.h> #include <link.h> void * dlopen(const char *pathname, int mode); void * dlmopen(Lmid_t lmid, const char *pathname, int mode);</pre>
DESCRIPTION	<p>The <code>dlopen()</code> function makes an executable object file available to a running process. It returns to the process a <i>handle</i> which the process may use on subsequent calls to <code>dlsym()</code> and <code>dlclose()</code>. The value of this <i>handle</i> should not be interpreted in any way by the process. The <i>pathname</i> argument is the path name of the object to be opened. A path name containing an embedded <code>'/'</code> is interpreted as an absolute path or relative to the current directory; otherwise, the set of search paths currently in effect by the runtime linker will be used to locate the specified file. See NOTES below.</p> <p>Any dependencies recorded within <i>pathname</i> are also loaded as part of the <code>dlopen()</code>. These dependencies are searched, in the order they are loaded, to locate any additional dependencies. This process will continue until all the dependencies of <i>pathname</i> are loaded. This dependency tree is referred to as a <i>group</i>.</p> <p>If the value of <i>pathname</i> is 0, <code>dlopen()</code> provides a <i>handle</i> on a global symbol object. This object provides access to the symbols from an ordered set of objects consisting of the original program image file, together with any dependencies loaded at program startup, and any objects that were loaded using <code>dlopen()</code> together with the <code>RTLD_GLOBAL</code> flag. As the latter set of objects can change during process execution, the set identified by <i>handle</i> can also change dynamically.</p> <p>The <code>dlmopen()</code> function is identical to the <code>dlopen()</code> routine, except that an identifying link-map id (<i>lmid</i>) is passed into it. This link-map id informs the dynamic linking facilities upon which link-map list to load the object. See <i>Linker and Libraries Guide</i>.</p> <p>The <i>mode</i> argument describes how <code>dlopen()</code> will operate upon <i>pathname</i> with respect to the processing of reference relocations and the scope of visibility of the symbols provided by <i>pathname</i> and its dependencies.</p> <p>When an object is brought into the address space of a process, it can contain references to symbols whose addresses are not known until the object is loaded. These references must be relocated before the symbols can be accessed and can be categorized as either <i>immediate</i> or <i>lazy</i> references. <i>immediate</i> references are typically to data items used by the object code, pointers to functions, and even calls to functions made from position <i>dependent</i> shared objects. <i>lazy</i> references are typically calls to global functions made from a position <i>independent</i> shared objects. For more information on these types of reference see <i>Linker and Libraries Guide</i>. The <i>mode</i> argument governs when these references take place and can have the following values:</p> <p><code>RTLD_LAZY</code> Only <i>immediate</i> symbol references are relocated when the object is first loaded. <i>lazy</i> references are not relocated until a given function</p>

dlopen(3DL)

	is invoked for the first time. This <i>mode</i> should improve performance, since a process cannot require all lazy references in any given object. This behavior mimics the normal loading of dependencies during process initialization.
RTLD_NOW	All necessary relocations are performed when the object is first loaded. This may waste some processing, if relocations are performed for <i>lazy</i> references that are never used. This behavior can be useful for applications that need to know as soon as an object is loaded that all symbols referenced during execution will be available. This option mimics the loading of dependencies when the environment variable LD_BIND_NOW is in effect.
To determine the scope of visibility for symbols loaded with a <code>dlopen()</code> invocation, the <i>mode</i> parameter should be bitwise or'ed with one of the following values:	
RTLD_GLOBAL	The object's global symbols are made available for the relocation processing of any other object. In addition, symbol lookup using <code>dlopen(0, mode)</code> and an associated <code>dlsym()</code> , allows objects loaded with RTLD_GLOBAL to be searched.
RTLD_LOCAL	The object's global symbols are only available for the relocation processing of other objects that comprise the same group.
The program image file, and any objects loaded at program startup, have the mode RTLD_GLOBAL. The mode RTLD_LOCAL is the default mode for any objects acquired with <code>dlopen()</code> . A local object may be a dependency of more than one group. Any object of mode RTLD_LOCAL that is referenced as a dependency of an object of mode RTLD_GLOBAL will be promoted to RTLD_GLOBAL. In other words, the RTLD_LOCAL mode is ignored.	
Any object loaded by <code>dlopen()</code> that requires relocations against global symbols can reference the symbols in any RTLD_GLOBAL object, which are at least the program image file and any objects loaded at program startup, from the object itself, and from any dependencies the object references. However, the <i>mode</i> parameter may also be bitwise OR-ed with the following values to affect the scope of symbol availability:	
RTLD_GROUP	Only symbols from the associated group are made available for relocation. A group is established from the defined object and all the dependencies of that object. A group must be completely self-contained. All dependency relationships between the members of the group must be sufficient to satisfy the relocation requirements of each object that comprises the group.
RTLD_PARENT	The symbols of the object initiating the <code>dlopen()</code> call are made available to the objects obtained by <code>dlopen()</code> itself. This option is useful when hierarchical <code>dlopen()</code> families are created. Note that although the parent object can supply symbols for the relocation of this object, the parent object is not available to <code>dlsym()</code> through the returned <i>handle</i> .

RTLD_WORLD Only symbols from **RTLD_GLOBAL** objects are made available for relocation.

The default modes for `dlopen()` are both **RTLD_WORLD** and **RTLD_GROUP**. These modes are `or'ed` together if an object is required by different dependencies specifying differing modes.

The following modes provide additional capabilities outside of relocation processing:

RTLD_NODELETE The specified object will not be deleted from the address space as part of a `dclose()`.

RTLD_NOLOAD The specified object is not loaded as part of the `dlopen()`, but a valid *handle* is returned if the object already exists as part of the process address space. Additional modes can be specified and will be `or'ed` with the present mode of the object and its dependencies. The **RTLD_NOLOAD** mode provides a means of querying the presence, or promoting the modes, of an existing dependency.

The *lmid* passed to `dlopen()` identifies the link-map list where the object will be loaded. This can be any valid `Lmid_t` returned by `dlinfo()` or one of the following special values:

LM_ID_BASE Load the object on the applications link-map list.

LM_ID_LDSO Load the object on the dynamic linkers (`ld.so.1`) link-map list.

LM_ID_NEWLM Causes the object to create a new link-map list as part of loading. It is vital that any object opened on a new link-map list have all of its dependencies expressed because there will be no other objects on this link-map.

RETURN VALUES If *pathname* cannot be found, cannot be opened for reading, is not a shared or relocatable object, or if an error occurs during the process of loading *pathname* or relocating its symbolic references, `dlopen()` will return `NULL`. More detailed diagnostic information will be available through `dLError()`.

USAGE The `dlopen()` and `dlopen()` functions are members of a family of functions that give the user direct access to the dynamic linking facilities (see *Linker and Libraries Guide*) and are available to dynamically-linked processes only.

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
MT-Level	MT-Safe

SEE ALSO `ld(1)`, `ld.so.1(1)`, `dladdr(3DL)`, `dldclose(3DL)`, `dldump(3DL)`, `dLError(3DL)`, `dlinfo(3DL)`, `dlsym(3DL)`, `attributes(5)`

NOTES If other objects were link-edited with *pathname* when *pathname* was built, that is, the *pathname* has dependencies on other objects, those objects will automatically be loaded by `dlopen()`. The directory search path used to find both *pathname* and the other *needed* objects may be affected by setting the environment variable `LD_LIBRARY_PATH`, which is analyzed once at process startup, and from a `runpath` setting within the object from which the call to `dlopen()` originated. These search rules will only be applied to path names that do not contain an embedded `' / '`. Objects whose names resolve to the same absolute or relative path name may be opened any number of times using `dlopen()`; however, the object referenced will only be loaded once into the address space of the current process.

When loading shared objects the application should open a specific version of the shared object, as opposed to relying on the version of the shared object pointed to by the symbolic link.

When building objects that are to be loaded on a new link-map list (see `LM_ID_NEWLM`), some precautions need to be taken. In general, all dependencies must be included when building an object. Also, include `/usr/lib/libmapmalloc.so.1` before `/usr/lib/libc.so.1` when building an object.

When an object is loaded into memory on a new link-map list, it is isolated from the main running program. There are certain global resources that are only usable from one link-map list. A few examples of these would be the `sbrk()` based `malloc()`, `libthread()`, and the signal vectors. Because of this, care must be taken not to use any of these resources on any but the primary link-map list. These issues are discussed in further detail in the *Linker and Libraries Guide*.

Some symbols defined in dynamic executables or shared objects may not be available to the runtime linker. The symbol table created by `ld` for use by the runtime linker might contain only a subset of the symbols defined in the object.

NAME	dlopen, dlmopen – gain access to an executable object file
SYNOPSIS	<pre>cc [flag...] file... -ldl [library...] #include <dlfcn.h> #include <link.h> void * dlopen(const char *pathname, int mode); void * dlmopen(Lmid_t lmid, const char *pathname, int mode);</pre>

Linker and Libraries Guide

NOTES If other objects were link-edited with *pathname* when *pathname* was built, that is, the *pathname* has dependencies on other objects, those objects will automatically be loaded by `dlopen()`. The directory search path used to find both *pathname* and the other *needed* objects may be affected by setting the environment variable `LD_LIBRARY_PATH`, which is analyzed once at process startup, and from a `runpath` setting within the object from which the call to `dlopen()` originated. These search rules will only be applied to path names that do not contain an embedded `' / '`. Objects whose names resolve to the same absolute or relative path name may be opened any number of times using `dlopen()`; however, the object referenced will only be loaded once into the address space of the current process.

When loading shared objects the application should open a specific version of the shared object, as opposed to relying on the version of the shared object pointed to by the symbolic link.

When building objects that are to be loaded on a new link-map list (see `LM_ID_NEWLM`), some precautions need to be taken. In general, all dependencies must be included when building an object. Also, include `/usr/lib/libmapmalloc.so.1` before `/usr/lib/libc.so.1` when building an object.

When an object is loaded into memory on a new link-map list, it is isolated from the main running program. There are certain global resources that are only usable from one link-map list. A few examples of these would be the `sbrk()` based `malloc()`, `libthread()`, and the signal vectors. Because of this, care must be taken not to use any of these resources on any but the primary link-map list. These issues are discussed in further detail in the *Linker and Libraries Guide*.

Some symbols defined in dynamic executables or shared objects may not be available to the runtime linker. The symbol table created by `ld` for use by the runtime linker might contain only a subset of the symbols defined in the object.

NAME	dlsym – get the address of a symbol in a shared object or executable
SYNOPSIS	<pre>cc [flag ...] file ... -ldl [library ...] #include <dlfcn.h> void *dlsym(void *handle, const char *name);</pre>
DESCRIPTION	<p>The <code>dlsym()</code> function allows a process to obtain the address of a symbol defined within a shared object or executable. The <i>handle</i> argument is either the value returned from a call to <code>dlopen()</code> or one of the special handles <code>RTLD_DEFAULT</code>, <code>RTLD_NEXT</code>, or <code>RTLD_SELF</code>. The <i>name</i> argument is the symbol's name as a character string.</p> <p>In the case of a handle returned from <code>dlopen()</code>, the corresponding shared object must not have been closed using <code>dlclose()</code>. The <code>dlsym()</code> function searches for the named symbol in all shared objects loaded automatically as a result of loading the object referenced by <i>handle</i>. See <code>dlopen(3DL)</code>.</p> <p>In the case of the special handle <code>RTLD_DEFAULT</code>, <code>dlsym()</code> searches for the named symbol starting with the first object loaded and proceeding through the list of initial loaded objects, and any global objects obtained with <code>dlopen(3DL)</code>, until a match is found. This search follows the default model employed to relocate all objects within the process.</p> <p>In the case of the special handle <code>RTLD_NEXT</code>, <code>dlsym()</code> searches for the named symbol in the objects that were loaded following the object from which the <code>dlsym()</code> call is being made.</p> <p>In the case of the special handle <code>RTLD_SELF</code>, <code>dlsym()</code> searches for the named symbol in the objects that were loaded starting with the object from which the <code>dlsym()</code> call is being made.</p> <p>In the case of <code>RTLD_DEFAULT</code>, <code>RTLD_NEXT</code>, and <code>RTLD_SELF</code>, if the objects being searched have been loaded from <code>dlopen()</code> calls, <code>dlsym()</code> searches the object only if the caller is part of the same <code>dlopen()</code> dependency hierarchy, or if the object was given global search access. See <code>dlopen(3DL)</code> for a discussion of the <code>RTLD_GLOBAL</code> mode.</p>
RETURN VALUES	<p>If <i>handle</i> does not refer to a valid object opened by <code>dlopen()</code>, is not the special handle <code>RTLD_DEFAULT</code>, <code>RTLD_NEXT</code>, or <code>RTLD_SELF</code>, or if the named symbol cannot be found within any of the objects associated with <i>handle</i>, <code>dlsym()</code> will return <code>NULL</code>. More detailed diagnostic information is available through <code>dLError(3DL)</code>.</p>
EXAMPLES	<p>EXAMPLE 1 Using <code>dlopen()</code> and <code>dlsym()</code> to access a function or data objects.</p> <p>The following example shows how one can use <code>dlopen()</code> and <code>dlsym()</code> to access either function or data objects. For simplicity, error checking has been omitted.</p> <pre>void *handle; int *iptr, (*fptr)(int); /* open the needed object */ handle = dlopen("/usr/home/me/libfoo.so.1", RTLD_LAZY);</pre>

dlsym(3DL)

EXAMPLE 1 Using `dlopen()` and `dlsym()` to access a function or data objects.
(Continued)

```
/* find the address of function and data objects */
fptr = (int (*)(int))dlsym(handle, "my_function");
iptr = (int *)dlsym(handle, "my_object");

/* invoke function, passing value of integer as a parameter */
(*fptr)(*iptr);
```

EXAMPLE 2 Using `dlsym()` to verify that a particular function is defined.

The following code fragment shows how `dlsym()` can be used to verify that a particular function is defined and to call it only if it is.

```
int (*fptr)();

if ((fptr = (int (*)())dlsym(RTLD_DEFAULT,
    "my_function")) != NULL) {
    (*fptr)();
}
```

USAGE The `dlsym()` function is one of a family of functions that give the user direct access to the dynamic linking facilities (see *Linker and Libraries Guide*) and are available to dynamically-linked processes only.

Linker and Libraries Guide

NAME	gettext, dgettext, dcgettext, ngettext, dngettext, dcngettext, textdomain, bindtextdomain, bind_textdomain_codeset – message handling functions
Solaris and GNU-compatible	<pre>#include <libintl.h> char *gettext(const char *msgid); char *dgettext(const char *domainname, const char *msgid); char *textdomain(const char *domainname); char *bindtextdomain(const char *domainname, const char *dirname); #include <libintl.h> #include <locale.h> char *dcgettext(const char *domainname, const char *msgid, int category);</pre>
GNU-compatible	<pre>#include <libintl.h> char *ngettext(const char *msgid1, const char *msgid2, unsigned long int n); char *dngettext(const char *domainname, const char *msgid1, const char *msgid2, unsigned long int n); char *bind_textdomain_codeset(const char *domainname, const char *codeset); #include <libintl.h> #include <locale.h> char *dcngettext(const char *domainname, const char *msgid1, const char *msgid2, unsigned long int n, int category);</pre>
DESCRIPTION	<p>The <code>gettext()</code>, <code>dgettext()</code>, and <code>dcgettext()</code> functions attempt to retrieve a target string based on the specified <code>msgid</code> argument within the context of a specific domain and the current locale. The length of strings returned by <code>gettext()</code>, <code>dgettext()</code>, and <code>dcgettext()</code> is undetermined until the function is called. The <code>msgid</code> argument is a null-terminated string.</p> <p>The <code>ngettext()</code>, <code>dngettext()</code>, and <code>dcngettext()</code> functions are equivalent to <code>gettext()</code>, <code>dgettext()</code>, and <code>dcgettext()</code>, respectively, except for the handling of plural forms. These functions work only with GNU-compatible message catalogues. The <code>ngettext()</code>, <code>dngettext()</code>, and <code>dcngettext()</code> functions search for the message string using the <code>msgid1</code> argument as the key and the <code>n</code> argument to determine the plural form. If no message catalogues are found, <code>msgid1</code> is returned if <code>n == 1</code>, otherwise <code>msgid2</code> is returned.</p> <p>The <code>NLSPATH</code> environment variable (see <code>environ(5)</code>) is searched first for the location of the <code>LC_MESSAGES</code> catalogue. The setting of the <code>LC_MESSAGES</code> category of the current locale determines the locale used by <code>gettext()</code> and <code>dgettext()</code> for string retrieval. The <code>category</code> argument determines the locale used by <code>dcgettext()</code>. If <code>NLSPATH</code> is not defined and the current locale is "C", <code>gettext()</code>, <code>dgettext()</code>, and</p>

dngettext(3C)

`dcgettext()` simply return the message string that was passed. In a locale other than "C", if `NLSPATH` is not defined or if a message catalogue is not found in any of the components specified by `NLSPATH`, the routines search for the message catalogue using the scheme described in the following paragraph.

The `LANGUAGE` environment variable is examined to determine the GNU-compatible message catalogues to be used. The value of `LANGUAGE` is a list of locale names separated by a colon (':') character. If `LANGUAGE` is defined, each locale name is tried in the specified order and if a GNU-compatible message catalogue is found, the message is returned. If a GNU-compatible message catalogue is found but failed to find a corresponding *msgid*, the *msgid* string is return. If `LANGUAGE` is not defined or if a Solaris message catalogue is found or no GNU-compatible message catalogue is found in processing `LANGUAGE`, the pathname used to locate the message catalogue is *dirname/locale/category/domainname.mo*, where *dirname* is the directory specified by `bindtextdomain()`, *locale* is a locale name, and *category* is either `LC_MESSAGES` if `gettext()`, `dgettext()`, `ngettext()`, or `dngettext()` is called, or `LC_XXX` where the name is the same as the locale category name specified by the *category* argument to `dcgettext()` or `dcngettext()`.

For `gettext()` and `ngettext()`, the domain used is set by the last valid call to `textdomain()`. If a valid call to `textdomain()` has not been made, the default domain (called `messages`) is used.

For `dgettext()`, `dcgettext()`, `dngettext()`, and `dcngettext()`, the domain used is specified by the *domainname* argument. The *domainname* argument is equivalent in syntax and meaning to the *domainname* argument to `textdomain()`, except that the selection of the domain is valid only for the duration of the `dgettext()`, `dcgettext()`, `dngettext()`, or `dcngettext()` function call.

The `textdomain()` function sets or queries the name of the current domain of the active `LC_MESSAGES` locale category. The *domainname* argument is a null-terminated string that can contain only the characters allowed in legal filenames.

The *domainname* argument is the unique name of a domain on the system. If there are multiple versions of the same domain on one system, namespace collisions can be avoided by using `bindtextdomain()`. If `textdomain()` is not called, a default domain is selected. The setting of domain made by the last valid call to `textdomain()` remains valid across subsequent calls to `setlocale(3C)`, and `gettext()`.

The *domainname* argument is applied to the currently active `LC_MESSAGES` locale.

The current setting of the domain can be queried without affecting the current state of the domain by calling `textdomain()` with *domainname* set to the null pointer. Calling `textdomain()` with a *domainname* argument of a null string sets the domain to the default domain (`messages`).

The `bindtextdomain()` function binds the path predicate for a message domain *domainname* to the value contained in *dirname*. If *domainname* is a non-empty string and has not been bound previously, `bindtextdomain()` binds *domainname* with *dirname*.

If *domainname* is a non-empty string and has been bound previously, `bindtextdomain()` replaces the old binding with *dirname*. The *dirname* argument can be an absolute or relative pathname being resolved when `gettext()`, `dgettext()`, or `dcgettext()` are called. If *domainname* is a null pointer or an empty string, `bindtextdomain()` returns NULL. User defined domain names cannot begin with the string `SYS_`. Domain names beginning with this string are reserved for system use.

The `bind_textdomain_codeset()` function can be used to specify the output codeset for message catalogues for domain *domainname*. The *codeset* argument must be a valid codeset name that can be used for the `iconv_open(3C)` function, or a null pointer. If the *codeset* argument is the null pointer, `bind_textdomain_codeset()` returns the currently selected codeset for the domain with the name *domainname*. It returns a null pointer if a codeset has not yet been selected. The `bind_textdomain_codeset()` function can be used multiple times. If used multiple times with the same *domainname* argument, the later call overrides the settings made by the earlier one. The `bind_textdomain_codeset()` function returns a pointer to a string containing the name of the selected codeset. The string is allocated internally in the function and must not be changed by the user.

RETURN VALUES

The `gettext()`, `dgettext()`, and `dcgettext()` functions return the message string if the search succeeds. Otherwise they return the *msgid* string.

The `ngettext()`, `dngettext()`, and `dcngettext()` functions return the message string if the search succeeds. If the search fails, *msgid1* is returned if *n* == 1. Otherwise *msgid2* is returned.

The individual bytes of the string returned by `gettext()`, `dgettext()`, `dcgettext()`, `ngettext()`, `dngettext()`, or `dcngettext()` can contain any value other than NULL. If *msgid* is a null pointer, the return value is undefined. The string returned must not be modified by the program and can be invalidated by a subsequent call to `bind_textdomain_codeset()` or `setlocale(3C)`. If the *domainname* argument to `dgettext()`, `dcgettext()`, `dngettext()`, or `dcngettext()` is a null pointer, the the domain currently bound by `textdomain()` is used.

The normal return value from `textdomain()` is a pointer to a string containing the current setting of the domain. If *domainname* is a null pointer, `textdomain()` returns a pointer to the string containing the current domain. If `textdomain()` was not previously called and *domainname* is a null string, the name of the default domain is returned. The name of the default domain is `messages`. If `textdomain()` fails, a null pointer is returned.

The return value from `bindtextdomain()` is a null-terminated string containing *dirname* or the directory binding associated with *domainname* if *dirname* is NULL. If no binding is found, the default return value is `/usr/lib/locale`. If *domainname* is a null pointer or an empty string, `bindtextdomain()` takes no action and returns a null pointer. The string returned must not be modified by the caller. If `bindtextdomain()` fails, a null pointer is returned.

dngettext(3C)

USAGE These functions impose no limit on message length. However, a text *domainname* is limited to TEXTDOMAINMAX (256) bytes.

The `gettext()`, `dgettext()`, `dcgettext()`, `ngettext()`, `dngettext()`, `dcngettext()`, `textdomain()`, and `bindtextdomain()` functions can be used safely in multithreaded applications, as long as `setlocale(3C)` is not being called to change the locale.

The `gettext()`, `dgettext()`, `dcgettext()`, `textdomain()`, and `bindtextdomain()` functions work with both Solaris message catalogues and GNU-compatible message catalogues. The `ngettext()`, `dngettext()`, `dcngettext()`, and `bind_textdomain_codeset()` functions work only with GNU-compatible message catalogues. See `msgfmt(1)` for information about Solaris message catalogues and GNU-compatible message catalogues.

FILES `/usr/lib/locale`
default path predicate for message domain files

`/usr/lib/locale/locale/LC_MESSAGES/domainname.mo`
system default location for file containing messages for language *locale* and *domainname*

`/usr/lib/locale/locale/LC_XXX/domainname.mo`
system default location for file containing messages for language *locale* and *domainname* for `dcgettext()` calls where `LC_XXX` is `LC_CTYPE`, `LC_NUMERIC`, `LC_TIME`, `LC_COLLATE`, `LC_MONETARY`, or `LC_MESSAGES`

`dirname/locale/LC_MESSAGES/domainname.mo`
location for file containing messages for domain *domainname* and path predicate *dirname* after a successful call to `bindtextdomain()`

`dirname/locale/LC_XXX/domainname.mo`
location for files containing messages for domain *domainname*, language *locale*, and path predicate *dirname* after a successful call to `bindtextdomain()` for `dcgettext()` calls where `LC_XXX` is one of `LC_CTYPE`, `LC_NUMERIC`, `LC_TIME`, `LC_COLLATE`, `LC_MONETARY`, or `LC_MESSAGES`

NAME	floating_to_decimal, single_to_decimal, double_to_decimal, extended_to_decimal, quadruple_to_decimal – convert floating-point value to decimal record
SYNOPSIS	<pre>#include <floatingpoint.h> void single_to_decimal(single *px, decimal_mode *pm, decimal_record *pd, fp_exception_field_type *ps); void double_to_decimal(double *px, decimal_mode *pm, decimal_record *pd, fp_exception_field_type *ps); void extended_to_decimal(extended *px, decimal_mode *pm, decimal_record *pd, fp_exception_field_type *ps); void quadruple_to_decimal(quadruple *px, decimal_mode *pm, decimal_record *pd, fp_exception_field_type *ps);</pre>
DESCRIPTION	<p>The <code>floating_to_decimal()</code> functions convert the floating-point value at <code>*px</code> into a decimal record at <code>*pd</code>, observing the modes specified in <code>*pm</code> and setting exceptions in <code>*ps</code>. If there are no IEEE exceptions, <code>*ps</code> will be zero.</p> <p>If <code>*px</code> is zero, infinity, or NaN, then only <code>pd->sign</code> and <code>pd->fpclass</code> are set. Otherwise <code>pd->exponent</code> and <code>pd->ds</code> are also set so that</p> <p>$(\text{sig}) * (\text{pd->ds}) * 10^{(\text{pd->exponent})}$ is a correctly rounded approximation to <code>*px</code>, where <code>sig</code> is +1 or -1, depending upon whether <code>pd->sign</code> is 0 or -1. <code>pd->ds</code> has at least one and no more than <code>DECIMAL_STRING_LENGTH-1</code> significant digits because one character is used to terminate the string with a NULL.</p> <p><code>pd->ds</code> is correctly rounded according to the IEEE rounding modes in <code>pm->rd</code>. <code>*ps</code> has <code>fp_inexact</code> set if the result was inexact, and has <code>fp_overflow</code> set if the string result does not fit in <code>pd->ds</code> because of the limitation <code>DECIMAL_STRING_LENGTH</code>.</p> <p>If <code>pm->df == floating_form</code>, then <code>pd->ds</code> always contains <code>pm->ndigits</code> significant digits. Thus if <code>*px == 12.34</code> and <code>pm->ndigits == 8</code>, then <code>pd->ds</code> will contain 12340000 and <code>pd->exponent</code> will contain -6.</p> <p>If <code>pm->df == fixed_form</code> and <code>pm->ndigits >= 0</code>, then <code>pd->ds</code> always contains <code>pm->ndigits</code> after the point and as many digits as necessary before the point. Since the latter is not known in advance, the total number of digits required is returned in <code>pd->ndigits</code>; if that number <code>>= DECIMAL_STRING_LENGTH</code>, then <code>ds</code> is undefined. <code>pd->exponent</code> always gets <code>-pm->ndigits</code>. Thus if <code>*px == 12.34</code> and <code>pm->ndigits == 1</code>, then <code>pd->ds</code> gets 123, <code>pd->exponent</code> gets -1, and <code>pd->ndigits</code> gets 3.</p> <p>If <code>pm->df == fixed_form</code> and <code>pm->ndigits < 0</code>, then <code>pd->ds</code> always contains <code>-pm->ndigits</code> trailing zeros; in other words, rounding occurs <code>-pm->ndigits</code> to the left of the decimal point, but the digits rounded away are retained as zeros. The total number of digits required is in <code>pd->ndigits</code>. <code>pd->exponent</code> always gets 0. Thus if <code>*px == 12.34</code> and <code>pm->ndigits == -1</code>, then <code>pd->ds</code> gets 10, <code>pd->exponent</code> gets 0, and <code>pd->ndigits</code> gets 2.</p> <p><code>pd->more</code> is not used.</p>

double_to_decimal(3C)

econvert(3C), fconvert(3C), gconvert(3C), printf(3C), and sprintf(3C) all use double_to_decimal().

NAME	drand48, erand48, lrand48, nrand48, mrand48, jrand48, srand48, seed48, lcong48 – generate uniformly distributed pseudo-random numbers
SYNOPSIS	<pre>#include <stdlib.h> double drand48(void); double erand48(unsigned short <i>x_i[3]</i>); long lrand48(void); long nrand48(unsigned short <i>x_i[3]</i>); long mrand48(void); long jrand48(unsigned short <i>x_i[3]</i>); void srand48(long <i>seedval</i>); unsigned short *seed48(unsigned short <i>seed16v[3]</i>); void lcong48(unsigned short <i>param[7]</i>);</pre>
DESCRIPTION	<p>This family of functions generates pseudo-random numbers using the well-known linear congruential algorithm and 48-bit integer arithmetic.</p> <p>Functions <code>drand48()</code> and <code>erand48()</code> return non-negative double-precision floating-point values uniformly distributed over the interval [0.0, 1.0).</p> <p>Functions <code>lrand48()</code> and <code>nrand48()</code> return non-negative long integers uniformly distributed over the interval $[0, 2^{31}]$.</p> <p>Functions <code>mrand48()</code> and <code>jrand48()</code> return signed long integers uniformly distributed over the interval $[-2^{31}, 2^{31}]$.</p> <p>Functions <code>srand48()</code>, <code>seed48()</code>, and <code>lcong48()</code> are initialization entry points, one of which should be invoked before either <code>drand48()</code>, <code>lrand48()</code>, or <code>mrand48()</code> is called. (Although it is not recommended practice, constant default initializer values will be supplied automatically if <code>drand48()</code>, <code>lrand48()</code>, or <code>mrand48()</code> is called without a prior call to an initialization entry point.) Functions <code>erand48()</code>, <code>nrand48()</code>, and <code>jrand48()</code> do not require an initialization entry point to be called first.</p> <p>All the routines work by generating a sequence of 48-bit integer values, X_i, according to the linear congruential formula</p> $X_{n+1} = (aX_n + c) \bmod m \quad n \geq 0.$ <p>The parameter $m = 2^{48}$; hence 48-bit integer arithmetic is performed. Unless <code>lcong48()</code> has been invoked, the multiplier value a and the addend value c are given by</p> $a = 5DEECE66D_{16} = 273673163155_8$

drand48(3C)

$c = B_{16} = 13_8$.

The value returned by any of the functions `drand48()`, `erand48()`, `lrand48()`, `nrand48()`, `mrnd48()`, or `jrand48()` is computed by first generating the next 48-bit X_i in the sequence. Then the appropriate number of bits, according to the type of data item to be returned, are copied from the high-order (leftmost) bits of X_i and transformed into the returned value.

The functions `drand48()`, `lrand48()`, and `mrnd48()` store the last 48-bit X_i generated in an internal buffer. X_i must be initialized prior to being invoked. The functions `erand48()`, `nrand48()`, and `jrand48()` require the calling program to provide storage for the successive X_i values in the array specified as an argument when the functions are invoked. These routines do not have to be initialized; the calling program must place the desired initial value of X_i into the array and pass it as an argument. By using different arguments, functions `erand48()`, `nrand48()`, and `jrand48()` allow separate modules of a large program to generate several *independent* streams of pseudo-random numbers, that is, the sequence of numbers in each stream will *not* depend upon how many times the routines have been called to generate numbers for the other streams.

The initializer function `srand48()` sets the high-order 32 bits of X_i to the 32 bits contained in its argument. The low-order 16 bits of X_i are set to the arbitrary value $330E_{16}$.

The initializer function `seed48()` sets the value of X_i to the 48-bit value specified in the argument array. In addition, the previous value of X_i is copied into a 48-bit internal buffer, used only by `seed48()`, and a pointer to this buffer is the value returned by `seed48()`. This returned pointer, which can just be ignored if not needed, is useful if a program is to be restarted from a given point at some future time — use the pointer to get at and store the last X_i value, and then use this value to reinitialize using `seed48()` when the program is restarted.

The initialization function `lcg48()` allows the user to specify the initial X_i , the multiplier value a , and the addend value c . Argument array elements `param[0-2]` specify X_i , `param[3-5]` specify the multiplier a , and `param[6]` specifies the 16-bit addend c . After `lcg48()` has been called, a subsequent call to either `srand48()` or `seed48()` will restore the “standard” multiplier and addend values, a and c , specified above.

NAME	dup2 – duplicate an open file descriptor								
SYNOPSIS	<pre>#include <unistd.h> int dup2 (int <i>fildes</i>, int <i>fildes2</i>);</pre>								
DESCRIPTION	<p>The dup2 () function causes the file descriptor <i>fildes2</i> to refer to the same file as <i>fildes</i>. The <i>fildes</i> argument is a file descriptor referring to an open file, and <i>fildes2</i> is a non-negative integer less than the current value for the maximum number of open file descriptors allowed the calling process. See getrlimit(2). If <i>fildes2</i> already refers to an open file, not <i>fildes</i>, it is closed first. If <i>fildes2</i> refers to <i>fildes</i>, or if <i>fildes</i> is not a valid open file descriptor, <i>fildes2</i> will not be closed first.</p> <p>The dup2 () function is equivalent to fcntl (<i>fildes</i>, F_DUP2FD, <i>fildes2</i>).</p>								
RETURN VALUES	Upon successful completion a non-negative integer representing the file descriptor is returned. Otherwise, -1 is returned and errno is set to indicate the error.								
ERRORS	<p>The dup2 () function will fail if:</p> <table> <tr> <td>EBADF</td> <td>The <i>fildes</i> argument is not a valid open file descriptor.</td> </tr> <tr> <td>EBADF</td> <td>The <i>files2</i> argument is negative or is not less than the current resource limit returned by getrlimit (RLIMIT_NOFILE, . . .).</td> </tr> <tr> <td>EINTR</td> <td>A signal was caught during the dup2 () call.</td> </tr> <tr> <td>EMFILE</td> <td>The process has too many open files. See fcntl(2).</td> </tr> </table>	EBADF	The <i>fildes</i> argument is not a valid open file descriptor.	EBADF	The <i>files2</i> argument is negative or is not less than the current resource limit returned by getrlimit (RLIMIT_NOFILE, . . .).	EINTR	A signal was caught during the dup2 () call.	EMFILE	The process has too many open files. See fcntl(2).
EBADF	The <i>fildes</i> argument is not a valid open file descriptor.								
EBADF	The <i>files2</i> argument is negative or is not less than the current resource limit returned by getrlimit (RLIMIT_NOFILE, . . .).								
EINTR	A signal was caught during the dup2 () call.								
EMFILE	The process has too many open files. See fcntl(2).

econvert(3C)

NAME	econvert, fconvert, gconvert, seconvert, sconvert, sgconvert, qeconvert, qfconvert, qgconvert – output conversion
SYNOPSIS	<pre>#include <floatingpoint.h> char *econvert(double value, int ndigit, int *decpt, int *sign, char *buf) ; char *fconvert(double value, int ndigit, int *decpt, int *sign, char *buf) ; char *gconvert(double value, int ndigit, int trailing, char *buf) ; char *seconvert(single *value, int ndigit, int *decpt, int *sign, char *buf) ; char *sconvert(single *value, int ndigit, int *decpt, int *sign, char *buf) ; char *sgconvert(single *value, int ndigit, int trailing, char *buf) ; char *qeconvert(quadruple *value, int ndigit, int *decpt, int *sign, char *buf) ; char *qfconvert(quadruple *value, int ndigit, int *decpt, int *sign, char *buf) ; char *qgconvert(quadruple *value, int ndigit, int trailing, char *buf) ;</pre>
DESCRIPTION	<p>The <code>econvert()</code> function converts the <i>value</i> to a null-terminated string of <i>ndigit</i> ASCII digits in <i>buf</i> and returns a pointer to <i>buf</i>. <i>buf</i> should contain at least <i>ndigit</i>+1 characters. The position of the decimal point relative to the beginning of the string is stored indirectly through <i>decpt</i>. Thus <i>buf</i> == "314" and <i>*decpt</i> == 1 corresponds to the numerical value 3.14, while <i>buf</i> == "314" and <i>*decpt</i> == -1 corresponds to the numerical value .0314. If the sign of the result is negative, the word pointed to by <i>sign</i> is nonzero; otherwise it is zero. The least significant digit is rounded.</p> <p>The <code>fconvert()</code> function works much like <code>econvert()</code>, except that the correct digit has been rounded as if for <code>sprintf(%w.nf)</code> output with <i>n</i>=<i>ndigit</i> digits to the right of the decimal point. <i>ndigit</i> can be negative to indicate rounding to the left of the decimal point. The return value is a pointer to <i>buf</i>. <i>buf</i> should contain at least <code>310+max(0,ndigit)</code> characters to accommodate any double-precision <i>value</i>.</p> <p>The <code>gconvert()</code> function converts the <i>value</i> to a null-terminated ASCII string in <i>buf</i> and returns a pointer to <i>buf</i>. It produces <i>ndigit</i> significant digits in fixed-decimal format, like <code>sprintf(%w.nf)</code>, if possible, and otherwise in floating-decimal format, like <code>sprintf(%w.ne)</code>; in either case <i>buf</i> is ready for printing, with sign and exponent. The result corresponds to that obtained by</p> <pre>(void) sprintf(buf, ``%w.ng'', value) ;</pre> <p>If <i>trailing</i> = 0, trailing zeros and a trailing point are suppressed, as in <code>sprintf(%g)</code>. If <i>trailing</i> != 0, trailing zeros and a trailing point are retained, as in <code>sprintf(%#g)</code>.</p>

The `seconvert()`, `sfconvert()`, and `sgconvert()` functions are single-precision versions of these functions, and are more efficient than the corresponding double-precision versions. A pointer rather than the value itself is passed to avoid C's usual conversion of single-precision arguments to double.

The `qeconvert()`, `qfconvert()`, and `qgconvert()` functions are quadruple-precision versions of these functions. The `qfconvert()` function can overflow the `decimal_record` field `ds` if `value` is too large. In that case, `buf[0]` is set to zero.

The `ecvt()`, `fcvt()` and `gcvt()` functions are versions of `econvert()`, `fconvert()`, and `gconvert()`, respectively, that are documented on the `ecvt(3C)` manual page. They constitute the default implementation of these functions and conform to the X/Open CAE Specification, System Interfaces and Headers, Issue 4, Version 2.

USAGE IEEE Infinities and NaNs are treated similarly by these functions. "NaN" is returned for NaN, and "Inf" or "Infinity" for Infinity. The longer form is produced when `ndigit` \geq 8.

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
MT-Level	MT-Safe

SEE ALSO `ecvt(3C)`, `sprintf(3C)`, `attributes(5)`

ecvt(3C)

NAME	ecvt, fcvt, gcvt – convert floating-point number to string
SYNOPSIS	<pre>#include <stdlib.h> char *ecvt(double value, int ndigit, int *decpt, int *sign); char *fcvt(double value, int ndigit, int *decpt, int *sign); char *gcvt(double value, int ndigit, char *buf);</pre>
DESCRIPTION	<p>The <code>ecvt()</code>, <code>fcvt()</code> and <code>gcvt()</code> functions convert floating-point numbers to null-terminated strings.</p> <p><code>ecvt()</code> The <code>ecvt()</code> function converts <i>value</i> to a null-terminated string of <i>ndigit</i> digits (where <i>ndigit</i> is reduced to an unspecified limit determined by the precision of a <code>double</code>) and returns a pointer to the string. The high-order digit is non-zero, unless the value is 0. The low-order digit is rounded. The position of the radix character relative to the beginning of the string is stored in the integer pointed to by <i>decpt</i> (negative means to the left of the returned digits). The radix character is not included in the returned string. If the sign of the result is negative, the integer pointed to by <i>sign</i> is non-zero, otherwise it is 0.</p> <p>If the converted value is out of range or is not representable, the contents of the returned string are unspecified.</p> <p><code>fcvt()</code> The <code>fcvt()</code> function is identical to <code>ecvt()</code> except that <i>ndigit</i> specifies the number of digits desired after the radix point. The total number of digits in the result string is restricted to an unspecified limit as determined by the precision of a <code>double</code>.</p> <p><code>gcvt()</code> The <code>gcvt()</code> function converts <i>value</i> to a null-terminated string (similar to that of the <code>%g</code> format of <code>printf(3C)</code>) in the array pointed to by <i>buf</i> and returns <i>buf</i>. It produces <i>ndigit</i> significant digits (limited to an unspecified value determined by the precision of a <code>double</code>) in <code>%f</code> if possible, or <code>%e</code> (scientific notation) otherwise. A minus sign is included in the returned string if <i>value</i> is less than 0. A radix character is included in the returned string if <i>value</i> is not a whole number. Trailing zeros are suppressed where <i>value</i> is not a whole number. The radix character is determined by the current locale. If <code>setlocale(3C)</code> has not been called successfully, the default locale, <code>POSIX</code>, is used. The default locale specifies a period (<code>.</code>) as the radix character. The <code>LC_NUMERIC</code> category determines the value of the radix character within the current locale.</p>
RETURN VALUES	<p>The <code>ecvt()</code> and <code>fcvt()</code> functions return a pointer to a null-terminated string of digits.</p> <p>The <code>gcvt()</code> function returns <i>buf</i>.</p>
ERRORS	No errors are defined.
USAGE	<p>The return values from <code>ecvt()</code> and <code>fcvt()</code> may point to static data which may be overwritten by subsequent calls to these functions.</p> <p>For portability to implementations conforming to earlier versions of this document, <code>sprintf(3C)</code> is preferred over this function.</p>

encrypt(3C)

NAME	encrypt – encoding function						
Default	<pre>#include <crypt.h> void encrypt(char <i>block</i>[64], int <i>edflag</i>);</pre>						
Standard conforming	<pre>#include <unistd.h> void encrypt(char <i>block</i>[64], int <i>edflag</i>);</pre>						
DESCRIPTION	<p>The <code>encrypt()</code> function provides (rather primitive) access to the hashing algorithm employed by the <code>crypt(3C)</code> function. The key generated by <code>setkey(3C)</code> is used to encrypt the string <i>block</i> with <code>encrypt()</code>.</p> <p>The <i>block</i> argument to <code>encrypt()</code> is an array of length 64 bytes containing only the bytes with numerical value of 0 and 1. The array is modified in place to a similar array using the key set by <code>setkey(3C)</code>. If <i>edflag</i> is 0, the argument is encoded. If <i>edflag</i> is 1, the argument may be decoded (see the USAGE section below); if the argument is not decoded, <code>errno</code> will be set to <code>ENOSYS</code>.</p>						
RETURN VALUES	The <code>encrypt()</code> function returns no value.						
ERRORS	The <code>encrypt()</code> function will fail if: <code>ENOSYS</code> The functionality is not supported on this implementation.						
USAGE	<p>In some environments, decoding may not be implemented. This is related to U.S. Government restrictions on encryption and decryption routines: the DES decryption algorithm cannot be exported outside the U.S.A. Historical practice has been to ship a different version of the encryption library without the decryption feature in the routines supplied. Thus the exported version of <code>encrypt()</code> does encoding but not decoding.</p> <p>Because <code>encrypt()</code> does not return a value, applications wishing to check for errors should set <code>errno</code> to 0, call <code>encrypt()</code>, then test <code>errno</code> and, if it is non-zero, assume an error has occurred.</p>

NAME	getgrnam, getgrnam_r, getgrent, getgrent_r, getgrgid, getgrgid_r, setgrent, endgrent, fgetgrent, fgetgrent_r – group database entry functions
SYNOPSIS	<pre>#include <grp.h> struct group *getgrnam(const char *name); struct group *getgrnam_r(const char *name, struct group *grp, char *buffer, int bufsize); struct group *getgrent(void); struct group *getgrent_r(struct group *grp, char *buffer, int bufsize); struct group *getgrgid(gid_t gid); struct group *getgrgid_r(gid_t gid, struct group *grp, char *buffer, int bufsize); void setgrent(void); void endgrent(void); struct group *fgetgrent(FILE *f); struct group *fgetgrent_r(FILE *f, struct group *grp, char *buffer, int bufsize);</pre>
POSIX	<pre>cc [flag...] file... -D_POSIX_PTHREAD_SEMANTICS [library...] int getgrnam_r(const char *name, struct group *grp, char *buffer, size_t bufsize, struct group **result); int getgrgid_r(gid_t gid, struct group *grp, char *buffer, size_t bufsize, struct group **result);</pre>
DESCRIPTION	<p>These functions are used to obtain entries describing user groups. Entries can come from any of the sources for group specified in the <code>/etc/nsswitch.conf</code> file (see <code>nsswitch.conf(4)</code>).</p> <p>The <code>getgrnam()</code> function searches the group database for an entry with the group name specified by the character string parameter <i>name</i>.</p> <p>The <code>getgrgid()</code> function searches the group database for an entry with the (numeric) group id specified by <i>gid</i>.</p> <p>The <code>setgrent()</code>, <code>getgrent()</code>, and <code>endgrent()</code> functions are used to enumerate group entries from the database.</p> <p>The <code>setgrent()</code> function effectively rewinds the group database to allow repeated searches. It sets (or resets) the enumeration to the beginning of the set of group entries. This function should be called before the first call to <code>getgrent()</code>.</p>

endgrent(3C)

The `getgrent()` function returns a pointer to a structure containing the broken-out fields of an entry in the group database. When first called, `getgrent()` returns a pointer to a `group` structure containing the next group structure in the group database. Successive calls may be used to search the entire database.

The `endgrent()` function may be called to close the group database and deallocate resources when processing is complete. It is permissible, though possibly less efficient, for the process to call more group functions after calling `endgrent()`.

The `fgetgrent()` function, unlike the other functions above, does not use `nsswitch.conf`. It reads and parses the next line from the stream *f*, which is assumed to have the format of the group file (see `group(4)`).

Reentrant Interfaces

The `getgrnam()`, `getgrgid()`, `getgrent()`, and `fgetgrent()` functions use static storage that is reused in each call, making them unsafe for multithreaded applications.

The parallel functions `getgrnam_r()`, `getgrgid_r()`, `getgrent_r()`, and `fgetgrent_r()` provide reentrant interfaces for these operations.

Each reentrant interface performs the same operation as its non-reentrant counterpart, named by removing the `_r` suffix. The reentrant interfaces, however, use buffers supplied by the caller to store returned results, and are safe for use in both single-threaded and multithreaded applications.

Each reentrant interface takes the same arguments as its non-reentrant counterpart, as well as the following additional parameters. The *grp* argument must be a pointer to a `struct group` structure allocated by the caller. On successful completion, the function returns the group entry in this structure. Storage referenced by the group structure is allocated from the memory provided with the *buffer* argument, which is *bufsize* characters in size. The maximum size needed for this buffer can be determined with the `_SC_GETGR_R_SIZE_MAX` `sysconf(3C)` parameter. The POSIX versions place a pointer to the modified *grp* structure in the *result* parameter, instead of returning a pointer to this structure.

For enumeration in multithreaded applications, the position within the enumeration is a process-wide property shared by all threads. `setgrent()` may be used in a multithreaded application but resets the enumeration position for all threads. If multiple threads interleave calls to `getgrent_r()`, the threads will enumerate disjoint subsets of the group database. Like their non-reentrant counterparts, `getgrnam_r()` and `getgrgid_r()` leave the enumeration position in an indeterminate state.

RETURN VALUES

Group entries are represented by the `struct group` structure defined in `<grp.h>`:

```
struct group {
    char *gr_name;           /* the name of the group */
    char *gr_passwd;        /* the encrypted group password */
    gid_t gr_gid;           /* the numerical group ID */
};
```

```
char **gr_mem;          /* vector of pointers to member names */
};
```

The `getgrnam()`, `getgrnam_r()`, `getgrgid()`, and `getgrgid_r()` functions each return a pointer to a `struct group` if they successfully locate the requested entry; otherwise they return `NULL`. The POSIX functions `getgrnam_r()` and `getgrgid_r()` return 0 upon success or the error number in case of failure.

The `getgrent()`, `getgrent_r()`, `fgetgrent()`, and `fgetgrent_r()` functions each return a pointer to a `struct group` if they successfully enumerate an entry; otherwise they return `NULL`, indicating the end of the enumeration.

The `getgrnam()`, `getgrgid()`, `getgrent()`, and `fgetgrent()` functions use static storage, so returned data must be copied before a subsequent call to any of these functions if the data is to be saved.

When the pointer returned by the reentrant functions `getgrnam_r()`, `getgrgid_r()`, `getgrent_r()`, and `fgetgrent_r()` is non-null, it is always equal to the `grp` pointer that was supplied by the caller.

ERRORS The `getgrnam()`, `getgrgid()`, `getgrent()`, `fgetgrent()`, and `fgetgrent_r()` functions may fail if:

<code>EINTR</code>	A signal was caught during the operation.
<code>EIO</code>	An I/O error has occurred.
<code>EMFILE</code>	There are <code>OPEN_MAX</code> file descriptors currently open in the calling process.
<code>ENFILE</code>	The maximum allowable number of files is currently open in the system.
<code>ERANGE</code>	The group file contains a line that exceeds 512 bytes.

The `getgrnam_r()`, `getgrgid_r()`, and `getgrent_r()` functions may fail if:

<code>ERANGE</code>	Insufficient storage was supplied by <code>buffer</code> and <code>bufsize</code> to contain the data to be referenced by the resulting <code>group</code> structure.
---------------------	---

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
MT-Level	See "Reentrant Interfaces" in <code>DESCRIPTION</code> .

SEE ALSO `Intro(3)`, `getpwnam(3C)`, `group(4)`, `nsswitch.conf(4)`, `passwd(4)`, `attributes(5)`, `standards(5)`

NOTES When compiling multithreaded programs, see `Intro(3)`, *Notes On Multithreaded Applications*.

endgrent(3C)

Programs that use the interfaces described in this manual page cannot be linked statically since the implementations of these functions employ dynamic loading and linking of shared objects at run time.

Use of the enumeration interfaces `getgrent()` and `getgrent_r()` is discouraged; enumeration is supported for the group file, NIS, and NIS+, but in general is not efficient and may not be supported for all database sources. The semantics of enumeration are discussed further in `nsswitch.conf(4)`.

Previous releases allowed the use of "+" and "-" entries in `/etc/group` to selectively include and exclude entries from NIS. The primary usage of these entries is superseded by the name service switch, so the "+/-" form *may not be supported in future releases*.

If required, the "+/-" functionality can still be obtained for NIS by specifying `compat` as the source for `group`.

If the "+/-" functionality is required in conjunction with NIS+, specify both `compat` as the source for `group` and `nisplus` as the source for the pseudo-database `group_compat`. See `group(4)`, and `nsswitch.conf(4)` for details.

Solaris 2.4 and earlier releases provided definitions of the `getgrnam_r()` and `getgrgid_r()` functions as specified in POSIX.1c Draft 6. The final POSIX.1c standard changed the interface for these functions. Support for the Draft 6 interface is provided for compatibility only and may not be supported in future releases. New applications and libraries should use the POSIX standard interface.

For POSIX.1c-compliant applications, the `_POSIX_PTHREAD_SEMANTICS` and `_REENTRANT` flags are automatically turned on by defining the `_POSIX_C_SOURCE` flag with a value `>= 199506L`.

NAME	getnetgrent, getnetgrent_r, setnetgrent, endnetgrent, innetgr – get network group entry
SYNOPSIS	<pre>#include <netdb.h> int getnetgrent(char **<i>machinep</i>, char **<i>userp</i>, char **<i>domainp</i>); int getnetgrent_r(char **<i>machinep</i>, char **<i>userp</i>, char **<i>domainp</i>, char *<i>buffer</i>, int<i>buflen</i>); int setnetgrent(const char *<i>netgroup</i>); int endnetgrent(void); int innetgr(const char *<i>netgroup</i>, const char *<i>machine</i>, const char *<i>user</i>, const char *<i>domain</i>);</pre>
DESCRIPTION	<p>These functions are used to test membership in and enumerate members of “netgroup” network groups defined in a system database. Netgroups are sets of (machine,user,domain) triples (see netgroup(4)).</p> <p>These functions consult the source specified for netgroup in the /etc/nsswitch.conf file (see nsswitch.conf(4)).</p> <p>The function innetgr() returns 1 if there is a netgroup <i>netgroup</i> that contains the specified <i>machine</i>, <i>user</i>, <i>domain</i> triple as a member; otherwise it returns 0. Any of the supplied pointers <i>machine</i>, <i>user</i>, and <i>domain</i> may be NULL, signifying a “wild card” that matches all values in that position of the triple.</p> <p>The innetgr() function is safe for use in single-threaded and multithreaded applications.</p> <p>The functions setnetgrent(), getnetgrent(), and endnetgrent() are used to enumerate the members of a given network group.</p> <p>The function setnetgrent() establishes the network group specified in the parameter <i>netgroup</i> as the current group whose members are to be enumerated.</p> <p>Successive calls to the function getnetgrent() will enumerate the members of the group established by calling setnetgrent(); each call returns 1 if it succeeds in obtaining another member of the network group, or 0 if there are no further members of the group.</p> <p>When calling either getnetgrent() or getnetgrent_r(), addresses of the three character pointers are used as arguments, for example:</p> <pre>char *<i>mp</i>, *<i>up</i>, *<i>dp</i>; getnetgrent(&<i>mp</i>, &<i>up</i>, &<i>dp</i>);</pre>

endnetgrent(3C)

Upon successful return from `getnetgrent()`, the pointer `mp` points to a string containing the name of the machine part of the member triple, `up` points to a string containing the user name and `dp` points to a string containing the domain name. If the pointer returned for `mp`, `up`, or `dp` is `NULL`, it signifies that the element of the netgroup contains wild card specifier in that position of the triple.

The pointers returned by `getnetgrent()` point into a buffer allocated by `setnetgrent()` that is reused by each call. This space is released when an `endnetgrent()` call is made, and should not be released by the caller. This implementation is not safe for use in multi-threaded applications.

The function `getnetgrent_r()` is similar to `getnetgrent()` function, but it uses a buffer supplied by the caller for the space needed to store the results. The parameter `buffer` should be a pointer to a buffer allocated by the caller and the length of this buffer should be specified by the parameter `buflen`. The buffer must be large enough to hold the data associated with the triple. The `getnetgrent_r()` function is safe for use both in single-threaded and multi-threaded applications.

The function `endnetgrent()` frees the space allocated by the previous `setnetgrent()` call. The equivalent of an `endnetgrent()` implicitly performed whenever a `setnetgrent()` call is made to a new network group.

Note that while `setnetgrent()` and `endnetgrent()` are safe for use in multi-threaded applications, the effect of each is process-wide. Calling `setnetgrent()` resets the enumeration position for all threads. If multiple threads interleave calls to `getnetgrent_r()` each will enumerate a disjoint subset of the netgroup. Thus the effective use of these functions in multi-threaded applications may require coordination by the caller.

ERRORS The function `getnetgrent_r()` will return 0 and set `errno` to `ERANGE` if the length of the buffer supplied by caller is not large enough to store the result. See `Intro(2)` for the proper usage and interpretation of `errno` in multi-threaded applications.

The functions `setnetgrent()` and `endnetgrent()` return 0 upon success.

FILES `/etc/nsswitch.conf`

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
MT-Level	See <code>DESCRIPTION</code> section.

SEE ALSO `Intro(2)`, `Intro(3)`, `netgroup(4)`, `nsswitch.conf(4)`, `attributes(5)`

WARNINGS The function `getnetgrent_r()` is included in this release on an uncommitted basis only, and is subject to change or removal in future minor releases.

NOTES Only the Network Information Services, NIS and NIS+, are supported as sources for the `netgroup` database.

Programs that use the interfaces described in this manual page cannot be linked statically since the implementations of these functions employ dynamic loading and linking of shared objects at run time.

When compiling multi-threaded applications, see `Intro(3)`, *Notes On Multithread Applications*, for information about the use of the `_REENTRANT` flag.

endpwent(3C)

NAME	getpwnam, getpwnam_r, getpwent, getpwent_r, getpwuid, getpwuid_r, setpwent, endpwent, fgetpwent, fgetpwent_r – get password entry
SYNOPSIS	<pre>#include <pwd.h> struct passwd *getpwnam(const char *name); struct passwd *getpwnam_r(const char *name, struct passwd *pwd, char *buffer, int buflen); struct passwd *getpwent(void); struct passwd *getpwent_r(struct passwd *pwd, char *buffer, int buflen); struct passwd *getpwuid(uid_t uid); struct passwd *getpwuid_r(uid_t uid, struct passwd *pwd, char *buffer, int buflen); void setpwent(void); void endpwent(void); struct passwd *fgetpwent(FILE *f); struct passwd *fgetpwent_r(FILE *f, struct passwd *pwd, char *buffer, int buflen);</pre>
POSIX	<pre>cc [flag...] file... -D_POSIX_PTHREAD_SEMANTICS [library...] int getpwnam_r(const char *name, struct passwd *pwd, char *buffer, size_t bufsize, struct passwd **result); int getpwuid_r(uid_t uid, struct passwd *pwd, char *buffer, size_t bufsize, struct passwd **result);</pre>
DESCRIPTION	<p>These functions are used to obtain password entries. Entries can come from any of the sources for passwd specified in the /etc/nsswitch.conf file (see nsswitch.conf(4)).</p> <p>The getpwnam() function searches for a password entry with the login name specified by the character string parameter <i>name</i>.</p> <p>The getpwuid() function searches for a password entry with the (numeric) user ID specified by the parameter <i>uid</i>.</p> <p>The setpwent(), getpwent(), and endpwent() functions are used to enumerate password entries from the database. setpwent() sets (or resets) the enumeration to the beginning of the set of password entries. This function should be called before the first call to getpwent(). Calls to getpwnam() and getpwuid() leave the enumeration position in an indeterminate state. Successive calls to getpwent() return either successive entries or NULL, indicating the end of the enumeration.</p>

The `endpwent()` function may be called to indicate that the caller expects to do no further password retrieval operations; the system may then close the password file, deallocate resources it was using, and so forth. It is still allowed, but possibly less efficient, for the process to call more password functions after calling `endpwent()`.

The `fgetpwent()` function, unlike the other functions above, does not use `nsswitch.conf`; it reads and parses the next line from the stream *f*, which is assumed to have the format of the `passwd` file. See `passwd(4)`.

Reentrant Interfaces

The functions `getpwnam()`, `getpwuid()`, `getpwent()`, and `fgetpwent()` use static storage that is reused in each call, making these routines unsafe for use in multithreaded applications.

The parallel functions `getpwnam_r()`, `getpwuid_r()`, `getpwent_r()`, and `fgetpwent_r()` provide reentrant interfaces for these operations.

Each reentrant interface performs the same operation as its non-reentrant counterpart, named by removing the “_r” suffix. The reentrant interfaces, however, use buffers supplied by the caller to store returned results, and are safe for use in both single-threaded and multithreaded applications.

Each reentrant interface takes the same parameters as its non-reentrant counterpart, as well as the following additional parameters. The parameter `pwd` must be a pointer to a `struct passwd` structure allocated by the caller. On successful completion, the function returns the password entry in this structure. The parameter *buffer* is a pointer to a buffer supplied by the caller, used as storage space for the password data. All of the pointers within the returned `struct passwd` `pwd` point to data stored within this buffer; see RETURN VALUES. The buffer must be large enough to hold all the data associated with the password entry. The parameter *buflen* (or *bufsize* for the POSIX versions; see standards(5)) should give the size in bytes of *buffer*. The POSIX versions place a pointer to the modified `pwd` structure in the *result* parameter, instead of returning a pointer to this structure.

For enumeration in multithreaded applications, the position within the enumeration is a process-wide property shared by all threads. The `setpwent()` function may be used in a multithreaded application but resets the enumeration position for all threads. If multiple threads interleave calls to `getpwent_r()`, the threads will enumerate disjoint subsets of the password database.

Like their non-reentrant counterparts, `getpwnam_r()` and `getpwuid_r()` leave the enumeration position in an indeterminate state.

RETURN VALUES

Password entries are represented by the `struct passwd` structure defined in `<pwd.h>`:

```
struct passwd {
    char *pw_name;          /* user's login name */
    char *pw_passwd;       /* no longer used */
    uid_t pw_uid;          /* user's uid */
    gid_t pw_gid;          /* user's gid */
    char *pw_age;          /* not used */
}
```

endpwent(3C)

```
char *pw_comment; /* not used */
char *pw_gecos; /* typically user's full name */
char *pw_dir; /* user's home dir */
char *pw_shell; /* user's login shell */
};
```

The `pw_passwd` member should not be used as the encrypted password for the user; use `getspnam()` or `getspnam_r()` instead. See `getspnam(3C)`.

The `getpwnam()`, `getpwnam_r()`, `getpwuid()`, and `getpwuid_r()` functions each return a pointer to a `struct passwd` if they successfully locate the requested entry; otherwise they return `NULL`. Upon successful completion (including the case when the requested entry is not found), the POSIX functions `getpwnam_r()` and `getpwuid_r()` return 0. Otherwise, an error number is returned to indicate the error.

The `getpwent()`, `getpwent_r()`, `fgetpwent()`, and `fgetpwent_r()` functions each return a pointer to a `struct passwd` if they successfully enumerate an entry; otherwise they return `NULL`, indicating the end of the enumeration.

The `getpwnam()`, `getpwuid()`, `getpwent()`, and `fgetpwent()` functions use static storage, so returned data must be copied before a subsequent call to any of these functions if the data is to be saved.

When the pointer returned by the reentrant functions `getpwnam_r()`, `getpwuid_r()`, `getpwent_r()`, and `fgetpwent_r()` is non-null, it is always equal to the `pwd` pointer that was supplied by the caller.

ERRORS The reentrant functions `getpwnam_r()`, `getpwuid_r()`, `getpwent_r()`, and `fgetpwent_r()` will return `NULL` and set `errno` to `ERANGE` (or in the case of POSIX functions `getpwnam_r()` and `getpwuid_r()` return the `ERANGE` error) if the length of the buffer supplied by caller is not large enough to store the result. See `Intro(2)` for the proper usage and interpretation of `errno` in multithreaded applications.

USAGE Applications that use the interfaces described on this manual page cannot be linked statically, since the implementations of these functions employ dynamic loading and linking of shared objects at run time.

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
MT-Level	See "Reentrant Interfaces" in <code>DESCRIPTION</code> .

SEE ALSO `nispasswd(1)`, `passwd(1)`, `yppasswd(1)`, `Intro(2)`, `Intro(3)`, `cuserid(3C)`, `getgrnam(3C)`, `getlogin(3C)`, `getspnam(3C)`, `nsswitch.conf(4)`, `passwd(4)`, `shadow(4)`, `attributes(5)`, `standards(5)`

NOTES When compiling multithreaded programs, see `Intro(3)`, *Notes On Multithreaded Applications*.

Use of the enumeration interfaces `getpwent()` and `getpwent_r()` is discouraged; enumeration is supported for the `passwd` file, NIS, and NIS+, but in general is not efficient and may not be supported for all database sources. The semantics of enumeration are discussed further in `nsswitch.conf(4)`.

Previous releases allowed the use of '+' and '-' entries in `/etc/passwd` to selectively include and exclude NIS entries. The primary usage of these '+/-' entries is superseded by the name service switch, so the '+/-' form may not be supported in future releases.

If required, the '+/-' functionality can still be obtained for NIS by specifying `compat` as the source for `passwd`.

If the '+/-' functionality is required in conjunction with NIS+, specify both `compat` as the source for `passwd` and `nisplus` as the source for the pseudo-database `passwd_compat`. See `passwd(4)`, `shadow(4)`, and `nsswitch.conf(4)` for details.

If the '+/-' is used, both `/etc/shadow` and `/etc/passwd` should have the same '+' and '-' entries to ensure consistency between the password and shadow databases.

If a password entry from any of the sources contains an empty `uid` or `gid` field, that entry will be ignored by the files, NIS, and NIS+ name service switch backends. This will cause the user to appear unknown to the system.

If a password entry contains an empty `gecos`, `home directory`, or `shell` field, `getpwnam()` and `getpwnam_r()` return a pointer to a null string in the respective field of the `passwd` structure.

If the shell field is empty, `login(1)` automatically assigns the default shell. See `login(1)`.

Solaris 2.4 and earlier releases provided definitions of the `getpwnam_r()` and `getpwuid_r()` functions as specified in POSIX.1c Draft 6. The final POSIX.1c standard changed the interface for these functions. Support for the Draft 6 interface is provided for compatibility only and may not be supported in future releases. New applications and libraries should use the POSIX standard interface.

For POSIX.1c-compliant applications, the `_POSIX_PTHREAD_SEMANTICS` and `_REENTRANT` flags are automatically turned on by defining the `_POSIX_C_SOURCE` flag with a value $\geq 199506L$.

endspent(3C)

NAME	getspnam, getspnam_r, getspent, getspent_r, setspent, endspent, fgetspent, fgetspent_r – get password entry
SYNOPSIS	<pre>#include <shadow.h> struct spwd *getspnam(const char *name); struct spwd *getspnam_r(const char *name, struct spwd *result, char *buffer, int buflen); struct spwd *getspent(void); struct spwd *getspent_r(struct spwd *result, char *buffer, int buflen); void setspent(void); void endspent(void); struct spwd *fgetspent(FILE *fp); struct spwd *fgetspent_r(FILE *fp, struct spwd *result, char *buffer, int buflen);</pre>
DESCRIPTION	<p>These functions are used to obtain shadow password entries. An entry may come from any of the sources for shadow specified in the <code>/etc/nsswitch.conf</code> file (see <code>nsswitch.conf(4)</code>).</p> <p>The <code>getspnam()</code> function searches for a shadow password entry with the login name specified by the character string argument <i>name</i>.</p> <p>The <code>setspent()</code>, <code>getspent()</code>, and <code>endspent()</code> functions are used to enumerate shadow password entries from the database.</p> <p>The <code>setspent()</code> function sets (or resets) the enumeration to the beginning of the set of shadow password entries. This function should be called before the first call to <code>getspent()</code>. Calls to <code>getspnam()</code> leave the enumeration position in an indeterminate state.</p> <p>Successive calls to <code>getspent()</code> return either successive entries or <code>NULL</code>, indicating the end of the enumeration.</p> <p>The <code>endspent()</code> function may be called to indicate that the caller expects to do no further shadow password retrieval operations; the system may then close the shadow password file, deallocate resources it was using, and so forth. It is still allowed, but possibly less efficient, for the process to call more shadow password functions after calling <code>endspent()</code>.</p> <p>The <code>fgetspent()</code> function, unlike the other functions above, does not use <code>nsswitch.conf</code>; it reads and parses the next line from the stream <i>fp</i>, which is assumed to have the format of the shadow file (see <code>shadow(4)</code>).</p>
Reentrant Interfaces	The <code>getspnam()</code> , <code>getspent()</code> , and <code>fgetspent()</code> functions use static storage that is re-used in each call, making these routines unsafe for use in multithreaded applications.

The `getspnam_r()`, `getspent_r()`, and `fgetspent_r()` functions provide reentrant interfaces for these operations.

Each reentrant interface performs the same operation as its non-reentrant counterpart, named by removing the `_r` suffix. The reentrant interfaces, however, use buffers supplied by the caller to store returned results, and are safe for use in both single-threaded and multithreaded applications.

Each reentrant interface takes the same argument as its non-reentrant counterpart, as well as the following additional arguments. The *result* argument must be a pointer to a `struct spwd` structure allocated by the caller. On successful completion, the function returns the shadow password entry in this structure. The *buffer* argument must be a pointer to a buffer supplied by the caller. This buffer is used as storage space for the shadow password data. All of the pointers within the returned `struct spwd result` point to data stored within this buffer (see RETURN VALUES). The buffer must be large enough to hold all of the data associated with the shadow password entry. The *buflen* argument should give the size in bytes of the buffer indicated by *buffer*.

For enumeration in multithreaded applications, the position within the enumeration is a process-wide property shared by all threads. The `setspent()` function may be used in a multithreaded application but resets the enumeration position for all threads. If multiple threads interleave calls to `getspent_r()`, the threads will enumerate disjoint subsets of the shadow password database.

Like its non-reentrant counterpart, `getspnam_r()` leaves the enumeration position in an indeterminate state.

RETURN VALUES

Password entries are represented by the `struct spwd` structure defined in `<shadow.h>`:

```
struct spwd{
    char      *sp_namp;      /* login name */
    char      *sp_pwdp;     /* encrypted passwd */
    long      sp_lstchg;     /* date of last change */
    long      sp_min;       /* min days to passwd change */
    long      sp_max;       /* max days to passwd change*/
    long      sp_warn;      /* warning period */
    long      sp_inact;     /* max days inactive */
    long      sp_expire;    /* account expiry date */
    unsigned long sp_flag;  /* not used */
};
```

See `shadow(4)` for more information on the interpretation of this data.

The `getspnam()` and `getspnam_r()` functions each return a pointer to a `struct spwd` if they successfully locate the requested entry; otherwise they return `NULL`.

The `getspent()`, `getspent_r()`, `fgetspent()`, and `fgetspent_r()` functions each return a pointer to a `struct spwd` if they successfully enumerate an entry; otherwise they return `NULL`, indicating the end of the enumeration.

endspent(3C)

The `getspnam()`, `getspent()`, and `fgetspent()` functions use static storage, so returned data must be copied before a subsequent call to any of these functions if the data is to be saved.

When the pointer returned by the reentrant functions `getspnam_r()`, `getspent_r()`, and `fgetspent_r()` is non-null, it is always equal to the *result* pointer that was supplied by the caller.

ERRORS The reentrant functions `getspnam_r()`, `getspent_r()`, and `fgetspent_r()` will return NULL and set `errno` to `ERANGE` if the length of the buffer supplied by caller is not large enough to store the result. See `intro(2)` for the proper usage and interpretation of `errno` in multithreaded applications.

USAGE Applications that use the interfaces described on this manual page cannot be linked statically, since the implementations of these functions employ dynamic loading and linking of shared objects at run time.

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
MT-Level	See "Reentrant Interfaces" in <code>DESCRIPTION</code> .

SEE ALSO `nispasswd(1)`, `passwd(1)`, `yppasswd(1)`, `intro(3)` `getlogin(3C)`, `getpwnam(3C)`, `nsswitch.conf(4)`, `passwd(4)`, `shadow(4)`, `attributes(5)`

WARNINGS The reentrant interfaces `getspnam_r()`, `getspent_r()`, and `fgetspent_r()` are included in this release on an uncommitted basis only, and are subject to change or removal in future minor releases.

NOTES When compiling multithreaded applications, see `intro(3)`, *Notes On Multithreaded Applications*, for information about the use of the `_REENTRANT` flag.

Use of the enumeration interfaces `getspent()` and `getspent_r()` is not recommended; enumeration is supported for the shadow file, NIS, and NIS+, but in general is not efficient and may not be supported for all database sources. The semantics of enumeration are discussed further in `nsswitch.conf(4)`.

Access to shadow password information may be restricted in a manner depending on the database source being used. Access to the `/etc/shadow` file is generally restricted to processes running as the super-user (root). Other database sources may impose stronger or less stringent restrictions.

When NIS is used as the database source, the information for the shadow password entries is obtained from the "passwd.byname" map. This map stores only the information for the `sp_namp` and `sp_pwdp` fields of the `struct spwd` structure. Shadow password entries obtained from NIS will contain the value -1 in the remainder of the fields.

endspent(3C)

When NIS+ is used as the database source, and the caller lacks the permission needed to retrieve the encrypted password from the NIS+ "passwd.org_dir" table, the NIS+ service returns the string "*NP*" instead of the actual encrypted password string. The functions described on this page will then return the string "*NP*" to the caller as the value of the member `sp_pwdp` in the returned shadow password structure.

endusershell(3C)

NAME	getusershell, setusershell, endusershell – get legal user shells																								
SYNOPSIS	<pre>char *getusershell() void setusershell() void endusershell()</pre>																								
DESCRIPTION	<p>The <code>getusershell()</code> function returns a pointer to a legal user shell as defined by the system manager in the file <code>/etc/shells</code>. If <code>/etc/shells</code> does not exist, the following locations of the standard system shells are used in its place:</p> <table><tr><td><code>/bin/bash</code></td><td><code>/bin/csh</code></td></tr><tr><td><code>/bin/jsh</code></td><td><code>/bin/ksh</code></td></tr><tr><td><code>/bin/pfcsh</code></td><td><code>/bin/pfksh</code></td></tr><tr><td><code>/bin/pfsh</code></td><td><code>/bin/sh</code></td></tr><tr><td><code>/bin/tcsh</code></td><td><code>/bin/zsh</code></td></tr><tr><td><code>/sbin/jsh</code></td><td><code>/sbin/sh</code></td></tr><tr><td><code>/usr/bin/bash</code></td><td><code>/usr/bin/csh</code></td></tr><tr><td><code>/usr/bin/jsh</code></td><td><code>/usr/bin/ksh</code></td></tr><tr><td><code>/usr/bin/pfcsh</code></td><td><code>/usr/bin/pfksh</code></td></tr><tr><td><code>/usr/bin/pfsh</code></td><td><code>/usr/bin/sh</code></td></tr><tr><td><code>/usr/bin/tcsh</code></td><td><code>/usr/bin/zsh</code></td></tr><tr><td><code>/usr/xpg4/bin/sh</code></td><td></td></tr></table> <p>The <code>getusershell()</code> function opens the file <code>/etc/shells</code>, if it exists, and returns the next entry in the list of shells.</p> <p>The <code>setusershell()</code> function rewinds the file or the list.</p> <p>The <code>endusershell()</code> function closes the file, frees any memory used by <code>getusershell()</code> and <code>setusershell()</code>, and rewinds the file <code>/etc/shells</code>.</p>	<code>/bin/bash</code>	<code>/bin/csh</code>	<code>/bin/jsh</code>	<code>/bin/ksh</code>	<code>/bin/pfcsh</code>	<code>/bin/pfksh</code>	<code>/bin/pfsh</code>	<code>/bin/sh</code>	<code>/bin/tcsh</code>	<code>/bin/zsh</code>	<code>/sbin/jsh</code>	<code>/sbin/sh</code>	<code>/usr/bin/bash</code>	<code>/usr/bin/csh</code>	<code>/usr/bin/jsh</code>	<code>/usr/bin/ksh</code>	<code>/usr/bin/pfcsh</code>	<code>/usr/bin/pfksh</code>	<code>/usr/bin/pfsh</code>	<code>/usr/bin/sh</code>	<code>/usr/bin/tcsh</code>	<code>/usr/bin/zsh</code>	<code>/usr/xpg4/bin/sh</code>

<code>/bin/pfsh</code>	<code>/bin/sh</code>																								
<code>/bin/tcsh</code>	<code>/bin/zsh</code>																								
<code>/sbin/jsh</code>	<code>/sbin/sh</code>																								
<code>/usr/bin/bash</code>	<code>/usr/bin/csh</code>																								
<code>/usr/bin/jsh</code>	<code>/usr/bin/ksh</code>																								
<code>/usr/bin/pfcsh</code>	<code>/usr/bin/pfksh</code>																								
<code>/usr/bin/pfsh</code>	<code>/usr/bin/sh</code>																								
<code>/usr/bin/tcsh</code>	<code>/usr/bin/zsh</code>																								
<code>/usr/xpg4/bin/sh</code>																									
RETURN VALUES	The <code>getusershell()</code> function returns a null pointer on EOF.																								
BUGS	All information is contained in memory that may be freed with a call to <code>endusershell()</code> , so it must be copied if it is to be saved.																								

NAME	getutent, getutid, getutline, pututline, setutent, endument, utmpname – user accounting database functions
SYNOPSIS	<pre>#include <utmp.h> struct utmp *getutent(void); struct utmp *getutid(const struct utmp *id); struct utmp *getutline(const struct utmp *line); struct utmp *pututline(const struct utmp *utmp); void setutent(void); void endument(void); int utmpname(const char *file);</pre>
DESCRIPTION	<p>These functions provide access to the user accounting database, utmp. Entries in the database are described by the definitions and data structures in <utmp.h>.</p> <p>The utmp structure contains the following members:</p> <pre>char ut_user[8]; /* user login name */ char ut_id[4]; /* /sbin/inittab id (usually line #) */ char ut_line[12]; /* device name (console, lnxx) */ short ut_pid; /* process id */ short ut_type; /* type of entry */ struct exit_status ut_exit; /* exit status of a process */ /* marked as DEAD_PROCESS */ time_t ut_time; /* time entry was made */</pre> <p>The structure exit_status includes the following members:</p> <pre>short e_termination; /* termination status */ short e_exit; /* exit status */</pre> <p>getutent() The getutent() function reads in the next entry from a utmp database. If the database is not already open, it opens it. If it reaches the end of the database, it fails.</p> <p>getutid() The getutid() function searches forward from the current point in the utmp database until it finds an entry with a ut_type matching <i>id</i>->ut_type if the type specified is RUN_LVL, BOOT_TIME, OLD_TIME, or NEW_TIME. If the type specified in <i>id</i> is INIT_PROCESS, LOGIN_PROCESS, USER_PROCESS, or DEAD_PROCESS, then getutid() will return a pointer to the first entry whose type is one of these four and whose ut_id member matches <i>id</i>->ut_id. If the end of database is reached without a match, it fails.</p> <p>getutline() The getutline() function searches forward from the current point in the utmp database until it finds an entry of the type LOGIN_PROCESS or ut_line string matching the <i>line</i>->ut_line string. If the end of database is reached without a match, it fails.</p>

endutent(3C)

- `pututline()` | The `pututline()` function writes the supplied `utmp` structure into the `utmp` database. It uses `getutid()` to search forward for the proper place if it finds that it is not already at the proper place. It is expected that normally the user of `pututline()` will have searched for the proper entry using one of the these functions. If so, `pututline()` will not search. If `pututline()` does not find a matching slot for the new entry, it will add a new entry to the end of the database. It returns a pointer to the `utmp` structure. When called by a non-root user, `pututline()` invokes a `setuid()` root program to verify and write the entry, since the `utmp` database is normally writable only by root. In this event, the `ut_name` member must correspond to the actual user name associated with the process; the `ut_type` member must be either `USER_PROCESS` or `DEAD_PROCESS`; and the `ut_line` member must be a device special file and be writable by the user.
- `setutent()` | The `setutent()` function resets the input stream to the beginning. This reset should be done before each search for a new entry if it is desired that the entire database be examined.
- `endutent()` | The `endutent()` function closes the currently open database.
- `utmpname()` | The `utmpname()` function allows the user to change the name of the database file examined to another file. If the file does not exist, this will not be apparent until the first attempt to reference the file is made. The `utmpname()` function does not open the file but closes the old file if it is currently open and saves the new file name.

RETURN VALUES

A null pointer is returned upon failure to read, whether for permissions or having reached the end of file, or upon failure to write. If the file name given is longer than 79 characters, `utmpname()` returns 0. Otherwise, it returns 1.

USAGE

These functions use buffered standard I/O for input, but `pututline()` uses an unbuffered non-standard write to avoid race conditions between processes trying to modify the `utmp` and `wtmp` databases.

Applications should not access the `utmp` and `wtmp` databases directly, but should use these functions to ensure that these databases are maintained consistently. Using these functions, however, may cause applications to fail if user accounting data cannot be represented properly in the `utmp` structure (for example, on a system where PIDs can exceed 32767). Use the functions described on the `getutxent(3C)` manual page instead.

ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
MT-Level	Unsafe

SEE ALSO

`getutxent(3C)`, `ttyslot(3C)`, `utmpx(4)`, `attributes(5)`

NOTES | The most current entry is saved in a static structure. Multiple accesses require that it be copied before further accesses are made. On each call to either `getutid()` or `getutline()`, the function examines the static structure before performing more I/O. If the contents of the static structure match what it is searching for, it looks no further. For this reason, to use `getutline()` to search for multiple occurrences, it would be necessary to zero out the static area after each success, or `getutline()` would just return the same structure over and over again. There is one exception to the rule about emptying the structure before further reads are done. The implicit read done by `pututline()` (if it finds that it is not already at the correct place in the file) will not hurt the contents of the static structure returned by the `getutent()`, `getutid()` or `getutline()` functions, if the user has just modified those contents and passed the pointer back to `pututline()`.

endutxent(3C)

NAME	getutxent, getutxid, getutxline, pututxline, setutxent, endutxent, utmpxname, getutmp, getutmpx, updwtmp, updwtmpx – user accounting database functions
SYNOPSIS	<pre>#include <utmpx.h> struct utmpx *getutxent(void); struct utmpx *getutxid(const struct utmpx *id); struct utmpx *getutxline(const struct utmpx *line); struct utmpx *pututxline(const struct utmpx *utmpx); void setutxent(void); void endutxent(void); int utmpxname(const char *file); void getutmp(struct utmpx *utmpx, struct utmp *utmp); void getutmpx(struct utmp *utmp, struct utmpx *utmpx); void updwtmp(char *wfile, struct utmp *utmp); void updwtmpx(char *wfilex, struct utmpx *utmpx);</pre>
DESCRIPTION	<p>These functions provide access to the user accounting database, utmpx (see utmpx(4)). Entries in the database are described by the definitions and data structures in <utmpx.h>.</p> <p>The utmpx structure contains the following members:</p> <pre>char ut_user[32]; /* user login name */ char ut_id[4]; /* /etc/inittab id (usually line #) */ char ut_line[32]; /* device name (console, lnxx) */ pid_t ut_pid; /* process id */ short ut_type; /* type of entry */ struct exit_status ut_exit; /* exit status of a process */ /* marked as DEAD_PROCESS */ struct timeval ut_tv; /* time entry was made */ int ut_session; /* session ID, used for windowing */ short ut_syslen; /* significant length of ut_host */ /* including terminating null */ char ut_host[257]; /* host name, if remote */</pre> <p>The exit_status structure includes the following members:</p> <pre>short e_termination; /* termination status */ short e_exit; /* exit status */</pre>
getutxent()	The getutxent() function reads in the next entry from a utmpx database. If the database is not already open, it opens it. If it reaches the end of the database, it fails.
getutxid()	The getutxid() function searches forward from the current point in the utmpx database until it finds an entry with a ut_type matching id->ut_type, if the type specified is RUN_LVL, BOOT_TIME, OLD_TIME, or NEW_TIME. If the type specified in

	<i>id</i> is INIT_PROCESS, LOGIN_PROCESS, USER_PROCESS, or DEAD_PROCESS, then <code>getutxid()</code> will return a pointer to the first entry whose type is one of these four and whose <code>ut_id</code> member matches <i>id</i> -> <code>ut_id</code> . If the end of database is reached without a match, it fails.
<code>getutxline()</code>	The <code>getutxline()</code> function searches forward from the current point in the <code>utmpx</code> database until it finds an entry of the type LOGIN_PROCESS or USER_PROCESS which also has a <code>ut_line</code> string matching the <i>line</i> -> <code>ut_line</code> string. If the end of the database is reached without a match, it fails.
<code>pututxline()</code>	The <code>pututxline()</code> function writes the supplied <code>utmpx</code> structure into the <code>utmpx</code> database. It uses <code>getutxid()</code> to search forward for the proper place if it finds that it is not already at the proper place. It is expected that normally the user of <code>pututxline()</code> will have searched for the proper entry using one of the <code>getutx()</code> routines. If so, <code>pututxline()</code> will not search. If <code>pututxline()</code> does not find a matching slot for the new entry, it will add a new entry to the end of the database. It returns a pointer to the <code>utmpx</code> structure. When called by a non-root user, <code>pututxline()</code> invokes a <code>setuid()</code> root program to verify and write the entry, since the <code>utmpx</code> database is normally writable only by root. In this event, the <code>ut_name</code> member must correspond to the actual user name associated with the process; the <code>ut_type</code> member must be either USER_PROCESS or DEAD_PROCESS; and the <code>ut_line</code> member must be a device special file and be writable by the user.
<code>setutxent()</code>	The <code>setutxent()</code> function resets the input stream to the beginning. This should be done before each search for a new entry if it is desired that the entire database be examined.
<code>endutxent()</code>	The <code>endutxent()</code> function closes the currently open database.
<code>utmpxname()</code>	The <code>utmpxname()</code> function allows the user to change the name of the database file examined from <code>/var/adm/utmpx</code> to any other file, most often <code>/var/adm/wtmpx</code> . If the file does not exist, this will not be apparent until the first attempt to reference the file is made. The <code>utmpxname()</code> function does not open the file, but closes the old file if it is currently open and saves the new file name. The new file name must end with the "x" character to allow the name of the corresponding <code>utmp</code> file to be easily obtainable.; otherwise, an error value of 0 is returned. The function returns 1 on success.
<code>getutmp()</code>	The <code>getutmp()</code> function copies the information stored in the members of the <code>utmpx</code> structure to the corresponding members of the <code>utmp</code> structure. If the information in any member of <code>utmpx</code> does not fit in the corresponding <code>utmp</code> member, the data is silently truncated. (See <code>getutent(3C)</code> for <code>utmp</code> structure)
<code>getutmpx()</code>	The <code>getutmpx()</code> function copies the information stored in the members of the <code>utmp</code> structure to the corresponding members of the <code>utmpx</code> structure. (See <code>getutent(3C)</code> for <code>utmp</code> structure)
<code>updwtmp()</code>	The <code>updwtmp()</code> function can be used in two ways.

endutxent(3C)

If *wfile* is `/var/adm/wtmp`, the `utmp` format record supplied by the caller is converted to a `utmpx` format record and the `/var/adm/wtmpx` file is updated (because the `/var/adm/wtmp` file no longer exists, operations on `wtmp` are converted to operations on `wtmpx` by the library functions).

If *wfile* is a file other than `/var/adm/wtmp`, it is assumed to be an old file in `utmp` format and is updated directly with the `utmp` format record supplied by the caller.

`updwtmpx()` The `updwtmpx()` function writes the contents of the `utmpx` structure pointed to by *utmpx* to the database.

utmpx structure The values of the `e_termination` and `e_exit` members of the `ut_exit` structure are valid only for records of type `DEAD_PROCESS`. For `utmpx` entries created by `init(1M)`, these values are set according to the result of the `wait()` call that `init` performs on the process when the process exits. See the `wait(2)` manual page for the values `init` uses. Applications creating `utmpx` entries can set `ut_exit` values using the following code example:

```
u->ut_exit.e_termination = WTERMSIG(process->p_exit)
u->ut_exit.e_exit = WEXITSTATUS(process->p_exit)
```

See `wstat(3XFN)` for descriptions of the `WTERMSIG` and `WEXITSTATUS` macros.

The `ut_session` member is not acted upon by the operating system. It is used by applications interested in creating `utmpx` entries.

For records of type `USER_PROCESS`, the `nonuser()` and `nonuserx()` macros use the value of the `ut_exit.e_exit` member to mark `utmpx` entries as real logins (as opposed to multiple `xterms` started by the same user on a window system). This allows the system utilities that display users to obtain an accurate indication of the number of actual users, while still permitting each `pty` to have a `utmpx` record (as most applications expect.). The `NONROOT_USER` macro defines the value that `login` places in the `ut_exit.e_exit` member.

RETURN VALUES Upon successful completion, `getutxent()`, `getutxid()`, and `getutxline()` each return a pointer to a `utmpx` structure containing a copy of the requested entry in the user accounting database. Otherwise a null pointer is returned.

The return value may point to a static area which is overwritten by a subsequent call to `getutxid()` or `getutxline()`.

Upon successful completion, `pututxline()` returns a pointer to a `utmpx` structure containing a copy of the entry added to the user accounting database. Otherwise a null pointer is returned.

The `endutxent()` and `setutxent()` functions return no value.

A null pointer is returned upon failure to read, whether for permissions or having reached the end of file, or upon failure to write.

USAGE These functions use buffered standard I/O for input, but `pututxline()` uses an unbuffered write to avoid race conditions between processes trying to modify the `utmpx` and `wtmpx` files.

Applications should not access the `utmpx` and `wtmpx` databases directly, but should use these functions to ensure that these databases are maintained consistently.

NOTES The most current entry is saved in a static structure. Multiple accesses require that it be copied before further accesses are made. On each call to either `getutxid()` or `getutxline()`, the routine examines the static structure before performing more I/O. If the contents of the static structure match what it is searching for, it looks no further. For this reason, to use `getutxline()` to search for multiple occurrences it would be necessary to zero out the static after each success, or `getutxline()` would just return the same structure over and over again. There is one exception to the rule about emptying the structure before further reads are done. The implicit read done by `pututxline()` (if it finds that it is not already at the correct place in the file) will not hurt the contents of the static structure returned by the `getutxent()`, `getutxid()`, or `getutxline()` routines, if the user has just modified those contents and passed the pointer back to `pututxline()`.

erand48(3C)

NAME	drand48, erand48, lrand48, nrand48, mrand48, jrand48, srand48, seed48, lcong48 – generate uniformly distributed pseudo-random numbers
SYNOPSIS	<pre>#include <stdlib.h> double drand48(void); double erand48(unsigned short <i>x_i[3]</i>); long lrand48(void); long nrand48(unsigned short <i>x_i[3]</i>); long mrand48(void); long jrand48(unsigned short <i>x_i[3]</i>); void srand48(long <i>seedval</i>); unsigned short *seed48(unsigned short <i>seed16v[3]</i>); void lcong48(unsigned short <i>param[7]</i>);</pre>
DESCRIPTION	<p>This family of functions generates pseudo-random numbers using the well-known linear congruential algorithm and 48-bit integer arithmetic.</p> <p>Functions <code>drand48()</code> and <code>erand48()</code> return non-negative double-precision floating-point values uniformly distributed over the interval [0.0, 1.0).</p> <p>Functions <code>lrand48()</code> and <code>nrand48()</code> return non-negative long integers uniformly distributed over the interval $[0, 2^{31}]$.</p> <p>Functions <code>mrand48()</code> and <code>jrand48()</code> return signed long integers uniformly distributed over the interval $[-2^{31}, 2^{31}]$.</p> <p>Functions <code>srand48()</code>, <code>seed48()</code>, and <code>lcong48()</code> are initialization entry points, one of which should be invoked before either <code>drand48()</code>, <code>lrand48()</code>, or <code>mrand48()</code> is called. (Although it is not recommended practice, constant default initializer values will be supplied automatically if <code>drand48()</code>, <code>lrand48()</code>, or <code>mrand48()</code> is called without a prior call to an initialization entry point.) Functions <code>erand48()</code>, <code>nrand48()</code>, and <code>jrand48()</code> do not require an initialization entry point to be called first.</p> <p>All the routines work by generating a sequence of 48-bit integer values, X_i, according to the linear congruential formula</p> $X_{n+1} = (aX_n + c) \bmod m \quad n \geq 0.$ <p>The parameter $m = 2^{48}$; hence 48-bit integer arithmetic is performed. Unless <code>lcong48()</code> has been invoked, the multiplier value a and the addend value c are given by</p> $a = 5DEECE66D_{16} = 273673163155_8$

$c = B_{16} = 13_8$.

The value returned by any of the functions `drand48()`, `erand48()`, `lrand48()`, `nrand48()`, `mrnd48()`, or `jrand48()` is computed by first generating the next 48-bit X_i in the sequence. Then the appropriate number of bits, according to the type of data item to be returned, are copied from the high-order (leftmost) bits of X_i and transformed into the returned value.

The functions `drand48()`, `lrand48()`, and `mrnd48()` store the last 48-bit X_i generated in an internal buffer. X_i must be initialized prior to being invoked. The functions `erand48()`, `nrand48()`, and `jrand48()` require the calling program to provide storage for the successive X_i values in the array specified as an argument when the functions are invoked. These routines do not have to be initialized; the calling program must place the desired initial value of X_i into the array and pass it as an argument. By using different arguments, functions `erand48()`, `nrand48()`, and `jrand48()` allow separate modules of a large program to generate several *independent* streams of pseudo-random numbers, that is, the sequence of numbers in each stream will *not* depend upon how many times the routines have been called to generate numbers for the other streams.

The initializer function `srand48()` sets the high-order 32 bits of X_i to the 32 bits contained in its argument. The low-order 16 bits of X_i are set to the arbitrary value $330E_{16}$.

The initializer function `seed48()` sets the value of X_i to the 48-bit value specified in the argument array. In addition, the previous value of X_i is copied into a 48-bit internal buffer, used only by `seed48()`, and a pointer to this buffer is the value returned by `seed48()`. This returned pointer, which can just be ignored if not needed, is useful if a program is to be restarted from a given point at some future time — use the pointer to get at and store the last X_i value, and then use this value to reinitialize using `seed48()` when the program is restarted.

The initialization function `lcg48()` allows the user to specify the initial X_i , the multiplier value a , and the addend value c . Argument array elements `param[0-2]` specify X_i , `param[3-5]` specify the multiplier a , and `param[6]` specifies the 16-bit addend c . After `lcg48()` has been called, a subsequent call to either `srand48()` or `seed48()` will restore the “standard” multiplier and addend values, a and c , specified above.

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
MT-Level	Safe

SEE ALSO `rand(3C)`, `attributes(5)`

errno(3C)

NAME	perror, errno – print system error messages				
SYNOPSIS	<pre>#include <stdio.h> void perror(const char *s); #include <errno.h> int errno;</pre>				
DESCRIPTION	The <code>perror()</code> function produces a message on the standard error output (file descriptor 2) describing the last error encountered during a call to a system or library function. The argument string <code>s</code> is printed, followed by a colon and a blank, followed by the message and a NEWLINE character. If <code>s</code> is a null pointer or points to a null string, the colon is not printed. The argument string should include the name of the program that incurred the error. The error number is taken from the external variable <code>errno</code> , which is set when errors occur but not cleared when non-erroneous calls are made. See <code>intro(2)</code> .				
USAGE	If the application is linked with <code>-lintl</code> , then messages printed from this function are in the native language specified by the <code>LC_MESSAGES</code> locale category. See <code>setlocale(3C)</code> .

exit(3C)

NAME exit, _exithandle – terminate process

SYNOPSIS #include <stdlib.h>

```
void exit(int status);  
void _exithandle(void);
```

DESCRIPTION The `exit()` function terminates a process by calling first `_exithandle()` and then `_exit()` (see `exit(2)`).

The `_exithandle()` function calls any functions registered through the `atexit(3C)` function in the reverse order of their registration. This action includes executing all finalization code from the `.fini` sections of all objects that are part of the process.

The `_exithandle()` function is intended for use *only* with `_exit()`, and allows for specialized processing such as `dldump(3DL)` to be performed. Normal process execution should not be continued after a call to `_exithandle()` has occurred, as internal data structures may have been torn down due to `atexit()` or `.fini` processing.

The symbols `EXIT_SUCCESS` and `EXIT_FAILURE` are defined in the header `<stdlib.h>` and may be used as the value of `status` to indicate successful or unsuccessful termination, respectively.

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
MT-Level	Safe

SEE ALSO `exit(2)`, `atexit(3C)`, `dldump(3DL)`, `attributes(5)`

NAME | exit, _exithandle – terminate process

SYNOPSIS | #include <stdlib.h>
 void **exit**(int *status*) ;
 void **_exithandle**(void) ;

DESCRIPTION | The `exit()` function terminates a process by calling first `_exithandle()` and then `_exit()` (see `exit(2)`).

The `_exithandle()` function calls any functions registered through the `atexit(3C)` function in the reverse order of their registration. This action includes executing all finalization code from the `.fini` sections of all objects that are part of the process.

The `_exithandle()` function is intended for use *only* with `_exit()`, and allows for specialized processing such as `dldump(3DL)` to be performed. Normal process execution should not be continued after a call to `_exithandle()` has occurred, as internal data structures may have been torn down due to `atexit()` or `.fini` processing.

The symbols `EXIT_SUCCESS` and `EXIT_FAILURE` are defined in the header `<stdlib.h>` and may be used as the value of `status` to indicate successful or unsuccessful termination, respectively.

ATTRIBUTES | See `attributes(5)` for descriptions of the following attributes:

extended_to_decimal(3C)

NAME	floating_to_decimal, single_to_decimal, double_to_decimal, extended_to_decimal, quadruple_to_decimal – convert floating-point value to decimal record
SYNOPSIS	<pre>#include <floatingpoint.h> void single_to_decimal(single *px, decimal_mode *pm, decimal_record *pd, fp_exception_field_type *ps); void double_to_decimal(double *px, decimal_mode *pm, decimal_record *pd, fp_exception_field_type *ps); void extended_to_decimal(extended *px, decimal_mode *pm, decimal_record *pd, fp_exception_field_type *ps); void quadruple_to_decimal(quadruple *px, decimal_mode *pm, decimal_record *pd, fp_exception_field_type *ps);</pre>
DESCRIPTION	<p>The <code>floating_to_decimal()</code> functions convert the floating-point value at <code>*px</code> into a decimal record at <code>*pd</code>, observing the modes specified in <code>*pm</code> and setting exceptions in <code>*ps</code>. If there are no IEEE exceptions, <code>*ps</code> will be zero.</p> <p>If <code>*px</code> is zero, infinity, or NaN, then only <code>pd->sign</code> and <code>pd->fpclass</code> are set. Otherwise <code>pd->exponent</code> and <code>pd->ds</code> are also set so that</p> <p>$(\text{sig}) * (\text{pd}->\text{ds}) * 10^{(\text{pd}->\text{exponent})}$ is a correctly rounded approximation to <code>*px</code>, where <code>sig</code> is +1 or -1, depending upon whether <code>pd->sign</code> is 0 or -1. <code>pd->ds</code> has at least one and no more than <code>DECIMAL_STRING_LENGTH-1</code> significant digits because one character is used to terminate the string with a NULL.</p> <p><code>pd->ds</code> is correctly rounded according to the IEEE rounding modes in <code>pm->rd</code>. <code>*ps</code> has <code>fp_inexact</code> set if the result was inexact, and has <code>fp_overflow</code> set if the string result does not fit in <code>pd->ds</code> because of the limitation <code>DECIMAL_STRING_LENGTH</code>.</p> <p>If <code>pm->df == floating_form</code>, then <code>pd->ds</code> always contains <code>pm->ndigits</code> significant digits. Thus if <code>*px == 12.34</code> and <code>pm->ndigits == 8</code>, then <code>pd->ds</code> will contain 12340000 and <code>pd->exponent</code> will contain -6.</p> <p>If <code>pm->df == fixed_form</code> and <code>pm->ndigits >= 0</code>, then <code>pd->ds</code> always contains <code>pm->ndigits</code> after the point and as many digits as necessary before the point. Since the latter is not known in advance, the total number of digits required is returned in <code>pd->ndigits</code>; if that number <code>>= DECIMAL_STRING_LENGTH</code>, then <code>ds</code> is undefined. <code>pd->exponent</code> always gets <code>-pm->ndigits</code>. Thus if <code>*px == 12.34</code> and <code>pm->ndigits == 1</code>, then <code>pd->ds</code> gets 123, <code>pd->exponent</code> gets -1, and <code>pd->ndigits</code> gets 3.</p> <p>If <code>pm->df == fixed_form</code> and <code>pm->ndigits < 0</code>, then <code>pd->ds</code> always contains <code>-pm->ndigits</code> trailing zeros; in other words, rounding occurs <code>-pm->ndigits</code> to the left of the decimal point, but the digits rounded away are retained as zeros. The total number of digits required is in <code>pd->ndigits</code>. <code>pd->exponent</code> always gets 0. Thus if <code>*px == 12.34</code> and <code>pm->ndigits == -1</code>, then <code>pd->ds</code> gets 10, <code>pd->exponent</code> gets 0, and <code>pd->ndigits</code> gets 2.</p> <p><code>pd->more</code> is not used.</p>

extended_to_decimal(3C)

econvert(3C), fconvert(3C), gconvert(3C), printf(3C), and sprintf(3C) all use double_to_decimal().

fattach(3C)

NAME	fattach – attach a STREAMS-based file descriptor to an object in the file system name space																				
SYNOPSIS	<pre>#include <stropts.h> int fattach(int <i>fildev</i>, const char *<i>path</i>);</pre>																				
DESCRIPTION	<p>The <code>fattach()</code> function attaches a STREAMS-based file descriptor to an object in the file system name space, effectively associating a name with <i>fildev</i>. <i>fildev</i> must be a valid open file descriptor representing a STREAMS file. <i>path</i> is a path name of an existing object and the user must have appropriate privileges or be the owner of the file and have write permissions. All subsequent operations on <i>path</i> will operate on the STREAMS file until the STREAMS file is detached from the node. <i>fildev</i> can be attached to more than one <i>path</i>, that is, a stream can have several names associated with it.</p> <p>The attributes of the named stream (see <code>stat(2)</code>), are initialized as follows: the permissions, user ID, group ID, and times are set to those of <i>path</i>, the number of links is set to 1, and the size and device identifier are set to those of the streams device associated with <i>fildev</i>. If any attributes of the named stream are subsequently changed (for example, <code>chmod(2)</code>), the attributes of the underlying object are not affected.</p>																				
RETURN VALUES	Upon successful completion, <code>fattach()</code> returns 0. Otherwise it returns -1 and sets <code>errno</code> to indicate an error.																				
ERRORS	<p>The <code>fattach()</code> function will fail if:</p> <table><tr><td>EACCES</td><td>The user is the owner of <i>path</i> but does not have write permissions on <i>path</i> or <i>fildev</i> is locked.</td></tr><tr><td>EBADF</td><td>The <i>fildev</i> argument is not a valid open file descriptor.</td></tr><tr><td>EBUSY</td><td>The <i>path</i> argument is currently a mount point or has a STREAMS file descriptor attached it.</td></tr><tr><td>EINVAL</td><td>The <i>path</i> argument is a file in a remotely mounted directory.</td></tr><tr><td>EINVAL</td><td>The <i>fildev</i> argument does not represent a STREAMS file.</td></tr><tr><td>ELOOP</td><td>Too many symbolic links were encountered in translating <i>path</i>.</td></tr><tr><td>ENAMETOOLONG</td><td>The size of <i>path</i> exceeds <code>{PATH_MAX}</code>, or the component of a path name is longer than <code>{NAME_MAX}</code> while <code>{_POSIX_NO_TRUNC}</code> is in effect.</td></tr><tr><td>ENOENT</td><td>The <i>path</i> argument does not exist.</td></tr><tr><td>ENOTDIR</td><td>A component of a path prefix is not a directory.</td></tr><tr><td>EPERM</td><td>The effective user ID is not the owner of <i>path</i> or a user with the appropriate privileges.</td></tr></table>	EACCES	The user is the owner of <i>path</i> but does not have write permissions on <i>path</i> or <i>fildev</i> is locked.	EBADF	The <i>fildev</i> argument is not a valid open file descriptor.	EBUSY	The <i>path</i> argument is currently a mount point or has a STREAMS file descriptor attached it.	EINVAL	The <i>path</i> argument is a file in a remotely mounted directory.	EINVAL	The <i>fildev</i> argument does not represent a STREAMS file.	ELOOP	Too many symbolic links were encountered in translating <i>path</i> .	ENAMETOOLONG	The size of <i>path</i> exceeds <code>{PATH_MAX}</code> , or the component of a path name is longer than <code>{NAME_MAX}</code> while <code>{_POSIX_NO_TRUNC}</code> is in effect.	ENOENT	The <i>path</i> argument does not exist.	ENOTDIR	A component of a path prefix is not a directory.	EPERM	The effective user ID is not the owner of <i>path</i> or a user with the appropriate privileges.
EACCES	The user is the owner of <i>path</i> but does not have write permissions on <i>path</i> or <i>fildev</i> is locked.																				
EBADF	The <i>fildev</i> argument is not a valid open file descriptor.																				
EBUSY	The <i>path</i> argument is currently a mount point or has a STREAMS file descriptor attached it.																				
EINVAL	The <i>path</i> argument is a file in a remotely mounted directory.																				
EINVAL	The <i>fildev</i> argument does not represent a STREAMS file.																				
ELOOP	Too many symbolic links were encountered in translating <i>path</i> .																				
ENAMETOOLONG	The size of <i>path</i> exceeds <code>{PATH_MAX}</code> , or the component of a path name is longer than <code>{NAME_MAX}</code> while <code>{_POSIX_NO_TRUNC}</code> is in effect.																				
ENOENT	The <i>path</i> argument does not exist.																				
ENOTDIR	A component of a path prefix is not a directory.																				
EPERM	The effective user ID is not the owner of <i>path</i> or a user with the appropriate privileges.

STREAMS Programming Guide

__fbufsize(3C)

NAME	<code>__fbufsize</code> , <code>__flbf</code> , <code>__fpending</code> , <code>__fpurge</code> , <code>__freadable</code> , <code>__freading</code> , <code>__fsetlocking</code> , <code>__fwritable</code> , <code>__fwriting</code> , <code>_flushlbf</code> – interfaces to <code>stdio</code> FILE structure
SYNOPSIS	<pre>#include <stdio.h> #include <stdio_ext.h> size_t __fbufsiz(FILE *stream); int __flbf(FILE *stream); size_t __fpending(FILE *stream); void __fpurge(FILE *stream); int __freadable(FILE *stream); int __freading(FILE *stream); int __fsetlocking(FILE *stream, int type); int __fwritable(FILE *stream); int __fwriting(FILE *stream); void _flushlbf(void);</pre>
DESCRIPTION	<p>These functions provide portable access to the members of the <code>stdio(3C)</code> FILE structure.</p> <p>The <code>__fbufsize()</code> function returns in bytes the size of the buffer currently in use by the given stream.</p> <p>The <code>__flbf()</code> function returns non-zero if the stream is line-buffered.</p> <p>The <code>__fpending</code> function returns in bytes the amount of output pending on a stream.</p> <p>The <code>__fpurge()</code> function discards any pending buffered I/O on the stream.</p> <p>The <code>__freadable()</code> function returns non-zero if it is possible to read from a stream.</p> <p>The <code>__freading()</code> function returns non-zero if the file is open readonly, or if the last operation on the stream was a read operation such as <code>fread(3C)</code> or <code>fgetc(3C)</code>. Otherwise it returns 0.</p> <p>The <code>__fsetlocking()</code> function allows the type of locking performed by <code>stdio</code> on a given stream to be controlled by the programmer.</p> <p>If <code>type</code> is <code>FSETLOCKING_INTERNAL</code>, <code>stdio</code> performs implicit locking around every operation on the given stream. This is the default system behavior on that stream.</p> <p>If <code>type</code> is <code>FSETLOCKING_BYCALLER</code>, <code>stdio</code> assumes that the caller is responsible for maintaining the integrity of the stream in the face of access by multiple threads. If there is only one thread accessing the stream, nothing further needs to be done. If multiple threads are accessing the stream, then the caller can use the <code>flockfile()</code>,</p>

__fbufsize(3C)

funlockfile(), and ftrylockfile() functions described on the flockfile(3C) manual page to provide the appropriate locking. In both this and the case where *type* is FSETLOCKING_INTERNAL, __fsetlocking() returns the previous state of the stream.

If *type* is FSETLOCKING_QUERY, __fsetlocking() returns the current state of the stream without changing it.

The __fwritable() function returns non-zero if it is possible to write on a stream.

The __fwriting() function returns non-zero if the file is open write-only or append-only, or if the last operation on the stream was a write operation such as fwrite(3C) or fputc(3C). Otherwise it returns 0.

The _flushlbf() function flushes all line-buffered files. It is used when reading from a line-buffered file.

USAGE

Although the contents of the `stdio` FILE structure have always been private to the `stdio` implementation, some applications have needed to obtain information about a `stdio` stream that was not accessible through a supported interface. These applications have resorted to accessing fields of the FILE structure directly, rendering them possibly non-portable to new implementations of `stdio`, or more likely, preventing enhancements to `stdio` that would cause those applications to break.

In the 64-bit environment, the FILE structure is opaque. The functions described here are provided as a means of obtaining the information that up to now has been retrieved directly from the FILE structure. Because they are based on the needs of existing applications (such as `mh` and `emacs`), they may be extended as other programs are ported. Although they may still be non-portable to other operating systems, they will be compatible from each Solaris release to the next. Interfaces that are more portable are under development.

ATTRIBUTES

fclose(3C)

NAME	fclose – close a stream																
SYNOPSIS	<pre>#include <stdio.h> int fclose(FILE *<i>stream</i>);</pre>																
DESCRIPTION	<p>The <code>fclose()</code> function causes the stream pointed to by <i>stream</i> to be flushed and the associated file to be closed. Any unwritten buffered data for the stream is written to the file; any unread buffered data is discarded. The stream is disassociated from the file. If the associated buffer was automatically allocated, it is deallocated.</p> <p>The <code>fclose()</code> function marks for update the <code>st_ctime</code> and <code>st_mtime</code> fields of the underlying file if the stream is writable and if buffered data has not yet been written to the file. It will perform a <code>close(2)</code> operation on the file descriptor that is associated with the stream pointed to by <i>stream</i>.</p> <p>After the call to <code>fclose()</code>, any use of <i>stream</i> causes undefined behavior.</p> <p>The <code>fclose()</code> function is performed automatically for all open files upon calling <code>exit(2)</code>.</p>																
RETURN VALUES	Upon successful completion, <code>fclose()</code> returns 0. Otherwise, it returns EOF and sets <code>errno</code> to indicate the error.																
ERRORS	<p>The <code>fclose()</code> function will fail if:</p> <table><tr><td>EAGAIN</td><td>The <code>O_NONBLOCK</code> flag is set for the file descriptor underlying <i>stream</i> and the process would be delayed in the write operation.</td></tr><tr><td>EBADF</td><td>The file descriptor underlying stream is not valid.</td></tr><tr><td>EFBIG</td><td>An attempt was made to write a file that exceeds the maximum file size or the process's file size limit; or the file is a regular file and an attempt was made to write at or beyond the offset maximum associated with the corresponding stream.</td></tr><tr><td>EINTR</td><td>The <code>fclose()</code> function was interrupted by a signal.</td></tr><tr><td>EIO</td><td>The process is a member of a background process group attempting to write to its controlling terminal, <code>TOSTOP</code> is set, the process is neither ignoring nor blocking <code>SIGTTOU</code> and the process group of the process is orphaned.</td></tr><tr><td>ENOSPC</td><td>There was no free space remaining on the device containing the file.</td></tr><tr><td>EPIPE</td><td>An attempt is made to write to a pipe or FIFO that is not open for reading by any process. A <code>SIGPIPE</code> signal will also be sent to the process.</td></tr></table> <p>The <code>fclose()</code> function may fail if:</p> <table><tr><td>ENXIO</td><td>A request was made of a non-existent device, or the request was beyond the limits of the device.</td></tr></table>	EAGAIN	The <code>O_NONBLOCK</code> flag is set for the file descriptor underlying <i>stream</i> and the process would be delayed in the write operation.	EBADF	The file descriptor underlying stream is not valid.	EFBIG	An attempt was made to write a file that exceeds the maximum file size or the process's file size limit; or the file is a regular file and an attempt was made to write at or beyond the offset maximum associated with the corresponding stream.	EINTR	The <code>fclose()</code> function was interrupted by a signal.	EIO	The process is a member of a background process group attempting to write to its controlling terminal, <code>TOSTOP</code> is set, the process is neither ignoring nor blocking <code>SIGTTOU</code> and the process group of the process is orphaned.	ENOSPC	There was no free space remaining on the device containing the file.	EPIPE	An attempt is made to write to a pipe or FIFO that is not open for reading by any process. A <code>SIGPIPE</code> signal will also be sent to the process.	ENXIO	A request was made of a non-existent device, or the request was beyond the limits of the device.
EAGAIN	The <code>O_NONBLOCK</code> flag is set for the file descriptor underlying <i>stream</i> and the process would be delayed in the write operation.																
EBADF	The file descriptor underlying stream is not valid.																
EFBIG	An attempt was made to write a file that exceeds the maximum file size or the process's file size limit; or the file is a regular file and an attempt was made to write at or beyond the offset maximum associated with the corresponding stream.																
EINTR	The <code>fclose()</code> function was interrupted by a signal.																
EIO	The process is a member of a background process group attempting to write to its controlling terminal, <code>TOSTOP</code> is set, the process is neither ignoring nor blocking <code>SIGTTOU</code> and the process group of the process is orphaned.

fconvert(3C)

NAME	<code>econvert</code> , <code>fconvert</code> , <code>gconvert</code> , <code>seconvert</code> , <code>sfconvert</code> , <code>sgconvert</code> , <code>qeconvert</code> , <code>qfconvert</code> , <code>qgconvert</code> – output conversion
SYNOPSIS	<pre>#include <floatingpoint.h> char *econvert(double value, int ndigit, int *decpt, int *sign, char *buf) ; char *fconvert(double value, int ndigit, int *decpt, int *sign, char *buf) ; char *gconvert(double value, int ndigit, int trailing, char *buf) ; char *seconvert(single *value, int ndigit, int *decpt, int *sign, char *buf) ; char *sfconvert(single *value, int ndigit, int *decpt, int *sign, char *buf) ; char *sgconvert(single *value, int ndigit, int trailing, char *buf) ; char *qeconvert(quadruple *value, int ndigit, int *decpt, int *sign, char *buf) ; char *qfconvert(quadruple *value, int ndigit, int *decpt, int *sign, char *buf) ; char *qgconvert(quadruple *value, int ndigit, int trailing, char *buf) ;</pre>
DESCRIPTION	<p>The <code>econvert()</code> function converts the <i>value</i> to a null-terminated string of <i>ndigit</i> ASCII digits in <i>buf</i> and returns a pointer to <i>buf</i>. <i>buf</i> should contain at least <i>ndigit</i>+1 characters. The position of the decimal point relative to the beginning of the string is stored indirectly through <i>decpt</i>. Thus <i>buf</i> == "314" and <i>*decpt</i> == 1 corresponds to the numerical value 3.14, while <i>buf</i> == "314" and <i>*decpt</i> == -1 corresponds to the numerical value .0314. If the sign of the result is negative, the word pointed to by <i>sign</i> is nonzero; otherwise it is zero. The least significant digit is rounded.</p> <p>The <code>fconvert()</code> function works much like <code>econvert()</code>, except that the correct digit has been rounded as if for <code>sprintf(%w.nf)</code> output with <i>n</i>=<i>ndigit</i> digits to the right of the decimal point. <i>ndigit</i> can be negative to indicate rounding to the left of the decimal point. The return value is a pointer to <i>buf</i>. <i>buf</i> should contain at least <code>310+max(0,ndigit)</code> characters to accomodate any double-precision <i>value</i>.</p> <p>The <code>gconvert()</code> function converts the <i>value</i> to a null-terminated ASCII string in <i>buf</i> and returns a pointer to <i>buf</i>. It produces <i>ndigit</i> significant digits in fixed-decimal format, like <code>sprintf(%w.nf)</code>, if possible, and otherwise in floating-decimal format, like <code>sprintf(%w.ne)</code>; in either case <i>buf</i> is ready for printing, with sign and exponent. The result corresponds to that obtained by</p> <pre>(void) sprintf(buf, ``%w.ng'', value) ;</pre> <p>If <i>trailing</i> = 0, trailing zeros and a trailing point are suppressed, as in <code>sprintf(%g)</code>. If <i>trailing</i> != 0, trailing zeros and a trailing point are retained, as in <code>sprintf(%#g)</code>.</p>

The `seconvert()`, `sfconvert()`, and `sgconvert()` functions are single-precision versions of these functions, and are more efficient than the corresponding double-precision versions. A pointer rather than the value itself is passed to avoid C's usual conversion of single-precision arguments to double.

The `geconvert()`, `qfconvert()`, and `ggconvert()` functions are quadruple-precision versions of these functions. The `qfconvert()` function can overflow the `decimal_record` field `ds` if `value` is too large. In that case, `buf[0]` is set to zero.

The `ecvt()`, `fcvt()` and `gcvt()` functions are versions of `econvert()`, `fconvert()`, and `gconvert()`, respectively, that are documented on the `ecvt(3C)` manual page. They constitute the default implementation of these functions and conform to the X/Open CAE Specification, System Interfaces and Headers, Issue 4, Version 2.

USAGE IEEE Infinities and NaNs are treated similarly by these functions. "NaN" is returned for NaN, and "Inf" or "Infinity" for Infinity. The longer form is produced when `ndigit` \geq 8.

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

fcvt(3C)

NAME	ecvt, fcvt, gcvt – convert floating-point number to string
SYNOPSIS	<pre>#include <stdlib.h> char *ecvt(double value, int ndigit, int *decpt, int *sign); char *fcvt(double value, int ndigit, int *decpt, int *sign); char *gcvt(double value, int ndigit, char *buf);</pre>
DESCRIPTION	<p>The <code>ecvt()</code>, <code>fcvt()</code> and <code>gcvt()</code> functions convert floating-point numbers to null-terminated strings.</p> <p><code>ecvt()</code> The <code>ecvt()</code> function converts <i>value</i> to a null-terminated string of <i>ndigit</i> digits (where <i>ndigit</i> is reduced to an unspecified limit determined by the precision of a <code>double</code>) and returns a pointer to the string. The high-order digit is non-zero, unless the value is 0. The low-order digit is rounded. The position of the radix character relative to the beginning of the string is stored in the integer pointed to by <i>decpt</i> (negative means to the left of the returned digits). The radix character is not included in the returned string. If the sign of the result is negative, the integer pointed to by <i>sign</i> is non-zero, otherwise it is 0.</p> <p>If the converted value is out of range or is not representable, the contents of the returned string are unspecified.</p> <p><code>fcvt()</code> The <code>fcvt()</code> function is identical to <code>ecvt()</code> except that <i>ndigit</i> specifies the number of digits desired after the radix point. The total number of digits in the result string is restricted to an unspecified limit as determined by the precision of a <code>double</code>.</p> <p><code>gcvt()</code> The <code>gcvt()</code> function converts <i>value</i> to a null-terminated string (similar to that of the <code>%g</code> format of <code>printf(3C)</code>) in the array pointed to by <i>buf</i> and returns <i>buf</i>. It produces <i>ndigit</i> significant digits (limited to an unspecified value determined by the precision of a <code>double</code>) in <code>%f</code> if possible, or <code>%e</code> (scientific notation) otherwise. A minus sign is included in the returned string if <i>value</i> is less than 0. A radix character is included in the returned string if <i>value</i> is not a whole number. Trailing zeros are suppressed where <i>value</i> is not a whole number. The radix character is determined by the current locale. If <code>setlocale(3C)</code> has not been called successfully, the default locale, <code>POSIX</code>, is used. The default locale specifies a period (<code>.</code>) as the radix character. The <code>LC_NUMERIC</code> category determines the value of the radix character within the current locale.</p>
RETURN VALUES	<p>The <code>ecvt()</code> and <code>fcvt()</code> functions return a pointer to a null-terminated string of digits.</p> <p>The <code>gcvt()</code> function returns <i>buf</i>.</p>
ERRORS	No errors are defined.
USAGE	<p>The return values from <code>ecvt()</code> and <code>fcvt()</code> may point to static data which may be overwritten by subsequent calls to these functions.</p> <p>For portability to implementations conforming to earlier versions of this document, <code>sprintf(3C)</code> is preferred over this function.</p>

FD_CLR(3C)

NAME	<code>select</code> , <code>FD_SET</code> , <code>FD_CLR</code> , <code>FD_ISSET</code> , <code>FD_ZERO</code> – synchronous I/O multiplexing
SYNOPSIS	<pre>#include <sys/time.h> int select(int <i>nfds</i>, fd_set *<i>readfds</i>, fd_set *<i>writefds</i>, fd_set *<i>errorfds</i>, struct timeval *<i>timeout</i>); void FD_SET(int <i>fd</i>, fd_set *<i>fdset</i>); void FD_CLR(int <i>fd</i>, fd_set *<i>fdset</i>); int FD_ISSET(int <i>fd</i>, fd_set *<i>fdset</i>); void FD_ZERO(fd_set *<i>fdset</i>);</pre>
DESCRIPTION	<p>The <code>select()</code> function indicates which of the specified file descriptors is ready for reading, ready for writing, or has an error condition pending. If the specified condition is false for all of the specified file descriptors, <code>select()</code> blocks, up to the specified timeout interval, until the specified condition is true for at least one of the specified file descriptors.</p> <p>The <code>select()</code> function supports regular files, terminal and pseudo-terminal devices, STREAMS-based files, FIFOs and pipes. The behavior of <code>select()</code> on file descriptors that refer to other types of file is unspecified.</p> <p>The <i>nfds</i> argument specifies the range of file descriptors to be tested. The <code>select()</code> function tests file descriptors in the range of 0 to <i>nfds</i>-1.</p> <p>If the <i>readfds</i> argument is not a null pointer, it points to an object of type <code>fd_set</code> that on input specifies the file descriptors to be checked for being ready to read, and on output indicates which file descriptors are ready to read.</p> <p>If the <i>writefds</i> argument is not a null pointer, it points to an object of type <code>fd_set</code> that on input specifies the file descriptors to be checked for being ready to write, and on output indicates which file descriptors are ready to write.</p> <p>If the <i>errorfds</i> argument is not a null pointer, it points to an object of type <code>fd_set</code> that on input specifies the file descriptors to be checked for error conditions pending, and on output indicates which file descriptors have error conditions pending.</p> <p>On successful completion, the objects pointed to by the <i>readfds</i>, <i>writefds</i>, and <i>errorfds</i> arguments are modified to indicate which file descriptors are ready for reading, ready for writing, or have an error condition pending, respectively. For each file descriptor less than <i>nfds</i>, the corresponding bit will be set on successful completion if it was set on input and the associated condition is true for that file descriptor.</p> <p>If the <i>timeout</i> argument is not a null pointer, it points to an object of type <code>struct timeval</code> that specifies a maximum interval to wait for the selection to complete. If the <i>timeout</i> argument points to an object of type <code>struct timeval</code> whose members are 0, <code>select()</code> does not block. If the <i>timeout</i> argument is a null pointer, <code>select()</code> blocks</p>

until an event causes one of the masks to be returned with a valid (non-zero) value. If the time limit expires before any event occurs that would cause one of the masks to be set to a non-zero value, `select()` completes successfully and returns 0.

If the *readfs*, *writes*, and *errorfds* arguments are all null pointers and the *timeout* argument is not a null pointer, `select()` blocks for the time specified, or until interrupted by a signal. If the *readfs*, *writes*, and *errorfds* arguments are all null pointers and the *timeout* argument is a null pointer, `select()` blocks until interrupted by a signal.

File descriptors associated with regular files always select true for ready to read, ready to write, and error conditions.

On failure, the objects pointed to by the *readfs*, *writes*, and *errorfds* arguments are not modified. If the timeout interval expires without the specified condition being true for any of the specified file descriptors, the objects pointed to by the *readfs*, *writes*, and *errorfds* arguments have all bits set to 0.

A file descriptor for a socket that is listening for connections will indicate that it is ready for reading, when connections are available. A file descriptor for a socket that is connecting asynchronously will indicate that it is ready for writing, when a connection has been established.

Selecting true for reading on a socket descriptor upon which a `listen(3SOCKET)` call has been performed indicates that a subsequent `accept(3SOCKET)` call on that descriptor will not block.

File descriptor masks of type `fd_set` can be initialized and tested with the macros `FD_CLR()`, `FD_ISSET()`, `FD_SET()`, and `FD_ZERO()`.

<code>FD_CLR(<i>fd</i>, &<i>fdset</i>)</code>	Clears the bit for the file descriptor <i>fd</i> in the file descriptor set <i>fdset</i> .
<code>FD_ISSET(<i>fd</i>, &<i>fdset</i>)</code>	Returns a non-zero value if the bit for the file descriptor <i>fd</i> is set in the file descriptor set pointed to by <i>fdset</i> , and 0 otherwise.
<code>FD_SET(<i>fd</i>, &<i>fdset</i>)</code>	Sets the bit for the file descriptor <i>fd</i> in the file descriptor set <i>fdset</i> .
<code>FD_ZERO(&<i>fdset</i>)</code>	Initializes the file descriptor set <i>fdset</i> to have zero bits for all file descriptors.

The behavior of these macros is undefined if the *fd* argument is less than 0 or greater than or equal to `FD_SETSIZE`.

RETURN VALUES

The `FD_CLR()`, `FD_SET()`, and `FD_ZERO()` macros return no value. The `FD_ISSET()` macro returns a non-zero value if the bit for the file descriptor *fd* is set in the file descriptor set pointed to by *fdset*, and 0 otherwise.

FD_CLR(3C)

On successful completion, `select()` returns the total number of bits set in the bit masks. Otherwise, `-1` is returned, and `errno` is set to indicate the error.

ERRORS

The `select()` function will fail if:

- | | |
|--------|---|
| EBADF | One or more of the file descriptor sets specified a file descriptor that is not a valid open file descriptor. |
| EINTR | The <code>select()</code> function was interrupted before any of the selected events occurred and before the timeout interval expired.

If <code>SA_RESTART</code> has been set for the interrupting signal, it is implementation-dependent whether <code>select()</code> restarts or returns with <code>EINTR</code> . |
| EINVAL | An invalid timeout interval was specified. |
| EINVAL | The <code>nfds</code> argument is less than 0 or greater than <code>FD_SETSIZE</code> . |
| EINVAL | One of the specified file descriptors refers to a <code>STREAM</code> or multiplexer that is linked (directly or indirectly) downstream from a multiplexer. |
| EINVAL | A component of the pointed-to time limit is outside the acceptable range: <code>t_sec</code> must be between 0 and 10^8 , inclusive. <code>t_usec</code> must be greater than or equal to 0, and less than 10^6 . |

USAGE

The `poll(2)` function is preferred over this function. It must be used when the number of file descriptors exceeds `FD_SETSIZE`.

The use of a timeout does not affect any pending timers set up by `alarm(2)`, `ualarm(3C)` or `setitimer(2)`.

On successful completion, the object pointed to by the `timeout` argument may be modified.

ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
MT-Level	MT-Safe

SEE ALSO

`alarm(2)`, `fcntl(2)`, `poll(2)`, `read(2)`, `setitimer(2)`, `write(2)`, `accept(3SOCKET)`, `listen(3SOCKET)`, `ualarm(3C)`, `attributes(5)`

NOTES

The default value for `FD_SETSIZE` (currently 1024) is larger than the default limit on the number of open files. To accommodate 32-bit applications that wish to use a larger number of open files with `select()`, it is possible to increase this size at compile time

by providing a larger definition of `FD_SETSIZE` before the inclusion of any system-supplied header. The maximum supported size for `FD_SETSIZE` is 65536. The default value is already 65536 for 64-bit applications.

fdetach(3C)

NAME	fdetach – detach a name from a STREAMS-based file descriptor																
SYNOPSIS	<pre>#include <stropts.h> int fdetach(const char *path);</pre>																
DESCRIPTION	<p>The <code>fdetach()</code> function detaches a STREAMS-based file from the file to which it was attached by a previous call to <code>fattach(3C)</code>. The <i>path</i> argument points to the pathname of the attached STREAMS file. The process must have appropriate privileges or be the owner of the file. A successful call to <code>fdetach()</code> causes all pathnames that named the attached STREAMS file to again name the file to which the STREAMS file was attached. All subsequent operations on <i>path</i> will operate on the underlying file and not on the STREAMS file.</p> <p>All open file descriptions established while the STREAMS file was attached to the file referenced by <i>path</i>, will still refer to the STREAMS file after the <code>fdetach()</code> has taken effect.</p> <p>If there are no open file descriptors or other references to the STREAMS file, then a successful call to <code>fdetach()</code> has the same effect as performing the last <code>close(2)</code> on the attached file.</p>																
RETURN VALUES	Upon successful completion, <code>fdetach()</code> returns 0. Otherwise, it returns -1 and sets <code>errno</code> to indicate the error.																
ERRORS	<p>The <code>fdetach()</code> function will fail if:</p> <table><tr><td>EACCES</td><td>Search permission is denied on a component of the path prefix.</td></tr><tr><td>EPERM</td><td>The effective user ID is not the owner of <i>path</i> and the process does not have appropriate privileges.</td></tr><tr><td>ENOTDIR</td><td>A component of the path prefix is not a directory.</td></tr><tr><td>ENOENT</td><td>A component of <i>path</i> does not name an existing file or <i>path</i> is an empty string.</td></tr><tr><td>EINVAL</td><td>The <i>path</i> argument names a file that is not currently attached.</td></tr><tr><td>ENAMETOOLONG</td><td>The size of a pathname exceeds <code>PATH_MAX</code>, or a pathname component is longer than <code>NAME_MAX</code> while <code>_POSIX_NO_TRUNC</code> is in effect.</td></tr><tr><td>ELOOP</td><td>Too many symbolic links were encountered in resolving <i>path</i>.</td></tr></table> <p>The <code>fdetach()</code> function may fail if:</p> <table><tr><td>ENAMETOOLONG</td><td>Pathname resolution of a symbolic link produced an intermediate result whose length exceeds <code>PATH_MAX</code>.</td></tr></table>	EACCES	Search permission is denied on a component of the path prefix.	EPERM	The effective user ID is not the owner of <i>path</i> and the process does not have appropriate privileges.	ENOTDIR	A component of the path prefix is not a directory.	ENOENT	A component of <i>path</i> does not name an existing file or <i>path</i> is an empty string.	EINVAL	The <i>path</i> argument names a file that is not currently attached.	ENAMETOOLONG	The size of a pathname exceeds <code>PATH_MAX</code> , or a pathname component is longer than <code>NAME_MAX</code> while <code>_POSIX_NO_TRUNC</code> is in effect.	ELOOP	Too many symbolic links were encountered in resolving <i>path</i> . FD_ISSET(3C)

NAME	select, FD_SET, FD_CLR, FD_ISSET, FD_ZERO – synchronous I/O multiplexing
SYNOPSIS	<pre>#include <sys/time.h> int select(int nfds, fd_set *readfds, fd_set *writefds, fd_set *errorfds, struct timeval *timeout); void FD_SET(int fd, fd_set *fdset); void FD_CLR(int fd, fd_set *fdset); int FD_ISSET(int fd, fd_set *fdset); void FD_ZERO(fd_set *fdset);</pre>
DESCRIPTION	<p>The <code>select()</code> function indicates which of the specified file descriptors is ready for reading, ready for writing, or has an error condition pending. If the specified condition is false for all of the specified file descriptors, <code>select()</code> blocks, up to the specified timeout interval, until the specified condition is true for at least one of the specified file descriptors.</p> <p>The <code>select()</code> function supports regular files, terminal and pseudo-terminal devices, STREAMS-based files, FIFOs and pipes. The behavior of <code>select()</code> on file descriptors that refer to other types of file is unspecified.</p> <p>The <code>nfds</code> argument specifies the range of file descriptors to be tested. The <code>select()</code> function tests file descriptors in the range of 0 to <code>nfds-1</code>.</p> <p>If the <code>readfds</code> argument is not a null pointer, it points to an object of type <code>fd_set</code> that on input specifies the file descriptors to be checked for being ready to read, and on output indicates which file descriptors are ready to read.</p> <p>If the <code>writefds</code> argument is not a null pointer, it points to an object of type <code>fd_set</code> that on input specifies the file descriptors to be checked for being ready to write, and on output indicates which file descriptors are ready to write.</p> <p>If the <code>errorfds</code> argument is not a null pointer, it points to an object of type <code>fd_set</code> that on input specifies the file descriptors to be checked for error conditions pending, and on output indicates which file descriptors have error conditions pending.</p> <p>On successful completion, the objects pointed to by the <code>readfds</code>, <code>writefds</code>, and <code>errorfds</code> arguments are modified to indicate which file descriptors are ready for reading, ready for writing, or have an error condition pending, respectively. For each file descriptor less than <code>nfds</code>, the corresponding bit will be set on successful completion if it was set on input and the associated condition is true for that file descriptor.</p> <p>If the <code>timeout</code> argument is not a null pointer, it points to an object of type <code>struct timeval</code> that specifies a maximum interval to wait for the selection to complete. If the <code>timeout</code> argument points to an object of type <code>struct timeval</code> whose members are 0, <code>select()</code> does not block. If the <code>timeout</code> argument is a null pointer, <code>select()</code> blocks</p>

until an event causes one of the masks to be returned with a valid (non-zero) value. If the time limit expires before any event occurs that would cause one of the masks to be set to a non-zero value, `select()` completes successfully and returns 0.

If the `readfs`, `writes`, and `errorfds` arguments are all null pointers and the `timeout` argument is not a null pointer, `select()` blocks for the time specified, or until interrupted by a signal. If the `readfs`, `writes`, and `errorfds` arguments are all null pointers and the `timeout` argument is a null pointer, `select()` blocks until interrupted by a signal.

File descriptors associated with regular files always select true for ready to read, ready to write, and error conditions.

On failure, the objects pointed to by the `readfs`, `writes`, and `errorfds` arguments are not modified. If the timeout interval expires without the specified condition being true for any of the specified file descriptors, the objects pointed to by the `readfs`, `writes`, and `errorfds` arguments have all bits set to 0.

A file descriptor for a socket that is listening for connections will indicate that it is ready for reading, when connections are available. A file descriptor for a socket that is connecting asynchronously will indicate that it is ready for writing, when a connection has been established.

Selecting true for reading on a socket descriptor upon which a `listen(3SOCKET)` call has been performed indicates that a subsequent `accept(3SOCKET)` call on that descriptor will not block.

File descriptor masks of type `fd_set` can be initialized and tested with the macros `FD_CLR()`, `FD_ISSET()`, `FD_SET()`, and `FD_ZERO()`.

<code>FD_CLR(<i>fd</i>, &<i>fdset</i>)</code>	Clears the bit for the file descriptor <i>fd</i> in the file descriptor set <i>fdset</i> .
<code>FD_ISSET(<i>fd</i>, &<i>fdset</i>)</code>	Returns a non-zero value if the bit for the file descriptor <i>fd</i> is set in the file descriptor set pointed to by <i>fdset</i> , and 0 otherwise.
<code>FD_SET(<i>fd</i>, &<i>fdset</i>)</code>	Sets the bit for the file descriptor <i>fd</i> in the file descriptor set <i>fdset</i> .
<code>FD_ZERO(&<i>fdset</i>)</code>	Initializes the file descriptor set <i>fdset</i> to have zero bits for all file descriptors.

The behavior of these macros is undefined if the *fd* argument is less than 0 or greater than or equal to `FD_SETSIZE`.

RETURN VALUES

The `FD_CLR()`, `FD_SET()`, and `FD_ZERO()` macros return no value. The `FD_ISSET()` macro returns a non-zero value if the bit for the file descriptor *fd* is set in the file descriptor set pointed to by *fdset*, and 0 otherwise.

FD_ISSET(3C)

On successful completion, `select()` returns the total number of bits set in the bit masks. Otherwise, `-1` is returned, and `errno` is set to indicate the error.

ERRORS

The `select()` function will fail if:

- | | |
|--------|---|
| EBADF | One or more of the file descriptor sets specified a file descriptor that is not a valid open file descriptor. |
| EINTR | The <code>select()</code> function was interrupted before any of the selected events occurred and before the timeout interval expired.

If <code>SA_RESTART</code> has been set for the interrupting signal, it is implementation-dependent whether <code>select()</code> restarts or returns with <code>EINTR</code> . |
| EINVAL | An invalid timeout interval was specified. |
| EINVAL | The <code>nfds</code> argument is less than 0 or greater than <code>FD_SETSIZE</code> . |
| EINVAL | One of the specified file descriptors refers to a <code>STREAM</code> or multiplexer that is linked (directly or indirectly) downstream from a multiplexer. |
| EINVAL | A component of the pointed-to time limit is outside the acceptable range: <code>t_sec</code> must be between 0 and 10^8 , inclusive. <code>t_usec</code> must be greater than or equal to 0, and less than 10^6 . |

USAGE

The `poll(2)` function is preferred over this function. It must be used when the number of file descriptors exceeds `FD_SETSIZE`.

The use of a timeout does not affect any pending timers set up by `alarm(2)`, `ualarm(3C)` or `setitimer(2)`.

On successful completion, the object pointed to by the `timeout` argument may be modified.

ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
MT-Level	MT-Safe

SEE ALSO

`alarm(2)`, `fcntl(2)`, `poll(2)`, `read(2)`, `setitimer(2)`, `write(2)`, `accept(3SOCKET)`, `listen(3SOCKET)`, `ualarm(3C)`, `attributes(5)`

NOTES

The default value for `FD_SETSIZE` (currently 1024) is larger than the default limit on the number of open files. To accommodate 32-bit applications that wish to use a larger number of open files with `select()`, it is possible to increase this size at compile time

by providing a larger definition of `FD_SETSIZE` before the inclusion of any system-supplied header. The maximum supported size for `FD_SETSIZE` is 65536. The default value is already 65536 for 64-bit applications.

fdopen(3C)

NAME	fdopen – associate a stream with a file descriptor												
SYNOPSIS	<pre>#include <stdio.h> FILE *fdopen(int <i>fildes</i>, const char *<i>mode</i>);</pre>												
DESCRIPTION	<p>The <code>fdopen()</code> function associates a stream with a file descriptor <i>fildes</i>.</p> <p>The <i>mode</i> argument is a character string having one of the following values:</p> <table><tr><td>r or rb</td><td>Open a file for reading.</td></tr><tr><td>w or wb</td><td>Open a file for writing.</td></tr><tr><td>a or ab</td><td>Open a file for writing at end of file.</td></tr><tr><td>r+ or rb+ or r+b</td><td>Open a file for update (reading and writing).</td></tr><tr><td>w+ or wb+ or w+b</td><td>Open a file for update (reading and writing).</td></tr><tr><td>a+ or ab+ or a+b</td><td>Open a file for update (reading and writing) at end of file.</td></tr></table> <p>The meaning of these flags is exactly as specified for the <code>fopen(3C)</code> function, except that modes beginning with <i>w</i> do not cause truncation of the file.</p> <p>The mode of the stream must be allowed by the file access mode of the open file. The file position indicator associated with the new stream is set to the position indicated by the file offset associated with the file descriptor.</p> <p>The <code>fdopen()</code> function preserves the offset maximum previously set for the open file description corresponding to <i>fildes</i>.</p> <p>The error and end-of-file indicators for the stream are cleared. The <code>fdopen()</code> function may cause the <code>st_atime</code> field of the underlying file to be marked for update.</p> <p>If <i>fildes</i> refers to a shared memory object, the result of the <code>fdopen()</code> function is unspecified.</p>	r or rb	Open a file for reading.	w or wb	Open a file for writing.	a or ab	Open a file for writing at end of file.	r+ or rb+ or r+b	Open a file for update (reading and writing).	w+ or wb+ or w+b	Open a file for update (reading and writing).	a+ or ab+ or a+b	Open a file for update (reading and writing) at end of file.
r or rb	Open a file for reading.												
w or wb	Open a file for writing.												
a or ab	Open a file for writing at end of file.												
r+ or rb+ or r+b	Open a file for update (reading and writing).												
w+ or wb+ or w+b	Open a file for update (reading and writing).												
a+ or ab+ or a+b	Open a file for update (reading and writing) at end of file.												
RETURN VALUES	<p>Upon successful completion, <code>fdopen()</code> returns a pointer to a stream. Otherwise, a null pointer is returned and <code>errno</code> is set to indicate the error.</p> <p>The <code>fdopen()</code> function may fail and not set <code>errno</code> if there are no free <code>stdio</code> streams.</p>												
ERRORS	<p>The <code>fdopen()</code> function may fail if:</p> <table><tr><td>EBADF</td><td>The <i>fildes</i> argument is not a valid file descriptor.</td></tr><tr><td>EINVAL</td><td>The <i>mode</i> argument is not a valid mode.</td></tr><tr><td>EMFILE</td><td>The number of streams currently open in the calling process is either <code>FOPEN_MAX</code> or <code>STREAM_MAX</code>.</td></tr></table>	EBADF	The <i>fildes</i> argument is not a valid file descriptor.	EINVAL	The <i>mode</i> argument is not a valid mode.	EMFILE	The number of streams currently open in the calling process is either <code>FOPEN_MAX</code> or <code>STREAM_MAX</code> .						
EBADF	The <i>fildes</i> argument is not a valid file descriptor.												
EINVAL	The <i>mode</i> argument is not a valid mode.												
EMFILE	The number of streams currently open in the calling process is either <code>FOPEN_MAX</code> or <code>STREAM_MAX</code> .												

ENOMEM Insufficient space to allocate a buffer.

USAGE The number of streams that a process can have open at one time is `STREAM_MAX`. If defined, it has the same value as `FOPEN_MAX`.

File descriptors are obtained from calls like `open(2)`, `dup(2)`, `creat(2)` or `pipe(2)`, which open files but do not return streams. Streams are necessary input for almost all of the Section 3S library routines.

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
MT-Level	MT-Safe

fdopendir(3C)

NAME	opendir, fdopendir – open directory																
SYNOPSIS	<pre>#include <sys/types.h> #include <dirent.h> DIR *opendir(const char *dirname); DIR *fdopendir(int fildes);</pre>																
DESCRIPTION	<p>The <code>opendir()</code> function opens a directory stream corresponding to the directory named by the <code>dirname</code> argument.</p> <p>The <code>fdopendir()</code> function opens a directory stream for the directory file descriptor <code>fildes</code>. The directory file descriptor should not be used or closed following a successful function call, as this might cause undefined results from future operations on the directory stream obtained from the call. Use <code>closedir(3C)</code> to close a directory stream.</p> <p>The directory stream is positioned at the first entry. If the type <code>DIR</code> is implemented using a file descriptor, applications will only be able to open up to a total of <code>{OPEN_MAX}</code> files and directories. A successful call to any of the <code>exec</code> functions will close any directory streams that are open in the calling process. See <code>exec(2)</code>.</p>																
RETURN VALUES	Upon successful completion, <code>opendir()</code> and <code>fdopendir()</code> return a pointer to an object of type <code>DIR</code> . Otherwise, a null pointer is returned and <code>errno</code> is set to indicate the error.																
ERRORS	<p>The <code>opendir()</code> function will fail if:</p> <table><tr><td>EACCES</td><td>Search permission is denied for the component of the path prefix of <code>dirname</code> or read permission is denied for <code>dirname</code>.</td></tr><tr><td>ELOOP</td><td>Too many symbolic links were encountered in resolving <code>path</code>.</td></tr><tr><td>ENAMETOOLONG</td><td>The length of the <code>dirname</code> argument exceeds <code>{PATH_MAX}</code>, or a path name component is longer than <code>{NAME_MAX}</code> while <code>{_POSIX_NO_TRUNC}</code> is in effect.</td></tr><tr><td>ENOENT</td><td>A component of <code>dirname</code> does not name an existing directory or <code>dirname</code> is an empty string.</td></tr><tr><td>ENOTDIR</td><td>A component of <code>dirname</code> is not a directory.</td></tr></table> <p>The <code>fdopendir()</code> function will fail if:</p> <table><tr><td>ENOTDIR</td><td>The file descriptor <code>fildes</code> does not reference a directory.</td></tr></table> <p>The <code>opendir()</code> function may fail if:</p> <table><tr><td>EMFILE</td><td>There are <code>{OPEN_MAX}</code> file descriptors currently open in the calling process.</td></tr><tr><td>ENAMETOOLONG</td><td>Pathname resolution of a symbolic link produced an intermediate result whose length exceeds <code>PATH_MAX</code>.</td></tr></table>	EACCES	Search permission is denied for the component of the path prefix of <code>dirname</code> or read permission is denied for <code>dirname</code> .	ELOOP	Too many symbolic links were encountered in resolving <code>path</code> .	ENAMETOOLONG	The length of the <code>dirname</code> argument exceeds <code>{PATH_MAX}</code> , or a path name component is longer than <code>{NAME_MAX}</code> while <code>{_POSIX_NO_TRUNC}</code> is in effect.	ENOENT	A component of <code>dirname</code> does not name an existing directory or <code>dirname</code> is an empty string.	ENOTDIR	A component of <code>dirname</code> is not a directory.	ENOTDIR	The file descriptor <code>fildes</code> does not reference a directory.	EMFILE	There are <code>{OPEN_MAX}</code> file descriptors currently open in the calling process.	ENAMETOOLONG	Pathname resolution of a symbolic link produced an intermediate result whose length exceeds <code>PATH_MAX</code> .
EACCES	Search permission is denied for the component of the path prefix of <code>dirname</code> or read permission is denied for <code>dirname</code> .																
ELOOP	Too many symbolic links were encountered in resolving <code>path</code> .																
ENAMETOOLONG	The length of the <code>dirname</code> argument exceeds <code>{PATH_MAX}</code> , or a path name component is longer than <code>{NAME_MAX}</code> while <code>{_POSIX_NO_TRUNC}</code> is in effect.																
ENOENT	A component of <code>dirname</code> does not name an existing directory or <code>dirname</code> is an empty string.																
ENOTDIR	A component of <code>dirname</code> is not a directory.																
ENOTDIR	The file descriptor <code>fildes</code> does not reference a directory.																
EMFILE	There are <code>{OPEN_MAX}</code> file descriptors currently open in the calling process.																
ENAMETOOLONG	Pathname resolution of a symbolic link produced an intermediate result whose length exceeds <code>PATH_MAX</code> .																

ENFILE Too many files are currently open on the system.

USAGE The `opendir()` and `fdopendir()` functions should be used in conjunction with `readdir(3C)`, `closedir(3C)` and `rewinddir(3C)` to examine the contents of the directory (see the `EXAMPLES` section in `readdir(3C)`). This method is recommended for portability.

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Interface Stability	<code>opendir()</code> is Standard; <code>fdopendir()</code> is Evolving
MT-Level	Safe

SEE ALSO `lstat(2)`, `symlink(2)`, `closedir(3C)`, `readdir(3C)`, `rewinddir(3C)`, `attributes(5)`

FD_SET(3C)

NAME	<code>select</code> , <code>FD_SET</code> , <code>FD_CLR</code> , <code>FD_ISSET</code> , <code>FD_ZERO</code> – synchronous I/O multiplexing
SYNOPSIS	<pre>#include <sys/time.h> int select(int <i>nfds</i>, fd_set *<i>readfds</i>, fd_set *<i>writefds</i>, fd_set *<i>errorfds</i>, struct timeval *<i>timeout</i>); void FD_SET(int <i>fd</i>, fd_set *<i>fdset</i>); void FD_CLR(int <i>fd</i>, fd_set *<i>fdset</i>); int FD_ISSET(int <i>fd</i>, fd_set *<i>fdset</i>); void FD_ZERO(fd_set *<i>fdset</i>);</pre>
DESCRIPTION	<p>The <code>select()</code> function indicates which of the specified file descriptors is ready for reading, ready for writing, or has an error condition pending. If the specified condition is false for all of the specified file descriptors, <code>select()</code> blocks, up to the specified timeout interval, until the specified condition is true for at least one of the specified file descriptors.</p> <p>The <code>select()</code> function supports regular files, terminal and pseudo-terminal devices, STREAMS-based files, FIFOs and pipes. The behavior of <code>select()</code> on file descriptors that refer to other types of file is unspecified.</p> <p>The <i>nfds</i> argument specifies the range of file descriptors to be tested. The <code>select()</code> function tests file descriptors in the range of 0 to <i>nfds</i>-1.</p> <p>If the <i>readfds</i> argument is not a null pointer, it points to an object of type <code>fd_set</code> that on input specifies the file descriptors to be checked for being ready to read, and on output indicates which file descriptors are ready to read.</p> <p>If the <i>writefds</i> argument is not a null pointer, it points to an object of type <code>fd_set</code> that on input specifies the file descriptors to be checked for being ready to write, and on output indicates which file descriptors are ready to write.</p> <p>If the <i>errorfds</i> argument is not a null pointer, it points to an object of type <code>fd_set</code> that on input specifies the file descriptors to be checked for error conditions pending, and on output indicates which file descriptors have error conditions pending.</p> <p>On successful completion, the objects pointed to by the <i>readfds</i>, <i>writefds</i>, and <i>errorfds</i> arguments are modified to indicate which file descriptors are ready for reading, ready for writing, or have an error condition pending, respectively. For each file descriptor less than <i>nfds</i>, the corresponding bit will be set on successful completion if it was set on input and the associated condition is true for that file descriptor.</p> <p>If the <i>timeout</i> argument is not a null pointer, it points to an object of type <code>struct timeval</code> that specifies a maximum interval to wait for the selection to complete. If the <i>timeout</i> argument points to an object of type <code>struct timeval</code> whose members are 0, <code>select()</code> does not block. If the <i>timeout</i> argument is a null pointer, <code>select()</code> blocks</p>

until an event causes one of the masks to be returned with a valid (non-zero) value. If the time limit expires before any event occurs that would cause one of the masks to be set to a non-zero value, `select()` completes successfully and returns 0.

If the *readfs*, *writes*, and *errorfds* arguments are all null pointers and the *timeout* argument is not a null pointer, `select()` blocks for the time specified, or until interrupted by a signal. If the *readfs*, *writes*, and *errorfds* arguments are all null pointers and the *timeout* argument is a null pointer, `select()` blocks until interrupted by a signal.

File descriptors associated with regular files always select true for ready to read, ready to write, and error conditions.

On failure, the objects pointed to by the *readfs*, *writes*, and *errorfds* arguments are not modified. If the timeout interval expires without the specified condition being true for any of the specified file descriptors, the objects pointed to by the *readfs*, *writes*, and *errorfds* arguments have all bits set to 0.

A file descriptor for a socket that is listening for connections will indicate that it is ready for reading, when connections are available. A file descriptor for a socket that is connecting asynchronously will indicate that it is ready for writing, when a connection has been established.

Selecting true for reading on a socket descriptor upon which a `listen(3SOCKET)` call has been performed indicates that a subsequent `accept(3SOCKET)` call on that descriptor will not block.

File descriptor masks of type `fd_set` can be initialized and tested with the macros `FD_CLR()`, `FD_ISSET()`, `FD_SET()`, and `FD_ZERO()`.

<code>FD_CLR(<i>fd</i>, &<i>fdset</i>)</code>	Clears the bit for the file descriptor <i>fd</i> in the file descriptor set <i>fdset</i> .
<code>FD_ISSET(<i>fd</i>, &<i>fdset</i>)</code>	Returns a non-zero value if the bit for the file descriptor <i>fd</i> is set in the file descriptor set pointed to by <i>fdset</i> , and 0 otherwise.
<code>FD_SET(<i>fd</i>, &<i>fdset</i>)</code>	Sets the bit for the file descriptor <i>fd</i> in the file descriptor set <i>fdset</i> .
<code>FD_ZERO(&<i>fdset</i>)</code>	Initializes the file descriptor set <i>fdset</i> to have zero bits for all file descriptors.

The behavior of these macros is undefined if the *fd* argument is less than 0 or greater than or equal to `FD_SETSIZE`.

RETURN VALUES

The `FD_CLR()`, `FD_SET()`, and `FD_ZERO()` macros return no value. The `FD_ISSET()` macro returns a non-zero value if the bit for the file descriptor *fd* is set in the file descriptor set pointed to by *fdset*, and 0 otherwise.

FD_SET(3C)

On successful completion, `select()` returns the total number of bits set in the bit masks. Otherwise, `-1` is returned, and `errno` is set to indicate the error.

ERRORS

The `select()` function will fail if:

- | | |
|--------|---|
| EBADF | One or more of the file descriptor sets specified a file descriptor that is not a valid open file descriptor. |
| EINTR | The <code>select()</code> function was interrupted before any of the selected events occurred and before the timeout interval expired.

If <code>SA_RESTART</code> has been set for the interrupting signal, it is implementation-dependent whether <code>select()</code> restarts or returns with <code>EINTR</code> . |
| EINVAL | An invalid timeout interval was specified. |
| EINVAL | The <code>nfds</code> argument is less than 0 or greater than <code>FD_SETSIZE</code> . |
| EINVAL | One of the specified file descriptors refers to a <code>STREAM</code> or multiplexer that is linked (directly or indirectly) downstream from a multiplexer. |
| EINVAL | A component of the pointed-to time limit is outside the acceptable range: <code>t_sec</code> must be between 0 and 10^8 , inclusive. <code>t_usec</code> must be greater than or equal to 0, and less than 10^6 . |

USAGE

The `poll(2)` function is preferred over this function. It must be used when the number of file descriptors exceeds `FD_SETSIZE`.

The use of a timeout does not affect any pending timers set up by `alarm(2)`, `ualarm(3C)` or `setitimer(2)`.

On successful completion, the object pointed to by the `timeout` argument may be modified.

ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
MT-Level	MT-Safe

SEE ALSO

`alarm(2)`, `fcntl(2)`, `poll(2)`, `read(2)`, `setitimer(2)`, `write(2)`, `accept(3SOCKET)`, `listen(3SOCKET)`, `ualarm(3C)`, `attributes(5)`

NOTES

The default value for `FD_SETSIZE` (currently 1024) is larger than the default limit on the number of open files. To accommodate 32-bit applications that wish to use a larger number of open files with `select()`, it is possible to increase this size at compile time

FD_SET(3C)

by providing a larger definition of `FD_SETSIZE` before the inclusion of any system-supplied header. The maximum supported size for `FD_SETSIZE` is 65536. The default value is already 65536 for 64-bit applications.

fdwalk(3C)

NAME	closefrom, fdwalk – close or iterate over open file descriptors
SYNOPSIS	<pre>#include <stdlib.h> void closefrom(int <i>lowfd</i>); int fdwalk(int (*<i>func</i>)(void *, int), void *<i>cd</i>);</pre>
DESCRIPTION	<p>The <code>closefrom()</code> function calls <code>close(2)</code> on all open file descriptors greater than or equal to <i>lowfd</i>.</p> <p>The effect of <code>closefrom(<i>lowfd</i>)</code> is the same as the code</p> <pre>#include <sys/resource.h> struct rlimit rl; int i; getrlimit(RLIMIT_NOFILE, &rl); for (i = lowfd; i < rl.rlim_max; i++) (void) close(i);</pre> <p>except that <code>close()</code> is called only on file descriptors that are actually open, not on every possible file descriptor greater than or equal to <i>lowfd</i>, and <code>close()</code> is also called on any open file descriptors greater than or equal to <code>rl.rlim_max</code> (and <i>lowfd</i>), should any exist.</p> <p>The <code>fdwalk()</code> function first makes a list of all currently open file descriptors. Then for each file descriptor in the list, it calls the user-defined function, <code>func(<i>cd</i>, <i>fd</i>)</code>, passing it the pointer to the callback data, <i>cd</i>, and the value of the file descriptor from the list, <i>fd</i>. The list is processed in file descriptor value order, lowest numeric value first.</p> <p>If <code>func()</code> returns a non-zero value, the iteration over the list is terminated and <code>fdwalk()</code> returns the non-zero value returned by <code>func()</code>. Otherwise, <code>fdwalk()</code> returns 0 after having called <code>func()</code> for every file descriptor in the list.</p> <p>The <code>fdwalk()</code> function can be used for fine-grained control over the closing of file descriptors. For example, the <code>closefrom()</code> function can be implemented as:</p> <pre>static int close_func(void *lowfdp, int fd) { if (fd >= *(int *)lowfdp) (void) close(fd); return (0); } void closefrom(int lowfd) { (void) fdwalk(close_func, &lowfd); }</pre> <p>The <code>fdwalk()</code> function can then be used to count the number of open files in the process.</p>

RETURN VALUES No return value is defined for `closefrom()`. If `close()` fails for any of the open file descriptors, the error is ignored and the file descriptors whose `close()` operation failed might remain open on return from `closefrom()`.

The `fdwalk()` function returns the return value of the last call to the callback function `func()`, or 0 if `func()` is never called (no open files).

ERRORS No errors are defined. The `closefrom()` and `fdwalk()` functions do not set `errno` but `errno` can be set by `close()` or by another function called by the callback function, `func()`.

FILES `/proc/self/fd` directory (list of open files)

USAGE The act of closing all open file descriptors should be performed only as the first action of a daemon process. Closing file descriptors that are in use elsewhere in the current process normally leads to disastrous results.

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
MT-Level	Unsafe

SEE ALSO `close(2)`, `getrlimit(2)`, `proc(4)`, `attributes(5)`

FD_ZERO(3C)

NAME	<code>select</code> , <code>FD_SET</code> , <code>FD_CLR</code> , <code>FD_ISSET</code> , <code>FD_ZERO</code> – synchronous I/O multiplexing
SYNOPSIS	<pre>#include <sys/time.h> int select(int <i>nfds</i>, fd_set *<i>readfds</i>, fd_set *<i>writefds</i>, fd_set *<i>errorfds</i>, struct timeval *<i>timeout</i>); void FD_SET(int <i>fd</i>, fd_set *<i>fdset</i>); void FD_CLR(int <i>fd</i>, fd_set *<i>fdset</i>); int FD_ISSET(int <i>fd</i>, fd_set *<i>fdset</i>); void FD_ZERO(fd_set *<i>fdset</i>);</pre>
DESCRIPTION	<p>The <code>select()</code> function indicates which of the specified file descriptors is ready for reading, ready for writing, or has an error condition pending. If the specified condition is false for all of the specified file descriptors, <code>select()</code> blocks, up to the specified timeout interval, until the specified condition is true for at least one of the specified file descriptors.</p> <p>The <code>select()</code> function supports regular files, terminal and pseudo-terminal devices, STREAMS-based files, FIFOs and pipes. The behavior of <code>select()</code> on file descriptors that refer to other types of file is unspecified.</p> <p>The <i>nfds</i> argument specifies the range of file descriptors to be tested. The <code>select()</code> function tests file descriptors in the range of 0 to <i>nfds</i>-1.</p> <p>If the <i>readfds</i> argument is not a null pointer, it points to an object of type <code>fd_set</code> that on input specifies the file descriptors to be checked for being ready to read, and on output indicates which file descriptors are ready to read.</p> <p>If the <i>writefds</i> argument is not a null pointer, it points to an object of type <code>fd_set</code> that on input specifies the file descriptors to be checked for being ready to write, and on output indicates which file descriptors are ready to write.</p> <p>If the <i>errorfds</i> argument is not a null pointer, it points to an object of type <code>fd_set</code> that on input specifies the file descriptors to be checked for error conditions pending, and on output indicates which file descriptors have error conditions pending.</p> <p>On successful completion, the objects pointed to by the <i>readfds</i>, <i>writefds</i>, and <i>errorfds</i> arguments are modified to indicate which file descriptors are ready for reading, ready for writing, or have an error condition pending, respectively. For each file descriptor less than <i>nfds</i>, the corresponding bit will be set on successful completion if it was set on input and the associated condition is true for that file descriptor.</p> <p>If the <i>timeout</i> argument is not a null pointer, it points to an object of type <code>struct timeval</code> that specifies a maximum interval to wait for the selection to complete. If the <i>timeout</i> argument points to an object of type <code>struct timeval</code> whose members are 0, <code>select()</code> does not block. If the <i>timeout</i> argument is a null pointer, <code>select()</code> blocks</p>

until an event causes one of the masks to be returned with a valid (non-zero) value. If the time limit expires before any event occurs that would cause one of the masks to be set to a non-zero value, `select()` completes successfully and returns 0.

If the *readfs*, *writes*, and *errorfds* arguments are all null pointers and the *timeout* argument is not a null pointer, `select()` blocks for the time specified, or until interrupted by a signal. If the *readfs*, *writes*, and *errorfds* arguments are all null pointers and the *timeout* argument is a null pointer, `select()` blocks until interrupted by a signal.

File descriptors associated with regular files always select true for ready to read, ready to write, and error conditions.

On failure, the objects pointed to by the *readfs*, *writes*, and *errorfds* arguments are not modified. If the timeout interval expires without the specified condition being true for any of the specified file descriptors, the objects pointed to by the *readfs*, *writes*, and *errorfds* arguments have all bits set to 0.

A file descriptor for a socket that is listening for connections will indicate that it is ready for reading, when connections are available. A file descriptor for a socket that is connecting asynchronously will indicate that it is ready for writing, when a connection has been established.

Selecting true for reading on a socket descriptor upon which a `listen(3SOCKET)` call has been performed indicates that a subsequent `accept(3SOCKET)` call on that descriptor will not block.

File descriptor masks of type `fd_set` can be initialized and tested with the macros `FD_CLR()`, `FD_ISSET()`, `FD_SET()`, and `FD_ZERO()`.

<code>FD_CLR(<i>fd</i>, &<i>fdset</i>)</code>	Clears the bit for the file descriptor <i>fd</i> in the file descriptor set <i>fdset</i> .
<code>FD_ISSET(<i>fd</i>, &<i>fdset</i>)</code>	Returns a non-zero value if the bit for the file descriptor <i>fd</i> is set in the file descriptor set pointed to by <i>fdset</i> , and 0 otherwise.
<code>FD_SET(<i>fd</i>, &<i>fdset</i>)</code>	Sets the bit for the file descriptor <i>fd</i> in the file descriptor set <i>fdset</i> .
<code>FD_ZERO(&<i>fdset</i>)</code>	Initializes the file descriptor set <i>fdset</i> to have zero bits for all file descriptors.

The behavior of these macros is undefined if the *fd* argument is less than 0 or greater than or equal to `FD_SETSIZE`.

RETURN VALUES

The `FD_CLR()`, `FD_SET()`, and `FD_ZERO()` macros return no value. The `FD_ISSET()` macro returns a non-zero value if the bit for the file descriptor *fd* is set in the file descriptor set pointed to by *fdset*, and 0 otherwise.

FD_ZERO(3C)

On successful completion, `select()` returns the total number of bits set in the bit masks. Otherwise, `-1` is returned, and `errno` is set to indicate the error.

ERRORS

The `select()` function will fail if:

- | | |
|--------|---|
| EBADF | One or more of the file descriptor sets specified a file descriptor that is not a valid open file descriptor. |
| EINTR | The <code>select()</code> function was interrupted before any of the selected events occurred and before the timeout interval expired.

If <code>SA_RESTART</code> has been set for the interrupting signal, it is implementation-dependent whether <code>select()</code> restarts or returns with <code>EINTR</code> . |
| EINVAL | An invalid timeout interval was specified. |
| EINVAL | The <code>nfds</code> argument is less than 0 or greater than <code>FD_SETSIZE</code> . |
| EINVAL | One of the specified file descriptors refers to a <code>STREAM</code> or multiplexer that is linked (directly or indirectly) downstream from a multiplexer. |
| EINVAL | A component of the pointed-to time limit is outside the acceptable range: <code>t_sec</code> must be between 0 and 10^8 , inclusive. <code>t_usec</code> must be greater than or equal to 0, and less than 10^6 . |

USAGE

The `poll(2)` function is preferred over this function. It must be used when the number of file descriptors exceeds `FD_SETSIZE`.

The use of a timeout does not affect any pending timers set up by `alarm(2)`, `ualarm(3C)` or `setitimer(2)`.

On successful completion, the object pointed to by the `timeout` argument may be modified.

NOTES

The default value for `FD_SETSIZE` (currently 1024) is larger than the default limit on the number of open files. To accommodate 32-bit applications that wish to use a larger number of open files with `select()`, it is possible to increase this size at compile time

FD_ZERO(3C)

by providing a larger definition of `FD_SETSIZE` before the inclusion of any system-supplied header. The maximum supported size for `FD_SETSIZE` is 65536. The default value is already 65536 for 64-bit applications.

feof(3C)

NAME | `ferror`, `feof`, `clearerr`, `fileno` – stream status inquiries

SYNOPSIS | `#include <stdio.h>`
`int ferror(FILE *stream);`
`int feof(FILE *stream);`
`void clearerr(FILE *stream);`
`int fileno(FILE *stream);`

DESCRIPTION | The `ferror()` function returns a non-zero value when an error has previously occurred reading from or writing to the named *stream* (see `intro(3)`). It returns 0 otherwise.

The `feof()` function returns a non-zero value when EOF has previously been detected reading the named input *stream*. It returns 0 otherwise.

The `clearerr()` function resets the error indicator and EOF indicator to 0 on the named *stream*.

The `fileno()` function returns the integer file descriptor associated with the named *stream*; see `open(2)`.

ATTRIBUTES | See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
MT-Level	MT-Safe

SEE ALSO | `open(2)`, `intro(3)`, `fopen(3C)`, `stdio(3C)`, `attributes(5)`

NAME | ferror, feof, clearerr, fileno – stream status inquiries

SYNOPSIS | `#include <stdio.h>`
`int ferror(FILE *stream);`
`int feof(FILE *stream);`

fetch(3UCB)

NAME	dbm, dbmopen, dbmclose, fetch, store, delete, firstkey, nextkey – data base subroutines
SYNOPSIS	<pre>/usr/ucb/cc [flag ...] file ... -ldb #include <dbm.h> typedef struct { char *dptr; int dsize; } datum; int dbmopen (file) ; char *file; int dbmclose () ; datum fetch (key) ; datum key; int store (key, dat) ; datum key, dat; int delete (key) ; datum key; datum firstkey() datum nextkey (key) ; datum key;</pre>
DESCRIPTION	<p>The dbm() library has been superseded by ndbm (see ndbm(3C)).</p> <p>These functions maintain key/content pairs in a data base. The functions will handle very large (a billion blocks) databases and will access a keyed item in one or two file system accesses.</p> <p><i>key/dat</i> and their content are described by the datum typedef. A datum specifies a string of <i>dsize</i> bytes pointed to by <i>dptr</i>. Arbitrary binary data, as well as normal ASCII strings, are allowed. The data base is stored in two files. One file is a directory containing a bit map and has <i>.dir</i> as its suffix. The second file contains all data and has <i>.pag</i> as its suffix.</p> <p>Before a database can be accessed, it must be opened by dbmopen(). At the time of this call, the files <i>file.dir</i> and <i>file.pag</i> must exist. An empty database is created by creating zero-length <i>.dir</i> and <i>.pag</i> files.</p> <p>A database may be closed by calling dbmclose(). You must close a database before opening a new one.</p>

fetch(3UCB)

Once open, the data stored under a key is accessed by `fetch()` and data is placed under a key by `store`. A key (and its associated contents) is deleted by `delete()`. A linear pass through all keys in a database may be made, in an (apparently) random order, by use of `firstkey()` and `nextkey()`. `firstkey()` will return the first key in the database. With any key `nextkey()` will return the next key in the database. This code will traverse the data base:

```
for (key = firstkey; key.dptr != NULL; key = nextkey(key))
```

RETURN VALUES

All functions that return an `int` indicate errors with negative values. A zero return indicates no error. Routines that return a `datum` indicate errors with a `NULL (0) dptr`.

SEE ALSO

`ar(1)`, `cat(1)`, `cp(1)`, `tar(1)`, `ndbm(3C)`

NOTES

Use of these interfaces should be restricted to only applications written on BSD platforms. Use of these interfaces with any of the system libraries or in multi-thread applications is unsupported.

The `.pag` file will contain holes so that its apparent size may be larger than its actual content. Older versions of the UNIX operating system may create real file blocks for these holes when touched. These files cannot be copied by normal means (`cp(1)`, `cat(1)`, `tar(1)`, `ar(1)`) without filling in the holes.

`dptr` pointers returned by these subroutines point into static storage that is changed by subsequent calls.

The sum of the sizes of a key/content pair must not exceed the internal block size (currently 1024 bytes). Moreover all key/content pairs that hash together must fit on a single block. `store` will return an error in the event that a disk block fills with inseparable data.

`delete()` does not physically reclaim file space, although it does make it available for reuse.

The order of keys presented by `firstkey()` and `nextkey()` depends on a hashing function, not on anything interesting.

There are no interlocks and no reliable cache flushing; thus concurrent updating and reading is risky.

The database files (`file.dir` and `file.pag`) are binary and are architecture-specific (for example, they depend on the architecture's byte order.) These files are not guaranteed to be portable across architectures.

fflush(3C)

NAME	<code>fflush</code> – flush a stream																
SYNOPSIS	<pre>#include <stdio.h> int fflush(FILE *<i>stream</i>);</pre>																
DESCRIPTION	<p>If <i>stream</i> points to an output stream or an update stream in which the most recent operation was not input, <code>fflush()</code> causes any unwritten data for that stream to be written to the file, and the <code>st_ctime</code> and <code>st_mtime</code> fields of the underlying file are marked for update.</p> <p>If <i>stream</i> is a null pointer, <code>fflush()</code> performs this flushing action on all streams for which the behavior is defined above. Additionally, an input stream or an update stream into which the most recent operation was input is also flushed if it is seekable and is not already at end-of-file. Flushing an input stream discards any buffered input and adjusts the file pointer such that the next input operation accesses the byte after the last one read. A stream is seekable if the underlying file is not a pipe, FIFO, socket, or TTY device. An input stream, seekable or non-seekable, can be flushed by explicitly calling <code>fflush()</code> with a non-null argument specifying that stream.</p>																
RETURN VALUES	Upon successful completion, <code>fflush()</code> returns 0. Otherwise, it returns EOF and sets <code>errno</code> to indicate the error.																
ERRORS	<p>The <code>fflush()</code> function will fail if:</p> <table><tr><td>EAGAIN</td><td>The <code>O_NONBLOCK</code> flag is set for the file descriptor underlying <i>stream</i> and the process would be delayed in the write operation.</td></tr><tr><td>EBADF</td><td>The file descriptor underlying <i>stream</i> is not valid.</td></tr><tr><td>EFBIG</td><td>An attempt was made to write a file that exceeds the maximum file size or the process's file size limit; or the file is a regular file and an attempt was made to write at or beyond the offset maximum associated with the corresponding stream.</td></tr><tr><td>EINTR</td><td>The <code>fflush()</code> function was interrupted by a signal.</td></tr><tr><td>EIO</td><td>The process is a member of a background process group attempting to write to its controlling terminal, <code>TOSTOP</code> is set, the process is neither ignoring nor blocking <code>SIGTTOU</code>, and the process group of the process is orphaned.</td></tr><tr><td>ENOSPC</td><td>There was no free space remaining on the device containing the file.</td></tr><tr><td>EPIPE</td><td>An attempt is made to write to a pipe or FIFO that is not open for reading by any process. A <code>SIGPIPE</code> signal will also be sent to the process.</td></tr></table> <p>The <code>fflush()</code> function may fail if:</p> <table><tr><td>ENXIO</td><td>A request was made of a non-existent device, or the request was beyond the limits of the device.</td></tr></table>	EAGAIN	The <code>O_NONBLOCK</code> flag is set for the file descriptor underlying <i>stream</i> and the process would be delayed in the write operation.	EBADF	The file descriptor underlying <i>stream</i> is not valid.	EFBIG	An attempt was made to write a file that exceeds the maximum file size or the process's file size limit; or the file is a regular file and an attempt was made to write at or beyond the offset maximum associated with the corresponding stream. NAME	fgetc, getc, getc_unlocked, getchar, getchar_unlocked, getw – get a byte from a stream
SYNOPSIS	<pre>#include <stdio.h> int fgetc(FILE *stream); int getc(FILE *stream); int getc_unlocked(FILE *stream); int getchar(void); int getchar_unlocked(void); int getw(FILE *stream);</pre>
DESCRIPTION	<p>The <code>fgetc()</code> function obtains the next byte (if present) as an unsigned char converted to an <code>int</code>, from the input stream pointed to by <i>stream</i>, and advances the associated file position indicator for the stream (if defined).</p> <p>The <code>fgetc()</code> function may mark the <code>st_atime</code> field of the file associated with <i>stream</i> for update. The <code>st_atime</code> field will be marked for update by the first successful execution of <code>fgetc()</code>, <code>fgets(3C)</code>, <code>fgetwc(3C)</code>, <code>fgetws(3C)</code>, <code>fread(3C)</code>, <code>fscanf(3C)</code>, <code>getc()</code>, <code>getchar()</code>, <code>gets(3C)</code> or <code>scanf(3C)</code> using <i>stream</i> that returns data not supplied by a prior call to <code>ungetc(3C)</code> or <code>ungetwc(3C)</code>.</p> <p>The <code>getc()</code> routine is functionally identical to <code>fgetc()</code>, except that it is implemented as a macro. It runs faster than <code>fgetc()</code>, but it takes up more space per invocation and its name cannot be passed as an argument to a function call.</p> <p>The <code>getchar()</code> routine is equivalent to <code>getc(stdin)</code>. It is implemented as a macro.</p> <p>The <code>getc_unlocked()</code> and <code>getchar_unlocked()</code> routines are variants of <code>getc()</code> and <code>getchar()</code>, respectively, that do not lock the stream. It is the caller's responsibility to acquire the stream lock before calling these routines and releasing the lock afterwards; see <code>flockfile(3C)</code> and <code>stdio(3C)</code>. These routines are implemented as macros.</p> <p>The <code>getw()</code> function reads the next word from the <i>stream</i>. The size of a word is the size of an <code>int</code> and may vary from environment to environment. The <code>getw()</code> function presumes no special alignment in the file.</p> <p>The <code>getw()</code> function may mark the <code>st_atime</code> field of the file associated with <i>stream</i> for update. The <code>st_atime</code> field will be marked for update by the first successful execution of <code>fgetc()</code>, <code>fgets(3C)</code>, <code>fread(3C)</code>, <code>getc()</code>, <code>getchar()</code>, <code>gets(3C)</code>, <code>fscanf(3C)</code> or <code>scanf(3C)</code> using <i>stream</i> that returns data not supplied by a prior call to <code>ungetc(3C)</code>.</p>
RETURN VALUES	<p>Upon successful completion, <code>fgetc()</code>, <code>getc()</code>, <code>getc_unlocked()</code>, <code>getchar()</code>, <code>getchar_unlocked()</code>, and <code>getw()</code> return the next byte from the input stream pointed to by <i>stream</i>. If the stream is at end-of-file, the end-of-file indicator for the stream is set and these functions return EOF. If a read error occurs, the error indicator for the stream is set, EOF is returned, and <code>errno</code> is set to indicate the error.</p>

fgetc(3C)

ERRORS	The <code>fgetc()</code> , <code>getc()</code> , <code>getc_unlocked()</code> , <code>getchar()</code> , <code>getchar_unlocked()</code> , and <code>getw()</code> functions will fail if data needs to be read and:	
	EAGAIN	The <code>O_NONBLOCK</code> flag is set for the file descriptor underlying <i>stream</i> and the process would be delayed in the <code>fgetc()</code> operation.
	EBADF	The file descriptor underlying <i>stream</i> is not a valid file descriptor open for reading.
	EINTR	The read operation was terminated due to the receipt of a signal, and no data was transferred.
	EIO	A physical I/O error has occurred, or the process is in a background process group attempting to read from its controlling terminal, and either the process is ignoring or blocking the <code>SIGTTIN</code> signal or the process group is orphaned. This error may also be generated for implementation-dependent reasons.
	EOVERFLOW	The file is a regular file and an attempt was made to read at or beyond the offset maximum associated with the corresponding stream.
	The <code>fgetc()</code> , <code>getc()</code> , <code>getc_unlocked()</code> , <code>getchar()</code> , <code>getchar_unlocked()</code> , and <code>getw()</code> functions may fail if:	
	ENOMEM	Insufficient storage space is available.
	ENXIO	A request was made of a non-existent device, or the request was outside the capabilities of the device.
USAGE	If the integer value returned by <code>fgetc()</code> , <code>getc()</code> , <code>getc_unlocked()</code> , <code>getchar()</code> , <code>getchar_unlocked()</code> , and <code>getw()</code> is stored into a variable of type <code>char</code> and then compared against the integer constant <code>EOF</code> , the comparison may never succeed, because sign-extension of a variable of type <code>char</code> on widening to integer is implementation-dependent.	
	The <code>ferror(3C)</code> or <code>feof(3C)</code> functions must be used to distinguish between an error condition and an end-of-file condition.	
	Functions exist for the <code>getc()</code> , <code>getc_unlocked()</code> , <code>getchar()</code> , and <code>getchar_unlocked()</code> macros. To get the function form, the macro name must be undefined (for example, <code>#undef getc</code>).	
	When the macro forms are used, <code>getc()</code> and <code>getc_unlocked()</code> evaluate the <i>stream</i> argument more than once. In particular, <code>getc(*f++)</code> ; does not work sensibly. The <code>fgetc()</code> function should be used instead when evaluating the <i>stream</i> argument has side effects.	
	Because of possible differences in word length and byte ordering, files written using <code>getw()</code> are machine-dependent, and may not be read using <code>getw()</code> on a different processor.	

fgetc(3C)

The `getw()` function is inherently byte stream-oriented and is not tenable in the context of either multibyte character streams or wide-character streams. Application programmers are recommended to use one of the character-based input functions instead.

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
MT-Level	See NOTES below.

SEE ALSO `intro(3)`, `fclose(3C)`, `feof(3C)`, `fgets(3C)`, `fgetwc(3C)`, `fgetws(3C)`, `flockfile(3C)`, `fopen(3C)`, `fread(3C)`, `fscanf(3C)`, `gets(3C)`, `putc(3C)`, `scanf(3C)`, `stdio(3C)`, `ungetc(3C)`, `ungetwc(3C)`, `attributes(5)`

NOTES The `fgetc()`, `getc()`, `getchar()`, and `getw()` routines are MT-Safe in multithreaded applications. The `getc_unlocked()` and `getchar_unlocked()` routines are unsafe in multithreaded applications.

fgetgrent(3C)

NAME	getgrnam, getgrnam_r, getgrent, getgrent_r, getgrgid, getgrgid_r, setgrent, endgrent, fgetgrent, fgetgrent_r – group database entry functions
SYNOPSIS	<pre>#include <grp.h> struct group *getgrnam(const char *name); struct group *getgrnam_r(const char *name, struct group *grp, char *buffer, int bufsize); struct group *getgrent(void); struct group *getgrent_r(struct group *grp, char *buffer, int bufsize); struct group *getgrgid(gid_t gid); struct group *getgrgid_r(gid_t gid, struct group *grp, char *buffer, int bufsize); void setgrent(void); void endgrent(void); struct group *fgetgrent(FILE *f); struct group *fgetgrent_r(FILE *f, struct group *grp, char *buffer, int bufsize);</pre>
POSIX	<pre>cc [flag...] file... -D_POSIX_PTHREAD_SEMANTICS [library...] int getgrnam_r(const char *name, struct group *grp, char *buffer, size_t bufsize, struct group **result); int getgrgid_r(gid_t gid, struct group *grp, char *buffer, size_t bufsize, struct group **result);</pre>
DESCRIPTION	<p>These functions are used to obtain entries describing user groups. Entries can come from any of the sources for group specified in the <code>/etc/nsswitch.conf</code> file (see <code>nsswitch.conf(4)</code>).</p> <p>The <code>getgrnam()</code> function searches the group database for an entry with the group name specified by the character string parameter <i>name</i>.</p> <p>The <code>getgrgid()</code> function searches the group database for an entry with the (numeric) group id specified by <i>gid</i>.</p> <p>The <code>setgrent()</code>, <code>getgrent()</code>, and <code>endgrent()</code> functions are used to enumerate group entries from the database.</p> <p>The <code>setgrent()</code> function effectively rewinds the group database to allow repeated searches. It sets (or resets) the enumeration to the beginning of the set of group entries. This function should be called before the first call to <code>getgrent()</code>.</p>

The `getgrent()` function returns a pointer to a structure containing the broken-out fields of an entry in the group database. When first called, `getgrent()` returns a pointer to a `group` structure containing the next group structure in the group database. Successive calls may be used to search the entire database.

The `endgrent()` function may be called to close the group database and deallocate resources when processing is complete. It is permissible, though possibly less efficient, for the process to call more group functions after calling `endgrent()`.

The `fgetgrent()` function, unlike the other functions above, does not use `nsswitch.conf`. It reads and parses the next line from the stream *f*, which is assumed to have the format of the group file (see `group(4)`).

Reentrant Interfaces

The `getgrnam()`, `getgrgid()`, `getgrent()`, and `fgetgrent()` functions use static storage that is reused in each call, making them unsafe for multithreaded applications.

The parallel functions `getgrnam_r()`, `getgrgid_r()`, `getgrent_r()`, and `fgetgrent_r()` provide reentrant interfaces for these operations.

Each reentrant interface performs the same operation as its non-reentrant counterpart, named by removing the `_r` suffix. The reentrant interfaces, however, use buffers supplied by the caller to store returned results, and are safe for use in both single-threaded and multithreaded applications.

Each reentrant interface takes the same arguments as its non-reentrant counterpart, as well as the following additional parameters. The *grp* argument must be a pointer to a `struct group` structure allocated by the caller. On successful completion, the function returns the group entry in this structure. Storage referenced by the group structure is allocated from the memory provided with the *buffer* argument, which is *bufsize* characters in size. The maximum size needed for this buffer can be determined with the `_SC_GETGR_R_SIZE_MAX` `sysconf(3C)` parameter. The POSIX versions place a pointer to the modified *grp* structure in the *result* parameter, instead of returning a pointer to this structure.

For enumeration in multithreaded applications, the position within the enumeration is a process-wide property shared by all threads. `setgrent()` may be used in a multithreaded application but resets the enumeration position for all threads. If multiple threads interleave calls to `getgrent_r()`, the threads will enumerate disjoint subsets of the group database. Like their non-reentrant counterparts, `getgrnam_r()` and `getgrgid_r()` leave the enumeration position in an indeterminate state.

RETURN VALUES

Group entries are represented by the `struct group` structure defined in `<grp.h>`:

```
struct group {
    char *gr_name;           /* the name of the group */
    char *gr_passwd;        /* the encrypted group password */
    gid_t gr_gid;           /* the numerical group ID */
    char **gr_mem;          /* vector of pointers to member names */
};
```

fgetgrent(3C)

The `getgrnam()`, `getgrnam_r()`, `getgrgid()`, and `getgrgid_r()` functions each return a pointer to a `struct group` if they successfully locate the requested entry; otherwise they return `NULL`. The POSIX functions `getgrnam_r()` and `getgrgid_r()` return 0 upon success or the error number in case of failure.

The `getgrent()`, `getgrent_r()`, `fgetgrent()`, and `fgetgrent_r()` functions each return a pointer to a `struct group` if they successfully enumerate an entry; otherwise they return `NULL`, indicating the end of the enumeration.

The `getgrnam()`, `getgrgid()`, `getgrent()`, and `fgetgrent()` functions use static storage, so returned data must be copied before a subsequent call to any of these functions if the data is to be saved.

When the pointer returned by the reentrant functions `getgrnam_r()`, `getgrgid_r()`, `getgrent_r()`, and `fgetgrent_r()` is non-null, it is always equal to the `grp` pointer that was supplied by the caller.

ERRORS The `getgrnam()`, `getgrgid()`, `getgrent()`, `fgetgrent()`, and `fgetgrent_r()` functions may fail if:

<code>EINTR</code>	A signal was caught during the operation.
<code>EIO</code>	An I/O error has occurred.
<code>EMFILE</code>	There are <code>OPEN_MAX</code> file descriptors currently open in the calling process.
<code>ENFILE</code>	The maximum allowable number of files is currently open in the system.
<code>ERANGE</code>	The group file contains a line that exceeds 512 bytes.

The `getgrnam_r()`, `getgrgid_r()`, and `getgrent_r()` functions may fail if:

<code>ERANGE</code>	Insufficient storage was supplied by <i>buffer</i> and <i>bufsize</i> to contain the data to be referenced by the resulting <code>group</code> structure.
---------------------	---

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
MT-Level	See "Reentrant Interfaces" in <code>DESCRIPTION</code> .

SEE ALSO `Intro(3)`, `getpwnam(3C)`, `group(4)`, `nsswitch.conf(4)`, `passwd(4)`, `attributes(5)`, `standards(5)`

NOTES When compiling multithreaded programs, see `Intro(3)`, *Notes On Multithreaded Applications*.

Programs that use the interfaces described in this manual page cannot be linked statically since the implementations of these functions employ dynamic loading and linking of shared objects at run time.

Use of the enumeration interfaces `getgrent()` and `getgrent_r()` is discouraged; enumeration is supported for the group file, NIS, and NIS+, but in general is not efficient and may not be supported for all database sources. The semantics of enumeration are discussed further in `nsswitch.conf(4)`.

Previous releases allowed the use of "+" and "-" entries in `/etc/group` to selectively include and exclude entries from NIS. The primary usage of these entries is superseded by the name service switch, so the "+/-" form *may not be supported in future releases*.

If required, the "+/-" functionality can still be obtained for NIS by specifying `compat` as the source for `group`.

If the "+/-" functionality is required in conjunction with NIS+, specify both `compat` as the source for `group` and `nisplus` as the source for the pseudo-database `group_compat`. See `group(4)`, and `nsswitch.conf(4)` for details.

Solaris 2.4 and earlier releases provided definitions of the `getgrnam_r()` and `getgrgid_r()` functions as specified in POSIX.1c Draft 6. The final POSIX.1c standard changed the interface for these functions. Support for the Draft 6 interface is provided for compatibility only and may not be supported in future releases. New applications and libraries should use the POSIX standard interface.

For POSIX.1c-compliant applications, the `_POSIX_PTHREAD_SEMANTICS` and `_REENTRANT` flags are automatically turned on by defining the `_POSIX_C_SOURCE` flag with a value $\geq 199506L$.

fgetgrent_r(3C)

NAME	getgrnam, getgrnam_r, getgrent, getgrent_r, getgrgid, getgrgid_r, setgrent, endgrent, fgetgrent, fgetgrent_r – group database entry functions
SYNOPSIS	<pre>#include <grp.h> struct group *getgrnam(const char *name); struct group *getgrnam_r(const char *name, struct group *grp, char *buffer, int bufsize); struct group *getgrent(void); struct group *getgrent_r(struct group *grp, char *buffer, int bufsize); struct group *getgrgid(gid_t gid); struct group *getgrgid_r(gid_t gid, struct group *grp, char *buffer, int bufsize); void setgrent(void); void endgrent(void); struct group *fgetgrent(FILE *f); struct group *fgetgrent_r(FILE *f, struct group *grp, char *buffer, int bufsize);</pre>
POSIX	<pre>cc [flag...] file... -D_POSIX_PTHREAD_SEMANTICS [library...] int getgrnam_r(const char *name, struct group *grp, char *buffer, size_t bufsize, struct group **result); int getgrgid_r(gid_t gid, struct group *grp, char *buffer, size_t bufsize, struct group **result);</pre>
DESCRIPTION	<p>These functions are used to obtain entries describing user groups. Entries can come from any of the sources for group specified in the <code>/etc/nsswitch.conf</code> file (see <code>nsswitch.conf(4)</code>).</p> <p>The <code>getgrnam()</code> function searches the group database for an entry with the group name specified by the character string parameter <i>name</i>.</p> <p>The <code>getgrgid()</code> function searches the group database for an entry with the (numeric) group id specified by <i>gid</i>.</p> <p>The <code>setgrent()</code>, <code>getgrent()</code>, and <code>endgrent()</code> functions are used to enumerate group entries from the database.</p> <p>The <code>setgrent()</code> function effectively rewinds the group database to allow repeated searches. It sets (or resets) the enumeration to the beginning of the set of group entries. This function should be called before the first call to <code>getgrent()</code>.</p>

The `getgrent()` function returns a pointer to a structure containing the broken-out fields of an entry in the group database. When first called, `getgrent()` returns a pointer to a `group` structure containing the next group structure in the group database. Successive calls may be used to search the entire database.

The `endgrent()` function may be called to close the group database and deallocate resources when processing is complete. It is permissible, though possibly less efficient, for the process to call more group functions after calling `endgrent()`.

The `fgetgrent()` function, unlike the other functions above, does not use `nsswitch.conf`. It reads and parses the next line from the stream *f*, which is assumed to have the format of the group file (see `group(4)`).

Reentrant Interfaces

The `getgrnam()`, `getgrgid()`, `getgrent()`, and `fgetgrent()` functions use static storage that is reused in each call, making them unsafe for multithreaded applications.

The parallel functions `getgrnam_r()`, `getgrgid_r()`, `getgrent_r()`, and `fgetgrent_r()` provide reentrant interfaces for these operations.

Each reentrant interface performs the same operation as its non-reentrant counterpart, named by removing the `_r` suffix. The reentrant interfaces, however, use buffers supplied by the caller to store returned results, and are safe for use in both single-threaded and multithreaded applications.

Each reentrant interface takes the same arguments as its non-reentrant counterpart, as well as the following additional parameters. The *grp* argument must be a pointer to a `struct group` structure allocated by the caller. On successful completion, the function returns the group entry in this structure. Storage referenced by the group structure is allocated from the memory provided with the *buffer* argument, which is *bufsize* characters in size. The maximum size needed for this buffer can be determined with the `_SC_GETGR_R_SIZE_MAX` `sysconf(3C)` parameter. The POSIX versions place a pointer to the modified *grp* structure in the *result* parameter, instead of returning a pointer to this structure.

For enumeration in multithreaded applications, the position within the enumeration is a process-wide property shared by all threads. `setgrent()` may be used in a multithreaded application but resets the enumeration position for all threads. If multiple threads interleave calls to `getgrent_r()`, the threads will enumerate disjoint subsets of the group database. Like their non-reentrant counterparts, `getgrnam_r()` and `getgrgid_r()` leave the enumeration position in an indeterminate state.

RETURN VALUES

Group entries are represented by the `struct group` structure defined in `<grp.h>`:

```
struct group {
    char *gr_name;           /* the name of the group */
    char *gr_passwd;        /* the encrypted group password */
    gid_t gr_gid;          /* the numerical group ID */
    char **gr_mem;         /* vector of pointers to member names */
};
```

fgetgrent_r(3C)

The `getgrnam()`, `getgrnam_r()`, `getgrgid()`, and `getgrgid_r()` functions each return a pointer to a `struct group` if they successfully locate the requested entry; otherwise they return `NULL`. The POSIX functions `getgrnam_r()` and `getgrgid_r()` return 0 upon success or the error number in case of failure.

The `getgrent()`, `getgrent_r()`, `fgetgrent()`, and `fgetgrent_r()` functions each return a pointer to a `struct group` if they successfully enumerate an entry; otherwise they return `NULL`, indicating the end of the enumeration.

The `getgrnam()`, `getgrgid()`, `getgrent()`, and `fgetgrent()` functions use static storage, so returned data must be copied before a subsequent call to any of these functions if the data is to be saved.

When the pointer returned by the reentrant functions `getgrnam_r()`, `getgrgid_r()`, `getgrent_r()`, and `fgetgrent_r()` is non-null, it is always equal to the `grp` pointer that was supplied by the caller.

ERRORS The `getgrnam()`, `getgrgid()`, `getgrent()`, `fgetgrent()`, and `fgetgrent_r()` functions may fail if:

<code>EINTR</code>	A signal was caught during the operation.
<code>EIO</code>	An I/O error has occurred.
<code>EMFILE</code>	There are <code>OPEN_MAX</code> file descriptors currently open in the calling process.
<code>ENFILE</code>	The maximum allowable number of files is currently open in the system.
<code>ERANGE</code>	The group file contains a line that exceeds 512 bytes.

The `getgrnam_r()`, `getgrgid_r()`, and `getgrent_r()` functions may fail if:

<code>ERANGE</code>	Insufficient storage was supplied by <i>buffer</i> and <i>bufsize</i> to contain the data to be referenced by the resulting <code>group</code> structure.
---------------------	---

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

MT-Level	See "Reentrant Interfaces" in <code>DESCRIPTION</code> .

SEE ALSO `Intro(3)`, `getpwnam(3C)`, `group(4)`, `nsswitch.conf(4)`, `passwd(4)`, `attributes(5)`, `standards(5)`

NOTES When compiling multithreaded programs, see `Intro(3)`, *Notes On Multithreaded Applications*.

Programs that use the interfaces described in this manual page cannot be linked statically since the implementations of these functions employ dynamic loading and linking of shared objects at run time.

Use of the enumeration interfaces `getgrent()` and `getgrent_r()` is discouraged; enumeration is supported for the group file, NIS, and NIS+, but in general is not efficient and may not be supported for all database sources. The semantics of enumeration are discussed further in `nsswitch.conf(4)`.

Previous releases allowed the use of "+" and "-" entries in `/etc/group` to selectively include and exclude entries from NIS. The primary usage of these entries is superseded by the name service switch, so the "+/-" form *may not be supported in future releases*.

If required, the "+/-" functionality can still be obtained for NIS by specifying `compat` as the source for `group`.

If the "+/-" functionality is required in conjunction with NIS+, specify both `compat` as the source for `group` and `nisplus` as the source for the pseudo-database `group_compat`. See `group(4)`, and `nsswitch.conf(4)` for details.

Solaris 2.4 and earlier releases provided definitions of the `getgrnam_r()` and `getgrgid_r()` functions as specified in POSIX.1c Draft 6. The final POSIX.1c standard changed the interface for these functions. Support for the Draft 6 interface is provided for compatibility only and may not be supported in future releases. New applications and libraries should use the POSIX standard interface.

For POSIX.1c-compliant applications, the `_POSIX_PTHREAD_SEMANTICS` and `_REENTRANT` flags are automatically turned on by defining the `_POSIX_C_SOURCE` flag with a value $\geq 199506L$.

fgetpos(3C)

NAME	fgetpos – get current file position information
SYNOPSIS	<pre>#include <stdio.h> int fgetpos(FILE *<i>stream</i>, fpos_t *<i>pos</i>);</pre>
DESCRIPTION	The <code>fgetpos()</code> function stores the current value of the file position indicator for the stream pointed to by <i>stream</i> in the object pointed to by <i>pos</i> . The value stored contains unspecified information usable by <code>fsetpos(3C)</code> for repositioning the stream to its position at the time of the call to <code>fgetpos()</code> .
RETURN VALUES	Upon successful completion, <code>fgetpos()</code> returns 0. Otherwise, it returns a non-zero value and sets <code>errno</code> to indicate the error.
ERRORS	The <code>fgetpos()</code> function may fail if: EBADF The file descriptor underlying <i>stream</i> is not valid. ESPIPE The file descriptor underlying <i>stream</i> is associated with a pipe, a FIFO, or a socket. EOVERFLOW The current value of the file position cannot be represented correctly in an object of type <code>fpos_t</code> .
USAGE	The <code>fgetpos()</code> function has a transitional interface for 64-bit file offsets. See <code>lf64(5)</code> .
SEE ALSO	<code>fopen(3C)</code> , <code>fsetpos(3C)</code> , <code>ftell(3C)</code> , <code>rewind(3C)</code> , <code>ungetc(3C)</code> , <code>lf64(5)</code>

NAME	getpwnam, getpwnam_r, getpwent, getpwent_r, getpwuid, getpwuid_r, setpwent, endpwent, fgetpwent, fgetpwent_r – get password entry
SYNOPSIS	<pre>#include <pwd.h> struct passwd *getpwnam(const char *name); struct passwd *getpwnam_r(const char *name, struct passwd *pwd, char *buffer, int buflen); struct passwd *getpwent(void); struct passwd *getpwent_r(struct passwd *pwd, char *buffer, int buflen); struct passwd *getpwuid(uid_t uid); struct passwd *getpwuid_r(uid_t uid, struct passwd *pwd, char *buffer, int buflen); void setpwent(void); void endpwent(void); struct passwd *fgetpwent(FILE *f); struct passwd *fgetpwent_r(FILE *f, struct passwd *pwd, char *buffer, int buflen);</pre>
POSIX	<pre>cc [flag...] file... -D_POSIX_PTHREAD_SEMANTICS [library...] int getpwnam_r(const char *name, struct passwd *pwd, char *buffer, size_t bufsize, struct passwd **result); int getpwuid_r(uid_t uid, struct passwd *pwd, char *buffer, size_t bufsize, struct passwd **result);</pre>
DESCRIPTION	<p>These functions are used to obtain password entries. Entries can come from any of the sources for passwd specified in the <code>/etc/nsswitch.conf</code> file (see <code>nsswitch.conf(4)</code>).</p> <p>The <code>getpwnam()</code> function searches for a password entry with the login name specified by the character string parameter <i>name</i>.</p> <p>The <code>getpwuid()</code> function searches for a password entry with the (numeric) user ID specified by the parameter <i>uid</i>.</p> <p>The <code>setpwent()</code>, <code>getpwent()</code>, and <code>endpwent()</code> functions are used to enumerate password entries from the database. <code>setpwent()</code> sets (or resets) the enumeration to the beginning of the set of password entries. This function should be called before the first call to <code>getpwent()</code>. Calls to <code>getpwnam()</code> and <code>getpwuid()</code> leave the enumeration position in an indeterminate state. Successive calls to <code>getpwent()</code> return either successive entries or <code>NULL</code>, indicating the end of the enumeration.</p>

fgetpwent(3C)

The `endpwent()` function may be called to indicate that the caller expects to do no further password retrieval operations; the system may then close the password file, deallocate resources it was using, and so forth. It is still allowed, but possibly less efficient, for the process to call more password functions after calling `endpwent()`.

The `fgetpwent()` function, unlike the other functions above, does not use `nsswitch.conf`; it reads and parses the next line from the stream `f`, which is assumed to have the format of the `passwd` file. See `passwd(4)`.

Reentrant Interfaces

The functions `getpwnam()`, `getpwuid()`, `getpwent()`, and `fgetpwent()` use static storage that is reused in each call, making these routines unsafe for use in multithreaded applications.

The parallel functions `getpwnam_r()`, `getpwuid_r()`, `getpwent_r()`, and `fgetpwent_r()` provide reentrant interfaces for these operations.

Each reentrant interface performs the same operation as its non-reentrant counterpart, named by removing the “`_r`” suffix. The reentrant interfaces, however, use buffers supplied by the caller to store returned results, and are safe for use in both single-threaded and multithreaded applications.

Each reentrant interface takes the same parameters as its non-reentrant counterpart, as well as the following additional parameters. The parameter `pwd` must be a pointer to a `struct passwd` structure allocated by the caller. On successful completion, the function returns the password entry in this structure. The parameter `buffer` is a pointer to a buffer supplied by the caller, used as storage space for the password data. All of the pointers within the returned `struct passwd` `pwd` point to data stored within this buffer; see RETURN VALUES. The buffer must be large enough to hold all the data associated with the password entry. The parameter `buflen` (or `bufsize` for the POSIX versions; see `standards(5)`) should give the size in bytes of `buffer`. The POSIX versions place a pointer to the modified `pwd` structure in the `result` parameter, instead of returning a pointer to this structure.

For enumeration in multithreaded applications, the position within the enumeration is a process-wide property shared by all threads. The `setpwent()` function may be used in a multithreaded application but resets the enumeration position for all threads. If multiple threads interleave calls to `getpwent_r()`, the threads will enumerate disjoint subsets of the password database.

Like their non-reentrant counterparts, `getpwnam_r()` and `getpwuid_r()` leave the enumeration position in an indeterminate state.

RETURN VALUES

Password entries are represented by the `struct passwd` structure defined in `<pwd.h>`:

```
struct passwd {
    char *pw_name;          /* user's login name */
    char *pw_passwd;       /* no longer used */
    uid_t pw_uid;          /* user's uid */
    gid_t pw_gid;          /* user's gid */
};
```

```

char *pw_age;      /* not used */
char *pw_comment; /* not used */
char *pw_gecos;   /* typically user's full name */
char *pw_dir;     /* user's home dir */
char *pw_shell;   /* user's login shell */
};

```

The `pw_passwd` member should not be used as the encrypted password for the user; use `getspnam()` or `getspnam_r()` instead. See `getspnam(3C)`.

The `getpwnam()`, `getpwnam_r()`, `getpwuid()`, and `getpwuid_r()` functions each return a pointer to a `struct passwd` if they successfully locate the requested entry; otherwise they return `NULL`. Upon successful completion (including the case when the requested entry is not found), the POSIX functions `getpwnam_r()` and `getpwuid_r()` return 0. Otherwise, an error number is returned to indicate the error.

The `getpwent()`, `getpwent_r()`, `fgetpwent()`, and `fgetpwent_r()` functions each return a pointer to a `struct passwd` if they successfully enumerate an entry; otherwise they return `NULL`, indicating the end of the enumeration.

The `getpwnam()`, `getpwuid()`, `getpwent()`, and `fgetpwent()` functions use static storage, so returned data must be copied before a subsequent call to any of these functions if the data is to be saved.

When the pointer returned by the reentrant functions `getpwnam_r()`, `getpwuid_r()`, `getpwent_r()`, and `fgetpwent_r()` is non-null, it is always equal to the `pwd` pointer that was supplied by the caller.

ERRORS The reentrant functions `getpwnam_r()`, `getpwuid_r()`, `getpwent_r()`, and `fgetpwent_r()` will return `NULL` and set `errno` to `ERANGE` (or in the case of POSIX functions `getpwnam_r()` and `getpwuid_r()` return the `ERANGE` error) if the length of the buffer supplied by caller is not large enough to store the result. See `Intro(2)` for the proper usage and interpretation of `errno` in multithreaded applications.

USAGE Applications that use the interfaces described on this manual page cannot be linked statically, since the implementations of these functions employ dynamic loading and linking of shared objects at run time.

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
MT-Level	See "Reentrant Interfaces" in <code>DESCRIPTION</code> .

SEE ALSO `nispasswd(1)`, `passwd(1)`, `yppasswd(1)`, `Intro(2)`, `Intro(3)`, `cuserid(3C)`, `getgrnam(3C)`, `getlogin(3C)`, `getspnam(3C)`, `nsswitch.conf(4)`, `passwd(4)`, `shadow(4)`, `attributes(5)`, `standards(5)`

fgetpwent(3C)

NOTES | When compiling multithreaded programs, see `Intro(3)`, *Notes On Multithreaded Applications*.

Use of the enumeration interfaces `getpwent()` and `getpwent_r()` is discouraged; enumeration is supported for the `passwd` file, NIS, and NIS+, but in general is not efficient and may not be supported for all database sources. The semantics of enumeration are discussed further in `nsswitch.conf(4)`.

Previous releases allowed the use of '+' and '-' entries in `/etc/passwd` to selectively include and exclude NIS entries. The primary usage of these '+/-' entries is superseded by the name service switch, so the '+/-' form may not be supported in future releases.

If required, the '+/-' functionality can still be obtained for NIS by specifying `compat` as the source for `passwd`.

If the '+/-' functionality is required in conjunction with NIS+, specify both `compat` as the source for `passwd` and `nisplus` as the source for the pseudo-database `passwd_compat`. See `passwd(4)`, `shadow(4)`, and `nsswitch.conf(4)` for details.

If the '+/-' is used, both `/etc/shadow` and `/etc/passwd` should have the same '+' and '-' entries to ensure consistency between the password and shadow databases.

If a password entry from any of the sources contains an empty `uid` or `gid` field, that entry will be ignored by the files, NIS, and NIS+ name service switch backends. This will cause the user to appear unknown to the system.

If a password entry contains an empty `gecos`, `home directory`, or `shell` field, `getpwnam()` and `getpwnam_r()` return a pointer to a null string in the respective field of the `passwd` structure.

If the shell field is empty, `login(1)` automatically assigns the default shell. See `login(1)`.

Solaris 2.4 and earlier releases provided definitions of the `getpwnam_r()` and `getpwuid_r()` functions as specified in POSIX.1c Draft 6. The final POSIX.1c standard changed the interface for these functions. Support for the Draft 6 interface is provided for compatibility only and may not be supported in future releases. New applications and libraries should use the POSIX standard interface.

For POSIX.1c-compliant applications, the `_POSIX_PTHREAD_SEMANTICS` and `_REENTRANT` flags are automatically turned on by defining the `_POSIX_C_SOURCE` flag with a value `>= 199506L`.

NAME	getpwnam, getpwnam_r, getpwent, getpwent_r, getpwuid, getpwuid_r, setpwent, endpwent, fgetpwent, fgetpwent_r – get password entry
SYNOPSIS	<pre>#include <pwd.h> struct passwd *getpwnam(const char *name); struct passwd *getpwnam_r(const char *name, struct passwd *pwd, char *buffer, int buflen); struct passwd *getpwent(void); struct passwd *getpwent_r(struct passwd *pwd, char *buffer, int buflen); struct passwd *getpwuid(uid_t uid); struct passwd *getpwuid_r(uid_t uid, struct passwd *pwd, char *buffer, int buflen); void setpwent(void); void endpwent(void); struct passwd *fgetpwent(FILE *f); struct passwd *fgetpwent_r(FILE *f, struct passwd *pwd, char *buffer, int buflen);</pre>
POSIX	<pre>cc [flag...] file... -D_POSIX_PTHREAD_SEMANTICS [library...] int getpwnam_r(const char *name, struct passwd *pwd, char *buffer, size_t bufsize, struct passwd **result); int getpwuid_r(uid_t uid, struct passwd *pwd, char *buffer, size_t bufsize, struct passwd **result);</pre>
DESCRIPTION	<p>These functions are used to obtain password entries. Entries can come from any of the sources for <code>passwd</code> specified in the <code>/etc/nsswitch.conf</code> file (see <code>nsswitch.conf(4)</code>).</p> <p>The <code>getpwnam()</code> function searches for a password entry with the login name specified by the character string parameter <i>name</i>.</p> <p>The <code>getpwuid()</code> function searches for a password entry with the (numeric) user ID specified by the parameter <i>uid</i>.</p> <p>The <code>setpwent()</code>, <code>getpwent()</code>, and <code>endpwent()</code> functions are used to enumerate password entries from the database. <code>setpwent()</code> sets (or resets) the enumeration to the beginning of the set of password entries. This function should be called before the first call to <code>getpwent()</code>. Calls to <code>getpwnam()</code> and <code>getpwuid()</code> leave the enumeration position in an indeterminate state. Successive calls to <code>getpwent()</code> return either successive entries or <code>NULL</code>, indicating the end of the enumeration.</p>

fgetpwent_r(3C)

The `endpwent()` function may be called to indicate that the caller expects to do no further password retrieval operations; the system may then close the password file, deallocate resources it was using, and so forth. It is still allowed, but possibly less efficient, for the process to call more password functions after calling `endpwent()`.

The `fgetpwent()` function, unlike the other functions above, does not use `nsswitch.conf`; it reads and parses the next line from the stream *f*, which is assumed to have the format of the `passwd` file. See `passwd(4)`.

Reentrant Interfaces

The functions `getpwnam()`, `getpwuid()`, `getpwent()`, and `fgetpwent()` use static storage that is reused in each call, making these routines unsafe for use in multithreaded applications.

The parallel functions `getpwnam_r()`, `getpwuid_r()`, `getpwent_r()`, and `fgetpwent_r()` provide reentrant interfaces for these operations.

Each reentrant interface performs the same operation as its non-reentrant counterpart, named by removing the “_r” suffix. The reentrant interfaces, however, use buffers supplied by the caller to store returned results, and are safe for use in both single-threaded and multithreaded applications.

Each reentrant interface takes the same parameters as its non-reentrant counterpart, as well as the following additional parameters. The parameter `pwd` must be a pointer to a `struct passwd` structure allocated by the caller. On successful completion, the function returns the password entry in this structure. The parameter *buffer* is a pointer to a buffer supplied by the caller, used as storage space for the password data. All of the pointers within the returned `struct passwd` `pwd` point to data stored within this buffer; see RETURN VALUES. The buffer must be large enough to hold all the data associated with the password entry. The parameter *buflen* (or *bufsize* for the POSIX versions; see `standards(5)`) should give the size in bytes of *buffer*. The POSIX versions place a pointer to the modified `pwd` structure in the *result* parameter, instead of returning a pointer to this structure.

For enumeration in multithreaded applications, the position within the enumeration is a process-wide property shared by all threads. The `setpwent()` function may be used in a multithreaded application but resets the enumeration position for all threads. If multiple threads interleave calls to `getpwent_r()`, the threads will enumerate disjoint subsets of the password database.

Like their non-reentrant counterparts, `getpwnam_r()` and `getpwuid_r()` leave the enumeration position in an indeterminate state.

RETURN VALUES

Password entries are represented by the `struct passwd` structure defined in `<pwd.h>`:

```
struct passwd {
    char *pw_name;           /* user's login name */
    char *pw_passwd;        /* no longer used */
    uid_t pw_uid;           /* user's uid */
    gid_t pw_gid;           /* user's gid */
    char *pw_age;           /* not used */
}
```

```

char *pw_comment; /* not used */
char *pw_gecos; /* typically user's full name */
char *pw_dir; /* user's home dir */
char *pw_shell; /* user's login shell */
};

```

The `pw_passwd` member should not be used as the encrypted password for the user; use `getspnam()` or `getspnam_r()` instead. See `getspnam(3C)`.

The `getpwnam()`, `getpwnam_r()`, `getpwuid()`, and `getpwuid_r()` functions each return a pointer to a `struct passwd` if they successfully locate the requested entry; otherwise they return `NULL`. Upon successful completion (including the case when the requested entry is not found), the POSIX functions `getpwnam_r()` and `getpwuid_r()` return 0. Otherwise, an error number is returned to indicate the error.

The `getpwent()`, `getpwent_r()`, `fgetpwent()`, and `fgetpwent_r()` functions each return a pointer to a `struct passwd` if they successfully enumerate an entry; otherwise they return `NULL`, indicating the end of the enumeration.

The `getpwnam()`, `getpwuid()`, `getpwent()`, and `fgetpwent()` functions use static storage, so returned data must be copied before a subsequent call to any of these functions if the data is to be saved.

When the pointer returned by the reentrant functions `getpwnam_r()`, `getpwuid_r()`, `getpwent_r()`, and `fgetpwent_r()` is non-null, it is always equal to the `pwd` pointer that was supplied by the caller.

ERRORS The reentrant functions `getpwnam_r()`, `getpwuid_r()`, `getpwent_r()`, and `fgetpwent_r()` will return `NULL` and set `errno` to `ERANGE` (or in the case of POSIX functions `getpwnam_r()` and `getpwuid_r()` return the `ERANGE` error) if the length of the buffer supplied by caller is not large enough to store the result. See `Intro(2)` for the proper usage and interpretation of `errno` in multithreaded applications.

USAGE Applications that use the interfaces described on this manual page cannot be linked statically, since the implementations of these functions employ dynamic loading and linking of shared objects at run time.

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
MT-Level	See "Reentrant Interfaces" in <code>DESCRIPTION</code> .

SEE ALSO `nispasswd(1)`, `passwd(1)`, `yppasswd(1)`, `Intro(2)`, `Intro(3)`, `cuserid(3C)`, `getgrnam(3C)`, `getlogin(3C)`, `getspnam(3C)`, `nsswitch.conf(4)`, `passwd(4)`, `shadow(4)`, `attributes(5)`, `standards(5)`

NOTES When compiling multithreaded programs, see `Intro(3)`, *Notes On Multithreaded Applications*.

fgetpwent_r(3C)

Use of the enumeration interfaces `getpwent()` and `getpwent_r()` is discouraged; enumeration is supported for the `passwd` file, NIS, and NIS+, but in general is not efficient and may not be supported for all database sources. The semantics of enumeration are discussed further in `nsswitch.conf(4)`.

Previous releases allowed the use of '+' and '-' entries in `/etc/passwd` to selectively include and exclude NIS entries. The primary usage of these '+/-' entries is superseded by the name service switch, so the '+/-' form may not be supported in future releases.

If required, the '+/-' functionality can still be obtained for NIS by specifying `compat` as the source for `passwd`.

If the '+/-' functionality is required in conjunction with NIS+, specify both `compat` as the source for `passwd` and `nisplus` as the source for the pseudo-database `passwd_compat`. See `passwd(4)`, `shadow(4)`, and `nsswitch.conf(4)` for details.

If the '+/-' is used, both `/etc/shadow` and `/etc/passwd` should have the same '+' and '-' entries to ensure consistency between the password and shadow databases.

If a password entry from any of the sources contains an empty `uid` or `gid` field, that entry will be ignored by the files, NIS, and NIS+ name service switch backends. This will cause the user to appear unknown to the system.

If a password entry contains an empty `gecos`, `home directory`, or `shell` field, `getpwnam()` and `getpwnam_r()` return a pointer to a null string in the respective field of the `passwd` structure.

If the shell field is empty, `login(1)` automatically assigns the default shell. See `login(1)`.

Solaris 2.4 and earlier releases provided definitions of the `getpwnam_r()` and `getpwuid_r()` functions as specified in POSIX.1c Draft 6. The final POSIX.1c standard changed the interface for these functions. Support for the Draft 6 interface is provided for compatibility only and may not be supported in future releases. New applications and libraries should use the POSIX standard interface.

For POSIX.1c-compliant applications, the `_POSIX_PTHREAD_SEMANTICS` and `_REENTRANT` flags are automatically turned on by defining the `_POSIX_C_SOURCE` flag with a value `>= 199506L`.

NAME	gets, fgets – get a string from a stream				
SYNOPSIS	<pre>#include <stdio.h> char *gets(char *s); char *fgets(char *s, int n, FILE *stream);</pre>				
DESCRIPTION	<p>The <code>gets()</code> function reads bytes from the standard input stream (see <code>intro(3)</code>), <code>stdin</code>, into the array pointed to by <code>s</code>, until a newline character is read or an end-of-file condition is encountered. The newline character is discarded and the string is terminated with a null byte.</p> <p>If the length of an input line exceeds the size of <code>s</code>, indeterminate behavior may result. For this reason, it is strongly recommended that <code>gets()</code> be avoided in favor of <code>fgets()</code>.</p> <p>The <code>fgets()</code> function reads bytes from the <code>stream</code> into the array pointed to by <code>s</code>, until <code>n-1</code> bytes are read, or a newline character is read and transferred to <code>s</code>, or an end-of-file condition is encountered. The string is then terminated with a null byte.</p> <p>The <code>fgets()</code> function may mark the <code>st_atime</code> field of the file associated with <code>stream</code> for update. The <code>st_atime</code> field will be marked for update by the first successful execution of <code>fgetc(3C)</code>, <code>fgets()</code>, <code>fgetc(3C)</code>, <code>fgetwc(3C)</code>, <code>fgetws(3C)</code>, <code>fread(3C)</code>, <code>fscanf(3C)</code>, <code>getc(3C)</code>, <code>getchar(3C)</code>, <code>gets()</code>, or <code>scanf(3C)</code> using <code>stream</code> that returns data not supplied by a prior call to <code>ungetc(3C)</code> or <code>ungetwc(3C)</code>.</p>				
RETURN VALUES	If end-of-file is encountered and no bytes have been read, no bytes are transferred to <code>s</code> and a null pointer is returned. If a read error occurs, such as trying to use these functions on a file that has not been opened for reading, a null pointer is returned and the error indicator for the stream is set. If end-of-file is encountered, the EOF indicator for the stream is set. Otherwise <code>s</code> is returned.				
ERRORS	Refer to <code>fgetc(3C)</code> .				
ATTRIBUTES	See <code>attributes(5)</code> for descriptions of the following attributes:				
	<table border="1" style="width: 100%; border-collapse: collapse;"> <thead> <tr> <th style="text-align: center;">ATTRIBUTE TYPE</th> <th style="text-align: center;">ATTRIBUTE VALUE</th> </tr> </thead> <tbody> <tr> <td>MT-Level</td> <td>MT-Safe</td> </tr> </tbody> </table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	MT-Level	MT-Safe

fgetspent(3C)

NAME	getspnam, getspnam_r, getspent, getspent_r, setspent, endspent, fgetspent, fgetspent_r – get password entry
SYNOPSIS	<pre>#include <shadow.h> struct spwd *getspnam(const char *name); struct spwd *getspnam_r(const char *name, struct spwd *result, char *buffer, int buflen); struct spwd *getspent(void); struct spwd *getspent_r(struct spwd *result, char *buffer, int buflen); void setspent(void); void endspent(void); struct spwd *fgetspent(FILE *fp); struct spwd *fgetspent_r(FILE *fp, struct spwd *result, char *buffer, int buflen);</pre>
DESCRIPTION	<p>These functions are used to obtain shadow password entries. An entry may come from any of the sources for shadow specified in the <code>/etc/nsswitch.conf</code> file (see <code>nsswitch.conf(4)</code>).</p> <p>The <code>getspnam()</code> function searches for a shadow password entry with the login name specified by the character string argument <i>name</i>.</p> <p>The <code>setspent()</code>, <code>getspent()</code>, and <code>endspent()</code> functions are used to enumerate shadow password entries from the database.</p> <p>The <code>setspent()</code> function sets (or resets) the enumeration to the beginning of the set of shadow password entries. This function should be called before the first call to <code>getspent()</code>. Calls to <code>getspnam()</code> leave the enumeration position in an indeterminate state.</p> <p>Successive calls to <code>getspent()</code> return either successive entries or NULL, indicating the end of the enumeration.</p> <p>The <code>endspent()</code> function may be called to indicate that the caller expects to do no further shadow password retrieval operations; the system may then close the shadow password file, deallocate resources it was using, and so forth. It is still allowed, but possibly less efficient, for the process to call more shadow password functions after calling <code>endspent()</code>.</p> <p>The <code>fgetspent()</code> function, unlike the other functions above, does not use <code>nsswitch.conf</code>; it reads and parses the next line from the stream <i>fp</i>, which is assumed to have the format of the shadow file (see <code>shadow(4)</code>).</p>
Reentrant Interfaces	The <code>getspnam()</code> , <code>getspent()</code> , and <code>fgetspent()</code> functions use static storage that is re-used in each call, making these routines unsafe for use in multithreaded applications.

The `getspnam_r()`, `getspent_r()`, and `fgetspent_r()` functions provide reentrant interfaces for these operations.

Each reentrant interface performs the same operation as its non-reentrant counterpart, named by removing the `_r` suffix. The reentrant interfaces, however, use buffers supplied by the caller to store returned results, and are safe for use in both single-threaded and multithreaded applications.

Each reentrant interface takes the same argument as its non-reentrant counterpart, as well as the following additional arguments. The *result* argument must be a pointer to a `struct spwd` structure allocated by the caller. On successful completion, the function returns the shadow password entry in this structure. The *buffer* argument must be a pointer to a buffer supplied by the caller. This buffer is used as storage space for the shadow password data. All of the pointers within the returned `struct spwd result` point to data stored within this buffer (see RETURN VALUES). The buffer must be large enough to hold all of the data associated with the shadow password entry. The *buflen* argument should give the size in bytes of the buffer indicated by *buffer*.

For enumeration in multithreaded applications, the position within the enumeration is a process-wide property shared by all threads. The `setspent()` function may be used in a multithreaded application but resets the enumeration position for all threads. If multiple threads interleave calls to `getspent_r()`, the threads will enumerate disjoint subsets of the shadow password database.

Like its non-reentrant counterpart, `getspnam_r()` leaves the enumeration position in an indeterminate state.

RETURN VALUES

Password entries are represented by the `struct spwd` structure defined in `<shadow.h>`:

```
struct spwd{
    char      *sp_namp;      /* login name */
    char      *sp_pwdp;     /* encrypted passwd */
    long      sp_lstchg;     /* date of last change */
    long      sp_min;       /* min days to passwd change */
    long      sp_max;       /* max days to passwd change*/
    long      sp_warn;      /* warning period */
    long      sp_inact;     /* max days inactive */
    long      sp_expire;    /* account expiry date */
    unsigned long sp_flag;  /* not used */
};
```

See `shadow(4)` for more information on the interpretation of this data.

The `getspnam()` and `getspnam_r()` functions each return a pointer to a `struct spwd` if they successfully locate the requested entry; otherwise they return `NULL`.

The `getspent()`, `getspent_r()`, `fgetspent()`, and `fgetspent_r()` functions each return a pointer to a `struct spwd` if they successfully enumerate an entry; otherwise they return `NULL`, indicating the end of the enumeration.

fgetspent(3C)

The `getspnam()`, `getspent()`, and `fgetspent()` functions use static storage, so returned data must be copied before a subsequent call to any of these functions if the data is to be saved.

When the pointer returned by the reentrant functions `getspnam_r()`, `getspent_r()`, and `fgetspent_r()` is non-null, it is always equal to the *result* pointer that was supplied by the caller.

ERRORS The reentrant functions `getspnam_r()`, `getspent_r()`, and `fgetspent_r()` will return NULL and set `errno` to `ERANGE` if the length of the buffer supplied by caller is not large enough to store the result. See `intro(2)` for the proper usage and interpretation of `errno` in multithreaded applications.

USAGE Applications that use the interfaces described on this manual page cannot be linked statically, since the implementations of these functions employ dynamic loading and linking of shared objects at run time.

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
MT-Level	See "Reentrant Interfaces" in <code>DESCRIPTION</code> .

SEE ALSO `nispasswd(1)`, `passwd(1)`, `yppasswd(1)`, `intro(3)` `getlogin(3C)`, `getpwnam(3C)`, `nsswitch.conf(4)`, `passwd(4)`, `shadow(4)`, `attributes(5)`

WARNINGS The reentrant interfaces `getspnam_r()`, `getspent_r()`, and `fgetspent_r()` are included in this release on an uncommitted basis only, and are subject to change or removal in future minor releases.

NOTES When compiling multithreaded applications, see `intro(3)`, *Notes On Multithreaded Applications*, for information about the use of the `_REENTRANT` flag.

Use of the enumeration interfaces `getspent()` and `getspent_r()` is not recommended; enumeration is supported for the shadow file, NIS, and NIS+, but in general is not efficient and may not be supported for all database sources. The semantics of enumeration are discussed further in `nsswitch.conf(4)`.

Access to shadow password information may be restricted in a manner depending on the database source being used. Access to the `/etc/shadow` file is generally restricted to processes running as the super-user (root). Other database sources may impose stronger or less stringent restrictions.

When NIS is used as the database source, the information for the shadow password entries is obtained from the "passwd.byname" map. This map stores only the information for the `sp_namp` and `sp_pwdp` fields of the `struct spwd` structure. Shadow password entries obtained from NIS will contain the value -1 in the remainder of the fields.

fgetspent(3C)

When NIS+ is used as the database source, and the caller lacks the permission needed to retrieve the encrypted password from the NIS+ "passwd.org_dir" table, the NIS+ service returns the string "*NP*" instead of the actual encrypted password string. The functions described on this page will then return the string "*NP*" to the caller as the value of the member `sp_pwdp` in the returned shadow password structure.

fgetspent_r(3C)

NAME	getspnam, getspnam_r, getspent, getspent_r, setspent, endspent, fgetspent, fgetspent_r – get password entry
SYNOPSIS	<pre>#include <shadow.h> struct spwd *getspnam(const char *name); struct spwd *getspnam_r(const char *name, struct spwd *result, char *buffer, int buflen); struct spwd *getspent(void); struct spwd *getspent_r(struct spwd *result, char *buffer, int buflen); void setspent(void); void endspent(void); struct spwd *fgetspent(FILE *fp); struct spwd *fgetspent_r(FILE *fp, struct spwd *result, char *buffer, int buflen);</pre>
DESCRIPTION	<p>These functions are used to obtain shadow password entries. An entry may come from any of the sources for shadow specified in the <code>/etc/nsswitch.conf</code> file (see <code>nsswitch.conf(4)</code>).</p> <p>The <code>getspnam()</code> function searches for a shadow password entry with the login name specified by the character string argument <i>name</i>.</p> <p>The <code>setspent()</code>, <code>getspent()</code>, and <code>endspent()</code> functions are used to enumerate shadow password entries from the database.</p> <p>The <code>setspent()</code> function sets (or resets) the enumeration to the beginning of the set of shadow password entries. This function should be called before the first call to <code>getspent()</code>. Calls to <code>getspnam()</code> leave the enumeration position in an indeterminate state.</p> <p>Successive calls to <code>getspent()</code> return either successive entries or <code>NULL</code>, indicating the end of the enumeration.</p> <p>The <code>endspent()</code> function may be called to indicate that the caller expects to do no further shadow password retrieval operations; the system may then close the shadow password file, deallocate resources it was using, and so forth. It is still allowed, but possibly less efficient, for the process to call more shadow password functions after calling <code>endspent()</code>.</p> <p>The <code>fgetspent()</code> function, unlike the other functions above, does not use <code>nsswitch.conf</code>; it reads and parses the next line from the stream <i>fp</i>, which is assumed to have the format of the shadow file (see <code>shadow(4)</code>).</p>
Reentrant Interfaces	The <code>getspnam()</code> , <code>getspent()</code> , and <code>fgetspent()</code> functions use static storage that is re-used in each call, making these routines unsafe for use in multithreaded applications.

The `getspnam_r()`, `getspent_r()`, and `fgetspent_r()` functions provide reentrant interfaces for these operations.

Each reentrant interface performs the same operation as its non-reentrant counterpart, named by removing the `_r` suffix. The reentrant interfaces, however, use buffers supplied by the caller to store returned results, and are safe for use in both single-threaded and multithreaded applications.

Each reentrant interface takes the same argument as its non-reentrant counterpart, as well as the following additional arguments. The *result* argument must be a pointer to a `struct spwd` structure allocated by the caller. On successful completion, the function returns the shadow password entry in this structure. The *buffer* argument must be a pointer to a buffer supplied by the caller. This buffer is used as storage space for the shadow password data. All of the pointers within the returned `struct spwd result` point to data stored within this buffer (see RETURN VALUES). The buffer must be large enough to hold all of the data associated with the shadow password entry. The *buflen* argument should give the size in bytes of the buffer indicated by *buffer*.

For enumeration in multithreaded applications, the position within the enumeration is a process-wide property shared by all threads. The `setspent()` function may be used in a multithreaded application but resets the enumeration position for all threads. If multiple threads interleave calls to `getspent_r()`, the threads will enumerate disjoint subsets of the shadow password database.

Like its non-reentrant counterpart, `getspnam_r()` leaves the enumeration position in an indeterminate state.

RETURN VALUES

Password entries are represented by the `struct spwd` structure defined in `<shadow.h>`:

```
struct spwd{
    char      *sp_namp;      /* login name */
    char      *sp_pwdp;     /* encrypted passwd */
    long      sp_lstchg;    /* date of last change */
    long      sp_min;      /* min days to passwd change */
    long      sp_max;      /* max days to passwd change*/
    long      sp_warn;     /* warning period */
    long      sp_inact;    /* max days inactive */
    long      sp_expire;   /* account expiry date */
    unsigned long sp_flag;  /* not used */
};
```

See `shadow(4)` for more information on the interpretation of this data.

The `getspnam()` and `getspnam_r()` functions each return a pointer to a `struct spwd` if they successfully locate the requested entry; otherwise they return `NULL`.

The `getspent()`, `getspent_r()`, `fgetspent()`, and `fgetspent_r()` functions each return a pointer to a `struct spwd` if they successfully enumerate an entry; otherwise they return `NULL`, indicating the end of the enumeration.

fgetspent_r(3C)

The `getspnam()`, `getspent()`, and `fgetspent()` functions use static storage, so returned data must be copied before a subsequent call to any of these functions if the data is to be saved.

When the pointer returned by the reentrant functions `getspnam_r()`, `getspent_r()`, and `fgetspent_r()` is non-null, it is always equal to the *result* pointer that was supplied by the caller.

ERRORS The reentrant functions `getspnam_r()`, `getspent_r()`, and `fgetspent_r()` will return NULL and set `errno` to `ERANGE` if the length of the buffer supplied by caller is not large enough to store the result. See `intro(2)` for the proper usage and interpretation of `errno` in multithreaded applications.

USAGE Applications that use the interfaces described on this manual page cannot be linked statically, since the implementations of these functions employ dynamic loading and linking of shared objects at run time.

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
MT-Level	See "Reentrant Interfaces" in <code>DESCRIPTION</code> .

SEE ALSO `nispasswd(1)`, `passwd(1)`, `yppasswd(1)`, `intro(3)`, `getlogin(3C)`, `getpwnam(3C)`, `nsswitch.conf(4)`, `passwd(4)`, `shadow(4)`, `attributes(5)`

WARNINGS The reentrant interfaces `getspnam_r()`, `getspent_r()`, and `fgetspent_r()` are included in this release on an uncommitted basis only, and are subject to change or removal in future minor releases.

NOTES When compiling multithreaded applications, see `intro(3)`, *Notes On Multithreaded Applications*, for information about the use of the `_REENTRANT` flag.

Use of the enumeration interfaces `getspent()` and `getspent_r()` is not recommended; enumeration is supported for the shadow file, NIS, and NIS+, but in general is not efficient and may not be supported for all database sources. The semantics of enumeration are discussed further in `nsswitch.conf(4)`.

Access to shadow password information may be restricted in a manner depending on the database source being used. Access to the `/etc/shadow` file is generally restricted to processes running as the super-user (root). Other database sources may impose stronger or less stringent restrictions.

When NIS is used as the database source, the information for the shadow password entries is obtained from the "passwd.byname" map. This map stores only the information for the `sp_namp` and `sp_pwdp` fields of the `struct spwd` structure. Shadow password entries obtained from NIS will contain the value -1 in the remainder of the fields.

fgetspent_r(3C)

When NIS+ is used as the database source, and the caller lacks the permission needed to retrieve the encrypted password from the NIS+ "passwd.org_dir" table, the NIS+ service returns the string "*NP*" instead of the actual encrypted password string. The functions described on this page will then return the string "*NP*" to the caller as the value of the member `sp_pwdp` in the returned shadow password structure.

fgetwc(3C)

NAME	fgetwc – get a wide-character code from a stream										
SYNOPSIS	<pre>#include <stdio.h> #include <wchar.h> wint_t fgetwc (FILE*stream) ;</pre>										
DESCRIPTION	<p>The fgetwc () function obtains the next character (if present) from the input stream pointed to by <i>stream</i>, converts that to the corresponding wide-character code and advances the associated file position indicator for the stream (if defined).</p> <p>If an error occurs, the resulting value of the file position indicator for the stream is indeterminate.</p> <p>The fgetwc () function may mark the st_atime field of the file associated with <i>stream</i> for update. The st_atime field will be marked for update by the first successful execution of fgetwc (), fgetc(3C), fgets(3C), fgetws(3C), fread(3C), fscanf(3C),getc(3C), getchar(3C), gets(3C), or scanf(3C) using <i>stream</i> that returns data not supplied by a prior call to ungetc(3C) or ungetwc(3C).</p>										
RETURN VALUES	<p>Upon successful completion the fgetwc () function returns the wide-character code of the character read from the input stream pointed to by <i>stream</i> converted to a type wint_t.</p> <p>If the stream is at end-of-file, the end-of-file indicator for the stream is set and fgetwc () returns WEOF.</p> <p>If a read error occurs, the error indicator for the stream is set, fgetwc () returns WEOF and sets errno to indicate the error.</p>										
ERRORS	<p>The fgetwc () function will fail if data needs to be read and:</p> <table><tr><td>EAGAIN</td><td>The O_NONBLOCK flag is set for the file descriptor underlying <i>stream</i> and the process would be delayed in the fgetwc () operation.</td></tr><tr><td>EBADF</td><td>The file descriptor underlying <i>stream</i> is not a valid file descriptor open for reading.</td></tr><tr><td>EINTR</td><td>The read operation was terminated due to the receipt of a signal, and no data was transferred.</td></tr><tr><td>EIO</td><td>A physical I/O error has occurred, or the process is in a background process group attempting to read from its controlling terminal and either the process is ignoring or blocking the SIGTTIN signal or the process group is orphaned.</td></tr><tr><td>EOVERFLOW</td><td>The file is a regular file and an attempt was made to read at or beyond the offset maximum associated with the corresponding <i>stream</i>.</td></tr></table> <p>The fgetwc () function may fail if:</p>	EAGAIN	The O_NONBLOCK flag is set for the file descriptor underlying <i>stream</i> and the process would be delayed in the fgetwc () operation.	EBADF	The file descriptor underlying <i>stream</i> is not a valid file descriptor open for reading.	EINTR	The read operation was terminated due to the receipt of a signal, and no data was transferred.	EIO	A physical I/O error has occurred, or the process is in a background process group attempting to read from its controlling terminal and either the process is ignoring or blocking the SIGTTIN signal or the process group is orphaned.	EOVERFLOW	The file is a regular file and an attempt was made to read at or beyond the offset maximum associated with the corresponding <i>stream</i> .
EAGAIN	The O_NONBLOCK flag is set for the file descriptor underlying <i>stream</i> and the process would be delayed in the fgetwc () operation.										
EBADF	The file descriptor underlying <i>stream</i> is not a valid file descriptor open for reading.										
EINTR	The read operation was terminated due to the receipt of a signal, and no data was transferred.										
EIO	A physical I/O error has occurred, or the process is in a background process group attempting to read from its controlling terminal and either the process is ignoring or blocking the SIGTTIN signal or the process group is orphaned.										
EOVERFLOW	The file is a regular file and an attempt was made to read at or beyond the offset maximum associated with the corresponding <i>stream</i> .										

ENOMEM	Insufficient storage space is available.
ENXIO	A request was made of a non-existent device, or the request was outside the capabilities of the device.
EILSEQ	The data obtained from the input stream does not form a valid character.

USAGE The `ferror(3C)` or `feof(3C)` functions must be used to distinguish between an error condition and an end-of-file condition.

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
MT-Level	MT-Safe with exceptions
CSI	Enabled

SEE ALSO `feof(3C)`, `ferror(3C)`, `fgetc(3C)`, `fgets(3C)`, `fgetws(3C)`, `fopen(3C)`, `fread(3C)`, `fscanf(3C)`, `getc(3C)`, `getchar(3C)`, `gets(3C)`, `scanf(3C)`, `setlocale(3C)`, `ungetc(3C)`, `ungetwc(3C)`, `attributes(5)`

fgetws(3C)

NAME	getws, fgetws – get a wide-character string from a stream				
SYNOPSIS	<pre>#include <stdio.h> #include <wchar.h> wchar_t *getws (wchar_t *ws); #include <stdio.h> #include <wchar.h> wchar_t *fgetws (wchar_t *ws, int n, FILE *stream);</pre>				
DESCRIPTION	<p>The <code>getws()</code> function reads a string of characters from the standard input stream, <code>stdin</code>, converts these characters to the corresponding wide-character codes, and writes them to the array pointed to by <code>ws</code>, until a newline character is read, converted and transferred to <code>ws</code> or an end-of-file condition is encountered. The wide-character string, <code>ws</code>, is then terminated with a null wide-character code.</p> <p>The <code>fgetws()</code> function reads characters from the <code>stream</code>, converts them to the corresponding wide-character codes, and places them in the <code>wchar_t</code> array pointed to by <code>ws</code> until <code>n-1</code> characters are read, or until a newline character is read, converted and transferred to <code>ws</code>, or an end-of-file condition is encountered. The wide-character string, <code>ws</code>, is then terminated with a null wide-character code.</p> <p>If an error occurs, the resulting value of the file position indicator for the stream is indeterminate.</p> <p>The <code>fgetws()</code> function may mark the <code>st_atime</code> field of the file associated with <code>stream</code> for update. The <code>st_atime</code> field will be marked for update by the first successful execution of <code>fgetc(3C)</code>, <code>fgets(3C)</code>, <code>fgetwc(3C)</code>, <code>fgetws()</code>, <code>fread(3C)</code>, <code>fscanf(3C)</code>, <code>getc(3C)</code>, <code>getchar(3C)</code>, <code>gets(3C)</code>, or <code>scanf(3C)</code> using <code>stream</code> that returns data not supplied by a prior call to <code>scanf(3C)</code> or <code>scanf(3C)</code>.</p>				
RETURN VALUES	Upon successful completion, <code>getws()</code> and <code>fgetws()</code> returns <code>ws</code> . If the stream is at end-of-file, the end-of-file indicator for the stream is set and <code>fgetws()</code> returns a null pointer. If a read error occurs, the error indicator for the stream is set, <code>fgetws()</code> returns a null pointer and sets <code>errno</code> to indicate the error.				
ERRORS	See <code>fgetwc(3C)</code> for the conditions that will cause <code>fgetws()</code> to fail.				
ATTRIBUTES	See <code>attributes(5)</code> for descriptions of the following attributes:

NAME | `error, feof, clearerr, fileno` – stream status inquiries

SYNOPSIS | `#include <stdio.h>`
`int error(FILE *stream);`
`int feof(FILE *stream);`
`void clearerr(FILE *stream);`
`int fileno(FILE *stream);`

DESCRIPTION | The `error()` function returns a non-zero value when an error has previously occurred reading from or writing to the named *stream* (see `intro(3)`). It returns 0 otherwise.

The `feof()` function returns a non-zero value when EOF has previously been detected reading the named input *stream*. It returns 0 otherwise.

The `clearerr()` function resets the error indicator and EOF indicator to 0 on the named *stream*.

The `fileno()` function returns the integer file descriptor associated with the named *stream*; see `open(2)`.

ATTRIBUTES | See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
MT-Level	MT-Safe

file_to_decimal(3C)

NAME	string_to_decimal, file_to_decimal, func_to_decimal – parse characters into decimal record																
SYNOPSIS	<pre>#include <floatingpoint.h> void string_to_decimal(char **pc, int nmax, int fortran_conventions, decimal_record *pd, enum decimal_string_form *pform, char **pechar); void func_to_decimal(char **pc, int nmax, int fortran_conventions, decimal_record *pd, enum decimal_string_form *pform, char **pechar, int (*pget)(void), int *pnread, int (*punget)(int c)); #include <stdio.h> void file_to_decimal(char **pc, int nmax, int fortran_conventions, decimal_record *pd, enum decimal_string_form *pform, char **pechar, FILE *pf, int *pnread);</pre>																
DESCRIPTION	<p>The char_to_decimal functions parse a numeric token from at most <i>nmax</i> characters in a string <i>**pc</i> or file <i>*pf</i> or function (<i>*pget</i>)() into a decimal record <i>*pd</i>, classifying the form of the string in <i>*pform</i> and <i>*pechar</i>. The accepted syntax is intended to be sufficiently flexible to accommodate many languages: <i>whitespace value</i> or <i>whitespace sign value</i>, where <i>whitespace</i> is any number of characters defined by <i>isspace</i> in <i><ctype.h></i>, <i>sign</i> is either of [+–], and <i>value</i> can be <i>number</i>, <i>nan</i>, or <i>inf</i>. <i>inf</i> can be INF (<i>inf_form</i>) or INFINITY (<i>infinity_form</i>) without regard to case. <i>nan</i> can be NAN (<i>nan_form</i>) or NAN(<i>nstring</i>) (<i>nanstring_form</i>) without regard to case; <i>nstring</i> is any string of characters not containing ' ' or NULL; <i>nstring</i> is copied to <i>pd</i>→<i>ds</i> and, currently, not used subsequently. <i>number</i> consists of <i>significand</i> or <i>significand efield</i> where <i>significand</i> must contain one or more digits and may contain one point; possible forms are</p> <table><tr><td><i>digits</i></td><td>(<i>int_form</i>)</td></tr><tr><td><i>digits.</i></td><td>(<i>intdot_form</i>)</td></tr><tr><td><i>.digits</i></td><td>(<i>dotfrac_form</i>)</td></tr><tr><td><i>digits.digits</i></td><td>(<i>intdotfrac_form</i>)</td></tr></table> <p><i>efield</i> consists of <i>echar digits</i> or <i>echar sign digits</i>, where <i>echar</i> is one of [Ee], and <i>digits</i> contains one or more digits.</p> <p>When <i>fortran_conventions</i> is nonzero, additional input forms are accepted according to various Fortran conventions:</p> <table><tr><td>0</td><td>no Fortran conventions</td></tr><tr><td>1</td><td>Fortran list-directed input conventions</td></tr><tr><td>2</td><td>Fortran formatted input conventions, ignore blanks (BN)</td></tr><tr><td>3</td><td>Fortran formatted input conventions, blanks are zeros (BZ)</td></tr></table> <p>When <i>fortran_conventions</i> is nonzero, <i>echar</i> may also be one of [DdQq], and <i>efield</i> may also have the form</p>	<i>digits</i>	(<i>int_form</i>)	<i>digits.</i>	(<i>intdot_form</i>)	<i>.digits</i>	(<i>dotfrac_form</i>)	<i>digits.digits</i>	(<i>intdotfrac_form</i>)	0	no Fortran conventions	1	Fortran list-directed input conventions	2	Fortran formatted input conventions, ignore blanks (BN)	3	Fortran formatted input conventions, blanks are zeros (BZ)
<i>digits</i>	(<i>int_form</i>)																
<i>digits.</i>	(<i>intdot_form</i>)																
<i>.digits</i>	(<i>dotfrac_form</i>)																
<i>digits.digits</i>	(<i>intdotfrac_form</i>)																
0	no Fortran conventions																
1	Fortran list-directed input conventions																
2	Fortran formatted input conventions, ignore blanks (BN)																
3	Fortran formatted input conventions, blanks are zeros (BZ)																

sign digits.

When *fortran_conventions* ≥ 2 , blanks may appear in the *digits* strings for the integer, fraction, and exponent fields and may appear between *echar* and the exponent sign and after the infinity and NaN forms. If *fortran_conventions* $= 2$, the blanks are ignored. When *fortran_conventions* $= 3$, the blanks that appear in *digits* strings are interpreted as zeros, and other blanks are ignored.

When *fortran_conventions* is zero, the current locale's decimal point character is used as the decimal point; when *fortran_conventions* is nonzero, the period is used as the decimal point.

The form of the accepted decimal string is placed in *pform*. If an *efield* is recognized, *pechar* is set to point to the *echar*.

On input, *pc* points to the beginning of a character string buffer of length $\geq nmax$. On output, *pc* points to a character in that buffer, one past the last accepted character. `string_to_decimal()` gets its characters from the buffer; `file_to_decimal()` gets its characters from *pf* and records them in the buffer, and places a null after the last character read. `func_to_decimal()` gets its characters from an int function (*pget*()).

The scan continues until no more characters could possibly fit the acceptable syntax or until *nmax* characters have been scanned. If the *nmax* limit is not reached then at least one extra character will usually be scanned that is not part of the accepted syntax. `file_to_decimal()` and `func_to_decimal()` set *pnread* to the number of characters read from the file; if greater than *nmax*, some characters were lost. If no characters were lost, `file_to_decimal()` and `func_to_decimal()` attempt to push back, with `ungetc(3C)` or (*punget*()), as many as possible of the excess characters read, adjusting *pnread* accordingly. If all `unget` calls are successful, then *pc* will be NULL. No push back will be attempted if (*punget*()) is NULL.

Typical declarations for *pget*() and *punget*() are:

```
int xget(void)
{ . . . }
int (*pget)(void) = xget;
int xunget(int c)
{ . . . }
int (*punget)(int) = xunget;
```

If no valid number was detected, *pd* \rightarrow *fpclass* is set to *fp_signaling*, *pc* is unchanged, and *pform* is set to *invalid_form*.

`atof(3C)` and `strtod(3C)` use `string_to_decimal()`. `scanf(3C)` uses `file_to_decimal()`.

NAME	dbm, dbm _{init} , dbm _{close} , fetch, store, delete, firstkey, nextkey – data base subroutines
SYNOPSIS	<pre> /usr/ucb/cc [flag ...] file ... -ldb_m #include <dbm.h> typedef struct { char *dp_{tr}; int dsize; }datum; int dbm_{init} (file); char *file; int dbm_{close} (); datum fetch (key); datum key; int store (key, dat); datum key, dat; int delete (key); datum key; datum firstkey() datum nextkey (key); datum key; </pre>
DESCRIPTION	<p>The dbm() library has been superseded by ndbm (see ndbm(3C)).</p> <p>These functions maintain key/content pairs in a data base. The functions will handle very large (a billion blocks) databases and will access a keyed item in one or two file system accesses.</p> <p><i>key/dat</i> and their content are described by the datum typedef. A datum specifies a string of <i>dsize</i> bytes pointed to by <i>dptr</i>. Arbitrary binary data, as well as normal ASCII strings, are allowed. The data base is stored in two files. One file is a directory containing a bit map and has <i>.dir</i> as its suffix. The second file contains all data and has <i>.pag</i> as its suffix.</p> <p>Before a database can be accessed, it must be opened by dbm_{init} (). At the time of this call, the files <i>file.dir</i> and <i>file.pag</i> must exist. An empty database is created by creating zero-length <i>.dir</i> and <i>.pag</i> files.</p> <p>A database may be closed by calling dbm_{close} (). You must close a database before opening a new one.</p>

firstkey(3UCB)

Once open, the data stored under a key is accessed by `fetch()` and data is placed under a key by `store`. A key (and its associated contents) is deleted by `delete()`. A linear pass through all keys in a database may be made, in an (apparently) random order, by use of `firstkey()` and `nextkey()`. `firstkey()` will return the first key in the database. With any key `nextkey()` will return the next key in the database. This code will traverse the data base:

```
for (key = firstkey; key.dptr != NULL; key = nextkey(key))
```

RETURN VALUES All functions that return an `int` indicate errors with negative values. A zero return indicates no error. Routines that return a datum indicate errors with a `NULL (0) dptr`.

SEE ALSO `ar(1)`, `cat(1)`, `cp(1)`, `tar(1)`, `ndbm(3C)`

NOTES Use of these interfaces should be restricted to only applications written on BSD platforms. Use of these interfaces with any of the system libraries or in multi-thread applications is unsupported.

The `.pag` file will contain holes so that its apparent size may be larger than its actual content. Older versions of the UNIX operating system may create real file blocks for these holes when touched. These files cannot be copied by normal means (`cp(1)`, `cat(1)`, `tar(1)`, `ar(1)`) without filling in the holes.

`dptr` pointers returned by these subroutines point into static storage that is changed by subsequent calls.

The sum of the sizes of a key/content pair must not exceed the internal block size (currently 1024 bytes). Moreover all key/content pairs that hash together must fit on a single block. `store` will return an error in the event that a disk block fills with inseparable data.

`delete()` does not physically reclaim file space, although it does make it available for reuse.

The order of keys presented by `firstkey()` and `nextkey()` depends on a hashing function, not on anything interesting.

There are no interlocks and no reliable cache flushing; thus concurrent updating and reading is risky.

The database files (`file.dir` and `file.pag`) are binary and are architecture-specific (for example, they depend on the architecture's byte order.) These files are not guaranteed to be portable across architectures.

NAME	<code>__fbufsize</code> , <code>__flbf</code> , <code>__fpending</code> , <code>__fpurge</code> , <code>__freadable</code> , <code>__freading</code> , <code>__fsetlocking</code> , <code>__fwritable</code> , <code>__fwriting</code> , <code>_flushlbf</code> – interfaces to stdio FILE structure
SYNOPSIS	<pre>#include <stdio.h> #include <stdio_ext.h> size_t __fbufsiz(FILE *stream); int __flbf(FILE *stream); size_t __fpending(FILE *stream); void __fpurge(FILE *stream); int __freadable(FILE *stream); int __freading(FILE *stream); int __fsetlocking(FILE *stream, int type); int __fwritable(FILE *stream); int __fwriting(FILE *stream); void _flushlbf(void);</pre>
DESCRIPTION	<p>These functions provide portable access to the members of the <code>stdio(3C)</code> FILE structure.</p> <p>The <code>__fbufsize()</code> function returns in bytes the size of the buffer currently in use by the given stream.</p> <p>The <code>__flbf()</code> function returns non-zero if the stream is line-buffered.</p> <p>The <code>__fpending</code> function returns in bytes the amount of output pending on a stream.</p> <p>The <code>__fpurge()</code> function discards any pending buffered I/O on the stream.</p> <p>The <code>__freadable()</code> function returns non-zero if it is possible to read from a stream.</p> <p>The <code>__freading()</code> function returns non-zero if the file is open readonly, or if the last operation on the stream was a read operation such as <code>fread(3C)</code> or <code>fgetc(3C)</code>. Otherwise it returns 0.</p> <p>The <code>__fsetlocking()</code> function allows the type of locking performed by <code>stdio</code> on a given stream to be controlled by the programmer.</p> <p>If <code>type</code> is <code>FSETLOCKING_INTERNAL</code>, <code>stdio</code> performs implicit locking around every operation on the given stream. This is the default system behavior on that stream.</p> <p>If <code>type</code> is <code>FSETLOCKING_BYCALLER</code>, <code>stdio</code> assumes that the caller is responsible for maintaining the integrity of the stream in the face of access by multiple threads. If there is only one thread accessing the stream, nothing further needs to be done. If multiple threads are accessing the stream, then the caller can use the <code>flockfile()</code>,</p>

__flbf(3C)

`funlockfile()`, and `ftrylockfile()` functions described on the `flockfile(3C)` manual page to provide the appropriate locking. In both this and the case where *type* is `FSETLOCKING_INTERNAL`, `__fsetlocking()` returns the previous state of the stream.

If *type* is `FSETLOCKING_QUERY`, `__fsetlocking()` returns the current state of the stream without changing it.

The `__fwritable()` function returns non-zero if it is possible to write on a stream.

The `__fwriting()` function returns non-zero if the file is open write-only or append-only, or if the last operation on the stream was a write operation such as `fwrite(3C)` or `fputc(3C)`. Otherwise it returns 0.

The `_flushlbf()` function flushes all line-buffered files. It is used when reading from a line-buffered file.

USAGE

Although the contents of the `stdio` `FILE` structure have always been private to the `stdio` implementation, some applications have needed to obtain information about a `stdio` stream that was not accessible through a supported interface. These applications have resorted to accessing fields of the `FILE` structure directly, rendering them possibly non-portable to new implementations of `stdio`, or more likely, preventing enhancements to `stdio` that would cause those applications to break.

In the 64-bit environment, the `FILE` structure is opaque. The functions described here are provided as a means of obtaining the information that up to now has been retrieved directly from the `FILE` structure. Because they are based on the needs of existing applications (such as `mh` and `emacs`), they may be extended as other programs are ported. Although they may still be non-portable to other operating systems, they will be compatible from each Solaris release to the next. Interfaces that are more portable are under development.

ATTRIBUTES

NAME	floating_to_decimal, single_to_decimal, double_to_decimal, extended_to_decimal, quadruple_to_decimal – convert floating-point value to decimal record
SYNOPSIS	<pre>#include <floatingpoint.h> void single_to_decimal(single *px, decimal_mode *pm, decimal_record *pd, fp_exception_field_type *ps); void double_to_decimal(double *px, decimal_mode *pm, decimal_record *pd, fp_exception_field_type *ps); void extended_to_decimal(extended *px, decimal_mode *pm, decimal_record *pd, fp_exception_field_type *ps); void quadruple_to_decimal(quadruple *px, decimal_mode *pm, decimal_record *pd, fp_exception_field_type *ps);</pre>
DESCRIPTION	<p>The <code>floating_to_decimal()</code> functions convert the floating-point value at <code>*px</code> into a decimal record at <code>*pd</code>, observing the modes specified in <code>*pm</code> and setting exceptions in <code>*ps</code>. If there are no IEEE exceptions, <code>*ps</code> will be zero.</p> <p>If <code>*px</code> is zero, infinity, or NaN, then only <code>pd->sign</code> and <code>pd->fpclass</code> are set. Otherwise <code>pd->exponent</code> and <code>pd->ds</code> are also set so that</p> <p>$(\text{sig}) * (\text{pd->ds}) * 10^{(\text{pd->exponent})}$ is a correctly rounded approximation to <code>*px</code>, where <code>sig</code> is +1 or -1, depending upon whether <code>pd->sign</code> is 0 or -1. <code>pd->ds</code> has at least one and no more than <code>DECIMAL_STRING_LENGTH-1</code> significant digits because one character is used to terminate the string with a NULL.</p> <p><code>pd->ds</code> is correctly rounded according to the IEEE rounding modes in <code>pm->rd</code>. <code>*ps</code> has <code>fp_inexact</code> set if the result was inexact, and has <code>fp_overflow</code> set if the string result does not fit in <code>pd->ds</code> because of the limitation <code>DECIMAL_STRING_LENGTH</code>.</p> <p>If <code>pm->df == floating_form</code>, then <code>pd->ds</code> always contains <code>pm->ndigits</code> significant digits. Thus if <code>*px == 12.34</code> and <code>pm->ndigits == 8</code>, then <code>pd->ds</code> will contain 12340000 and <code>pd->exponent</code> will contain -6.</p> <p>If <code>pm->df == fixed_form</code> and <code>pm->ndigits >= 0</code>, then <code>pd->ds</code> always contains <code>pm->ndigits</code> after the point and as many digits as necessary before the point. Since the latter is not known in advance, the total number of digits required is returned in <code>pd->ndigits</code>; if that number <code>>= DECIMAL_STRING_LENGTH</code>, then <code>ds</code> is undefined. <code>pd->exponent</code> always gets <code>-pm->ndigits</code>. Thus if <code>*px == 12.34</code> and <code>pm->ndigits == 1</code>, then <code>pd->ds</code> gets 123, <code>pd->exponent</code> gets -1, and <code>pd->ndigits</code> gets 3.</p> <p>If <code>pm->df == fixed_form</code> and <code>pm->ndigits < 0</code>, then <code>pd->ds</code> always contains <code>-pm->ndigits</code> trailing zeros; in other words, rounding occurs <code>-pm->ndigits</code> to the left of the decimal point, but the digits rounded away are retained as zeros. The total number of digits required is in <code>pd->ndigits</code>. <code>pd->exponent</code> always gets 0. Thus if <code>*px == 12.34</code> and <code>pm->ndigits == -1</code>, then <code>pd->ds</code> gets 10, <code>pd->exponent</code> gets 0, and <code>pd->ndigits</code> gets 2.</p> <p><code>pd->more</code> is not used.</p>

floating_to_decimal(3C)

econvert(3C), fconvert(3C), gconvert(3C), printf(3C), and sprintf(3C) all use double_to_decimal().

NAME	flock – apply or remove an advisory lock on an open file
SYNOPSIS	<pre> /usr/ucb/cc[flag ...] file ... #include <sys/file.h> int flock(fd, operation); int fd, operation; </pre>
DESCRIPTION	<p><code>flock()</code> applies or removes an <i>advisory</i> lock on the file associated with the file descriptor <i>fd</i>. The compatibility version of <code>flock()</code> has been implemented on top of <code>fcntl(2)</code> locking. It does not provide complete binary compatibility.</p> <p>Advisory locks allow cooperating processes to perform consistent operations on files, but do not guarantee exclusive access (that is, processes may still access files without using advisory locks, possibly resulting in inconsistencies).</p> <p>The locking mechanism allows two types of locks: shared locks and exclusive locks. More than one process may hold a shared lock for a file at any given time, but multiple exclusive, or both shared and exclusive, locks may not exist simultaneously on a file.</p> <p>A lock is applied by specifying an <i>operation</i> parameter <code>LOCK_SH</code> for a shared lock or <code>LOCK_EX</code> for an exclusive lock. The <i>operation</i> parameter may be ORed with <code>LOCK_NB</code> to make the operation non-blocking. To unlock an existing lock, the <i>operation</i> should be <code>LOCK_UN</code>.</p> <p>Read permission is required on a file to obtain a shared lock, and write permission is required to obtain an exclusive lock. Locking a segment that is already locked by the calling process causes the old lock type to be removed and the new lock type to take effect.</p> <p>Requesting a lock on an object that is already locked normally causes the caller to block until the lock may be acquired. If <code>LOCK_NB</code> is included in <i>operation</i>, then this will not happen; instead, the call will fail and the error <code>EWOULDBLOCK</code> will be returned.</p>
RETURN VALUES	<p><code>flock()</code> returns:</p> <p>0 on success.</p> <p>-1 on failure and sets <code>errno</code> to indicate the error.</p>
ERRORS	<p><code>EBADF</code> The argument <i>fd</i> is an invalid descriptor.</p> <p><code>EINVAL</code> <i>operation</i> is not a valid argument.</p> <p><code>EOPNOTSUPP</code> The argument <i>fd</i> refers to an object other than a file.</p> <p><code>EWOULDBLOCK</code> The file is locked and the <code>LOCK_NB</code> option was specified.</p>
SEE ALSO	lockd(1M), chmod(2), close(2), dup(2), exec(2), fcntl(2), fork(2), open(2), lockf(3C)

flock(3UCB)

NOTES Use of these interfaces should be restricted to only applications written on BSD platforms. Use of these interfaces with any of the system libraries or in multi-thread applications is unsupported.

Locks are on files, not file descriptors. That is, file descriptors duplicated through `dup(2)` or `fork(2)` do not result in multiple instances of a lock, but rather multiple references to a single lock. If a process holding a lock on a file forks and the child explicitly unlocks the file, the parent will lose its lock. Locks are not inherited by a child process.

Processes blocked awaiting a lock may be awakened by signals.

Mandatory locking may occur, depending on the mode bits of the file. See `chmod(2)`.

Locks obtained through the `flock()` mechanism under SunOS 4.1 were known only within the system on which they were placed. This is no longer true.

NAME	flockfile, funlockfile, ftrylockfile – acquire and release stream lock
SYNOPSIS	<pre>#include <stdio.h> void flockfile(FILE *stream) ; void funlockfile(FILE *stream) ; int ftrylockfile(FILE *stream) ;</pre>
DESCRIPTION	<p>The flockfile() function acquires an internal lock of a stream <i>stream</i>. If the lock is already acquired by another thread, the thread calling flockfile() is suspended until it can acquire the lock. In the case that the stream lock is available, flockfile() not only acquires the lock, but keeps track of the number of times it is being called by the current thread. This implies that the stream lock can be acquired more than once by the same thread.</p> <p>The funlockfile() function releases the lock being held by the current thread. In the case of recursive locking, this function must be called the same number of times flockfile() was called. After the number of funlockfile() calls is equal to the number of flockfile() calls, the stream lock is available for other threads to acquire.</p> <p>The ftrylockfile() function acquires an internal lock of a stream <i>stream</i>, only if that object is available. In essence ftrylockfile() is a non-blocking version of flockfile().</p>
RETURN VALUES	The ftrylockfile() function returns 0 on success and non-zero to indicate a lock cannot be acquired.
EXAMPLES	<p>EXAMPLE 1 A sample program of flockfile().</p> <p>The following example prints everything out together, blocking other threads that might want to write to the same file between calls to fprintf(3C):</p> <pre>FILE iop; flockfile(iop); fprintf(iop, "hello "); fprintf(iop, "world"); fputc(iop, 'a'); funlockfile(iop);</pre> <p>An unlocked interface is available in case performance is an issue. For example:</p> <pre>flockfile(iop); while (!feof(iop)) { *c++ = getc_unlocked(iop); } funlockfile(iop);</pre>

NAME	fmtmsg – display a message on stderr or system console
SYNOPSIS	<pre>#include <fmtmsg.h> int fmtmsg(long <i>classification</i>, const char *<i>label</i>, int <i>severity</i>, const char *<i>text</i>, const char *<i>action</i>, const char *<i>tag</i>);</pre>
DESCRIPTION	<p>The <code>fmtmsg()</code> function writes a formatted message to <code>stderr</code>, to the console, or to both, on a message's classification component. It can be used instead of the traditional <code>printf(3C)</code> interface to display messages to <code>stderr</code>, and in conjunction with <code>gettext(3C)</code>, provides a simple interface for producing language-independent applications.</p> <p>A formatted message consists of up to five standard components (<i>label</i>, <i>severity</i>, <i>text</i>, <i>action</i>, and <i>tag</i>) as described below. The <i>classification</i> component is not part of the standard message displayed to the user, but rather defines the source of the message and directs the display of the formatted message.</p> <p><i>classification</i></p> <p>Contains identifiers from the following groups of major classifications and subclassifications. Any one identifier from a subclass may be used in combination by ORing the values together with a single identifier from a different subclass. Two or more identifiers from the same subclass should not be used together, with the exception of identifiers from the display subclass. (Both display subclass identifiers may be used so that messages can be displayed to both <code>stderr</code> and the system console).</p> <ul style="list-style-type: none"> ■ “Major classifications” identify the source of the condition. Identifiers are: <code>MM_HARD</code> (hardware), <code>MM_SOFT</code> (software), and <code>MM_FIRM</code> (firmware). ■ “Message source subclassifications” identify the type of software in which the problem is spotted. Identifiers are: <code>MM_APPL</code> (application), <code>MM_UTIL</code> (utility), and <code>MM_OPSYS</code> (operating system). ■ “Display subclassifications” indicate where the message is to be displayed. Identifiers are: <code>MM_PRINT</code> to display the message on the standard error stream, <code>MM_CONSOLE</code> to display the message on the system console. Neither, either, or both identifiers may be used. ■ “Status subclassifications” indicate whether the application will recover from the condition. Identifiers are: <code>MM_RECOVER</code> (recoverable) and <code>MM_NRECOV</code> (non-recoverable). ■ An additional identifier, <code>MM_NULLMC</code>, indicates that no classification component is supplied for the message. <p><i>label</i></p> <p>Identifies the source of the message. The format of this component is two fields separated by a colon. The first field is up to 10 characters long; the second is up to 14 characters. Suggested usage is that <i>label</i> identifies the package in which the application resides</p>

<i>severity</i>	<p>as well as the program or application name. For example, the <i>label</i> <code>UX:cat</code> indicates the UNIX System V package and the <code>cat(1)</code> utility.</p> <p>Indicates the seriousness of the condition. Identifiers for the standard levels of <i>severity</i> are:</p> <ul style="list-style-type: none"> ■ <code>MM_HALT</code> indicates that the application has encountered a severe fault and is halting. Produces the print string <code>HALT</code>. ■ <code>MM_ERROR</code> indicates that the application has detected a fault. Produces the print string <code>ERROR</code>. ■ <code>MM_WARNING</code> indicates a condition out of the ordinary that might be a problem and should be watched. Produces the print string <code>WARNING</code>. ■ <code>MM_INFO</code> provides information about a condition that is not in error. Produces the print string <code>INFO</code>. ■ <code>MM_NOSEV</code> indicates that no severity level is supplied for the message. <p>Other severity levels may be added by using the <code>addseverity()</code> routine.</p>
<i>text</i>	<p>Describes the condition that produced the message. The <i>text</i> string is not limited to a specific size.</p>
<i>action</i>	<p>Describes the first step to be taken in the error recovery process. <code>fmtmsg()</code> precedes each action string with the prefix: <code>TOFIX: .</code> The <i>action</i> string is not limited to a specific size.</p>
<i>tag</i>	<p>An identifier which references on-line documentation for the message. Suggested usage is that <i>tag</i> includes the <i>label</i> and a unique identifying number. A sample <i>tag</i> is <code>UX:cat:146</code>.</p>

Environment Variables

The <code>MSGVERB</code> and <code>SEV_LEVEL</code> environment variables control the behavior of <code>fmtmsg()</code> as follows:	
<code>MSGVERB</code>	<p>This variable determines which message components <code>fmtmsg()</code> selects when writing messages to <code>stderr</code>. Its value is a colon-separated list of optional keywords and can be set as follows:</p> <pre>MSGVERB=[keyword[:keyword[: . . .]]] export MSGVERB</pre> <p>Valid <i>keywords</i> are: <code>label</code>, <code>severity</code>, <code>text</code>, <code>action</code>, and <code>tag</code>. If <code>MSGVERB</code> contains a keyword for a component and the component's value is not the component's null value, <code>fmtmsg()</code> includes that component in the message when writing the message to <code>stderr</code>. If <code>MSGVERB</code> does not include a keyword for a message component, that component is not included in the display of the message. The keywords may appear in any order. If <code>MSGVERB</code> is</p>

not defined, if its value is the null string, if its value is not of the correct format, or if it contains keywords other than the valid ones listed above, `fmtmsg()` selects all components.

The first time `fmtmsg()` is called, it examines `MSGVERB` to determine which message components are to be selected when generating a message to write to the standard error stream, `stderr`. The values accepted on the initial call are saved for future calls.

The `MSGVERB` environment variable affects only those components that are selected for display to the standard error stream. All message components are included in console messages.

SEV_LEVEL

This variable defines severity levels and associates print strings with them for use by `fmtmsg()`. The standard severity levels listed below cannot be modified. Additional severity levels can also be defined, redefined, and removed using `addseverity()` (see `addseverity(3C)`). If the same severity level is defined by both `SEV_LEVEL` and `addseverity()`, the definition by `addseverity()` takes precedence.

0	(no severity is used)
1	HALT
2	ERROR
3	WARNING
4	INFO

The `SEV_LEVEL` variable can be set as follows:

```
SEV_LEVEL=[description[:description[: . . .]]]
export SEV_LEVEL
```

where *description* is a comma-separated list containing three fields:

description=severity_keyword,level,printstring

The *severity_keyword* field is a character string that is used as the keyword on the `-s severity` option to the `fmtmsg(1)` utility. (This field is not used by the `fmtmsg()` function.)

The *level* field is a character string that evaluates to a positive integer (other than 0, 1, 2, 3, or 4, which are reserved for the standard severity levels). If the keyword *severity_keyword* is used, *level* is the severity value passed on to the `fmtmsg()` function.

fmtmsg(3C)

The *printstring* field is the character string used by `fmtmsg()` in the standard message format whenever the severity value *level* is used.

If a *description* in the colon list is not a three-field comma list, or if the second field of a comma list does not evaluate to a positive integer, that *description* in the colon list is ignored.

The first time `fmtmsg()` is called, it examines the `SEV_LEVEL` environment variable, if defined, to determine whether the environment expands the levels of severity beyond the five standard levels and those defined using `addseverity()`. The values accepted on the initial call are saved for future calls.

Use in Applications

One or more message components may be systematically omitted from messages generated by an application by using the null value of the argument for that component.

The table below indicates the null values and identifiers for `fmtmsg()` arguments.

Argument	Type	Null-Value	Identifier
<i>label</i>	char*	(char*) NULL	MM_NULLLBL
<i>severity</i>	int	0	MM_NULLSEV
<i>class</i>	long	0L	MM_NULLMC
<i>text</i>	char*	(char*) NULL	MM_NULLTXT
<i>action</i>	char*	(char*) NULL	MM_NULLACT
<i>tag</i>	char*	(char*) NULL	MM_NULLTAG

Another means of systematically omitting a component is by omitting the component keyword(s) when defining the `MSGVERB` environment variable (see the `Environment Variables` section above).

RETURN VALUES

The `fmtmsg()` returns the following values:

MM_OK	The function succeeded.
MM_NOTOK	The function failed completely.
MM_NOMSG	The function was unable to generate a message on the standard error stream, but otherwise succeeded.
MM_NOCON	The function was unable to generate a console message, but otherwise succeeded.

EXAMPLES

EXAMPLE 1 The following example of `fmtmsg()`:

```
fmtmsg(MM_PRINT, "UX:cat", MM_ERROR, "invalid syntax",
"refer to manual", "UX:cat:001")
```

produces a complete message in the standard message format:

```
UX:cat: ERROR: invalid syntax
TO FIX: refer to manual    UX:cat:001
```

EXAMPLE 2 When the environment variable `MSGVERB` is set as follows:

```
MSGVERB=severity:text:action
```

and the Example 1 is used, `fmtmsg()` produces:

```
ERROR: invalid syntax
TO FIX: refer to manual
```

EXAMPLE 3 When the environment variable `SEV_LEVEL` is set as follows:

```
SEV_LEVEL=note,5,NOTE
```

the following call to `fmtmsg()`

```
fmtmsg(MM_UTIL | MM_PRINT, "UX:cat", 5, "invalid syntax",
"refer to manual", "UX:cat:001")
```

produces

```
UX:cat: NOTE: invalid syntax
TO FIX: refer to manual    UX:cat:001
```

fnmatch(3C)

NAME	fnmatch – match filename or path name														
SYNOPSIS	<pre>#include <fnmatch.h> int fnmatch(const char *<i>pattern</i>, const char *<i>string</i>, int <i>flags</i>);</pre>														
DESCRIPTION	<p>The <code>fnmatch()</code> function matches patterns as described on the <code>fnmatch(5)</code> manual page. It checks the <i>string</i> argument to see if it matches the <i>pattern</i> argument.</p> <p>The <i>flags</i> argument modifies the interpretation of <i>pattern</i> and <i>string</i>. It is the bitwise inclusive OR of zero or more of the following flags defined in the header <code><fnmatch.h></code>.</p> <table><tr><td><code>FNM_PATHNAME</code></td><td>If set, a slash (/) character in <i>string</i> will be explicitly matched by a slash in <i>pattern</i>; it will not be matched by either the asterisk (*) or question-mark (?) special characters, nor by a bracket ([]) expression.</td></tr><tr><td></td><td>If not set, the slash character is treated as an ordinary character.</td></tr><tr><td><code>FNM_NOESCAPE</code></td><td>If not set, a backslash character (\) in <i>pattern</i> followed by any other character will match that second character in <i>string</i>. In particular, "\\\" will match a backslash in <i>string</i>.</td></tr><tr><td></td><td>If set, a backslash character will be treated as an ordinary character.</td></tr><tr><td><code>FNM_PERIOD</code></td><td>If set, a leading period in <i>string</i> will match a period in <i>pattern</i>; where the location of “leading” is indicated by the value of <code>FNM_PATHNAME</code>:</td></tr><tr><td></td><td><ul style="list-style-type: none">■ If <code>FNM_PATHNAME</code> is set, a period is “leading” if it is the first character in <i>string</i> or if it immediately follows a slash.■ If <code>FNM_PATHNAME</code> is not set, a period is “leading” only if it is the first character of <i>string</i>.</td></tr><tr><td></td><td>If not set, no special restrictions are placed on matching a period.</td></tr></table>	<code>FNM_PATHNAME</code>	If set, a slash (/) character in <i>string</i> will be explicitly matched by a slash in <i>pattern</i> ; it will not be matched by either the asterisk (*) or question-mark (?) special characters, nor by a bracket ([]) expression.		If not set, the slash character is treated as an ordinary character.	<code>FNM_NOESCAPE</code>	If not set, a backslash character (\) in <i>pattern</i> followed by any other character will match that second character in <i>string</i> . In particular, "\\\" will match a backslash in <i>string</i> .		If set, a backslash character will be treated as an ordinary character.	<code>FNM_PERIOD</code>	If set, a leading period in <i>string</i> will match a period in <i>pattern</i> ; where the location of “leading” is indicated by the value of <code>FNM_PATHNAME</code> :		<ul style="list-style-type: none">■ If <code>FNM_PATHNAME</code> is set, a period is “leading” if it is the first character in <i>string</i> or if it immediately follows a slash.■ If <code>FNM_PATHNAME</code> is not set, a period is “leading” only if it is the first character of <i>string</i>.		If not set, no special restrictions are placed on matching a period.
<code>FNM_PATHNAME</code>	If set, a slash (/) character in <i>string</i> will be explicitly matched by a slash in <i>pattern</i> ; it will not be matched by either the asterisk (*) or question-mark (?) special characters, nor by a bracket ([]) expression.														
	If not set, the slash character is treated as an ordinary character.														
<code>FNM_NOESCAPE</code>	If not set, a backslash character (\) in <i>pattern</i> followed by any other character will match that second character in <i>string</i> . In particular, "\\\" will match a backslash in <i>string</i> .														
	If set, a backslash character will be treated as an ordinary character.														
<code>FNM_PERIOD</code>	If set, a leading period in <i>string</i> will match a period in <i>pattern</i> ; where the location of “leading” is indicated by the value of <code>FNM_PATHNAME</code> :														
	<ul style="list-style-type: none">■ If <code>FNM_PATHNAME</code> is set, a period is “leading” if it is the first character in <i>string</i> or if it immediately follows a slash.■ If <code>FNM_PATHNAME</code> is not set, a period is “leading” only if it is the first character of <i>string</i>.														
	If not set, no special restrictions are placed on matching a period.														
RETURN VALUES	If <i>string</i> matches the pattern specified by <i>pattern</i> , then <code>fnmatch()</code> returns 0. If there is no match, <code>fnmatch()</code> returns <code>FNM_NOMATCH</code> , which is defined in the header <code><fnmatch.h></code> . If an error occurs, <code>fnmatch()</code> returns another non-zero value.														
USAGE	The <code>fnmatch()</code> function has two major uses. It could be used by an application or utility that needs to read a directory and apply a pattern against each entry. The <code>find(1)</code> utility is an example of this. It can also be used by the <code>pax(1)</code> utility to process its <i>pattern</i> operands, or by applications that need to match strings in a similar manner.														

The name `fnmatch()` is intended to imply *filename* match, rather than *pathname* match. The default action of this function is to match filenames, rather than path names, since it gives no special significance to the slash character. With the `FNM_PATHNAME` flag, `fnmatch()` does match path names, but without tilde expansion, parameter expansion, or special treatment for period at the beginning of a filename.

The `fnmatch()` function can be used safely in multithreaded applications, as long as `setlocale(3C)` is not being called to change the locale.

fopen(3C)

NAME	fopen – open a stream												
SYNOPSIS	<pre>#include <stdio.h> FILE *fopen(const char *filename, const char *mode);</pre>												
DESCRIPTION	<p>The <code>fopen()</code> function opens the file whose pathname is the string pointed to by <i>filename</i>, and associates a stream with it.</p> <p>The argument <i>mode</i> points to a string beginning with one of the following sequences:</p> <table><tr><td>r or rb</td><td>Open file for reading.</td></tr><tr><td>w or wb</td><td>Truncate to zero length or create file for writing.</td></tr><tr><td>a or ab</td><td>Append; open or create file for writing at end-of-file.</td></tr><tr><td>r+ or rb+ or r+b</td><td>Open file for update (reading and writing).</td></tr><tr><td>w+ or wb+ or w+b</td><td>Truncate to zero length or create file for update.</td></tr><tr><td>a+ or ab+ or a+b</td><td>Append; open or create file for update, writing at end-of-file.</td></tr></table> <p>The character <code>b</code> has no effect, but is allowed for ISO C standard conformance (see <code>standards(5)</code>). Opening a file with read mode (<code>r</code> as the first character in the <i>mode</i> argument) fails if the file does not exist or cannot be read.</p> <p>Opening a file with append mode (<code>a</code> as the first character in the <i>mode</i> argument) causes all subsequent writes to the file to be forced to the then current end-of-file, regardless of intervening calls to <code>fseek(3C)</code>. If two separate processes open the same file for append, each process may write freely to the file without fear of destroying output being written by the other. The output from the two processes will be intermixed in the file in the order in which it is written.</p> <p>When a file is opened with update mode (<code>+</code> as the second or third character in the <i>mode</i> argument), both input and output may be performed on the associated stream. However, output must not be directly followed by input without an intervening call to <code>fflush(3C)</code> or to a file positioning function (<code>fseek(3C)</code>, <code>fsetpos(3C)</code> or <code>rewind(3C)</code>), and input must not be directly followed by output without an intervening call to a file positioning function, unless the input operation encounters end-of-file.</p> <p>When opened, a stream is fully buffered if and only if it can be determined not to refer to an interactive device. The error and end-of-file indicators for the stream are cleared.</p> <p>If <i>mode</i> is <code>w</code>, <code>a</code>, <code>w+</code> or <code>a+</code> and the file did not previously exist, upon successful completion, <code>fopen()</code> function will mark for update the <code>st_atime</code>, <code>st_ctime</code> and <code>st_mtime</code> fields of the file and the <code>st_ctime</code> and <code>st_mtime</code> fields of the parent directory.</p>	r or rb	Open file for reading.	w or wb	Truncate to zero length or create file for writing.	a or ab	Append; open or create file for writing at end-of-file.	r+ or rb+ or r+b	Open file for update (reading and writing).	w+ or wb+ or w+b	Truncate to zero length or create file for update.	a+ or ab+ or a+b	Append; open or create file for update, writing at end-of-file.
r or rb	Open file for reading.												
w or wb	Truncate to zero length or create file for writing.												
a or ab	Append; open or create file for writing at end-of-file.												
r+ or rb+ or r+b	Open file for update (reading and writing).												
w+ or wb+ or w+b	Truncate to zero length or create file for update.												
a+ or ab+ or a+b	Append; open or create file for update, writing at end-of-file.												

If *mode* is *w* or *w+* and the file did previously exist, upon successful completion, `fopen()` will mark for update the `st_ctime` and `st_mtime` fields of the file. The `fopen()` function will allocate a file descriptor as `open(2)` does.

The largest value that can be represented correctly in an object of type `off_t` will be established as the offset maximum in the open file description.

RETURN VALUES

Upon successful completion, `fopen()` returns a pointer to the object controlling the stream. Otherwise, a null pointer is returned and `errno` is set to indicate the error.

The `fopen()` function may fail and not set `errno` if there are no free `stdio` streams.

ERRORS

The `fopen()` function will fail if:

EACCES	Search permission is denied on a component of the path prefix, or the file exists and the permissions specified by <i>mode</i> are denied, or the file does not exist and write permission is denied for the parent directory of the file to be created.
EINTR	A signal was caught during the execution of <code>fopen()</code> .
EISDIR	The named file is a directory and <i>mode</i> requires write access.
ELOOP	Too many symbolic links were encountered in resolving <i>path</i> .
EMFILE	There are <code>OPEN_MAX</code> file descriptors currently open in the calling process.
ENAMETOOLONG	The length of the <i>filename</i> exceeds <code>PATH_MAX</code> or a pathname component is longer than <code>NAME_MAX</code> .
ENFILE	The maximum allowable number of files is currently open in the system.
ENOENT	A component of <i>filename</i> does not name an existing file or <i>filename</i> is an empty string.
ENOSPC	The directory or file system that would contain the new file cannot be expanded, the file does not exist, and it was to be created.
ENOTDIR	A component of the path prefix is not a directory.
ENXIO	The named file is a character special or block special file, and the device associated with this special file does not exist.
EOVERFLOW	The current value of the file position cannot be represented correctly in an object of type <code>fpos_t</code> .

fopen(3C)

EROFS The named file resides on a read-only file system and *mode* requires write access.

The `fopen()` function may fail if:

EINVAL The value of the *mode* argument is not valid.

EMFILE The number of streams currently open in the calling process is either `FOPEN_MAX` or `STREAM_MAX`.

ENAMETOOLONG Pathname resolution of a symbolic link produced an intermediate result whose length exceeds `PATH_MAX`.

ENOMEM Insufficient storage space is available.

ETXTBSY The file is a pure procedure (shared text) file that is being executed and *mode* requires write access.

USAGE The number of streams that a process can have open at one time is `STREAM_MAX`. If defined, it has the same value as `FOPEN_MAX`.

The `fopen()` function has a transitional interface for 64-bit file offsets. See `lf64(5)`.

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

NAME	fopen, freopen – open a stream												
SYNOPSIS	<pre> /usr/ucb/cc[flag ...] file ... #include <stdio.h> FILE *fopen(file, mode); const char *file, *mode; FILE *freopen(file, mode, iop); const char *file, *mode; register FILE *iop; </pre>												
DESCRIPTION	<p>fopen() opens the file named by <i>file</i> and associates a stream with it. If the open succeeds, fopen() returns a pointer to be used to identify the stream in subsequent operations.</p> <p><i>file</i> points to a character string that contains the name of the file to be opened.</p> <p><i>mode</i> is a character string having one of the following values:</p> <table border="0"> <tr><td>r</td><td>open for reading</td></tr> <tr><td>w</td><td>truncate or create for writing</td></tr> <tr><td>a</td><td>append: open for writing at end of file, or create for writing</td></tr> <tr><td>r+</td><td>open for update (reading and writing)</td></tr> <tr><td>w+</td><td>truncate or create for update</td></tr> <tr><td>a+</td><td>append; open or create for update at EOF</td></tr> </table> <p>freopen() opens the file named by <i>file</i> and associates the stream pointed to by <i>iop</i> with it. The <i>mode</i> argument is used just as in fopen(). The original stream is closed, regardless of whether the open ultimately succeeds. If the open succeeds, freopen() returns the original value of <i>iop</i>.</p> <p>freopen() is typically used to attach the preopened streams associated with stdin, stdout, and stderr to other files.</p> <p>When a file is opened for update, both input and output may be done on the resulting stream. However, output may not be directly followed by input without an intervening fseek(3C) or rewind(3C), and input may not be directly followed by output without an intervening fseek(3C) or rewind(3C). An input operation which encounters EOF will fail.</p>	r	open for reading	w	truncate or create for writing	a	append: open for writing at end of file, or create for writing	r+	open for update (reading and writing)	w+	truncate or create for update	a+	append; open or create for update at EOF
r	open for reading												
w	truncate or create for writing												
a	append: open for writing at end of file, or create for writing												
r+	open for update (reading and writing)												
w+	truncate or create for update												
a+	append; open or create for update at EOF												
RETURN VALUES	fopen() and freopen() return a NULL pointer on failure.												
SEE ALSO	open(2), fclose(3C), fopen(3C), freopen(3C), fseek(3C), malloc(3C), rewind(3C)												

fopen(3UCB)

NOTES Use of these interfaces should be restricted to only applications written on BSD platforms. Use of these interfaces with any of the system libraries or in multi-thread applications is unsupported.

In order to support the same number of open files that the system does, `fopen()` must allocate additional memory for data structures using `malloc(3C)` after 64 files have been opened. This confuses some programs which use their own memory allocators.

The interfaces of `fopen()` and `freopen()` differ from the Standard I/O Functions `fopen(3C)` and `freopen(3C)`. The Standard I/O Functions distinguish binary from text files with an additional use of 'b' as part of the *mode*. This enables portability of `fopen(3C)` and `freopen(3C)` beyond SunOS 4.X systems.

NAME	isnan, isnand, isnanf, finite, fpclass, unordered – determine type of floating-point number																				
SYNOPSIS	<pre>#include <ieeefp.h> int isnand(double <i>dsrc</i>); int isnanf(float <i>fsrc</i>); int finite(double <i>dsrc</i>); fpclass_t fpclass(double <i>dsrc</i>); int unordered(double <i>dsrc1</i>, double <i>dsrc2</i>); #include <math.h> int isnan(double <i>dsrc</i>);</pre>																				
DESCRIPTION	<p>The <code>isnan()</code> function is identical to the <code>isnand()</code> function.</p> <p>The <code>isnanf()</code> function is implemented as a macro included in the <code><ieeefp.h></code> header.</p> <p>The <code>fpclass()</code> function returns one of the following classes to which <i>dsrc</i> belongs:</p> <table border="0"> <tr><td>FP_SNAN</td><td>signaling NaN</td></tr> <tr><td>FP_QNAN</td><td>quiet NaN</td></tr> <tr><td>FP_NINF</td><td>negative infinity</td></tr> <tr><td>FP_PINF</td><td>positive infinity</td></tr> <tr><td>FP_NDENORM</td><td>negative denormalized non-zero</td></tr> <tr><td>FP_PDENORM</td><td>positive denormalized non-zero</td></tr> <tr><td>FP_NZERO</td><td>negative zero</td></tr> <tr><td>FP_PZERO</td><td>positive zero</td></tr> <tr><td>FP_NNORM</td><td>negative normalized non-zero</td></tr> <tr><td>FP_PNORM</td><td>positive normalized non-zero</td></tr> </table> <p>None of these routines generates an exception, even for signaling NaNs.</p>	FP_SNAN	signaling NaN	FP_QNAN	quiet NaN	FP_NINF	negative infinity	FP_PINF	positive infinity	FP_NDENORM	negative denormalized non-zero	FP_PDENORM	positive denormalized non-zero	FP_NZERO	negative zero	FP_PZERO	positive zero	FP_NNORM	negative normalized non-zero	FP_PNORM	positive normalized non-zero
FP_SNAN	signaling NaN																				
FP_QNAN	quiet NaN																				
FP_NINF	negative infinity																				
FP_PINF	positive infinity																				
FP_NDENORM	negative denormalized non-zero																				
FP_PDENORM	positive denormalized non-zero																				
FP_NZERO	negative zero																				
FP_PZERO	positive zero																				
FP_NNORM	negative normalized non-zero																				
FP_PNORM	positive normalized non-zero																				
RETURN VALUES	<p>The <code>isnan()</code>, <code>isnand()</code>, and <code>isnanf()</code> function return TRUE (1) if the argument <i>dsrc</i> or <i>fsrc</i> is a NaN; otherwise they return FALSE (0).</p> <p>The <code>finite()</code> function returns TRUE (1) if the argument <i>dsrc</i> is neither infinity nor NaN; otherwise it returns FALSE (0).</p> <p>The <code>unordered()</code> function returns TRUE (1) if one of its two arguments is unordered with respect to the other argument. This is equivalent to reporting whether either argument is NaN. If neither argument is NaN, FALSE (0) is returned.</p>																				

fpclass(3C)

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
MT-Level	MT-Safe

SEE ALSO `fpgetround(3C)`, `attributes(5)`

__fpending(3C)

NAME	<code>__fbufsize</code> , <code>__flbf</code> , <code>__fpending</code> , <code>__fpurge</code> , <code>__freadable</code> , <code>__freading</code> , <code>__fsetlocking</code> , <code>__fwritable</code> , <code>__fwriting</code> , <code>_flushlbf</code> – interfaces to stdio FILE structure
SYNOPSIS	<pre>#include <stdio.h> #include <stdio_ext.h> size_t __fbufsiz(FILE *stream); int __flbf(FILE *stream); size_t __fpending(FILE *stream); void __fpurge(FILE *stream); int __freadable(FILE *stream); int __freading(FILE *stream); int __fsetlocking(FILE *stream, int type); int __fwritable(FILE *stream); int __fwriting(FILE *stream); void _flushlbf(void);</pre>
DESCRIPTION	<p>These functions provide portable access to the members of the <code>stdio(3C)</code> FILE structure.</p> <p>The <code>__fbufsize()</code> function returns in bytes the size of the buffer currently in use by the given stream.</p> <p>The <code>__flbf()</code> function returns non-zero if the stream is line-buffered.</p> <p>The <code>__fpending</code> function returns in bytes the amount of output pending on a stream.</p> <p>The <code>__fpurge()</code> function discards any pending buffered I/O on the stream.</p> <p>The <code>__freadable()</code> function returns non-zero if it is possible to read from a stream.</p> <p>The <code>__freading()</code> function returns non-zero if the file is open readonly, or if the last operation on the stream was a read operation such as <code>fread(3C)</code> or <code>fgetc(3C)</code>. Otherwise it returns 0.</p> <p>The <code>__fsetlocking()</code> function allows the type of locking performed by <code>stdio</code> on a given stream to be controlled by the programmer.</p> <p>If <code>type</code> is <code>FSETLOCKING_INTERNAL</code>, <code>stdio</code> performs implicit locking around every operation on the given stream. This is the default system behavior on that stream.</p> <p>If <code>type</code> is <code>FSETLOCKING_BYCALLER</code>, <code>stdio</code> assumes that the caller is responsible for maintaining the integrity of the stream in the face of access by multiple threads. If there is only one thread accessing the stream, nothing further needs to be done. If multiple threads are accessing the stream, then the caller can use the <code>flockfile()</code>,</p>

__fpending(3C)

`funlockfile()`, and `ftrylockfile()` functions described on the `flockfile(3C)` manual page to provide the appropriate locking. In both this and the case where *type* is `FSETLOCKING_INTERNAL`, `__fsetlocking()` returns the previous state of the stream.

If *type* is `FSETLOCKING_QUERY`, `__fsetlocking()` returns the current state of the stream without changing it.

The `__fwritable()` function returns non-zero if it is possible to write on a stream.

The `__fwriting()` function returns non-zero if the file is open write-only or append-only, or if the last operation on the stream was a write operation such as `fwrite(3C)` or `fputc(3C)`. Otherwise it returns 0.

The `_flushlbf()` function flushes all line-buffered files. It is used when reading from a line-buffered file.

USAGE

Although the contents of the `stdio` `FILE` structure have always been private to the `stdio` implementation, some applications have needed to obtain information about a `stdio` stream that was not accessible through a supported interface. These applications have resorted to accessing fields of the `FILE` structure directly, rendering them possibly non-portable to new implementations of `stdio`, or more likely, preventing enhancements to `stdio` that would cause those applications to break.

In the 64-bit environment, the `FILE` structure is opaque. The functions described here are provided as a means of obtaining the information that up to now has been retrieved directly from the `FILE` structure. Because they are based on the needs of existing applications (such as `mh` and `emacs`), they may be extended as other programs are ported. Although they may still be non-portable to other operating systems, they will be compatible from each Solaris release to the next. Interfaces that are more portable are under development.

ATTRIBUTES

NAME	fpgetround, fpsetround, fpgetmask, fpsetmask, fpgetsticky, fpsetsticky – IEEE floating-point environment control
SYNOPSIS	<pre>#include <ieeefp.h> fp_rnd fpgetround(void); fp_rnd fpsetround(fp_rnd rnd_dir); fp_except fpgetmask(void); fp_except fpsetmask(fp_except mask); fp_except fpgetsticky(void); fp_except fpsetsticky(fp_except sticky);</pre>
DESCRIPTION	<p>There are five floating-point exceptions:</p> <ul style="list-style-type: none"> ■ divide-by-zero, ■ overflow, ■ underflow, ■ imprecise (inexact) result, and ■ invalid operation. <p>When a floating-point exception occurs, the corresponding sticky bit is set (1), and if the mask bit is enabled (1), the trap takes place. These routines let the user change the behavior on occurrence of any of these exceptions, as well as change the rounding mode for floating-point operations.</p> <p>The <i>mask</i> argument is formed by the logical OR operation of the following floating-point exception masks:</p> <pre>FP_X_INV /* invalid operation exception */ FP_X_OFL /* overflow exception */ FP_X_UFL /* underflow exception */ FP_X_DZ /* divide-by-zero exception */ FP_X_IMP /* imprecise (loss of precision) */</pre> <p>The following floating-point rounding modes are passed to <code>fpsetround</code> and returned by <code>fpgetround()</code>.</p> <pre>FP_RN /* round to nearest representative number */ FP_RP /* round to plus infinity */ FP_RM /* round to minus infinity */ FP_RZ /* round to zero (truncate) */</pre> <p>The default environment is rounding mode set to nearest (FP_RN) and all traps disabled.</p> <p>The <code>fpsetsticky()</code> function modifies all sticky flags. The <code>fpsetmask()</code> function changes all mask bits. The <code>fpsetmask()</code> function clears the sticky bit corresponding to any exception being enabled.</p>
RETURN VALUES	The <code>fpgetround()</code> function returns the current rounding mode.

fpgetmask(3C)

The `fpsetround()` function sets the rounding mode and returns the previous rounding mode.

The `fpgetmask()` function returns the current exception masks.

The `fpsetmask()` function sets the exception masks and returns the previous setting.

The `fpgetsticky()` function returns the current exception sticky flags.

The `fpsetsticky()` function sets (clears) the exception sticky flags and returns the previous setting.

USAGE The C programming language requires truncation (round to zero) for floating point to integral conversions. The current rounding mode has no effect on these conversions.

The sticky bit must be cleared to recover from the trap and proceed. If the sticky bit is not cleared before the next trap occurs, a wrong exception type may be signaled.

Individual bits may be examined using the constants defined in `<ieeefp.h>`.

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
MT-Level	MT-Safe

NAME	fpgetround, fpsetround, fpgetmask, fpsetmask, fpgetsticky, fpsetsticky – IEEE floating-point environment control
SYNOPSIS	<pre>#include <ieeefp.h> fp_rnd fpgetround(void); fp_rnd fpsetround(fp_rnd rnd_dir); fp_except fpgetmask(void); fp_except fpsetmask(fp_except mask); fp_except fpgetsticky(void); fp_except fpsetsticky(fp_except sticky);</pre>
DESCRIPTION	<p>There are five floating-point exceptions:</p> <ul style="list-style-type: none"> ■ divide-by-zero, ■ overflow, ■ underflow, ■ imprecise (inexact) result, and ■ invalid operation. <p>When a floating-point exception occurs, the corresponding sticky bit is set (1), and if the mask bit is enabled (1), the trap takes place. These routines let the user change the behavior on occurrence of any of these exceptions, as well as change the rounding mode for floating-point operations.</p> <p>The <i>mask</i> argument is formed by the logical OR operation of the following floating-point exception masks:</p> <pre>FP_X_INV /* invalid operation exception */ FP_X_OFL /* overflow exception */ FP_X_UFL /* underflow exception */ FP_X_DZ /* divide-by-zero exception */ FP_X_IMP /* imprecise (loss of precision) */</pre> <p>The following floating-point rounding modes are passed to <code>fpsetround</code> and returned by <code>fpgetround()</code>.</p> <pre>FP_RN /* round to nearest representative number */ FP_RP /* round to plus infinity */ FP_RM /* round to minus infinity */ FP_RZ /* round to zero (truncate) */</pre> <p>The default environment is rounding mode set to nearest (FP_RN) and all traps disabled.</p> <p>The <code>fpsetsticky()</code> function modifies all sticky flags. The <code>fpsetmask()</code> function changes all mask bits. The <code>fpsetmask()</code> function clears the sticky bit corresponding to any exception being enabled.</p>
RETURN VALUES	The <code>fpgetround()</code> function returns the current rounding mode.

fpgetsticky(3C)

The `fpsetround()` function sets the rounding mode and returns the previous rounding mode.

The `fpgetmask()` function returns the current exception masks.

The `fpsetmask()` function sets the exception masks and returns the previous setting.

The `fpgetsticky()` function returns the current exception sticky flags.

The `fpsetsticky()` function sets (clears) the exception sticky flags and returns the previous setting.

USAGE The C programming language requires truncation (round to zero) for floating point to integral conversions. The current rounding mode has no effect on these conversions.

The sticky bit must be cleared to recover from the trap and proceed. If the sticky bit is not cleared before the next trap occurs, a wrong exception type may be signaled.

Individual bits may be examined using the constants defined in `<ieeefp.h>`.

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
MT-Level	MT-Safe

NAME	printf, fprintf, sprintf, snprintf – print formatted output
SYNOPSIS	<pre>#include <stdio.h> int printf(const char *format, /* args*/ ...); int fprintf(FILE *stream, const char *format, /* args*/ ...); int sprintf(char *s, const char *format, /* args*/ ...); int snprintf(char *s, size_t n, const char *format, /* args*/ ...);</pre>
DESCRIPTION	<p>The <code>printf()</code> function places output on the standard output stream <code>stdout</code>.</p> <p>The <code>fprintf()</code> function places output on on the named output stream <i>stream</i>.</p> <p>The <code>sprintf()</code> function places output, followed by the null byte (<code>\0</code>), in consecutive bytes starting at <i>s</i>; it is the user's responsibility to ensure that enough storage is available.</p> <p>The <code>snprintf()</code> function is identical to <code>sprintf()</code> with the addition of the argument <i>n</i>, which specifies the size of the buffer referred to by <i>s</i>. The buffer is always terminated with the null byte.</p> <p>Each of these functions converts, formats, and prints its arguments under control of the <i>format</i>. The <i>format</i> is a character string, beginning and ending in its initial shift state, if any. The <i>format</i> is composed of zero or more directives: <i>ordinary characters</i>, which are simply copied to the output stream and <i>conversion specifications</i>, each of which results in the fetching of zero or more arguments. The results are undefined if there are insufficient arguments for the <i>format</i>. If the <i>format</i> is exhausted while arguments remain, the excess arguments are evaluated but are otherwise ignored.</p> <p>Conversions can be applied to the <i>n</i>th argument after the <i>format</i> in the argument list, rather than to the next unused argument. In this case, the conversion character <code>%</code> (see below) is replaced by the sequence <code>%n\$</code>, where <i>n</i> is a decimal integer in the range <code>[1, NL_ARGMAX]</code>, giving the position of the argument in the argument list. This feature provides for the definition of format strings that select arguments in an order appropriate to specific languages (see the <code>EXAMPLES</code> section).</p> <p>In format strings containing the <code>%n\$</code> form of conversion specifications, numbered arguments in the argument list can be referenced from the format string as many times as required.</p> <p>In format strings containing the <code>%</code> form of conversion specifications, each argument in the argument list is used exactly once.</p> <p>All forms of the <code>printf()</code> functions allow for the insertion of a language-dependent radix character in the output string. The radix character is defined by the program's locale (category <code>LC_NUMERIC</code>). In the POSIX locale, or in a locale where the radix character is not defined, the radix character defaults to a period (<code>.</code>).</p>

fprintf(3C)

Conversion Specifications

Each conversion specification is introduced by the % character or by the character sequence %n\$, after which the following appear in sequence:

- An optional field, consisting of a decimal digit string followed by a \$, specifying the next argument to be converted. If this field is not provided, the *args* following the last argument converted will be used.
- Zero or more *flags* (in any order), which modify the meaning of the conversion specification.
- An optional minimum *field width*. If the converted value has fewer bytes than the field width, it will be padded with spaces by default on the left; it will be padded on the right, if the left-adjustment flag (‐), described below, is given to the field width. The field width takes the form of an asterisk (*), described below, or a decimal integer.

If the conversion character is *s*, a standard-conforming application (see *standards(5)*) interprets the field width as the minimum number of bytes to be printed; an application that is not standard-conforming interprets the field width as the minimum number of columns of screen display. For an application that is not standard-conforming, %10*s* means if the converted value has a screen width of 7 columns, 3 spaces would be padded on the right.

If the format is %*ws*, then the field width should be interpreted as the minimum number of columns of screen display.

- An optional *precision* that gives the minimum number of digits to appear for the *d*, *i*, *o*, *u*, *x*, and *X* conversions (the field is padded with leading zeros); the number of digits to appear after the radix character for the *e*, *E*, and *f* conversions, the maximum number of significant digits for the *g* and *G* conversions; or the maximum number of bytes to be printed from a string in *s* and *S* conversions. The precision takes the form of a period (.) followed either by an asterisk (*), described below, or an optional decimal digit string, where a null digit string is treated as 0. If a precision appears with any other conversion character, the behavior is undefined.

If the conversion character is *s* or *S*, a standard-conforming application (see *standards(5)*) interprets the precision as the maximum number of bytes to be written; an application that is not standard-conforming interprets the precision as the maximum number of columns of screen display. For an application that is not standard-conforming, % .5*s* would print only the portion of the string that would display in 5 screen columns. Only complete characters are written.

For %*ws*, the precision should be interpreted as the maximum number of columns of screen display. The precision takes the form of a period (.) followed by a decimal digit string; a null digit string is treated as zero. Padding specified by the precision overrides the padding specified by the field width.

- An optional *h* specifies that a following *d*, *i*, *o*, *u*, *x*, or *X* conversion character applies to a type `short int` or type `unsigned short int` argument (the argument will be promoted according to the integral promotions, and its value converted to type `short int` or `unsigned short int` before printing); an optional *h* specifying that a following *n* conversion character applies to a pointer to a type `short int` argument; an optional *l* (ell) specifying that a following *d*, *i*, *o*, *u*, *x*, or *X* conversion character applies to a type `long int` or `unsigned long`

int argument; an optional l (ell) specifying that a following n conversion character applies to a pointer to a type long int argument; an optional ll (ell ell) specifying that a following d, i, o, u, x, or X conversion character applies to a type long long or unsigned long long argument; an optional ll (ell ell) specifying that a following n conversion character applies to a pointer to a long long argument; or an optional L specifying that a following e, E, f, g, or G conversion character applies to a type long double argument. If an h, l, ll, or L appears with any other conversion character, the behavior is undefined.

- An optional l (ell) specifying that a following c conversion character applies to a wint_t argument; an optional l (ell) specifying that a following s conversion character applies to a pointer to a wchar_t argument.
- A *conversion character* (see below) that indicates the type of conversion to be applied.

A field width, or precision, or both may be indicated by an asterisk (*). In this case, an argument of type int supplies the field width or precision. Arguments specifying field width, or precision, or both must appear in that order before the argument, if any, to be converted. A negative field width is taken as a – flag followed by a positive field width. A negative precision is taken as if the precision were omitted. In format strings containing the %n\$ form of a conversion specification, a field width or precision may be indicated by the sequence *m\$, where m is a decimal integer in the range [1, NL_ARGMAX] giving the position in the argument list (after the format argument) of an integer argument containing the field width or precision, for example:

```
printf("%1$d:%2$.*3$d:%4$.*3$d\n", hour, min, precision, sec);
```

The *format* can contain either numbered argument specifications (that is, %n\$ and *m\$), or unnumbered argument specifications (that is, % and *), but normally not both. The only exception to this is that %% can be mixed with the %n\$ form. The results of mixing numbered and unnumbered argument specifications in a *format* string are undefined. When numbered argument specifications are used, specifying the Nth argument requires that all the leading arguments, from the first to the (N–1)th, are specified in the format string.

Flag Characters

The flag characters and their meanings are:

- ' The integer portion of the result of a decimal conversion (%i, %d, %u, %f, %g, or %G) will be formatted with thousands' grouping characters. For other conversions the behavior is undefined. The non-monetary grouping character is used.
- The result of the conversion will be left-justified within the field. The conversion will be right-justified if this flag is not specified.
- + The result of a signed conversion will always begin with a sign (+ or –). The conversion will begin with a sign only when a negative value is converted if this flag is not specified.

fprintf(3C)

space	If the first character of a signed conversion is not a sign or if a signed conversion results in no characters, a space will be placed before the result. This means that if the <code>space</code> and <code>+</code> flags both appear, the space flag will be ignored.								
#	The value is to be converted to an alternate form. For <code>c</code> , <code>d</code> , <code>i</code> , <code>s</code> , and <code>u</code> conversions, the flag has no effect. For an <code>o</code> conversion, it increases the precision (if necessary) to force the first digit of the result to be a zero. For <code>x</code> or <code>X</code> conversion, a non-zero result will have <code>0x</code> (or <code>0X</code>) prepended to it. For <code>e</code> , <code>E</code> , <code>f</code> , <code>g</code> , and <code>G</code> conversions, the result will always contain a radix character, even if no digits follow the radix character. Without this flag, the radix character appears in the result of these conversions only if a digit follows it. For <code>g</code> and <code>G</code> conversions, trailing zeros will not be removed from the result as they normally are.								
0	For <code>d</code> , <code>i</code> , <code>o</code> , <code>u</code> , <code>x</code> , <code>X</code> , <code>e</code> , <code>E</code> , <code>f</code> , <code>g</code> , and <code>G</code> conversions, leading zeros (following any indication of sign or base) are used to pad to the field width; no space padding is performed. If the <code>0</code> and <code>-</code> flags both appear, the <code>0</code> flag will be ignored. For <code>d</code> , <code>i</code> , <code>o</code> , <code>u</code> , <code>x</code> , and <code>X</code> conversions, if a precision is specified, the <code>0</code> flag will be ignored. If the <code>0</code> and <code>'</code> flags both appear, the grouping characters are inserted before zero padding. For other conversions, the behavior is undefined.								
Conversion Characters	Each conversion character results in fetching zero or more arguments. The results are undefined if there are insufficient arguments for the format. If the format is exhausted while arguments remain, the excess arguments are ignored. The conversion characters and their meanings are: <table><tr><td><code>d,i</code></td><td>The <code>int</code> argument is converted to a signed decimal in the style <code>[-] dddd</code>. The precision specifies the minimum number of digits to appear; if the value being converted can be represented in fewer digits, it will be expanded with leading zeros. The default precision is 1. The result of converting 0 with an explicit precision of 0 is no characters.</td></tr><tr><td><code>o</code></td><td>The unsigned <code>int</code> argument is converted to unsigned octal format in the style <code>dddd</code>. The precision specifies the minimum number of digits to appear; if the value being converted can be represented in fewer digits, it will be expanded with leading zeros. The default precision is 1. The result of converting 0 with an explicit precision of 0 is no characters.</td></tr><tr><td><code>u</code></td><td>The unsigned <code>int</code> argument is converted to unsigned decimal format in the style <code>dddd</code>. The precision specifies the minimum number of digits to appear; if the value being converted can be represented in fewer digits, it will be expanded with leading zeros. The default precision is 1. The result of converting 0 with an explicit precision of 0 is no characters.</td></tr><tr><td><code>x</code></td><td>The unsigned <code>int</code> argument is converted to unsigned hexadecimal format in the style <code>dddd</code>; the letters <code>abcdef</code> are used. The precision specifies the minimum number of digits to appear; if the value being</td></tr></table>	<code>d,i</code>	The <code>int</code> argument is converted to a signed decimal in the style <code>[-] dddd</code> . The precision specifies the minimum number of digits to appear; if the value being converted can be represented in fewer digits, it will be expanded with leading zeros. The default precision is 1. The result of converting 0 with an explicit precision of 0 is no characters.	<code>o</code>	The unsigned <code>int</code> argument is converted to unsigned octal format in the style <code>dddd</code> . The precision specifies the minimum number of digits to appear; if the value being converted can be represented in fewer digits, it will be expanded with leading zeros. The default precision is 1. The result of converting 0 with an explicit precision of 0 is no characters.	<code>u</code>	The unsigned <code>int</code> argument is converted to unsigned decimal format in the style <code>dddd</code> . The precision specifies the minimum number of digits to appear; if the value being converted can be represented in fewer digits, it will be expanded with leading zeros. The default precision is 1. The result of converting 0 with an explicit precision of 0 is no characters.	<code>x</code>	The unsigned <code>int</code> argument is converted to unsigned hexadecimal format in the style <code>dddd</code> ; the letters <code>abcdef</code> are used. The precision specifies the minimum number of digits to appear; if the value being
<code>d,i</code>	The <code>int</code> argument is converted to a signed decimal in the style <code>[-] dddd</code> . The precision specifies the minimum number of digits to appear; if the value being converted can be represented in fewer digits, it will be expanded with leading zeros. The default precision is 1. The result of converting 0 with an explicit precision of 0 is no characters.								
<code>o</code>	The unsigned <code>int</code> argument is converted to unsigned octal format in the style <code>dddd</code> . The precision specifies the minimum number of digits to appear; if the value being converted can be represented in fewer digits, it will be expanded with leading zeros. The default precision is 1. The result of converting 0 with an explicit precision of 0 is no characters.								
<code>u</code>	The unsigned <code>int</code> argument is converted to unsigned decimal format in the style <code>dddd</code> . The precision specifies the minimum number of digits to appear; if the value being converted can be represented in fewer digits, it will be expanded with leading zeros. The default precision is 1. The result of converting 0 with an explicit precision of 0 is no characters.								
<code>x</code>	The unsigned <code>int</code> argument is converted to unsigned hexadecimal format in the style <code>dddd</code> ; the letters <code>abcdef</code> are used. The precision specifies the minimum number of digits to appear; if the value being								

	converted can be represented in fewer digits, it will be expanded with leading zeros. The default precision is 1. The result of converting 0 with an explicit precision of 0 is no characters.
X	Behaves the same as the x conversion character except that letters ABCDEF are used instead of abcdef.
f	The double argument is converted to decimal notation in the style <code>[-]ddd.ddd</code> , where the number of digits after the radix character (see <code>setlocale(3C)</code>) is equal to the precision specification. If the precision is missing it is taken as 6; if the precision is explicitly 0 and the # flag is not specified, no radix character appears. If a radix character appears, at least 1 digit appears before it. The value is rounded to the appropriate number of digits.
e,E	The double argument is converted to the style <code>[-]d.ddd\pmddd</code> , where there is one digit before the radix character (which is non-zero if the argument is non-zero) and the number of digits after it is equal to the precision. When the precision is missing it is taken as 6; if the precision is 0 and the # flag is not specified, no radix character appears. The E conversion character will produce a number with E instead of e introducing the exponent. The exponent always contains at least two digits. The value is rounded to the appropriate number of digits.
g,G	The double argument is printed in style f or e (or in style E in the case of a G conversion character), with the precision specifying the number of significant digits. If an explicit precision is 0, it is taken as 1. The style used depends on the value converted: style e (or E) will be used only if the exponent resulting from the conversion is less than -4 or greater than or equal to the precision. Trailing zeros are removed from the fractional part of the result. A radix character appears only if it is followed by a digit.
c	The int argument is converted to an unsigned char, and the resulting byte is printed. If an l (ell) qualifier is present, the <code>wint_t</code> argument is converted as if by an <code>ls</code> conversion specification with no precision and an argument that points to a two-element array of type <code>wchar_t</code> , the first element of which contains the <code>wint_t</code> argument to the <code>ls</code> conversion specification and the second element contains a null wide-character.
C	Same as <code>lc</code> .
wc	The int argument is converted to a wide character (<code>wchar_t</code>), and the resulting wide character is printed.
s	The argument must be a pointer to an array of <code>char</code> . Bytes from the array are written up to (but not including) any terminating null byte. If a precision is specified, a standard-conforming application (see <code>standards(5)</code>) will write only the number of bytes specified by precision; an application that is not standard-conforming will write only the portion

fprintf(3C)

of the string that will display in the number of columns of screen display specified by precision. If the precision is not specified, it is taken to be infinite, so all bytes up to the first null byte are printed. An argument with a null value will yield undefined results.

If an `l` (ell) qualifier is present, the argument must be a pointer to an array of type `wchar_t`. Wide-characters from the array are converted to characters (each as if by a call to the `wcrtomb(3C)` function, with the conversion state described by an `mbstate_t` object initialized to zero before the first wide-character is converted) up to and including a terminating null wide-character. The resulting characters are written up to (but not including) the terminating null character (byte). If no precision is specified, the array must contain a null wide-character. If a precision is specified, no more than that many characters (bytes) are written (including shift sequences, if any), and the array must contain a null wide-character if, to equal the character sequence length given by the precision, the function would need to access a wide-character one past the end of the array. In no case is a partial character written.

`S` Same as `ls`.

`ws` The argument must be a pointer to an array of `wchar_t`. Bytes from the array are written up to (but not including) any terminating null character. If the precision is specified, only that portion of the wide-character array that will display in the number of columns of screen display specified by precision will be written. If the precision is not specified, it is taken to be infinite, so all wide characters up to the first null character are printed. An argument with a null value will yield undefined results.

`p` The argument must be a pointer to `void`. The value of the pointer is converted to a set of sequences of printable characters, which should be the same as the set of sequences that are matched by the `%p` conversion of the `scanf(3C)` function.

`n` The argument must be a pointer to an integer into which is written the number of bytes written to the output standard I/O stream so far by this call to one of the `printf()` functions. No argument is converted.

`%` Print a `%`; no argument is converted. The entire conversion specification must be `%%`.

If a conversion specification does not match one of the above forms, the behavior is undefined.

If a floating-point value is the internal representation for infinity, the output is `[±]Infinity`, where *Infinity* is either `Infinity` or `Inf`, depending on the desired output string length. Printing of the sign follows the rules described above.

If a floating-point value is the internal representation for “not-a-number,” the output is `[±]NaN`. Printing of the sign follows the rules described above.

	In no case does a non-existent or small field width cause truncation of a field; if the result of a conversion is wider than the field width, the field is simply expanded to contain the conversion result. Characters generated by <code>printf()</code> and <code>fprintf()</code> are printed as if the <code>putc(3C)</code> function had been called.						
	The <code>st_ctime</code> and <code>st_mtime</code> fields of the file will be marked for update between the call to a successful execution of <code>printf()</code> or <code>fprintf()</code> and the next successful completion of a call to <code>fflush(3C)</code> or <code>fclose(3C)</code> on the same stream or a call to <code>exit(3C)</code> or <code>abort(3C)</code> .						
RETURN VALUES	<p>The <code>printf()</code>, <code>fprintf()</code>, and <code>sprintf()</code> functions return the number of bytes transmitted (excluding the terminating null byte in the case of <code>sprintf()</code>).</p> <p>The <code>snprintf()</code> function returns the number of characters formatted, that is, the number of characters that would have been written to the buffer if it were large enough. If the value of <code>n</code> is 0 on a call to <code>snprintf()</code>, an unspecified value less than 1 is returned.</p> <p>Each function returns a negative value if an output error was encountered.</p>						
ERRORS	<p>For the conditions under which <code>printf()</code> and <code>fprintf()</code> will fail and may fail, refer to <code>fputc(3C)</code> or <code>fputwc(3C)</code>.</p> <p>In addition, all forms of <code>printf()</code> may fail if:</p> <table border="0"> <tr> <td><code>EILSEQ</code></td> <td>A wide-character code that does not correspond to a valid character has been detected.</td> </tr> <tr> <td><code>EINVAL</code></td> <td>There are insufficient arguments.</td> </tr> </table> <p>In addition, <code>printf()</code> and <code>fprintf()</code> may fail if:</p> <table border="0"> <tr> <td><code>ENOMEM</code></td> <td>Insufficient storage space is available.</td> </tr> </table>	<code>EILSEQ</code>	A wide-character code that does not correspond to a valid character has been detected.	<code>EINVAL</code>	There are insufficient arguments.	<code>ENOMEM</code>	Insufficient storage space is available.
<code>EILSEQ</code>	A wide-character code that does not correspond to a valid character has been detected.						
<code>EINVAL</code>	There are insufficient arguments.						
<code>ENOMEM</code>	Insufficient storage space is available.						
USAGE	<p>If the application calling the <code>printf()</code> functions has any objects of type <code>wint_t</code> or <code>wchar_t</code>, it must also include the header <code><wchar.h></code> to have these objects defined.</p> <p>The <code>sprintf()</code> and <code>snprintf()</code> functions are MT-Safe in multithreaded applications. The <code>printf()</code> and <code>fprintf()</code> functions can be used safely in multithreaded applications, as long as <code>setlocale(3C)</code> is not being called to change the locale.</p>						
Escape Character Sequences	<p>It is common to use the following escape sequences built into the C language when entering format strings for the <code>printf()</code> functions, but these sequences are processed by the C compiler, not by the <code>printf()</code> function.</p> <table border="0"> <tr> <td><code>\a</code></td> <td>Alert. Ring the bell.</td> </tr> <tr> <td><code>\b</code></td> <td>Backspace. Move the printing position to one character before the current position, unless the current position is the start of a line.</td> </tr> </table>	<code>\a</code>	Alert. Ring the bell.	<code>\b</code>	Backspace. Move the printing position to one character before the current position, unless the current position is the start of a line.		
<code>\a</code>	Alert. Ring the bell.						
<code>\b</code>	Backspace. Move the printing position to one character before the current position, unless the current position is the start of a line.						

fprintf(3C)

<code>\f</code>	Form feed. Move the printing position to the initial printing position of the next logical page.
<code>\n</code>	Newline. Move the printing position to the start of the next line.
<code>\r</code>	Carriage return. Move the printing position to the start of the current line.
<code>\t</code>	Horizontal tab. Move the printing position to the next implementation-defined horizontal tab position on the current line.
<code>\v</code>	Vertical tab. Move the printing position to the start of the next implementation-defined vertical tab position.

In addition, the C language supports character sequences of the form

`\octal-numberand`

`\hex-number` which translates into the character represented by the octal or hexadecimal number. For example, if ASCII representations are being used, the letter 'a' may be written as `'\141'` and 'Z' as `'\132'`. This syntax is most frequently used to represent the null character as `'\0'`. This is exactly equivalent to the numeric constant zero (0). Note that the octal number does not include the zero prefix as it would for a normal octal constant. To specify a hexadecimal number, omit the zero so that the prefix is an 'x' (uppercase 'X' is not allowed in this context). Support for hexadecimal sequences is an ANSI extension. See `standards(5)`.

EXAMPLES

EXAMPLE 1 To print the language-independent date and time format, the following statement could be used:

```
printf (format, weekday, month, day, hour, min);
```

For American usage, *format* could be a pointer to the string:

```
"%s, %s %d, %d:%.2d\n"
```

producing the message:

```
Sunday, July 3, 10:02
```

whereas for German usage, *format* could be a pointer to the string:

```
"%1$s, %3$d. %2$s, %4$d:%5$.2d\n"
```

producing the message:

```
Sonntag, 3. Juli, 10:02
```

EXAMPLE 2 To print a date and time in the form `Sunday, July 3, 10:02`, where *weekday* and *month* are pointers to null-terminated strings:

```
printf("%s, %s %i, %d:%.2d", weekday, month, day, hour, min);
```

EXAMPLE 2 To print a date and time in the form *Sunday, July 3, 10:02*, where *weekday* and *month* are pointers to null-terminated strings: *(Continued)*

EXAMPLE 3 To print pi to 5 decimal places:

```
printf("pi = %.5f", 4 * atan(1.0));
```

Default

EXAMPLE 4 The following example applies only to applications which are not standard-conforming (see *standards(5)*). To print a list of names in columns which are 20 characters wide:

```
printf("%20s%20s%20s", lastname, firstname, middlename);
```

fprintf(3UCB)

NAME	printf, fprintf, sprintf, vprintf, vfprintf, vsprintf – formatted output conversion
SYNOPSIS	<pre>/usr/ucb/cc [flag ...] file ... #include <stdio.h> int printf(format, ...); const char *format; int fprintf(stream, format, va_list); FILE *stream; char *format; va_dcl; char *sprintf(s, format, va_list); char *s, *format; va_dcl; int vprintf(format, ap); char *format; va_list ap; int vfprintf(stream, format, ap); FILE *stream; char *format; va_list ap; char *vsprintf(s, format, ap); char *s, *format; va_list ap;</pre>
DESCRIPTION	<p>printf() places output on the standard output stream stdout. fprintf() places output on the named output stream. sprintf() places “output,” followed by the NULL character (\0), in consecutive bytes starting at *s; it is the user’s responsibility to ensure that enough storage is available.</p> <p>vprintf(), vfprintf(), and vsprintf() are the same as printf(), fprintf(), and sprintf() respectively, except that instead of being called with a variable number of arguments, they are called with an argument list as defined by varargs(3HEAD).</p> <p>Each of these functions converts, formats, and prints its args under control of the format. The format is a character string which contains two types of objects: plain characters, which are simply copied to the output stream, and conversion specifications, each of which causes conversion and printing of zero or more args. The results are undefined if there are insufficient args for the format. If the format is exhausted while args remain, the excess args are simply ignored.</p> <p>Each conversion specification is introduced by the character %. After the %, the following appear in sequence:</p>

- Zero or more *flags*, which modify the meaning of the conversion specification.
- An optional decimal digit string specifying a minimum *field width*. If the converted value has fewer characters than the field width, it will be padded on the left (or right, if the left-adjustment flag ‘-’, described below, has been given) to the field width. The padding is with blanks unless the field width digit string starts with a zero, in which case the padding is with zeros.
- A *precision* that gives the minimum number of digits to appear for the `d`, `i`, `o`, `u`, `x`, or `X` conversions, the number of digits to appear after the decimal point for the `e`, `E`, and `f` conversions, the maximum number of significant digits for the `g` and `G` conversion, or the maximum number of characters to be printed from a string in `s` conversion. The precision takes the form of a period (.) followed by a decimal digit string; a `NULL` digit string is treated as zero. Padding specified by the precision overrides the padding specified by the field width.
- An optional `l` (ell) specifying that a following `d`, `i`, `o`, `u`, `x`, or `X` conversion character applies to a long integer *arg*. An `l` before any other conversion character is ignored.
- A character that indicates the type of conversion to be applied.

A field width or precision or both may be indicated by an asterisk (*) instead of a digit string. In this case, an integer *arg* supplies the field width or precision. The *arg* that is actually converted is not fetched until the conversion letter is seen, so the *args* specifying field width or precision must appear *before* the *arg* (if any) to be converted. A negative field width argument is taken as a ‘-’ flag followed by a positive field width. If the precision argument is negative, it will be changed to zero.

The flag characters and their meanings are:

-	The result of the conversion will be left-justified within the field.
+	The result of a signed conversion will always begin with a sign (+ or -).
blank	If the first character of a signed conversion is not a sign, a blank will be prefixed to the result. This implies that if the blank and + flags both appear, the blank flag will be ignored.
#	This flag specifies that the value is to be converted to an “alternate form.” For <code>c</code> , <code>d</code> , <code>i</code> , <code>s</code> , and <code>u</code> conversions, the flag has no effect. For <code>o</code> conversion, it increases the precision to force the first digit of the result to be a zero. For <code>x</code> or <code>X</code> conversion, a non-zero result will have <code>0x</code> or <code>0X</code> prefixed to it. For <code>e</code> , <code>E</code> , <code>f</code> , <code>g</code> , and <code>G</code> conversions, the result will always contain a decimal point, even if no digits follow the point (normally, a decimal point appears in the result of these conversions only if a digit follows it). For <code>g</code> and <code>G</code> conversions, trailing zeroes will <i>not</i> be removed from the result (which they normally are).

The conversion characters and their meanings are:

fprintf(3UCB)

d,i,o,u,x,X	The integer <i>arg</i> is converted to signed decimal (d or i), unsigned octal (o), unsigned decimal (u), or unsigned hexadecimal notation (x and X), respectively; the letters abcdef are used for x conversion and the letters ABCDEF for X conversion. The precision specifies the minimum number of digits to appear; if the value being converted can be represented in fewer digits, it will be expanded with leading zeroes. (For compatibility with older versions, padding with leading zeroes may alternatively be specified by prepending a zero to the field width. This does not imply an octal value for the field width.) The default precision is 1. The result of converting a zero value with a precision of zero is a NULL string.
f	The float or double <i>arg</i> is converted to decimal notation in the style <code>[-]ddd.ddd</code> where the number of digits after the decimal point is equal to the precision specification. If the precision is missing, 6 digits are given; if the precision is explicitly 0, no digits and no decimal point are printed.
e,E	The float or double <i>arg</i> is converted in the style <code>[-]d.ddd_{e±}ddd</code> , where there is one digit before the decimal point and the number of digits after it is equal to the precision; when the precision is missing, 6 digits are produced; if the precision is zero, no decimal point appears. The E format code will produce a number with E instead of e introducing the exponent. The exponent always contains at least two digits.
g,G	The float or double <i>arg</i> is printed in style f or e (or in style E in the case of a G format code), with the precision specifying the number of significant digits. The style used depends on the value converted: style e or E will be used only if the exponent resulting from the conversion is less than -4 or greater than the precision. Trailing zeroes are removed from the result; a decimal point appears only if it is followed by a digit.
The e, E f, g, and G formats print IEEE indeterminate values (infinity or not-a-number) as "Infinity" or "NaN" respectively.	
c	The character <i>arg</i> is printed.
s	The <i>arg</i> is taken to be a string (character pointer) and characters from the string are printed until a NULL character (\0) is encountered or until the number of characters indicated by the precision specification is reached. If the precision is missing, it is taken to be infinite, so all characters up to the first NULL character are printed. A NULL value for <i>arg</i> will yield undefined results.
%	Print a %; no argument is converted.

fprintf(3UCB)

In no case does a non-existent or small field width cause truncation of a field; if the result of a conversion is wider than the field width, the field is simply expanded to contain the conversion result. Padding takes place only if the specified field width exceeds the actual width. Characters generated by `printf()` and `fprintf()` are printed as if `putc(3C)` had been called.

RETURN VALUES Upon success, `printf()` and `fprintf()` return the number of characters transmitted, excluding the null character. `vprintf()` and `vfprintf()` return the number of characters transmitted. `sprintf()` and `vsprintf()` always return `s`. If an output error is encountered, `printf()`, `fprintf()`, `vprintf()`, and `vfprintf()` return EOF.

EXAMPLES **EXAMPLE 1** Examples of the `printf` Command To Print a Date and Time

To print a date and time in the form "Sunday, July 3, 10:02," where *weekday* and *month* are pointers to NULL-terminated strings:

```
printf("%s, %s %i, %d:%.2d", weekday, month, day, hour, min);
```

EXAMPLE 2 Examples of the `printf` Command To Print to Five Decimal Places

To print to five decimal places:

```
printf("pi = %.5f", 4 * atan(1. 0));
```

SEE ALSO `econvert(3C)`, `putc(3C)`, `scanf(3C)`, `vprintf(3C)`, `varargs(3HEAD)`

NOTES Use of these interfaces should be restricted to only applications written on BSD platforms. Use of these interfaces with any of the system libraries or in multi-thread applications is unsupported.

Very wide fields (>128 characters) fail.

fpsetmask(3C)

NAME	fpgetround, fpsetround, fpgetmask, fpsetmask, fpgetsticky, fpsetsticky – IEEE floating-point environment control
SYNOPSIS	<pre>#include <ieeefp.h> fp_rnd fpgetround(void); fp_rnd fpsetround(fp_rnd <i>rnd_dir</i>); fp_except fpgetmask(void); fp_except fpsetmask(fp_except <i>mask</i>); fp_except fpgetsticky(void); fp_except fpsetsticky(fp_except <i>sticky</i>);</pre>
DESCRIPTION	<p>There are five floating-point exceptions:</p> <ul style="list-style-type: none">■ divide-by-zero,■ overflow,■ underflow,■ imprecise (inexact) result, and■ invalid operation. <p>When a floating-point exception occurs, the corresponding sticky bit is set (1), and if the mask bit is enabled (1), the trap takes place. These routines let the user change the behavior on occurrence of any of these exceptions, as well as change the rounding mode for floating-point operations.</p> <p>The <i>mask</i> argument is formed by the logical OR operation of the following floating-point exception masks:</p> <pre>FP_X_INV /* invalid operation exception */ FP_X_OFL /* overflow exception */ FP_X_UFL /* underflow exception */ FP_X_DZ /* divide-by-zero exception */ FP_X_IMP /* imprecise (loss of precision) */</pre> <p>The following floating-point rounding modes are passed to <code>fpsetround</code> and returned by <code>fpgetround()</code>.</p> <pre>FP_RN /* round to nearest representative number */ FP_RP /* round to plus infinity */ FP_RM /* round to minus infinity */ FP_RZ /* round to zero (truncate) */</pre> <p>The default environment is rounding mode set to nearest (FP_RN) and all traps disabled.</p> <p>The <code>fpsetsticky()</code> function modifies all sticky flags. The <code>fpsetmask()</code> function changes all mask bits. The <code>fpsetmask()</code> function clears the sticky bit corresponding to any exception being enabled.</p>
RETURN VALUES	The <code>fpgetround()</code> function returns the current rounding mode.

The `fpsetround()` function sets the rounding mode and returns the previous rounding mode.

The `fpgetmask()` function returns the current exception masks.

The `fpsetmask()` function sets the exception masks and returns the previous setting.

The `fpgetsticky()` function returns the current exception sticky flags.

The `fpsetsticky()` function sets (clears) the exception sticky flags and returns the previous setting.

USAGE The C programming language requires truncation (round to zero) for floating point to integral conversions. The current rounding mode has no effect on these conversions.

The sticky bit must be cleared to recover from the trap and proceed. If the sticky bit is not cleared before the next trap occurs, a wrong exception type may be signaled.

Individual bits may be examined using the constants defined in `<ieeefp.h>`.

__fpurge(3C)

NAME	<code>__fbufsize</code> , <code>__flbf</code> , <code>__fpending</code> , <code>__fpurge</code> , <code>__freadable</code> , <code>__freading</code> , <code>__fsetlocking</code> , <code>__fwritable</code> , <code>__fwriting</code> , <code>_flushlbf</code> – interfaces to <code>stdio</code> FILE structure
SYNOPSIS	<pre>#include <stdio.h> #include <stdio_ext.h> size_t __fbufsiz(FILE *stream); int __flbf(FILE *stream); size_t __fpending(FILE *stream); void __fpurge(FILE *stream); int __freadable(FILE *stream); int __freading(FILE *stream); int __fsetlocking(FILE *stream, int type); int __fwritable(FILE *stream); int __fwriting(FILE *stream); void _flushlbf(void);</pre>
DESCRIPTION	<p>These functions provide portable access to the members of the <code>stdio(3C)</code> FILE structure.</p> <p>The <code>__fbufsize()</code> function returns in bytes the size of the buffer currently in use by the given stream.</p> <p>The <code>__flbf()</code> function returns non-zero if the stream is line-buffered.</p> <p>The <code>__fpending</code> function returns in bytes the amount of output pending on a stream.</p> <p>The <code>__fpurge()</code> function discards any pending buffered I/O on the stream.</p> <p>The <code>__freadable()</code> function returns non-zero if it is possible to read from a stream.</p> <p>The <code>__freading()</code> function returns non-zero if the file is open readonly, or if the last operation on the stream was a read operation such as <code>fread(3C)</code> or <code>fgetc(3C)</code>. Otherwise it returns 0.</p> <p>The <code>__fsetlocking()</code> function allows the type of locking performed by <code>stdio</code> on a given stream to be controlled by the programmer.</p> <p>If <code>type</code> is <code>FSETLOCKING_INTERNAL</code>, <code>stdio</code> performs implicit locking around every operation on the given stream. This is the default system behavior on that stream.</p> <p>If <code>type</code> is <code>FSETLOCKING_BYCALLER</code>, <code>stdio</code> assumes that the caller is responsible for maintaining the integrity of the stream in the face of access by multiple threads. If there is only one thread accessing the stream, nothing further needs to be done. If multiple threads are accessing the stream, then the caller can use the <code>flockfile()</code>,</p>

`__fpurge(3C)`

`funlockfile()`, and `ftrylockfile()` functions described on the `flockfile(3C)` manual page to provide the appropriate locking. In both this and the case where *type* is `FSETLOCKING_INTERNAL`, `__fsetlocking()` returns the previous state of the stream.

If *type* is `FSETLOCKING_QUERY`, `__fsetlocking()` returns the current state of the stream without changing it.

The `__fwritable()` function returns non-zero if it is possible to write on a stream.

The `__fwriting()` function returns non-zero if the file is open write-only or append-only, or if the last operation on the stream was a write operation such as `fwrite(3C)` or `fputc(3C)`. Otherwise it returns 0.

The `_flushlbf()` function flushes all line-buffered files. It is used when reading from a line-buffered file.

USAGE

Although the contents of the `stdio` FILE structure have always been private to the `stdio` implementation, some applications have needed to obtain information about a `stdio` stream that was not accessible through a supported interface. These applications have resorted to accessing fields of the FILE structure directly, rendering them possibly non-portable to new implementations of `stdio`, or more likely, preventing enhancements to `stdio` that would cause those applications to break.

In the 64-bit environment, the FILE structure is opaque. The functions described here are provided as a means of obtaining the information that up to now has been retrieved directly from the FILE structure. Because they are based on the needs of existing applications (such as `mh` and `emacs`), they may be extended as other programs are ported. Although they may still be non-portable to other operating systems, they will be compatible from each Solaris release to the next. Interfaces that are more portable are under development.

ATTRIBUTES

fputc(3C)

NAME	fputc, putc, putc_unlocked, putchar, putchar_unlocked, putw – put a byte on a stream
SYNOPSIS	<pre>#include <stdio.h> int fputc(int <i>c</i>, FILE *<i>stream</i>); int putc(int <i>c</i>, FILE *<i>stream</i>); int putc_unlocked(int <i>c</i>, FILE *<i>stream</i>); int putchar(int <i>c</i>); int putchar_unlocked(int <i>c</i>); int putw(int <i>w</i>, FILE *<i>stream</i>);</pre>
DESCRIPTION	<p>The <code>fputc()</code> function writes the byte specified by <i>c</i> (converted to an unsigned char) to the output stream pointed to by <i>stream</i>, at the position indicated by the associated file-position indicator for the stream (if defined), and advances the indicator appropriately. If the file cannot support positioning requests, or if the stream was opened with append mode, the byte is appended to the output stream.</p> <p>The <code>st_ctime</code> and <code>st_mtime</code> fields of the file will be marked for update between the successful execution of <code>fputc()</code> and the next successful completion of a call to <code>fflush(3C)</code> or <code>fclose(3C)</code> on the same stream or a call to <code>exit(3C)</code> or <code>abort(3C)</code>.</p> <p>The <code>putc()</code> routine behaves like <code>fputc()</code>, except that it is implemented as a macro. It runs faster than <code>fputc()</code>, but it takes up more space per invocation and its name cannot be passed as an argument to a function call.</p> <p>The call <code>putchar(<i>c</i>)</code> is equivalent to <code>putc(<i>c</i>, <i>stdout</i>)</code>. The <code>putchar()</code> routine is implemented as a macro.</p> <p>The <code>putc_unlocked()</code> and <code>putchar_unlocked()</code> routines are variants of <code>putc()</code> and <code>putchar()</code>, respectively, that do not lock the stream. It is the caller's responsibility to acquire the stream lock before calling these routines and releasing the lock afterwards; see <code>flockfile(3C)</code> and <code>stdio(3C)</code>. These routines are implemented as macros.</p> <p>The <code>putw()</code> function writes the word (that is, type <code>int</code>) <i>w</i> to the output <i>stream</i> (at the position at which the file offset, if defined, is pointing). The size of a word is the size of a type <code>int</code> and varies from machine to machine. The <code>putw()</code> function neither assumes nor causes special alignment in the file.</p> <p>The <code>st_ctime</code> and <code>st_mtime</code> fields of the file will be marked for update between the successful execution of <code>putw()</code> and the next successful completion of a call to <code>fflush(3C)</code> or <code>fclose(3C)</code> on the same stream or a call to <code>exit(3C)</code> or <code>abort(3C)</code>.</p>
RETURN VALUES	Upon successful completion, <code>fputc()</code> , <code>putc()</code> , <code>putc_unlocked()</code> , <code>putchar()</code> , and <code>putchar_unlocked()</code> return the value that was written. Otherwise, these functions return EOF, the error indicator for the stream is set, and <code>errno</code> is set to indicate the error.

Upon successful completion, `putw()` returns 0. Otherwise, it returns a non-zero value, sets the error indicator for the associated *stream*, and sets `errno` to indicate the error.

An unsuccessful completion will occur, for example, if the file associated with *stream* is not open for writing or if the output file cannot grow.

ERRORS

The `fputc()`, `putc()`, `putc_unlocked()`, `putchar()`, `putchar_unlocked()`, and `putw()` functions will fail if either the *stream* is unbuffered or the *stream's* buffer needs to be flushed, and:

EAGAIN	The <code>O_NONBLOCK</code> flag is set for the file descriptor underlying <i>stream</i> and the process would be delayed in the write operation.
EBADF	The file descriptor underlying <i>stream</i> is not a valid file descriptor open for writing.
EFBIG	An attempt was made to write to a file that exceeds the maximum file size or the process' file size limit.
EFBIG	The file is a regular file and an attempt was made to write at or beyond the offset maximum.
EINTR	The write operation was terminated due to the receipt of a signal, and no data was transferred.
EIO	A physical I/O error has occurred, or the process is a member of a background process group attempting to write to its controlling terminal, <code>TOSTOP</code> is set, the process is neither ignoring nor blocking <code>SIGTTOU</code> and the process group of the process is orphaned. This error may also be returned under implementation-dependent conditions.
ENOSPC	There was no free space remaining on the device containing the file.
EPIPE	An attempt is made to write to a pipe or FIFO that is not open for reading by any process. A <code>SIGPIPE</code> signal will also be sent to the process.

The `fputc()`, `putc()`, `putc_unlocked()`, `putchar()`, `putchar_unlocked()`, and `putw()` functions may fail if:

ENOMEM	Insufficient storage space is available.
ENXIO	A request was made of a non-existent device, or the request was outside the capabilities of the device.

USAGE

Functions exist for the `putc()`, `putc_unlocked()`, `putchar()`, and `putchar_unlocked()` macros. To get the function form, the macro name must be undefined (for example, `#undef putc`).

fputc(3C)

When the macro forms are used, `putc()` and `putc_unlocked()` evaluate the *stream* argument more than once. In particular, `putc(c, *f++)`; does not work sensibly. The `fputc()` function should be used instead when evaluating the *stream* argument has side effects.

Because of possible differences in word length and byte ordering, files written using `putw()` are implementation-dependent, and possibly cannot be read using `getw(3C)` by a different application or by the same application running in a different environment.

The `putw()` function is inherently byte stream oriented and is not tenable in the context of either multibyte character streams or wide-character streams. Application programmers are encouraged to use one of the character-based output functions instead.

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
MT-Level	See NOTES below.

SEE ALSO `getrlimit(2)`, `ulimit(2)`, `write(2)`, `intro(3)`, `abort(3C)`, `exit(3C)`, `fclose(3C)`, `ferror(3C)`, `fflush(3C)`, `flockfile(3C)`, `fopen(3UCB)`, `printf(3C)`, `putc(3C)`, `puts(3C)`, `setbuf(3C)`, `stdio(3C)`, `attributes(5)`

NOTES The `fputc()`, `putc()`, `putchar()`, and `putw()` routines are MT-Safe in multithreaded applications. The `putc_unlocked()` and `putchar_unlocked()` routines are unsafe in multithreaded applications.

NAME	puts, fputs – put a string on a stream				
SYNOPSIS	<pre>#include <stdio.h> int puts(const char *s); int fputs(const char *s, FILE *stream);</pre>				
DESCRIPTION	<p>The <code>puts()</code> function writes the string pointed to by <code>s</code>, followed by a <code>NEWLINE</code> character, to the standard output stream <code>stdout</code> (see <code>intro(3)</code>). The terminating null byte is not written.</p> <p>The <code>fputs()</code> function writes the null-terminated string pointed to by <code>s</code> to the named output <code>stream</code>. The terminating null byte is not written.</p> <p>The <code>st_ctime</code> and <code>st_mtime</code> fields of the file will be marked for update between the successful execution of <code>fputs()</code> and the next successful completion of a call to <code>fflush(3C)</code> or <code>fclose(3C)</code> on the same stream or a call to <code>exit(2)</code> or <code>abort(3C)</code>.</p>				
RETURN VALUES	On successful completion, both functions return the number of bytes written; otherwise they return <code>EOF</code> and set <code>errno</code> to indicate the error.				
ERRORS	Refer to <code>fputc(3C)</code> .

fputc(3C)

NAME	fputc, putwc, putwchar – put wide-character code on a stream
SYNOPSIS	<pre>#include <stdio.h> #include <wchar.h> wint_t fputc(wchar_t <i>wc</i>, FILE*<i>stream</i>); wint_t putwc(wchar_t <i>wc</i>, FILE*<i>stream</i>); #include <wchar.h> wint_t putwchar(wchar_t <i>wc</i>);</pre>
DESCRIPTION	<p>The <code>fputc()</code> function writes the character corresponding to the wide-character code <code>wc</code> to the output stream pointed to by <code>stream</code>, at the position indicated by the associated file-position indicator for the stream (if defined), and advances the indicator appropriately. If the file cannot support positioning requests, or if the stream was opened with append mode, the character is appended to the output stream. If an error occurs while writing the character, the shift state of the output file is left in an undefined state.</p> <p>The <code>st_ctime</code> and <code>st_mtime</code> fields of the file will be marked for update between the successful execution of <code>fputc()</code> and the next successful completion of a call to <code>fflush(3C)</code> or <code>fclose(3C)</code> on the same stream or a call to <code>exit(2)</code> or <code>abort(3C)</code>.</p> <p>The <code>putwc()</code> function is equivalent to <code>fputc()</code>, except that it is implemented as a macro.</p> <p>The call <code>putwchar(<i>wc</i>)</code> is equivalent to <code>putwc(<i>wc</i>, stdout)</code>. The <code>putwchar()</code> routine is implemented as a macro.</p>
RETURN VALUES	Upon successful completion, <code>fputc()</code> , <code>putwc()</code> , and <code>putwchar()</code> return <code>wc</code> . Otherwise, they return <code>WEOF</code> , the error indicator for the stream is set, and <code>errno</code> is set to indicate the error.
ERRORS	The <code>fputc()</code> , <code>putwc()</code> , and <code>putwchar()</code> functions will fail if either the stream is unbuffered or data in the <code>stream</code> 's buffer needs to be written, and:
EAGAIN	The <code>O_NONBLOCK</code> flag is set for the file descriptor underlying <code>stream</code> and the process would be delayed in the write operation.
EBADF	The file descriptor underlying <code>stream</code> is not a valid file descriptor open for writing.
EFBIG	An attempt was made to write to a file that exceeds the maximum file size or the process's file size limit; or the file is a regular file and an attempt was made to write at or beyond the offset maximum associated with the corresponding stream.
EINTR	The write operation was terminated due to the receipt of a signal, and no data was transferred.
EIO	A physical I/O error has occurred, or the process is a member of a background process group attempting to write to its controlling

terminal, TOSTOP is set, the process is neither ignoring nor blocking SIGTTOU, and the process group of the process is orphaned.

ENOSPC There was no free space remaining on the device containing the file.

EPIPE An attempt is made to write to a pipe or FIFO that is not open for reading by any process. A SIGPIPE signal will also be sent to the process.

The fputc(), putc(), and putchar() functions may fail if:

ENOMEM Insufficient storage space is available.

ENXIO A request was made of a non-existent device, or the request was outside the capabilities of the device.

EILSEQ The wide-character code *wc* does not correspond to a valid character.

USAGE Functions exist for the putc() and putchar() macros. To get the function form, the macro name must be undefined (for example, #undef putc).

When the macro form is used, putc() evaluates the *stream* argument more than once. In particular, putc(wc, *f++) does not work sensibly. The fputc() function should be used instead when evaluating the *stream* argument has side effects.

fputws(3C)

NAME	fputws – put wide character string on a stream				
SYNOPSIS	<pre>#include <stdio.h> #include <wchar.h> int fputws(const wchar_t *s, FILE *stream);</pre>				
DESCRIPTION	<p>The <code>fputws()</code> function writes a character string corresponding to the (null-terminated) wide character string pointed to by <code>ws</code> to the stream pointed to by <code>stream</code>. No character corresponding to the terminating null wide-character code is written, nor is a <code>NEWLINE</code> character appended.</p> <p>The <code>st_ctime</code> and <code>st_mtime</code> fields of the file will be marked for update between the successful execution of <code>fputws()</code> and the next successful completion of a call to <code>fflush(3C)</code> or <code>fclose(3C)</code> on the same stream or a call to <code>exit(2)</code> or <code>abort(3C)</code>.</p>				
RETURN VALUES	Upon successful completion, <code>fputws()</code> returns a non-negative value. Otherwise, it returns <code>-1</code> , sets an error indicator for the stream, and sets <code>errno</code> to indicate the error.				
ERRORS	Refer to <code>fputwc(3C)</code> .				
ATTRIBUTES	See <code>attributes(5)</code> for descriptions of the following attributes:

NAME	fread – binary input
SYNOPSIS	<pre>#include <stdio.h> size_t fread(void *ptr, size_t size, size_t nitems, FILE *stream);</pre>
DESCRIPTION	<p>The <code>fread()</code> function reads into the array pointed to by <i>ptr</i> up to <i>nitems</i> elements whose size is specified by <i>size</i> in bytes, from the stream pointed to by <i>stream</i>. For each object, <i>size</i> calls are made to the <code>fgetc(3C)</code> function and the results stored, in the order read, in an array of unsigned char exactly overlaying the object. The file-position indicator for the stream (if defined) is advanced by the number of bytes successfully read. If an error occurs, the resulting value of the file-position indicator for the stream is unspecified. If a partial element is read, its value is unspecified.</p> <p>The <code>fread()</code> function may mark the <code>st_atime</code> field of the file associated with <i>stream</i> for update. The <code>st_atime</code> field will be marked for update by the first successful execution of <code>fgetc(3C)</code>, <code>fgets(3C)</code>, <code>fgetwc(3C)</code>, <code>fgetws(3C)</code>, <code>fread()</code>, <code>fscanf(3C)</code>, <code>getc(3C)</code>, <code>getchar(3C)</code>, <code>gets(3C)</code>, or <code>scanf(3C)</code> using <i>stream</i> that returns data not supplied by a prior call to <code>ungetc(3C)</code> or <code>ungetwc(3C)</code>.</p>
RETURN VALUES	Upon successful completion, <code>fread()</code> returns the number of elements successfully read, which is less than <i>nitems</i> only if a read error or end-of-file is encountered. If <i>size</i> or <i>nitems</i> is 0, <code>fread()</code> returns 0 and the contents of the array and the state of the stream remain unchanged. Otherwise, if a read error occurs, the error indicator for the stream is set and <code>errno</code> is set to indicate the error.
ERRORS	Refer to <code>fgetc(3C)</code> .
EXAMPLES	<p>EXAMPLE 1 Reading from a Stream</p> <p>The following example reads a single element from the <i>fp</i> stream into the array pointed to by <i>buf</i>.</p> <pre>#include <stdio.h> ... size_t bytes_read; char buf[100]; FILE *fp; ... bytes_read = fread(buf, sizeof(buf), 1, fp); ...</pre>
USAGE	<p>The <code>ferror()</code> or <code>feof()</code> functions must be used to distinguish between an error condition and end-of-file condition. See <code>ferror(3C)</code>.</p> <p>Because of possible differences in element length and byte ordering, files written using <code>fwrite(3C)</code> are application-dependent, and possibly cannot be read using <code>fread()</code> by a different application or by the same application on a different processor.</p>

fread(3C)

__freadable(3C)

NAME	<code>__fbufsize</code> , <code>__flbf</code> , <code>__fpending</code> , <code>__fpurge</code> , <code>__freadable</code> , <code>__freading</code> , <code>__fsetlocking</code> , <code>__fwritable</code> , <code>__fwriting</code> , <code>_flushlbf</code> – interfaces to stdio FILE structure
SYNOPSIS	<pre>#include <stdio.h> #include <stdio_ext.h> size_t __fbufsiz(FILE *stream); int __flbf(FILE *stream); size_t __fpending(FILE *stream); void __fpurge(FILE *stream); int __freadable(FILE *stream); int __freading(FILE *stream); int __fsetlocking(FILE *stream, int type); int __fwritable(FILE *stream); int __fwriting(FILE *stream); void _flushlbf(void);</pre>
DESCRIPTION	<p>These functions provide portable access to the members of the <code>stdio(3C)</code> FILE structure.</p> <p>The <code>__fbufsize()</code> function returns in bytes the size of the buffer currently in use by the given stream.</p> <p>The <code>__flbf()</code> function returns non-zero if the stream is line-buffered.</p> <p>The <code>__fpending</code> function returns in bytes the amount of output pending on a stream.</p> <p>The <code>__fpurge()</code> function discards any pending buffered I/O on the stream.</p> <p>The <code>__freadable()</code> function returns non-zero if it is possible to read from a stream.</p> <p>The <code>__freading()</code> function returns non-zero if the file is open readonly, or if the last operation on the stream was a read operation such as <code>fread(3C)</code> or <code>fgetc(3C)</code>. Otherwise it returns 0.</p> <p>The <code>__fsetlocking()</code> function allows the type of locking performed by <code>stdio</code> on a given stream to be controlled by the programmer.</p> <p>If <code>type</code> is <code>FSETLOCKING_INTERNAL</code>, <code>stdio</code> performs implicit locking around every operation on the given stream. This is the default system behavior on that stream.</p> <p>If <code>type</code> is <code>FSETLOCKING_BYCALLER</code>, <code>stdio</code> assumes that the caller is responsible for maintaining the integrity of the stream in the face of access by multiple threads. If there is only one thread accessing the stream, nothing further needs to be done. If multiple threads are accessing the stream, then the caller can use the <code>flockfile()</code>,</p>

__freadable(3C)

`funlockfile()`, and `ftrylockfile()` functions described on the `flockfile(3C)` manual page to provide the appropriate locking. In both this and the case where *type* is `FSETLOCKING_INTERNAL`, `__fsetlocking()` returns the previous state of the stream.

If *type* is `FSETLOCKING_QUERY`, `__fsetlocking()` returns the current state of the stream without changing it.

The `__fwritable()` function returns non-zero if it is possible to write on a stream.

The `__fwriting()` function returns non-zero if the file is open write-only or append-only, or if the last operation on the stream was a write operation such as `fwrite(3C)` or `fputc(3C)`. Otherwise it returns 0.

The `_flushlbf()` function flushes all line-buffered files. It is used when reading from a line-buffered file.

USAGE

Although the contents of the `stdio` `FILE` structure have always been private to the `stdio` implementation, some applications have needed to obtain information about a `stdio` stream that was not accessible through a supported interface. These applications have resorted to accessing fields of the `FILE` structure directly, rendering them possibly non-portable to new implementations of `stdio`, or more likely, preventing enhancements to `stdio` that would cause those applications to break.

In the 64-bit environment, the `FILE` structure is opaque. The functions described here are provided as a means of obtaining the information that up to now has been retrieved directly from the `FILE` structure. Because they are based on the needs of existing applications (such as `mh` and `emacs`), they may be extended as other programs are ported. Although they may still be non-portable to other operating systems, they will be compatible from each Solaris release to the next. Interfaces that are more portable are under development.

ATTRIBUTES

NAME	malloc, calloc, free, memalign, realloc, valloc, alloca – memory allocator
SYNOPSIS	<pre>#include <stdlib.h> void *malloc(size_t size); void *calloc(size_t nelem, size_t elsize); void free(void *ptr); void *memalign(size_t alignment, size_t size); void *realloc(void *ptr, size_t size); void *valloc(size_t size); #include <alloca.h> void *alloca(size_t size);</pre>
DESCRIPTION	<p>The <code>malloc()</code> and <code>free()</code> functions provide a simple, general-purpose memory allocation package. The <code>malloc()</code> function returns a pointer to a block of at least <i>size</i> bytes suitably aligned for any use. If the space assigned by <code>malloc()</code> is overrun, the results are undefined.</p> <p>The argument to <code>free()</code> is a pointer to a block previously allocated by <code>malloc()</code>, <code>calloc()</code>, or <code>realloc()</code>. After <code>free()</code> is executed, this space is made available for further allocation by the application, though not returned to the system. Memory is returned to the system only upon termination of the application. If <i>ptr</i> is a null pointer, no action occurs. If a random number is passed to <code>free()</code>, the results are undefined.</p> <p>The <code>calloc()</code> function allocates space for an array of <i>nelem</i> elements of size <i>elsize</i>. The space is initialized to zeros.</p> <p>The <code>memalign()</code> function allocates <i>size</i> bytes on a specified alignment boundary and returns a pointer to the allocated block. The value of the returned address is guaranteed to be an even multiple of <i>alignment</i>. The value of <i>alignment</i> must be a power of two and must be greater than or equal to the size of a word.</p> <p>The <code>realloc()</code> function changes the size of the block pointed to by <i>ptr</i> to <i>size</i> bytes and returns a pointer to the (possibly moved) block. The contents will be unchanged up to the lesser of the new and old sizes. If <i>ptr</i> is NULL, <code>realloc()</code> behaves like <code>malloc()</code> for the specified size. If <i>size</i> is 0 and <i>ptr</i> is not a null pointer, the space pointed to is made available for further allocation by the application, though not returned to the system. Memory is returned to the system only upon termination of the application.</p> <p>The <code>valloc()</code> function has the same effect as <code>malloc()</code>, except that the allocated memory will be aligned to a multiple of the value returned by <code>sysconf(_SC_PAGESIZE)</code>.</p>

free(3C)

The `alloca()` function allocates *size* bytes of space in the stack frame of the caller, and returns a pointer to the allocated block. This temporary space is automatically freed when the caller returns. If the allocated block is beyond the current stack limit, the resulting behavior is undefined.

RETURN VALUES Upon successful completion, each of the allocation functions returns a pointer to space suitably aligned (after possible pointer coercion) for storage of any type of object.

If there is no available memory, `malloc()`, `realloc()`, `memalign()`, `valloc()`, and `calloc()` return a null pointer. When `realloc()` is called with *size* > 0 and returns `NULL`, the block pointed to by *ptr* is left intact. If *size*, *nelem*, or *elsize* is 0, either a null pointer or a unique pointer that can be passed to `free()` is returned.

If `malloc()`, `calloc()`, or `realloc()` returns unsuccessfully, `errno` will be set to indicate the error. The `free()` function does not set `errno`.

ERRORS The `malloc()`, `calloc()`, and `realloc()` functions will fail if:

ENOMEM The physical limits of the system are exceeded by *size* bytes of memory which cannot be allocated.

EAGAIN There is not enough memory available to allocate *size* bytes of memory; but the application could try again later.

USAGE Portable applications should avoid using `valloc()` but should instead use `malloc()` or `mmap(2)`. On systems with a large page size, the number of successful `valloc()` operations might be 0.

Comparative features of `malloc(3C)`, `bsdmalloc(3MALLOC)`, and `malloc(3MALLOC)` are as follows:

- The `bsdmalloc(3MALLOC)` routines afford better performance, but are space-inefficient.
- The `malloc(3MALLOC)` routines are space-efficient, but have slower performance.
- The standard, fully SCD-compliant `malloc` routines are a trade-off between performance and space-efficiency.

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Interface Stability	<code>malloc()</code> , <code>calloc()</code> , <code>free()</code> , <code>realloc()</code> , <code>valloc()</code> are Standard; <code>memalign()</code> and <code>alloca()</code> are Stable.
MT-Level	Safe

SEE ALSO `brk(2)`, `getrlimit(2)`, `bsdmalloc(3MALLOC)`, `malloc(3MALLOC)`, `mapmalloc(3MALLOC)`, `watchmalloc(3MALLOC)`, `attributes(5)`

WARNINGS Undefined results will occur if the size requested for a block of memory exceeds the maximum size of a process's heap, which can be obtained with `getrlimit(2)`

The `alloca()` function is machine-, compiler-, and most of all, system-dependent. Its use is strongly discouraged.

free(3MALLOC)

NAME	<code>malloc, free, realloc, calloc, malloc, mallinfo</code> – memory allocator				
SYNOPSIS	<pre>cc [<i>flag</i> ...] <i>file</i> ... -lmalloc [<i>library</i> ...] #include <stdlib.h> void *malloc(size_t <i>size</i>); void free(void *<i>ptr</i>); void *realloc(void *<i>ptr</i>, size_t <i>size</i>); void *calloc(size_t <i>nelem</i>, size_t <i>elsize</i>); #include <malloc.h> int mallopt(int <i>cmd</i>, int <i>value</i>); struct mallinfo mallinfo(void);</pre>				
DESCRIPTION	<p>The <code>malloc()</code> and <code>free()</code> functions provide a simple general-purpose memory allocation package.</p> <p>The <code>malloc()</code> function returns a pointer to a block of at least <i>size</i> bytes suitably aligned for any use.</p> <p>The argument to <code>free()</code> is a pointer to a block previously allocated by <code>malloc()</code>. After <code>free()</code> is performed, this space is made available for further allocation, and its contents have been destroyed. See <code>mallopt()</code> below for a way to change this behavior. If <i>ptr</i> is a null pointer, no action occurs.</p> <p>Undefined results occur if the space assigned by <code>malloc()</code> is overrun or if some random number is handed to <code>free()</code>.</p> <p>The <code>realloc()</code> function changes the size of the block pointed to by <i>ptr</i> to <i>size</i> bytes and returns a pointer to the (possibly moved) block. The contents are unchanged up to the lesser of the new and old sizes. If <i>ptr</i> is a null pointer, <code>realloc()</code> behaves like <code>malloc()</code> for the specified size. If <i>size</i> is 0 and <i>ptr</i> is not a null pointer, the object it points to is freed.</p> <p>The <code>calloc()</code> function allocates space for an array of <i>nelem</i> elements of size <i>elsize</i>. The space is initialized to zeros.</p> <p>The <code>mallopt()</code> function provides for control over the allocation algorithm. The available values for <i>cmd</i> are:</p> <table><tr><td><code>M_MXFAST</code></td><td>Set <i>maxfast</i> to <i>value</i>. The algorithm allocates all blocks below the size of <i>maxfast</i> in large groups and then does them out very quickly. The default value for <i>maxfast</i> is 24.</td></tr><tr><td><code>M_NLBLKS</code></td><td>Set <i>numlblks</i> to <i>value</i>. The above mentioned “large groups” each contain <i>numlblks</i> blocks. <i>numlblks</i> must be greater than 0. The default value for <i>numlblks</i> is 100.</td></tr></table>	<code>M_MXFAST</code>	Set <i>maxfast</i> to <i>value</i> . The algorithm allocates all blocks below the size of <i>maxfast</i> in large groups and then does them out very quickly. The default value for <i>maxfast</i> is 24.	<code>M_NLBLKS</code>	Set <i>numlblks</i> to <i>value</i> . The above mentioned “large groups” each contain <i>numlblks</i> blocks. <i>numlblks</i> must be greater than 0. The default value for <i>numlblks</i> is 100.
<code>M_MXFAST</code>	Set <i>maxfast</i> to <i>value</i> . The algorithm allocates all blocks below the size of <i>maxfast</i> in large groups and then does them out very quickly. The default value for <i>maxfast</i> is 24.				
<code>M_NLBLKS</code>	Set <i>numlblks</i> to <i>value</i> . The above mentioned “large groups” each contain <i>numlblks</i> blocks. <i>numlblks</i> must be greater than 0. The default value for <i>numlblks</i> is 100.				

free(3MALLOC)

M_GRAIN	Set <i>grain</i> to <i>value</i> . The sizes of all blocks smaller than <i>maxfast</i> are considered to be rounded up to the nearest multiple of <i>grain</i> . <i>grain</i> must be greater than 0. The default value of <i>grain</i> is the smallest number of bytes that will allow alignment of any data type. Value will be rounded up to a multiple of the default when <i>grain</i> is set.
M_KEEP	Preserve data in a freed block until the next <code>malloc()</code> , <code>realloc()</code> , or <code>calloc()</code> . This option is provided only for compatibility with the old version of <code>malloc()</code> , and it is not recommended.

These values are defined in the `<malloc.h>` header.

The `malloc()` function can be called repeatedly, but cannot be called after the first small block is allocated.

The `mallinfo()` function provides instrumentation describing space usage. It returns the `mallinfo` structure with the following members:

```
unsigned long arena;      /* total space in arena */
unsigned long ordblks;    /* number of ordinary blocks */
unsigned long smlbks;    /* number of small blocks */
unsigned long hblkhd;    /* space in holding block headers */
unsigned long hblks;     /* number of holding blocks */
unsigned long usmlbks;   /* space in small blocks in use */
unsigned long fsmblks;   /* space in free small blocks */
unsigned long uordblks;  /* space in ordinary blocks in use */
unsigned long fordblks;  /* space in free ordinary blocks */
unsigned long keepcost;  /* space penalty if keep option */
                        /* is used */
```

The `mallinfo` structure is defined in the `<malloc.h>` header.

Each of the allocation routines returns a pointer to space suitably aligned (after possible pointer coercion) for storage of any type of object.

RETURN VALUES

The `malloc()`, `realloc()`, and `calloc()` functions return a null pointer if there is not enough available memory. When `realloc()` returns `NULL`, the block pointed to by *ptr* is left intact. If `malloc()` is called after any allocation or if *cmd* or *value* are invalid, a non-zero value is returned. Otherwise, it returns 0.

ERRORS

If `malloc()`, `calloc()`, or `realloc()` returns unsuccessfully, `errno` is set to indicate the error:

ENOMEM	<i>size</i> bytes of memory exceeds the physical limits of your system, and cannot be allocated.
EAGAIN	There is not enough memory available at this point in time to allocate <i>size</i> bytes of memory; but the application could try again later.

free(3MALLOC)

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
MT-Level	Safe

SEE ALSO `brk(2)`, `bsdmalloc(3MALLOC)`, `libmtmalloc(3LIB)`, `malloc(3C)`, `mapmalloc(3MALLOC)`, `mtmalloc(3MALLOC)`, `watchmalloc(3MALLOC)`, `attributes(5)`

NOTES Note that unlike `malloc(3C)`, this package does not preserve the contents of a block when it is freed, unless the `M_KEEP` option of `mallopt()` is used.

Undocumented features of `malloc(3C)` have not been duplicated.

Function prototypes for `malloc()`, `realloc()`, `calloc()`, and `free()` are also defined in the `<malloc.h>` header for compatibility with old applications. New applications should include `<stdlib.h>` to access the prototypes for these functions. Comparative Features of these `malloc` routines, `bsdmalloc(3MALLOC)`, and `malloc(3C)`

- These `malloc` routines are space-efficient but have slower performance.
- The `bsdmalloc(3MALLOC)` routines afford better performance but are space-inefficient.
- The standard, fully SCD-compliant `malloc(3C)` routines are a trade-off between performance and space-efficiency.

The `free()` function does not set `errno`.

NAME	freopen – open a stream																
SYNOPSIS	<pre>#include <stdio.h> FILE *freopen(const char *filename, const char *mode, FILE *stream);</pre>																
DESCRIPTION	<p>The <code>freopen()</code> function first attempts to flush the stream and close any file descriptor associated with <i>stream</i>. Failure to flush or close the file successfully is ignored. The error and end-of-file indicators for the stream are cleared.</p> <p>The <code>freopen()</code> function opens the file whose pathname is the string pointed to by <i>filename</i> and associates the stream pointed to by <i>stream</i> with it. The <i>mode</i> argument is used just as in <code>fopen(3C)</code>.</p> <p>The original stream is closed regardless of whether the subsequent open succeeds.</p> <p>After a successful call to the <code>freopen()</code> function, the orientation of the stream is cleared and the associated <code>mbstate_t</code> object is set to describe an initial conversion state.</p> <p>The largest value that can be represented correctly in an object of type <code>off_t</code> will be established as the offset maximum in the open file description.</p>																
RETURN VALUES	Upon successful completion, <code>freopen()</code> returns the value of <i>stream</i> . Otherwise, a null pointer is returned and <code>errno</code> is set to indicate the error.																
ERRORS	<p>The <code>freopen()</code> function will fail if:</p> <table border="0" style="width: 100%;"> <tr> <td style="vertical-align: top; padding-right: 20px;">EACCES</td> <td>Search permission is denied on a component of the path prefix, or the file exists and the permissions specified by <i>mode</i> are denied, or the file does not exist and write permission is denied for the parent directory of the file to be created.</td> </tr> <tr> <td style="vertical-align: top; padding-right: 20px;">EINTR</td> <td>A signal was caught during <code>freopen()</code>.</td> </tr> <tr> <td style="vertical-align: top; padding-right: 20px;">EISDIR</td> <td>The named file is a directory and <i>mode</i> requires write access.</td> </tr> <tr> <td style="vertical-align: top; padding-right: 20px;">ELOOP</td> <td>Too many symbolic links were encountered in resolving <i>path</i>.</td> </tr> <tr> <td style="vertical-align: top; padding-right: 20px;">EMFILE</td> <td>There are <code>OPEN_MAX</code> file descriptors currently open in the calling process.</td> </tr> <tr> <td style="vertical-align: top; padding-right: 20px;">ENAMETOOLONG</td> <td>The length of the <i>filename</i> exceeds <code>PATH_MAX</code> or a pathname component is longer than <code>NAME_MAX</code>.</td> </tr> <tr> <td style="vertical-align: top; padding-right: 20px;">ENFILE</td> <td>The maximum allowable number of files is currently open in the system.</td> </tr> <tr> <td style="vertical-align: top; padding-right: 20px;">ENOENT</td> <td>A component of <i>filename</i> does not name an existing file or <i>filename</i> is an empty string.</td> </tr> </table>	EACCES	Search permission is denied on a component of the path prefix, or the file exists and the permissions specified by <i>mode</i> are denied, or the file does not exist and write permission is denied for the parent directory of the file to be created.	EINTR	A signal was caught during <code>freopen()</code> .	EISDIR	The named file is a directory and <i>mode</i> requires write access.	ELOOP	Too many symbolic links were encountered in resolving <i>path</i> .	EMFILE	There are <code>OPEN_MAX</code> file descriptors currently open in the calling process.	ENAMETOOLONG	The length of the <i>filename</i> exceeds <code>PATH_MAX</code> or a pathname component is longer than <code>NAME_MAX</code> .	ENFILE	The maximum allowable number of files is currently open in the system.	ENOENT	A component of <i>filename</i> does not name an existing file or <i>filename</i> is an empty string.
EACCES	Search permission is denied on a component of the path prefix, or the file exists and the permissions specified by <i>mode</i> are denied, or the file does not exist and write permission is denied for the parent directory of the file to be created.																
EINTR	A signal was caught during <code>freopen()</code> .																
EISDIR	The named file is a directory and <i>mode</i> requires write access.																
ELOOP	Too many symbolic links were encountered in resolving <i>path</i> .																
EMFILE	There are <code>OPEN_MAX</code> file descriptors currently open in the calling process.																
ENAMETOOLONG	The length of the <i>filename</i> exceeds <code>PATH_MAX</code> or a pathname component is longer than <code>NAME_MAX</code> .																
ENFILE	The maximum allowable number of files is currently open in the system.																
ENOENT	A component of <i>filename</i> does not name an existing file or <i>filename</i> is an empty string.																

freopen(3C)

ENOSPC	The directory or file system that would contain the new file cannot be expanded, the file does not exist, and it was to be created.
ENOTDIR	A component of the path prefix is not a directory.
ENXIO	The named file is a character special or block special file, and the device associated with this special file does not exist.
EOVERFLOW	The current value of the file position cannot be represented correctly in an object of type <code>off_t</code> .
EROFS	The named file resides on a read-only file system and <i>mode</i> requires write access.

The `freopen()` function may fail if:

EINVAL	The value of the <i>mode</i> argument is not valid.
ENAMETOOLONG	Pathname resolution of a symbolic link produced an intermediate result whose length exceeds <code>PATH_MAX</code> .
ENOMEM	Insufficient storage space is available.
ENXIO	A request was made of a non-existent device, or the request was outside the capabilities of the device.
ETXTBSY	The file is a pure procedure (shared text) file that is being executed and <i>mode</i> requires write access.

USAGE The `freopen()` function is typically used to attach the preopened *streams* associated with `stdin`, `stdout` and `stderr` to other files. By default `stderr` is unbuffered, but the use of `freopen()` will cause it to become buffered or line-buffered.

The `freopen()` function has a transitional interface for 64-bit file offsets. See `lf64(5)`.

freopen(3UCB)

NOTES Use of these interfaces should be restricted to only applications written on BSD platforms. Use of these interfaces with any of the system libraries or in multi-thread applications is unsupported.

In order to support the same number of open files that the system does, `fopen()` must allocate additional memory for data structures using `malloc(3C)` after 64 files have been opened. This confuses some programs which use their own memory allocators.

The interfaces of `fopen()` and `freopen()` differ from the Standard I/O Functions `fopen(3C)` and `freopen(3C)`. The Standard I/O Functions distinguish binary from text files with an additional use of 'b' as part of the *mode*. This enables portability of `fopen(3C)` and `freopen(3C)` beyond SunOS 4.X systems.

NAME frexp – extract mantissa and exponent from double precision number

SYNOPSIS `#include <math.h>`
`double frexp(double num, int *exp);`

DESCRIPTION The `frexp()` function breaks a floating-point number into a normalized fraction and an integral power of 2. It stores the integer exponent in the `int` object pointed to by *exp*.

RETURN VALUES The `frexp()` function returns the value *x*, such that *x* is a `double` with magnitude in the interval $[\frac{1}{2}, 1)$ or 0, and *num* equals *x* times 2 raised to the power **exp*.

If *num* is 0, both parts of the result are 0.

If *num* is NaN, NaN is returned and the value of **exp* is unspecified.

If *num* is $\pm\text{Inf}$, *num* is returned and the value of **exp* is unspecified.

USAGE An application wishing to check for error situations should set `errno` to 0 before calling `frexp()`. If `errno` is non-zero on return, or the return value is NaN, an error has occurred.

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

fscanf(3C)

NAME	scanf, fscanf, sscanf, vscanf, vfscanf, vsscanf – convert formatted input
SYNOPSIS	<pre>#include <stdio.h> int scanf(const char *format, ...); int fscanf(FILE*stream, const char *format, ...); int sscanf(const char *s, const char *format, ...); #include <stdarg.h> #include <stdio.h> int vscanf(const char *format, va_list arg); int vfscanf(FILE *stream, const char *format, va_list arg); int vsscanf(const char *s, const char *format, va_list arg);</pre>
DESCRIPTION	<p>The <code>scanf()</code> function reads from the standard input stream <code>stdin</code>.</p> <p>The <code>fscanf()</code> function reads from the named input <i>stream</i>.</p> <p>The <code>sscanf()</code> function reads from the string <i>s</i>.</p> <p>The <code>vscanf()</code>, <code>vfscanf()</code>, and <code>vsscanf()</code> functions are equivalent to the <code>scanf()</code>, <code>fscanf()</code>, and <code>sscanf()</code> functions, respectively, except that instead of being called with a variable number of arguments, they are called with an argument list as defined by the <code><stdarg.h></code> header (see <code>stdarg(3HEAD)</code>). These functions do not invoke the <code>va_end()</code> macro. Applications using these functions should call <code>va_end(ap)</code> afterwards to clean up.</p> <p>Each function reads bytes, interprets them according to a format, and stores the results in its arguments. Each expects, as arguments, a control string <i>format</i> described below, and a set of <i>pointer</i> arguments indicating where the converted input should be stored. The result is undefined if there are insufficient arguments for the format. If the format is exhausted while arguments remain, the excess arguments are evaluated but are otherwise ignored.</p> <p>Conversions can be applied to the <i>n</i>th argument after the <i>format</i> in the argument list, rather than to the next unused argument. In this case, the conversion character <code>%</code> (see below) is replaced by the sequence <code>%n\$</code>, where <i>n</i> is a decimal integer in the range <code>[1, NL_ARGMAX]</code>. This feature provides for the definition of format strings that select arguments in an order appropriate to specific languages. In format strings containing the <code>%n\$</code> form of conversion specifications, it is unspecified whether numbered arguments in the argument list can be referenced from the format string more than once.</p> <p>The <i>format</i> can contain either form of a conversion specification, that is, <code>%</code> or <code>%n\$</code>, but the two forms cannot normally be mixed within a single <i>format</i> string. The only exception to this is that <code>%%</code> or <code>%*</code> can be mixed with the <code>%n\$</code> form.</p>

The `scanf()` function in all its forms allows for detection of a language-dependent radix character in the input string. The radix character is defined in the program's locale (category `LC_NUMERIC`). In the POSIX locale, or in a locale where the radix character is not defined, the radix character defaults to a period (`.`).

The format is a character string, beginning and ending in its initial shift state, if any, composed of zero or more directives. Each directive is composed of one of the following:

- one or more *white-space characters* (space, tab, newline, vertical-tab or form-feed characters);
- an *ordinary character* (neither `%` nor a white-space character); or
- a *conversion specification*.

Conversion Specifications

Each conversion specification is introduced by the character `%` or the character sequence `%n$`, after which the following appear in sequence:

- An optional assignment-suppressing character `*`.
- An optional non-zero decimal integer that specifies the maximum field width.
- An optional size modifier `h`, `l` (ell), `ll` (ell ell), or `L` indicating the size of the receiving object. The conversion characters `d`, `i`, and `n` must be preceded by `h` if the corresponding argument is a pointer to `short int` rather than a pointer to `int`, by `l` (ell) if it is a pointer to `long int`, or by `ll` (ell ell) if it is a pointer to `long long int`. Similarly, the conversion characters `o`, `u`, and `x` must be preceded by `h` if the corresponding argument is a pointer to `unsigned short int` rather than a pointer to `unsigned int`, by `l` (ell) if it is a pointer to `unsigned long int`, or by `ll` (ell ell) if it is a pointer to `unsigned long long int`. The conversion characters `e`, `f`, and `g` must be preceded by `l` (ell) if the corresponding argument is a pointer to `double` rather than a pointer to `float`, or by `L` if it is a pointer to `long double`. Finally, the conversion characters `c`, `s`, and `[` must be preceded by `l` (ell) if the corresponding argument is a pointer to `wchar_t` rather than a pointer to a character type. If an `h`, `l` (ell), `ll` (ell ell), or `L` appears with any other conversion character, the behavior is undefined.
- A conversion character that specifies the type of conversion to be applied. The valid conversion characters are described below.

The `scanf()` functions execute each directive of the format in turn. If a directive fails, as detailed below, the function returns. Failures are described as input failures (due to the unavailability of input bytes) or matching failures (due to inappropriate input).

A directive composed of one or more white-space characters is executed by reading input until no more valid input can be read, or up to the first byte which is not a white-space character which remains unread.

A directive that is an ordinary character is executed as follows. The next byte is read from the input and compared with the byte that comprises the directive; if the comparison shows that they are not equivalent, the directive fails, and the differing and subsequent bytes remain unread.

fscanf(3C)

A directive that is a conversion specification defines a set of matching input sequences, as described below for each conversion character. A conversion specification is executed in the following steps:

Input white-space characters (as specified by `isspace(3C)`) are skipped, unless the conversion specification includes a `l`, `c`, `C`, or `n` conversion character.

An item is read from the input, unless the conversion specification includes an `n` conversion character. An input item is defined as the longest sequence of input bytes (up to any specified maximum field width, which may be measured in characters or bytes dependent on the conversion character) which is an initial subsequence of a matching sequence. The first byte, if any, after the input item remains unread. If the length of the input item is 0, the execution of the conversion specification fails; this condition is a matching failure, unless end-of-file, an encoding error, or a read error prevented input from the stream, in which case it is an input failure.

Except in the case of a `%` conversion character, the input item (or, in the case of a `%n` conversion specification, the count of input bytes) is converted to a type appropriate to the conversion character. If the input item is not a matching sequence, the execution of the conversion specification fails; this condition is a matching failure. Unless assignment suppression was indicated by a `*`, the result of the conversion is placed in the object pointed to by the first argument following the *format* argument that has not already received a conversion result if the conversion specification is introduced by `%`, or in the *n*th argument if introduced by the character sequence `%n$`. If this object does not have an appropriate type, or if the result of the conversion cannot be represented in the space provided, the behavior is undefined.

Conversion Characters

The following conversion characters are valid:

- `d` Matches an optionally signed decimal integer, whose format is the same as expected for the subject sequence of `strtol(3C)` with the value 10 for the *base* argument. In the absence of a size modifier, the corresponding argument must be a pointer to `int`.
- `i` Matches an optionally signed integer, whose format is the same as expected for the subject sequence of `strtol()` with 0 for the *base* argument. In the absence of a size modifier, the corresponding argument must be a pointer to `int`.
- `o` Matches an optionally signed octal integer, whose format is the same as expected for the subject sequence of `strtoul(3C)` with the value 8 for the *base* argument. In the absence of a size modifier, the corresponding argument must be a pointer to `unsigned int`.
- `u` Matches an optionally signed decimal integer, whose format is the same as expected for the subject sequence of `strtoul()` with the value 10 for the *base* argument. In the absence of a size modifier, the corresponding argument must be a pointer to `unsigned int`.
- `x` Matches an optionally signed hexadecimal integer, whose format is the same as expected for the subject sequence of `strtoul()` with the value 16

for the *base* argument. In the absence of a size modifier, the corresponding argument must be a pointer to `unsigned int`.

e,f,g Matches an optionally signed floating-point number, whose format is the same as expected for the subject sequence of `strtod(3C)`. In the absence of a size modifier, the corresponding argument must be a pointer to `float`.

If the `printf(3C)` family of functions generates character string representations for infinity and NaN (a 7858 symbolic entity encoded in floating-point format) to support the ANSI/IEEE Std 754: 1985 standard, the `scanf()` family of functions will recognize them as input.

s Matches a sequence of bytes that are not white-space characters. The corresponding argument must be a pointer to the initial byte of an array of `char`, `signed char`, or `unsigned char` large enough to accept the sequence and a terminating null character code, which will be added automatically.

If an `l` (`ell`) qualifier is present, the input is a sequence of characters that begins in the initial shift state. Each character is converted to a wide-character as if by a call to the `mbrtowc(3C)` function, with the conversion state described by an `mbstate_t` object initialized to zero before the first character is converted. The corresponding argument must be a pointer to an array of `wchar_t` large enough to accept the sequence and the terminating null wide-character, which will be added automatically.

[Matches a non-empty sequence of characters from a set of expected characters (the *scanset*). The normal skip over white-space characters is suppressed in this case. The corresponding argument must be a pointer to the initial byte of an array of `char`, `signed char`, or `unsigned char` large enough to accept the sequence and a terminating null byte, which will be added automatically.

If an `l` (`ell`) qualifier is present, the input is a sequence of characters that begins in the initial shift state. Each character in the sequence is converted to a wide-character as if by a call to the `mbrtowc()` function, with the conversion state described by an `mbstate_t` object initialized to zero before the first character is converted. The corresponding argument must be a pointer to an array of `wchar_t` large enough to accept the sequence and the terminating null wide-character, which will be added automatically.

The conversion specification includes all subsequent characters in the *format* string up to and including the matching right square bracket (`]`). The characters between the square brackets (the *scanlist*) comprise the *scanset*, unless the character after the left square bracket is a circumflex (`^`), in which case the *scanset* contains all characters that do not appear in the *scanlist* between the circumflex and the right square bracket. If the

fscanf(3C)

	conversion specification begins with [] or [^], the right square bracket is included in the scanlist and the next right square bracket is the matching right square bracket that ends the conversion specification; otherwise the first right square bracket is the one that ends the conversion specification. If a - is in the scanlist and is not the first character, nor the second where the first character is a ^, nor the last character, it indicates a range of characters to be matched.
c	Matches a sequence of characters of the number specified by the field width (1 if no field width is present in the conversion specification). The corresponding argument must be a pointer to the initial byte of an array of char, signed char, or unsigned char large enough to accept the sequence. No null byte is added. The normal skip over white-space characters is suppressed in this case. If an l (ell) qualifier is present, the input is a sequence of characters that begins in the initial shift state. Each character in the sequence is converted to a wide-character as if by a call to the <code>mbrtowc()</code> function, with the conversion state described by an <code>mbstate_t</code> object initialized to zero before the first character is converted. The corresponding argument must be a pointer to an array of <code>wchar_t</code> large enough to accept the resulting sequence of wide-characters. No null wide-character is added.
p	Matches the set of sequences that is the same as the set of sequences that is produced by the %p conversion of the corresponding <code>printf(3C)</code> functions. The corresponding argument must be a pointer to a pointer to void. If the input item is a value converted earlier during the same program execution, the pointer that results will compare equal to that value; otherwise the behavior of the %p conversion is undefined.
n	No input is consumed. The corresponding argument must be a pointer to the integer into which is to be written the number of bytes read from the input so far by this call to the <code>scanf()</code> functions. Execution of a %n conversion specification does not increment the assignment count returned at the completion of execution of the function.
C	Same as lc.
S	Same as ls.
%	Matches a single %; no conversion or assignment occurs. The complete conversion specification must be %%.

If a conversion specification is invalid, the behavior is undefined.

The conversion characters E, G, and X are also valid and behave the same as, respectively, e, g, and x.

If end-of-file is encountered during input, conversion is terminated. If end-of-file occurs before any bytes matching the current conversion specification (except for %n) have been read (other than leading white-space characters, where permitted),

execution of the current conversion specification terminates with an input failure. Otherwise, unless execution of the current conversion specification is terminated with a matching failure, execution of the following conversion specification (if any) is terminated with an input failure.

Reaching the end of the string in `sscanf()` is equivalent to encountering end-of-file for `fscanf()`.

If conversion terminates on a conflicting input, the offending input is left unread in the input. Any trailing white space (including newline characters) is left unread unless matched by a conversion specification. The success of literal matches and suppressed assignments is only directly determinable via the `%n` conversion specification.

The `fscanf()` and `scanf()` functions may mark the `st_atime` field of the file associated with *stream* for update. The `st_atime` field will be marked for update by the first successful execution of `fgetc(3C)`, `fgets(3C)`, `fread(3C)`, `fscanf()`, `getc(3C)`, `getchar(3C)`, `gets(3C)`, or `scanf()` using *stream* that returns data not supplied by a prior call to `ungetc(3C)`.

RETURN VALUES

Upon successful completion, these functions return the number of successfully matched and assigned input items; this number can be 0 in the event of an early matching failure. If the input ends before the first matching failure or conversion, EOF is returned. If a read error occurs the error indicator for the stream is set, EOF is returned, and `errno` is set to indicate the error.

ERRORS

For the conditions under which the `scanf()` functions will fail and may fail, refer to `fgetc(3C)` or `fgetwc(3C)`.

In addition, `fscanf()` may fail if:

`EILSEQ` Input byte sequence does not form a valid character.
`EINVAL` There are insufficient arguments.

USAGE

If the application calling the `scanf()` functions has any objects of type `wint_t` or `wchar_t`, it must also include the header `<wchar.h>` to have these objects defined.

EXAMPLES

EXAMPLE 1 The call:

```
int i, n; float x; char name[50];
n = scanf("%d%f%s", &i, &x, name)
```

with the input line:

```
25 54.32E-1 Hamster
```

will assign to *n* the value 3, to *i* the value 25, to *x* the value 5.432, and *name* will contain the string Hamster.

fscanf(3C)

EXAMPLE 2 The call:

```
int i; float x; char name[50];
(void) scanf("%2d%f%d %[0123456789]", &i, &x, name);
```

with input:

```
56789 0123 56a72
```

will assign 56 to *i*, 789.0 to *x*, skip 0123, and place the string 56\0 in *name*. The next call to `getchar(3C)` will return the character a.

NAME	fseek, fseeko – reposition a file-position indicator in a stream						
SYNOPSIS	<pre>#include <stdio.h> int fseek(FILE *stream, long offset, int whence); int fseeko(FILE *stream, off_t offset, int whence);</pre>						
DESCRIPTION	<p>The <code>fseek()</code> function sets the file-position indicator for the stream pointed to by <i>stream</i>. The <code>fseeko()</code> function is identical to <code>fseek()</code> except for the type of <i>offset</i>.</p> <p>The new position, measured in bytes from the beginning of the file, is obtained by adding <i>offset</i> to the position specified by <i>whence</i>, whose values are defined in <code><stdio.h></code> as follows:</p> <table border="0"> <tr> <td>SEEK_SET</td> <td>Set position equal to <i>offset</i> bytes.</td> </tr> <tr> <td>SEEK_CUR</td> <td>Set position to current location plus <i>offset</i>.</td> </tr> <tr> <td>SEEK_END</td> <td>Set position to EOF plus <i>offset</i>.</td> </tr> </table> <p>If the stream is to be used with wide character input/output functions, <i>offset</i> must either be 0 or a value returned by an earlier call to <code>ftell(3C)</code> on the same stream and <i>whence</i> must be <code>SEEK_SET</code>.</p> <p>A successful call to <code>fseek()</code> clears the end-of-file indicator for the stream and undoes any effects of <code>ungetc(3C)</code> and <code>ungetwc(3C)</code> on the same stream. After an <code>fseek()</code> call, the next operation on an update stream may be either input or output.</p> <p>If the most recent operation, other than <code>ftell(3C)</code>, on a given stream is <code>fflush(3C)</code>, the file offset in the underlying open file description will be adjusted to reflect the location specified by <code>fseek()</code>.</p> <p>The <code>fseek()</code> function allows the file-position indicator to be set beyond the end of existing data in the file. If data is later written at this point, subsequent reads of data in the gap will return bytes with the value 0 until data is actually written into the gap.</p> <p>The value of the file offset returned by <code>fseek()</code> on devices which are incapable of seeking is undefined.</p> <p>If the stream is writable and buffered data had not been written to the underlying file, <code>fseek()</code> will cause the unwritten data to be written to the file and mark the <code>st_ctime</code> and <code>st_mtime</code> fields of the file for update.</p>	SEEK_SET	Set position equal to <i>offset</i> bytes.	SEEK_CUR	Set position to current location plus <i>offset</i> .	SEEK_END	Set position to EOF plus <i>offset</i> .
SEEK_SET	Set position equal to <i>offset</i> bytes.						
SEEK_CUR	Set position to current location plus <i>offset</i> .						
SEEK_END	Set position to EOF plus <i>offset</i> .						
RETURN VALUES	The <code>fseek()</code> and <code>fseeko()</code> functions return 0 on success; otherwise, they returned -1 and set <code>errno</code> to indicate the error.						
ERRORS	<p>The <code>fseek()</code> and <code>fseeko()</code> functions will fail if, either the <i>stream</i> is unbuffered or the <i>stream</i>'s buffer needed to be flushed, and the call to <code>fseek()</code> or <code>fseeko()</code> causes an underlying <code>lseek(2)</code> or <code>write(2)</code> to be invoked:</p> <table border="0"> <tr> <td>EAGAIN</td> <td>The <code>O_NONBLOCK</code> flag is set for the file descriptor and the process would be delayed in the write operation.</td> </tr> </table>	EAGAIN	The <code>O_NONBLOCK</code> flag is set for the file descriptor and the process would be delayed in the write operation.				
EAGAIN	The <code>O_NONBLOCK</code> flag is set for the file descriptor and the process would be delayed in the write operation.						

fseek(3C)

EBADF	The file descriptor underlying the stream file is not open for writing or the stream's buffer needed to be flushed and the file is not open.
EFBIG	An attempt was made to write a file that exceeds the maximum file size or the process's file size limit, or the file is a regular file and an attempt was made to write at or beyond the offset maximum associated with the corresponding stream.
EINTR	The write operation was terminated due to the receipt of a signal, and no data was transferred.
EINVAL	The <i>whence</i> argument is invalid. The resulting file-position indicator would be set to a negative value.
EIO	A physical I/O error has occurred; or the process is a member of a background process group attempting to perform a <code>write(2)</code> operation to its controlling terminal, <code>TOSTOP</code> is set, the process is neither ignoring nor blocking <code>SIGTTOU</code> , and the process group of the process is orphaned.
ENOSPC	There was no free space remaining on the device containing the file.
EPIPE	The file descriptor underlying <i>stream</i> is associated with a pipe or FIFO.
EPIPE	An attempt was made to write to a pipe or FIFO that is not open for reading by any process. A <code>SIGPIPE</code> signal will also be sent to the process.
ENXIO	A request was made of a non-existent device, or the request was outside the capabilities of the device.

The `fseek()` function will fail if:

E_OVERFLOW	The resulting file offset would be a value which cannot be represented correctly in an object of type <code>long</code> .
------------	---

The `fseeko()` function will fail if:

E_OVERFLOW	The resulting file offset would be a value which cannot be represented correctly in an object of type <code>off_t</code> .
------------	--

USAGE Although on the UNIX system an offset returned by `ftell()` or `ftello()` (see `ftell(3C)`) is measured in bytes, and it is permissible to seek to positions relative to that offset, portability to non-UNIX systems requires that an offset be used by `fseek()` directly. Arithmetic may not meaningfully be performed on such an offset, which is not necessarily measured in bytes.

The `fseeko()` function has a transitional interface for 64-bit file offsets. See `1f64(5)`.

fseek(3C)

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
MT-Level	MT-Safe

SEE ALSO `getrlimit(2)`, `ulimit(2)`, `fopen(3UCB)`, `ftell(3C)`, `rewind(3C)`, `ungetc(3C)`, `ungetwc(3C)`, `attributes(5)`, `lf64(5)`

fseeko(3C)

NAME	fseek, fseeko – reposition a file-position indicator in a stream						
SYNOPSIS	<pre>#include <stdio.h> int fseek(FILE *stream, long offset, int whence); int fseeko(FILE *stream, off_t offset, int whence);</pre>						
DESCRIPTION	<p>The <code>fseek()</code> function sets the file-position indicator for the stream pointed to by <code>stream</code>. The <code>fseeko()</code> function is identical to <code>fseek()</code> except for the type of <code>offset</code>.</p> <p>The new position, measured in bytes from the beginning of the file, is obtained by adding <code>offset</code> to the position specified by <code>whence</code>, whose values are defined in <code><stdio.h></code> as follows:</p> <table><tr><td><code>SEEK_SET</code></td><td>Set position equal to <code>offset</code> bytes.</td></tr><tr><td><code>SEEK_CUR</code></td><td>Set position to current location plus <code>offset</code>.</td></tr><tr><td><code>SEEK_END</code></td><td>Set position to EOF plus <code>offset</code>.</td></tr></table> <p>If the stream is to be used with wide character input/output functions, <code>offset</code> must either be 0 or a value returned by an earlier call to <code>ftell(3C)</code> on the same stream and <code>whence</code> must be <code>SEEK_SET</code>.</p> <p>A successful call to <code>fseek()</code> clears the end-of-file indicator for the stream and undoes any effects of <code>ungetc(3C)</code> and <code>ungetwc(3C)</code> on the same stream. After an <code>fseek()</code> call, the next operation on an update stream may be either input or output.</p> <p>If the most recent operation, other than <code>ftell(3C)</code>, on a given stream is <code>fflush(3C)</code>, the file offset in the underlying open file description will be adjusted to reflect the location specified by <code>fseek()</code>.</p> <p>The <code>fseek()</code> function allows the file-position indicator to be set beyond the end of existing data in the file. If data is later written at this point, subsequent reads of data in the gap will return bytes with the value 0 until data is actually written into the gap.</p> <p>The value of the file offset returned by <code>fseek()</code> on devices which are incapable of seeking is undefined.</p> <p>If the stream is writable and buffered data had not been written to the underlying file, <code>fseek()</code> will cause the unwritten data to be written to the file and mark the <code>st_ctime</code> and <code>st_mtime</code> fields of the file for update.</p>	<code>SEEK_SET</code>	Set position equal to <code>offset</code> bytes.	<code>SEEK_CUR</code>	Set position to current location plus <code>offset</code> .	<code>SEEK_END</code>	Set position to EOF plus <code>offset</code> .
<code>SEEK_SET</code>	Set position equal to <code>offset</code> bytes.						
<code>SEEK_CUR</code>	Set position to current location plus <code>offset</code> .						
<code>SEEK_END</code>	Set position to EOF plus <code>offset</code> .						
RETURN VALUES	The <code>fseek()</code> and <code>fseeko()</code> functions return 0 on success; otherwise, they returned -1 and set <code>errno</code> to indicate the error.						
ERRORS	<p>The <code>fseek()</code> and <code>fseeko()</code> functions will fail if, either the <code>stream</code> is unbuffered or the <code>stream</code>'s buffer needed to be flushed, and the call to <code>fseek()</code> or <code>fseeko()</code> causes an underlying <code>lseek(2)</code> or <code>write(2)</code> to be invoked:</p> <table><tr><td><code>EAGAIN</code></td><td>The <code>O_NONBLOCK</code> flag is set for the file descriptor and the process would be delayed in the write operation.</td></tr></table>	<code>EAGAIN</code>	The <code>O_NONBLOCK</code> flag is set for the file descriptor and the process would be delayed in the write operation.				
<code>EAGAIN</code>	The <code>O_NONBLOCK</code> flag is set for the file descriptor and the process would be delayed in the write operation.						

EBADF	The file descriptor underlying the stream file is not open for writing or the stream's buffer needed to be flushed and the file is not open.
EFBIG	An attempt was made to write a file that exceeds the maximum file size or the process's file size limit, or the file is a regular file and an attempt was made to write at or beyond the offset maximum associated with the corresponding stream.
EINTR	The write operation was terminated due to the receipt of a signal, and no data was transferred.
EINVAL	The <i>whence</i> argument is invalid. The resulting file-position indicator would be set to a negative value.
EIO	A physical I/O error has occurred; or the process is a member of a background process group attempting to perform a <code>write(2)</code> operation to its controlling terminal, <code>TOSTOP</code> is set, the process is neither ignoring nor blocking <code>SIGTTOU</code> , and the process group of the process is orphaned.
ENOSPC	There was no free space remaining on the device containing the file.
EPIPE	The file descriptor underlying <i>stream</i> is associated with a pipe or FIFO.
EPIPE	An attempt was made to write to a pipe or FIFO that is not open for reading by any process. A <code>SIGPIPE</code> signal will also be sent to the process.
ENXIO	A request was made of a non-existent device, or the request was outside the capabilities of the device.

The `fseek()` function will fail if:

E_OVERFLOW	The resulting file offset would be a value which cannot be represented correctly in an object of type <code>long</code> .
------------	---

The `fseeko()` function will fail if:

E_OVERFLOW	The resulting file offset would be a value which cannot be represented correctly in an object of type <code>off_t</code> .
------------	--

USAGE Although on the UNIX system an offset returned by `ftell()` or `ftello()` (see `ftell(3C)`) is measured in bytes, and it is permissible to seek to positions relative to that offset, portability to non-UNIX systems requires that an offset be used by `fseek()` directly. Arithmetic may not meaningfully be performed on such an offset, which is not necessarily measured in bytes.

The `fseeko()` function has a transitional interface for 64-bit file offsets. See `1f64(5)`.

fseeko(3C)

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
MT-Level	MT-Safe

SEE ALSO `getrlimit(2)`, `ulimit(2)`, `fopen(3UCB)`, `ftell(3C)`, `rewind(3C)`, `ungetc(3C)`, `ungetwc(3C)`, `attributes(5)`, `lf64(5)`

NAME	<code>__fbufsize</code> , <code>__flbf</code> , <code>__fpending</code> , <code>__fpurge</code> , <code>__freadable</code> , <code>__freading</code> , <code>__fsetlocking</code> , <code>__fwritable</code> , <code>__fwriting</code> , <code>_flushlbf</code> – interfaces to stdio FILE structure
SYNOPSIS	<pre>#include <stdio.h> #include <stdio_ext.h> size_t __fbufsiz(FILE *stream); int __flbf(FILE *stream); size_t __fpending(FILE *stream); void __fpurge(FILE *stream); int __freadable(FILE *stream); int __freading(FILE *stream); int __fsetlocking(FILE *stream, int type); int __fwritable(FILE *stream); int __fwriting(FILE *stream); void _flushlbf(void);</pre>
DESCRIPTION	<p>These functions provide portable access to the members of the <code>stdio(3C)</code> FILE structure.</p> <p>The <code>__fbufsize()</code> function returns in bytes the size of the buffer currently in use by the given stream.</p> <p>The <code>__flbf()</code> function returns non-zero if the stream is line-buffered.</p> <p>The <code>__fpending</code> function returns in bytes the amount of output pending on a stream.</p> <p>The <code>__fpurge()</code> function discards any pending buffered I/O on the stream.</p> <p>The <code>__freadable()</code> function returns non-zero if it is possible to read from a stream.</p> <p>The <code>__freading()</code> function returns non-zero if the file is open readonly, or if the last operation on the stream was a read operation such as <code>fread(3C)</code> or <code>fgetc(3C)</code>. Otherwise it returns 0.</p> <p>The <code>__fsetlocking()</code> function allows the type of locking performed by <code>stdio</code> on a given stream to be controlled by the programmer.</p> <p>If <code>type</code> is <code>FSETLOCKING_INTERNAL</code>, <code>stdio</code> performs implicit locking around every operation on the given stream. This is the default system behavior on that stream.</p> <p>If <code>type</code> is <code>FSETLOCKING_BYCALLER</code>, <code>stdio</code> assumes that the caller is responsible for maintaining the integrity of the stream in the face of access by multiple threads. If there is only one thread accessing the stream, nothing further needs to be done. If multiple threads are accessing the stream, then the caller can use the <code>flockfile()</code>,</p>

__fsetlocking(3C)

`funlockfile()`, and `ftrylockfile()` functions described on the `flockfile(3C)` manual page to provide the appropriate locking. In both this and the case where *type* is `FSETLOCKING_INTERNAL`, `__fsetlocking()` returns the previous state of the stream.

If *type* is `FSETLOCKING_QUERY`, `__fsetlocking()` returns the current state of the stream without changing it.

The `__fwritable()` function returns non-zero if it is possible to write on a stream.

The `__fwriting()` function returns non-zero if the file is open write-only or append-only, or if the last operation on the stream was a write operation such as `fwrite(3C)` or `fputc(3C)`. Otherwise it returns 0.

The `_flushlbf()` function flushes all line-buffered files. It is used when reading from a line-buffered file.

USAGE

Although the contents of the `stdio` `FILE` structure have always been private to the `stdio` implementation, some applications have needed to obtain information about a `stdio` stream that was not accessible through a supported interface. These applications have resorted to accessing fields of the `FILE` structure directly, rendering them possibly non-portable to new implementations of `stdio`, or more likely, preventing enhancements to `stdio` that would cause those applications to break.

In the 64-bit environment, the `FILE` structure is opaque. The functions described here are provided as a means of obtaining the information that up to now has been retrieved directly from the `FILE` structure. Because they are based on the needs of existing applications (such as `mh` and `emacs`), they may be extended as other programs are ported. Although they may still be non-portable to other operating systems, they will be compatible from each Solaris release to the next. Interfaces that are more portable are under development.

ATTRIBUTES

fsync(3C)

NAME	fsync – synchronize changes to a file										
SYNOPSIS	<pre>#include <unistd.h> int fsync(int <i>fildev</i>);</pre>										
DESCRIPTION	<p>The <code>fsync()</code> function moves all modified data and attributes of the file descriptor <i>fildev</i> to a storage device. When <code>fsync()</code> returns, all in-memory modified copies of buffers associated with <i>fildev</i> have been written to the physical medium. The <code>fsync()</code> function is different from <code>sync()</code>, which schedules disk I/O for all files but returns before the I/O completes. The <code>fsync()</code> function forces all outstanding data operations to synchronized file integrity completion (see <code>fcntl(3HEAD)</code> definition of <code>O_SYNC</code>.)</p> <p>The <code>fsync()</code> function forces all currently queued I/O operations associated with the file indicated by the file descriptor <i>fildev</i> to the synchronized I/O completion state. All I/O operations are completed as defined for synchronized I/O file integrity completion.</p>										
RETURN VALUES	Upon successful completion, 0 is returned. Otherwise, -1 is returned and <code>errno</code> is set to indicate the error. If the <code>fsync()</code> function fails, outstanding I/O operations are not guaranteed to have been completed.										
ERRORS	<p>The <code>fsync()</code> function will fail if:</p> <table><tr><td>EBADF</td><td>The <i>fildev</i> argument is not a valid file descriptor.</td></tr><tr><td>EINTR</td><td>A signal was caught during execution of the <code>fsync()</code> function.</td></tr><tr><td>EIO</td><td>An I/O error occurred while reading from or writing to the file system.</td></tr><tr><td>ENOSPC</td><td>There was no free space remaining on the device containing the file.</td></tr><tr><td>ETIMEDOUT</td><td>Remote connection timed out. This occurs when the file is on an NFS file system mounted with the <i>soft</i> option. See <code>mount_nfs(1M)</code>.</td></tr></table> <p>In the event that any of the queued I/O operations fail, <code>fsync()</code> returns the error conditions defined for <code>read(2)</code> and <code>write(2)</code>.</p>	EBADF	The <i>fildev</i> argument is not a valid file descriptor.	EINTR	A signal was caught during execution of the <code>fsync()</code> function.	EIO	An I/O error occurred while reading from or writing to the file system.	ENOSPC	There was no free space remaining on the device containing the file.	ETIMEDOUT	Remote connection timed out. This occurs when the file is on an NFS file system mounted with the <i>soft</i> option. See <code>mount_nfs(1M)</code> .
EBADF	The <i>fildev</i> argument is not a valid file descriptor.										
EINTR	A signal was caught during execution of the <code>fsync()</code> function.										
EIO	An I/O error occurred while reading from or writing to the file system.										
ENOSPC	There was no free space remaining on the device containing the file.										
ETIMEDOUT	Remote connection timed out. This occurs when the file is on an NFS file system mounted with the <i>soft</i> option. See <code>mount_nfs(1M)</code> .										
USAGE	<p>The <code>fsync()</code> function should be used by applications that require that a file be in a known state. For example, an application that contains a simple transaction facility might use <code>fsync()</code> to ensure that all changes to a file or files caused by a given transaction were recorded on a storage medium.</p> <p>The manner in which the data reach the physical medium depends on both implementation and hardware. The <code>fsync()</code> function returns when notified by the device driver that the write has taken place.</p>

NAME ftell, ftello – return a file offset in a stream

SYNOPSIS

```
#include <stdio.h>

long ftell(FILE *stream);
off_t ftello(FILE *stream);
```

DESCRIPTION The ftell() function obtains the current value of the file-position indicator for the stream pointed to by *stream*. The ftello() function is identical to ftell() except for the return type.

RETURN VALUES Upon successful completion, the ftell() and ftello() functions return the current value of the file-position indicator for the stream measured in bytes from the beginning of the file. Otherwise, they return -1 and sets errno to indicate the error.

ERRORS The ftell() and ftello() functions will fail if:

EBADF The file descriptor underlying *stream* is not an open file descriptor.

ESPIPE The file descriptor underlying *stream* is associated with a pipe, a FIFO, or a socket.

The ftell() function will fail if:

EOVERFLOW The current file offset cannot be represented correctly in an object of type long.

The ftello() function will fail if:

EOVERFLOW The current file offset cannot be represented correctly in an object of type off_t.

USAGE The ftello() function has a transitional interface for 64-bit file offsets. See l_f64(5).

ATTRIBUTES See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
MT-Level	MT-Safe

SEE ALSO lseek(2), fopen(3C), fseek(3C), attributes(5), l_f64(5)

ftime(3C)

NAME	ftime – get date and time
SYNOPSIS	<pre>#include <sys/timeb.h> int ftime(struct timeb *tp);</pre>
DESCRIPTION	<p>The <code>ftime()</code> function sets the <code>time</code> and <code>millitm</code> members of the <code>timeb</code> structure pointed to by <code>tp</code>. The structure is defined in <code><sys/timeb.h></code> and contains the following members:</p> <pre>time_t time; unsigned short millitm; short timezone; short dstflag;</pre> <p>The <code>time</code> and <code>millitm</code> members contain the seconds and milliseconds portions, respectively, of the current time in seconds since 00:00:00 UTC (Coordinated Universal Time), January 1, 1970.</p> <p>The <code>timezone</code> member contains the local time zone. The <code>dstflag</code> member contains a flag that, if non-zero, indicates that Daylight Saving time applies locally during the appropriate part of the year.</p> <p>The contents of the <code>timezone</code> and <code>dstflag</code> members of <code>tp</code> after a call to <code>ftime()</code> are unspecified.</p>
RETURN VALUES	Upon successful completion, the <code>ftime()</code> function returns 0. Otherwise -1 is returned.
ERRORS	No errors are defined.
USAGE	<p>For portability to implementations conforming to earlier versions of this document, <code>time(2)</code> is preferred over this function.</p> <p>The millisecond value usually has a granularity greater than one due to the resolution of the system clock. Depending on any granularity (particularly a granularity of one) renders code non-portable.</p>
SEE ALSO	<code>date(1)</code> , <code>time(2)</code> , <code>ctime(3C)</code> , <code>gettimeofday(3C)</code> , <code>timezone(4)</code>

NAME	ftok – generate an IPC key												
SYNOPSIS	<pre>#include <sys/ipc.h> key_t ftok(const char *path, int id);</pre>												
DESCRIPTION	<p>The <code>ftok()</code> function returns a key based on <i>path</i> and <i>id</i> that is usable in subsequent calls to <code>msgget(2)</code>, <code>semget(2)</code> and <code>shmget(2)</code>. The <i>path</i> argument must be the pathname of an existing file that the process is able to <code>stat(2)</code>.</p> <p>The <code>ftok()</code> function will return the same key value for all paths that name the same file, when called with the same <i>id</i> value, and will return different key values when called with different <i>id</i> values.</p> <p>If the file named by <i>path</i> is removed while still referred to by a key, a call to <code>ftok()</code> with the same <i>path</i> and <i>id</i> returns an error. If the same file is recreated, then a call to <code>ftok()</code> with the same <i>path</i> and <i>id</i> is likely to return a different key.</p> <p>Only the low order 8-bits of <i>id</i> are significant. The behavior of <code>ftok()</code> is unspecified if these bits are 0.</p>												
RETURN VALUES	Upon successful completion, <code>ftok()</code> returns a key. Otherwise, <code>ftok()</code> returns <code>(key_t)-1</code> and sets <code>errno</code> to indicate the error.												
ERRORS	<p>The <code>ftok()</code> function will fail if:</p> <table border="0"> <tr> <td style="vertical-align: top;">EACCES</td> <td>Search permission is denied for a component of the path prefix.</td> </tr> <tr> <td style="vertical-align: top;">ELOOP</td> <td>Too many symbolic links were encountered in resolving <i>path</i>.</td> </tr> <tr> <td style="vertical-align: top;">ENAMETOOLONG</td> <td>The length of the <i>path</i> argument exceeds <code>{PATH_MAX}</code> or a pathname component is longer than <code>{NAME_MAX}</code>.</td> </tr> <tr> <td style="vertical-align: top;">ENOENT</td> <td>A component of <i>path</i> does not name an existing file or <i>path</i> is an empty string.</td> </tr> <tr> <td style="vertical-align: top;">ENOTDIR</td> <td>A component of the path prefix is not a directory.</td> </tr> </table> <p>The <code>ftok()</code> function may fail if:</p> <table border="0"> <tr> <td style="vertical-align: top;">ENAMETOOLONG</td> <td>Pathname resolution of a symbolic link produced an intermediate result whose length exceeds <code>{PATH_MAX}</code>.</td> </tr> </table>	EACCES	Search permission is denied for a component of the path prefix.	ELOOP	Too many symbolic links were encountered in resolving <i>path</i> .	ENAMETOOLONG	The length of the <i>path</i> argument exceeds <code>{PATH_MAX}</code> or a pathname component is longer than <code>{NAME_MAX}</code> .	ENOENT	A component of <i>path</i> does not name an existing file or <i>path</i> is an empty string.	ENOTDIR	A component of the path prefix is not a directory.	ENAMETOOLONG	Pathname resolution of a symbolic link produced an intermediate result whose length exceeds <code>{PATH_MAX}</code> .
EACCES	Search permission is denied for a component of the path prefix.												
ELOOP	Too many symbolic links were encountered in resolving <i>path</i> .												
ENAMETOOLONG	The length of the <i>path</i> argument exceeds <code>{PATH_MAX}</code> or a pathname component is longer than <code>{NAME_MAX}</code> .												
ENOENT	A component of <i>path</i> does not name an existing file or <i>path</i> is an empty string.												
ENOTDIR	A component of the path prefix is not a directory.												
ENAMETOOLONG	Pathname resolution of a symbolic link produced an intermediate result whose length exceeds <code>{PATH_MAX}</code> .												
USAGE	<p>For maximum portability, <i>id</i> should be a single-byte character.</p> <p>Another way to compose keys is to include the project ID in the most significant byte and to use the remaining portion as a sequence number. There are many other ways to form keys, but it is necessary for each system to define standards for forming them. If some standard is not adhered to, it will be possible for unrelated processes to</p>												

ftok(3C)

unintentionally interfere with each other's operation. It is still possible to interfere intentionally. Therefore, it is strongly suggested that the most significant byte of a key in some sense refer to a project so that keys do not conflict across a given system.

NOTES Since the `ftok()` function returns a value based on the *id* given and the file serial number of the file named by *path* in a type that is no longer large enough to hold all file serial numbers, it may return the same key for paths naming different files on large filesystems.

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

NAME	truncate, ftruncate – set a file to a specified length														
SYNOPSIS	<pre>#include <unistd.h> int truncate(const char *path, off_t length); int ftruncate(int fildes, off_t length);</pre>														
DESCRIPTION	<p>The <code>truncate()</code> function causes the regular file named by <i>path</i> to have a size of <i>length</i> bytes.</p> <p>The <code>ftruncate()</code> function causes the regular file referenced by <i>fildes</i> to have a size of <i>length</i> bytes.</p> <p>The effect of <code>ftruncate()</code> and <code>truncate()</code> on other types of files is unspecified. If the file previously was larger than <i>length</i>, the extra data is lost. If it was previously shorter than <i>length</i>, bytes between the old and new lengths are read as zeroes. With <code>ftruncate()</code>, the file must be open for writing; for <code>truncate()</code>, the process must have write permission for the file.</p> <p>If the request would cause the file size to exceed the soft file size limit for the process, the request will fail and the implementation will generate the SIGXFSZ signal for the process.</p> <p>These functions do not modify the file offset for any open file descriptions associated with the file. On successful completion, if the file size is changed, these functions will mark for update the <code>st_ctime</code> and <code>st_mtime</code> fields of the file, and if the file is a regular file, the <code>S_ISUID</code> and <code>S_ISGID</code> bits of the file mode may be cleared.</p>														
RETURN VALUES	Upon successful completion, <code>ftruncate()</code> and <code>truncate()</code> return 0. Otherwise, <code>-1</code> is returned and <code>errno</code> is set to indicate the error.														
ERRORS	<p>The <code>ftruncate()</code> and <code>truncate()</code> functions will fail if:</p> <table border="0"> <tr> <td style="padding-right: 20px;">EINTR</td> <td>A signal was caught during execution.</td> </tr> <tr> <td>EINVAL</td> <td>The <i>length</i> argument was less than 0.</td> </tr> <tr> <td>EFBIG or EINVAL</td> <td>The <i>length</i> argument was greater than the maximum file size.</td> </tr> <tr> <td>EIO</td> <td>An I/O error occurred while reading from or writing to a file system.</td> </tr> </table> <p>The <code>truncate()</code> function will fail if:</p> <table border="0"> <tr> <td style="padding-right: 20px;">EACCES</td> <td>A component of the path prefix denies search permission, or write permission is denied on the file.</td> </tr> <tr> <td>EFAULT</td> <td>The <i>path</i> argument points outside the process' allocated address space.</td> </tr> <tr> <td>EINVAL</td> <td>The <i>path</i> argument is not an ordinary file.</td> </tr> </table>	EINTR	A signal was caught during execution.	EINVAL	The <i>length</i> argument was less than 0.	EFBIG or EINVAL	The <i>length</i> argument was greater than the maximum file size.	EIO	An I/O error occurred while reading from or writing to a file system.	EACCES	A component of the path prefix denies search permission, or write permission is denied on the file.	EFAULT	The <i>path</i> argument points outside the process' allocated address space.	EINVAL	The <i>path</i> argument is not an ordinary file.
EINTR	A signal was caught during execution.														
EINVAL	The <i>length</i> argument was less than 0.														
EFBIG or EINVAL	The <i>length</i> argument was greater than the maximum file size.														
EIO	An I/O error occurred while reading from or writing to a file system.														
EACCES	A component of the path prefix denies search permission, or write permission is denied on the file.														
EFAULT	The <i>path</i> argument points outside the process' allocated address space.														
EINVAL	The <i>path</i> argument is not an ordinary file.														

ftruncate(3C)

EISDIR	The named file is a directory.
ELOOP	Too many symbolic links were encountered in resolving <i>path</i> .
EMFILE	The maximum number of file descriptors available to the process has been reached.
ENAMETOOLONG	The length of the specified pathname exceeds <code>PATH_MAX</code> bytes, or the length of a component of the pathname exceeds <code>NAME_MAX</code> bytes.
ENOENT	A component of <i>path</i> does not name an existing file or <i>path</i> is an empty string.
ENFILE	Additional space could not be allocated for the system file table.
ENOTDIR	A component of the path prefix of <i>path</i> is not a directory.
ENOLINK	The <i>path</i> argument points to a remote machine and the link to that machine is no longer active.
EROFS	The named file resides on a read-only file system.
The <code>ftruncate()</code> function will fail if:	
EAGAIN	The file exists, mandatory file/record locking is set, and there are outstanding record locks on the file (see <code>chmod(2)</code>).
EBADF or EINVAL	The <i>fildev</i> argument is not a file descriptor open for writing.
EFBIG	The file is a regular file and <i>length</i> is greater than the offset maximum established in the open file description associated with <i>fildev</i> .
EINVAL	The <i>fildev</i> argument references a file that was opened without write permission.
EINVAL	The <i>fildev</i> argument does not correspond to an ordinary file.
ENOLINK	The <i>fildev</i> argument points to a remote machine and the link to that machine is no longer active.
The <code>truncate()</code> function may fail if:	
ENAMETOOLONG	Pathname resolution of a symbolic link produced an intermediate result whose

USAGE The `truncate()` and `ftruncate()` functions have transitional interfaces for 64-bit file offsets. See `lf64(5)`.

ftrylockfile(3C)

NAME	flockfile, funlockfile, ftrylockfile – acquire and release stream lock
SYNOPSIS	<pre>#include <stdio.h> void flockfile(FILE *stream); void funlockfile(FILE *stream); int ftrylockfile(FILE *stream);</pre>
DESCRIPTION	<p>The <code>flockfile()</code> function acquires an internal lock of a stream <i>stream</i>. If the lock is already acquired by another thread, the thread calling <code>flockfile()</code> is suspended until it can acquire the lock. In the case that the stream lock is available, <code>flockfile()</code> not only acquires the lock, but keeps track of the number of times it is being called by the current thread. This implies that the stream lock can be acquired more than once by the same thread.</p> <p>The <code>funlockfile()</code> function releases the lock being held by the current thread. In the case of recursive locking, this function must be called the same number of times <code>flockfile()</code> was called. After the number of <code>funlockfile()</code> calls is equal to the number of <code>flockfile()</code> calls, the stream lock is available for other threads to acquire.</p> <p>The <code>ftrylockfile()</code> function acquires an internal lock of a stream <i>stream</i>, only if that object is available. In essence <code>ftrylockfile()</code> is a non-blocking version of <code>flockfile()</code>.</p>
RETURN VALUES	The <code>ftrylockfile()</code> function returns 0 on success and non-zero to indicate a lock cannot be acquired.
EXAMPLES	<p>EXAMPLE 1 A sample program of <code>flockfile()</code>.</p> <p>The following example prints everything out together, blocking other threads that might want to write to the same file between calls to <code>fprintf(3C)</code>:</p> <pre>FILE iop; flockfile(iop); fprintf(iop, "hello "); fprintf(iop, "world"); fputc(iop, 'a'); funlockfile(iop);</pre> <p>An unlocked interface is available in case performance is an issue. For example:</p> <pre>flockfile(iop); while (!feof(iop)) { *c++ = getc_unlocked(iop); } funlockfile(iop);</pre>

NOTES The interfaces on this page are as specified in IEEE Std 1003.1c. See `standards(5)`.

ftw(3C)

NAME	ftw, nftw – walk a file tree																
SYNOPSIS	<pre>#include <ftw.h> int ftw(const char *<i>path</i>, int (*<i>fn</i>) (const char *, const struct stat *, int), int <i>depth</i>); int nftw(const char *<i>path</i>, int (*<i>fn</i>) (const char *, const struct stat *, int, struct FTW *), int <i>depth</i>, int <i>flags</i>);</pre>																
DESCRIPTION	<p>The <code>ftw()</code> function recursively descends the directory hierarchy rooted in <i>path</i>. For each object in the hierarchy, <code>ftw()</code> calls the user-defined function <i>fn</i>, passing it a pointer to a null-terminated character string containing the name of the object, a pointer to a <code>stat</code> structure (see <code>stat(2)</code>) containing information about the object, and an integer. Possible values of the integer, defined in the <code><ftw.h></code> header, are:</p> <table><tr><td>FTW_F</td><td>The object is a file.</td></tr><tr><td>FTW_D</td><td>The object is a directory.</td></tr><tr><td>FTW_DNR</td><td>The object is a directory that cannot be read. Descendants of the directory are not processed.</td></tr><tr><td>FTW_NS</td><td>The <code>stat()</code> function failed on the object because of lack of appropriate permission or the object is a symbolic link that points to a non-existent file. The <code>stat</code> buffer passed to <i>fn</i> is undefined.</td></tr></table> <p>The <code>ftw()</code> function visits a directory before visiting any of its descendants.</p> <p>The tree traversal continues until the tree is exhausted, an invocation of <i>fn</i> returns a non-zero value, or some error is detected within <code>ftw()</code> (such as an I/O error). If the tree is exhausted, <code>ftw()</code> returns 0. If <i>fn</i> returns a non-zero value, <code>ftw()</code> stops its tree traversal and returns whatever value was returned by <i>fn</i>.</p> <p>The <code>nftw()</code> function is similar to <code>ftw()</code> except that it takes the additional argument <i>flags</i>, which is a bitwise-inclusive OR of zero or more of the following flags:</p> <table><tr><td>FTW_CHDIR</td><td>If set, <code>nftw()</code> changes the current working directory to each directory as it reports files in that directory. If clear, <code>nftw()</code> does not change the current working directory.</td></tr><tr><td>FTW_DEPTH</td><td>If set, <code>nftw()</code> reports all files in a directory before reporting the directory itself. If clear, <code>nftw()</code> reports any directory before reporting the files in that directory.</td></tr><tr><td>FTW_MOUNT</td><td>If set, <code>nftw()</code> reports only files in the same file system as <i>path</i>. If clear, <code>nftw()</code> reports all files encountered during the walk.</td></tr><tr><td>FTW_PHYS</td><td>If set, <code>nftw()</code> performs a physical walk and does not follow symbolic links.</td></tr></table>	FTW_F	The object is a file.	FTW_D	The object is a directory.	FTW_DNR	The object is a directory that cannot be read. Descendants of the directory are not processed.	FTW_NS	The <code>stat()</code> function failed on the object because of lack of appropriate permission or the object is a symbolic link that points to a non-existent file. The <code>stat</code> buffer passed to <i>fn</i> is undefined.	FTW_CHDIR	If set, <code>nftw()</code> changes the current working directory to each directory as it reports files in that directory. If clear, <code>nftw()</code> does not change the current working directory.	FTW_DEPTH	If set, <code>nftw()</code> reports all files in a directory before reporting the directory itself. If clear, <code>nftw()</code> reports any directory before reporting the files in that directory.	FTW_MOUNT	If set, <code>nftw()</code> reports only files in the same file system as <i>path</i> . If clear, <code>nftw()</code> reports all files encountered during the walk.	FTW_PHYS	If set, <code>nftw()</code> performs a physical walk and does not follow symbolic links.
FTW_F	The object is a file.																
FTW_D	The object is a directory.																
FTW_DNR	The object is a directory that cannot be read. Descendants of the directory are not processed.																
FTW_NS	The <code>stat()</code> function failed on the object because of lack of appropriate permission or the object is a symbolic link that points to a non-existent file. The <code>stat</code> buffer passed to <i>fn</i> is undefined.																
FTW_CHDIR	If set, <code>nftw()</code> changes the current working directory to each directory as it reports files in that directory. If clear, <code>nftw()</code> does not change the current working directory.																
FTW_DEPTH	If set, <code>nftw()</code> reports all files in a directory before reporting the directory itself. If clear, <code>nftw()</code> reports any directory before reporting the files in that directory.																
FTW_MOUNT	If set, <code>nftw()</code> reports only files in the same file system as <i>path</i> . If clear, <code>nftw()</code> reports all files encountered during the walk.																
FTW_PHYS	If set, <code>nftw()</code> performs a physical walk and does not follow symbolic links.																

If `FTW_PHYS` is clear and `FTW_DEPTH` is set, `nftw()` follows links instead of reporting them, but does not report any directory that would be a descendant of itself. If `FTW_PHYS` is clear and `FTW_DEPTH` is clear, `nftw()` follows links instead of reporting them, but does not report the contents of any directory that would be a descendant of itself.

At each file it encounters, `nftw()` calls the user-supplied function `fn` with four arguments:

- The first argument is the pathname of the object.
- The second argument is a pointer to the `stat` buffer containing information on the object.
- The third argument is an integer giving additional information. Its value is one of the following:

<code>FTW_F</code>	The object is a file.
<code>FTW_D</code>	The object is a directory.
<code>FTW_DP</code>	The object is a directory and subdirectories have been visited. (This condition only occurs if the <code>FTW_DEPTH</code> flag is included in flags.)
<code>FTW_SL</code>	The object is a symbolic link. (This condition only occurs if the <code>FTW_PHYS</code> flag is included in flags.)
<code>FTW_SLN</code>	The object is a symbolic link that points to a non-existent file. (This condition only occurs if the <code>FTW_PHYS</code> flag is not included in flags.)
<code>FTW_DNR</code>	The object is a directory that cannot be read. The user-defined function <code>fn</code> will not be called for any of its descendants.
<code>FTW_NS</code>	The <code>stat()</code> function failed on the object because of lack of appropriate permission. The <code>stat</code> buffer passed to <code>fn</code> is undefined. Failure of <code>stat()</code> for any other reason is considered an error and <code>nftw()</code> returns <code>-1</code> .

- The fourth argument is a pointer to an `FTW` structure that contains the following members:

```
int    base;
int    level;
```

The `base` member is the offset of the object's filename in the pathname passed as the first argument to `fn()`. The value of `level` indicates the depth relative to the root of the walk, where the root level is 0.

Both `ftw()` and `nftw()` use one file descriptor for each level in the tree. The `depth` argument limits the number of file descriptors used. If `depth` is zero or negative, the effect is the same as if it were 1. It must not be greater than the number of file

ftw(3C)

descriptors currently available for use. The `ftw()` function runs faster if *depth* is at least as large as the number of levels in the tree. When `ftw()` and `nftw()` return, they close any file descriptors they have opened; they do not close any file descriptors that might have been opened by *fn*.

RETURN VALUES

If the tree is exhausted, `ftw()` and `nftw()` return 0. If the function pointed to by *fn* returns a non-zero value, `ftw()` and `nftw()` stop their tree traversal and return whatever value was returned by the function pointed to by *fn*. If `ftw()` and `nftw()` detect an error, they return `-1` and set `errno` to indicate the error.

If `ftw()` and `nftw()` encounter an error other than `EACCES` (see `FTW_DNR` and `FTW_NS` above), they return `-1` and set `errno` to indicate the error. The external variable `errno` can contain any error value that is possible when a directory is opened or when one of the `stat` functions is executed on a directory or file.

ERRORS

The `ftw()` and `nftw()` functions will fail if:

<code>ELOOP</code>	A loop exists in symbolic links encountered during resolution of the <i>path</i> argument
<code>ENAMETOOLONG</code>	The length of the path exceeds <code>{PATH_MAX}</code> , or a path name component is longer than <code>{NAME_MAX}</code> .
<code>ENOENT</code>	A component of <i>path</i> does not name an existing file or <i>path</i> is an empty string.
<code>ENOTDIR</code>	A component of <i>path</i> is not a directory.
<code>EOVERFLOW</code>	A field in the <code>stat</code> structure cannot be represented correctly in the current programming environment for one or more files found in the file hierarchy.

The `ftw()` function will fail if:

<code>EACCES</code>	Search permission is denied for any component of <i>path</i> or read permission is denied for <i>path</i> .
---------------------	---

The `nftw()` function will fail if:

<code>EACCES</code>	Search permission is denied for any component of <i>path</i> or read permission is denied for <i>path</i> , or <i>fn()</i> returns <code>-1</code> and does not reset <code>errno</code> .
---------------------	--

The `nftw()` and `ftw()` functions may fail if:

<code>ELOOP</code>	Too many symbolic links were encountered during resolution of the <i>path</i> argument.
<code>ENAMETOOLONG</code>	Pathname resolution of a symbolic link produced an intermediate result whose length exceeds <code>{PATH_MAX}</code> .

The `ftw()` function may fail if:

EINVAL The value of the *ndirs* argument is invalid.

The `nftw()` function may fail if:

EMFILE There are `{OPEN_MAX}` file descriptors currently open in the calling process.

ENFILE Too many files are currently open in the system.

If the function pointed to by *fn* encounters system errors, `errno` may be set accordingly.

EXAMPLES

EXAMPLE 1 Walk a directory structure using `ftw()`.

The following example walks the current directory structure, calling the *fn()* function for every directory entry, using at most 10 file descriptors:

```
#include <ftw.h>
...
if (ftw(".", fn, 10) != 0) {
    perror("ftw"); exit(2);
}
```

EXAMPLE 2 Walk a directory structure using `nftw()`.

The following example walks the `/tmp` directory and its subdirectories, calling the `nftw()` function for every directory entry, to a maximum of 5 levels deep.

```
#include <ftw.h>
...
int nftwfunc(const char *, const struct stat *, int, struct FTW *);
int nftwfunc(const char *filename, const struct stat *statptr,
             int fileflags, struct FTW *pftw)
{
    return 0;
}
...
char *startpath = "/tmp";
int depth = 5;
int flags = FTW_CHDIR | FTW_DEPTH | FTW_MOUNT;
int ret;
ret = nftw(startpath, nftwfunc, depth, flags);
```

USAGE

Because `ftw()` is recursive, it can terminate with a memory fault when applied to very deep file structures.

The `ftw()` function uses `malloc(3C)` to allocate dynamic storage during its operation. If `ftw()` is forcibly terminated, such as by `longjmp(3C)` being executed by *fn* or an interrupt routine, `ftw()` will not have a chance to free that storage, so it remains permanently allocated. A safe way to handle interrupts is to store the fact that an interrupt has occurred and arrange to have *fn* return a non-zero value at its next invocation.

ftw(3C)

The `ftw()` and `nftw()` functions have transitional interfaces for 64-bit file offsets. See `lf64(5)`.

The `ftw()` function is safe in multithreaded applications. The `nftw()` function is safe in multithreaded applications when the `FTW_CHDIR` flag is not set.

NAME	string_to_decimal, file_to_decimal, func_to_decimal – parse characters into decimal record																
SYNOPSIS	<pre>#include <floatingpoint.h> void string_to_decimal(char **pc, int nmax, int fortran_conventions, decimal_record *pd, enum decimal_string_form *pform, char **pechar); void func_to_decimal(char **pc, int nmax, int fortran_conventions, decimal_record *pd, enum decimal_string_form *pform, char **pechar, int (*pget)(void), int *pnread, int (*punget)(int c)); #include <stdio.h> void file_to_decimal(char **pc, int nmax, int fortran_conventions, decimal_record *pd, enum decimal_string_form *pform, char **pechar, FILE *pf, int *pnread);</pre>																
DESCRIPTION	<p>The char_to_decimal functions parse a numeric token from at most <i>nmax</i> characters in a string <i>**pc</i> or file <i>*pf</i> or function <i>(*pget)()</i> into a decimal record <i>*pd</i>, classifying the form of the string in <i>*pform</i> and <i>*pechar</i>. The accepted syntax is intended to be sufficiently flexible to accommodate many languages: <i>whitespace value</i> or <i>whitespace sign value</i>, where <i>whitespace</i> is any number of characters defined by <i>isspace</i> in <i><ctype.h></i>, <i>sign</i> is either of <i>[+-]</i>, and <i>value</i> can be <i>number</i>, <i>nan</i>, or <i>inf</i>. <i>inf</i> can be <i>INF</i> (<i>inf_form</i>) or <i>INFINITY</i> (<i>infinity_form</i>) without regard to case. <i>nan</i> can be <i>NAN</i> (<i>nan_form</i>) or <i>NAN(nstring)</i> (<i>nanstring_form</i>) without regard to case; <i>nstring</i> is any string of characters not containing <i>'</i> or <i>NULL</i>; <i>nstring</i> is copied to <i>pd->ds</i> and, currently, not used subsequently. <i>number</i> consists of <i>significand</i> or <i>significand efield</i> where <i>significand</i> must contain one or more digits and may contain one point; possible forms are</p> <table border="0" style="margin-left: 2em;"> <tr> <td><i>digits</i></td> <td>(<i>int_form</i>)</td> </tr> <tr> <td><i>digits.</i></td> <td>(<i>intdot_form</i>)</td> </tr> <tr> <td><i>.digits</i></td> <td>(<i>dotfrac_form</i>)</td> </tr> <tr> <td><i>digits.digits</i></td> <td>(<i>intdotfrac_form</i>)</td> </tr> </table> <p><i>efield</i> consists of <i>echar digits</i> or <i>echar sign digits</i>, where <i>echar</i> is one of <i>[Ee]</i>, and <i>digits</i> contains one or more digits.</p> <p>When <i>fortran_conventions</i> is nonzero, additional input forms are accepted according to various Fortran conventions:</p> <table border="0" style="margin-left: 2em;"> <tr> <td>0</td> <td>no Fortran conventions</td> </tr> <tr> <td>1</td> <td>Fortran list-directed input conventions</td> </tr> <tr> <td>2</td> <td>Fortran formatted input conventions, ignore blanks (BN)</td> </tr> <tr> <td>3</td> <td>Fortran formatted input conventions, blanks are zeros (BZ)</td> </tr> </table> <p>When <i>fortran_conventions</i> is nonzero, <i>echar</i> may also be one of <i>[DdQq]</i>, and <i>efield</i> may also have the form</p>	<i>digits</i>	(<i>int_form</i>)	<i>digits.</i>	(<i>intdot_form</i>)	<i>.digits</i>	(<i>dotfrac_form</i>)	<i>digits.digits</i>	(<i>intdotfrac_form</i>)	0	no Fortran conventions	1	Fortran list-directed input conventions	2	Fortran formatted input conventions, ignore blanks (BN)	3	Fortran formatted input conventions, blanks are zeros (BZ)
<i>digits</i>	(<i>int_form</i>)																
<i>digits.</i>	(<i>intdot_form</i>)																
<i>.digits</i>	(<i>dotfrac_form</i>)																
<i>digits.digits</i>	(<i>intdotfrac_form</i>)																
0	no Fortran conventions																
1	Fortran list-directed input conventions																
2	Fortran formatted input conventions, ignore blanks (BN)																
3	Fortran formatted input conventions, blanks are zeros (BZ)																

func_to_decimal(3C)

sign digits.

When *fortran_conventions* ≥ 2 , blanks may appear in the *digits* strings for the integer, fraction, and exponent fields and may appear between *echar* and the exponent sign and after the infinity and NaN forms. If *fortran_conventions* $= 2$, the blanks are ignored. When *fortran_conventions* $= 3$, the blanks that appear in *digits* strings are interpreted as zeros, and other blanks are ignored.

When *fortran_conventions* is zero, the current locale's decimal point character is used as the decimal point; when *fortran_conventions* is nonzero, the period is used as the decimal point.

The form of the accepted decimal string is placed in *pform*. If an *efield* is recognized, *pechar* is set to point to the *echar*.

On input, *pc* points to the beginning of a character string buffer of length $\geq nmax$. On output, *pc* points to a character in that buffer, one past the last accepted character. `string_to_decimal()` gets its characters from the buffer; `file_to_decimal()` gets its characters from *pf* and records them in the buffer, and places a null after the last character read. `func_to_decimal()` gets its characters from an int function (*pget*()).

The scan continues until no more characters could possibly fit the acceptable syntax or until *nmax* characters have been scanned. If the *nmax* limit is not reached then at least one extra character will usually be scanned that is not part of the accepted syntax. `file_to_decimal()` and `func_to_decimal()` set *pnread* to the number of characters read from the file; if greater than *nmax*, some characters were lost. If no characters were lost, `file_to_decimal()` and `func_to_decimal()` attempt to push back, with `ungetc(3C)` or (*punget*()), as many as possible of the excess characters read, adjusting *pnread* accordingly. If all `unget` calls are successful, then *pc* will be NULL. No push back will be attempted if (*punget*()) is NULL.

Typical declarations for *pget*() and *punget*() are:

```
int xget(void)
{ . . . }
int (*pget)(void) = xget;
int xunget(int c)
{ . . . }
int (*punget)(int) = xunget;
```

If no valid number was detected, *pd* \rightarrow *fpclass* is set to *fp_signaling*, *pc* is unchanged, and *pform* is set to *invalid_form*.

`atof(3C)` and `strtod(3C)` use `string_to_decimal()`. `scanf(3C)` uses `file_to_decimal()`.

fwide(3C)

NAME	fwide – set stream orientation				
SYNOPSIS	<pre>#include <stdio.h> #include <wchar.h> int fwide(FILE *<i>stream</i>, int <i>mode</i>);</pre>				
DESCRIPTION	<p>The <code>fwide()</code> function determines the orientation of the stream pointed to by <i>stream</i>. If <i>mode</i> is greater than 0, the function first attempts to make the stream wide-orientated. If <i>mode</i> is less than 0, the function first attempts to make the stream byte-orientated. Otherwise, <i>mode</i> is 0 and the function does not alter the orientation of the stream.</p> <p>If the orientation of the stream has already been determined, <code>fwide()</code> does not change it.</p> <p>Because no return value is reserved to indicate an error, an application wishing to check for error situations should set <code>errno</code> to 0, then call <code>fwide()</code>, then check <code>errno</code> and if it is non-zero, assume an error has occurred.</p>				
RETURN VALUES	The <code>fwide()</code> function returns a value greater than 0 if, after the call, the stream has wide-orientation, a value less than 0 if the stream has byte-orientation, or 0 if the stream has no orientation.				
ERRORS	The <code>fwide()</code> function may fail if: EBADF The <i>stream</i> argument is not a valid stream.				
USAGE	A call to <code>fwide()</code> with <i>mode</i> set to 0 can be used to determine the current orientation of a stream.

NAME	fwprintf, wprintf, swprintf – print formatted wide-character output
SYNOPSIS	<pre>#include <stdio.h> #include <wchar.h> int fwprintf(FILE *stream, const wchar_t *format, ...); int wprintf(const wchar_t *format, <...>); int swprintf(wchar_t *s, size_t n, const wchar_t *format, ...);</pre>
DESCRIPTION	<p>The <code>fwprintf()</code> function places output on the named output <i>stream</i>. The <code>wprintf()</code> function places output on the standard output stream <code>stdout</code>. The <code>swprintf()</code> function places output followed by the null wide-character in consecutive wide-characters starting at <i>*s</i>; no more than <i>n</i> wide-characters are written, including a terminating null wide-character, which is always added (unless <i>n</i> is zero).</p> <p>Each of these functions converts, formats and prints its arguments under control of the <i>format</i> wide-character string. The <i>format</i> is composed of zero or more directives: <i>ordinary wide-characters</i>, which are simply copied to the output stream and <i>conversion specifications</i>, each of which results in the fetching of zero or more arguments. The results are undefined if there are insufficient arguments for the <i>format</i>. If the <i>format</i> is exhausted while arguments remain, the excess arguments are evaluated but are otherwise ignored.</p> <p>Conversions can be applied to the <i>n</i>th argument after the <i>format</i> in the argument list, rather than to the next unused argument. In this case, the conversion wide-character <code>%</code> (see below) is replaced by the sequence <code>%n\$</code>, where <i>n</i> is a decimal integer in the range <code>[1, NL_ARGMAX]</code>, giving the position of the argument in the argument list. This feature provides for the definition of format wide-character strings that select arguments in an order appropriate to specific languages (see the <code>EXAMPLES</code> section).</p> <p>In format wide-character strings containing the <code>%n\$</code> form of conversion specifications, numbered arguments in the argument list can be referenced from the format wide-character string as many times as required.</p> <p>In format wide-character strings containing the <code>%</code> form of conversion specifications, each argument in the argument list is used exactly once.</p> <p>All forms of the <code>fwprintf()</code> functions allow for the insertion of a language-dependent radix character in the output string, output as a wide-character value. The radix character is defined in the program's locale (category <code>LC_NUMERIC</code>). In the POSIX locale, or in a locale where the radix character is not defined, the radix character defaults to a period (<code>.</code>).</p> <p>Each conversion specification is introduced by the <code>%</code> wide-character or by the wide-character sequence <code>%n\$</code>, after which the following appear in sequence:</p> <ul style="list-style-type: none"> ▪ Zero or more <i>flags</i> (in any order), which modify the meaning of the conversion specification.

fwprintf(3C)

- An optional minimum *field width*. If the converted value has fewer wide-characters than the field width, it will be padded with spaces by default on the left; it will be padded on the right, if the left-adjustment flag (-), described below, is given to the field width. The field width takes the form of an asterisk (*), described below, or a decimal integer.
- An optional *precision* that gives the minimum number of digits to appear for the d, i, o, u, x, and X conversions; the number of digits to appear after the radix character for the e, E, and f conversions; the maximum number of significant digits for the g and G conversions; or the maximum number of wide-characters to be printed from a string in s conversions. The precision takes the form of a period (.) followed by either an asterisk (*), described below, or an optional decimal digit string, where a null digit string is treated as 0. If a precision appears with any other conversion wide-character, the behavior is undefined.
- An optional l (ell) specifying that a following c conversion wide-character applies to a `wint_t` argument; an optional l specifying that a following s conversion wide-character applies to a `wchar_t` argument; an optional h specifying that a following d, i, o, u, x, and X conversion wide-character applies to a type `short int` or type `unsigned short int` argument (the argument will have been promoted according to the integral promotions, and its value will be converted to type `short int` or `unsigned short int` before printing); an optional h specifying that a following n conversion wide-character applies to a pointer to a type `short int` argument; an optional l (ell) specifying that a following d, i, o, u, x, and X conversion wide-character applies to a type `long int` or `unsigned long int` argument; an optional l (ell) specifying that a following n conversion wide-character applies to a pointer to a type `long int` argument; or an optional L specifying that a following e, E, f, g, or G conversion wide-character applies to a type `long double` argument. If an h, l, or L appears with any other conversion wide-character, the behavior is undefined.
- A *conversion wide-character* that indicates the type of conversion to be applied.

A field width, or precision, or both, may be indicated by an asterisk (*). In this case an argument of type `int` supplies the field width or precision. Arguments specifying field width, or precision, or both must appear in that order before the argument, if any, to be converted. A negative field width is taken as a - flag followed by a positive field width. A negative precision is taken as if the precision were omitted. In format wide-character strings containing the `%n$` form of a conversion specification, a field width or precision may be indicated by the sequence `*m$`, where *m* is a decimal integer in the range [1, `NL_ARGMAX`] giving the position in the argument list (after the format argument) of an integer argument containing the field width or precision, for example:

```
wprintf(L"%1$d:%2$.*3$d:%4$.*3$d\n", hour, min, precision, sec);
```

The *format* can contain either numbered argument specifications (that is, `%n$` and `*m$`), or unnumbered argument specifications (that is, `%` and `*`), but normally not both. The only exception to this is that `%%` can be mixed with the `%n$` form. The results of mixing numbered and unnumbered argument specifications in a *format*

wide-character string are undefined. When numbered argument specifications are used, specifying the N th argument requires that all the leading arguments, from the first to the $(N-1)$ th, are specified in the format wide-character string.

The flag wide-characters and their meanings are:

'	The integer portion of the result of a decimal conversion (<code>%i</code> , <code>%d</code> , <code>%u</code> , <code>%f</code> , <code>%g</code> , or <code>%G</code>) will be formatted with thousands' grouping wide-characters. For other conversions the behavior is undefined. The non-monetary grouping wide-character is used.
-	The result of the conversion will be left-justified within the field. The conversion will be right-justified if this flag is not specified.
+	The result of a signed conversion will always begin with a sign (+ or -). The conversion will begin with a sign only when a negative value is converted if this flag is not specified.
space	If the first wide-character of a signed conversion is not a sign or if a signed conversion results in no wide-characters, a space will be prefixed to the result. This means that if the space and + flags both appear, the space flag will be ignored.
#	This flag specifies that the value is to be converted to an alternative form. For <code>o</code> conversion, it increases the precision (if necessary) to force the first digit of the result to be 0. For <code>x</code> or <code>X</code> conversions, a non-zero result will have <code>0x</code> (or <code>0X</code>) prefixed to it. For <code>e</code> , <code>E</code> , <code>f</code> , <code>g</code> , or <code>G</code> conversions, the result will always contain a radix character, even if no digits follow it. Without this flag, a radix character appears in the result of these conversions only if a digit follows it. For <code>g</code> and <code>G</code> conversions, trailing zeros will <i>not</i> be removed from the result as they normally are. For other conversions, the behavior is undefined.
0	For <code>d</code> , <code>i</code> , <code>o</code> , <code>u</code> , <code>x</code> , <code>X</code> , <code>e</code> , <code>E</code> , <code>f</code> , <code>g</code> , and <code>G</code> conversions, leading zeros (following any indication of sign or base) are used to pad to the field width; no space padding is performed. If the 0 and - flags both appear, the 0 flag will be ignored. For <code>d</code> , <code>i</code> , <code>o</code> , <code>u</code> , <code>x</code> , and <code>X</code> conversions, if a precision is specified, the 0 flag will be ignored. If the 0 and ' flags both appear, the grouping wide-characters are inserted before zero padding. For other conversions, the behavior is undefined.

The conversion wide-characters and their meanings are:

<code>d, i</code>	The <code>int</code> argument is converted to a signed decimal in the style <code>[-]ddd</code> . The precision specifies the minimum number of digits to appear; if the value being converted can be represented in fewer digits, it will be expanded with leading zeros. The default precision is 1. The result of converting 0 with an explicit precision of 0 is no wide-characters.
-------------------	--

fwprintf(3C)

- o The unsigned `int` argument is converted to unsigned octal format in the style *dddd*. The precision specifies the minimum number of digits to appear; if the value being converted can be represented in fewer digits, it will be expanded with leading zeros. The default precision is 1. The result of converting 0 with an explicit precision of 0 is no wide-characters.
- u The unsigned `int` argument is converted to unsigned decimal format in the style *dddd*. The precision specifies the minimum number of digits to appear; if the value being converted can be represented in fewer digits, it will be expanded with leading zeros. The default precision is 1. The result of converting 0 with an explicit precision of 0 is no wide-characters.
- x The unsigned `int` argument is converted to unsigned hexadecimal format in the style *dddd*; the letters `abcdef` are used. The precision specifies the minimum number of digits to appear; if the value being converted can be represented in fewer digits, it will be expanded with leading zeros. The default precision is 1. The result of converting 0 with an explicit precision of 0 is no wide-characters.
- X Behaves the same as the `x` conversion wide-character except that letters `ABCDEF` are used instead of `abcdef`.
- f The `double` argument is converted to decimal notation in the style `[-]ddd.ddd`, where the number of digits after the radix character is equal to the precision specification. If the precision is missing, it is taken as 6; if the precision is explicitly 0 and no `#` flag is present, no radix character appears. If a radix character appears, at least one digit appears before it. The value is rounded to the appropriate number of digits.

The `fwprintf()` family of functions may make available wide-character string representations for infinity and NaN.
- e, E The `double` argument is converted in the style `[-]d.ddde ± dd`, where there is one digit before the radix character (which is non-zero if the argument is non-zero) and the number of digits after it is equal to the precision; if the precision is missing, it is taken as 6; if the precision is 0 and no `#` flag is present, no radix character appears. The value is rounded to the appropriate number of digits. The `E` conversion wide-character will produce a number with `E` instead of `e` introducing the exponent. The exponent always contains at least two digits. If the value is 0, the exponent is 0.

The `fwprintf()` family of functions may make available wide-character string representations for infinity and NaN.
- g, G The `double` argument is converted in the style `f` or `e` (or in the style `E` in the case of a `G` conversion wide-character), with the precision specifying the number of significant digits. If an explicit precision is 0, it is taken as 1. The style used depends on the value converted; style `e` (or `E`) will be used only if the exponent resulting from such a conversion is less than `-4` or

greater than or equal to the precision. Trailing zeros are removed from the fractional portion of the result; a radix character appears only if it is followed by a digit.

The `fwprintf()` family of functions may make available wide-character string representations for infinity and NaN.

- c If no `l` (ell) qualifier is present, the `int` argument is converted to a wide-character as if by calling the `btowc(3C)` function and the resulting wide-character is written. Otherwise the `wint_t` argument is converted to `wchar_t`, and written.
- s If no `l` (ell) qualifier is present, the argument must be a pointer to a character array containing a character sequence beginning in the initial shift state. Characters from the array are converted as if by repeated calls to the `mbrtowc(3C)` function, with the conversion state described by an `mbstate_t` object initialized to zero before the first character is converted, and written up to (but not including) the terminating null wide-character. If the precision is specified, no more than that many wide-characters are written. If the precision is not specified or is greater than the size of the array, the array must contain a null wide-character.

If an `l` (ell) qualifier is present, the argument must be a pointer to an array of type `wchar_t`. Wide characters from the array are written up to (but not including) a terminating null wide-character. If no precision is specified or is greater than the size of the array, the array must contain a null wide-character. If a precision is specified, no more than that many wide-characters are written.
- p The argument must be a pointer to `void`. The value of the pointer is converted to a sequence of printable wide-characters.
- n The argument must be a pointer to an integer into which is written the number of wide-characters written to the output so far by this call to one of the `fwprintf()` functions. No argument is converted.
- C Same as `lc`.
- S Same as `ls`.
- % Output a % wide-character; no argument is converted. The entire conversion specification must be `%%`.

If a conversion specification does not match one of the above forms, the behavior is undefined.

In no case does a non-existent or small field width cause truncation of a field; if the result of a conversion is wider than the field width, the field is simply expanded to contain the conversion result. Characters generated by `fwprintf()` and `wprintf()` are printed as if `fputwc(3C)` had been called.

fwprintf(3C)

The `st_ctime` and `st_mtime` fields of the file will be marked for update between the call to a successful execution of `fwprintf()` or `wprintf()` and the next successful completion of a call to `fflush(3C)` or `fclose(3C)` on the same stream or a call to `exit(3C)` or `abort(3C)`.

RETURN VALUES Upon successful completion, these functions return the number of wide-characters transmitted excluding the terminating null wide-character in the case of `swprintf()` or a negative value if an output error was encountered.

ERRORS For the conditions under which `fwprintf()` and `wprintf()` will fail and may fail, refer to `fputwc(3C)`.

In addition, all forms of `fwprintf()` may fail if:

`EILSEQ` A wide-character code that does not correspond to a valid character has been detected.

`EINVAL` There are insufficient arguments.

In addition, `wprintf()` and `fwprintf()` may fail if:

`ENOMEM` Insufficient storage space is available.

EXAMPLES **EXAMPLE 1** Print language-dependent date and time format.

To print the language-independent date and time format, the following statement could be used:

```
wprintf(format, weekday, month, day, hour, min);
```

For American usage, *format* could be a pointer to the wide-character string:

```
L"%s, %s %d, %d:%.2d\n"
```

producing the message:

```
Sunday, July 3, 10:02
```

whereas for German usage, *format* could be a pointer to the wide-character string:

```
L"%1$s, %3$d. %2$s, %4$d:%5$.2d\n"
```

producing the message:

```
Sonntag, 3. Juli, 10:02
```

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
MT-Level	MT-Safe with exceptions

SEE ALSO `btowc(3C)`, `fputwc(3C)`, `fwscanf(3C)`, `mbrtowc(3C)`, `setlocale(3C)`, `attributes(5)`

NOTES The `fwprintf()`, `wprintf()`, and `swprintf()` functions can be used safely in multithreaded applications, as long as `setlocale(3C)` is not being called to change the locale.

__fwritable(3C)

NAME	<code>__fbufsize</code> , <code>__flbf</code> , <code>__fpending</code> , <code>__fpurge</code> , <code>__freadable</code> , <code>__freading</code> , <code>__fsetlocking</code> , <code>__fwritable</code> , <code>__fwriting</code> , <code>_flushlbf</code> – interfaces to <code>stdio</code> FILE structure
SYNOPSIS	<pre>#include <stdio.h> #include <stdio_ext.h> size_t __fbufsiz(FILE *stream); int __flbf(FILE *stream); size_t __fpending(FILE *stream); void __fpurge(FILE *stream); int __freadable(FILE *stream); int __freading(FILE *stream); int __fsetlocking(FILE *stream, int type); int __fwritable(FILE *stream); int __fwriting(FILE *stream); void _flushlbf(void);</pre>
DESCRIPTION	<p>These functions provide portable access to the members of the <code>stdio(3C)</code> FILE structure.</p> <p>The <code>__fbufsize()</code> function returns in bytes the size of the buffer currently in use by the given stream.</p> <p>The <code>__flbf()</code> function returns non-zero if the stream is line-buffered.</p> <p>The <code>__fpending</code> function returns in bytes the amount of output pending on a stream.</p> <p>The <code>__fpurge()</code> function discards any pending buffered I/O on the stream.</p> <p>The <code>__freadable()</code> function returns non-zero if it is possible to read from a stream.</p> <p>The <code>__freading()</code> function returns non-zero if the file is open readonly, or if the last operation on the stream was a read operation such as <code>fread(3C)</code> or <code>fgetc(3C)</code>. Otherwise it returns 0.</p> <p>The <code>__fsetlocking()</code> function allows the type of locking performed by <code>stdio</code> on a given stream to be controlled by the programmer.</p> <p>If <code>type</code> is <code>FSETLOCKING_INTERNAL</code>, <code>stdio</code> performs implicit locking around every operation on the given stream. This is the default system behavior on that stream.</p> <p>If <code>type</code> is <code>FSETLOCKING_BYCALLER</code>, <code>stdio</code> assumes that the caller is responsible for maintaining the integrity of the stream in the face of access by multiple threads. If there is only one thread accessing the stream, nothing further needs to be done. If multiple threads are accessing the stream, then the caller can use the <code>flockfile()</code>,</p>

__fwritable(3C)

`funlockfile()`, and `ftrylockfile()` functions described on the `flockfile(3C)` manual page to provide the appropriate locking. In both this and the case where *type* is `FSETLOCKING_INTERNAL`, `__fsetlocking()` returns the previous state of the stream.

If *type* is `FSETLOCKING_QUERY`, `__fsetlocking()` returns the current state of the stream without changing it.

The `__fwritable()` function returns non-zero if it is possible to write on a stream.

The `__fwriting()` function returns non-zero if the file is open write-only or append-only, or if the last operation on the stream was a write operation such as `fwrite(3C)` or `fputc(3C)`. Otherwise it returns 0.

The `_flushlbf()` function flushes all line-buffered files. It is used when reading from a line-buffered file.

USAGE

Although the contents of the `stdio` FILE structure have always been private to the `stdio` implementation, some applications have needed to obtain information about a `stdio` stream that was not accessible through a supported interface. These applications have resorted to accessing fields of the FILE structure directly, rendering them possibly non-portable to new implementations of `stdio`, or more likely, preventing enhancements to `stdio` that would cause those applications to break.

In the 64-bit environment, the FILE structure is opaque. The functions described here are provided as a means of obtaining the information that up to now has been retrieved directly from the FILE structure. Because they are based on the needs of existing applications (such as `mh` and `emacs`), they may be extended as other programs are ported. Although they may still be non-portable to other operating systems, they will be compatible from each Solaris release to the next. Interfaces that are more portable are under development.

ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

fwrite(3C)

NAME	fwrite – binary output				
SYNOPSIS	<pre>#include <stdio.h> size_t fwrite(const void *ptr, size_t size, size_t nitems, FILE *stream);</pre>				
DESCRIPTION	<p>The <code>fwrite()</code> function writes, from the array pointed to by <code>ptr</code>, up to <code>nitems</code> elements whose size is specified by <code>size</code>, to the stream pointed to by <code>stream</code>. For each object, <code>size</code> calls are made to the <code>fputc(3C)</code> function, taking the values (in order) from an array of unsigned char exactly overlaying the object. The file-position indicator for the stream (if defined) is advanced by the number of bytes successfully written. If an error occurs, the resulting value of the file-position indicator for the stream is unspecified.</p> <p>The <code>st_ctime</code> and <code>st_mtime</code> fields of the file will be marked for update between the successful execution of <code>fwrite()</code> and the next successful completion of a call to <code>fflush(3C)</code> or <code>fclose(3C)</code> on the same stream or a call to <code>exit(2)</code> or <code>abort(3C)</code>.</p>				
RETURN VALUES	<p>The <code>fwrite()</code> function returns the number of elements successfully written, which might be less than <code>nitems</code> if a write error is encountered. If <code>size</code> or <code>nitems</code> is 0, <code>fwrite()</code> returns 0 and the state of the stream remains unchanged. Otherwise, if a write error occurs, the error indicator for the stream is set and <code>errno</code> is set to indicate the error.</p>				
ERRORS	Refer to <code>fputc(3C)</code> .				
USAGE	Because of possible differences in element length and byte ordering, files written using <code>fwrite()</code> are application-dependent, and possibly cannot be read using <code>fread(3C)</code> by a different application or by the same application on a different processor.				
ATTRIBUTES	See <code>attributes(5)</code> for descriptions of the following attributes:

Otherwise it returns 0.</p> <p>The <code>__fsetlocking()</code> function allows the type of locking performed by <code>stdio</code> on a given stream to be controlled by the programmer.</p> <p>If <code>type</code> is <code>FSETLOCKING_INTERNAL</code>, <code>stdio</code> performs implicit locking around every operation on the given stream. This is the default system behavior on that stream.</p> <p>If <code>type</code> is <code>FSETLOCKING_BYCALLER</code>, <code>stdio</code> assumes that the caller is responsible for maintaining the integrity of the stream in the face of access by multiple threads. If there is only one thread accessing the stream, nothing further needs to be done. If multiple threads are accessing the stream, then the caller can use the <code>flockfile()</code>,</p>

__fwriting(3C)

`funlockfile()`, and `ftrylockfile()` functions described on the `flockfile(3C)` manual page to provide the appropriate locking. In both this and the case where *type* is `FSETLOCKING_INTERNAL`, `__fsetlocking()` returns the previous state of the stream.

If *type* is `FSETLOCKING_QUERY`, `__fsetlocking()` returns the current state of the stream without changing it.

The `__fwritable()` function returns non-zero if it is possible to write on a stream.

The `__fwriting()` function returns non-zero if the file is open write-only or append-only, or if the last operation on the stream was a write operation such as `fwrite(3C)` or `fputc(3C)`. Otherwise it returns 0.

The `_flushlbf()` function flushes all line-buffered files. It is used when reading from a line-buffered file.

USAGE

Although the contents of the `stdio` `FILE` structure have always been private to the `stdio` implementation, some applications have needed to obtain information about a `stdio` stream that was not accessible through a supported interface. These applications have resorted to accessing fields of the `FILE` structure directly, rendering them possibly non-portable to new implementations of `stdio`, or more likely, preventing enhancements to `stdio` that would cause those applications to break.

In the 64-bit environment, the `FILE` structure is opaque. The functions described here are provided as a means of obtaining the information that up to now has been retrieved directly from the `FILE` structure. Because they are based on the needs of existing applications (such as `mh` and `emacs`), they may be extended as other programs are ported. Although they may still be non-portable to other operating systems, they will be compatible from each Solaris release to the next. Interfaces that are more portable are under development.

NAME	fwscanf, wscanf, swscanf, vfwscanf, vwscanf, vswscanf – convert formatted wide-character input
SYNOPSIS	<pre>#include <stdio.h> #include <wchar.h> int fwscanf(FILE *stream, const wchar_t *format, ...); int wscanf(const wchar_t *format, ...); int swscanf(const wchar_t *s, const wchar_t *format, ...); #include <stdarg.h> #include <stdio.h> #include <wchar.h> int vfwscanf(FILE *stream, const wchar_t *format, va_list arg); int vwscanf(const wchar_t *ws, const wchar_t *format, va_list arg); int vswscanf(const wchar_t *format, va_list arg);</pre>
DESCRIPTION	<p>The fwscanf () function reads from the named input <i>stream</i>.</p> <p>The wscanf () function reads from the standard input stream stdin.</p> <p>The swscanf () function reads from the wide-character string <i>s</i>.</p> <p>The vfwscanf (), vwscanf (), and vswscanf () functions are equivalent to the fwscanf (), swscanf (), and wscanf () functions, respectively, except that instead of being called with a variable number of arguments, they are called with an argument list as defined by the <stdarg.h> header (see stdarg(3HEAD)). These functions do not invoke the va_end () macro. Applications using these functions should call va_end(<i>ap</i>) afterwards to clean up.</p> <p>Each function reads wide-characters, interprets them according to a format, and stores the results in its arguments. Each expects, as arguments, a control wide-character string <i>format</i> described below, and a set of <i>pointer</i> arguments indicating where the converted input should be stored. The result is undefined if there are insufficient arguments for the format. If the format is exhausted while arguments remain, the excess arguments are evaluated but are otherwise ignored.</p> <p>Conversions can be applied to the <i>n</i>th argument after the <i>format</i> in the argument list, rather than to the next unused argument. In this case, the conversion wide-character % (see below) is replaced by the sequence %<i>n</i>\$, where <i>n</i> is a decimal integer in the range [1, NL_ARGMAX]. This feature provides for the definition of format wide-character strings that select arguments in an order appropriate to specific languages. In format wide-character strings containing the %<i>n</i>\$ form of conversion specifications, it is unspecified whether numbered arguments in the argument list can be referenced from the format wide-character string more than once.</p>

fwscanf(3C)

The *format* can contain either form of a conversion specification, that is, % or %n\$, but the two forms cannot normally be mixed within a single *format* wide-character string. The only exception to this is that %% or %* can be mixed with the %n\$ form.

The `fwscanf()` function in all its forms allows for detection of a language-dependent radix character in the input string, encoded as a wide-character value. The radix character is defined in the program's locale (category `LC_NUMERIC`). In the POSIX locale, or in a locale where the radix character is not defined, the radix character defaults to a period (.).

The format is a wide-character string composed of zero or more directives. Each directive is composed of one of the following: one or more white-space wide-characters (space, tab, newline, vertical-tab or form-feed characters); an ordinary wide-character (neither % nor a white-space character); or a conversion specification. Each conversion specification is introduced by a % or the sequence %n\$ after which the following appear in sequence:

- An optional assignment-suppressing character *.
- An optional non-zero decimal integer that specifies the maximum field width.
- An optional size modifier h, l(ell), or L indicating the size of the receiving object. The conversion wide-characters c, s, and [must be preceded by l (ell) if the corresponding argument is a pointer to `wchar_t` rather than a pointer to a character type. The conversion wide-characters d, i, and n must be preceded by h if the corresponding argument is a pointer to `short int` rather than a pointer to `int`, or by l (ell) if it is a pointer to `long int`. Similarly, the conversion wide-characters o, u, and x must be preceded by h if the corresponding argument is a pointer to `unsigned short int` rather than a pointer to `unsigned int`, or by l (ell) if it is a pointer to `unsigned long int`. The conversion wide-characters e, f, and g must be preceded by l (ell) if the corresponding argument is a pointer to `double` rather than a pointer to `float`, or by L if it is a pointer to `long double`. If an h, l (ell), or L appears with any other conversion wide-character, the behavior is undefined.
- A conversion wide-character that specifies the type of conversion to be applied. The valid conversion wide-characters are described below.

The `fwscanf()` functions execute each directive of the format in turn. If a directive fails, as detailed below, the function returns. Failures are described as input failures (due to the unavailability of input bytes) or matching failures (due to inappropriate input).

A directive composed of one or more white-space wide-characters is executed by reading input until no more valid input can be read, or up to the first wide-character which is not a white-space wide-character, which remains unread.

A directive that is an ordinary wide-character is executed as follows. The next wide-character is read from the input and compared with the wide-character that comprises the directive; if the comparison shows that they are not equivalent, the directive fails, and the differing and subsequent wide-characters remain unread.

A directive that is a conversion specification defines a set of matching input sequences, as described below for each conversion wide-character. A conversion specification is executed in the following steps:

Input white-space wide-characters (as specified by `isspace(3C)`) are skipped, unless the conversion specification includes a `l`, `c`, or `n` conversion character.

An item is read from the input, unless the conversion specification includes an `n` conversion wide-character. An input item is defined as the longest sequence of input wide-characters, not exceeding any specified field width, which is an initial subsequence of a matching sequence. The first wide-character, if any, after the input item remains unread. If the length of the input item is 0, the execution of the conversion specification fails; this condition is a matching failure, unless end-of-file, an encoding error, or a read error prevented input from the stream, in which case it is an input failure.

Except in the case of a `%` conversion wide-character, the input item (or, in the case of a `%n` conversion specification, the count of input wide-characters) is converted to a type appropriate to the conversion wide-character. If the input item is not a matching sequence, the execution of the conversion specification fails; this condition is a matching failure. Unless assignment suppression was indicated by a `*`, the result of the conversion is placed in the object pointed to by the first argument following the *format* argument that has not already received a conversion result if the conversion specification is introduced by `%`, or in the *n*th argument if introduced by the wide-character sequence `%n$`. If this object does not have an appropriate type, or if the result of the conversion cannot be represented in the space provided, the behavior is undefined.

The following conversion wide-characters are valid:

- d Matches an optionally signed decimal integer, whose format is the same as expected for the subject sequence of `wcstol(3C)` with the value 10 for the *base* argument. In the absence of a size modifier, the corresponding argument must be a pointer to `int`.
- i Matches an optionally signed integer, whose format is the same as expected for the subject sequence of `wcstol(3C)` with 0 for the *base* argument. In the absence of a size modifier, the corresponding argument must be a pointer to `int`.
- o Matches an optionally signed octal integer, whose format is the same as expected for the subject sequence of `wcstoul(3C)` with the value 8 for the *base* argument. In the absence of a size modifier, the corresponding argument must be a pointer to `unsigned int`.
- u Matches an optionally signed decimal integer, whose format is the same as expected for the subject sequence of `wcstoul(3C)` with the value 10 for the *base* argument. In the absence of a size modifier, the corresponding argument must be a pointer to `unsigned int`.

fwscanf(3C)

- x** Matches an optionally signed hexadecimal integer, whose format is the same as expected for the subject sequence of `wcstoul(3C)` with the value 16 for the *base* argument. In the absence of a size modifier, the corresponding argument must be a pointer to `unsigned int`.
- e,f,g** Matches an optionally signed floating-point number, whose format is the same as expected for the subject sequence of `wcstod(3C)`. In the absence of a size modifier, the corresponding argument must be a pointer to `float`.
- If the `fwprintf()` family of functions generates character string representations for infinity and NaN (a 7858 symbolic entity encoded in floating-point format) to support the ANSI/IEEE Std 754:1985 standard, the `fwscanf()` family of functions will recognize them as input.
- s** Matches a sequence of non white-space wide-characters. If no `l` (ell) qualifier is present, characters from the input field are converted as if by repeated calls to the `wcrtomb(3C)` function, with the conversion state described by an `mbstate_t` object initialized to zero before the first wide-character is converted. The corresponding argument must be a pointer to a character array large enough to accept the sequence and the terminating null character, which will be added automatically.
- Otherwise, the corresponding argument must be a pointer to an array of `wchar_t` large enough to accept the sequence and the terminating null wide-character, which will be added automatically.
- [** Matches a non-empty sequence of wide-characters from a set of expected wide-characters (the *scanset*). If no `l` (ell) qualifier is present, wide-characters from the input field are converted as if by repeated calls to the `wcrtomb()` function, with the conversion state described by an `mbstate_t` object initialized to zero before the first wide-character is converted. The corresponding argument must be a pointer to a character array large enough to accept the sequence and the terminating null character, which will be added automatically.
- If an `l` (ell) qualifier is present, the corresponding argument must be a pointer to an array of `wchar_t` large enough to accept the sequence and the terminating null wide-character, which will be added automatically.
- The conversion specification includes all subsequent `widw` characters in the *format* string up to and including the matching right square bracket (`]`). The wide-characters between the square brackets (the *scanlist*) comprise the scanset, unless the wide-character after the left square bracket is a circumflex (`^`), in which case the scanset contains all wide-characters that do not appear in the scanlist between the circumflex and the right square bracket. If the conversion specification begins with `[]` or `[^]`, the right square bracket is included in the scanlist and the next right square bracket is the matching right square bracket that ends the conversion specification; otherwise the first right square bracket is the one that ends the conversion

specification. If a minus-sign (-) is in the scanlist and is not the first wide-character, nor the second where the first wide-character is a ^, nor the last wide-character, it indicates a range of characters to be matched.

c Matches a sequence of wide-characters of the number specified by the field width (1 if no field width is present in the conversion specification). If no l (ell) qualifier is present, wide-characters from the input field are converted as if by repeated calls to the `wcrtomb()` function, with the conversion state described by an `mbstate_t` object initialized to zero before the first wide-character is converted. The corresponding argument must be a pointer to a character array large enough to accept the sequence. No null character is added.

Otherwise, the corresponding argument must be a pointer to an array of `wchar_t` large enough to accept the sequence. No null wide-character is added.

p Matches the set of sequences that is the same as the set of sequences that is produced by the `%p` conversion of the corresponding `fwprintf(3C)` functions. The corresponding argument must be a pointer to a pointer to `void`. If the input item is a value converted earlier during the same program execution, the pointer that results will compare equal to that value; otherwise the behavior of the `%p` conversion is undefined.

n No input is consumed. The corresponding argument must be a pointer to the integer into which is to be written the number of wide-characters read from the input so far by this call to the `fwscanf()` functions. Execution of a `%n` conversion specification does not increment the assignment count returned at the completion of execution of the function.

C Same as `lc`.

S Same as `ls`.

% Matches a single `%`; no conversion or assignment occurs. The complete conversion specification must be `%%`.

If a conversion specification is invalid, the behavior is undefined.

The conversion characters `E`, `G`, and `X` are also valid and behave the same as, respectively, `e`, `g`, and `x`.

If end-of-file is encountered during input, conversion is terminated. If end-of-file occurs before any wide-characters matching the current conversion specification (except for `%n`) have been read (other than leading white-space, where permitted), execution of the current conversion specification terminates with an input failure. Otherwise, unless execution of the current conversion specification is terminated with a matching failure, execution of the following conversion specification (if any) is terminated with an input failure.

fwscanf(3C)

Reaching the end of the string in `swscanf()` is equivalent to encountering end-of-file for `fwscanf()`.

If conversion terminates on a conflicting input, the offending input is left unread in the input. Any trailing white space (including newline) is left unread unless matched by a conversion specification. The success of literal matches and suppressed assignments is only directly determinable via the `%n` conversion specification.

The `fwscanf()` and `wscanf()` functions may mark the `st_atime` field of the file associated with *stream* for update. The `st_atime` field will be marked for update by the first successful execution of `fgetc(3C)`, `fgetwc(3C)`, `fgets(3C)`, `fgetws(3C)`, `fread(3C)`, `getc(3C)`, `getwc(3C)`, `getchar(3C)`, `getwchar(3C)`, `gets(3C)`, `fscanf(3C)` or `fwscanf()` using *stream* that returns data not supplied by a prior call to `ungetc(3C)`.

RETURN VALUES

Upon successful completion, these functions return the number of successfully matched and assigned input items; this number can be 0 in the event of an early matching failure. If the input ends before the first matching failure or conversion, EOF is returned. If a read error occurs the error indicator for the stream is set, EOF is returned, and `errno` is set to indicate the error.

ERRORS

For the conditions under which the `fwscanf()` functions will fail and may fail, refer to `fgetwc(3C)`.

In addition, `fwscanf()` may fail if:

EILSEQ Input byte sequence does not form a valid character.

EINVAL There are insufficient arguments.

USAGE

In format strings containing the `%` form of conversion specifications, each argument in the argument list is used exactly once.

EXAMPLES

EXAMPLE 1 `wscanf()` example

The call:

```
int i, n; float x; char name[50];
n = wscanf(L"%d%f%s", &i, &x, name);
```

with the input line:

```
25 54.32E-1 Hamster
```

will assign to *n* the value 3, to *i* the value 25, to *x* the value 5.432, and *name* will contain the string Hamster.

The call:

```
int i; float x; char name[50];
(void) wscanf(L"%2d%f*d %[0123456789]", &i, &x, name);
```

with input:

EXAMPLE 1 wscanf () example (Continued)

56789 0123 56a72

will assign 56 to *i*, 789.0 to *x*, skip 0123, and place the string 56\0 in *name*. The next call to `getchar(3C)` will return the character *a*.

gconvert(3C)

NAME	<code>econvert</code> , <code>fconvert</code> , <code>gconvert</code> , <code>seconvert</code> , <code>sconvert</code> , <code>sgconvert</code> , <code>qeconvert</code> , <code>qfconvert</code> , <code>qgconvert</code> – output conversion
SYNOPSIS	<pre>#include <floatingpoint.h> char *econvert(double value, int ndigit, int *decpt, int *sign, char *buf) ; char *fconvert(double value, int ndigit, int *decpt, int *sign, char *buf) ; char *gconvert(double value, int ndigit, int trailing, char *buf) ; char *seconvert(single *value, int ndigit, int *decpt, int *sign, char *buf) ; char *sconvert(single *value, int ndigit, int *decpt, int *sign, char *buf) ; char *sgconvert(single *value, int ndigit, int trailing, char *buf) ; char *qeconvert(quadruple *value, int ndigit, int *decpt, int *sign, char *buf) ; char *qfconvert(quadruple *value, int ndigit, int *decpt, int *sign, char *buf) ; char *qgconvert(quadruple *value, int ndigit, int trailing, char *buf) ;</pre>
DESCRIPTION	<p>The <code>econvert()</code> function converts the <i>value</i> to a null-terminated string of <i>ndigit</i> ASCII digits in <i>buf</i> and returns a pointer to <i>buf</i>. <i>buf</i> should contain at least <i>ndigit</i>+1 characters. The position of the decimal point relative to the beginning of the string is stored indirectly through <i>decpt</i>. Thus <i>buf</i> == "314" and <i>*decpt</i> == 1 corresponds to the numerical value 3.14, while <i>buf</i> == "314" and <i>*decpt</i> == -1 corresponds to the numerical value .0314. If the sign of the result is negative, the word pointed to by <i>sign</i> is nonzero; otherwise it is zero. The least significant digit is rounded.</p> <p>The <code>fconvert()</code> function works much like <code>econvert()</code>, except that the correct digit has been rounded as if for <code>sprintf(%w.nf)</code> output with <i>n</i>=<i>ndigit</i> digits to the right of the decimal point. <i>ndigit</i> can be negative to indicate rounding to the left of the decimal point. The return value is a pointer to <i>buf</i>. <i>buf</i> should contain at least <code>310+max(0,ndigit)</code> characters to accomodate any double-precision <i>value</i>.</p> <p>The <code>gconvert()</code> function converts the <i>value</i> to a null-terminated ASCII string in <i>buf</i> and returns a pointer to <i>buf</i>. It produces <i>ndigit</i> significant digits in fixed-decimal format, like <code>sprintf(%w.nf)</code>, if possible, and otherwise in floating-decimal format, like <code>sprintf(%w.ne)</code>; in either case <i>buf</i> is ready for printing, with sign and exponent. The result corresponds to that obtained by</p> <pre>(void) sprintf(buf, ``%w.ng'', value) ;</pre> <p>If <i>trailing</i> = 0, trailing zeros and a trailing point are suppressed, as in <code>sprintf(%g)</code>. If <i>trailing</i> != 0, trailing zeros and a trailing point are retained, as in <code>sprintf(%#g)</code>.</p>

The `seconvert()`, `sfconvert()`, and `sgconvert()` functions are single-precision versions of these functions, and are more efficient than the corresponding double-precision versions. A pointer rather than the value itself is passed to avoid C's usual conversion of single-precision arguments to double.

The `geconvert()`, `qfconvert()`, and `ggconvert()` functions are quadruple-precision versions of these functions. The `qfconvert()` function can overflow the `decimal_record` field `ds` if `value` is too large. In that case, `buf[0]` is set to zero.

The `ecvt()`, `fcvt()` and `gcvt()` functions are versions of `econvert()`, `fconvert()`, and `gconvert()`, respectively, that are documented on the `ecvt(3C)` manual page. They constitute the default implementation of these functions and conform to the X/Open CAE Specification, System Interfaces and Headers, Issue 4, Version 2.

USAGE IEEE Infinities and NaNs are treated similarly by these functions. "NaN" is returned for NaN, and "Inf" or "Infinity" for Infinity. The longer form is produced when `ndigit` \geq 8.

gcv(3C)

NAME	ecvt, fcvt, gcv – convert floating-point number to string
SYNOPSIS	<pre>#include <stdlib.h> char *ecvt(double value, int ndigit, int *decpt, int *sign); char *fcvt(double value, int ndigit, int *decpt, int *sign); char *gcv(double value, int ndigit, char *buf);</pre>
DESCRIPTION	<p>The <code>ecvt()</code>, <code>fcvt()</code> and <code>gcv()</code> functions convert floating-point numbers to null-terminated strings.</p> <p><code>ecvt()</code> The <code>ecvt()</code> function converts <i>value</i> to a null-terminated string of <i>ndigit</i> digits (where <i>ndigit</i> is reduced to an unspecified limit determined by the precision of a <code>double</code>) and returns a pointer to the string. The high-order digit is non-zero, unless the value is 0. The low-order digit is rounded. The position of the radix character relative to the beginning of the string is stored in the integer pointed to by <i>decpt</i> (negative means to the left of the returned digits). The radix character is not included in the returned string. If the sign of the result is negative, the integer pointed to by <i>sign</i> is non-zero, otherwise it is 0.</p> <p>If the converted value is out of range or is not representable, the contents of the returned string are unspecified.</p> <p><code>fcvt()</code> The <code>fcvt()</code> function is identical to <code>ecvt()</code> except that <i>ndigit</i> specifies the number of digits desired after the radix point. The total number of digits in the result string is restricted to an unspecified limit as determined by the precision of a <code>double</code>.</p> <p><code>gcv()</code> The <code>gcv()</code> function converts <i>value</i> to a null-terminated string (similar to that of the <code>%g</code> format of <code>printf(3C)</code>) in the array pointed to by <i>buf</i> and returns <i>buf</i>. It produces <i>ndigit</i> significant digits (limited to an unspecified value determined by the precision of a <code>double</code>) in <code>%f</code> if possible, or <code>%e</code> (scientific notation) otherwise. A minus sign is included in the returned string if <i>value</i> is less than 0. A radix character is included in the returned string if <i>value</i> is not a whole number. Trailing zeros are suppressed where <i>value</i> is not a whole number. The radix character is determined by the current locale. If <code>setlocale(3C)</code> has not been called successfully, the default locale, <code>POSIX</code>, is used. The default locale specifies a period (<code>.</code>) as the radix character. The <code>LC_NUMERIC</code> category determines the value of the radix character within the current locale.</p>
RETURN VALUES	<p>The <code>ecvt()</code> and <code>fcvt()</code> functions return a pointer to a null-terminated string of digits.</p> <p>The <code>gcv()</code> function returns <i>buf</i>.</p>
ERRORS	No errors are defined.
USAGE	<p>The return values from <code>ecvt()</code> and <code>fcvt()</code> may point to static data which may be overwritten by subsequent calls to these functions.</p> <p>For portability to implementations conforming to earlier versions of this document, <code>sprintf(3C)</code> is preferred over this function.</p>

getc(3C)

NAME	<code>fgetc</code> , <code>getc</code> , <code>getc_unlocked</code> , <code>getchar</code> , <code>getchar_unlocked</code> , <code>getw</code> – get a byte from a stream
SYNOPSIS	<pre>#include <stdio.h> int fgetc(FILE *stream); int getc(FILE *stream); int getc_unlocked(FILE *stream); int getchar(void); int getchar_unlocked(void); int getw(FILE *stream);</pre>
DESCRIPTION	<p>The <code>fgetc()</code> function obtains the next byte (if present) as an unsigned char converted to an <code>int</code>, from the input stream pointed to by <i>stream</i>, and advances the associated file position indicator for the stream (if defined).</p> <p>The <code>fgetc()</code> function may mark the <code>st_atime</code> field of the file associated with <i>stream</i> for update. The <code>st_atime</code> field will be marked for update by the first successful execution of <code>fgetc()</code>, <code>fgets(3C)</code>, <code>fgetwc(3C)</code>, <code>fgetws(3C)</code>, <code>fread(3C)</code>, <code>fscanf(3C)</code>, <code>getc()</code>, <code>getchar()</code>, <code>gets(3C)</code> or <code>scanf(3C)</code> using <i>stream</i> that returns data not supplied by a prior call to <code>ungetc(3C)</code> or <code>ungetwc(3C)</code>.</p> <p>The <code>getc()</code> routine is functionally identical to <code>fgetc()</code>, except that it is implemented as a macro. It runs faster than <code>fgetc()</code>, but it takes up more space per invocation and its name cannot be passed as an argument to a function call.</p> <p>The <code>getchar()</code> routine is equivalent to <code>getc(stdin)</code>. It is implemented as a macro.</p> <p>The <code>getc_unlocked()</code> and <code>getchar_unlocked()</code> routines are variants of <code>getc()</code> and <code>getchar()</code>, respectively, that do not lock the stream. It is the caller's responsibility to acquire the stream lock before calling these routines and releasing the lock afterwards; see <code>flockfile(3C)</code> and <code>stdio(3C)</code>. These routines are implemented as macros.</p> <p>The <code>getw()</code> function reads the next word from the <i>stream</i>. The size of a word is the size of an <code>int</code> and may vary from environment to environment. The <code>getw()</code> function presumes no special alignment in the file.</p> <p>The <code>getw()</code> function may mark the <code>st_atime</code> field of the file associated with <i>stream</i> for update. The <code>st_atime</code> field will be marked for update by the first successful execution of <code>fgetc()</code>, <code>fgets(3C)</code>, <code>fread(3C)</code>, <code>getc()</code>, <code>getchar()</code>, <code>gets(3C)</code>, <code>fscanf(3C)</code> or <code>scanf(3C)</code> using <i>stream</i> that returns data not supplied by a prior call to <code>ungetc(3C)</code>.</p>
RETURN VALUES	Upon successful completion, <code>fgetc()</code> , <code>getc()</code> , <code>getc_unlocked()</code> , <code>getchar()</code> , <code>getchar_unlocked()</code> , and <code>getw()</code> return the next byte from the input stream pointed to by <i>stream</i> . If the stream is at end-of-file, the end-of-file indicator for the stream is set and these functions return EOF. If a read error occurs, the error indicator for the stream is set, EOF is returned, and <code>errno</code> is set to indicate the error.

ERRORS	<p>The <code>fgetc()</code>, <code>getc()</code>, <code>getc_unlocked()</code>, <code>getchar()</code>, <code>getchar_unlocked()</code>, and <code>getw()</code> functions will fail if data needs to be read and:</p> <p>EAGAIN The <code>O_NONBLOCK</code> flag is set for the file descriptor underlying <i>stream</i> and the process would be delayed in the <code>fgetc()</code> operation.</p> <p>EBADF The file descriptor underlying <i>stream</i> is not a valid file descriptor open for reading.</p> <p>EINTR The read operation was terminated due to the receipt of a signal, and no data was transferred.</p> <p>EIO A physical I/O error has occurred, or the process is in a background process group attempting to read from its controlling terminal, and either the process is ignoring or blocking the <code>SIGTTIN</code> signal or the process group is orphaned. This error may also be generated for implementation-dependent reasons.</p> <p>EOVERFLOW The file is a regular file and an attempt was made to read at or beyond the offset maximum associated with the corresponding stream.</p> <p>The <code>fgetc()</code>, <code>getc()</code>, <code>getc_unlocked()</code>, <code>getchar()</code>, <code>getchar_unlocked()</code>, and <code>getw()</code> functions may fail if:</p> <p>ENOMEM Insufficient storage space is available.</p> <p>ENXIO A request was made of a non-existent device, or the request was outside the capabilities of the device.</p>
USAGE	<p>If the integer value returned by <code>fgetc()</code>, <code>getc()</code>, <code>getc_unlocked()</code>, <code>getchar()</code>, <code>getchar_unlocked()</code>, and <code>getw()</code> is stored into a variable of type <code>char</code> and then compared against the integer constant <code>EOF</code>, the comparison may never succeed, because sign-extension of a variable of type <code>char</code> on widening to integer is implementation-dependent.</p> <p>The <code>ferror(3C)</code> or <code>feof(3C)</code> functions must be used to distinguish between an error condition and an end-of-file condition.</p> <p>Functions exist for the <code>getc()</code>, <code>getc_unlocked()</code>, <code>getchar()</code>, and <code>getchar_unlocked()</code> macros. To get the function form, the macro name must be undefined (for example, <code>#undef getc</code>).</p> <p>When the macro forms are used, <code>getc()</code> and <code>getc_unlocked()</code> evaluate the <i>stream</i> argument more than once. In particular, <code>getc(*f++)</code>; does not work sensibly. The <code>fgetc()</code> function should be used instead when evaluating the <i>stream</i> argument has side effects.</p> <p>Because of possible differences in word length and byte ordering, files written using <code>getw()</code> are machine-dependent, and may not be read using <code>getw()</code> on a different processor.</p>

getc(3C)

The `getw()` function is inherently byte stream-oriented and is not tenable in the context of either multibyte character streams or wide-character streams. Application programmers are recommended to use one of the character-based input functions instead.

NOTES The `fgetc()`, `getc()`, `getchar()`, and `getw()` routines are MT-Safe in multithreaded applications. The `getc_unlocked()` and `getchar_unlocked()` routines are unsafe in multithreaded applications.

NAME	fgetc, getc, getc_unlocked, getchar, getchar_unlocked, getw – get a byte from a stream
SYNOPSIS	<pre>#include <stdio.h> int fgetc(FILE *stream); int getc(FILE *stream); int getc_unlocked(FILE *stream); int getchar(void); int getchar_unlocked(void); int getw(FILE *stream);</pre>
DESCRIPTION	<p>The <code>fgetc()</code> function obtains the next byte (if present) as an unsigned char converted to an int, from the input stream pointed to by <i>stream</i>, and advances the associated file position indicator for the stream (if defined).</p> <p>The <code>fgetc()</code> function may mark the <code>st_atime</code> field of the file associated with <i>stream</i> for update. The <code>st_atime</code> field will be marked for update by the first successful execution of <code>fgetc()</code>, <code>fgets(3C)</code>, <code>fgetwc(3C)</code>, <code>fgetws(3C)</code>, <code>fread(3C)</code>, <code>fscanf(3C)</code>, <code>getc()</code>, <code>getchar()</code>, <code>gets(3C)</code> or <code>scanf(3C)</code> using <i>stream</i> that returns data not supplied by a prior call to <code>ungetc(3C)</code> or <code>ungetwc(3C)</code>.</p> <p>The <code>getc()</code> routine is functionally identical to <code>fgetc()</code>, except that it is implemented as a macro. It runs faster than <code>fgetc()</code>, but it takes up more space per invocation and its name cannot be passed as an argument to a function call.</p> <p>The <code>getchar()</code> routine is equivalent to <code>getc(stdin)</code>. It is implemented as a macro.</p> <p>The <code>getc_unlocked()</code> and <code>getchar_unlocked()</code> routines are variants of <code>getc()</code> and <code>getchar()</code>, respectively, that do not lock the stream. It is the caller's responsibility to acquire the stream lock before calling these routines and releasing the lock afterwards; see <code>flockfile(3C)</code> and <code>stdio(3C)</code>. These routines are implemented as macros.</p> <p>The <code>getw()</code> function reads the next word from the <i>stream</i>. The size of a word is the size of an int and may vary from environment to environment. The <code>getw()</code> function presumes no special alignment in the file.</p> <p>The <code>getw()</code> function may mark the <code>st_atime</code> field of the file associated with <i>stream</i> for update. The <code>st_atime</code> field will be marked for update by the first successful execution of <code>fgetc()</code>, <code>fgets(3C)</code>, <code>fread(3C)</code>, <code>getc()</code>, <code>getchar()</code>, <code>gets(3C)</code>, <code>fscanf(3C)</code> or <code>scanf(3C)</code> using <i>stream</i> that returns data not supplied by a prior call to <code>ungetc(3C)</code>.</p>
RETURN VALUES	<p>Upon successful completion, <code>fgetc()</code>, <code>getc()</code>, <code>getc_unlocked()</code>, <code>getchar()</code>, <code>getchar_unlocked()</code>, and <code>getw()</code> return the next byte from the input stream pointed to by <i>stream</i>. If the stream is at end-of-file, the end-of-file indicator for the stream is set and these functions return EOF. If a read error occurs, the error indicator for the stream is set, EOF is returned, and <code>errno</code> is set to indicate the error.</p>

getchar(3C)

ERRORS	<p>The <code>fgetc()</code>, <code>getc()</code>, <code>getc_unlocked()</code>, <code>getchar()</code>, <code>getchar_unlocked()</code>, and <code>getw()</code> functions will fail if data needs to be read and:</p> <p>EAGAIN The <code>O_NONBLOCK</code> flag is set for the file descriptor underlying <i>stream</i> and the process would be delayed in the <code>fgetc()</code> operation.</p> <p>EBADF The file descriptor underlying <i>stream</i> is not a valid file descriptor open for reading.</p> <p>EINTR The read operation was terminated due to the receipt of a signal, and no data was transferred.</p> <p>EIO A physical I/O error has occurred, or the process is in a background process group attempting to read from its controlling terminal, and either the process is ignoring or blocking the <code>SIGTTIN</code> signal or the process group is orphaned. This error may also be generated for implementation-dependent reasons.</p> <p>EOVERFLOW The file is a regular file and an attempt was made to read at or beyond the offset maximum associated with the corresponding stream.</p> <p>The <code>fgetc()</code>, <code>getc()</code>, <code>getc_unlocked()</code>, <code>getchar()</code>, <code>getchar_unlocked()</code>, and <code>getw()</code> functions may fail if:</p> <p>ENOMEM Insufficient storage space is available.</p> <p>ENXIO A request was made of a non-existent device, or the request was outside the capabilities of the device.</p>
USAGE	<p>If the integer value returned by <code>fgetc()</code>, <code>getc()</code>, <code>getc_unlocked()</code>, <code>getchar()</code>, <code>getchar_unlocked()</code>, and <code>getw()</code> is stored into a variable of type <code>char</code> and then compared against the integer constant <code>EOF</code>, the comparison may never succeed, because sign-extension of a variable of type <code>char</code> on widening to integer is implementation-dependent.</p> <p>The <code>ferror(3C)</code> or <code>feof(3C)</code> functions must be used to distinguish between an error condition and an end-of-file condition.</p> <p>Functions exist for the <code>getc()</code>, <code>getc_unlocked()</code>, <code>getchar()</code>, and <code>getchar_unlocked()</code> macros. To get the function form, the macro name must be undefined (for example, <code>#undef getc</code>).</p> <p>When the macro forms are used, <code>getc()</code> and <code>getc_unlocked()</code> evaluate the <i>stream</i> argument more than once. In particular, <code>getc(*f++)</code>; does not work sensibly. The <code>fgetc()</code> function should be used instead when evaluating the <i>stream</i> argument has side effects.</p> <p>Because of possible differences in word length and byte ordering, files written using <code>getw()</code> are machine-dependent, and may not be read using <code>getw()</code> on a different processor.</p>

getchar(3C)

The `getw()` function is inherently byte stream-oriented and is not tenable in the context of either multibyte character streams or wide-character streams. Application programmers are recommended to use one of the character-based input functions instead.

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
MT-Level	See NOTES below.

SEE ALSO `intro(3)`, `fclose(3C)`, `feof(3C)`, `fgets(3C)`, `fgetwc(3C)`, `fgetws(3C)`, `flockfile(3C)`, `fopen(3C)`, `fread(3C)`, `fscanf(3C)`, `gets(3C)`, `putc(3C)`, `scanf(3C)`, `stdio(3C)`, `ungetc(3C)`, `ungetwc(3C)`, `attributes(5)`

NOTES The `fgetc()`, `getc()`, `getchar()`, and `getw()` routines are MT-Safe in multithreaded applications. The `getc_unlocked()` and `getchar_unlocked()` routines are unsafe in multithreaded applications.

getchar_unlocked(3C)

NAME	<code>fgetc</code> , <code>getc</code> , <code>getc_unlocked</code> , <code>getchar</code> , <code>getchar_unlocked</code> , <code>getw</code> – get a byte from a stream
SYNOPSIS	<pre>#include <stdio.h> int fgetc(FILE *<i>stream</i>) ; int getc(FILE *<i>stream</i>) ; int getc_unlocked(FILE *<i>stream</i>) ; int getchar(void) ; int getchar_unlocked(void) ; int getw(FILE *<i>stream</i>) ;</pre>
DESCRIPTION	<p>The <code>fgetc()</code> function obtains the next byte (if present) as an unsigned char converted to an <code>int</code>, from the input stream pointed to by <i>stream</i>, and advances the associated file position indicator for the stream (if defined).</p> <p>The <code>fgetc()</code> function may mark the <code>st_atime</code> field of the file associated with <i>stream</i> for update. The <code>st_atime</code> field will be marked for update by the first successful execution of <code>fgetc()</code>, <code>fgets(3C)</code>, <code>fgetwc(3C)</code>, <code>fgetws(3C)</code>, <code>fread(3C)</code>, <code>fscanf(3C)</code>, <code>getc()</code>, <code>getchar()</code>, <code>gets(3C)</code> or <code>scanf(3C)</code> using <i>stream</i> that returns data not supplied by a prior call to <code>ungetc(3C)</code> or <code>ungetwc(3C)</code>.</p> <p>The <code>getc()</code> routine is functionally identical to <code>fgetc()</code>, except that it is implemented as a macro. It runs faster than <code>fgetc()</code>, but it takes up more space per invocation and its name cannot be passed as an argument to a function call.</p> <p>The <code>getchar()</code> routine is equivalent to <code>getc(stdin)</code>. It is implemented as a macro.</p> <p>The <code>getc_unlocked()</code> and <code>getchar_unlocked()</code> routines are variants of <code>getc()</code> and <code>getchar()</code>, respectively, that do not lock the stream. It is the caller's responsibility to acquire the stream lock before calling these routines and releasing the lock afterwards; see <code>flockfile(3C)</code> and <code>stdio(3C)</code>. These routines are implemented as macros.</p> <p>The <code>getw()</code> function reads the next word from the <i>stream</i>. The size of a word is the size of an <code>int</code> and may vary from environment to environment. The <code>getw()</code> function presumes no special alignment in the file.</p> <p>The <code>getw()</code> function may mark the <code>st_atime</code> field of the file associated with <i>stream</i> for update. The <code>st_atime</code> field will be marked for update by the first successful execution of <code>fgetc()</code>, <code>fgets(3C)</code>, <code>fread(3C)</code>, <code>getc()</code>, <code>getchar()</code>, <code>gets(3C)</code>, <code>fscanf(3C)</code> or <code>scanf(3C)</code> using <i>stream</i> that returns data not supplied by a prior call to <code>ungetc(3C)</code>.</p>
RETURN VALUES	Upon successful completion, <code>fgetc()</code> , <code>getc()</code> , <code>getc_unlocked()</code> , <code>getchar()</code> , <code>getchar_unlocked()</code> , and <code>getw()</code> return the next byte from the input stream pointed to by <i>stream</i> . If the stream is at end-of-file, the end-of-file indicator for the stream is set and these functions return EOF. If a read error occurs, the error indicator for the stream is set, EOF is returned, and <code>errno</code> is set to indicate the error.

ERRORS	<p>The <code>fgetc()</code>, <code>getc()</code>, <code>getc_unlocked()</code>, <code>getchar()</code>, <code>getchar_unlocked()</code>, and <code>getw()</code> functions will fail if data needs to be read and:</p> <p>EAGAIN The <code>O_NONBLOCK</code> flag is set for the file descriptor underlying <i>stream</i> and the process would be delayed in the <code>fgetc()</code> operation.</p> <p>EBADF The file descriptor underlying <i>stream</i> is not a valid file descriptor open for reading.</p> <p>EINTR The read operation was terminated due to the receipt of a signal, and no data was transferred.</p> <p>EIO A physical I/O error has occurred, or the process is in a background process group attempting to read from its controlling terminal, and either the process is ignoring or blocking the <code>SIGTTIN</code> signal or the process group is orphaned. This error may also be generated for implementation-dependent reasons.</p> <p>EOVERFLOW The file is a regular file and an attempt was made to read at or beyond the offset maximum associated with the corresponding stream.</p> <p>The <code>fgetc()</code>, <code>getc()</code>, <code>getc_unlocked()</code>, <code>getchar()</code>, <code>getchar_unlocked()</code>, and <code>getw()</code> functions may fail if:</p> <p>ENOMEM Insufficient storage space is available.</p> <p>ENXIO A request was made of a non-existent device, or the request was outside the capabilities of the device.</p>
USAGE	<p>If the integer value returned by <code>fgetc()</code>, <code>getc()</code>, <code>getc_unlocked()</code>, <code>getchar()</code>, <code>getchar_unlocked()</code>, and <code>getw()</code> is stored into a variable of type <code>char</code> and then compared against the integer constant <code>EOF</code>, the comparison may never succeed, because sign-extension of a variable of type <code>char</code> on widening to integer is implementation-dependent.</p> <p>The <code>ferror(3C)</code> or <code>feof(3C)</code> functions must be used to distinguish between an error condition and an end-of-file condition.</p> <p>Functions exist for the <code>getc()</code>, <code>getc_unlocked()</code>, <code>getchar()</code>, and <code>getchar_unlocked()</code> macros. To get the function form, the macro name must be undefined (for example, <code>#undef getc</code>).</p> <p>When the macro forms are used, <code>getc()</code> and <code>getc_unlocked()</code> evaluate the <i>stream</i> argument more than once. In particular, <code>getc(*f++)</code>; does not work sensibly. The <code>fgetc()</code> function should be used instead when evaluating the <i>stream</i> argument has side effects.</p> <p>Because of possible differences in word length and byte ordering, files written using <code>getw()</code> are machine-dependent, and may not be read using <code>getw()</code> on a different processor.</p>

getchar_unlocked(3C)

The `getw()` function is inherently byte stream-oriented and is not tenable in the context of either multibyte character streams or wide-character streams. Application programmers are recommended to use one of the character-based input functions instead.

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
MT-Level	See NOTES below.

NOTES The `fgetc()`, `getc()`, `getchar()`, and `getw()` routines are MT-Safe in multithreaded applications. The `getc_unlocked()` and `getchar_unlocked()` routines are unsafe in multithreaded applications.

NAME	getcpuid, gethomelgroup – obtain information on scheduling decisions
SYNOPSIS	<pre>#include <sys/processor.h> processorid_t getcpuid(void); lgrp_t gethomelgroup(void);</pre>
DESCRIPTION	<p>The <code>getcpuid()</code> function returns the processor ID on which the calling thread is currently executing.</p> <p>The <code>gethomelgroup()</code> function returns the home latency group ID of the calling thread.</p>
RETURN VALUES	See <code>DESCRIPTION</code> .
ERRORS	No errors are defined.
USAGE	Both the current CPU and the home latency group are subject to change at any time, so the value returned by these functions might already be incorrect upon completion of the call.
ATTRIBUTES	See <code>attributes(5)</code> for descriptions of the following attributes:

NOTES The `fgetc()`, `getc()`, `getchar()`, and `getw()` routines are MT-Safe in multithreaded applications. The `getc_unlocked()` and `getchar_unlocked()` routines are unsafe in multithreaded applications.

NAME	getcwd – get pathname of current working directory								
SYNOPSIS	<pre>#include <unistd.h> char *getcwd(char *buf, size_t size);</pre>								
DESCRIPTION	<p>The <code>getcwd()</code> function places an absolute pathname of the current working directory in the array pointed to by <i>buf</i>, and returns <i>buf</i>. The <i>size</i> argument is the size in bytes of the character array pointed to by <i>buf</i> and must be at least one greater than the length of the pathname to be returned.</p> <p>If <i>buf</i> is not a null pointer, the pathname is stored in the space pointed to by <i>buf</i>.</p> <p>If <i>buf</i> is a null pointer, <code>getcwd()</code> obtains <i>size</i> bytes of space using <code>malloc(3C)</code>. The pointer returned by <code>getcwd()</code> can be used as the argument in a subsequent call to <code>free()</code>.</p>								
RETURN VALUES	Upon successful completion, <code>getcwd()</code> returns the <i>buf</i> argument. Otherwise, the function returns a null pointer and sets <code>errno</code> to indicate the error.								
ERRORS	<p>The <code>getcwd()</code> function will fail if:</p> <table border="0"> <tr> <td style="padding-right: 20px;">EINVAL</td> <td>The <i>size</i> argument is equal to 0.</td> </tr> <tr> <td>ERANGE</td> <td>The <i>size</i> argument is greater than 0 and less than the length of the pathname plus 1.</td> </tr> </table> <p>The <code>getcwd()</code> function may fail if:</p> <table border="0"> <tr> <td style="padding-right: 20px;">EACCES</td> <td>A parent directory cannot be read to get its name.</td> </tr> <tr> <td>ENOMEM</td> <td>Insufficient storage space is available.</td> </tr> </table>	EINVAL	The <i>size</i> argument is equal to 0.	ERANGE	The <i>size</i> argument is greater than 0 and less than the length of the pathname plus 1.	EACCES	A parent directory cannot be read to get its name.	ENOMEM	Insufficient storage space is available.
EINVAL	The <i>size</i> argument is equal to 0.								
ERANGE	The <i>size</i> argument is greater than 0 and less than the length of the pathname plus 1.								
EACCES	A parent directory cannot be read to get its name.								
ENOMEM	Insufficient storage space is available.								
USAGE	Applications should exercise care when using <code>chdir(2)</code> in conjunction with <code>getcwd()</code> . The current working directory is global to all threads within a process. If more than one thread calls <code>chdir()</code> to change the working directory, a subsequent call to <code>getcwd()</code> could produce unexpected results.								
EXAMPLES	<p>EXAMPLE 1 Printing the current working directory</p> <p>The following example prints the current working directory.</p> <pre>#include <unistd.h> #include <stdio.h> main() { char *cwd; if ((cwd = getcwd(NULL, 64)) == NULL) { perror("pwd"); exit(2); } (void)printf("%s\n", cwd); return(0); }</pre>								

getcwd(3C)

NAME	getdate – convert user format date and time																														
SYNOPSIS	<pre>#include <time.h> struct tm *getdate(const char *string); extern int getdate_err;</pre>																														
DESCRIPTION	<p>The <code>getdate()</code> function converts user-definable date and/or time specifications pointed to by <i>string</i> to a <code>tm</code> structure. The <code>tm</code> structure is defined in the <code><time.h></code> header.</p> <p>User-supplied templates are used to parse and interpret the input string. The templates are text files created by the user and identified via the environment variable <code>DATEMSK</code>. Each line in the template represents an acceptable date and/or time specification using conversion specifications similar to those used by <code>strptime(3C)</code> and <code>strptime(3C)</code>. Dates before 1902 and after 2037 are illegal. The first line in the template that matches the input specification is used for interpretation and conversion into the internal time format.</p>																														
Conversion Specifications	<p>The following conversion specifications are supported:</p> <table border="0"> <tr> <td style="padding-right: 20px;">%%</td> <td>Same as %.</td> </tr> <tr> <td>%a</td> <td>Locale's abbreviated weekday name.</td> </tr> <tr> <td>%A</td> <td>Locale's full weekday name.</td> </tr> <tr> <td>%b</td> <td>Locale's abbreviated month name.</td> </tr> <tr> <td>%B</td> <td>Locale's full month name.</td> </tr> <tr> <td>%c</td> <td>Locale's appropriate date and time representation.</td> </tr> <tr> <td>%C</td> <td>Century number (the year divided by 100 and truncated to an integer as a decimal number [1,99]); single digits are preceded by 0; see <code>standards(5)</code>. If used without the %y specifier, this format specifier will assume the current year offset in whichever century is specified. The only valid years are between 1902-2037.</td> </tr> <tr> <td>%d</td> <td>day of month [01,31]; leading zero is permitted but not required.</td> </tr> <tr> <td>%D</td> <td>Date as %m/%d/%y.</td> </tr> <tr> <td>%e</td> <td>Same as %d.</td> </tr> <tr> <td>%h</td> <td>Locale's abbreviated month name.</td> </tr> <tr> <td>%H</td> <td>Hour (24-hour clock) [0,23]; leading zero is permitted but not required.</td> </tr> <tr> <td>%I</td> <td>Hour (12-hour clock) [1,12]; leading zero is permitted but not required.</td> </tr> <tr> <td>%j</td> <td>Day number of the year [1,366]; leading zeros are permitted but not required.</td> </tr> <tr> <td>%m</td> <td>Month number [1,12]; leading zero is permitted but not required.</td> </tr> </table>	%%	Same as %.	%a	Locale's abbreviated weekday name.	%A	Locale's full weekday name.	%b	Locale's abbreviated month name.	%B	Locale's full month name.	%c	Locale's appropriate date and time representation.	%C	Century number (the year divided by 100 and truncated to an integer as a decimal number [1,99]); single digits are preceded by 0; see <code>standards(5)</code> . If used without the %y specifier, this format specifier will assume the current year offset in whichever century is specified. The only valid years are between 1902-2037.	%d	day of month [01,31]; leading zero is permitted but not required.	%D	Date as %m/%d/%y.	%e	Same as %d.	%h	Locale's abbreviated month name.	%H	Hour (24-hour clock) [0,23]; leading zero is permitted but not required.	%I	Hour (12-hour clock) [1,12]; leading zero is permitted but not required.	%j	Day number of the year [1,366]; leading zeros are permitted but not required.	%m	Month number [1,12]; leading zero is permitted but not required.
%%	Same as %.																														
%a	Locale's abbreviated weekday name.																														
%A	Locale's full weekday name.																														
%b	Locale's abbreviated month name.																														
%B	Locale's full month name.																														
%c	Locale's appropriate date and time representation.																														
%C	Century number (the year divided by 100 and truncated to an integer as a decimal number [1,99]); single digits are preceded by 0; see <code>standards(5)</code> . If used without the %y specifier, this format specifier will assume the current year offset in whichever century is specified. The only valid years are between 1902-2037.																														
%d	day of month [01,31]; leading zero is permitted but not required.																														
%D	Date as %m/%d/%y.																														
%e	Same as %d.																														
%h	Locale's abbreviated month name.																														
%H	Hour (24-hour clock) [0,23]; leading zero is permitted but not required.																														
%I	Hour (12-hour clock) [1,12]; leading zero is permitted but not required.																														
%j	Day number of the year [1,366]; leading zeros are permitted but not required.																														
%m	Month number [1,12]; leading zero is permitted but not required.																														

getdate(3C)

%M	Minute [0,59]; leading zero is permitted but not required.
%n	Any white space.
%p	Locale's equivalent of either a.m. or p.m.
%r	Appropriate time representation in the 12-hour clock format with %p.
%R	Time as %H:%M.
%S	Seconds [0,61]; leading zero is permitted but not required. The range of values is [00,61] rather than [00,59] to allow for the occasional leap second and even more occasional double leap second.
%t	Any white space.
%T	Time as %H:%M:%S.
%U	Week number of the year as a decimal number [0,53], with Sunday as the first day of the week; leading zero is permitted but not required.
%w	Weekday as a decimal number [0,6], with 0 representing Sunday.
%W	Week number of the year as a decimal number [0,53], with Monday as the first day of the week; leading zero is permitted but not required.
%x	Locale's appropriate date representation.
%X	Locale's appropriate time representation.
%y	Year within century. When a century is not otherwise specified, values in the range 69-99 refer to years in the twentieth century (1969 to 1999 inclusive); values in the range 00-68 refer to years in the twenty-first century (2000 to 2068 inclusive).
%Y	Year, including the century (for example, 1993).
%Z	Time zone name or no characters if no time zone exists.

Modified Conversion Specifications

Some conversion specifications can be modified by the E and O modifier characters to indicate that an alternative format or specification should be used rather than the one normally used by the unmodified specification. If the alternative format or specification does not exist in the current locale, the behavior be as if the unmodified conversion specification were used.

%Ec	Locale's alternative appropriate date and time representation.
%EC	Name of the base year (period) in the locale's alternative representation.
%Ex	Locale's alternative date representation.
%EX	Locale's alternative time representation.
%Ey	Offset from %EC (year only) in the locale's alternative representation.
%EY	Full alternative year representation.

%Od	Day of the month using the locale's alternative numeric symbols; leading zeros are permitted but not required.
%Oe	Same as %Od.
%OH	Hour (24-hour clock) using the locale's alternative numeric symbols.
%OI	Hour (12-hour clock) using the locale's alternative numeric symbols.
%Om	Month using the locale's alternative numeric symbols.
%OM	Minutes using the locale's alternative numeric symbols.
%OS	Seconds using the locale's alternative numeric symbols.
%OU	Week number of the year (Sunday as the first day of the week) using the locale's alternative numeric symbols.
%Ow	Number of the weekday (Sunday=0) using the locale's alternative numeric symbols.
%OW	Week number of the year (Monday as the first day of the week) using the locale's alternative numeric symbols.
%Oy	Year (offset from %C) in the locale's alternative representation and using the locale's alternative numeric symbols.

Internal Format Conversion

The following rules are applied for converting the input specification into the internal format:

- If only the weekday is given, today is assumed if the given day is equal to the current day and next week if it is less.
- If only the month is given, the current month is assumed if the given month is equal to the current month and next year if it is less and no year is given. (The first day of month is assumed if no day is given.)
- If only the year is given, the values of the `tm_mon`, `tm_mday`, `tm_yday`, `tm_wday`, and `tm_isdst` members of the returned `tm` structure are not specified.
- If the century is given, but the year within the century is not given, the current year within the century is assumed.
- If no hour, minute, and second are given, the current hour, minute, and second are assumed.
- If no date is given, today is assumed if the given hour is greater than the current hour and tomorrow is assumed if it is less.

General Specifications

A conversion specification that is an ordinary character is executed by scanning the next character from the buffer. If the character scanned from the buffer differs from the one comprising the conversion specification, the specification fails, and the differing and subsequent characters remain unscanned.

getdate(3C)

A series of conversion specifications composed of `%n`, `%t`, white space characters, or any combination is executed by scanning up to the first character that is not white space (which remains unscanned), or until no more characters can be scanned.

Any other conversion specification is executed by scanning characters until a character matching the next conversion specification is scanned, or until no more characters can be scanned. These characters, except the one matching the next conversion specification, are then compared to the locale values associated with the conversion specifier. If a match is found, values for the appropriate *tm* structure members are set to values corresponding to the locale information. If no match is found, `getdate()` fails and no more characters are scanned.

The month names, weekday names, era names, and alternative numeric symbols can consist of any combination of upper and lower case letters. The user can request that the input date or time specification be in a specific language by setting the `LC_TIME` category using `setlocale(3C)`.

RETURN VALUES

If successful, `getdate()` returns a pointer to a *tm* structure; otherwise, it returns `NULL` and sets the global variable `getdate_err` to indicate the error. Subsequent calls to `getdate()` alter the contents of `getdate_err`.

The following is a complete list of the `getdate_err` settings and their meanings:

- 1 The `DATETIME` environment variable is null or undefined.
- 2 The template file cannot be opened for reading.
- 3 Failed to get file status information.
- 4 The template file is not a regular file.
- 5 An error is encountered while reading the template file.
- 6 The `malloc()` function failed (not enough memory is available).
- 7 There is no line in the template that matches the input.
- 8 The input specification is invalid (for example, February 31).

USAGE

The `getdate()` function makes explicit use of macros described on the `ctype(3C)` manual page.

EXAMPLES

EXAMPLE 1 Examples of the `getdate()` function.

The following example shows the possible contents of a template:

```
%m
%A %B %d %Y, %H:%M:%S
%A
%B
%m/%d/%y %I %p
%d, %m, %Y %H:%M
at %A the %dst of %B in %Y
```

EXAMPLE 1 Examples of the `getdate()` function. (Continued)

```
run job at %I %p,%B %dnd
%A den %d. %B %Y %H.%M Uhr
```

The following are examples of valid input specifications for the above template:

```
getdate("10/1/87 4 PM")
getdate("Friday")
getdate("Friday September 19 1987, 10:30:30")
getdate("24,9,1986 10:30")
getdate("at monday the 1st of december in 1986")
getdate("run job at 3 PM, december 2nd")
```

If the `LANG` environment variable is set to `de` (German), the following is valid:

```
getdate("freitag den 10. oktober 1986 10.30 Uhr")
```

Local time and date specification are also supported. The following examples show how local date and time specification can be defined in the template.

Invocation	Line in Template
<code>getdate("11/27/86")</code>	<code>%m/%d/%y</code>
<code>getdate("27.11.86")</code>	<code>%d.%m.%y</code>
<code>getdate("86-11-27")</code>	<code>%y-%m-%d</code>
<code>getdate("Friday 12:00:00")</code>	<code>%A %H:%M:%S</code>

The following examples illustrate the Internal Format Conversion rules. Assume that the current date is Mon Sep 22 12:19:47 EDT 1986 and the `LANG` environment variable is not set.

Input	Template Line	Date
Mon	<code>%a</code>	Mon Sep 22 12:19:48 EDT 1986
Sun	<code>%a</code>	Sun Sep 28 12:19:49 EDT 1986
Fri	<code>%a</code>	Fri Sep 26 12:19:49 EDT 1986
September	<code>%B</code>	Mon Sep 1 12:19:49 EDT 1986
January	<code>%B</code>	Thu Jan 1 12:19:49 EST 1987
December	<code>%B</code>	Mon Dec 1 12:19:49 EDT 1986
Sep Mon	<code>%b %a</code>	Mon Sep 1 12:19:50 EDT 1986
Jan Fri	<code>%b %a</code>	Fri Jan 2 12:19:50 EST 1987

getdate(3C)

Dec Mon	%b %a	Mon Dec 1 12:19:50 EST 1986
Jan Wed 1989	%b %a %Y	Wed Jan 4 12:19:51 EST 1989
Fri 9	%a %H	Fri Sep 26 09:00:00 EDT 1986
Feb 10:30	%b %H:%S	Sun Feb 1 10:00:30 EST 1987
10:30	%H:%M	Tue Sep 23 10:30:00 EDT 1986
13:30	%H:%M	Mon Sep 22 13:30:00 EDT 1986

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
MT-Level	MT-Safe

NAME	getdtablesize – get the file descriptor table size
SYNOPSIS	<pre>#include <unistd.h> int getdtablesize(void);</pre>
DESCRIPTION	The <code>getdtablesize()</code> function is equivalent to <code>getrlimit(2)</code> with the <code>RLIMIT_NOFILE</code> option.
RETURN VALUES	The <code>getdtablesize()</code> function returns the current soft limit as if obtained from a call to <code>getrlimit()</code> with the <code>RLIMIT_NOFILE</code> option.
ERRORS	No errors are defined.
USAGE	<p>There is no direct relationship between the value returned by <code>getdtablesize()</code> and <code>OPEN_MAX</code> defined in <code><limits.h></code>.</p> <p>Each process has a file descriptor table which is guaranteed to have at least 20 slots. The entries in the descriptor table are numbered with small integers starting at 0. The <code>getdtablesize()</code> function returns the current maximum size of this table by calling the <code>getrlimit()</code> function.</p>
SEE ALSO	<code>close(2)</code> , <code>getrlimit(2)</code> , <code>open(2)</code> , <code>setrlimit(2)</code> , <code>select(3C)</code>

getenv(3C)

NAME	getenv – return value for environment name				
SYNOPSIS	<pre>#include <stdlib.h> char *getenv(const char *name) ;</pre>				
DESCRIPTION	The <code>getenv()</code> function searches the environment list (see <code>environ(5)</code>) for a string of the form <code>name=value</code> and, if the string is present, returns a pointer to the <code>value</code> in the current environment.				
RETURN VALUES	If successful, <code>getenv()</code> returns a pointer to the <code>value</code> in the current environment; otherwise, it returns a null pointer.				
USAGE	The <code>getenv()</code> function can be safely called from a multithreaded application. Care must be exercised when using both <code>getenv()</code> and <code>putenv(3C)</code> in a multithreaded application. These functions examine and modify the environment list, which is shared by all threads in an application. The system prevents the list from being accessed simultaneously by two different threads. It does not, however, prevent two threads from successively accessing the environment list using <code>getenv()</code> or <code>putenv(3C)</code> .

NAME	getexecname – return pathname of executable				
SYNOPSIS	<pre>#include <stdlib.h> const char *getexecname(void);</pre>				
DESCRIPTION	<p>The <code>getexecname()</code> function returns the pathname (the first argument of one of the <code>exec</code> family of functions; see <code>exec(2)</code>) of the executable that started the process.</p> <p>Normally this is an absolute pathname, as the majority of commands are executed by the shells that append the command name to the user's <code>PATH</code> components. If this is not an absolute path, the output of <code>getcwd(3C)</code> can be prepended to it to create an absolute path, unless the process or one of its ancestors has changed its root directory or current working directory since the last successful call to one of the <code>exec</code> family of functions.</p>				
RETURN VALUES	If successful, <code>getexecname()</code> returns a pointer to the executables pathname; otherwise, it returns 0.				
USAGE	<p>The <code>getexecname()</code> function obtains the executable pathname from the <code>AT_SUN_EXECNAME</code> aux vector. These vectors are made available to dynamically linked processes only.</p> <p>A successful call to one of the <code>exec</code> family of functions will always have <code>AT_SUN_EXECNAME</code> in the aux vector. The associated pathname is guaranteed to be less than or equal to <code>PATH_MAX</code>, not counting the trailing null byte that is always present.</p>				
ATTRIBUTES	See <code>attributes(5)</code> for descriptions of the following attributes:				
	<table border="1" style="width: 100%; border-collapse: collapse;"> <thead> <tr> <th style="text-align: center;">ATTRIBUTE TYPE</th> <th style="text-align: center;">ATTRIBUTE VALUE</th> </tr> </thead> <tbody> <tr> <td>MT-Level</td> <td>Safe</td> </tr> </tbody> </table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	MT-Level	Safe
ATTRIBUTE TYPE	ATTRIBUTE VALUE

getextmntent(3C)

NAME	getmntent, getmntany, getextmntent, hasmntopt, putmntent, resetmnttab – get mounted device information
SYNOPSIS	<pre>#include <stdio.h> #include <sys/mnttab.h> int getmntent(FILE *fp, struct mnttab *mp); int getmntany(FILE *fp, struct mnttab *mp, struct mnttab *mpref); int getextmntent(FILE *fp, struct extmnttab *mp, int len); char *hasmntopt(struct mnttab *mnt, char *opt); int putmntent(FILE *iop, struct mnttab *mp); void resetmnttab(FILE *fp);</pre>
getmntent() and getmntany()	<p>The <code>getmntent()</code> and <code>getmntany()</code> functions each fill in the structure pointed to by <code>mp</code> with the broken-out fields of a line in the <code>mnttab</code> file. Each line read from the file contains a <code>mnttab</code> structure, which is defined in the <code><sys/mnttab.h></code> header. The structure contains the following members, which correspond to the broken-out fields from a line in <code>/etc/mnttab</code> (see <code>mnttab(4)</code>).</p> <pre>char *mnt_special; /* name of mounted resource */ char *mnt_mountp; /* mount point */ char *mnt_fstype; /* type of file system mounted */ char *mnt_mntopts; /* options for this mount */ char *mnt_time; /* time file system mounted */</pre> <p>Each <code>getmntent()</code> call causes a new line to be read from the <code>mnttab</code> file. Successive calls can be used to search the entire list. The <code>getmntany()</code> function searches the file referenced by <code>fp</code> until a match is found between a line in the file and <code>mpref</code>. A match occurs if all non-null entries in <code>mpref</code> match the corresponding fields in the file. Note that these functions do not open, close, or rewind the file.</p>
getextmntent()	<p>The <code>getextmntent()</code> function is an extended version of the <code>getmntent()</code> function that returns, in addition to the information that <code>getmntent()</code> returns, the major and minor number of the mounted resource to which the line in <code>mnttab</code> corresponds. The <code>getextmntent()</code> function also fills in the <code>extmntent</code> structure defined in the <code><sys/mnttab.h></code> header. For <code>getextmntent()</code> to function properly, it must be notified when the <code>mnttab</code> file has been reopened or rewound since a previous <code>getextmntent()</code> call. This notification is accomplished by calling <code>resetmnttab()</code>. Otherwise, it behaves exactly as <code>getmntent()</code> described above.</p> <p>The data pointed to by the <code>mnttab</code> structure members are stored in a static area and must be copied to be saved between successive calls.</p>
hasmntopt()	<p>The <code>hasmntopt()</code> function scans the <code>mnt_mntopts</code> member of the <code>mnttab</code> structure <code>mnt</code> for a substring that matches <code>opt</code>. It returns the address of the substring if a match is found; otherwise it returns 0. Substrings are delimited by commas and the end of the <code>mnt_mntopts</code> string.</p>

- `putmntent()` The `putmntent()` function is obsolete and no longer has any effect. Entries appear in `mnttab` as a side effect of a `mount(2)` call. The function name is still defined for transition purposes.
- `resetmnttab()` The `resetmnttab()` function notifies `getextmntent()` to reload from the kernel the device information that corresponds to the new snapshot of the `mnttab` information (see `mnttab(4)`). Subsequent `getextmntent()` calls then return correct `extmnttab` information. This function should be called whenever the `mnttab` file is either rewound or closed and reopened before any calls are made to `getextmntent()`.
- `getmntent()` and `getmntany()` If the next entry is successfully read by `getmntent()` or a match is found with `getmntany()`, 0 is returned. If an EOF is encountered on reading, these functions return -1. If an error is encountered, a value greater than 0 is returned. The following error values are defined in `<sys/mnttab.h>`:
- `MNT_TOOLONG` A line in the file exceeded the internal buffer size of `MNT_LINE_MAX`.
- `MNT_TOOMANY` A line in the file contains too many fields.
- `MNT_TOOFEW` A line in the file contains too few fields.
- `hasmntopt()` Upon successful completion, `hasmntopt()` returns the address of the substring if a match is found. Otherwise, it returns 0.
- `putmntent()` The `putmntent()` is obsolete and always returns -1.
- ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
MT-Level	Safe

SEE ALSO `mount(2)`, `mnttab(4)`, `attributes(5)`

getgrent(3C)

NAME	getgrnam, getgrnam_r, getgrent, getgrent_r, getgrgid, getgrgid_r, setgrent, endgrent, fgetgrent, fgetgrent_r – group database entry functions
SYNOPSIS	<pre>#include <grp.h> struct group *getgrnam(const char *name); struct group *getgrnam_r(const char *name, struct group *grp, char *buffer, int bufsize); struct group *getgrent(void); struct group *getgrent_r(struct group *grp, char *buffer, int bufsize); struct group *getgrgid(gid_t gid); struct group *getgrgid_r(gid_t gid, struct group *grp, char *buffer, int bufsize); void setgrent(void); void endgrent(void); struct group *fgetgrent(FILE *f); struct group *fgetgrent_r(FILE *f, struct group *grp, char *buffer, int bufsize);</pre>
POSIX	<pre>cc [flag...] file... -D_POSIX_PTHREAD_SEMANTICS [library...] int getgrnam_r(const char *name, struct group *grp, char *buffer, size_t bufsize, struct group **result); int getgrgid_r(gid_t gid, struct group *grp, char *buffer, size_t bufsize, struct group **result);</pre>
DESCRIPTION	<p>These functions are used to obtain entries describing user groups. Entries can come from any of the sources for group specified in the <code>/etc/nsswitch.conf</code> file (see <code>nsswitch.conf(4)</code>).</p> <p>The <code>getgrnam()</code> function searches the group database for an entry with the group name specified by the character string parameter <i>name</i>.</p> <p>The <code>getgrgid()</code> function searches the group database for an entry with the (numeric) group id specified by <i>gid</i>.</p> <p>The <code>setgrent()</code>, <code>getgrent()</code>, and <code>endgrent()</code> functions are used to enumerate group entries from the database.</p> <p>The <code>setgrent()</code> function effectively rewinds the group database to allow repeated searches. It sets (or resets) the enumeration to the beginning of the set of group entries. This function should be called before the first call to <code>getgrent()</code>.</p>

The `getgrent()` function returns a pointer to a structure containing the broken-out fields of an entry in the group database. When first called, `getgrent()` returns a pointer to a `group` structure containing the next group structure in the group database. Successive calls may be used to search the entire database.

The `endgrent()` function may be called to close the group database and deallocate resources when processing is complete. It is permissible, though possibly less efficient, for the process to call more group functions after calling `endgrent()`.

The `fgetgrent()` function, unlike the other functions above, does not use `nsswitch.conf`. It reads and parses the next line from the stream *f*, which is assumed to have the format of the group file (see `group(4)`).

Reentrant Interfaces

The `getgrnam()`, `getgrgid()`, `getgrent()`, and `fgetgrent()` functions use static storage that is reused in each call, making them unsafe for multithreaded applications.

The parallel functions `getgrnam_r()`, `getgrgid_r()`, `getgrent_r()`, and `fgetgrent_r()` provide reentrant interfaces for these operations.

Each reentrant interface performs the same operation as its non-reentrant counterpart, named by removing the `_r` suffix. The reentrant interfaces, however, use buffers supplied by the caller to store returned results, and are safe for use in both single-threaded and multithreaded applications.

Each reentrant interface takes the same arguments as its non-reentrant counterpart, as well as the following additional parameters. The *grp* argument must be a pointer to a `struct group` structure allocated by the caller. On successful completion, the function returns the group entry in this structure. Storage referenced by the group structure is allocated from the memory provided with the *buffer* argument, which is *bufsize* characters in size. The maximum size needed for this buffer can be determined with the `_SC_GETGR_R_SIZE_MAX` `sysconf(3C)` parameter. The POSIX versions place a pointer to the modified *grp* structure in the *result* parameter, instead of returning a pointer to this structure.

For enumeration in multithreaded applications, the position within the enumeration is a process-wide property shared by all threads. `setgrent()` may be used in a multithreaded application but resets the enumeration position for all threads. If multiple threads interleave calls to `getgrent_r()`, the threads will enumerate disjoint subsets of the group database. Like their non-reentrant counterparts, `getgrnam_r()` and `getgrgid_r()` leave the enumeration position in an indeterminate state.

RETURN VALUES

Group entries are represented by the `struct group` structure defined in `<grp.h>`:

```
struct group {
    char *gr_name;           /* the name of the group */
    char *gr_passwd;        /* the encrypted group password */
    gid_t gr_gid;          /* the numerical group ID */
    char **gr_mem;         /* vector of pointers to member names */
};
```

getgrent(3C)

The `getgrnam()`, `getgrnam_r()`, `getgrgid()`, and `getgrgid_r()` functions each return a pointer to a `struct group` if they successfully locate the requested entry; otherwise they return `NULL`. The POSIX functions `getgrnam_r()` and `getgrgid_r()` return 0 upon success or the error number in case of failure.

The `getgrent()`, `getgrent_r()`, `fgetgrent()`, and `fgetgrent_r()` functions each return a pointer to a `struct group` if they successfully enumerate an entry; otherwise they return `NULL`, indicating the end of the enumeration.

The `getgrnam()`, `getgrgid()`, `getgrent()`, and `fgetgrent()` functions use static storage, so returned data must be copied before a subsequent call to any of these functions if the data is to be saved.

When the pointer returned by the reentrant functions `getgrnam_r()`, `getgrgid_r()`, `getgrent_r()`, and `fgetgrent_r()` is non-null, it is always equal to the `grp` pointer that was supplied by the caller.

ERRORS The `getgrnam()`, `getgrgid()`, `getgrent()`, `fgetgrent()`, and `fgetgrent_r()` functions may fail if:

<code>EINTR</code>	A signal was caught during the operation.
<code>EIO</code>	An I/O error has occurred.
<code>EMFILE</code>	There are <code>OPEN_MAX</code> file descriptors currently open in the calling process.
<code>ENFILE</code>	The maximum allowable number of files is currently open in the system.
<code>ERANGE</code>	The group file contains a line that exceeds 512 bytes.

The `getgrnam_r()`, `getgrgid_r()`, and `getgrent_r()` functions may fail if:

<code>ERANGE</code>	Insufficient storage was supplied by <i>buffer</i> and <i>bufsize</i> to contain the data to be referenced by the resulting <code>group</code> structure.
---------------------	---

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
MT-Level	See "Reentrant Interfaces" in <code>DESCRIPTION</code> .

SEE ALSO `Intro(3)`, `getpwnam(3C)`, `group(4)`, `nsswitch.conf(4)`, `passwd(4)`, `attributes(5)`, `standards(5)`

NOTES When compiling multithreaded programs, see `Intro(3)`, *Notes On Multithreaded Applications*.

Programs that use the interfaces described in this manual page cannot be linked statically since the implementations of these functions employ dynamic loading and linking of shared objects at run time.

Use of the enumeration interfaces `getgrent()` and `getgrent_r()` is discouraged; enumeration is supported for the group file, NIS, and NIS+, but in general is not efficient and may not be supported for all database sources. The semantics of enumeration are discussed further in `nsswitch.conf(4)`.

Previous releases allowed the use of "+" and "-" entries in `/etc/group` to selectively include and exclude entries from NIS. The primary usage of these entries is superseded by the name service switch, so the "+/-" form *may not be supported in future releases*.

If required, the "+/-" functionality can still be obtained for NIS by specifying `compat` as the source for `group`.

If the "+/-" functionality is required in conjunction with NIS+, specify both `compat` as the source for `group` and `nisplus` as the source for the pseudo-database `group_compat`. See `group(4)`, and `nsswitch.conf(4)` for details.

Solaris 2.4 and earlier releases provided definitions of the `getgrnam_r()` and `getgrgid_r()` functions as specified in POSIX.1c Draft 6. The final POSIX.1c standard changed the interface for these functions. Support for the Draft 6 interface is provided for compatibility only and may not be supported in future releases. New applications and libraries should use the POSIX standard interface.

For POSIX.1c-compliant applications, the `_POSIX_PTHREAD_SEMANTICS` and `_REENTRANT` flags are automatically turned on by defining the `_POSIX_C_SOURCE` flag with a value $\geq 199506L$.

getgrent_r(3C)

NAME	getgrnam, getgrnam_r, getgrent, getgrent_r, getgrgid, getgrgid_r, setgrent, endgrent, fgetgrent, fgetgrent_r – group database entry functions
SYNOPSIS	<pre>#include <grp.h> struct group *getgrnam(const char *name); struct group *getgrnam_r(const char *name, struct group *grp, char *buffer, int bufsize); struct group *getgrent(void); struct group *getgrent_r(struct group *grp, char *buffer, int bufsize); struct group *getgrgid(gid_t gid); struct group *getgrgid_r(gid_t gid, struct group *grp, char *buffer, int bufsize); void setgrent(void); void endgrent(void); struct group *fgetgrent(FILE *f); struct group *fgetgrent_r(FILE *f, struct group *grp, char *buffer, int bufsize);</pre>
POSIX	<pre>cc [flag...] file... -D_POSIX_PTHREAD_SEMANTICS [library...] int getgrnam_r(const char *name, struct group *grp, char *buffer, size_t bufsize, struct group **result); int getgrgid_r(gid_t gid, struct group *grp, char *buffer, size_t bufsize, struct group **result);</pre>
DESCRIPTION	<p>These functions are used to obtain entries describing user groups. Entries can come from any of the sources for group specified in the <code>/etc/nsswitch.conf</code> file (see <code>nsswitch.conf(4)</code>).</p> <p>The <code>getgrnam()</code> function searches the group database for an entry with the group name specified by the character string parameter <i>name</i>.</p> <p>The <code>getgrgid()</code> function searches the group database for an entry with the (numeric) group id specified by <i>gid</i>.</p> <p>The <code>setgrent()</code>, <code>getgrent()</code>, and <code>endgrent()</code> functions are used to enumerate group entries from the database.</p> <p>The <code>setgrent()</code> function effectively rewinds the group database to allow repeated searches. It sets (or resets) the enumeration to the beginning of the set of group entries. This function should be called before the first call to <code>getgrent()</code>.</p>

The `getgrent()` function returns a pointer to a structure containing the broken-out fields of an entry in the group database. When first called, `getgrent()` returns a pointer to a `group` structure containing the next group structure in the group database. Successive calls may be used to search the entire database.

The `endgrent()` function may be called to close the group database and deallocate resources when processing is complete. It is permissible, though possibly less efficient, for the process to call more group functions after calling `endgrent()`.

The `fgetgrent()` function, unlike the other functions above, does not use `nsswitch.conf`. It reads and parses the next line from the stream *f*, which is assumed to have the format of the group file (see `group(4)`).

Reentrant Interfaces

The `getgrnam()`, `getgrgid()`, `getgrent()`, and `fgetgrent()` functions use static storage that is reused in each call, making them unsafe for multithreaded applications.

The parallel functions `getgrnam_r()`, `getgrgid_r()`, `getgrent_r()`, and `fgetgrent_r()` provide reentrant interfaces for these operations.

Each reentrant interface performs the same operation as its non-reentrant counterpart, named by removing the `_r` suffix. The reentrant interfaces, however, use buffers supplied by the caller to store returned results, and are safe for use in both single-threaded and multithreaded applications.

Each reentrant interface takes the same arguments as its non-reentrant counterpart, as well as the following additional parameters. The *grp* argument must be a pointer to a `struct group` structure allocated by the caller. On successful completion, the function returns the group entry in this structure. Storage referenced by the group structure is allocated from the memory provided with the *buffer* argument, which is *bufsize* characters in size. The maximum size needed for this buffer can be determined with the `_SC_GETGR_R_SIZE_MAX` `sysconf(3C)` parameter. The POSIX versions place a pointer to the modified *grp* structure in the *result* parameter, instead of returning a pointer to this structure.

For enumeration in multithreaded applications, the position within the enumeration is a process-wide property shared by all threads. `setgrent()` may be used in a multithreaded application but resets the enumeration position for all threads. If multiple threads interleave calls to `getgrent_r()`, the threads will enumerate disjoint subsets of the group database. Like their non-reentrant counterparts, `getgrnam_r()` and `getgrgid_r()` leave the enumeration position in an indeterminate state.

RETURN VALUES

Group entries are represented by the `struct group` structure defined in `<grp.h>`:

```
struct group {
    char *gr_name;           /* the name of the group */
    char *gr_passwd;        /* the encrypted group password */
    gid_t gr_gid;           /* the numerical group ID */
    char **gr_mem;          /* vector of pointers to member names */
};
```

getgrent_r(3C)

The `getgrnam()`, `getgrnam_r()`, `getgrgid()`, and `getgrgid_r()` functions each return a pointer to a `struct group` if they successfully locate the requested entry; otherwise they return `NULL`. The POSIX functions `getgrnam_r()` and `getgrgid_r()` return 0 upon success or the error number in case of failure.

The `getgrent()`, `getgrent_r()`, `fgetgrent()`, and `fgetgrent_r()` functions each return a pointer to a `struct group` if they successfully enumerate an entry; otherwise they return `NULL`, indicating the end of the enumeration.

The `getgrnam()`, `getgrgid()`, `getgrent()`, and `fgetgrent()` functions use static storage, so returned data must be copied before a subsequent call to any of these functions if the data is to be saved.

When the pointer returned by the reentrant functions `getgrnam_r()`, `getgrgid_r()`, `getgrent_r()`, and `fgetgrent_r()` is non-null, it is always equal to the `grp` pointer that was supplied by the caller.

ERRORS The `getgrnam()`, `getgrgid()`, `getgrent()`, `fgetgrent()`, and `fgetgrent_r()` functions may fail if:

<code>EINTR</code>	A signal was caught during the operation.
<code>EIO</code>	An I/O error has occurred.
<code>EMFILE</code>	There are <code>OPEN_MAX</code> file descriptors currently open in the calling process.
<code>ENFILE</code>	The maximum allowable number of files is currently open in the system.
<code>ERANGE</code>	The group file contains a line that exceeds 512 bytes.

The `getgrnam_r()`, `getgrgid_r()`, and `getgrent_r()` functions may fail if:

<code>ERANGE</code>	Insufficient storage was supplied by <i>buffer</i> and <i>bufsize</i> to contain the data to be referenced by the resulting <code>group</code> structure.
---------------------	---

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
MT-Level	See "Reentrant Interfaces" in <code>DESCRIPTION</code> .

SEE ALSO `Intro(3)`, `getpwnam(3C)`, `group(4)`, `nsswitch.conf(4)`, `passwd(4)`, `attributes(5)`, `standards(5)`

NOTES When compiling multithreaded programs, see `Intro(3)`, *Notes On Multithreaded Applications*.

Programs that use the interfaces described in this manual page cannot be linked statically since the implementations of these functions employ dynamic loading and linking of shared objects at run time.

Use of the enumeration interfaces `getgrent()` and `getgrent_r()` is discouraged; enumeration is supported for the group file, NIS, and NIS+, but in general is not efficient and may not be supported for all database sources. The semantics of enumeration are discussed further in `nsswitch.conf(4)`.

Previous releases allowed the use of "+" and "-" entries in `/etc/group` to selectively include and exclude entries from NIS. The primary usage of these entries is superseded by the name service switch, so the "+/-" form *may not be supported in future releases*.

If required, the "+/-" functionality can still be obtained for NIS by specifying `compat` as the source for `group`.

If the "+/-" functionality is required in conjunction with NIS+, specify both `compat` as the source for `group` and `nisplus` as the source for the pseudo-database `group_compat`. See `group(4)`, and `nsswitch.conf(4)` for details.

Solaris 2.4 and earlier releases provided definitions of the `getgrnam_r()` and `getgrgid_r()` functions as specified in POSIX.1c Draft 6. The final POSIX.1c standard changed the interface for these functions. Support for the Draft 6 interface is provided for compatibility only and may not be supported in future releases. New applications and libraries should use the POSIX standard interface.

For POSIX.1c-compliant applications, the `_POSIX_PTHREAD_SEMANTICS` and `_REENTRANT` flags are automatically turned on by defining the `_POSIX_C_SOURCE` flag with a value $\geq 199506L$.

getgrgid(3C)

NAME	getgrnam, getgrnam_r, getgrent, getgrent_r, getgrgid, getgrgid_r, setgrent, endgrent, fgetgrent, fgetgrent_r – group database entry functions
SYNOPSIS	<pre>#include <grp.h> struct group *getgrnam(const char *name); struct group *getgrnam_r(const char *name, struct group *grp, char *buffer, int bufsize); struct group *getgrent(void); struct group *getgrent_r(struct group *grp, char *buffer, int bufsize); struct group *getgrgid(gid_t gid); struct group *getgrgid_r(gid_t gid, struct group *grp, char *buffer, int bufsize); void setgrent(void); void endgrent(void); struct group *fgetgrent(FILE *f); struct group *fgetgrent_r(FILE *f, struct group *grp, char *buffer, int bufsize);</pre>
POSIX	<pre>cc [flag...] file... -D_POSIX_PTHREAD_SEMANTICS [library...] int getgrnam_r(const char *name, struct group *grp, char *buffer, size_t bufsize, struct group **result); int getgrgid_r(gid_t gid, struct group *grp, char *buffer, size_t bufsize, struct group **result);</pre>
DESCRIPTION	<p>These functions are used to obtain entries describing user groups. Entries can come from any of the sources for group specified in the <code>/etc/nsswitch.conf</code> file (see <code>nsswitch.conf(4)</code>).</p> <p>The <code>getgrnam()</code> function searches the group database for an entry with the group name specified by the character string parameter <i>name</i>.</p> <p>The <code>getgrgid()</code> function searches the group database for an entry with the (numeric) group id specified by <i>gid</i>.</p> <p>The <code>setgrent()</code>, <code>getgrent()</code>, and <code>endgrent()</code> functions are used to enumerate group entries from the database.</p> <p>The <code>setgrent()</code> function effectively rewinds the group database to allow repeated searches. It sets (or resets) the enumeration to the beginning of the set of group entries. This function should be called before the first call to <code>getgrent()</code>.</p>

The `getgrent()` function returns a pointer to a structure containing the broken-out fields of an entry in the group database. When first called, `getgrent()` returns a pointer to a `group` structure containing the next group structure in the group database. Successive calls may be used to search the entire database.

The `endgrent()` function may be called to close the group database and deallocate resources when processing is complete. It is permissible, though possibly less efficient, for the process to call more group functions after calling `endgrent()`.

The `fgetgrent()` function, unlike the other functions above, does not use `nsswitch.conf`. It reads and parses the next line from the stream *f*, which is assumed to have the format of the group file (see `group(4)`).

Reentrant Interfaces

The `getgrnam()`, `getgrgid()`, `getgrent()`, and `fgetgrent()` functions use static storage that is reused in each call, making them unsafe for multithreaded applications.

The parallel functions `getgrnam_r()`, `getgrgid_r()`, `getgrent_r()`, and `fgetgrent_r()` provide reentrant interfaces for these operations.

Each reentrant interface performs the same operation as its non-reentrant counterpart, named by removing the `_r` suffix. The reentrant interfaces, however, use buffers supplied by the caller to store returned results, and are safe for use in both single-threaded and multithreaded applications.

Each reentrant interface takes the same arguments as its non-reentrant counterpart, as well as the following additional parameters. The *grp* argument must be a pointer to a `struct group` structure allocated by the caller. On successful completion, the function returns the group entry in this structure. Storage referenced by the group structure is allocated from the memory provided with the *buffer* argument, which is *bufsize* characters in size. The maximum size needed for this buffer can be determined with the `_SC_GETGR_R_SIZE_MAX` `sysconf(3C)` parameter. The POSIX versions place a pointer to the modified *grp* structure in the *result* parameter, instead of returning a pointer to this structure.

For enumeration in multithreaded applications, the position within the enumeration is a process-wide property shared by all threads. `setgrent()` may be used in a multithreaded application but resets the enumeration position for all threads. If multiple threads interleave calls to `getgrent_r()`, the threads will enumerate disjoint subsets of the group database. Like their non-reentrant counterparts, `getgrnam_r()` and `getgrgid_r()` leave the enumeration position in an indeterminate state.

RETURN VALUES

Group entries are represented by the `struct group` structure defined in `<grp.h>`:

```
struct group {
    char *gr_name;           /* the name of the group */
    char *gr_passwd;        /* the encrypted group password */
    gid_t gr_gid;          /* the numerical group ID */
    char **gr_mem;         /* vector of pointers to member names */
};
```

getgrgid(3C)

The `getgrnam()`, `getgrnam_r()`, `getgrgid()`, and `getgrgid_r()` functions each return a pointer to a `struct group` if they successfully locate the requested entry; otherwise they return `NULL`. The POSIX functions `getgrnam_r()` and `getgrgid_r()` return 0 upon success or the error number in case of failure.

The `getgrent()`, `getgrent_r()`, `fgetgrent()`, and `fgetgrent_r()` functions each return a pointer to a `struct group` if they successfully enumerate an entry; otherwise they return `NULL`, indicating the end of the enumeration.

The `getgrnam()`, `getgrgid()`, `getgrent()`, and `fgetgrent()` functions use static storage, so returned data must be copied before a subsequent call to any of these functions if the data is to be saved.

When the pointer returned by the reentrant functions `getgrnam_r()`, `getgrgid_r()`, `getgrent_r()`, and `fgetgrent_r()` is non-null, it is always equal to the `grp` pointer that was supplied by the caller.

ERRORS The `getgrnam()`, `getgrgid()`, `getgrent()`, `fgetgrent()`, and `fgetgrent_r()` functions may fail if:

<code>EINTR</code>	A signal was caught during the operation.
<code>EIO</code>	An I/O error has occurred.
<code>EMFILE</code>	There are <code>OPEN_MAX</code> file descriptors currently open in the calling process.
<code>ENFILE</code>	The maximum allowable number of files is currently open in the system.
<code>ERANGE</code>	The group file contains a line that exceeds 512 bytes.

The `getgrnam_r()`, `getgrgid_r()`, and `getgrent_r()` functions may fail if:

<code>ERANGE</code>	Insufficient storage was supplied by <i>buffer</i> and <i>bufsize</i> to contain the data to be referenced by the resulting <code>group</code> structure.
---------------------	---

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
MT-Level	See "Reentrant Interfaces" in <code>DESCRIPTION</code> .

SEE ALSO `Intro(3)`, `getpwnam(3C)`, `group(4)`, `nsswitch.conf(4)`, `passwd(4)`, `attributes(5)`, `standards(5)`

NOTES When compiling multithreaded programs, see `Intro(3)`, *Notes On Multithreaded Applications*.

Programs that use the interfaces described in this manual page cannot be linked statically since the implementations of these functions employ dynamic loading and linking of shared objects at run time.

Use of the enumeration interfaces `getgrent()` and `getgrent_r()` is discouraged; enumeration is supported for the group file, NIS, and NIS+, but in general is not efficient and may not be supported for all database sources. The semantics of enumeration are discussed further in `nsswitch.conf(4)`.

Previous releases allowed the use of "+" and "-" entries in `/etc/group` to selectively include and exclude entries from NIS. The primary usage of these entries is superseded by the name service switch, so the "+/-" form *may not be supported in future releases*.

If required, the "+/-" functionality can still be obtained for NIS by specifying `compat` as the source for `group`.

If the "+/-" functionality is required in conjunction with NIS+, specify both `compat` as the source for `group` and `nisplus` as the source for the pseudo-database `group_compat`. See `group(4)`, and `nsswitch.conf(4)` for details.

Solaris 2.4 and earlier releases provided definitions of the `getgrnam_r()` and `getgrgid_r()` functions as specified in POSIX.1c Draft 6. The final POSIX.1c standard changed the interface for these functions. Support for the Draft 6 interface is provided for compatibility only and may not be supported in future releases. New applications and libraries should use the POSIX standard interface.

For POSIX.1c-compliant applications, the `_POSIX_PTHREAD_SEMANTICS` and `_REENTRANT` flags are automatically turned on by defining the `_POSIX_C_SOURCE` flag with a value $\geq 199506L$.

getgrgid_r(3C)

NAME	getgrnam, getgrnam_r, getgrent, getgrent_r, getgrgid, getgrgid_r, setgrent, endgrent, fgetgrent, fgetgrent_r – group database entry functions
SYNOPSIS	<pre>#include <grp.h> struct group *getgrnam(const char *name); struct group *getgrnam_r(const char *name, struct group *grp, char *buffer, int bufsize); struct group *getgrent(void); struct group *getgrent_r(struct group *grp, char *buffer, int bufsize); struct group *getgrgid(gid_t gid); struct group *getgrgid_r(gid_t gid, struct group *grp, char *buffer, int bufsize); void setgrent(void); void endgrent(void); struct group *fgetgrent(FILE *f); struct group *fgetgrent_r(FILE *f, struct group *grp, char *buffer, int bufsize);</pre>
POSIX	<pre>cc [flag...] file... -D_POSIX_PTHREAD_SEMANTICS [library...] int getgrnam_r(const char *name, struct group *grp, char *buffer, size_t bufsize, struct group **result); int getgrgid_r(gid_t gid, struct group *grp, char *buffer, size_t bufsize, struct group **result);</pre>
DESCRIPTION	<p>These functions are used to obtain entries describing user groups. Entries can come from any of the sources for group specified in the <code>/etc/nsswitch.conf</code> file (see <code>nsswitch.conf(4)</code>).</p> <p>The <code>getgrnam()</code> function searches the group database for an entry with the group name specified by the character string parameter <i>name</i>.</p> <p>The <code>getgrgid()</code> function searches the group database for an entry with the (numeric) group id specified by <i>gid</i>.</p> <p>The <code>setgrent()</code>, <code>getgrent()</code>, and <code>endgrent()</code> functions are used to enumerate group entries from the database.</p> <p>The <code>setgrent()</code> function effectively rewinds the group database to allow repeated searches. It sets (or resets) the enumeration to the beginning of the set of group entries. This function should be called before the first call to <code>getgrent()</code>.</p>

The `getgrent()` function returns a pointer to a structure containing the broken-out fields of an entry in the group database. When first called, `getgrent()` returns a pointer to a `group` structure containing the next group structure in the group database. Successive calls may be used to search the entire database.

The `endgrent()` function may be called to close the group database and deallocate resources when processing is complete. It is permissible, though possibly less efficient, for the process to call more group functions after calling `endgrent()`.

The `fgetgrent()` function, unlike the other functions above, does not use `nsswitch.conf`. It reads and parses the next line from the stream *f*, which is assumed to have the format of the group file (see `group(4)`).

Reentrant Interfaces

The `getgrnam()`, `getgrgid()`, `getgrent()`, and `fgetgrent()` functions use static storage that is reused in each call, making them unsafe for multithreaded applications.

The parallel functions `getgrnam_r()`, `getgrgid_r()`, `getgrent_r()`, and `fgetgrent_r()` provide reentrant interfaces for these operations.

Each reentrant interface performs the same operation as its non-reentrant counterpart, named by removing the `_r` suffix. The reentrant interfaces, however, use buffers supplied by the caller to store returned results, and are safe for use in both single-threaded and multithreaded applications.

Each reentrant interface takes the same arguments as its non-reentrant counterpart, as well as the following additional parameters. The *grp* argument must be a pointer to a `struct group` structure allocated by the caller. On successful completion, the function returns the group entry in this structure. Storage referenced by the group structure is allocated from the memory provided with the *buffer* argument, which is *bufsize* characters in size. The maximum size needed for this buffer can be determined with the `_SC_GETGR_R_SIZE_MAX` `sysconf(3C)` parameter. The POSIX versions place a pointer to the modified *grp* structure in the *result* parameter, instead of returning a pointer to this structure.

For enumeration in multithreaded applications, the position within the enumeration is a process-wide property shared by all threads. `setgrent()` may be used in a multithreaded application but resets the enumeration position for all threads. If multiple threads interleave calls to `getgrent_r()`, the threads will enumerate disjoint subsets of the group database. Like their non-reentrant counterparts, `getgrnam_r()` and `getgrgid_r()` leave the enumeration position in an indeterminate state.

RETURN VALUES

Group entries are represented by the `struct group` structure defined in `<grp.h>`:

```
struct group {
    char *gr_name;           /* the name of the group */
    char *gr_passwd;        /* the encrypted group password */
    gid_t gr_gid;           /* the numerical group ID */
    char **gr_mem;          /* vector of pointers to member names */
};
```

getgrgid_r(3C)

The `getgrnam()`, `getgrnam_r()`, `getgrgid()`, and `getgrgid_r()` functions each return a pointer to a `struct group` if they successfully locate the requested entry; otherwise they return `NULL`. The POSIX functions `getgrnam_r()` and `getgrgid_r()` return 0 upon success or the error number in case of failure.

The `getgrent()`, `getgrent_r()`, `fgetgrent()`, and `fgetgrent_r()` functions each return a pointer to a `struct group` if they successfully enumerate an entry; otherwise they return `NULL`, indicating the end of the enumeration.

The `getgrnam()`, `getgrgid()`, `getgrent()`, and `fgetgrent()` functions use static storage, so returned data must be copied before a subsequent call to any of these functions if the data is to be saved.

When the pointer returned by the reentrant functions `getgrnam_r()`, `getgrgid_r()`, `getgrent_r()`, and `fgetgrent_r()` is non-null, it is always equal to the `grp` pointer that was supplied by the caller.

ERRORS The `getgrnam()`, `getgrgid()`, `getgrent()`, `fgetgrent()`, and `fgetgrent_r()` functions may fail if:

<code>EINTR</code>	A signal was caught during the operation.
<code>EIO</code>	An I/O error has occurred.
<code>EMFILE</code>	There are <code>OPEN_MAX</code> file descriptors currently open in the calling process.
<code>ENFILE</code>	The maximum allowable number of files is currently open in the system.
<code>ERANGE</code>	The group file contains a line that exceeds 512 bytes.

The `getgrnam_r()`, `getgrgid_r()`, and `getgrent_r()` functions may fail if:

<code>ERANGE</code>	Insufficient storage was supplied by <i>buffer</i> and <i>bufsize</i> to contain the data to be referenced by the resulting <code>group</code> structure.
---------------------	---

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
MT-Level	See "Reentrant Interfaces" in <code>DESCRIPTION</code> .

SEE ALSO `Intro(3)`, `getpwnam(3C)`, `group(4)`, `nsswitch.conf(4)`, `passwd(4)`, `attributes(5)`, `standards(5)`

NOTES When compiling multithreaded programs, see `Intro(3)`, *Notes On Multithreaded Applications*.

Programs that use the interfaces described in this manual page cannot be linked statically since the implementations of these functions employ dynamic loading and linking of shared objects at run time.

Use of the enumeration interfaces `getgrent()` and `getgrent_r()` is discouraged; enumeration is supported for the group file, NIS, and NIS+, but in general is not efficient and may not be supported for all database sources. The semantics of enumeration are discussed further in `nsswitch.conf(4)`.

Previous releases allowed the use of "+" and "-" entries in `/etc/group` to selectively include and exclude entries from NIS. The primary usage of these entries is superseded by the name service switch, so the "+/-" form *may not be supported in future releases*.

If required, the "+/-" functionality can still be obtained for NIS by specifying `compat` as the source for `group`.

If the "+/-" functionality is required in conjunction with NIS+, specify both `compat` as the source for `group` and `nisplus` as the source for the pseudo-database `group_compat`. See `group(4)`, and `nsswitch.conf(4)` for details.

Solaris 2.4 and earlier releases provided definitions of the `getgrnam_r()` and `getgrgid_r()` functions as specified in POSIX.1c Draft 6. The final POSIX.1c standard changed the interface for these functions. Support for the Draft 6 interface is provided for compatibility only and may not be supported in future releases. New applications and libraries should use the POSIX standard interface.

For POSIX.1c-compliant applications, the `_POSIX_PTHREAD_SEMANTICS` and `_REENTRANT` flags are automatically turned on by defining the `_POSIX_C_SOURCE` flag with a value $\geq 199506L$.

getgrnam(3C)

NAME	getgrnam, getgrnam_r, getgrent, getgrent_r, getgrgid, getgrgid_r, setgrent, endgrent, fgetgrent, fgetgrent_r – group database entry functions
SYNOPSIS	<pre>#include <grp.h> struct group *getgrnam(const char *name); struct group *getgrnam_r(const char *name, struct group *grp, char *buffer, int bufsize); struct group *getgrent(void); struct group *getgrent_r(struct group *grp, char *buffer, int bufsize); struct group *getgrgid(gid_t gid); struct group *getgrgid_r(gid_t gid, struct group *grp, char *buffer, int bufsize); void setgrent(void); void endgrent(void); struct group *fgetgrent(FILE *f); struct group *fgetgrent_r(FILE *f, struct group *grp, char *buffer, int bufsize);</pre>
POSIX	<pre>cc [flag...] file... -D_POSIX_PTHREAD_SEMANTICS [library...] int getgrnam_r(const char *name, struct group *grp, char *buffer, size_t bufsize, struct group **result); int getgrgid_r(gid_t gid, struct group *grp, char *buffer, size_t bufsize, struct group **result);</pre>
DESCRIPTION	<p>These functions are used to obtain entries describing user groups. Entries can come from any of the sources for group specified in the <code>/etc/nsswitch.conf</code> file (see <code>nsswitch.conf(4)</code>).</p> <p>The <code>getgrnam()</code> function searches the group database for an entry with the group name specified by the character string parameter <i>name</i>.</p> <p>The <code>getgrgid()</code> function searches the group database for an entry with the (numeric) group id specified by <i>gid</i>.</p> <p>The <code>setgrent()</code>, <code>getgrent()</code>, and <code>endgrent()</code> functions are used to enumerate group entries from the database.</p> <p>The <code>setgrent()</code> function effectively rewinds the group database to allow repeated searches. It sets (or resets) the enumeration to the beginning of the set of group entries. This function should be called before the first call to <code>getgrent()</code>.</p>

The `getgrent()` function returns a pointer to a structure containing the broken-out fields of an entry in the group database. When first called, `getgrent()` returns a pointer to a `group` structure containing the next group structure in the group database. Successive calls may be used to search the entire database.

The `endgrent()` function may be called to close the group database and deallocate resources when processing is complete. It is permissible, though possibly less efficient, for the process to call more group functions after calling `endgrent()`.

The `fgetgrent()` function, unlike the other functions above, does not use `nsswitch.conf`. It reads and parses the next line from the stream *f*, which is assumed to have the format of the group file (see `group(4)`).

Reentrant Interfaces

The `getgrnam()`, `getgrgid()`, `getgrent()`, and `fgetgrent()` functions use static storage that is reused in each call, making them unsafe for multithreaded applications.

The parallel functions `getgrnam_r()`, `getgrgid_r()`, `getgrent_r()`, and `fgetgrent_r()` provide reentrant interfaces for these operations.

Each reentrant interface performs the same operation as its non-reentrant counterpart, named by removing the `_r` suffix. The reentrant interfaces, however, use buffers supplied by the caller to store returned results, and are safe for use in both single-threaded and multithreaded applications.

Each reentrant interface takes the same arguments as its non-reentrant counterpart, as well as the following additional parameters. The *grp* argument must be a pointer to a `struct group` structure allocated by the caller. On successful completion, the function returns the group entry in this structure. Storage referenced by the group structure is allocated from the memory provided with the *buffer* argument, which is *bufsize* characters in size. The maximum size needed for this buffer can be determined with the `_SC_GETGR_R_SIZE_MAX` `sysconf(3C)` parameter. The POSIX versions place a pointer to the modified *grp* structure in the *result* parameter, instead of returning a pointer to this structure.

For enumeration in multithreaded applications, the position within the enumeration is a process-wide property shared by all threads. `setgrent()` may be used in a multithreaded application but resets the enumeration position for all threads. If multiple threads interleave calls to `getgrent_r()`, the threads will enumerate disjoint subsets of the group database. Like their non-reentrant counterparts, `getgrnam_r()` and `getgrgid_r()` leave the enumeration position in an indeterminate state.

RETURN VALUES

Group entries are represented by the `struct group` structure defined in `<grp.h>`:

```
struct group {
    char *gr_name;           /* the name of the group */
    char *gr_passwd;        /* the encrypted group password */
    gid_t gr_gid;          /* the numerical group ID */
    char **gr_mem;         /* vector of pointers to member names */
};
```

getgrnam(3C)

The `getgrnam()`, `getgrnam_r()`, `getgrgid()`, and `getgrgid_r()` functions each return a pointer to a `struct group` if they successfully locate the requested entry; otherwise they return `NULL`. The POSIX functions `getgrnam_r()` and `getgrgid_r()` return 0 upon success or the error number in case of failure.

The `getgrent()`, `getgrent_r()`, `fgetgrent()`, and `fgetgrent_r()` functions each return a pointer to a `struct group` if they successfully enumerate an entry; otherwise they return `NULL`, indicating the end of the enumeration.

The `getgrnam()`, `getgrgid()`, `getgrent()`, and `fgetgrent()` functions use static storage, so returned data must be copied before a subsequent call to any of these functions if the data is to be saved.

When the pointer returned by the reentrant functions `getgrnam_r()`, `getgrgid_r()`, `getgrent_r()`, and `fgetgrent_r()` is non-null, it is always equal to the `grp` pointer that was supplied by the caller.

ERRORS The `getgrnam()`, `getgrgid()`, `getgrent()`, `fgetgrent()`, and `fgetgrent_r()` functions may fail if:

- `EINTR` A signal was caught during the operation.
- `EIO` An I/O error has occurred.
- `EMFILE` There are `OPEN_MAX` file descriptors currently open in the calling process.
- `ENFILE` The maximum allowable number of files is currently open in the system.
- `ERANGE` The group file contains a line that exceeds 512 bytes.

The `getgrnam_r()`, `getgrgid_r()`, and `getgrent_r()` functions may fail if:

- `ERANGE` Insufficient storage was supplied by *buffer* and *bufsize* to contain the data to be referenced by the resulting `group` structure.

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
MT-Level	See "Reentrant Interfaces" in <code>DESCRIPTION</code> .

SEE ALSO `Intro(3)`, `getpwnam(3C)`, `group(4)`, `nsswitch.conf(4)`, `passwd(4)`, `attributes(5)`, `standards(5)`

NOTES When compiling multithreaded programs, see `Intro(3)`, *Notes On Multithreaded Applications*.

Programs that use the interfaces described in this manual page cannot be linked statically since the implementations of these functions employ dynamic loading and linking of shared objects at run time.

Use of the enumeration interfaces `getgrent()` and `getgrent_r()` is discouraged; enumeration is supported for the group file, NIS, and NIS+, but in general is not efficient and may not be supported for all database sources. The semantics of enumeration are discussed further in `nsswitch.conf(4)`.

Previous releases allowed the use of "+" and "-" entries in `/etc/group` to selectively include and exclude entries from NIS. The primary usage of these entries is superseded by the name service switch, so the "+/-" form *may not be supported in future releases*.

If required, the "+/-" functionality can still be obtained for NIS by specifying `compat` as the source for `group`.

If the "+/-" functionality is required in conjunction with NIS+, specify both `compat` as the source for `group` and `nisplus` as the source for the pseudo-database `group_compat`. See `group(4)`, and `nsswitch.conf(4)` for details.

Solaris 2.4 and earlier releases provided definitions of the `getgrnam_r()` and `getgrgid_r()` functions as specified in POSIX.1c Draft 6. The final POSIX.1c standard changed the interface for these functions. Support for the Draft 6 interface is provided for compatibility only and may not be supported in future releases. New applications and libraries should use the POSIX standard interface.

For POSIX.1c-compliant applications, the `_POSIX_PTHREAD_SEMANTICS` and `_REENTRANT` flags are automatically turned on by defining the `_POSIX_C_SOURCE` flag with a value $\geq 199506L$.

getgrnam_r(3C)

NAME	getgrnam, getgrnam_r, getgrent, getgrent_r, getgrgid, getgrgid_r, setgrent, endgrent, fgetgrent, fgetgrent_r – group database entry functions
SYNOPSIS	<pre>#include <grp.h> struct group *getgrnam(const char *name); struct group *getgrnam_r(const char *name, struct group *grp, char *buffer, int bufsize); struct group *getgrent(void); struct group *getgrent_r(struct group *grp, char *buffer, int bufsize); struct group *getgrgid(gid_t gid); struct group *getgrgid_r(gid_t gid, struct group *grp, char *buffer, int bufsize); void setgrent(void); void endgrent(void); struct group *fgetgrent(FILE *f); struct group *fgetgrent_r(FILE *f, struct group *grp, char *buffer, int bufsize);</pre>
POSIX	<pre>cc [flag...] file... -D_POSIX_PTHREAD_SEMANTICS [library...] int getgrnam_r(const char *name, struct group *grp, char *buffer, size_t bufsize, struct group **result); int getgrgid_r(gid_t gid, struct group *grp, char *buffer, size_t bufsize, struct group **result);</pre>
DESCRIPTION	<p>These functions are used to obtain entries describing user groups. Entries can come from any of the sources for group specified in the <code>/etc/nsswitch.conf</code> file (see <code>nsswitch.conf(4)</code>).</p> <p>The <code>getgrnam()</code> function searches the group database for an entry with the group name specified by the character string parameter <i>name</i>.</p> <p>The <code>getgrgid()</code> function searches the group database for an entry with the (numeric) group id specified by <i>gid</i>.</p> <p>The <code>setgrent()</code>, <code>getgrent()</code>, and <code>endgrent()</code> functions are used to enumerate group entries from the database.</p> <p>The <code>setgrent()</code> function effectively rewinds the group database to allow repeated searches. It sets (or resets) the enumeration to the beginning of the set of group entries. This function should be called before the first call to <code>getgrent()</code>.</p>

The `getgrent()` function returns a pointer to a structure containing the broken-out fields of an entry in the group database. When first called, `getgrent()` returns a pointer to a `group` structure containing the next group structure in the group database. Successive calls may be used to search the entire database.

The `endgrent()` function may be called to close the group database and deallocate resources when processing is complete. It is permissible, though possibly less efficient, for the process to call more group functions after calling `endgrent()`.

The `fgetgrent()` function, unlike the other functions above, does not use `nsswitch.conf`. It reads and parses the next line from the stream *f*, which is assumed to have the format of the group file (see `group(4)`).

Reentrant Interfaces

The `getgrnam()`, `getgrgid()`, `getgrent()`, and `fgetgrent()` functions use static storage that is reused in each call, making them unsafe for multithreaded applications.

The parallel functions `getgrnam_r()`, `getgrgid_r()`, `getgrent_r()`, and `fgetgrent_r()` provide reentrant interfaces for these operations.

Each reentrant interface performs the same operation as its non-reentrant counterpart, named by removing the `_r` suffix. The reentrant interfaces, however, use buffers supplied by the caller to store returned results, and are safe for use in both single-threaded and multithreaded applications.

Each reentrant interface takes the same arguments as its non-reentrant counterpart, as well as the following additional parameters. The *grp* argument must be a pointer to a `struct group` structure allocated by the caller. On successful completion, the function returns the group entry in this structure. Storage referenced by the group structure is allocated from the memory provided with the *buffer* argument, which is *bufsize* characters in size. The maximum size needed for this buffer can be determined with the `_SC_GETGR_R_SIZE_MAX` `sysconf(3C)` parameter. The POSIX versions place a pointer to the modified *grp* structure in the *result* parameter, instead of returning a pointer to this structure.

For enumeration in multithreaded applications, the position within the enumeration is a process-wide property shared by all threads. `setgrent()` may be used in a multithreaded application but resets the enumeration position for all threads. If multiple threads interleave calls to `getgrent_r()`, the threads will enumerate disjoint subsets of the group database. Like their non-reentrant counterparts, `getgrnam_r()` and `getgrgid_r()` leave the enumeration position in an indeterminate state.

RETURN VALUES

Group entries are represented by the `struct group` structure defined in `<grp.h>`:

```
struct group {
    char *gr_name;           /* the name of the group */
    char *gr_passwd;        /* the encrypted group password */
    gid_t gr_gid;           /* the numerical group ID */
    char **gr_mem;          /* vector of pointers to member names */
};
```

getgrnam_r(3C)

The `getgrnam()`, `getgrnam_r()`, `getgrgid()`, and `getgrgid_r()` functions each return a pointer to a `struct group` if they successfully locate the requested entry; otherwise they return `NULL`. The POSIX functions `getgrnam_r()` and `getgrgid_r()` return 0 upon success or the error number in case of failure.

The `getgrent()`, `getgrent_r()`, `fgetgrent()`, and `fgetgrent_r()` functions each return a pointer to a `struct group` if they successfully enumerate an entry; otherwise they return `NULL`, indicating the end of the enumeration.

The `getgrnam()`, `getgrgid()`, `getgrent()`, and `fgetgrent()` functions use static storage, so returned data must be copied before a subsequent call to any of these functions if the data is to be saved.

When the pointer returned by the reentrant functions `getgrnam_r()`, `getgrgid_r()`, `getgrent_r()`, and `fgetgrent_r()` is non-null, it is always equal to the `grp` pointer that was supplied by the caller.

ERRORS The `getgrnam()`, `getgrgid()`, `getgrent()`, `fgetgrent()`, and `fgetgrent_r()` functions may fail if:

<code>EINTR</code>	A signal was caught during the operation.
<code>EIO</code>	An I/O error has occurred.
<code>EMFILE</code>	There are <code>OPEN_MAX</code> file descriptors currently open in the calling process.
<code>ENFILE</code>	The maximum allowable number of files is currently open in the system.
<code>ERANGE</code>	The group file contains a line that exceeds 512 bytes.

The `getgrnam_r()`, `getgrgid_r()`, and `getgrent_r()` functions may fail if:

<code>ERANGE</code>	Insufficient storage was supplied by <i>buffer</i> and <i>bufsize</i> to contain the data to be referenced by the resulting <code>group</code> structure.
---------------------	---

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
MT-Level	See "Reentrant Interfaces" in <code>DESCRIPTION</code> .

SEE ALSO `Intro(3)`, `getpwnam(3C)`, `group(4)`, `nsswitch.conf(4)`, `passwd(4)`, `attributes(5)`, `standards(5)`

NOTES When compiling multithreaded programs, see `Intro(3)`, *Notes On Multithreaded Applications*.

Programs that use the interfaces described in this manual page cannot be linked statically since the implementations of these functions employ dynamic loading and linking of shared objects at run time.

Use of the enumeration interfaces `getgrent()` and `getgrent_r()` is discouraged; enumeration is supported for the group file, NIS, and NIS+, but in general is not efficient and may not be supported for all database sources. The semantics of enumeration are discussed further in `nsswitch.conf(4)`.

Previous releases allowed the use of "+" and "-" entries in `/etc/group` to selectively include and exclude entries from NIS. The primary usage of these entries is superseded by the name service switch, so the "+/-" form *may not be supported in future releases*.

If required, the "+/-" functionality can still be obtained for NIS by specifying `compat` as the source for `group`.

If the "+/-" functionality is required in conjunction with NIS+, specify both `compat` as the source for `group` and `nisplus` as the source for the pseudo-database `group_compat`. See `group(4)`, and `nsswitch.conf(4)` for details.

Solaris 2.4 and earlier releases provided definitions of the `getgrnam_r()` and `getgrgid_r()` functions as specified in POSIX.1c Draft 6. The final POSIX.1c standard changed the interface for these functions. Support for the Draft 6 interface is provided for compatibility only and may not be supported in future releases. New applications and libraries should use the POSIX standard interface.

For POSIX.1c-compliant applications, the `_POSIX_PTHREAD_SEMANTICS` and `_REENTRANT` flags are automatically turned on by defining the `_POSIX_C_SOURCE` flag with a value $\geq 199506L$.

gethomelgroup(3C)

NAME | getcpuid, gethomelgroup – obtain information on scheduling decisions

SYNOPSIS | #include <sys/processor.h>
processorid_t **getcpuid**(void);
lgrp_t **gethomelgroup**(void);

DESCRIPTION | The getcpuid() function returns the processor ID on which the calling thread is currently executing.

The gethomelgroup() function returns the home latency group ID of the calling thread.

RETURN VALUES | See DESCRIPTION.

ERRORS | No errors are defined.

USAGE | Both the current CPU and the home latency group are subject to change at any time, so the value returned by these functions might already be incorrect upon completion of the call.

ATTRIBUTES | See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Interface Stability	Stable
MT-Level	MT-Safe

SEE ALSO | psradm(1M), psrinfo(1M), psrset(1M), p_online(2), processor_bind(2), processor_info(2), pset_assign(2), pset_bind(2), pset_info(2), meminfo(2), sysconf(3C), attributes(5)

NAME | gethostid – get an identifier for the current host

SYNOPSIS | `#include <unistd.h>`
| `long gethostid(void);`

DESCRIPTION | The `gethostid()` function returns the 32-bit identifier for the current host. This identifier is taken from the CPU board's ID PROM. It is not guaranteed to be unique.

ATTRIBUTES | See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE

gethostname(3C)

NAME	gethostname, sethostname – get or set name of current host				
SYNOPSIS	<pre>#include <unistd.h> int gethostname(char *name, int namelen); int sethostname(char *name, int namelen);</pre>				
DESCRIPTION	<p>The <code>gethostname()</code> function returns the standard host name for the current processor, as previously set by <code>sethostname()</code>. The <code>namelen</code> argument specifies the size of the array pointed to by <code>name</code>. The returned name is null-terminated unless insufficient space is provided.</p> <p>The <code>sethostname()</code> function sets the name of the host machine to be <code>name</code>, which has length <code>namelen</code>. This call is restricted to the superuser and is normally used only when the system is bootstrapped.</p> <p>Host names are limited to <code>MAXHOSTNAMELEN</code> characters, currently 256, defined in the <code><netdb.h></code> header.</p>				
RETURN VALUES	Upon successful completion, <code>gethostname()</code> and <code>sethostname()</code> return 0. Otherwise, they return <code>-1</code> and set <code>errno</code> to indicate the error.				
ERRORS	The <code>gethostname()</code> and <code>sethostname()</code> functions will fail if: EFAULT The <code>name</code> or <code>namelen</code> argument gave an invalid address. The <code>sethostname()</code> function will fail if: EPERM The caller was not the superuser.

NAME | gethrtime, gethrvtime – get high resolution time

SYNOPSIS | `#include <sys/time.h>`
`hrtime_t gethrtime(void);`
`hrtime_t gethrvtime(void);`

DESCRIPTION | The `gethrtime()` function returns the current high-resolution real time. Time is expressed as nanoseconds since some arbitrary time in the past; it is not correlated in any way to the time of day, and thus is *not* subject to resetting or drifting by way of `adjtime(2)` or `settimeofday(3C)`. The hi-res timer is ideally suited to performance measurement tasks, where cheap, accurate interval timing is required.

The `gethrvtime()` function returns the current high-resolution LWP virtual time, expressed as total nanoseconds of execution time. This function requires that micro state accounting be enabled with the `ptime` utility (see `proc(1)`).

The `gethrtime()` and `gethrvtime()` functions both return an `hrtime_t`, which is a 64-bit (long long) signed integer.

EXAMPLES | The following code fragment measures the average cost of `getpid(2)`:

```
hrtime_t start, end;
int i, iters = 100;

start = gethrtime();
for (i = 0; i < iters; i++)
    getpid();
end = gethrtime();

printf("Avg getpid() time = %lld nsec\n", (end - start) / iters);
```

ATTRIBUTES | See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
MT-Level	MT-Safe

SEE ALSO | `proc(1)`, `adjtime(2)`, `gettimeofday(3C)`, `settimeofday(3C)`, `attributes(5)`

NOTES | Although the units of hi-res time are always the same (nanoseconds), the actual resolution is hardware dependent. Hi-res time is guaranteed to be monotonic (it won't go backward, it won't periodically wrap) and linear (it won't occasionally speed up or slow down for adjustment, like the time of day can), but not necessarily unique: two sufficiently proximate calls may return the same value.

gethrvtime(3C)

NAME	gethrtime, gethrvtime – get high resolution time				
SYNOPSIS	<pre>#include <sys/time.h> hrtime_t gethrtime(void); hrtime_t gethrvtime(void);</pre>

NAME	getloadavg – get system load averages				
SYNOPSIS	<pre>#include <sys/loadavg.h> int getloadavg(double <i>loadavg</i>[], int <i>nelem</i>);</pre>				
DESCRIPTION	The <code>getloadavg()</code> function returns the number of processes in the system run queue averaged over various periods of time. Up to <i>nelem</i> samples are retrieved and assigned to successive elements of <i>loadavg</i> []. The system imposes a maximum of 3 samples, representing averages over the last 1, 5, and 15 minutes, respectively. The <code>LOADAVG_1MIN</code> , <code>LOADAVG_5MIN</code> , and <code>LOADAVG_15MIN</code> indices, defined in <code><sys/loadavg.h></code> , can be used to extract the data from the appropriate element of the <i>loadavg</i> [] array.				
RETURN VALUES	Upon successful completion, the number of samples actually retrieved is returned. If the load average was unobtainable, <code>-1</code> is returned and <code>errno</code> is set to indicate the error.				
ERRORS	The <code>getloadavg()</code> function will fail if: <code>EINVAL</code> The number of elements specified is less than 0.				
ATTRIBUTES	See <code>attributes(5)</code> for descriptions of the following attributes:				
	<table border="1" style="width: 100%; border-collapse: collapse;"> <thead> <tr> <th style="text-align: center;">ATTRIBUTE TYPE</th> <th style="text-align: center;">ATTRIBUTE VALUE</th> </tr> </thead> <tbody> <tr> <td>MT-Level</td> <td>Async-Signal-Safe</td> </tr> </tbody> </table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	MT-Level	Async-Signal-Safe

getlogin(3C)

NAME	getlogin, getlogin_r – get login name										
SYNOPSIS	<pre>#include <unistd.h> char *getlogin(void); char *getlogin_r(char *name, int namelen);</pre>										
POSIX	<pre>cc [flag ...] file... -D_POSIX_PTHREAD_SEMANTICS [library ...] int getlogin_r(char *name, size_t namesize);</pre>										
DESCRIPTION	<p>The <code>getlogin()</code> function returns a pointer to the login name as found in <code>/var/adm/utmpx</code>. It may be used in conjunction with <code>getpwnam(3C)</code> to locate the correct password file entry when the same user ID is shared by several login names.</p> <p>If <code>getlogin()</code> is called within a process that is not attached to a terminal, it returns a null pointer. The correct procedure for determining the login name is to call <code>cuserid(3C)</code>, or to call <code>getlogin()</code> and if it fails to call <code>getpwuid(3C)</code>.</p> <p>The <code>getlogin_r()</code> function has the same functionality as <code>getlogin()</code> except that the caller must supply a buffer <code>name</code> with length <code>namelen</code> to store the result. The <code>name</code> buffer must be at least <code>_POSIX_LOGIN_NAME_MAX</code> bytes in size (defined in <code><limits.h></code>). The POSIX version (see <code>standards(5)</code>) of <code>getlogin_r()</code> takes a <code>namesize</code> parameter of type <code>size_t</code>.</p>										
RETURN VALUES	<p>Upon successful completion, <code>getlogin()</code> returns a pointer to the login name or a null pointer if the user's login name cannot be found. Otherwise it returns a null pointer and sets <code>errno</code> to indicate the error.</p> <p>The POSIX <code>getlogin_r()</code> returns 0 if successful, or the error number upon failure.</p>										
ERRORS	<p>The <code>getlogin()</code> function may fail if:</p> <table><tr><td>EMFILE</td><td>There are <code>OPEN_MAX</code> file descriptors currently open in the calling process.</td></tr><tr><td>ENFILE</td><td>The maximum allowable number of files is currently open in the system.</td></tr><tr><td>ENXIO</td><td>The calling process has no controlling terminal.</td></tr></table> <p>The <code>getlogin_r()</code> function will fail if:</p> <table><tr><td>ERANGE</td><td>The size of the buffer is smaller than the result to be returned.</td></tr><tr><td>EINVAL</td><td>And entry for the current user was not found in the <code>/var/adm/utmpx</code> file.</td></tr></table>	EMFILE	There are <code>OPEN_MAX</code> file descriptors currently open in the calling process.	ENFILE	The maximum allowable number of files is currently open in the system.	ENXIO	The calling process has no controlling terminal.	ERANGE	The size of the buffer is smaller than the result to be returned.	EINVAL	And entry for the current user was not found in the <code>/var/adm/utmpx</code> file.
EMFILE	There are <code>OPEN_MAX</code> file descriptors currently open in the calling process.										
ENFILE	The maximum allowable number of files is currently open in the system.										
ENXIO	The calling process has no controlling terminal.										
ERANGE	The size of the buffer is smaller than the result to be returned.										
EINVAL	And entry for the current user was not found in the <code>/var/adm/utmpx</code> file.										
USAGE	The return value may point to static data whose content is overwritten by each call.										

Three names associated with the current process can be determined: `getpwuid(geteuid())` returns the name associated with the effective user ID of the process; `getlogin()` returns the name associated with the current login activity; and `getpwuid(getuid())` returns the name associated with the real user ID of the process.

FILES /var/adm/utmpx user access and administration information

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

getmntany(3C)

NAME	getmntent, getmntany, getextmntent, hasmntopt, putmntent, resetmnttab – get mounted device information
SYNOPSIS	<pre>#include <stdio.h> #include <sys/mnttab.h> int getmntent(FILE *fp, struct mnttab *mp); int getmntany(FILE *fp, struct mnttab *mp, struct mnttab *mpref); int getextmntent(FILE *fp, struct extmnttab *mp, int len); char *hasmntopt(struct mnttab *mnt, char *opt); int putmntent(FILE *iop, struct mnttab *mp); void resetmnttab(FILE *fp);</pre>
getmntent () and getmntany ()	<p>The <code>getmntent ()</code> and <code>getmntany ()</code> functions each fill in the structure pointed to by <code>mp</code> with the broken-out fields of a line in the <code>mnttab</code> file. Each line read from the file contains a <code>mnttab</code> structure, which is defined in the <code><sys/mnttab.h></code> header. The structure contains the following members, which correspond to the broken-out fields from a line in <code>/etc/mnttab</code> (see <code>mnttab(4)</code>).</p> <pre>char *mnt_special; /* name of mounted resource */ char *mnt_mountp; /* mount point */ char *mnt_fstype; /* type of file system mounted */ char *mnt_mntopts; /* options for this mount */ char *mnt_time; /* time file system mounted */</pre> <p>Each <code>getmntent ()</code> call causes a new line to be read from the <code>mnttab</code> file. Successive calls can be used to search the entire list. The <code>getmntany ()</code> function searches the file referenced by <code>fp</code> until a match is found between a line in the file and <code>mpref</code>. A match occurs if all non-null entries in <code>mpref</code> match the corresponding fields in the file. Note that these functions do not open, close, or rewind the file.</p>
getextmntent ()	<p>The <code>getextmntent ()</code> function is an extended version of the <code>getmntent ()</code> function that returns, in addition to the information that <code>getmntent ()</code> returns, the major and minor number of the mounted resource to which the line in <code>mnttab</code> corresponds. The <code>getextmntent ()</code> function also fills in the <code>extmntent</code> structure defined in the <code><sys/mnttab.h></code> header. For <code>getextmntent ()</code> to function properly, it must be notified when the <code>mnttab</code> file has been reopened or rewound since a previous <code>getextmntent ()</code> call. This notification is accomplished by calling <code>resetmnttab ()</code>. Otherwise, it behaves exactly as <code>getmntent ()</code> described above.</p> <p>The data pointed to by the <code>mnttab</code> structure members are stored in a static area and must be copied to be saved between successive calls.</p>
hasmntopt ()	<p>The <code>hasmntopt ()</code> function scans the <code>mnt_mntopts</code> member of the <code>mnttab</code> structure <code>mnt</code> for a substring that matches <code>opt</code>. It returns the address of the substring if a match is found; otherwise it returns 0. Substrings are delimited by commas and the end of the <code>mnt_mntopts</code> string.</p>

- `putmntent()` The `putmntent()` function is obsolete and no longer has any effect. Entries appear in `mnttab` as a side effect of a `mount(2)` call. The function name is still defined for transition purposes.
- `resetmnttab()` The `resetmnttab()` function notifies `getextmntent()` to reload from the kernel the device information that corresponds to the new snapshot of the `mnttab` information (see `mnttab(4)`). Subsequent `getextmntent()` calls then return correct `extmnttab` information. This function should be called whenever the `mnttab` file is either rewound or closed and reopened before any calls are made to `getextmntent()`.
- `getmntent()` and `getmntany()` If the next entry is successfully read by `getmntent()` or a match is found with `getmntany()`, 0 is returned. If an EOF is encountered on reading, these functions return -1. If an error is encountered, a value greater than 0 is returned. The following error values are defined in `<sys/mnttab.h>`:
- `MNT_TOOLONG` A line in the file exceeded the internal buffer size of `MNT_LINE_MAX`.
- `MNT_TOOMANY` A line in the file contains too many fields.
- `MNT_TOOFEW` A line in the file contains too few fields.
- `hasmntopt()` Upon successful completion, `hasmntopt()` returns the address of the substring if a match is found. Otherwise, it returns 0.
- `putmntent()` The `putmntent()` is obsolete and always returns -1.

getmntent(3C)

NAME	getmntent, getmntany, getextmntent, hasmntopt, putmntent, resetmnttab – get mounted device information
SYNOPSIS	<pre>#include <stdio.h> #include <sys/mnttab.h> int getmntent(FILE *fp, struct mnttab *mp); int getmntany(FILE *fp, struct mnttab *mp, struct mnttab *mpref); int getextmntent(FILE *fp, struct extmnttab *mp, int len); char *hasmntopt(struct mnttab *mnt, char *opt); int putmntent(FILE *iop, struct mnttab *mp); void resetmnttab(FILE *fp);</pre>
getmntent() and getmntany()	<p>The <code>getmntent()</code> and <code>getmntany()</code> functions each fill in the structure pointed to by <code>mp</code> with the broken-out fields of a line in the <code>mnttab</code> file. Each line read from the file contains a <code>mnttab</code> structure, which is defined in the <code><sys/mnttab.h></code> header. The structure contains the following members, which correspond to the broken-out fields from a line in <code>/etc/mnttab</code> (see <code>mnttab(4)</code>).</p> <pre>char *mnt_special; /* name of mounted resource */ char *mnt_mountp; /* mount point */ char *mnt_fstype; /* type of file system mounted */ char *mnt_mntopts; /* options for this mount */ char *mnt_time; /* time file system mounted */</pre> <p>Each <code>getmntent()</code> call causes a new line to be read from the <code>mnttab</code> file. Successive calls can be used to search the entire list. The <code>getmntany()</code> function searches the file referenced by <code>fp</code> until a match is found between a line in the file and <code>mpref</code>. A match occurs if all non-null entries in <code>mpref</code> match the corresponding fields in the file. Note that these functions do not open, close, or rewind the file.</p>
getextmntent()	<p>The <code>getextmntent()</code> function is an extended version of the <code>getmntent()</code> function that returns, in addition to the information that <code>getmntent()</code> returns, the major and minor number of the mounted resource to which the line in <code>mnttab</code> corresponds. The <code>getextmntent()</code> function also fills in the <code>extmntent</code> structure defined in the <code><sys/mnttab.h></code> header. For <code>getextmntent()</code> to function properly, it must be notified when the <code>mnttab</code> file has been reopened or rewound since a previous <code>getextmntent()</code> call. This notification is accomplished by calling <code>resetmnttab()</code>. Otherwise, it behaves exactly as <code>getmntent()</code> described above.</p> <p>The data pointed to by the <code>mnttab</code> structure members are stored in a static area and must be copied to be saved between successive calls.</p>
hasmntopt()	<p>The <code>hasmntopt()</code> function scans the <code>mnt_mntopts</code> member of the <code>mnttab</code> structure <code>mnt</code> for a substring that matches <code>opt</code>. It returns the address of the substring if a match is found; otherwise it returns 0. Substrings are delimited by commas and the end of the <code>mnt_mntopts</code> string.</p>

- `putmntent()` The `putmntent()` function is obsolete and no longer has any effect. Entries appear in `mnttab` as a side effect of a `mount(2)` call. The function name is still defined for transition purposes.
- `resetmnttab()` The `resetmnttab()` function notifies `getextmntent()` to reload from the kernel the device information that corresponds to the new snapshot of the `mnttab` information (see `mnttab(4)`). Subsequent `getextmntent()` calls then return correct `extmnttab` information. This function should be called whenever the `mnttab` file is either rewound or closed and reopened before any calls are made to `getextmntent()`.
- `getmntent()` and `getmntany()` If the next entry is successfully read by `getmntent()` or a match is found with `getmntany()`, 0 is returned. If an EOF is encountered on reading, these functions return -1. If an error is encountered, a value greater than 0 is returned. The following error values are defined in `<sys/mnttab.h>`:
- `MNT_TOOLONG` A line in the file exceeded the internal buffer size of `MNT_LINE_MAX`.
- `MNT_TOOMANY` A line in the file contains too many fields.
- `MNT_TOOFEW` A line in the file contains too few fields.
- `hasmntopt()` Upon successful completion, `hasmntopt()` returns the address of the substring if a match is found. Otherwise, it returns 0.
- `putmntent()` The `putmntent()` is obsolete and always returns -1.

getnetgrent(3C)

NAME	getnetgrent, getnetgrent_r, setnetgrent, endnetgrent, innetgr – get network group entry
SYNOPSIS	<pre>#include <netdb.h> int getnetgrent(char **<i>machinep</i>, char **<i>userp</i>, char **<i>domainp</i>); int getnetgrent_r(char **<i>machinep</i>, char **<i>userp</i>, char **<i>domainp</i>, char *<i>buffer</i>, int<i>buflen</i>); int setnetgrent(const char *<i>netgroup</i>); int endnetgrent(void); int innetgr(const char *<i>netgroup</i>, const char *<i>machine</i>, const char *<i>user</i>, const char *<i>domain</i>);</pre>
DESCRIPTION	<p>These functions are used to test membership in and enumerate members of “netgroup” network groups defined in a system database. Netgroups are sets of (machine,user,domain) triples (see netgroup(4)).</p> <p>These functions consult the source specified for netgroup in the /etc/nsswitch.conf file (see nsswitch.conf(4)).</p> <p>The function innetgr() returns 1 if there is a netgroup <i>netgroup</i> that contains the specified <i>machine</i>, <i>user</i>, <i>domain</i> triple as a member; otherwise it returns 0. Any of the supplied pointers <i>machine</i>, <i>user</i>, and <i>domain</i> may be NULL, signifying a “wild card” that matches all values in that position of the triple.</p> <p>The innetgr() function is safe for use in single-threaded and multithreaded applications.</p> <p>The functions setnetgrent(), getnetgrent(), and endnetgrent() are used to enumerate the members of a given network group.</p> <p>The function setnetgrent() establishes the network group specified in the parameter <i>netgroup</i> as the current group whose members are to be enumerated.</p> <p>Successive calls to the function getnetgrent() will enumerate the members of the group established by calling setnetgrent(); each call returns 1 if it succeeds in obtaining another member of the network group, or 0 if there are no further members of the group.</p> <p>When calling either getnetgrent() or getnetgrent_r(), addresses of the three character pointers are used as arguments, for example:</p> <pre>char *<i>mp</i>, *<i>up</i>, *<i>dp</i>; getnetgrent(&<i>mp</i>, &<i>up</i>, &<i>dp</i>);</pre>

Upon successful return from `getnetgrent()`, the pointer `mp` points to a string containing the name of the machine part of the member triple, `up` points to a string containing the user name and `dp` points to a string containing the domain name. If the pointer returned for `mp`, `up`, or `dp` is `NULL`, it signifies that the element of the netgroup contains wild card specifier in that position of the triple.

The pointers returned by `getnetgrent()` point into a buffer allocated by `setnetgrent()` that is reused by each call. This space is released when an `endnetgrent()` call is made, and should not be released by the caller. This implementation is not safe for use in multi-threaded applications.

The function `getnetgrent_r()` is similar to `getnetgrent()` function, but it uses a buffer supplied by the caller for the space needed to store the results. The parameter `buffer` should be a pointer to a buffer allocated by the caller and the length of this buffer should be specified by the parameter `buflen`. The buffer must be large enough to hold the data associated with the triple. The `getnetgrent_r()` function is safe for use both in single-threaded and multi-threaded applications.

The function `endnetgrent()` frees the space allocated by the previous `setnetgrent()` call. The equivalent of an `endnetgrent()` implicitly performed whenever a `setnetgrent()` call is made to a new network group.

Note that while `setnetgrent()` and `endnetgrent()` are safe for use in multi-threaded applications, the effect of each is process-wide. Calling `setnetgrent()` resets the enumeration position for all threads. If multiple threads interleave calls to `getnetgrent_r()` each will enumerate a disjoint subset of the netgroup. Thus the effective use of these functions in multi-threaded applications may require coordination by the caller.

ERRORS The function `getnetgrent_r()` will return 0 and set `errno` to `ERANGE` if the length of the buffer supplied by caller is not large enough to store the result. See `Intro(2)` for the proper usage and interpretation of `errno` in multi-threaded applications.

The functions `setnetgrent()` and `endnetgrent()` return 0 upon success.

FILES `/etc/nsswitch.conf`

getopt(3C)

NAME	getopt – get option letter from argument vector
SYNOPSIS	
SVID3, XPG3	<pre>#include <stdio.h> int getopt(int <i>argc</i>, char * const <i>argv</i>[], const char *<i>optstring</i>); extern char *<i>optarg</i>; extern int <i>optind</i>, <i>opterr</i>, <i>optopt</i>;</pre>
POSIX.2, XPG4, SUS, SUSv2	<pre>#include <unistd.h> int getopt(int <i>argc</i>, char * const <i>argv</i>[], const char *<i>optstring</i>); extern char *<i>optarg</i>; extern int <i>optind</i>, <i>opterr</i>, <i>optopt</i>;</pre>
DESCRIPTION	<p>The <code>getopt()</code> function returns the next option letter in <i>argv</i> that matches a letter in <i>optstring</i>. It supports all the rules of the command syntax standard (see <code>intro(1)</code>). Since all new commands are intended to adhere to the command syntax standard, they should use <code>getopts(1)</code>, <code>getopt(3C)</code>, or <code>getsubopt(3C)</code> to parse positional parameters and check for options that are legal for that command.</p> <p>The <i>optstring</i> argument must contain the option letters the command using <code>getopt()</code> will recognize; if a letter is followed by a colon, the option is expected to have an argument, or group of arguments, which may be separated from it by white space. The <i>optarg</i> argument is set to point to the start of the option argument on return from <code>getopt()</code>.</p> <p>The <code>getopt()</code> function places in <i>optind</i> the <i>argv</i> index of the next argument to be processed. <i>optind</i> is external and is initialized to 1 before the first call to <code>getopt()</code>. When all options have been processed (that is, up to the first non-option argument), <code>getopt()</code> returns -1. The special option “—” (two hyphens) may be used to delimit the end of the options; when it is encountered, -1 is returned and “—” is skipped. This is useful in delimiting non-option arguments that begin with “-” (hyphen).</p>
RETURN VALUES	<p>The <code>getopt()</code> function returns the next option character specified on the command line.</p> <p>A colon (':') is returned if <code>getopt()</code> detects a missing argument and the first character of <i>optstring</i> was a colon (':').</p> <p>The <code>getopt()</code> function outputs an error message to standard error and returns a question mark ('?') when it encounters an option letter not included in <i>optstring</i> or no argument after an option that expects one. This error message can be disabled by setting <i>opterr</i> to 0. The value of the character that caused the error is in <i>optopt</i>.</p> <p>Otherwise, <code>getopt()</code> returns -1 when all command line options are parsed.</p>
ERRORS	No errors are defined.

EXAMPLES **EXAMPLE 1** Parsing Command Line Options

The following code fragment shows how you might process the arguments for a utility that can take the mutually-exclusive options a and b and the options f and o, both of which require arguments:

```
#include <unistd.h>

int
main(int argc, char *argv[ ])
{
    int c;
    int bflg, aflag, errflag;
    char *ifile;
    char *ofile;
    extern char *optarg;
    extern int optind, optopt;
    . . .
    while ((c = getopt(argc, argv, ":abf:o:")) != -1) {
        switch(c) {
            case 'a':
                if (bflg)
                    errflag++;
                else
                    aflag++;
                break;
            case 'b':
                if (aflag)
                    errflag++;
                else {
                    bflg++;
                    bproc();
                }
                break;
            case 'f':
                ifile = optarg;
                break;
            case 'o':
                ofile = optarg;
                break;
            case ':': /* -f or -o without operand */
                fprintf(stderr,
                    "Option -%c requires an operand\n", optopt);
                errflag++;
                break;
            case '?':
                fprintf(stderr,
                    "Unrecognized option: -%c\n", optopt);
                errflag++;
        }
    }
    if (errflag) {
        fprintf(stderr, "usage: . . . ");
        exit(2);
    }
    for ( ; optind < argc; optind++) {
        if (access(argv[optind], R_OK)) {
            . . .
        }
    }
}
```

EXAMPLE 1 Parsing Command Line Options (Continued)

}

This code accepts any of the following as equivalent:

```
cmd -ao arg path path
cmd -a -o arg path path
cmd -o arg -a path path
cmd -a -o arg -- path path
cmd -a -oarg path path
cmd -aoarg path path
```

EXAMPLE 2 Check Options and Arguments.

The following example parses a set of command line options and prints messages to standard output for each option and argument that it encounters.

```
#include unistd.h>
#include <stdio.h>
...
int c;
char *filename;
extern char *optarg;
extern int optind, optopt, opterr;
...
while ((c = getopt(argc, argv, ":abf:")) != -1) {
    switch(c) {
        case 'a':
            printf("a is set\n");
            break;
        case 'b':
            printf("b is set\n");
            break;
        case 'f':
            filename = optarg;
            printf("filename is %s\n", filename);
            break;
        case ':':
            printf("-%c without filename\n", optopt);
            break;
        case '?':
            printf("unknown arg %c\n", optopt);
            break;
    }
}
```

EXAMPLE 3 Select Options from the Command Line.

The following example selects the type of database routines the user wants to use based on the *Options* argument.

```
#include <unistd.h>
#include <string.h>
...
```

EXAMPLE 3 Select Options from the Command Line. (Continued)

```
char *Options = "hdbt1";
...
int dbtype, i;
char c;
char *st;
...
dbtype = 0;
while ((c = getopt(argc, argv, Options)) != -1) {
    if ((st = strchr(Options, c)) != NULL) {
        dbtype = st - Options;
        break;
    }
}
```

ENVIRONMENT VARIABLES

See `environ(5)` for descriptions of the following environment variables that affect the execution of `getopt()`: `LANG`, `LC_ALL`, and `LC_MESSAGES`.

`LC_CTYPE` Determine the locale for the interpretation of sequences of bytes as characters in *optstring*.

USAGE

The `getopt()` function does not fully check for mandatory arguments; that is, given an option string `a:b` and the input `-a -b`, `getopt()` assumes that `-b` is the mandatory argument to the `-a` option and not that `-a` is missing a mandatory argument.

It is a violation of the command syntax standard (see `intro(1)`) for options with arguments to be grouped with other options, as in `cmd -abo filename`, where `a` and `b` are options, `o` is an option that requires an argument, and `filename` is the argument to `o`. Although this syntax is permitted in the current implementation, it should not be used because it may not be supported in future releases. The correct syntax to use is:

```
cmd- ab -o filename
```

ATTRIBUTES

getpagesize(3C)

NAME	getpagesize – get system page size				
SYNOPSIS	<pre>#include <unistd.h> int getpagesize(void);</pre>				
DESCRIPTION	<p>The <code>getpagesize()</code> function returns the number of bytes in a page. Page granularity is the granularity of many of the memory management calls.</p> <p>The page size is a system page size and need not be the same as the underlying hardware page size.</p> <p>The <code>getpagesize()</code> function is equivalent to <code>sysconf(_SC_PAGE_SIZE)</code> and <code>sysconf(_SC_PAGESIZE)</code>. See <code>sysconf(3C)</code>.</p>				
RETURN VALUES	The <code>getpagesize()</code> function returns the current page size.				
ERRORS	No errors are defined.				
USAGE	The value returned by <code>getpagesize()</code> need not be the minimum value that <code>malloc(3C)</code> can allocate. Moreover, the application cannot assume that an object of this size can be allocated with <code>malloc()</code> .				
ATTRIBUTES	See <code>attributes(5)</code> for descriptions of the following attributes:				
	<table border="1"><thead><tr><th>ATTRIBUTE TYPE</th><th>ATTRIBUTE VALUE</th></tr></thead><tbody><tr><td>MT-Level</td><td>MT-Safe</td></tr></tbody></table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	MT-Level	MT-Safe

MT-Level	MT-Safe				
SEE ALSO	<code>pagesize(1)</code> , <code>brk(2)</code> , <code>getrlimit(2)</code> , <code>mmap(2)</code> , <code>mprotect(2)</code> , <code>munmap(2)</code> , <code>malloc(3C)</code> , <code>msync(3C)</code> , <code>sysconf(3C)</code> , <code>attributes(5)</code>				

NAME	getpagesizes – get system supported page sizes				
SYNOPSIS	<pre>#include <sys/mman.h> int getpagesizes(size_t <i>pagesize</i>[], int <i>nelem</i>);</pre>				
DESCRIPTION	The <code>getpagesizes()</code> function returns either the number of different page sizes supported by the system or the actual sizes themselves. When called with <i>nelem</i> as 0 and <i>pagesize</i> as NULL, <code>getpagesizes()</code> returns the number of supported page sizes. Otherwise, up to <i>nelem</i> page sizes are retrieved and assigned to successive elements of <i>pagesize</i> []. The return value is the number of page sizes retrieved and set in <i>pagesize</i> [].				
RETURN VALUES	Upon successful completion, the number of pagesizes supported or actually retrieved is returned. Otherwise, -1 is returned and <code>errno</code> is set to indicate the error.				
ERRORS	The <code>getpagesizes()</code> function will fail if: <p><code>EINVAL</code> The <i>nelem</i> argument is less than 0 or <i>pagesize</i> is NULL but <i>nelem</i> is non-zero.</p>				
USAGE	The <code>getpagesizes()</code> function returns all the page sizes for which the hardware and system software provide support for the <code>mencnt1(2)</code> command <code>MC_HATMAPSIZE</code> . However, not all processors support all page sizes and/or combinations of page sizes with equal efficiency. Applications programmers should take this into consideration when using <code>getpagesizes()</code> .

getpriority(3C)

NAME	getpriority, setpriority – get or set process scheduling priority				
SYNOPSIS	<pre>#include <sys/resource.h> int getpriority(int <i>which</i>, id_t <i>who</i>); int setpriority(int <i>which</i>, id_t <i>who</i>, int <i>priority</i>);</pre>				
DESCRIPTION	<p>The <code>getpriority()</code> function obtains the current scheduling priority of a process, process group, or user. The <code>setpriority()</code> function sets the scheduling priority of a process, process group, or user.</p> <p>Target processes are specified by the values of the <i>which</i> and <i>who</i> arguments. The <i>which</i> argument may be one of the following values: <code>PRIO_PROCESS</code>, <code>PRIO_PGRP</code>, <code>PRIO_USER</code>, <code>PRIO_GROUP</code>, <code>PRIO_SESSION</code>, <code>PRIO_LWP</code>, <code>PRIO_LWP</code>, or <code>PRIO_PROJECT</code>, indicating that the <i>who</i> argument is to be interpreted as a process ID, a process group ID, a user ID, a group ID, a session ID, an lwp ID, a task ID, or a project ID, respectively. A 0 value for the <i>who</i> argument specifies the current process, process group, or user. A 0 value for the <i>who</i> argument is treated as valid group ID, session ID, lwp ID, task ID, or project ID. A <code>P_MYID</code> value for the <i>who</i> argument can be used to specify the current group, session, lwp, task, or project, respectively.</p> <p>If more than one process is specified, <code>getpriority()</code> returns the highest priority (lowest numerical value) pertaining to any of the specified processes, and <code>setpriority()</code> sets the priorities of all of the specified processes to the specified value.</p> <p>The default <i>priority</i> is 0; negative priorities cause more favorable scheduling. While the range of valid priority values is <code>[-20, 20]</code>, implementations may enforce more restrictive limits. If the value specified to <code>setpriority()</code> is less than the system's lowest supported priority value, the system's lowest supported value is used. If it is greater than the system's highest supported value, the system's highest supported value is used.</p> <p>Only a process with appropriate privileges can raise its priority (that is, assign a lower numerical priority value).</p>				
RETURN VALUES	<p>Upon successful completion, <code>getpriority()</code> returns an integer in the range from <code>-20</code> to <code>20</code>. Otherwise, <code>-1</code> is returned and <code>errno</code> is set to indicate the error.</p> <p>Upon successful completion, <code>setpriority()</code> returns <code>0</code>. Otherwise, <code>-1</code> is returned and <code>errno</code> is set to indicate the error.</p>				
ERRORS	<p>The <code>getpriority()</code> and <code>setpriority()</code> functions will fail if:</p> <table><tr><td>ESRCH</td><td>No process could be located using the <i>which</i> and <i>who</i> argument values specified.</td></tr><tr><td>EINVAL</td><td>The value of the <i>which</i> argument was not recognized, or the value of the <i>who</i> argument is not a valid process ID, process group ID, user ID, group ID, session ID, lwp ID, task ID, or project ID.</td></tr></table>	ESRCH	No process could be located using the <i>which</i> and <i>who</i> argument values specified.	EINVAL	The value of the <i>which</i> argument was not recognized, or the value of the <i>who</i> argument is not a valid process ID, process group ID, user ID, group ID, session ID, lwp ID, task ID, or project ID.
ESRCH	No process could be located using the <i>which</i> and <i>who</i> argument values specified.				
EINVAL	The value of the <i>which</i> argument was not recognized, or the value of the <i>who</i> argument is not a valid process ID, process group ID, user ID, group ID, session ID, lwp ID, task ID, or project ID.				

In addition, `setpriority()` may fail if:

- EPERM** A process was located, but neither the real nor effective user ID of the executing process is the privileged user or match the effective user ID of the process whose priority is being changed.
- EACCES** A request was made to change the priority to a lower numeric value (that is, to a higher priority) and the current process does not have appropriate privileges.

USAGE The effect of changing the scheduling priority can vary depending on the process-scheduling algorithm in effect.

Because `getpriority()` can return `-1` on successful completion, it is necessary to set `errno` to `0` prior to a call to `getpriority()`. If `getpriority()` returns `-1`, then `errno` can be checked to see if an error occurred or if the value is a legitimate priority.

getpw(3C)

NAME | getpw – get passwd entry from UID

SYNOPSIS | `#include <stdlib.h>`
| `int getpw(uid_t uid, char *buf);`

DESCRIPTION | The `getpw()` function searches the user data base for a user id number that equals *uid*, copies the line of the password file in which *uid* was found into the array pointed to by *buf*, and returns 0. `getpw()` returns non-zero if *uid* cannot be found.

USAGE | This function is included only for compatibility with prior systems and should not be used; the functions described on the `getpwnam(3C)` manual page should be used instead.

| If the `/etc/passwd` and the `/etc/group` files have a plus sign (+) for the NIS entry, then `getpwent()` and `getgrent()` will not return NULL when the end of file is reached. See `getpwnam(3C)`.

RETURN VALUES | The `getpw()` function returns non-zero on error.

ATTRIBUTES | See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
MT-Level	Safe

SEE ALSO | `getpwnam(3C)`, `passwd(4)`, `attributes(5)`

NAME	getpwnam, getpwnam_r, getpwent, getpwent_r, getpwuid, getpwuid_r, setpwent, endpwent, fgetpwent, fgetpwent_r – get password entry
SYNOPSIS	<pre>#include <pwd.h> struct passwd *getpwnam(const char *name); struct passwd *getpwnam_r(const char *name, struct passwd *pwd, char *buffer, int buflen); struct passwd *getpwent(void); struct passwd *getpwent_r(struct passwd *pwd, char *buffer, int buflen); struct passwd *getpwuid(uid_t uid); struct passwd *getpwuid_r(uid_t uid, struct passwd *pwd, char *buffer, int buflen); void setpwent(void); void endpwent(void); struct passwd *fgetpwent(FILE *f); struct passwd *fgetpwent_r(FILE *f, struct passwd *pwd, char *buffer, int buflen);</pre>
POSIX	<pre>cc [flag...] file... -D_POSIX_PTHREAD_SEMANTICS [library...] int getpwnam_r(const char *name, struct passwd *pwd, char *buffer, size_t bufsize, struct passwd **result); int getpwuid_r(uid_t uid, struct passwd *pwd, char *buffer, size_t bufsize, struct passwd **result);</pre>
DESCRIPTION	<p>These functions are used to obtain password entries. Entries can come from any of the sources for <code>passwd</code> specified in the <code>/etc/nsswitch.conf</code> file (see <code>nsswitch.conf(4)</code>).</p> <p>The <code>getpwnam()</code> function searches for a password entry with the login name specified by the character string parameter <i>name</i>.</p> <p>The <code>getpwuid()</code> function searches for a password entry with the (numeric) user ID specified by the parameter <i>uid</i>.</p> <p>The <code>setpwent()</code>, <code>getpwent()</code>, and <code>endpwent()</code> functions are used to enumerate password entries from the database. <code>setpwent()</code> sets (or resets) the enumeration to the beginning of the set of password entries. This function should be called before the first call to <code>getpwent()</code>. Calls to <code>getpwnam()</code> and <code>getpwuid()</code> leave the enumeration position in an indeterminate state. Successive calls to <code>getpwent()</code> return either successive entries or <code>NULL</code>, indicating the end of the enumeration.</p>

getpwent(3C)

The `endpwent()` function may be called to indicate that the caller expects to do no further password retrieval operations; the system may then close the password file, deallocate resources it was using, and so forth. It is still allowed, but possibly less efficient, for the process to call more password functions after calling `endpwent()`.

The `fgetpwent()` function, unlike the other functions above, does not use `nsswitch.conf`; it reads and parses the next line from the stream *f*, which is assumed to have the format of the `passwd` file. See `passwd(4)`.

Reentrant Interfaces

The functions `getpwnam()`, `getpwuid()`, `getpwent()`, and `fgetpwent()` use static storage that is reused in each call, making these routines unsafe for use in multithreaded applications.

The parallel functions `getpwnam_r()`, `getpwuid_r()`, `getpwent_r()`, and `fgetpwent_r()` provide reentrant interfaces for these operations.

Each reentrant interface performs the same operation as its non-reentrant counterpart, named by removing the “`_r`” suffix. The reentrant interfaces, however, use buffers supplied by the caller to store returned results, and are safe for use in both single-threaded and multithreaded applications.

Each reentrant interface takes the same parameters as its non-reentrant counterpart, as well as the following additional parameters. The parameter `pwd` must be a pointer to a `struct passwd` structure allocated by the caller. On successful completion, the function returns the password entry in this structure. The parameter *buffer* is a pointer to a buffer supplied by the caller, used as storage space for the password data. All of the pointers within the returned `struct passwd` `pwd` point to data stored within this buffer; see RETURN VALUES. The buffer must be large enough to hold all the data associated with the password entry. The parameter *buflen* (or *bufsize* for the POSIX versions; see `standards(5)`) should give the size in bytes of *buffer*. The POSIX versions place a pointer to the modified `pwd` structure in the *result* parameter, instead of returning a pointer to this structure.

For enumeration in multithreaded applications, the position within the enumeration is a process-wide property shared by all threads. The `setpwent()` function may be used in a multithreaded application but resets the enumeration position for all threads. If multiple threads interleave calls to `getpwent_r()`, the threads will enumerate disjoint subsets of the password database.

Like their non-reentrant counterparts, `getpwnam_r()` and `getpwuid_r()` leave the enumeration position in an indeterminate state.

RETURN VALUES

Password entries are represented by the `struct passwd` structure defined in `<pwd.h>`:

```
struct passwd {
    char *pw_name;           /* user's login name */
    char *pw_passwd;        /* no longer used */
    uid_t pw_uid;           /* user's uid */
    gid_t pw_gid;           /* user's gid */
    char *pw_age;           /* not used */
}
```

```

char *pw_comment; /* not used */
char *pw_gecos; /* typically user's full name */
char *pw_dir; /* user's home dir */
char *pw_shell; /* user's login shell */
};

```

The `pw_passwd` member should not be used as the encrypted password for the user; use `getspnam()` or `getspnam_r()` instead. See `getspnam(3C)`.

The `getpwnam()`, `getpwnam_r()`, `getpwuid()`, and `getpwuid_r()` functions each return a pointer to a `struct passwd` if they successfully locate the requested entry; otherwise they return `NULL`. Upon successful completion (including the case when the requested entry is not found), the POSIX functions `getpwnam_r()` and `getpwuid_r()` return 0. Otherwise, an error number is returned to indicate the error.

The `getpwent()`, `getpwent_r()`, `fgetpwent()`, and `fgetpwent_r()` functions each return a pointer to a `struct passwd` if they successfully enumerate an entry; otherwise they return `NULL`, indicating the end of the enumeration.

The `getpwnam()`, `getpwuid()`, `getpwent()`, and `fgetpwent()` functions use static storage, so returned data must be copied before a subsequent call to any of these functions if the data is to be saved.

When the pointer returned by the reentrant functions `getpwnam_r()`, `getpwuid_r()`, `getpwent_r()`, and `fgetpwent_r()` is non-null, it is always equal to the `pwd` pointer that was supplied by the caller.

ERRORS The reentrant functions `getpwnam_r()`, `getpwuid_r()`, `getpwent_r()`, and `fgetpwent_r()` will return `NULL` and set `errno` to `ERANGE` (or in the case of POSIX functions `getpwnam_r()` and `getpwuid_r()` return the `ERANGE` error) if the length of the buffer supplied by caller is not large enough to store the result. See `Intro(2)` for the proper usage and interpretation of `errno` in multithreaded applications.

USAGE Applications that use the interfaces described on this manual page cannot be linked statically, since the implementations of these functions employ dynamic loading and linking of shared objects at run time.

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
MT-Level	See "Reentrant Interfaces" in <code>DESCRIPTION</code> .

SEE ALSO `nispasswd(1)`, `passwd(1)`, `yppasswd(1)`, `Intro(2)`, `Intro(3)`, `cuserid(3C)`, `getgrnam(3C)`, `getlogin(3C)`, `getspnam(3C)`, `nsswitch.conf(4)`, `passwd(4)`, `shadow(4)`, `attributes(5)`, `standards(5)`

NOTES When compiling multithreaded programs, see `Intro(3)`, *Notes On Multithreaded Applications*.

getpwent(3C)

Use of the enumeration interfaces `getpwent()` and `getpwent_r()` is discouraged; enumeration is supported for the `passwd` file, NIS, and NIS+, but in general is not efficient and may not be supported for all database sources. The semantics of enumeration are discussed further in `nsswitch.conf(4)`.

Previous releases allowed the use of '+' and '-' entries in `/etc/passwd` to selectively include and exclude NIS entries. The primary usage of these '+/-' entries is superseded by the name service switch, so the '+/-' form may not be supported in future releases.

If required, the '+/-' functionality can still be obtained for NIS by specifying `compat` as the source for `passwd`.

If the '+/-' functionality is required in conjunction with NIS+, specify both `compat` as the source for `passwd` and `nisplus` as the source for the pseudo-database `passwd_compat`. See `passwd(4)`, `shadow(4)`, and `nsswitch.conf(4)` for details.

If the '+/-' is used, both `/etc/shadow` and `/etc/passwd` should have the same '+' and '-' entries to ensure consistency between the password and shadow databases.

If a password entry from any of the sources contains an empty `uid` or `gid` field, that entry will be ignored by the files, NIS, and NIS+ name service switch backends. This will cause the user to appear unknown to the system.

If a password entry contains an empty `gecos`, `home directory`, or `shell` field, `getpwnam()` and `getpwnam_r()` return a pointer to a null string in the respective field of the `passwd` structure.

If the shell field is empty, `login(1)` automatically assigns the default shell. See `login(1)`.

Solaris 2.4 and earlier releases provided definitions of the `getpwnam_r()` and `getpwuid_r()` functions as specified in POSIX.1c Draft 6. The final POSIX.1c standard changed the interface for these functions. Support for the Draft 6 interface is provided for compatibility only and may not be supported in future releases. New applications and libraries should use the POSIX standard interface.

For POSIX.1c-compliant applications, the `_POSIX_PTHREAD_SEMANTICS` and `_REENTRANT` flags are automatically turned on by defining the `_POSIX_C_SOURCE` flag with a value `>= 199506L`.

NAME	getpwnam, getpwnam_r, getpwent, getpwent_r, getpwuid, getpwuid_r, setpwent, endpwent, fgetpwent, fgetpwent_r – get password entry
SYNOPSIS	<pre>#include <pwd.h> struct passwd *getpwnam(const char *name); struct passwd *getpwnam_r(const char *name, struct passwd *pwd, char *buffer, int buflen); struct passwd *getpwent(void); struct passwd *getpwent_r(struct passwd *pwd, char *buffer, int buflen); struct passwd *getpwuid(uid_t uid); struct passwd *getpwuid_r(uid_t uid, struct passwd *pwd, char *buffer, int buflen); void setpwent(void); void endpwent(void); struct passwd *fgetpwent(FILE *f); struct passwd *fgetpwent_r(FILE *f, struct passwd *pwd, char *buffer, int buflen);</pre>
POSIX	<pre>cc [flag...] file... -D_POSIX_PTHREAD_SEMANTICS [library...] int getpwnam_r(const char *name, struct passwd *pwd, char *buffer, size_t bufsize, struct passwd **result); int getpwuid_r(uid_t uid, struct passwd *pwd, char *buffer, size_t bufsize, struct passwd **result);</pre>
DESCRIPTION	<p>These functions are used to obtain password entries. Entries can come from any of the sources for <code>passwd</code> specified in the <code>/etc/nsswitch.conf</code> file (see <code>nsswitch.conf(4)</code>).</p> <p>The <code>getpwnam()</code> function searches for a password entry with the login name specified by the character string parameter <i>name</i>.</p> <p>The <code>getpwuid()</code> function searches for a password entry with the (numeric) user ID specified by the parameter <i>uid</i>.</p> <p>The <code>setpwent()</code>, <code>getpwent()</code>, and <code>endpwent()</code> functions are used to enumerate password entries from the database. <code>setpwent()</code> sets (or resets) the enumeration to the beginning of the set of password entries. This function should be called before the first call to <code>getpwent()</code>. Calls to <code>getpwnam()</code> and <code>getpwuid()</code> leave the enumeration position in an indeterminate state. Successive calls to <code>getpwent()</code> return either successive entries or <code>NULL</code>, indicating the end of the enumeration.</p>

getpwent_r(3C)

The `endpwent()` function may be called to indicate that the caller expects to do no further password retrieval operations; the system may then close the password file, deallocate resources it was using, and so forth. It is still allowed, but possibly less efficient, for the process to call more password functions after calling `endpwent()`.

The `fgetpwent()` function, unlike the other functions above, does not use `nsswitch.conf`; it reads and parses the next line from the stream *f*, which is assumed to have the format of the `passwd` file. See `passwd(4)`.

Reentrant Interfaces

The functions `getpwnam()`, `getpwuid()`, `getpwent()`, and `fgetpwent()` use static storage that is reused in each call, making these routines unsafe for use in multithreaded applications.

The parallel functions `getpwnam_r()`, `getpwuid_r()`, `getpwent_r()`, and `fgetpwent_r()` provide reentrant interfaces for these operations.

Each reentrant interface performs the same operation as its non-reentrant counterpart, named by removing the “_r” suffix. The reentrant interfaces, however, use buffers supplied by the caller to store returned results, and are safe for use in both single-threaded and multithreaded applications.

Each reentrant interface takes the same parameters as its non-reentrant counterpart, as well as the following additional parameters. The parameter `pwd` must be a pointer to a `struct passwd` structure allocated by the caller. On successful completion, the function returns the password entry in this structure. The parameter *buffer* is a pointer to a buffer supplied by the caller, used as storage space for the password data. All of the pointers within the returned `struct passwd` `pwd` point to data stored within this buffer; see RETURN VALUES. The buffer must be large enough to hold all the data associated with the password entry. The parameter *buflen* (or *bufsize* for the POSIX versions; see `standards(5)`) should give the size in bytes of *buffer*. The POSIX versions place a pointer to the modified `pwd` structure in the *result* parameter, instead of returning a pointer to this structure.

For enumeration in multithreaded applications, the position within the enumeration is a process-wide property shared by all threads. The `setpwent()` function may be used in a multithreaded application but resets the enumeration position for all threads. If multiple threads interleave calls to `getpwent_r()`, the threads will enumerate disjoint subsets of the password database.

Like their non-reentrant counterparts, `getpwnam_r()` and `getpwuid_r()` leave the enumeration position in an indeterminate state.

RETURN VALUES

Password entries are represented by the `struct passwd` structure defined in `<pwd.h>`:

```
struct passwd {
    char *pw_name;           /* user's login name */
    char *pw_passwd;        /* no longer used */
    uid_t pw_uid;           /* user's uid */
    gid_t pw_gid;           /* user's gid */
    char *pw_age;           /* not used */
};
```

```

char *pw_comment; /* not used */
char *pw_gecos; /* typically user's full name */
char *pw_dir; /* user's home dir */
char *pw_shell; /* user's login shell */
};

```

The `pw_passwd` member should not be used as the encrypted password for the user; use `getspnam()` or `getspnam_r()` instead. See `getspnam(3C)`.

The `getpwnam()`, `getpwnam_r()`, `getpwuid()`, and `getpwuid_r()` functions each return a pointer to a `struct passwd` if they successfully locate the requested entry; otherwise they return `NULL`. Upon successful completion (including the case when the requested entry is not found), the POSIX functions `getpwnam_r()` and `getpwuid_r()` return 0. Otherwise, an error number is returned to indicate the error.

The `getpwent()`, `getpwent_r()`, `fgetpwent()`, and `fgetpwent_r()` functions each return a pointer to a `struct passwd` if they successfully enumerate an entry; otherwise they return `NULL`, indicating the end of the enumeration.

The `getpwnam()`, `getpwuid()`, `getpwent()`, and `fgetpwent()` functions use static storage, so returned data must be copied before a subsequent call to any of these functions if the data is to be saved.

When the pointer returned by the reentrant functions `getpwnam_r()`, `getpwuid_r()`, `getpwent_r()`, and `fgetpwent_r()` is non-null, it is always equal to the `pwd` pointer that was supplied by the caller.

ERRORS The reentrant functions `getpwnam_r()`, `getpwuid_r()`, `getpwent_r()`, and `fgetpwent_r()` will return `NULL` and set `errno` to `ERANGE` (or in the case of POSIX functions `getpwnam_r()` and `getpwuid_r()` return the `ERANGE` error) if the length of the buffer supplied by caller is not large enough to store the result. See `Intro(2)` for the proper usage and interpretation of `errno` in multithreaded applications.

USAGE Applications that use the interfaces described on this manual page cannot be linked statically, since the implementations of these functions employ dynamic loading and linking of shared objects at run time.

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
MT-Level	See "Reentrant Interfaces" in <code>DESCRIPTION</code> .

SEE ALSO `nispasswd(1)`, `passwd(1)`, `yppasswd(1)`, `Intro(2)`, `Intro(3)`, `cuserid(3C)`, `getgrnam(3C)`, `getlogin(3C)`, `getspnam(3C)`, `nsswitch.conf(4)`, `passwd(4)`, `shadow(4)`, `attributes(5)`, `standards(5)`

NOTES When compiling multithreaded programs, see `Intro(3)`, *Notes On Multithreaded Applications*.

getpwent_r(3C)

Use of the enumeration interfaces `getpwent()` and `getpwent_r()` is discouraged; enumeration is supported for the `passwd` file, NIS, and NIS+, but in general is not efficient and may not be supported for all database sources. The semantics of enumeration are discussed further in `nsswitch.conf(4)`.

Previous releases allowed the use of '+' and '-' entries in `/etc/passwd` to selectively include and exclude NIS entries. The primary usage of these '+/-' entries is superseded by the name service switch, so the '+/-' form may not be supported in future releases.

If required, the '+/-' functionality can still be obtained for NIS by specifying `compat` as the source for `passwd`.

If the '+/-' functionality is required in conjunction with NIS+, specify both `compat` as the source for `passwd` and `nisplus` as the source for the pseudo-database `passwd_compat`. See `passwd(4)`, `shadow(4)`, and `nsswitch.conf(4)` for details.

If the '+/-' is used, both `/etc/shadow` and `/etc/passwd` should have the same '+' and '-' entries to ensure consistency between the password and shadow databases.

If a password entry from any of the sources contains an empty `uid` or `gid` field, that entry will be ignored by the files, NIS, and NIS+ name service switch backends. This will cause the user to appear unknown to the system.

If a password entry contains an empty `gecos`, `home directory`, or `shell` field, `getpwnam()` and `getpwnam_r()` return a pointer to a null string in the respective field of the `passwd` structure.

If the shell field is empty, `login(1)` automatically assigns the default shell. See `login(1)`.

Solaris 2.4 and earlier releases provided definitions of the `getpwnam_r()` and `getpwuid_r()` functions as specified in POSIX.1c Draft 6. The final POSIX.1c standard changed the interface for these functions. Support for the Draft 6 interface is provided for compatibility only and may not be supported in future releases. New applications and libraries should use the POSIX standard interface.

For POSIX.1c-compliant applications, the `_POSIX_PTHREAD_SEMANTICS` and `_REENTRANT` flags are automatically turned on by defining the `_POSIX_C_SOURCE` flag with a value `>= 199506L`.

NAME	getpwnam, getpwnam_r, getpwent, getpwent_r, getpwuid, getpwuid_r, setpwent, endpwent, fgetpwent, fgetpwent_r – get password entry
SYNOPSIS	<pre>#include <pwd.h> struct passwd *getpwnam(const char *name); struct passwd *getpwnam_r(const char *name, struct passwd *pwd, char *buffer, int buflen); struct passwd *getpwent(void); struct passwd *getpwent_r(struct passwd *pwd, char *buffer, int buflen); struct passwd *getpwuid(uid_t uid); struct passwd *getpwuid_r(uid_t uid, struct passwd *pwd, char *buffer, int buflen); void setpwent(void); void endpwent(void); struct passwd *fgetpwent(FILE *f); struct passwd *fgetpwent_r(FILE *f, struct passwd *pwd, char *buffer, int buflen);</pre>
POSIX	<pre>cc [flag...] file... -D_POSIX_PTHREAD_SEMANTICS [library...] int getpwnam_r(const char *name, struct passwd *pwd, char *buffer, size_t bufsize, struct passwd **result); int getpwuid_r(uid_t uid, struct passwd *pwd, char *buffer, size_t bufsize, struct passwd **result);</pre>
DESCRIPTION	<p>These functions are used to obtain password entries. Entries can come from any of the sources for <code>passwd</code> specified in the <code>/etc/nsswitch.conf</code> file (see <code>nsswitch.conf(4)</code>).</p> <p>The <code>getpwnam()</code> function searches for a password entry with the login name specified by the character string parameter <i>name</i>.</p> <p>The <code>getpwuid()</code> function searches for a password entry with the (numeric) user ID specified by the parameter <i>uid</i>.</p> <p>The <code>setpwent()</code>, <code>getpwent()</code>, and <code>endpwent()</code> functions are used to enumerate password entries from the database. <code>setpwent()</code> sets (or resets) the enumeration to the beginning of the set of password entries. This function should be called before the first call to <code>getpwent()</code>. Calls to <code>getpwnam()</code> and <code>getpwuid()</code> leave the enumeration position in an indeterminate state. Successive calls to <code>getpwent()</code> return either successive entries or <code>NULL</code>, indicating the end of the enumeration.</p>

getpwnam(3C)

The `endpwent()` function may be called to indicate that the caller expects to do no further password retrieval operations; the system may then close the password file, deallocate resources it was using, and so forth. It is still allowed, but possibly less efficient, for the process to call more password functions after calling `endpwent()`.

The `fgetpwent()` function, unlike the other functions above, does not use `nsswitch.conf`; it reads and parses the next line from the stream *f*, which is assumed to have the format of the `passwd` file. See `passwd(4)`.

Reentrant Interfaces

The functions `getpwnam()`, `getpwuid()`, `getpwent()`, and `fgetpwent()` use static storage that is reused in each call, making these routines unsafe for use in multithreaded applications.

The parallel functions `getpwnam_r()`, `getpwuid_r()`, `getpwent_r()`, and `fgetpwent_r()` provide reentrant interfaces for these operations.

Each reentrant interface performs the same operation as its non-reentrant counterpart, named by removing the “_r” suffix. The reentrant interfaces, however, use buffers supplied by the caller to store returned results, and are safe for use in both single-threaded and multithreaded applications.

Each reentrant interface takes the same parameters as its non-reentrant counterpart, as well as the following additional parameters. The parameter `pwd` must be a pointer to a `struct passwd` structure allocated by the caller. On successful completion, the function returns the password entry in this structure. The parameter *buffer* is a pointer to a buffer supplied by the caller, used as storage space for the password data. All of the pointers within the returned `struct passwd` `pwd` point to data stored within this buffer; see RETURN VALUES. The buffer must be large enough to hold all the data associated with the password entry. The parameter *buflen* (or *bufsize* for the POSIX versions; see `standards(5)`) should give the size in bytes of *buffer*. The POSIX versions place a pointer to the modified `pwd` structure in the *result* parameter, instead of returning a pointer to this structure.

For enumeration in multithreaded applications, the position within the enumeration is a process-wide property shared by all threads. The `setpwent()` function may be used in a multithreaded application but resets the enumeration position for all threads. If multiple threads interleave calls to `getpwent_r()`, the threads will enumerate disjoint subsets of the password database.

Like their non-reentrant counterparts, `getpwnam_r()` and `getpwuid_r()` leave the enumeration position in an indeterminate state.

RETURN VALUES

Password entries are represented by the `struct passwd` structure defined in `<pwd.h>`:

```
struct passwd {
    char *pw_name;           /* user's login name */
    char *pw_passwd;        /* no longer used */
    uid_t pw_uid;           /* user's uid */
    gid_t pw_gid;           /* user's gid */
    char *pw_age;           /* not used */
}
```

```

char *pw_comment; /* not used */
char *pw_gecos; /* typically user's full name */
char *pw_dir; /* user's home dir */
char *pw_shell; /* user's login shell */
};

```

The `pw_passwd` member should not be used as the encrypted password for the user; use `getspnam()` or `getspnam_r()` instead. See `getspnam(3C)`.

The `getpwnam()`, `getpwnam_r()`, `getpwuid()`, and `getpwuid_r()` functions each return a pointer to a `struct passwd` if they successfully locate the requested entry; otherwise they return `NULL`. Upon successful completion (including the case when the requested entry is not found), the POSIX functions `getpwnam_r()` and `getpwuid_r()` return 0. Otherwise, an error number is returned to indicate the error.

The `getpwent()`, `getpwent_r()`, `fgetpwent()`, and `fgetpwent_r()` functions each return a pointer to a `struct passwd` if they successfully enumerate an entry; otherwise they return `NULL`, indicating the end of the enumeration.

The `getpwnam()`, `getpwuid()`, `getpwent()`, and `fgetpwent()` functions use static storage, so returned data must be copied before a subsequent call to any of these functions if the data is to be saved.

When the pointer returned by the reentrant functions `getpwnam_r()`, `getpwuid_r()`, `getpwent_r()`, and `fgetpwent_r()` is non-null, it is always equal to the `pwd` pointer that was supplied by the caller.

ERRORS The reentrant functions `getpwnam_r()`, `getpwuid_r()`, `getpwent_r()`, and `fgetpwent_r()` will return `NULL` and set `errno` to `ERANGE` (or in the case of POSIX functions `getpwnam_r()` and `getpwuid_r()` return the `ERANGE` error) if the length of the buffer supplied by caller is not large enough to store the result. See `Intro(2)` for the proper usage and interpretation of `errno` in multithreaded applications.

USAGE Applications that use the interfaces described on this manual page cannot be linked statically, since the implementations of these functions employ dynamic loading and linking of shared objects at run time.

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE

getpwnam_r(3C)

Reentrant Interfaces

The `endpwent()` function may be called to indicate that the caller expects to do no further password retrieval operations; the system may then close the password file, deallocate resources it was using, and so forth. It is still allowed, but possibly less efficient, for the process to call more password functions after calling `endpwent()`.

The `fgetpwent()` function, unlike the other functions above, does not use `nsswitch.conf`; it reads and parses the next line from the stream *f*, which is assumed to have the format of the `passwd` file. See `passwd(4)`.

The functions `getpwnam()`, `getpwuid()`, `getpwent()`, and `fgetpwent()` use static storage that is reused in each call, making these routines unsafe for use in multithreaded applications.

The parallel functions `getpwnam_r()`, `getpwuid_r()`, `getpwent_r()`, and `fgetpwent_r()` provide reentrant interfaces for these operations.

Each reentrant interface performs the same operation as its non-reentrant counterpart, named by removing the “_r” suffix. The reentrant interfaces, however, use buffers supplied by the caller to store returned results, and are safe for use in both single-threaded and multithreaded applications.

Each reentrant interface takes the same parameters as its non-reentrant counterpart, as well as the following additional parameters. The parameter `pwd` must be a pointer to a `struct passwd` structure allocated by the caller. On successful completion, the function returns the password entry in this structure. The parameter *buffer* is a pointer to a buffer supplied by the caller, used as storage space for the password data. All of the pointers within the returned `struct passwd` `pwd` point to data stored within this buffer; see RETURN VALUES. The buffer must be large enough to hold all the data associated with the password entry. The parameter *buflen* (or *bufsize* for the POSIX versions; see `standards(5)`) should give the size in bytes of *buffer*. The POSIX versions place a pointer to the modified `pwd` structure in the *result* parameter, instead of returning a pointer to this structure.

For enumeration in multithreaded applications, the position within the enumeration is a process-wide property shared by all threads. The `setpwent()` function may be used in a multithreaded application but resets the enumeration position for all threads. If multiple threads interleave calls to `getpwent_r()`, the threads will enumerate disjoint subsets of the password database.

Like their non-reentrant counterparts, `getpwnam_r()` and `getpwuid_r()` leave the enumeration position in an indeterminate state.

RETURN VALUES

Password entries are represented by the `struct passwd` structure defined in `<pwd.h>`:

```
struct passwd {
    char *pw_name;           /* user's login name */
    char *pw_passwd;        /* no longer used */
    uid_t pw_uid;           /* user's uid */
    gid_t pw_gid;           /* user's gid */
    char *pw_age;           /* not used */
}
```

```

char *pw_comment; /* not used */
char *pw_gecos; /* typically user's full name */
char *pw_dir; /* user's home dir */
char *pw_shell; /* user's login shell */
};

```

The `pw_passwd` member should not be used as the encrypted password for the user; use `getspnam()` or `getspnam_r()` instead. See `getspnam(3C)`.

The `getpwnam()`, `getpwnam_r()`, `getpwuid()`, and `getpwuid_r()` functions each return a pointer to a `struct passwd` if they successfully locate the requested entry; otherwise they return `NULL`. Upon successful completion (including the case when the requested entry is not found), the POSIX functions `getpwnam_r()` and `getpwuid_r()` return 0. Otherwise, an error number is returned to indicate the error.

The `getpwent()`, `getpwent_r()`, `fgetpwent()`, and `fgetpwent_r()` functions each return a pointer to a `struct passwd` if they successfully enumerate an entry; otherwise they return `NULL`, indicating the end of the enumeration.

The `getpwnam()`, `getpwuid()`, `getpwent()`, and `fgetpwent()` functions use static storage, so returned data must be copied before a subsequent call to any of these functions if the data is to be saved.

When the pointer returned by the reentrant functions `getpwnam_r()`, `getpwuid_r()`, `getpwent_r()`, and `fgetpwent_r()` is non-null, it is always equal to the `pwd` pointer that was supplied by the caller.

ERRORS The reentrant functions `getpwnam_r()`, `getpwuid_r()`, `getpwent_r()`, and `fgetpwent_r()` will return `NULL` and set `errno` to `ERANGE` (or in the case of POSIX functions `getpwnam_r()` and `getpwuid_r()` return the `ERANGE` error) if the length of the buffer supplied by caller is not large enough to store the result. See `Intro(2)` for the proper usage and interpretation of `errno` in multithreaded applications.

USAGE Applications that use the interfaces described on this manual page cannot be linked statically, since the implementations of these functions employ dynamic loading and linking of shared objects at run time.

NOTES When compiling multithreaded programs, see `Intro(3)`, *Notes On Multithreaded Applications*.

getpwnam_r(3C)

Use of the enumeration interfaces `getpwent()` and `getpwent_r()` is discouraged; enumeration is supported for the `passwd` file, NIS, and NIS+, but in general is not efficient and may not be supported for all database sources. The semantics of enumeration are discussed further in `nsswitch.conf(4)`.

Previous releases allowed the use of '+' and '-' entries in `/etc/passwd` to selectively include and exclude NIS entries. The primary usage of these '+/-' entries is superseded by the name service switch, so the '+/-' form may not be supported in future releases.

If required, the '+/-' functionality can still be obtained for NIS by specifying `compat` as the source for `passwd`.

If the '+/-' functionality is required in conjunction with NIS+, specify both `compat` as the source for `passwd` and `nisplus` as the source for the pseudo-database `passwd_compat`. See `passwd(4)`, `shadow(4)`, and `nsswitch.conf(4)` for details.

If the '+/-' is used, both `/etc/shadow` and `/etc/passwd` should have the same '+' and '-' entries to ensure consistency between the password and shadow databases.

If a password entry from any of the sources contains an empty `uid` or `gid` field, that entry will be ignored by the files, NIS, and NIS+ name service switch backends. This will cause the user to appear unknown to the system.

If a password entry contains an empty `gecos`, `home directory`, or `shell` field, `getpwnam()` and `getpwnam_r()` return a pointer to a null string in the respective field of the `passwd` structure.

If the shell field is empty, `login(1)` automatically assigns the default shell. See `login(1)`.

Solaris 2.4 and earlier releases provided definitions of the `getpwnam_r()` and `getpwuid_r()` functions as specified in POSIX.1c Draft 6. The final POSIX.1c standard changed the interface for these functions. Support for the Draft 6 interface is provided for compatibility only and may not be supported in future releases. New applications and libraries should use the POSIX standard interface.

For POSIX.1c-compliant applications, the `_POSIX_PTHREAD_SEMANTICS` and `_REENTRANT` flags are automatically turned on by defining the `_POSIX_C_SOURCE` flag with a value `>= 199506L`.

NAME	getpwnam, getpwnam_r, getpwent, getpwent_r, getpwuid, getpwuid_r, setpwent, endpwent, fgetpwent, fgetpwent_r – get password entry
SYNOPSIS	<pre>#include <pwd.h> struct passwd *getpwnam(const char *name); struct passwd *getpwnam_r(const char *name, struct passwd *pwd, char *buffer, int buflen); struct passwd *getpwent(void); struct passwd *getpwent_r(struct passwd *pwd, char *buffer, int buflen); struct passwd *getpwuid(uid_t uid); struct passwd *getpwuid_r(uid_t uid, struct passwd *pwd, char *buffer, int buflen); void setpwent(void); void endpwent(void); struct passwd *fgetpwent(FILE *f); struct passwd *fgetpwent_r(FILE *f, struct passwd *pwd, char *buffer, int buflen);</pre>
POSIX	<pre>cc [flag...] file... -D_POSIX_PTHREAD_SEMANTICS [library...] int getpwnam_r(const char *name, struct passwd *pwd, char *buffer, size_t bufsz, struct passwd **result); int getpwuid_r(uid_t uid, struct passwd *pwd, char *buffer, size_t bufsz, struct passwd **result);</pre>
DESCRIPTION	<p>These functions are used to obtain password entries. Entries can come from any of the sources for <code>passwd</code> specified in the <code>/etc/nsswitch.conf</code> file (see <code>nsswitch.conf(4)</code>).</p> <p>The <code>getpwnam()</code> function searches for a password entry with the login name specified by the character string parameter <i>name</i>.</p> <p>The <code>getpwuid()</code> function searches for a password entry with the (numeric) user ID specified by the parameter <i>uid</i>.</p> <p>The <code>setpwent()</code>, <code>getpwent()</code>, and <code>endpwent()</code> functions are used to enumerate password entries from the database. <code>setpwent()</code> sets (or resets) the enumeration to the beginning of the set of password entries. This function should be called before the first call to <code>getpwent()</code>. Calls to <code>getpwnam()</code> and <code>getpwuid()</code> leave the enumeration position in an indeterminate state. Successive calls to <code>getpwent()</code> return either successive entries or <code>NULL</code>, indicating the end of the enumeration.</p>

getpwuid(3C)

The `endpwent()` function may be called to indicate that the caller expects to do no further password retrieval operations; the system may then close the password file, deallocate resources it was using, and so forth. It is still allowed, but possibly less efficient, for the process to call more password functions after calling `endpwent()`.

The `fgetpwent()` function, unlike the other functions above, does not use `nsswitch.conf`; it reads and parses the next line from the stream *f*, which is assumed to have the format of the `passwd` file. See `passwd(4)`.

Reentrant Interfaces

The functions `getpwnam()`, `getpwuid()`, `getpwent()`, and `fgetpwent()` use static storage that is reused in each call, making these routines unsafe for use in multithreaded applications.

The parallel functions `getpwnam_r()`, `getpwuid_r()`, `getpwent_r()`, and `fgetpwent_r()` provide reentrant interfaces for these operations.

Each reentrant interface performs the same operation as its non-reentrant counterpart, named by removing the “_r” suffix. The reentrant interfaces, however, use buffers supplied by the caller to store returned results, and are safe for use in both single-threaded and multithreaded applications.

Each reentrant interface takes the same parameters as its non-reentrant counterpart, as well as the following additional parameters. The parameter `pwd` must be a pointer to a `struct passwd` structure allocated by the caller. On successful completion, the function returns the password entry in this structure. The parameter *buffer* is a pointer to a buffer supplied by the caller, used as storage space for the password data. All of the pointers within the returned `struct passwd` `pwd` point to data stored within this buffer; see RETURN VALUES. The buffer must be large enough to hold all the data associated with the password entry. The parameter *buflen* (or *bufsize* for the POSIX versions; see `standards(5)`) should give the size in bytes of *buffer*. The POSIX versions place a pointer to the modified `pwd` structure in the *result* parameter, instead of returning a pointer to this structure.

For enumeration in multithreaded applications, the position within the enumeration is a process-wide property shared by all threads. The `setpwent()` function may be used in a multithreaded application but resets the enumeration position for all threads. If multiple threads interleave calls to `getpwent_r()`, the threads will enumerate disjoint subsets of the password database.

Like their non-reentrant counterparts, `getpwnam_r()` and `getpwuid_r()` leave the enumeration position in an indeterminate state.

RETURN VALUES

Password entries are represented by the `struct passwd` structure defined in `<pwd.h>`:

```
struct passwd {
    char *pw_name;           /* user's login name */
    char *pw_passwd;        /* no longer used */
    uid_t pw_uid;           /* user's uid */
    gid_t pw_gid;           /* user's gid */
    char *pw_age;           /* not used */
}
```

```

char *pw_comment; /* not used */
char *pw_gecos; /* typically user's full name */
char *pw_dir; /* user's home dir */
char *pw_shell; /* user's login shell */
};

```

The `pw_passwd` member should not be used as the encrypted password for the user; use `getspnam()` or `getspnam_r()` instead. See `getspnam(3C)`.

The `getpwnam()`, `getpwnam_r()`, `getpwuid()`, and `getpwuid_r()` functions each return a pointer to a `struct passwd` if they successfully locate the requested entry; otherwise they return `NULL`. Upon successful completion (including the case when the requested entry is not found), the POSIX functions `getpwnam_r()` and `getpwuid_r()` return 0. Otherwise, an error number is returned to indicate the error.

The `getpwent()`, `getpwent_r()`, `fgetpwent()`, and `fgetpwent_r()` functions each return a pointer to a `struct passwd` if they successfully enumerate an entry; otherwise they return `NULL`, indicating the end of the enumeration.

The `getpwnam()`, `getpwuid()`, `getpwent()`, and `fgetpwent()` functions use static storage, so returned data must be copied before a subsequent call to any of these functions if the data is to be saved.

When the pointer returned by the reentrant functions `getpwnam_r()`, `getpwuid_r()`, `getpwent_r()`, and `fgetpwent_r()` is non-null, it is always equal to the `pwd` pointer that was supplied by the caller.

ERRORS The reentrant functions `getpwnam_r()`, `getpwuid_r()`, `getpwent_r()`, and `fgetpwent_r()` will return `NULL` and set `errno` to `ERANGE` (or in the case of POSIX functions `getpwnam_r()` and `getpwuid_r()` return the `ERANGE` error) if the length of the buffer supplied by caller is not large enough to store the result. See `Intro(2)` for the proper usage and interpretation of `errno` in multithreaded applications.

USAGE Applications that use the interfaces described on this manual page cannot be linked statically, since the implementations of these functions employ dynamic loading and linking of shared objects at run time.

NOTES When compiling multithreaded programs, see `Intro(3)`, *Notes On Multithreaded Applications*.

getpwuid(3C)

Use of the enumeration interfaces `getpwent()` and `getpwent_r()` is discouraged; enumeration is supported for the `passwd` file, NIS, and NIS+, but in general is not efficient and may not be supported for all database sources. The semantics of enumeration are discussed further in `nsswitch.conf(4)`.

Previous releases allowed the use of '+' and '-' entries in `/etc/passwd` to selectively include and exclude NIS entries. The primary usage of these '+/-' entries is superseded by the name service switch, so the '+/-' form may not be supported in future releases.

If required, the '+/-' functionality can still be obtained for NIS by specifying `compat` as the source for `passwd`.

If the '+/-' functionality is required in conjunction with NIS+, specify both `compat` as the source for `passwd` and `nisplus` as the source for the pseudo-database `passwd_compat`. See `passwd(4)`, `shadow(4)`, and `nsswitch.conf(4)` for details.

If the '+/-' is used, both `/etc/shadow` and `/etc/passwd` should have the same '+' and '-' entries to ensure consistency between the password and shadow databases.

If a password entry from any of the sources contains an empty `uid` or `gid` field, that entry will be ignored by the files, NIS, and NIS+ name service switch backends. This will cause the user to appear unknown to the system.

If a password entry contains an empty `gecos`, `home directory`, or `shell` field, `getpwnam()` and `getpwnam_r()` return a pointer to a null string in the respective field of the `passwd` structure.

If the shell field is empty, `login(1)` automatically assigns the default shell. See `login(1)`.

Solaris 2.4 and earlier releases provided definitions of the `getpwnam_r()` and `getpwuid_r()` functions as specified in POSIX.1c Draft 6. The final POSIX.1c standard changed the interface for these functions. Support for the Draft 6 interface is provided for compatibility only and may not be supported in future releases. New applications and libraries should use the POSIX standard interface.

For POSIX.1c-compliant applications, the `_POSIX_PTHREAD_SEMANTICS` and `_REENTRANT` flags are automatically turned on by defining the `_POSIX_C_SOURCE` flag with a value `>= 199506L`.

NAME	getpwnam, getpwnam_r, getpwent, getpwent_r, getpwuid, getpwuid_r, setpwent, endpwent, fgetpwent, fgetpwent_r – get password entry
SYNOPSIS	<pre>#include <pwd.h> struct passwd *getpwnam(const char *name); struct passwd *getpwnam_r(const char *name, struct passwd *pwd, char *buffer, int buflen); struct passwd *getpwent(void); struct passwd *getpwent_r(struct passwd *pwd, char *buffer, int buflen); struct passwd *getpwuid(uid_t uid); struct passwd *getpwuid_r(uid_t uid, struct passwd *pwd, char *buffer, int buflen); void setpwent(void); void endpwent(void); struct passwd *fgetpwent(FILE *f); struct passwd *fgetpwent_r(FILE *f, struct passwd *pwd, char *buffer, int buflen);</pre>
POSIX	<pre>cc [flag...] file... -D_POSIX_PTHREAD_SEMANTICS [library...] int getpwnam_r(const char *name, struct passwd *pwd, char *buffer, size_t bufsize, struct passwd **result); int getpwuid_r(uid_t uid, struct passwd *pwd, char *buffer, size_t bufsize, struct passwd **result);</pre>
DESCRIPTION	<p>These functions are used to obtain password entries. Entries can come from any of the sources for <code>passwd</code> specified in the <code>/etc/nsswitch.conf</code> file (see <code>nsswitch.conf(4)</code>).</p> <p>The <code>getpwnam()</code> function searches for a password entry with the login name specified by the character string parameter <i>name</i>.</p> <p>The <code>getpwuid()</code> function searches for a password entry with the (numeric) user ID specified by the parameter <i>uid</i>.</p> <p>The <code>setpwent()</code>, <code>getpwent()</code>, and <code>endpwent()</code> functions are used to enumerate password entries from the database. <code>setpwent()</code> sets (or resets) the enumeration to the beginning of the set of password entries. This function should be called before the first call to <code>getpwent()</code>. Calls to <code>getpwnam()</code> and <code>getpwuid()</code> leave the enumeration position in an indeterminate state. Successive calls to <code>getpwent()</code> return either successive entries or <code>NULL</code>, indicating the end of the enumeration.</p>

getpwuid_r(3C)

The `endpwent()` function may be called to indicate that the caller expects to do no further password retrieval operations; the system may then close the password file, deallocate resources it was using, and so forth. It is still allowed, but possibly less efficient, for the process to call more password functions after calling `endpwent()`.

The `fgetpwent()` function, unlike the other functions above, does not use `nsswitch.conf`; it reads and parses the next line from the stream *f*, which is assumed to have the format of the `passwd` file. See `passwd(4)`.

Reentrant Interfaces

The functions `getpwnam()`, `getpwuid()`, `getpwent()`, and `fgetpwent()` use static storage that is reused in each call, making these routines unsafe for use in multithreaded applications.

The parallel functions `getpwnam_r()`, `getpwuid_r()`, `getpwent_r()`, and `fgetpwent_r()` provide reentrant interfaces for these operations.

Each reentrant interface performs the same operation as its non-reentrant counterpart, named by removing the “_r” suffix. The reentrant interfaces, however, use buffers supplied by the caller to store returned results, and are safe for use in both single-threaded and multithreaded applications.

Each reentrant interface takes the same parameters as its non-reentrant counterpart, as well as the following additional parameters. The parameter `pwd` must be a pointer to a `struct passwd` structure allocated by the caller. On successful completion, the function returns the password entry in this structure. The parameter *buffer* is a pointer to a buffer supplied by the caller, used as storage space for the password data. All of the pointers within the returned `struct passwd` `pwd` point to data stored within this buffer; see RETURN VALUES. The buffer must be large enough to hold all the data associated with the password entry. The parameter *buflen* (or *bufsize* for the POSIX versions; see `standards(5)`) should give the size in bytes of *buffer*. The POSIX versions place a pointer to the modified `pwd` structure in the *result* parameter, instead of returning a pointer to this structure.

For enumeration in multithreaded applications, the position within the enumeration is a process-wide property shared by all threads. The `setpwent()` function may be used in a multithreaded application but resets the enumeration position for all threads. If multiple threads interleave calls to `getpwent_r()`, the threads will enumerate disjoint subsets of the password database.

Like their non-reentrant counterparts, `getpwnam_r()` and `getpwuid_r()` leave the enumeration position in an indeterminate state.

RETURN VALUES

Password entries are represented by the `struct passwd` structure defined in `<pwd.h>`:

```
struct passwd {
    char *pw_name;           /* user's login name */
    char *pw_passwd;        /* no longer used */
    uid_t pw_uid;           /* user's uid */
    gid_t pw_gid;           /* user's gid */
    char *pw_age;           /* not used */
}
```

```

char *pw_comment; /* not used */
char *pw_gecos; /* typically user's full name */
char *pw_dir; /* user's home dir */
char *pw_shell; /* user's login shell */
};

```

The `pw_passwd` member should not be used as the encrypted password for the user; use `getspnam()` or `getspnam_r()` instead. See `getspnam(3C)`.

The `getpwnam()`, `getpwnam_r()`, `getpwuid()`, and `getpwuid_r()` functions each return a pointer to a `struct passwd` if they successfully locate the requested entry; otherwise they return `NULL`. Upon successful completion (including the case when the requested entry is not found), the POSIX functions `getpwnam_r()` and `getpwuid_r()` return 0. Otherwise, an error number is returned to indicate the error.

The `getpwent()`, `getpwent_r()`, `fgetpwent()`, and `fgetpwent_r()` functions each return a pointer to a `struct passwd` if they successfully enumerate an entry; otherwise they return `NULL`, indicating the end of the enumeration.

The `getpwnam()`, `getpwuid()`, `getpwent()`, and `fgetpwent()` functions use static storage, so returned data must be copied before a subsequent call to any of these functions if the data is to be saved.

When the pointer returned by the reentrant functions `getpwnam_r()`, `getpwuid_r()`, `getpwent_r()`, and `fgetpwent_r()` is non-null, it is always equal to the `pwd` pointer that was supplied by the caller.

ERRORS The reentrant functions `getpwnam_r()`, `getpwuid_r()`, `getpwent_r()`, and `fgetpwent_r()` will return `NULL` and set `errno` to `ERANGE` (or in the case of POSIX functions `getpwnam_r()` and `getpwuid_r()` return the `ERANGE` error) if the length of the buffer supplied by caller is not large enough to store the result. See `Intro(2)` for the proper usage and interpretation of `errno` in multithreaded applications.

USAGE Applications that use the interfaces described on this manual page cannot be linked statically, since the implementations of these functions employ dynamic loading and linking of shared objects at run time.

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
MT-Level	See "Reentrant Interfaces" in <code>DESCRIPTION</code> .

NOTES When compiling multithreaded programs, see `Intro(3)`, *Notes On Multithreaded Applications*.

getpwuid_r(3C)

Use of the enumeration interfaces `getpwent()` and `getpwent_r()` is discouraged; enumeration is supported for the `passwd` file, NIS, and NIS+, but in general is not efficient and may not be supported for all database sources. The semantics of enumeration are discussed further in `nsswitch.conf(4)`.

Previous releases allowed the use of '+' and '-' entries in `/etc/passwd` to selectively include and exclude NIS entries. The primary usage of these '+/-' entries is superseded by the name service switch, so the '+/-' form may not be supported in future releases.

If required, the '+/-' functionality can still be obtained for NIS by specifying `compat` as the source for `passwd`.

If the '+/-' functionality is required in conjunction with NIS+, specify both `compat` as the source for `passwd` and `nisplus` as the source for the pseudo-database `passwd_compat`. See `passwd(4)`, `shadow(4)`, and `nsswitch.conf(4)` for details.

If the '+/-' is used, both `/etc/shadow` and `/etc/passwd` should have the same '+' and '-' entries to ensure consistency between the password and shadow databases.

If a password entry from any of the sources contains an empty `uid` or `gid` field, that entry will be ignored by the files, NIS, and NIS+ name service switch backends. This will cause the user to appear unknown to the system.

If a password entry contains an empty `gecos`, `home directory`, or `shell` field, `getpwnam()` and `getpwnam_r()` return a pointer to a null string in the respective field of the `passwd` structure.

If the shell field is empty, `login(1)` automatically assigns the default shell. See `login(1)`.

Solaris 2.4 and earlier releases provided definitions of the `getpwnam_r()` and `getpwuid_r()` functions as specified in POSIX.1c Draft 6. The final POSIX.1c standard changed the interface for these functions. Support for the Draft 6 interface is provided for compatibility only and may not be supported in future releases. New applications and libraries should use the POSIX standard interface.

For POSIX.1c-compliant applications, the `_POSIX_PTHREAD_SEMANTICS` and `_REENTRANT` flags are automatically turned on by defining the `_POSIX_C_SOURCE` flag with a value `>= 199506L`.

NAME	getrusage – get information about resource utilization										
SYNOPSIS	<pre>#include <sys/resource.h> int getrusage(int who, struct rusage *r_usage);</pre>										
DESCRIPTION	<p>The <code>getrusage()</code> function provides measures of the resources used by the current process or its terminated and waited-for child processes. If the value of the <code>who</code> argument is <code>RUSAGE_SELF</code>, information is returned about resources used by the current process. If the value of the <code>who</code> argument is <code>RUSAGE_CHILDREN</code>, information is returned about resources used by the terminated and waited-for children of the current process. If the child is never waited for (for instance, if the parent has <code>SA_NOCLDWAIT</code> set or sets <code>SIGCHLD</code> to <code>SIG_IGN</code>), the resource information for the child process is discarded and not included in the resource information provided by <code>getrusage()</code>.</p> <p>The <code>r_usage</code> argument is a pointer to an object of type <code>struct rusage</code> in which the returned information is stored. The members of <code>rusage</code> are as follows:</p> <pre>struct timeval ru_utime; /* user time used */ struct timeval ru_stime; /* system time used */ long ru_maxrss; /* maximum resident set size */ long ru_idrss; /* integral resident set size */ long ru_minflt; /* page faults not requiring physical I/O */ long ru_majflt; /* page faults requiring physical I/O */ long ru_nswap; /* swaps */ long ru_inblock; /* block input operations */ long ru_oublock; /* block output operations */ long ru_msgsnd; /* messages sent */ long ru_msgrcv; /* messages received */ long ru_nsignals; /* signals received */ long ru_nvcsw; /* voluntary context switches */ long ru_nivcsw; /* involuntary context switches */</pre> <p>The structure members are interpreted as follows:</p> <table border="0"> <tr> <td style="vertical-align: top; padding-right: 10px;"><code>ru_utime</code></td> <td>The total amount of time spent executing in user mode. Time is given in seconds and microseconds.</td> </tr> <tr> <td style="vertical-align: top; padding-right: 10px;"><code>ru_stime</code></td> <td>The total amount of time spent executing in system mode. Time is given in seconds and microseconds.</td> </tr> <tr> <td style="vertical-align: top; padding-right: 10px;"><code>ru_maxrss</code></td> <td>The maximum resident set size. Size is given in pages (the size of a page, in bytes, is given by the <code>getpagesize(3C)</code> function). See the NOTES section of this page.</td> </tr> <tr> <td style="vertical-align: top; padding-right: 10px;"><code>ru_idrss</code></td> <td>An “integral” value indicating the amount of memory in use by a process while the process is running. This value is the sum of the resident set sizes of the process running when a clock tick occurs. The value is given in pages times clock ticks. It does not take sharing into account. See the NOTES section of this page.</td> </tr> <tr> <td style="vertical-align: top; padding-right: 10px;"><code>ru_minflt</code></td> <td>The number of page faults serviced which did not require any physical I/O activity. See the NOTES section of this page.</td> </tr> </table>	<code>ru_utime</code>	The total amount of time spent executing in user mode. Time is given in seconds and microseconds.	<code>ru_stime</code>	The total amount of time spent executing in system mode. Time is given in seconds and microseconds.	<code>ru_maxrss</code>	The maximum resident set size. Size is given in pages (the size of a page, in bytes, is given by the <code>getpagesize(3C)</code> function). See the NOTES section of this page.	<code>ru_idrss</code>	An “integral” value indicating the amount of memory in use by a process while the process is running. This value is the sum of the resident set sizes of the process running when a clock tick occurs. The value is given in pages times clock ticks. It does not take sharing into account. See the NOTES section of this page.	<code>ru_minflt</code>	The number of page faults serviced which did not require any physical I/O activity. See the NOTES section of this page.
<code>ru_utime</code>	The total amount of time spent executing in user mode. Time is given in seconds and microseconds.										
<code>ru_stime</code>	The total amount of time spent executing in system mode. Time is given in seconds and microseconds.										
<code>ru_maxrss</code>	The maximum resident set size. Size is given in pages (the size of a page, in bytes, is given by the <code>getpagesize(3C)</code> function). See the NOTES section of this page.										
<code>ru_idrss</code>	An “integral” value indicating the amount of memory in use by a process while the process is running. This value is the sum of the resident set sizes of the process running when a clock tick occurs. The value is given in pages times clock ticks. It does not take sharing into account. See the NOTES section of this page.										
<code>ru_minflt</code>	The number of page faults serviced which did not require any physical I/O activity. See the NOTES section of this page.										

getrusage(3C)

<code>ru_majflt</code>	The number of page faults serviced which required physical I/O activity. This could include page ahead operations by the kernel. See the NOTES section of this page.
<code>ru_nswap</code>	The number of times a process was swapped out of main memory.
<code>ru_inblock</code>	The number of times the file system had to perform input in servicing a <code>read(2)</code> request.
<code>ru_oublock</code>	The number of times the file system had to perform output in servicing a <code>write(2)</code> request.
<code>ru_msgsnd</code>	The number of messages sent over sockets.
<code>ru_msgrcv</code>	The number of messages received from sockets.
<code>ru_nsignals</code>	The number of signals delivered.
<code>ru_nvcsw</code>	The number of times a context switch resulted due to a process voluntarily giving up the processor before its time slice was completed (usually to await availability of a resource).
<code>ru_nivcsw</code>	The number of times a context switch resulted due to a higher priority process becoming runnable or because the current process exceeded its time slice.

RETURN VALUES Upon successful completion, `getrusage()` returns 0. Otherwise, `-1` is returned and `errno` is set to indicate the error.

ERRORS The `getrusage()` function will fail if:

<code>EFAULT</code>	The address specified by the <code>r_usage</code> argument is not in a valid portion of the process' address space.
<code>EINVAL</code>	The <code>who</code> parameter is not a valid value.

SEE ALSO `sar(1M)`, `read(2)`, `times(2)`, `wait(2)`, `write(2)`, `getpagesize(3C)`, `gettimeofday(3C)`

NOTES Only the `timeval` member of `struct rusage` are supported in this implementation.

The numbers `ru_inblock` and `ru_oublock` account only for real I/O, and are approximate measures at best. Data supplied by the cache mechanism is charged only to the first process to read and the last process to write the data.

The way resident set size is calculated is an approximation, and could misrepresent the true resident set size.

Page faults can be generated from a variety of sources and for a variety of reasons. The customary cause for a page fault is a direct reference by the program to a page which is not in memory. Now, however, the kernel can generate page faults on behalf of the user, for example, servicing `read(2)` and `write(2)` functions. Also, a page fault can be caused by an absent hardware translation to a page, even though the page is in physical memory.

In addition to hardware detected page faults, the kernel may cause pseudo page faults in order to perform some housekeeping. For example, the kernel may generate page faults, even if the pages exist in physical memory, in order to lock down pages involved in a raw I/O request.

By definition, major page faults require physical I/O, while minor page faults do not require physical I/O. For example, reclaiming the page from the free list would avoid I/O and generate a minor page fault. More commonly, minor page faults occur during process startup as references to pages which are already in memory. For example, if an address space faults on some "hot" executable or shared library, this results in a minor page fault for the address space. Also, any one doing a `read(2)` or `write(2)` to something that is in the page cache will get a minor page fault(s) as well.

There is no way to obtain information about a child process which has not yet terminated.

gets(3C)

NAME	gets, fgets – get a string from a stream				
SYNOPSIS	<pre>#include <stdio.h> char *gets(char *s); char *fgets(char *s, int n, FILE *stream);</pre>				
DESCRIPTION	<p>The <code>gets()</code> function reads bytes from the standard input stream (see <code>intro(3)</code>), <code>stdin</code>, into the array pointed to by <code>s</code>, until a newline character is read or an end-of-file condition is encountered. The newline character is discarded and the string is terminated with a null byte.</p> <p>If the length of an input line exceeds the size of <code>s</code>, indeterminate behavior may result. For this reason, it is strongly recommended that <code>gets()</code> be avoided in favor of <code>fgets()</code>.</p> <p>The <code>fgets()</code> function reads bytes from the <code>stream</code> into the array pointed to by <code>s</code>, until <code>n-1</code> bytes are read, or a newline character is read and transferred to <code>s</code>, or an end-of-file condition is encountered. The string is then terminated with a null byte.</p> <p>The <code>fgets()</code> function may mark the <code>st_atime</code> field of the file associated with <code>stream</code> for update. The <code>st_atime</code> field will be marked for update by the first successful execution of <code>fgetc(3C)</code>, <code>fgets()</code>, <code>fgetwc(3C)</code>, <code>fgetws(3C)</code>, <code>fread(3C)</code>, <code>fscanf(3C)</code>, <code>getc(3C)</code>, <code>getchar(3C)</code>, <code>gets()</code>, or <code>scanf(3C)</code> using <code>stream</code> that returns data not supplied by a prior call to <code>ungetc(3C)</code> or <code>ungetwc(3C)</code>.</p>				
RETURN VALUES	If end-of-file is encountered and no bytes have been read, no bytes are transferred to <code>s</code> and a null pointer is returned. If a read error occurs, such as trying to use these functions on a file that has not been opened for reading, a null pointer is returned and the error indicator for the stream is set. If end-of-file is encountered, the EOF indicator for the stream is set. Otherwise <code>s</code> is returned.				
ERRORS	Refer to <code>fgetc(3C)</code> .				
ATTRIBUTES	See <code>attributes(5)</code> for descriptions of the following attributes:				
	<table border="1"><thead><tr><th>ATTRIBUTE TYPE</th><th>ATTRIBUTE VALUE</th></tr></thead><tbody><tr><td>MT-Level</td><td>MT-Safe</td></tr></tbody></table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	MT-Level	MT-Safe

NAME	getspnam, getspnam_r, getspent, getspent_r, setspent, endspent, fgetspent, fgetspent_r – get password entry
SYNOPSIS	<pre>#include <shadow.h> struct spwd *getspnam(const char *name); struct spwd *getspnam_r(const char *name, struct spwd *result, char *buffer, int buflen); struct spwd *getspent(void); struct spwd *getspent_r(struct spwd *result, char *buffer, int buflen); void setspent(void); void endspent(void); struct spwd *fgetspent(FILE *fp); struct spwd *fgetspent_r(FILE *fp, struct spwd *result, char *buffer, int buflen);</pre>
DESCRIPTION	<p>These functions are used to obtain shadow password entries. An entry may come from any of the sources for shadow specified in the <code>/etc/nsswitch.conf</code> file (see <code>nsswitch.conf(4)</code>).</p> <p>The <code>getspnam()</code> function searches for a shadow password entry with the login name specified by the character string argument <i>name</i>.</p> <p>The <code>setspent()</code>, <code>getspent()</code>, and <code>endspent()</code> functions are used to enumerate shadow password entries from the database.</p> <p>The <code>setspent()</code> function sets (or resets) the enumeration to the beginning of the set of shadow password entries. This function should be called before the first call to <code>getspent()</code>. Calls to <code>getspnam()</code> leave the enumeration position in an indeterminate state.</p> <p>Successive calls to <code>getspent()</code> return either successive entries or NULL, indicating the end of the enumeration.</p> <p>The <code>endspent()</code> function may be called to indicate that the caller expects to do no further shadow password retrieval operations; the system may then close the shadow password file, deallocate resources it was using, and so forth. It is still allowed, but possibly less efficient, for the process to call more shadow password functions after calling <code>endspent()</code>.</p> <p>The <code>fgetspent()</code> function, unlike the other functions above, does not use <code>nsswitch.conf</code>; it reads and parses the next line from the stream <i>fp</i>, which is assumed to have the format of the shadow file (see <code>shadow(4)</code>).</p>
Reentrant Interfaces	The <code>getspnam()</code> , <code>getspent()</code> , and <code>fgetspent()</code> functions use static storage that is re-used in each call, making these routines unsafe for use in multithreaded applications.

getspent(3C)

The `getspnam_r()`, `getspent_r()`, and `fgetspent_r()` functions provide reentrant interfaces for these operations.

Each reentrant interface performs the same operation as its non-reentrant counterpart, named by removing the `_r` suffix. The reentrant interfaces, however, use buffers supplied by the caller to store returned results, and are safe for use in both single-threaded and multithreaded applications.

Each reentrant interface takes the same argument as its non-reentrant counterpart, as well as the following additional arguments. The *result* argument must be a pointer to a `struct spwd` structure allocated by the caller. On successful completion, the function returns the shadow password entry in this structure. The *buffer* argument must be a pointer to a buffer supplied by the caller. This buffer is used as storage space for the shadow password data. All of the pointers within the returned `struct spwd result` point to data stored within this buffer (see RETURN VALUES). The buffer must be large enough to hold all of the data associated with the shadow password entry. The *buflen* argument should give the size in bytes of the buffer indicated by *buffer*.

For enumeration in multithreaded applications, the position within the enumeration is a process-wide property shared by all threads. The `setspent()` function may be used in a multithreaded application but resets the enumeration position for all threads. If multiple threads interleave calls to `getspent_r()`, the threads will enumerate disjoint subsets of the shadow password database.

Like its non-reentrant counterpart, `getspnam_r()` leaves the enumeration position in an indeterminate state.

RETURN VALUES

Password entries are represented by the `struct spwd` structure defined in `<shadow.h>`:

```
struct spwd{
    char          *sp_namp;      /* login name */
    char          *sp_pwdp;     /* encrypted passwd */
    long         sp_lstchg;     /* date of last change */
    long         sp_min;       /* min days to passwd change */
    long         sp_max;       /* max days to passwd change*/
    long         sp_warn;      /* warning period */
    long         sp_inact;     /* max days inactive */
    long         sp_expire;    /* account expiry date */
    unsigned long sp_flag;     /* not used */
};
```

See `shadow(4)` for more information on the interpretation of this data.

The `getspnam()` and `getspnam_r()` functions each return a pointer to a `struct spwd` if they successfully locate the requested entry; otherwise they return `NULL`.

The `getspent()`, `getspent_r()`, `fgetspent()`, and `fgetspent_r()` functions each return a pointer to a `struct spwd` if they successfully enumerate an entry; otherwise they return `NULL`, indicating the end of the enumeration.

The `getspnam()`, `getspent()`, and `fgetspent()` functions use static storage, so returned data must be copied before a subsequent call to any of these functions if the data is to be saved.

When the pointer returned by the reentrant functions `getspnam_r()`, `getspent_r()`, and `fgetspent_r()` is non-null, it is always equal to the *result* pointer that was supplied by the caller.

ERRORS The reentrant functions `getspnam_r()`, `getspent_r()`, and `fgetspent_r()` will return NULL and set `errno` to `ERANGE` if the length of the buffer supplied by caller is not large enough to store the result. See `intro(2)` for the proper usage and interpretation of `errno` in multithreaded applications.

USAGE Applications that use the interfaces described on this manual page cannot be linked statically, since the implementations of these functions employ dynamic loading and linking of shared objects at run time.

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
MT-Level	See "Reentrant Interfaces" in <code>DESCRIPTION</code> .

SEE ALSO `nispasswd(1)`, `passwd(1)`, `yppasswd(1)`, `intro(3)` `getlogin(3C)`, `getpwnam(3C)`, `nsswitch.conf(4)`, `passwd(4)`, `shadow(4)`, `attributes(5)`

WARNINGS The reentrant interfaces `getspnam_r()`, `getspent_r()`, and `fgetspent_r()` are included in this release on an uncommitted basis only, and are subject to change or removal in future minor releases.

NOTES When compiling multithreaded applications, see `intro(3)`, *Notes On Multithreaded Applications*, for information about the use of the `_REENTRANT` flag.

Use of the enumeration interfaces `getspent()` and `getspent_r()` is not recommended; enumeration is supported for the shadow file, NIS, and NIS+, but in general is not efficient and may not be supported for all database sources. The semantics of enumeration are discussed further in `nsswitch.conf(4)`.

Access to shadow password information may be restricted in a manner depending on the database source being used. Access to the `/etc/shadow` file is generally restricted to processes running as the super-user (root). Other database sources may impose stronger or less stringent restrictions.

When NIS is used as the database source, the information for the shadow password entries is obtained from the "passwd.byname" map. This map stores only the information for the `sp_namp` and `sp_pwdp` fields of the `struct spwd` structure. Shadow password entries obtained from NIS will contain the value -1 in the remainder of the fields.

getspent(3C)

When NIS+ is used as the database source, and the caller lacks the permission needed to retrieve the encrypted password from the NIS+ "passwd.org_dir" table, the NIS+ service returns the string "*NP*" instead of the actual encrypted password string. The functions described on this page will then return the string "*NP*" to the caller as the value of the member `sp_pwdp` in the returned shadow password structure.

NAME	getspnam, getspnam_r, getspent, getspent_r, setspent, endspent, fgetspent, fgetspent_r – get password entry
SYNOPSIS	<pre>#include <shadow.h> struct spwd *getspnam(const char *name); struct spwd *getspnam_r(const char *name, struct spwd *result, char *buffer, int buflen); struct spwd *getspent(void); struct spwd *getspent_r(struct spwd *result, char *buffer, int buflen); void setspent(void); void endspent(void); struct spwd *fgetspent(FILE *fp); struct spwd *fgetspent_r(FILE *fp, struct spwd *result, char *buffer, int buflen);</pre>
DESCRIPTION	<p>These functions are used to obtain shadow password entries. An entry may come from any of the sources for shadow specified in the <code>/etc/nsswitch.conf</code> file (see <code>nsswitch.conf(4)</code>).</p> <p>The <code>getspnam()</code> function searches for a shadow password entry with the login name specified by the character string argument <i>name</i>.</p> <p>The <code>setspent()</code>, <code>getspent()</code>, and <code>endspent()</code> functions are used to enumerate shadow password entries from the database.</p> <p>The <code>setspent()</code> function sets (or resets) the enumeration to the beginning of the set of shadow password entries. This function should be called before the first call to <code>getspent()</code>. Calls to <code>getspnam()</code> leave the enumeration position in an indeterminate state.</p> <p>Successive calls to <code>getspent()</code> return either successive entries or NULL, indicating the end of the enumeration.</p> <p>The <code>endspent()</code> function may be called to indicate that the caller expects to do no further shadow password retrieval operations; the system may then close the shadow password file, deallocate resources it was using, and so forth. It is still allowed, but possibly less efficient, for the process to call more shadow password functions after calling <code>endspent()</code>.</p> <p>The <code>fgetspent()</code> function, unlike the other functions above, does not use <code>nsswitch.conf</code>; it reads and parses the next line from the stream <i>fp</i>, which is assumed to have the format of the shadow file (see <code>shadow(4)</code>).</p>
Reentrant Interfaces	The <code>getspnam()</code> , <code>getspent()</code> , and <code>fgetspent()</code> functions use static storage that is re-used in each call, making these routines unsafe for use in multithreaded applications.

getspent_r(3C)

The `getspnam_r()`, `getspent_r()`, and `fgetspent_r()` functions provide reentrant interfaces for these operations.

Each reentrant interface performs the same operation as its non-reentrant counterpart, named by removing the `_r` suffix. The reentrant interfaces, however, use buffers supplied by the caller to store returned results, and are safe for use in both single-threaded and multithreaded applications.

Each reentrant interface takes the same argument as its non-reentrant counterpart, as well as the following additional arguments. The *result* argument must be a pointer to a `struct spwd` structure allocated by the caller. On successful completion, the function returns the shadow password entry in this structure. The *buffer* argument must be a pointer to a buffer supplied by the caller. This buffer is used as storage space for the shadow password data. All of the pointers within the returned `struct spwd result` point to data stored within this buffer (see RETURN VALUES). The buffer must be large enough to hold all of the data associated with the shadow password entry. The *buflen* argument should give the size in bytes of the buffer indicated by *buffer*.

For enumeration in multithreaded applications, the position within the enumeration is a process-wide property shared by all threads. The `setspent()` function may be used in a multithreaded application but resets the enumeration position for all threads. If multiple threads interleave calls to `getspent_r()`, the threads will enumerate disjoint subsets of the shadow password database.

Like its non-reentrant counterpart, `getspnam_r()` leaves the enumeration position in an indeterminate state.

RETURN VALUES

Password entries are represented by the `struct spwd` structure defined in `<shadow.h>`:

```
struct spwd{
    char          *sp_namp;      /* login name */
    char          *sp_pwdp;     /* encrypted passwd */
    long          sp_lstchg;     /* date of last change */
    long          sp_min;       /* min days to passwd change */
    long          sp_max;       /* max days to passwd change*/
    long          sp_warn;      /* warning period */
    long          sp_inact;     /* max days inactive */
    long          sp_expire;    /* account expiry date */
    unsigned long sp_flag;     /* not used */
};
```

See `shadow(4)` for more information on the interpretation of this data.

The `getspnam()` and `getspnam_r()` functions each return a pointer to a `struct spwd` if they successfully locate the requested entry; otherwise they return `NULL`.

The `getspent()`, `getspent_r()`, `fgetspent()`, and `fgetspent_r()` functions each return a pointer to a `struct spwd` if they successfully enumerate an entry; otherwise they return `NULL`, indicating the end of the enumeration.

The `getspnam()`, `getspent()`, and `fgetspent()` functions use static storage, so returned data must be copied before a subsequent call to any of these functions if the data is to be saved.

When the pointer returned by the reentrant functions `getspnam_r()`, `getspent_r()`, and `fgetspent_r()` is non-null, it is always equal to the *result* pointer that was supplied by the caller.

ERRORS The reentrant functions `getspnam_r()`, `getspent_r()`, and `fgetspent_r()` will return NULL and set `errno` to `ERANGE` if the length of the buffer supplied by caller is not large enough to store the result. See `intro(2)` for the proper usage and interpretation of `errno` in multithreaded applications.

USAGE Applications that use the interfaces described on this manual page cannot be linked statically, since the implementations of these functions employ dynamic loading and linking of shared objects at run time.

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
MT-Level	See "Reentrant Interfaces" in <code>DESCRIPTION</code> .

SEE ALSO `nispasswd(1)`, `passwd(1)`, `yppasswd(1)`, `intro(3)` `getlogin(3C)`, `getpwnam(3C)`, `nsswitch.conf(4)`, `passwd(4)`, `shadow(4)`, `attributes(5)`

WARNINGS The reentrant interfaces `getspnam_r()`, `getspent_r()`, and `fgetspent_r()` are included in this release on an uncommitted basis only, and are subject to change or removal in future minor releases.

NOTES When compiling multithreaded applications, see `intro(3)`, *Notes On Multithreaded Applications*, for information about the use of the `_REENTRANT` flag.

Use of the enumeration interfaces `getspent()` and `getspent_r()` is not recommended; enumeration is supported for the shadow file, NIS, and NIS+, but in general is not efficient and may not be supported for all database sources. The semantics of enumeration are discussed further in `nsswitch.conf(4)`.

Access to shadow password information may be restricted in a manner depending on the database source being used. Access to the `/etc/shadow` file is generally restricted to processes running as the super-user (root). Other database sources may impose stronger or less stringent restrictions.

When NIS is used as the database source, the information for the shadow password entries is obtained from the "passwd.byname" map. This map stores only the information for the `sp_namp` and `sp_pwdp` fields of the `struct spwd` structure. Shadow password entries obtained from NIS will contain the value -1 in the remainder of the fields.

getspent_r(3C)

When NIS+ is used as the database source, and the caller lacks the permission needed to retrieve the encrypted password from the NIS+ "passwd.org_dir" table, the NIS+ service returns the string "*NP*" instead of the actual encrypted password string. The functions described on this page will then return the string "*NP*" to the caller as the value of the member `sp_pwdp` in the returned shadow password structure.

NAME	getspnam, getspnam_r, getspent, getspent_r, setspent, endspent, fgetspent, fgetspent_r – get password entry
SYNOPSIS	<pre>#include <shadow.h> struct spwd *getspnam(const char *name); struct spwd *getspnam_r(const char *name, struct spwd *result, char *buffer, int buflen); struct spwd *getspent(void); struct spwd *getspent_r(struct spwd *result, char *buffer, int buflen); void setspent(void); void endspent(void); struct spwd *fgetspent(FILE *fp); struct spwd *fgetspent_r(FILE *fp, struct spwd *result, char *buffer, int buflen);</pre>
DESCRIPTION	<p>These functions are used to obtain shadow password entries. An entry may come from any of the sources for shadow specified in the <code>/etc/nsswitch.conf</code> file (see <code>nsswitch.conf(4)</code>).</p> <p>The <code>getspnam()</code> function searches for a shadow password entry with the login name specified by the character string argument <i>name</i>.</p> <p>The <code>setspent()</code>, <code>getspent()</code>, and <code>endspent()</code> functions are used to enumerate shadow password entries from the database.</p> <p>The <code>setspent()</code> function sets (or resets) the enumeration to the beginning of the set of shadow password entries. This function should be called before the first call to <code>getspent()</code>. Calls to <code>getspnam()</code> leave the enumeration position in an indeterminate state.</p> <p>Successive calls to <code>getspent()</code> return either successive entries or NULL, indicating the end of the enumeration.</p> <p>The <code>endspent()</code> function may be called to indicate that the caller expects to do no further shadow password retrieval operations; the system may then close the shadow password file, deallocate resources it was using, and so forth. It is still allowed, but possibly less efficient, for the process to call more shadow password functions after calling <code>endspent()</code>.</p> <p>The <code>fgetspent()</code> function, unlike the other functions above, does not use <code>nsswitch.conf</code>; it reads and parses the next line from the stream <i>fp</i>, which is assumed to have the format of the shadow file (see <code>shadow(4)</code>).</p>
Reentrant Interfaces	The <code>getspnam()</code> , <code>getspent()</code> , and <code>fgetspent()</code> functions use static storage that is re-used in each call, making these routines unsafe for use in multithreaded applications.

getspnam(3C)

The `getspnam_r()`, `getspent_r()`, and `fgetspent_r()` functions provide reentrant interfaces for these operations.

Each reentrant interface performs the same operation as its non-reentrant counterpart, named by removing the `_r` suffix. The reentrant interfaces, however, use buffers supplied by the caller to store returned results, and are safe for use in both single-threaded and multithreaded applications.

Each reentrant interface takes the same argument as its non-reentrant counterpart, as well as the following additional arguments. The *result* argument must be a pointer to a `struct spwd` structure allocated by the caller. On successful completion, the function returns the shadow password entry in this structure. The *buffer* argument must be a pointer to a buffer supplied by the caller. This buffer is used as storage space for the shadow password data. All of the pointers within the returned `struct spwd result` point to data stored within this buffer (see RETURN VALUES). The buffer must be large enough to hold all of the data associated with the shadow password entry. The *buflen* argument should give the size in bytes of the buffer indicated by *buffer*.

For enumeration in multithreaded applications, the position within the enumeration is a process-wide property shared by all threads. The `setspent()` function may be used in a multithreaded application but resets the enumeration position for all threads. If multiple threads interleave calls to `getspent_r()`, the threads will enumerate disjoint subsets of the shadow password database.

Like its non-reentrant counterpart, `getspnam_r()` leaves the enumeration position in an indeterminate state.

RETURN VALUES

Password entries are represented by the `struct spwd` structure defined in `<shadow.h>`:

```
struct spwd{
    char          *sp_namp;      /* login name */
    char          *sp_pwdp;     /* encrypted passwd */
    long         sp_lstchg;     /* date of last change */
    long         sp_min;        /* min days to passwd change */
    long         sp_max;        /* max days to passwd change*/
    long         sp_warn;       /* warning period */
    long         sp_inact;      /* max days inactive */
    long         sp_expire;     /* account expiry date */
    unsigned long sp_flag;      /* not used */
};
```

See `shadow(4)` for more information on the interpretation of this data.

The `getspnam()` and `getspnam_r()` functions each return a pointer to a `struct spwd` if they successfully locate the requested entry; otherwise they return `NULL`.

The `getspent()`, `getspent_r()`, `fgetspent()`, and `fgetspent_r()` functions each return a pointer to a `struct spwd` if they successfully enumerate an entry; otherwise they return `NULL`, indicating the end of the enumeration.

The `getspnam()`, `getspent()`, and `fgetspent()` functions use static storage, so returned data must be copied before a subsequent call to any of these functions if the data is to be saved.

When the pointer returned by the reentrant functions `getspnam_r()`, `getspent_r()`, and `fgetspent_r()` is non-null, it is always equal to the *result* pointer that was supplied by the caller.

ERRORS The reentrant functions `getspnam_r()`, `getspent_r()`, and `fgetspent_r()` will return NULL and set `errno` to `ERANGE` if the length of the buffer supplied by caller is not large enough to store the result. See `intro(2)` for the proper usage and interpretation of `errno` in multithreaded applications.

USAGE Applications that use the interfaces described on this manual page cannot be linked statically, since the implementations of these functions employ dynamic loading and linking of shared objects at run time.

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
MT-Level	See "Reentrant Interfaces" in <code>DESCRIPTION</code> .

SEE ALSO `nispasswd(1)`, `passwd(1)`, `yppasswd(1)`, `intro(3)` `getlogin(3C)`, `getpwnam(3C)`, `nsswitch.conf(4)`, `passwd(4)`, `shadow(4)`, `attributes(5)`

WARNINGS The reentrant interfaces `getspnam_r()`, `getspent_r()`, and `fgetspent_r()` are included in this release on an uncommitted basis only, and are subject to change or removal in future minor releases.

NOTES When compiling multithreaded applications, see `intro(3)`, *Notes On Multithreaded Applications*, for information about the use of the `_REENTRANT` flag.

Use of the enumeration interfaces `getspent()` and `getspent_r()` is not recommended; enumeration is supported for the shadow file, NIS, and NIS+, but in general is not efficient and may not be supported for all database sources. The semantics of enumeration are discussed further in `nsswitch.conf(4)`.

Access to shadow password information may be restricted in a manner depending on the database source being used. Access to the `/etc/shadow` file is generally restricted to processes running as the super-user (root). Other database sources may impose stronger or less stringent restrictions.

When NIS is used as the database source, the information for the shadow password entries is obtained from the "passwd.byname" map. This map stores only the information for the `sp_namp` and `sp_pwdp` fields of the `struct spwd` structure. Shadow password entries obtained from NIS will contain the value -1 in the remainder of the fields.

getspnam(3C)

When NIS+ is used as the database source, and the caller lacks the permission needed to retrieve the encrypted password from the NIS+ "passwd.org_dir" table, the NIS+ service returns the string "*NP*" instead of the actual encrypted password string. The functions described on this page will then return the string "*NP*" to the caller as the value of the member `sp_pwdp` in the returned shadow password structure.

NAME	getspnam, getspnam_r, getspent, getspent_r, setspent, endspent, fgetspent, fgetspent_r – get password entry
SYNOPSIS	<pre>#include <shadow.h> struct spwd *getspnam(const char *name); struct spwd *getspnam_r(const char *name, struct spwd *result, char *buffer, int buflen); struct spwd *getspent(void); struct spwd *getspent_r(struct spwd *result, char *buffer, int buflen); void setspent(void); void endspent(void); struct spwd *fgetspent(FILE *fp); struct spwd *fgetspent_r(FILE *fp, struct spwd *result, char *buffer, int buflen);</pre>
DESCRIPTION	<p>These functions are used to obtain shadow password entries. An entry may come from any of the sources for shadow specified in the <code>/etc/nsswitch.conf</code> file (see <code>nsswitch.conf(4)</code>).</p> <p>The <code>getspnam()</code> function searches for a shadow password entry with the login name specified by the character string argument <i>name</i>.</p> <p>The <code>setspent()</code>, <code>getspent()</code>, and <code>endspent()</code> functions are used to enumerate shadow password entries from the database.</p> <p>The <code>setspent()</code> function sets (or resets) the enumeration to the beginning of the set of shadow password entries. This function should be called before the first call to <code>getspent()</code>. Calls to <code>getspnam()</code> leave the enumeration position in an indeterminate state.</p> <p>Successive calls to <code>getspent()</code> return either successive entries or NULL, indicating the end of the enumeration.</p> <p>The <code>endspent()</code> function may be called to indicate that the caller expects to do no further shadow password retrieval operations; the system may then close the shadow password file, deallocate resources it was using, and so forth. It is still allowed, but possibly less efficient, for the process to call more shadow password functions after calling <code>endspent()</code>.</p> <p>The <code>fgetspent()</code> function, unlike the other functions above, does not use <code>nsswitch.conf</code>; it reads and parses the next line from the stream <i>fp</i>, which is assumed to have the format of the shadow file (see <code>shadow(4)</code>).</p>
Reentrant Interfaces	The <code>getspnam()</code> , <code>getspent()</code> , and <code>fgetspent()</code> functions use static storage that is re-used in each call, making these routines unsafe for use in multithreaded applications.

getspnam_r(3C)

The `getspnam_r()`, `getspent_r()`, and `fgetspent_r()` functions provide reentrant interfaces for these operations.

Each reentrant interface performs the same operation as its non-reentrant counterpart, named by removing the `_r` suffix. The reentrant interfaces, however, use buffers supplied by the caller to store returned results, and are safe for use in both single-threaded and multithreaded applications.

Each reentrant interface takes the same argument as its non-reentrant counterpart, as well as the following additional arguments. The *result* argument must be a pointer to a `struct spwd` structure allocated by the caller. On successful completion, the function returns the shadow password entry in this structure. The *buffer* argument must be a pointer to a buffer supplied by the caller. This buffer is used as storage space for the shadow password data. All of the pointers within the returned `struct spwd result` point to data stored within this buffer (see RETURN VALUES). The buffer must be large enough to hold all of the data associated with the shadow password entry. The *buflen* argument should give the size in bytes of the buffer indicated by *buffer*.

For enumeration in multithreaded applications, the position within the enumeration is a process-wide property shared by all threads. The `setspent()` function may be used in a multithreaded application but resets the enumeration position for all threads. If multiple threads interleave calls to `getspent_r()`, the threads will enumerate disjoint subsets of the shadow password database.

Like its non-reentrant counterpart, `getspnam_r()` leaves the enumeration position in an indeterminate state.

RETURN VALUES

Password entries are represented by the `struct spwd` structure defined in `<shadow.h>`:

```
struct spwd{
    char          *sp_namp;      /* login name */
    char          *sp_pwdp;     /* encrypted passwd */
    long         sp_lstchg;     /* date of last change */
    long         sp_min;        /* min days to passwd change */
    long         sp_max;        /* max days to passwd change */
    long         sp_warn;       /* warning period */
    long         sp_inact;      /* max days inactive */
    long         sp_expire;     /* account expiry date */
    unsigned long sp_flag;      /* not used */
};
```

See `shadow(4)` for more information on the interpretation of this data.

The `getspnam()` and `getspnam_r()` functions each return a pointer to a `struct spwd` if they successfully locate the requested entry; otherwise they return `NULL`.

The `getspent()`, `getspent_r()`, `fgetspent()`, and `fgetspent_r()` functions each return a pointer to a `struct spwd` if they successfully enumerate an entry; otherwise they return `NULL`, indicating the end of the enumeration.

The `getspnam()`, `getspent()`, and `fgetspent()` functions use static storage, so returned data must be copied before a subsequent call to any of these functions if the data is to be saved.

When the pointer returned by the reentrant functions `getspnam_r()`, `getspent_r()`, and `fgetspent_r()` is non-null, it is always equal to the *result* pointer that was supplied by the caller.

ERRORS The reentrant functions `getspnam_r()`, `getspent_r()`, and `fgetspent_r()` will return NULL and set `errno` to `ERANGE` if the length of the buffer supplied by caller is not large enough to store the result. See `intro(2)` for the proper usage and interpretation of `errno` in multithreaded applications.

USAGE Applications that use the interfaces described on this manual page cannot be linked statically, since the implementations of these functions employ dynamic loading and linking of shared objects at run time.

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
MT-Level	See "Reentrant Interfaces" in <code>DESCRIPTION</code> .

SEE ALSO `nispasswd(1)`, `passwd(1)`, `yppasswd(1)`, `intro(3)` `getlogin(3C)`, `getpwnam(3C)`, `nsswitch.conf(4)`, `passwd(4)`, `shadow(4)`, `attributes(5)`

WARNINGS The reentrant interfaces `getspnam_r()`, `getspent_r()`, and `fgetspent_r()` are included in this release on an uncommitted basis only, and are subject to change or removal in future minor releases.

NOTES When compiling multithreaded applications, see `intro(3)`, *Notes On Multithreaded Applications*, for information about the use of the `_REENTRANT` flag.

Use of the enumeration interfaces `getspent()` and `getspent_r()` is not recommended; enumeration is supported for the shadow file, NIS, and NIS+, but in general is not efficient and may not be supported for all database sources. The semantics of enumeration are discussed further in `nsswitch.conf(4)`.

Access to shadow password information may be restricted in a manner depending on the database source being used. Access to the `/etc/shadow` file is generally restricted to processes running as the super-user (root). Other database sources may impose stronger or less stringent restrictions.

When NIS is used as the database source, the information for the shadow password entries is obtained from the "passwd.byname" map. This map stores only the information for the `sp_namp` and `sp_pwdp` fields of the `struct spwd` structure. Shadow password entries obtained from NIS will contain the value -1 in the remainder of the fields.

getspnam_r(3C)

When NIS+ is used as the database source, and the caller lacks the permission needed to retrieve the encrypted password from the NIS+ "passwd.org_dir" table, the NIS+ service returns the string "*NP*" instead of the actual encrypted password string. The functions described on this page will then return the string "*NP*" to the caller as the value of the member `sp_pwdp` in the returned shadow password structure.

NAME	getsubopt – parse suboptions from a string
SYNOPSIS	<pre>#include <stdlib.h> int getsubopt(char **<i>optionp</i>, char * const *<i>tokens</i>, char **<i>valuep</i>);</pre>
DESCRIPTION	<p>The <code>getsubopt()</code> function parses suboptions in a flag argument that was initially parsed by <code>getopt(3C)</code>. The suboptions are separated by commas and may consist of either a single token or a token-value pair separated by an equal sign. Since commas delimit suboptions in the option string, they are not allowed to be part of the suboption or the value of a suboption; if present in the option input string, they are changed to null characters. White spaces within tokens or token-value pairs must be protected from the shell by quotes.</p> <p>The syntax described above is used in the following example by the <code>mount(1M)</code>, utility, which allows the user to specify mount parameters with the <code>-o</code> option as follows:</p> <pre>mount -o rw,hard,bg,wsiz=1024 speed:/usr /usr</pre> <p>In this example there are four suboptions: <code>rw</code>, <code>hard</code>, <code>bg</code>, and <code>wsiz=1024</code>, the last of which has an associated value of 1024.</p> <p>The <code>getsubopt()</code> function takes the address of a pointer to the option string, a vector of possible tokens, and the address of a value string pointer. It returns the index of the token that matched the suboption in the input string, or <code>-1</code> if there was no match. If the option string pointed to by <i>optionp</i> contains only one suboption, <code>getsubopt()</code> updates <i>optionp</i> to point to the null character at the end of the string; otherwise it isolates the suboption by replacing the comma separator with a null character, and updates <i>optionp</i> to point to the start of the next suboption. If the suboption has an associated value, <code>getsubopt()</code> updates <i>valuep</i> to point to the value's first character. Otherwise it sets <i>valuep</i> to <code>NULL</code>.</p> <p>The token vector is organized as a series of pointers to null strings. The end of the token vector is identified by a null pointer.</p> <p>When <code>getsubopt()</code> returns, a non-null value for <i>valuep</i> indicates that the suboption that was processed included a value. The calling program may use this information to determine if the presence or absence of a value for this suboption is an error.</p> <p>When <code>getsubopt()</code> fails to match the suboption with the tokens in the <i>tokens</i> array, the calling program should decide if this is an error, or if the unrecognized option should be passed to another program.</p>
RETURN VALUES	<p>The <code>getsubopt()</code> function returns <code>-1</code> when the token it is scanning is not in the token vector. The variable addressed by <i>valuep</i> contains a pointer to the first character of the token that was not recognized, rather than a pointer to a value for that token.</p> <p>The variable addressed by <i>optionp</i> points to the next option to be parsed, or a null character if there are no more options.</p>

getsubopt(3C)

EXAMPLES **EXAMPLE 1** Example of getsubopt () function.

The following example demonstrates the processing of options to the mount(1M) utility using getsubopt ().

```
#include <stdlib.h>

char *myopts[] = {
#define READONLY      0
    "ro",
#define READWRITE     1
    "rw",
#define WRITESIZE     2
    "wsize",
#define READSIZE      3
    "rsize",
    NULL};

main(argc, argv)
    int  argc;
    char **argv;
{
    int  sc, c, errflag;
    char *options, *value;
    extern char *optarg;
    extern int optind;
    .
    .
    .
    while((c = getopt(argc, argv, "abf:o:")) != -1) {
        switch (c) {
            case 'a': /* process a option */
                break;
            case 'b': /* process b option */
                break;
            case 'f':
                ofile = optarg;
                break;
            case '?':
                errflag++;
                break;
            case 'o':
                options = optarg;
                while (*options != '\0') {
                    switch(getsubopt(&options, myopts, &value)) {
                        case READONLY : /* process ro option */
                            break;
                        case READWRITE : /* process rw option */
                            break;

                                case WRITESIZE : /* process wsize option */
                                    if (value == NULL) {
                                        error_no_arg( );
                                        errflag++;
                                    } else
                                        write_size = atoi(value);
                                    break;
                        case READSIZE : /* process rsize option */
```

EXAMPLE 1 Example of getsubopt() function. (Continued)

```

        if (value == NULL) {
            error_no_arg( );
            errflag++;
        } else
            read_size = atoi(value);
        break;
    default :
        /* process unknown token */
        error_bad_token(value);
        errflag++;
        break;
    }
}
break;
}
}
if (errflag) {
    /* print usage instructions etc. */
}
for (; optind<argc; optind++) {
    /* process remaining arguments */
}
.
.
.
}

```

gettext(3C)

NAME	gettext, dgettext, dcgettext, ngettext, dngettext, dcgettext, textdomain, bindtextdomain, bind_textdomain_codeset – message handling functions
Solaris and GNU-compatible	<pre>#include <libintl.h> char *gettext(const char *msgid); char *dgettext(const char *domainname, const char *msgid); char *textdomain(const char *domainname); char *bindtextdomain(const char *domainname, const char *dirname); #include <libintl.h> #include <locale.h> char *dcgettext(const char *domainname, const char *msgid, int category);</pre>
GNU-compatible	<pre>#include <libintl.h> char *ngettext(const char *msgid1, const char *msgid2, unsigned long int n); char *dngettext(const char *domainname, const char *msgid1, const char *msgid2, unsigned long int n); char *bind_textdomain_codeset(const char *domainname, const char *codeset); #include <libintl.h> #include <locale.h> char *dcngettext(const char *domainname, const char *msgid1, const char *msgid2, unsigned long int n, int category);</pre>
DESCRIPTION	<p>The <code>gettext()</code>, <code>dgettext()</code>, and <code>dcgettext()</code> functions attempt to retrieve a target string based on the specified <code>msgid</code> argument within the context of a specific domain and the current locale. The length of strings returned by <code>gettext()</code>, <code>dgettext()</code>, and <code>dcgettext()</code> is undetermined until the function is called. The <code>msgid</code> argument is a null-terminated string.</p> <p>The <code>ngettext()</code>, <code>dngettext()</code>, and <code>dcngettext()</code> functions are equivalent to <code>gettext()</code>, <code>dgettext()</code>, and <code>dcgettext()</code>, respectively, except for the handling of plural forms. These functions work only with GNU-compatible message catalogues. The <code>ngettext()</code>, <code>dngettext()</code>, and <code>dcngettext()</code> functions search for the message string using the <code>msgid1</code> argument as the key and the <code>n</code> argument to determine the plural form. If no message catalogues are found, <code>msgid1</code> is returned if <code>n == 1</code>, otherwise <code>msgid2</code> is returned.</p> <p>The <code>NLSPATH</code> environment variable (see <code>environ(5)</code>) is searched first for the location of the <code>LC_MESSAGES</code> catalogue. The setting of the <code>LC_MESSAGES</code> category of the current locale determines the locale used by <code>gettext()</code> and <code>dgettext()</code> for string retrieval. The <code>category</code> argument determines the locale used by <code>dcgettext()</code>. If <code>NLSPATH</code> is not defined and the current locale is "C", <code>gettext()</code>, <code>dgettext()</code>, and</p>

`dcgettext()` simply return the message string that was passed. In a locale other than "C", if `NLSPATH` is not defined or if a message catalogue is not found in any of the components specified by `NLSPATH`, the routines search for the message catalogue using the scheme described in the following paragraph.

The `LANGUAGE` environment variable is examined to determine the GNU-compatible message catalogues to be used. The value of `LANGUAGE` is a list of locale names separated by a colon (':') character. If `LANGUAGE` is defined, each locale name is tried in the specified order and if a GNU-compatible message catalogue is found, the message is returned. If a GNU-compatible message catalogue is found but failed to find a corresponding `msgid`, the `msgid` string is return. If `LANGUAGE` is not defined or if a Solaris message catalogue is found or no GNU-compatible message catalogue is found in processing `LANGUAGE`, the pathname used to locate the message catalogue is `dirname/locale/category/domainname.mo`, where `dirname` is the directory specified by `bindtextdomain()`, `locale` is a locale name, and `category` is either `LC_MESSAGES` if `gettext()`, `dgettext()`, `ngettext()`, or `dngettext()` is called, or `LC_XXX` where the name is the same as the locale category name specified by the `category` argument to `dcgettext()` or `dcngettext()`.

For `gettext()` and `ngettext()`, the domain used is set by the last valid call to `textdomain()`. If a valid call to `textdomain()` has not been made, the default domain (called `messages`) is used.

For `dgettext()`, `dcgettext()`, `dngettext()`, and `dcngettext()`, the domain used is specified by the `domainname` argument. The `domainname` argument is equivalent in syntax and meaning to the `domainname` argument to `textdomain()`, except that the selection of the domain is valid only for the duration of the `dgettext()`, `dcgettext()`, `dngettext()`, or `dcngettext()` function call.

The `textdomain()` function sets or queries the name of the current domain of the active `LC_MESSAGES` locale category. The `domainname` argument is a null-terminated string that can contain only the characters allowed in legal filenames.

The `domainname` argument is the unique name of a domain on the system. If there are multiple versions of the same domain on one system, namespace collisions can be avoided by using `bindtextdomain()`. If `textdomain()` is not called, a default domain is selected. The setting of domain made by the last valid call to `textdomain()` remains valid across subsequent calls to `setlocale(3C)`, and `gettext()`.

The `domainname` argument is applied to the currently active `LC_MESSAGES` locale.

The current setting of the domain can be queried without affecting the current state of the domain by calling `textdomain()` with `domainname` set to the null pointer. Calling `textdomain()` with a `domainname` argument of a null string sets the domain to the default domain (`messages`).

The `bindtextdomain()` function binds the path predicate for a message domain `domainname` to the value contained in `dirname`. If `domainname` is a non-empty string and has not been bound previously, `bindtextdomain()` binds `domainname` with `dirname`.

gettext(3C)

If *domainname* is a non-empty string and has been bound previously, `bindtextdomain()` replaces the old binding with *dirname*. The *dirname* argument can be an absolute or relative pathname being resolved when `gettext()`, `dgettext()`, or `dcgettext()` are called. If *domainname* is a null pointer or an empty string, `bindtextdomain()` returns NULL. User defined domain names cannot begin with the string `SYS_`. Domain names beginning with this string are reserved for system use.

The `bind_textdomain_codeset()` function can be used to specify the output codeset for message catalogues for domain *domainname*. The *codeset* argument must be a valid codeset name that can be used for the `iconv_open(3C)` function, or a null pointer. If the *codeset* argument is the null pointer, `bind_textdomain_codeset()` returns the currently selected codeset for the domain with the name *domainname*. It returns a null pointer if a codeset has not yet been selected. The `bind_textdomain_codeset()` function can be used multiple times. If used multiple times with the same *domainname* argument, the later call overrides the settings made by the earlier one. The `bind_textdomain_codeset()` function returns a pointer to a string containing the name of the selected codeset. The string is allocated internally in the function and must not be changed by the user.

RETURN VALUES

The `gettext()`, `dgettext()`, and `dcgettext()` functions return the message string if the search succeeds. Otherwise they return the *msgid* string.

The `ngettext()`, `dngettext()`, and `dcngettext()` functions return the message string if the search succeeds. If the search fails, *msgid1* is returned if *n* == 1. Otherwise *msgid2* is returned.

The individual bytes of the string returned by `gettext()`, `dgettext()`, `dcgettext()`, `ngettext()`, `dngettext()`, or `dcngettext()` can contain any value other than NULL. If *msgid* is a null pointer, the return value is undefined. The string returned must not be modified by the program and can be invalidated by a subsequent call to `bind_textdomain_codeset()` or `setlocale(3C)`. If the *domainname* argument to `dgettext()`, `dcgettext()`, `dngettext()`, or `dcngettext()` is a null pointer, the the domain currently bound by `textdomain()` is used.

The normal return value from `textdomain()` is a pointer to a string containing the current setting of the domain. If *domainname* is a null pointer, `textdomain()` returns a pointer to the string containing the current domain. If `textdomain()` was not previously called and *domainname* is a null string, the name of the default domain is returned. The name of the default domain is `messages`. If `textdomain()` fails, a null pointer is returned.

The return value from `bindtextdomain()` is a null-terminated string containing *dirname* or the directory binding associated with *domainname* if *dirname* is NULL. If no binding is found, the default return value is `/usr/lib/locale`. If *domainname* is a null pointer or an empty string, `bindtextdomain()` takes no action and returns a null pointer. The string returned must not be modified by the caller. If `bindtextdomain()` fails, a null pointer is returned.

USAGE These functions impose no limit on message length. However, a text *domainname* is limited to TEXTDOMAINMAX (256) bytes.

The `gettext()`, `dgettext()`, `dcgettext()`, `ngettext()`, `dngettext()`, `dcngettext()`, `textdomain()`, and `bindtextdomain()` functions can be used safely in multithreaded applications, as long as `setlocale(3C)` is not being called to change the locale.

The `gettext()`, `dgettext()`, `dcgettext()`, `textdomain()`, and `bindtextdomain()` functions work with both Solaris message catalogues and GNU-compatible message catalogues. The `ngettext()`, `dngettext()`, `dcngettext()`, and `bind_textdomain_codeset()` functions work only with GNU-compatible message catalogues. See `msgfmt(1)` for information about Solaris message catalogues and GNU-compatible message catalogues.

FILES `/usr/lib/locale`
 default path predicate for message domain files

`/usr/lib/locale/locale/LC_MESSAGES/domainname.mo`
 system default location for file containing messages for language *locale* and *domainname*

`/usr/lib/locale/locale/LC_XXX/domainname.mo`
 system default location for file containing messages for language *locale* and *domainname* for `dcgettext()` calls where `LC_XXX` is `LC_CTYPE`, `LC_NUMERIC`, `LC_TIME`, `LC_COLLATE`, `LC_MONETARY`, or `LC_MESSAGES`

`dirname/locale/LC_MESSAGES/domainname.mo`
 location for file containing messages for domain *domainname* and path predicate *dirname* after a successful call to `bindtextdomain()`

`dirname/locale/LC_XXX/domainname.mo`
 location for files containing messages for domain *domainname*, language *locale*, and path predicate *dirname* after a successful call to `bindtextdomain()` for `dcgettext()` calls where `LC_XXX` is one of `LC_CTYPE`, `LC_NUMERIC`, `LC_TIME`, `LC_COLLATE`, `LC_MONETARY`, or `LC_MESSAGES`

gettimeofday(3C)

NAME	gettimeofday, settimeofday – get or set the date and time						
SYNOPSIS	<pre>#include <sys/time.h> int gettimeofday(struct timeval *tp, void *); int settimeofday(struct timeval *tp, void *);</pre>						
DESCRIPTION	<p>The <code>gettimeofday()</code> function gets and the <code>settimeofday()</code> function sets the system's notion of the current time. The current time is expressed in elapsed seconds and microseconds since 00:00 Universal Coordinated Time, January 1, 1970. The resolution of the system clock is hardware dependent; the time may be updated continuously or in clock ticks.</p> <p>The <i>tp</i> argument points to a <code>timeval</code> structure, which includes the following members:</p> <pre>long tv_sec; /* seconds since Jan. 1, 1970 */ long tv_usec; /* and microseconds */</pre> <p>If <i>tp</i> is a null pointer, the current time information is not returned or set.</p> <p>The TZ environment variable holds time zone information. See <code>TIMEZONE(4)</code>.</p> <p>The second argument to <code>gettimeofday()</code> and <code>settimeofday()</code> is ignored.</p> <p>Only the super-user may set the time of day.</p>						
RETURN VALUES	Upon successful completion, 0 is returned. Otherwise, -1 is returned and <code>errno</code> is set to indicate the error.						
ERRORS	<p>The <code>gettimeofday()</code> function will fail if:</p> <table><tr><td>EINVAL</td><td>The structure pointed to by <i>tp</i> specifies an invalid time.</td></tr><tr><td>EPERM</td><td>A user other than the privileged user attempted to set the time or time zone.</td></tr></table> <p>Additionally, the <code>gettimeofday()</code> function will fail for 32-bit interfaces if:</p> <table><tr><td>E_OVERFLOW</td><td>The system time has progressed beyond 2038, thus the size of the <code>tv_sec</code> member of the <code>timeval</code> structure pointed to by <i>tp</i> is insufficient to hold the current time in seconds.</td></tr></table>	EINVAL	The structure pointed to by <i>tp</i> specifies an invalid time.	EPERM	A user other than the privileged user attempted to set the time or time zone.	E_OVERFLOW	The system time has progressed beyond 2038, thus the size of the <code>tv_sec</code> member of the <code>timeval</code> structure pointed to by <i>tp</i> is insufficient to hold the current time in seconds.
EINVAL	The structure pointed to by <i>tp</i> specifies an invalid time.						
EPERM	A user other than the privileged user attempted to set the time or time zone.						
E_OVERFLOW	The system time has progressed beyond 2038, thus the size of the <code>tv_sec</code> member of the <code>timeval</code> structure pointed to by <i>tp</i> is insufficient to hold the current time in seconds.						
USAGE	If the <code>tv_usec</code> member of <i>tp</i> is > 500000, <code>settimeofday()</code> rounds the seconds upward. If the time needs to be set with better than one second accuracy, call <code>settimeofday()</code> for the seconds and then <code>adjtime(2)</code> for finer accuracy.						
ATTRIBUTES	See <code>attributes(5)</code> for descriptions of the following attributes:						

gettimeofday(3C)

ATTRIBUTE TYPE	ATTRIBUTE VALUE
MT-Level	MT-Safe

SEE ALSO adjtime(2), ctime(3C), TIMEZONE(4), attributes(5)

gettimeofday(3UCB)

NAME	gettimeofday, settimeofday – get or set the date and time
SYNOPSIS	<pre><code>/usr/ucb/cc[flag ...] file ... #include <sys/time.h> int gettimeofday(tp, tzp); struct timeval *tzp; struct timezone *tzp; int settimeofday(tp, tzp); struct timeval *tzp; struct timezone *tzp;</code></pre>
DESCRIPTION	<p>The system's notion of the current Greenwich time is obtained with the <code>gettimeofday()</code> call, and set with the <code>settimeofday()</code> call. The current time is expressed in elapsed seconds and microseconds since 00:00 GMT, January 1, 1970 (zero hour). The resolution of the system clock is hardware dependent; the time may be updated continuously, or in clock ticks.</p> <pre><code>long tv_sec; /* seconds since Jan. 1, 1970 */ long tv_usec; /* and microseconds */</code></pre> <p><i>tp</i> points to a <code>timeval</code> structure, which includes the following members:</p> <p>If <i>tp</i> is a NULL pointer, the current time information is not returned or set.</p> <p><i>tzp</i> is an obsolete pointer formerly used to get and set timezone information. <i>tzp</i> is now ignored. Timezone information is now handled using the TZ environment variable; see <code>TIMEZONE(4)</code>.</p> <p>Only the privileged user may set the time of day.</p>
RETURN VALUES	A -1 return value indicates an error occurred; in this case an error code is stored in the global variable <code>errno</code> .
ERRORS	The following error codes may be set in <code>errno</code> : EINVAL <i>tp</i> specifies an invalid time. EPERM A user other than the privileged user attempted to set the time.
SEE ALSO	<code>adjtime(2)</code> , <code>ctime(3C)</code> , <code>gettimeofday(3C)</code> , <code>TIMEZONE(4)</code>
NOTES	Use of these interfaces should be restricted to only applications written on BSD platforms. Use of these interfaces with any of the system libraries or in multi-thread applications is unsupported. <i>tzp</i> is ignored in SunOS 5.X releases. <code>tv_usec</code> is always 0.

NAME	gettxt – retrieve a text string
SYNOPSIS	<pre>#include <nl_types.h> char *gettxt(const char *msgid, const char *dflt_str);</pre>
DESCRIPTION	<p>The <code>gettxt()</code> function retrieves a text string from a message file. The arguments to the function are a message identification <code>msgid</code> and a default string <code>dflt_str</code> to be used if the retrieval fails.</p> <p>The text strings are in files created by the <code>mkmsgs</code> utility (see <code>mkmsgs(1)</code>) and installed in directories in <code>/usr/lib/locale/locale/LC_MESSAGES</code>.</p> <p>The directory <code>locale</code> can be viewed as the language in which the text strings are written. The user can request that messages be displayed in a specific language by setting the environment variable <code>LC_MESSAGES</code>. If <code>LC_MESSAGES</code> is not set, the environment variable <code>LANG</code> will be used. If <code>LANG</code> is not set, the files containing the strings are in <code>/usr/lib/locale/C/LC_MESSAGES/*</code>.</p> <p>The user can also change the language in which the messages are displayed by invoking the <code>setlocale(3C)</code> function with the appropriate arguments.</p> <p>If <code>gettxt()</code> fails to retrieve a message in a specific language it will try to retrieve the same message in U.S. English. On failure, the processing depends on what the second argument <code>dflt_str</code> points to. A pointer to the second argument is returned if the second argument is not the null string. If <code>dflt_str</code> points to the null string, a pointer to the U.S. English text string "Message not found!!\n" is returned.</p> <p>The following depicts the acceptable syntax of <code>msgid</code> for a call to <code>gettxt()</code>.</p> <pre><msgid> = <msgfilename>:<msgnumber></pre> <p>The first field is used to indicate the file that contains the text strings and must be limited to 14 characters. These characters must be selected from the set of all character values excluding <code>\0</code> (null) and the ASCII code for <code>/</code> (slash) and <code>:</code> (colon). The names of message files must be the same as the names of files created by <code>mkmsgs</code> and installed in <code>/usr/lib/locale/locale/LC_MESSAGES/*</code>. The numeric field indicates the sequence number of the string in the file. The strings are numbered from 1 to <code>n</code> where <code>n</code> is the number of strings in the file.</p>
RETURN VALUES	Upon failure to pass either the correct <code>msgid</code> or a valid message number to <code>gettxt()</code> , a pointer to the text string "Message not found!!\n" is returned.
USAGE	It is recommended that <code>gettext(3C)</code> be used in place of this function.
EXAMPLES	<p>EXAMPLE 1 Example of <code>gettxt()</code> function.</p> <p>In the following example,</p>

gettext(3C)

EXAMPLE 1 Example of gettext () function. (Continued)

```
gettext("UX:10", "hello world\n")
gettext("UX:10", "")
```

UX is the name of the file that contains the messages and 10 is the message number.

FILES /usr/lib/locale/C/LC_MESSAGES/*
contains default message files created by mkmsgs
/usr/lib/locale/locale/LC_MESSAGES/*
contains message files for different languages created by mkmsgs

NAME	getusershell, setusershell, endusershell – get legal user shells																								
SYNOPSIS	<pre>char *getusershell() void setusershell() void endusershell()</pre>																								
DESCRIPTION	<p>The <code>getusershell()</code> function returns a pointer to a legal user shell as defined by the system manager in the file <code>/etc/shells</code>. If <code>/etc/shells</code> does not exist, the following locations of the standard system shells are used in its place:</p> <table border="0"> <tr><td><code>/bin/bash</code></td><td><code>/bin/csh</code></td></tr> <tr><td><code>/bin/jsh</code></td><td><code>/bin/ksh</code></td></tr> <tr><td><code>/bin/pfcsh</code></td><td><code>/bin/pfksh</code></td></tr> <tr><td><code>/bin/pfsh</code></td><td><code>/bin/sh</code></td></tr> <tr><td><code>/bin/tcsh</code></td><td><code>/bin/zsh</code></td></tr> <tr><td><code>/sbin/jsh</code></td><td><code>/sbin/sh</code></td></tr> <tr><td><code>/usr/bin/bash</code></td><td><code>/usr/bin/csh</code></td></tr> <tr><td><code>/usr/bin/jsh</code></td><td><code>/usr/bin/ksh</code></td></tr> <tr><td><code>/usr/bin/pfcsh</code></td><td><code>/usr/bin/pfksh</code></td></tr> <tr><td><code>/usr/bin/pfsh</code></td><td><code>/usr/bin/sh</code></td></tr> <tr><td><code>/usr/bin/tcsh</code></td><td><code>/usr/bin/zsh</code></td></tr> <tr><td><code>/usr/xpg4/bin/sh</code></td><td></td></tr> </table> <p>The <code>getusershell()</code> function opens the file <code>/etc/shells</code>, if it exists, and returns the next entry in the list of shells.</p> <p>The <code>setusershell()</code> function rewinds the file or the list.</p> <p>The <code>endusershell()</code> function closes the file, frees any memory used by <code>getusershell()</code> and <code>setusershell()</code>, and rewinds the file <code>/etc/shells</code>.</p>	<code>/bin/bash</code>	<code>/bin/csh</code>	<code>/bin/jsh</code>	<code>/bin/ksh</code>	<code>/bin/pfcsh</code>	<code>/bin/pfksh</code>	<code>/bin/pfsh</code>	<code>/bin/sh</code>	<code>/bin/tcsh</code>	<code>/bin/zsh</code>	<code>/sbin/jsh</code>	<code>/sbin/sh</code>	<code>/usr/bin/bash</code>	<code>/usr/bin/csh</code>	<code>/usr/bin/jsh</code>	<code>/usr/bin/ksh</code>	<code>/usr/bin/pfcsh</code>	<code>/usr/bin/pfksh</code>	<code>/usr/bin/pfsh</code>	<code>/usr/bin/sh</code>	<code>/usr/bin/tcsh</code>	<code>/usr/bin/zsh</code>	<code>/usr/xpg4/bin/sh</code>	
<code>/bin/bash</code>	<code>/bin/csh</code>																								
<code>/bin/jsh</code>	<code>/bin/ksh</code>																								
<code>/bin/pfcsh</code>	<code>/bin/pfksh</code>																								
<code>/bin/pfsh</code>	<code>/bin/sh</code>																								
<code>/bin/tcsh</code>	<code>/bin/zsh</code>																								
<code>/sbin/jsh</code>	<code>/sbin/sh</code>																								
<code>/usr/bin/bash</code>	<code>/usr/bin/csh</code>																								
<code>/usr/bin/jsh</code>	<code>/usr/bin/ksh</code>																								
<code>/usr/bin/pfcsh</code>	<code>/usr/bin/pfksh</code>																								
<code>/usr/bin/pfsh</code>	<code>/usr/bin/sh</code>																								
<code>/usr/bin/tcsh</code>	<code>/usr/bin/zsh</code>																								
<code>/usr/xpg4/bin/sh</code>																									
RETURN VALUES	The <code>getusershell()</code> function returns a null pointer on EOF.																								
BUGS	All information is contained in memory that may be freed with a call to <code>endusershell()</code> , so it must be copied if it is to be saved.																								

getutent(3C)

NAME	getutent, getutid, getutline, pututline, setutent, endutent, utmpname – user accounting database functions
SYNOPSIS	<pre>#include <utmp.h> struct utmp *getutent(void); struct utmp *getutid(const struct utmp *id); struct utmp *getutline(const struct utmp *line); struct utmp *pututline(const struct utmp *utmp); void setutent(void); void endutent(void); int utmpname(const char *file);</pre>
DESCRIPTION	<p>These functions provide access to the user accounting database, utmp. Entries in the database are described by the definitions and data structures in <utmp.h>.</p> <p>The utmp structure contains the following members:</p> <pre>char ut_user[8]; /* user login name */ char ut_id[4]; /* /sbin/inittab id (usually line #) */ char ut_line[12]; /* device name (console, lnxx) */ short ut_pid; /* process id */ short ut_type; /* type of entry */ struct exit_status ut_exit; /* exit status of a process */ /* marked as DEAD_PROCESS */ time_t ut_time; /* time entry was made */</pre> <p>The structure exit_status includes the following members:</p> <pre>short e_termination; /* termination status */ short e_exit; /* exit status */</pre>
getutent()	The getutent() function reads in the next entry from a utmp database. If the database is not already open, it opens it. If it reaches the end of the database, it fails.
getutid()	The getutid() function searches forward from the current point in the utmp database until it finds an entry with a ut_type matching id->ut_type if the type specified is RUN_LVL, BOOT_TIME, OLD_TIME, or NEW_TIME. If the type specified in id is INIT_PROCESS, LOGIN_PROCESS, USER_PROCESS, or DEAD_PROCESS, then getutid() will return a pointer to the first entry whose type is one of these four and whose ut_id member matches id->ut_id. If the end of database is reached without a match, it fails.
getutline()	The getutline() function searches forward from the current point in the utmp database until it finds an entry of the type LOGIN_PROCESS or ut_line string matching the line->ut_line string. If the end of database is reached without a match, it fails.

`pututline()` The `pututline()` function writes the supplied `utmp` structure into the `utmp` database. It uses `getutid()` to search forward for the proper place if it finds that it is not already at the proper place. It is expected that normally the user of `pututline()` will have searched for the proper entry using one of the these functions. If so, `pututline()` will not search. If `pututline()` does not find a matching slot for the new entry, it will add a new entry to the end of the database. It returns a pointer to the `utmp` structure. When called by a non-root user, `pututline()` invokes a `setuid()` root program to verify and write the entry, since the `utmp` database is normally writable only by root. In this event, the `ut_name` member must correspond to the actual user name associated with the process; the `ut_type` member must be either `USER_PROCESS` or `DEAD_PROCESS`; and the `ut_line` member must be a device special file and be writable by the user.

`setutent()` The `setutent()` function resets the input stream to the beginning. This reset should be done before each search for a new entry if it is desired that the entire database be examined.

`endutent()` The `endutent()` function closes the currently open database.

`utmpname()` The `utmpname()` function allows the user to change the name of the database file examined to another file. If the file does not exist, this will not be apparent until the first attempt to reference the file is made. The `utmpname()` function does not open the file but closes the old file if it is currently open and saves the new file name.

RETURN VALUES A null pointer is returned upon failure to read, whether for permissions or having reached the end of file, or upon failure to write. If the file name given is longer than 79 characters, `utmpname()` returns 0. Otherwise, it returns 1.

USAGE These functions use buffered standard I/O for input, but `pututline()` uses an unbuffered non-standard write to avoid race conditions between processes trying to modify the `utmp` and `wtmp` databases.

Applications should not access the `utmp` and `wtmp` databases directly, but should use these functions to ensure that these databases are maintained consistently. Using these functions, however, may cause applications to fail if user accounting data cannot be represented properly in the `utmp` structure (for example, on a system where PIDs can exceed 32767). Use the functions described on the `getutxent(3C)` manual page instead.

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

getutent(3C)

NOTES | The most current entry is saved in a static structure. Multiple accesses require that it be copied before further accesses are made. On each call to either `getutid()` or `getutline()`, the function examines the static structure before performing more I/O. If the contents of the static structure match what it is searching for, it looks no further. For this reason, to use `getutline()` to search for multiple occurrences, it would be necessary to zero out the static area after each success, or `getutline()` would just return the same structure over and over again. There is one exception to the rule about emptying the structure before further reads are done. The implicit read done by `pututline()` (if it finds that it is not already at the correct place in the file) will not hurt the contents of the static structure returned by the `getutent()`, `getutid()` or `getutline()` functions, if the user has just modified those contents and passed the pointer back to `pututline()`.

NAME	getutent, getutid, getutline, pututline, setutent, endutent, utmpname – user accounting database functions
SYNOPSIS	<pre>#include <utmp.h> struct utmp *getutent(void); struct utmp *getutid(const struct utmp *id); struct utmp *getutline(const struct utmp *line); struct utmp *pututline(const struct utmp *utmp); void setutent(void); void endutent(void); int utmpname(const char *file);</pre>
DESCRIPTION	<p>These functions provide access to the user accounting database, utmp. Entries in the database are described by the definitions and data structures in <utmp.h>.</p> <p>The utmp structure contains the following members:</p> <pre>char ut_user[8]; /* user login name */ char ut_id[4]; /* /sbin/inittab id (usually line #) */ char ut_line[12]; /* device name (console, lnxx) */ short ut_pid; /* process id */ short ut_type; /* type of entry */ struct exit_status ut_exit; /* exit status of a process */ /* marked as DEAD_PROCESS */ time_t ut_time; /* time entry was made */</pre> <p>The structure exit_status includes the following members:</p> <pre>short e_termination; /* termination status */ short e_exit; /* exit status */</pre> <p>getutent() The getutent() function reads in the next entry from a utmp database. If the database is not already open, it opens it. If it reaches the end of the database, it fails.</p> <p>getutid() The getutid() function searches forward from the current point in the utmp database until it finds an entry with a ut_type matching <i>id</i>->ut_type if the type specified is RUN_LVL, BOOT_TIME, OLD_TIME, or NEW_TIME. If the type specified in <i>id</i> is INIT_PROCESS, LOGIN_PROCESS, USER_PROCESS, or DEAD_PROCESS, then getutid() will return a pointer to the first entry whose type is one of these four and whose ut_id member matches <i>id</i>->ut_id. If the end of database is reached without a match, it fails.</p> <p>getutline() The getutline() function searches forward from the current point in the utmp database until it finds an entry of the type LOGIN_PROCESS or ut_line string matching the <i>line</i>->ut_line string. If the end of database is reached without a match, it fails.</p>

getutid(3C)

- `pututline()` | The `pututline()` function writes the supplied `utmp` structure into the `utmp` database. It uses `getutid()` to search forward for the proper place if it finds that it is not already at the proper place. It is expected that normally the user of `pututline()` will have searched for the proper entry using one of the these functions. If so, `pututline()` will not search. If `pututline()` does not find a matching slot for the new entry, it will add a new entry to the end of the database. It returns a pointer to the `utmp` structure. When called by a non-root user, `pututline()` invokes a `setuid()` root program to verify and write the entry, since the `utmp` database is normally writable only by root. In this event, the `ut_name` member must correspond to the actual user name associated with the process; the `ut_type` member must be either `USER_PROCESS` or `DEAD_PROCESS`; and the `ut_line` member must be a device special file and be writable by the user.
- `setutent()` | The `setutent()` function resets the input stream to the beginning. This reset should be done before each search for a new entry if it is desired that the entire database be examined.
- `endutent()` | The `endutent()` function closes the currently open database.
- `utmpname()` | The `utmpname()` function allows the user to change the name of the database file examined to another file. If the file does not exist, this will not be apparent until the first attempt to reference the file is made. The `utmpname()` function does not open the file but closes the old file if it is currently open and saves the new file name.

RETURN VALUES | A null pointer is returned upon failure to read, whether for permissions or having reached the end of file, or upon failure to write. If the file name given is longer than 79 characters, `utmpname()` returns 0. Otherwise, it returns 1.

USAGE | These functions use buffered standard I/O for input, but `pututline()` uses an unbuffered non-standard write to avoid race conditions between processes trying to modify the `utmp` and `wtmp` databases.

Applications should not access the `utmp` and `wtmp` databases directly, but should use these functions to ensure that these databases are maintained consistently. Using these functions, however, may cause applications to fail if user accounting data cannot be represented properly in the `utmp` structure (for example, on a system where PIDs can exceed 32767). Use the functions described on the `getutxent(3C)` manual page instead.

NOTES | The most current entry is saved in a static structure. Multiple accesses require that it be copied before further accesses are made. On each call to either `getutid()` or `getutline()`, the function examines the static structure before performing more I/O. If the contents of the static structure match what it is searching for, it looks no further. For this reason, to use `getutline()` to search for multiple occurrences, it would be necessary to zero out the static area after each success, or `getutline()` would just return the same structure over and over again. There is one exception to the rule about emptying the structure before further reads are done. The implicit read done by `pututline()` (if it finds that it is not already at the correct place in the file) will not hurt the contents of the static structure returned by the `getutent()`, `getutid()` or `getutline()` functions, if the user has just modified those contents and passed the pointer back to `pututline()`.

getutline(3C)

NAME	getutent, getutid, getutline, pututline, setutent, endutent, utmpname – user accounting database functions
SYNOPSIS	<pre>#include <utmp.h> struct utmp *getutent(void); struct utmp *getutid(const struct utmp *id); struct utmp *getutline(const struct utmp *line); struct utmp *pututline(const struct utmp *utmp); void setutent(void); void endutent(void); int utmpname(const char *file);</pre>
DESCRIPTION	<p>These functions provide access to the user accounting database, utmp. Entries in the database are described by the definitions and data structures in <utmp.h>.</p> <p>The utmp structure contains the following members:</p> <pre>char ut_user[8]; /* user login name */ char ut_id[4]; /* /sbin/inittab id (usually line #) */ char ut_line[12]; /* device name (console, lnxx) */ short ut_pid; /* process id */ short ut_type; /* type of entry */ struct exit_status ut_exit; /* exit status of a process */ /* marked as DEAD_PROCESS */ time_t ut_time; /* time entry was made */</pre> <p>The structure exit_status includes the following members:</p> <pre>short e_termination; /* termination status */ short e_exit; /* exit status */</pre>
getutent()	The getutent() function reads in the next entry from a utmp database. If the database is not already open, it opens it. If it reaches the end of the database, it fails.
getutid()	The getutid() function searches forward from the current point in the utmp database until it finds an entry with a ut_type matching id->ut_type if the type specified is RUN_LVL, BOOT_TIME, OLD_TIME, or NEW_TIME. If the type specified in id is INIT_PROCESS, LOGIN_PROCESS, USER_PROCESS, or DEAD_PROCESS, then getutid() will return a pointer to the first entry whose type is one of these four and whose ut_id member matches id->ut_id. If the end of database is reached without a match, it fails.
getutline()	The getutline() function searches forward from the current point in the utmp database until it finds an entry of the type LOGIN_PROCESS or ut_line string matching the line->ut_line string. If the end of database is reached without a match, it fails.

`pututline()` The `pututline()` function writes the supplied `utmp` structure into the `utmp` database. It uses `getutid()` to search forward for the proper place if it finds that it is not already at the proper place. It is expected that normally the user of `pututline()` will have searched for the proper entry using one of the these functions. If so, `pututline()` will not search. If `pututline()` does not find a matching slot for the new entry, it will add a new entry to the end of the database. It returns a pointer to the `utmp` structure. When called by a non-root user, `pututline()` invokes a `setuid()` root program to verify and write the entry, since the `utmp` database is normally writable only by root. In this event, the `ut_name` member must correspond to the actual user name associated with the process; the `ut_type` member must be either `USER_PROCESS` or `DEAD_PROCESS`; and the `ut_line` member must be a device special file and be writable by the user.

`setutent()` The `setutent()` function resets the input stream to the beginning. This reset should be done before each search for a new entry if it is desired that the entire database be examined.

`endutent()` The `endutent()` function closes the currently open database.

`utmpname()` The `utmpname()` function allows the user to change the name of the database file examined to another file. If the file does not exist, this will not be apparent until the first attempt to reference the file is made. The `utmpname()` function does not open the file but closes the old file if it is currently open and saves the new file name.

RETURN VALUES A null pointer is returned upon failure to read, whether for permissions or having reached the end of file, or upon failure to write. If the file name given is longer than 79 characters, `utmpname()` returns 0. Otherwise, it returns 1.

USAGE These functions use buffered standard I/O for input, but `pututline()` uses an unbuffered non-standard write to avoid race conditions between processes trying to modify the `utmp` and `wtmp` databases.

Applications should not access the `utmp` and `wtmp` databases directly, but should use these functions to ensure that these databases are maintained consistently. Using these functions, however, may cause applications to fail if user accounting data cannot be represented properly in the `utmp` structure (for example, on a system where PIDs can exceed 32767). Use the functions described on the `getutxent(3C)` manual page instead.

The implicit read done by `pututline()` (if it finds that it is not already at the correct place in the file) will not hurt the contents of the static structure returned by the `getutent()`, `getutid()` or `getutline()` functions, if the user has just modified those contents and passed the pointer back to `pututline()`.

NAME	getutxent, getutxid, getutxline, pututxline, setutxent, endutxent, utmpxname, getutmp, getutmpx, updwtmp, updwtmpx – user accounting database functions
SYNOPSIS	<pre>#include <utmpx.h> struct utmpx *getutxent(void); struct utmpx *getutxid(const struct utmpx *id); struct utmpx *getutxline(const struct utmpx *line); struct utmpx *pututxline(const struct utmpx *utmpx); void setutxent(void); void endutxent(void); int utmpxname(const char *file); void getutmp(struct utmpx *utmpx, struct utmp *utmp); void getutmpx(struct utmp *utmp, struct utmpx *utmpx); void updwtmp(char *wfile, struct utmp *utmp); void updwtmpx(char *wfile, struct utmpx *utmpx);</pre>
DESCRIPTION	<p>These functions provide access to the user accounting database, utmpx (see utmpx(4)). Entries in the database are described by the definitions and data structures in <utmpx.h>.</p> <p>The utmpx structure contains the following members:</p> <pre>char ut_user[32]; /* user login name */ char ut_id[4]; /* /etc/inittab id (usually line #) */ char ut_line[32]; /* device name (console, lnxx) */ pid_t ut_pid; /* process id */ short ut_type; /* type of entry */ struct exit_status ut_exit; /* exit status of a process */ /* marked as DEAD_PROCESS */ struct timeval ut_tv; /* time entry was made */ int ut_session; /* session ID, used for windowing */ short ut_syslen; /* significant length of ut_host */ /* including terminating null */ char ut_host[257]; /* host name, if remote */</pre> <p>The exit_status structure includes the following members:</p> <pre>short e_termination; /* termination status */ short e_exit; /* exit status */</pre> <p>getutxent() The getutxent() function reads in the next entry from a utmpx database. If the database is not already open, it opens it. If it reaches the end of the database, it fails.</p> <p>getutxid() The getutxid() function searches forward from the current point in the utmpx database until it finds an entry with a ut_type matching id->ut_type, if the type specified is RUN_LVL, BOOT_TIME, OLD_TIME, or NEW_TIME. If the type specified in</p>

getutmp(3C)

	<p><i>id</i> is INIT_PROCESS, LOGIN_PROCESS, USER_PROCESS, or DEAD_PROCESS, then <code>getutxid()</code> will return a pointer to the first entry whose type is one of these four and whose <code>ut_id</code> member matches <i>id</i>-><code>ut_id</code>. If the end of database is reached without a match, it fails.</p>
<code>getutxline()</code>	<p>The <code>getutxline()</code> function searches forward from the current point in the <code>utmpx</code> database until it finds an entry of the type LOGIN_PROCESS or USER_PROCESS which also has a <code>ut_line</code> string matching the <i>line</i>-><code>ut_line</code> string. If the end of the database is reached without a match, it fails.</p>
<code>pututxline()</code>	<p>The <code>pututxline()</code> function writes the supplied <code>utmpx</code> structure into the <code>utmpx</code> database. It uses <code>getutxid()</code> to search forward for the proper place if it finds that it is not already at the proper place. It is expected that normally the user of <code>pututxline()</code> will have searched for the proper entry using one of the <code>getutx()</code> routines. If so, <code>pututxline()</code> will not search. If <code>pututxline()</code> does not find a matching slot for the new entry, it will add a new entry to the end of the database. It returns a pointer to the <code>utmpx</code> structure. When called by a non-root user, <code>pututxline()</code> invokes a <code>setuid()</code> root program to verify and write the entry, since the <code>utmpx</code> database is normally writable only by root. In this event, the <code>ut_name</code> member must correspond to the actual user name associated with the process; the <code>ut_type</code> member must be either USER_PROCESS or DEAD_PROCESS; and the <code>ut_line</code> member must be a device special file and be writable by the user.</p>
<code>setutxent()</code>	<p>The <code>setutxent()</code> function resets the input stream to the beginning. This should be done before each search for a new entry if it is desired that the entire database be examined.</p>
<code>endutxent()</code>	<p>The <code>endutxent()</code> function closes the currently open database.</p>

If the file does not exist, this will not be apparent until the first attempt to reference the file is made. The <code>utmpxname()</code> function does not open the file, but closes the old file if it is currently open and saves the new file name. The new file name must end with the "x" character to allow the name of the corresponding <code>utmp</code> file to be easily obtainable.; otherwise, an error value of 0 is returned. The function returns 1 on success.</p>
<code>getutmp()</code>	<p>The <code>getutmp()</code> function copies the information stored in the members of the <code>utmpx</code> structure to the corresponding members of the <code>utmp</code> structure. If the information in any member of <code>utmpx</code> does not fit in the corresponding <code>utmp</code> member, the data is silently truncated. (See <code>getutent(3C)</code> for <code>utmp</code> structure)</p>
<code>getutmpx()</code>	<p>The <code>getutmpx()</code> function copies the information stored in the members of the <code>utmp</code> structure to the corresponding members of the <code>utmpx</code> structure. (See <code>getutent(3C)</code> for <code>utmp</code> structure)</p>
<code>updwtmp()</code>	<p>The <code>updwtmp()</code> function can be used in two ways.</p>

If *wfile* is `/var/adm/wtmp`, the `utmp` format record supplied by the caller is converted to a `utmpx` format record and the `/var/adm/wtmpx` file is updated (because the `/var/adm/wtmp` file no longer exists, operations on `wtmp` are converted to operations on `wtmpx` by the library functions).

If *wfile* is a file other than `/var/adm/wtmp`, it is assumed to be an old file in `utmp` format and is updated directly with the `utmp` format record supplied by the caller.

`updwtmpx()` The `updwtmpx()` function writes the contents of the `utmpx` structure pointed to by *utmpx* to the database.

utmpx structure The values of the `e_termination` and `e_exit` members of the `ut_exit` structure are valid only for records of type `DEAD_PROCESS`. For `utmpx` entries created by `init(1M)`, these values are set according to the result of the `wait()` call that `init` performs on the process when the process exits. See the `wait(2)` manual page for the values `init` uses. Applications creating `utmpx` entries can set `ut_exit` values using the following code example:

```
u->ut_exit.e_termination = WTERMSIG(process->p_exit)
u->ut_exit.e_exit = WEXITSTATUS(process->p_exit)
```

See `wstat(3XFN)` for descriptions of the `WTERMSIG` and `WEXITSTATUS` macros.

The `ut_session` member is not acted upon by the operating system. It is used by applications interested in creating `utmpx` entries.

For records of type `USER_PROCESS`, the `nonuser()` and `nonuserx()` macros use the value of the `ut_exit.e_exit` member to mark `utmpx` entries as real logins (as opposed to multiple `xterms` started by the same user on a window system). This allows the system utilities that display users to obtain an accurate indication of the number of actual users, while still permitting each `pty` to have a `utmpx` record (as most applications expect.). The `NONROOT_USER` macro defines the value that `login` places in the `ut_exit.e_exit` member.

RETURN VALUES Upon successful completion, `getutxent()`, `getutxid()`, and `getutxline()` each return a pointer to a `utmpx` structure containing a copy of the requested entry in the user accounting database. Otherwise a null pointer is returned.

The return value may point to a static area which is overwritten by a subsequent call to `getutxid()` or `getutxline()`.

Upon successful completion, `pututxline()` returns a pointer to a `utmpx` structure containing a copy of the entry added to the user accounting database. Otherwise a null pointer is returned.

The `endutxent()` and `setutxent()` functions return no value.

A null pointer is returned upon failure to read, whether for permissions or having reached the end of file, or upon failure to write.

getutmp(3C)

USAGE These functions use buffered standard I/O for input, but `pututxline()` uses an unbuffered write to avoid race conditions between processes trying to modify the `utmpx` and `wtmpx` files.

Applications should not access the `utmpx` and `wtmpx` databases directly, but should use these functions to ensure that these databases are maintained consistently.

FILES

<code>/var/adm/utmpx</code>	user access and accounting information
<code>/var/adm/wtmpx</code>	history of user access and accounting information

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

If the type specified in</p>

getutmpx(3C)

	<p><i>id</i> is INIT_PROCESS, LOGIN_PROCESS, USER_PROCESS, or DEAD_PROCESS, then getutxid() will return a pointer to the first entry whose type is one of these four and whose ut_id member matches <i>id</i>->ut_id. If the end of database is reached without a match, it fails.</p>
getutxline()	<p>The getutxline() function searches forward from the current point in the utmpx database until it finds an entry of the type LOGIN_PROCESS or USER_PROCESS which also has a ut_line string matching the <i>line</i>->ut_line string. If the end of the database is reached without a match, it fails.</p>
pututxline()	<p>The pututxline() function writes the supplied utmpx structure into the utmpx database. It uses getutxid() to search forward for the proper place if it finds that it is not already at the proper place. It is expected that normally the user of pututxline() will have searched for the proper entry using one of the getutx() routines. If so, pututxline() will not search. If pututxline() does not find a matching slot for the new entry, it will add a new entry to the end of the database. It returns a pointer to the utmpx structure. When called by a non-root user, pututxline() invokes a setuid() root program to verify and write the entry, since the utmpx database is normally writable only by root. In this event, the ut_name member must correspond to the actual user name associated with the process; the ut_type member must be either USER_PROCESS or DEAD_PROCESS; and the ut_line member must be a device special file and be writable by the user.</p>
setutxent()	<p>The setutxent() function resets the input stream to the beginning. This should be done before each search for a new entry if it is desired that the entire database be examined.</p>
endutxent()	<p>The endutxent() function closes the currently open database.</p>
utmpxname()	<p>The utmpxname() function allows the user to change the name of the database file examined from /var/adm/utmpx to any other file, most often /var/adm/wtmpx. If the file does not exist, this will not be apparent until the first attempt to reference the file is made. The utmpxname() function does not open the file, but closes the old file if it is currently open and saves the new file name. The new file name must end with the "x" character to allow the name of the corresponding utmp file to be easily obtainable.; otherwise, an error value of 0 is returned. The function returns 1 on success.</p>
getutmp()	<p>The getutmp() function copies the information stored in the members of the utmpx structure to the corresponding members of the utmp structure. If the information in any member of utmpx does not fit in the corresponding utmp member, the data is silently truncated. (See getutent(3C) for utmp structure)</p>
getutmpx()	<p>The getutmpx() function copies the information stored in the members of the utmp structure to the corresponding members of the utmpx structure. (See getutent(3C) for utmp structure)</p>
updwtmp()	<p>The updwtmp() function can be used in two ways.</p>

If *wfile* is `/var/adm/wtmp`, the `utmp` format record supplied by the caller is converted to a `utmpx` format record and the `/var/adm/wtmpx` file is updated (because the `/var/adm/wtmp` file no longer exists, operations on `wtmp` are converted to operations on `wtmpx` by the library functions).

If *wfile* is a file other than `/var/adm/wtmp`, it is assumed to be an old file in `utmp` format and is updated directly with the `utmp` format record supplied by the caller.

`updwtmpx()` The `updwtmpx()` function writes the contents of the `utmpx` structure pointed to by *utmpx* to the database.

utmpx structure The values of the `e_termination` and `e_exit` members of the `ut_exit` structure are valid only for records of type `DEAD_PROCESS`. For `utmpx` entries created by `init(1M)`, these values are set according to the result of the `wait()` call that `init` performs on the process when the process exits. See the `wait(2)` manual page for the values `init` uses. Applications creating `utmpx` entries can set `ut_exit` values using the following code example:

```
u->ut_exit.e_termination = WTERMSIG(process->p_exit)
u->ut_exit.e_exit = WEXITSTATUS(process->p_exit)
```

See `wstat(3XFN)` for descriptions of the `WTERMSIG` and `WEXITSTATUS` macros.

The `ut_session` member is not acted upon by the operating system. It is used by applications interested in creating `utmpx` entries.

For records of type `USER_PROCESS`, the `nonuser()` and `nonuserx()` macros use the value of the `ut_exit.e_exit` member to mark `utmpx` entries as real logins (as opposed to multiple `xterms` started by the same user on a window system). This allows the system utilities that display users to obtain an accurate indication of the number of actual users, while still permitting each `pty` to have a `utmpx` record (as most applications expect.). The `NONROOT_USER` macro defines the value that `login` places in the `ut_exit.e_exit` member.

RETURN VALUES Upon successful completion, `getutxent()`, `getutxid()`, and `getutxline()` each return a pointer to a `utmpx` structure containing a copy of the requested entry in the user accounting database. Otherwise a null pointer is returned.

The return value may point to a static area which is overwritten by a subsequent call to `getutxid()` or `getutxline()`.

Upon successful completion, `pututxline()` returns a pointer to a `utmpx` structure containing a copy of the entry added to the user accounting database. Otherwise a null pointer is returned.

The `endutxent()` and `setutxent()` functions return no value.

A null pointer is returned upon failure to read, whether for permissions or having reached the end of file, or upon failure to write.

getutmpx(3C)

USAGE These functions use buffered standard I/O for input, but `pututxline()` uses an unbuffered write to avoid race conditions between processes trying to modify the `utmpx` and `wtmpx` files.

Applications should not access the `utmpx` and `wtmpx` databases directly, but should use these functions to ensure that these databases are maintained consistently.

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
MT-Level	Unsafe

SEE ALSO `wait(2)`, `getutent(3C)`, `ttyslot(3C)`, `utmpx(4)`, `attributes(5)`, `wstat(3XFN)`

NOTES The most current entry is saved in a static structure. Multiple accesses require that it be copied before further accesses are made. On each call to either `getutxid()` or `getutxline()`, the routine examines the static structure before performing more I/O. If the contents of the static structure match what it is searching for, it looks no further. For this reason, to use `getutxline()` to search for multiple occurrences it would be necessary to zero out the static after each success, or `getutxline()` would just return the same structure over and over again. There is one exception to the rule about emptying the structure before further reads are done. The implicit read done by `pututxline()` (if it finds that it is not already at the correct place in the file) will not hurt the contents of the static structure returned by the `getutxent()`, `getutxid()`, or `getutxline()` routines, if the user has just modified those contents and passed the pointer back to `pututxline()`.

NAME	getutxent, getutxid, getutxline, pututxline, setutxent, endutxent, utmpxname, getutmp, getutmpx, updwtmp, updwtmpx – user accounting database functions
SYNOPSIS	<pre>#include <utmpx.h> struct utmpx *getutxent (void); struct utmpx *getutxid (const struct utmpx *id); struct utmpx *getutxline (const struct utmpx *line); struct utmpx *pututxline (const struct utmpx *utmpx); void setutxent (void); void endutxent (void); int utmpxname (const char *file); void getutmp (struct utmpx *utmpx, struct utmp *utmp); void getutmpx (struct utmp *utmp, struct utmpx *utmpx); void updwtmp (char *wfile, struct utmp *utmp); void updwtmpx (char *wfile, struct utmpx *utmpx);</pre>
DESCRIPTION	<p>These functions provide access to the user accounting database, utmpx (see utmpx(4)). Entries in the database are described by the definitions and data structures in <utmpx.h>.</p> <p>The utmpx structure contains the following members:</p> <pre>char ut_user[32]; /* user login name */ char ut_id[4]; /* /etc/inittab id (usually line #) */ char ut_line[32]; /* device name (console, lnxx) */ pid_t ut_pid; /* process id */ short ut_type; /* type of entry */ struct exit_status ut_exit; /* exit status of a process */ /* marked as DEAD_PROCESS */ struct timeval ut_tv; /* time entry was made */ int ut_session; /* session ID, used for windowing */ short ut_syslen; /* significant length of ut_host */ /* including terminating null */ char ut_host[257]; /* host name, if remote */</pre> <p>The exit_status structure includes the following members:</p> <pre>short e_termination; /* termination status */ short e_exit; /* exit status */</pre> <p>getutxent () The getutxent () function reads in the next entry from a utmpx database. If the database is not already open, it opens it. If it reaches the end of the database, it fails.</p> <p>getutxid () The getutxid () function searches forward from the current point in the utmpx database until it finds an entry with a ut_type matching id->ut_type, if the type specified is RUN_LVL, BOOT_TIME, OLD_TIME, or NEW_TIME. If the type specified in</p>

getutxent(3C)

	<p><i>id</i> is INIT_PROCESS, LOGIN_PROCESS, USER_PROCESS, or DEAD_PROCESS, then getutxid() will return a pointer to the first entry whose type is one of these four and whose ut_id member matches <i>id</i>->ut_id. If the end of database is reached without a match, it fails.</p>
getutxline()	<p>The getutxline() function searches forward from the current point in the utmpx database until it finds an entry of the type LOGIN_PROCESS or USER_PROCESS which also has a ut_line string matching the <i>line</i>->ut_line string. If the end of the database is reached without a match, it fails.</p>
pututxline()	<p>The pututxline() function writes the supplied utmpx structure into the utmpx database. It uses getutxid() to search forward for the proper place if it finds that it is not already at the proper place. It is expected that normally the user of pututxline() will have searched for the proper entry using one of the getutx() routines. If so, pututxline() will not search. If pututxline() does not find a matching slot for the new entry, it will add a new entry to the end of the database. It returns a pointer to the utmpx structure. When called by a non-root user, pututxline() invokes a setuid() root program to verify and write the entry, since the utmpx database is normally writable only by root. In this event, the ut_name member must correspond to the actual user name associated with the process; the ut_type member must be either USER_PROCESS or DEAD_PROCESS; and the ut_line member must be a device special file and be writable by the user.</p>
setutxent()	<p>The setutxent() function resets the input stream to the beginning. This should be done before each search for a new entry if it is desired that the entire database be examined.</p>
endutxent()	<p>The endutxent() function closes the currently open database.</p>
utmpxname()	<p>The utmpxname() function allows the user to change the name of the database file examined from /var/adm/utmpx to any other file, most often /var/adm/wtmpx. If the file does not exist, this will not be apparent until the first attempt to reference the file is made. The utmpxname() function does not open the file, but closes the old file if it is currently open and saves the new file name. The new file name must end with the "x" character to allow the name of the corresponding utmp file to be easily obtainable.; otherwise, an error value of 0 is returned. The function returns 1 on success.</p>
getutmp()	<p>The getutmp() function copies the information stored in the members of the utmpx structure to the corresponding members of the utmp structure. If the information in any member of utmpx does not fit in the corresponding utmp member, the data is silently truncated. (See getutent(3C) for utmp structure)</p>
getutmpx()	<p>The getutmpx() function copies the information stored in the members of the utmp structure to the corresponding members of the utmpx structure. (See getutent(3C) for utmp structure)</p>
updwtmp()	<p>The updwtmp() function can be used in two ways.</p>

If *wfile* is `/var/adm/wtmp`, the `utmp` format record supplied by the caller is converted to a `utmpx` format record and the `/var/adm/wtmpx` file is updated (because the `/var/adm/wtmp` file no longer exists, operations on `wtmp` are converted to operations on `wtmpx` by the library functions).

If *wfile* is a file other than `/var/adm/wtmp`, it is assumed to be an old file in `utmp` format and is updated directly with the `utmp` format record supplied by the caller.

`updwtmpx()` The `updwtmpx()` function writes the contents of the `utmpx` structure pointed to by *utmpx* to the database.

utmpx structure The values of the `e_termination` and `e_exit` members of the `ut_exit` structure are valid only for records of type `DEAD_PROCESS`. For `utmpx` entries created by `init(1M)`, these values are set according to the result of the `wait()` call that `init` performs on the process when the process exits. See the `wait(2)` manual page for the values `init` uses. Applications creating `utmpx` entries can set `ut_exit` values using the following code example:

```
u->ut_exit.e_termination = WTERMSIG(process->p_exit)
u->ut_exit.e_exit = WEXITSTATUS(process->p_exit)
```

See `wstat(3XFN)` for descriptions of the `WTERMSIG` and `WEXITSTATUS` macros.

The `ut_session` member is not acted upon by the operating system. It is used by applications interested in creating `utmpx` entries.

For records of type `USER_PROCESS`, the `nonuser()` and `nonuserx()` macros use the value of the `ut_exit.e_exit` member to mark `utmpx` entries as real logins (as opposed to multiple `xterms` started by the same user on a window system). This allows the system utilities that display users to obtain an accurate indication of the number of actual users, while still permitting each `pty` to have a `utmpx` record (as most applications expect.). The `NONROOT_USER` macro defines the value that `login` places in the `ut_exit.e_exit` member.

RETURN VALUES Upon successful completion, `getutxent()`, `getutxid()`, and `getutxline()` each return a pointer to a `utmpx` structure containing a copy of the requested entry in the user accounting database. Otherwise a null pointer is returned.

The return value may point to a static area which is overwritten by a subsequent call to `getutxid()` or `getutxline()`.

Upon successful completion, `pututxline()` returns a pointer to a `utmpx` structure containing a copy of the entry added to the user accounting database. Otherwise a null pointer is returned.

The `endutxent()` and `setutxent()` functions return no value.

A null pointer is returned upon failure to read, whether for permissions or having reached the end of file, or upon failure to write.

getutxent(3C)

USAGE These functions use buffered standard I/O for input, but `pututxline()` uses an unbuffered write to avoid race conditions between processes trying to modify the `utmpx` and `wtmpx` files.

Applications should not access the `utmpx` and `wtmpx` databases directly, but should use these functions to ensure that these databases are maintained consistently.

endutxent()	<p>The endutxent() function closes the currently open database.</p>
utmpxname()	<p>The utmpxname() function allows the user to change the name of the database file examined from /var/adm/utmpx to any other file, most often /var/adm/wtmpx. If the file does not exist, this will not be apparent until the first attempt to reference the file is made. The utmpxname() function does not open the file, but closes the old file if it is currently open and saves the new file name. The new file name must end with the "x" character to allow the name of the corresponding utmp file to be easily obtainable.; otherwise, an error value of 0 is returned. The function returns 1 on success.</p>
getutmp()	<p>The getutmp() function copies the information stored in the members of the utmpx structure to the corresponding members of the utmp structure. If the information in any member of utmpx does not fit in the corresponding utmp member, the data is silently truncated. (See getutent(3C) for utmp structure)</p>
getutmpx()	<p>The getutmpx() function copies the information stored in the members of the utmp structure to the corresponding members of the utmpx structure. (See getutent(3C) for utmp structure)</p>
updwtmp()	<p>The updwtmp() function can be used in two ways.</p>

If *wfile* is `/var/adm/wtmp`, the `utmp` format record supplied by the caller is converted to a `utmpx` format record and the `/var/adm/wtmpx` file is updated (because the `/var/adm/wtmp` file no longer exists, operations on `wtmp` are converted to operations on `wtmpx` by the library functions).

If *wfile* is a file other than `/var/adm/wtmp`, it is assumed to be an old file in `utmp` format and is updated directly with the `utmp` format record supplied by the caller.

`updwtmpx()` The `updwtmpx()` function writes the contents of the `utmpx` structure pointed to by *utmpx* to the database.

utmpx structure The values of the `e_termination` and `e_exit` members of the `ut_exit` structure are valid only for records of type `DEAD_PROCESS`. For `utmpx` entries created by `init(1M)`, these values are set according to the result of the `wait()` call that `init` performs on the process when the process exits. See the `wait(2)` manual page for the values `init` uses. Applications creating `utmpx` entries can set `ut_exit` values using the following code example:

```
u->ut_exit.e_termination = WTERMSIG(process->p_exit)
u->ut_exit.e_exit = WEXITSTATUS(process->p_exit)
```

See `wstat(3XFN)` for descriptions of the `WTERMSIG` and `WEXITSTATUS` macros.

The `ut_session` member is not acted upon by the operating system. It is used by applications interested in creating `utmpx` entries.

For records of type `USER_PROCESS`, the `nonuser()` and `nonuserx()` macros use the value of the `ut_exit.e_exit` member to mark `utmpx` entries as real logins (as opposed to multiple `xterms` started by the same user on a window system). This allows the system utilities that display users to obtain an accurate indication of the number of actual users, while still permitting each `pty` to have a `utmpx` record (as most applications expect.). The `NONROOT_USER` macro defines the value that `login` places in the `ut_exit.e_exit` member.

RETURN VALUES Upon successful completion, `getutxent()`, `getutxid()`, and `getutxline()` each return a pointer to a `utmpx` structure containing a copy of the requested entry in the user accounting database. Otherwise a null pointer is returned.

The return value may point to a static area which is overwritten by a subsequent call to `getutxid()` or `getutxline()`.

Upon successful completion, `pututxline()` returns a pointer to a `utmpx` structure containing a copy of the entry added to the user accounting database. Otherwise a null pointer is returned.

The `endutxent()` and `setutxent()` functions return no value.

A null pointer is returned upon failure to read, whether for permissions or having reached the end of file, or upon failure to write.

getutxline(3C)

USAGE These functions use buffered standard I/O for input, but `pututxline()` uses an unbuffered write to avoid race conditions between processes trying to modify the `utmpx` and `wtmpx` files.

Applications should not access the `utmpx` and `wtmpx` databases directly, but should use these functions to ensure that these databases are maintained consistently.

FILES

<code>/var/adm/utmpx</code>	user access and accounting information
<code>/var/adm/wtmpx</code>	history of user access and accounting information

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
MT-Level	Unsafe

SEE ALSO `wait(2)`, `getutent(3C)`, `ttyslot(3C)`, `utmpx(4)`, `attributes(5)`, `wstat(3XFN)`

NOTES The most current entry is saved in a static structure. Multiple accesses require that it be copied before further accesses are made. On each call to either `getutxid()` or `getutxline()`, the routine examines the static structure before performing more I/O. If the contents of the static structure match what it is searching for, it looks no further. For this reason, to use `getutxline()` to search for multiple occurrences it would be necessary to zero out the static after each success, or `getutxline()` would just return the same structure over and over again. There is one exception to the rule about emptying the structure before further reads are done. The implicit read done by `pututxline()` (if it finds that it is not already at the correct place in the file) will not hurt the contents of the static structure returned by the `getutxent()`, `getutxid()`, or `getutxline()` routines, if the user has just modified those contents and passed the pointer back to `pututxline()`.

NAME	getvfsent, getvfsfile, getvfsspec, getvfsany – get vfstab file entry						
SYNOPSIS	<pre>#include <stdio.h> #include <sys/vfstab.h> int getvfsent(FILE *fp, struct vfstab *vp); int getvfsfile(FILE *fp, struct vfstab *vp, char *file); int getvfsspec(FILE *, struct vfstab *vp, char *spec); int getvfsany(FILE *, struct vfstab *vp, struct vfstab *vref);</pre>						
DESCRIPTION	<p>The <code>getvfsent()</code>, <code>getvfsfile()</code>, <code>getvfsspec()</code>, and <code>getvfsany()</code> functions each fill in the structure pointed to by <code>vp</code> with the broken-out fields of a line in the <code>/etc/vfstab</code> file. Each line in the file contains a <code>vfstab</code> structure, declared in the <code><sys/vfstab.h></code> header, whose following members are described on the <code>vfstab(4)</code> manual page:</p> <pre>char *vfs_special; char *vfs_fsckdev; char *vfs_mountp; char *vfs_fstype; char *vfs_fsckpass; char *vfs_automnt; char *vfs_mntopts;</pre> <p>The <code>getvfsent()</code> function returns a pointer to the next <code>vfstab</code> structure in the file; so successive calls can be used to search the entire file.</p> <p>The <code>getvfsfile()</code> function searches the file referenced by <code>fp</code> until a mount point matching file is found and fills <code>vp</code> with the fields from the line in the file.</p> <p>The <code>getvfsspec()</code> function searches the file referenced by <code>fp</code> until a special device matching <code>spec</code> is found and fills <code>vp</code> with the fields from the line in the file. The <code>spec</code> argument will try to match on device type (block or character special) and major and minor device numbers. If it cannot match in this manner, then it compares the strings.</p> <p>The <code>getvfsany()</code> function searches the file referenced by <code>fp</code> until a match is found between a line in the file and <code>vref</code>. A match occurs if all non-null entries in <code>vref</code> match the corresponding fields in the file.</p> <p>Note that these functions do not open, close, or rewind the file.</p>						
RETURN VALUES	<p>If the next entry is successfully read by <code>getvfsent()</code> or a match is found with <code>getvfsfile()</code>, <code>getvfsspec()</code>, or <code>getvfsany()</code>, 0 is returned. If an end-of-file is encountered on reading, these functions return -1. If an error is encountered, a value greater than 0 is returned. The possible error values are:</p> <table border="0"> <tr> <td style="padding-right: 20px;"><code>VFS_TOOLONG</code></td> <td>A line in the file exceeded the internal buffer size of <code>VFS_LINE_MAX</code>.</td> </tr> <tr> <td><code>VFS_TOOMANY</code></td> <td>A line in the file contains too many fields.</td> </tr> <tr> <td><code>VFS_TOOFEW</code></td> <td>A line in the file contains too few fields.</td> </tr> </table>	<code>VFS_TOOLONG</code>	A line in the file exceeded the internal buffer size of <code>VFS_LINE_MAX</code> .	<code>VFS_TOOMANY</code>	A line in the file contains too many fields.	<code>VFS_TOOFEW</code>	A line in the file contains too few fields.
<code>VFS_TOOLONG</code>	A line in the file exceeded the internal buffer size of <code>VFS_LINE_MAX</code> .						
<code>VFS_TOOMANY</code>	A line in the file contains too many fields.						
<code>VFS_TOOFEW</code>	A line in the file contains too few fields.

<code>VFS_TOOLONG</code>	A line in the file exceeded the internal buffer size of <code>VFS_LINE_MAX</code> .						
<code>VFS_TOOMANY</code>	A line in the file contains too many fields.						
<code>VFS_TOOFEW</code>	A line in the file contains too few fields.						

getvfsspec(3C)

FILES /etc/vfstab

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
MT-Level	Safe

SEE ALSO `vfstab(4)`, `attributes(5)`

NOTES The members of the `vfstab` structure point to information contained in a static area, so it must be copied if it is to be saved.

NAME	fgetc, getc, getc_unlocked, getchar, getchar_unlocked, getw – get a byte from a stream
SYNOPSIS	<pre>#include <stdio.h> int fgetc(FILE *stream); int getc(FILE *stream); int getc_unlocked(FILE *stream); int getchar(void); int getchar_unlocked(void); int getw(FILE *stream);</pre>
DESCRIPTION	<p>The <code>fgetc()</code> function obtains the next byte (if present) as an unsigned char converted to an int, from the input stream pointed to by <i>stream</i>, and advances the associated file position indicator for the stream (if defined).</p> <p>The <code>fgetc()</code> function may mark the <code>st_atime</code> field of the file associated with <i>stream</i> for update. The <code>st_atime</code> field will be marked for update by the first successful execution of <code>fgetc()</code>, <code>fgets(3C)</code>, <code>fgetwc(3C)</code>, <code>fgetws(3C)</code>, <code>fread(3C)</code>, <code>fscanf(3C)</code>, <code>getc()</code>, <code>getchar()</code>, <code>gets(3C)</code> or <code>scanf(3C)</code> using <i>stream</i> that returns data not supplied by a prior call to <code>ungetc(3C)</code> or <code>ungetwc(3C)</code>.</p> <p>The <code>getc()</code> routine is functionally identical to <code>fgetc()</code>, except that it is implemented as a macro. It runs faster than <code>fgetc()</code>, but it takes up more space per invocation and its name cannot be passed as an argument to a function call.</p> <p>The <code>getchar()</code> routine is equivalent to <code>getc(stdin)</code>. It is implemented as a macro.</p> <p>The <code>getc_unlocked()</code> and <code>getchar_unlocked()</code> routines are variants of <code>getc()</code> and <code>getchar()</code>, respectively, that do not lock the stream. It is the caller's responsibility to acquire the stream lock before calling these routines and releasing the lock afterwards; see <code>flockfile(3C)</code> and <code>stdio(3C)</code>. These routines are implemented as macros.</p> <p>The <code>getw()</code> function reads the next word from the <i>stream</i>. The size of a word is the size of an int and may vary from environment to environment. The <code>getw()</code> function presumes no special alignment in the file.</p> <p>The <code>getw()</code> function may mark the <code>st_atime</code> field of the file associated with <i>stream</i> for update. The <code>st_atime</code> field will be marked for update by the first successful execution of <code>fgetc()</code>, <code>fgets(3C)</code>, <code>fread(3C)</code>, <code>getc()</code>, <code>getchar()</code>, <code>gets(3C)</code>, <code>fscanf(3C)</code> or <code>scanf(3C)</code> using <i>stream</i> that returns data not supplied by a prior call to <code>ungetc(3C)</code>.</p>
RETURN VALUES	<p>Upon successful completion, <code>fgetc()</code>, <code>getc()</code>, <code>getc_unlocked()</code>, <code>getchar()</code>, <code>getchar_unlocked()</code>, and <code>getw()</code> return the next byte from the input stream pointed to by <i>stream</i>. If the stream is at end-of-file, the end-of-file indicator for the stream is set and these functions return EOF. If a read error occurs, the error indicator for the stream is set, EOF is returned, and <code>errno</code> is set to indicate the error.</p>

getw(3C)

ERRORS	The <code>fgetc()</code> , <code>getc()</code> , <code>getc_unlocked()</code> , <code>getchar()</code> , <code>getchar_unlocked()</code> , and <code>getw()</code> functions will fail if data needs to be read and:	
	EAGAIN	The <code>O_NONBLOCK</code> flag is set for the file descriptor underlying <i>stream</i> and the process would be delayed in the <code>fgetc()</code> operation.
	EBADF	The file descriptor underlying <i>stream</i> is not a valid file descriptor open for reading.
	EINTR	The read operation was terminated due to the receipt of a signal, and no data was transferred.
	EIO	A physical I/O error has occurred, or the process is in a background process group attempting to read from its controlling terminal, and either the process is ignoring or blocking the <code>SIGTTIN</code> signal or the process group is orphaned. This error may also be generated for implementation-dependent reasons.
	EOVERFLOW	The file is a regular file and an attempt was made to read at or beyond the offset maximum associated with the corresponding stream.
	The <code>fgetc()</code> , <code>getc()</code> , <code>getc_unlocked()</code> , <code>getchar()</code> , <code>getchar_unlocked()</code> , and <code>getw()</code> functions may fail if:	
	ENOMEM	Insufficient storage space is available.
	ENXIO	A request was made of a non-existent device, or the request was outside the capabilities of the device.
USAGE	If the integer value returned by <code>fgetc()</code> , <code>getc()</code> , <code>getc_unlocked()</code> , <code>getchar()</code> , <code>getchar_unlocked()</code> , and <code>getw()</code> is stored into a variable of type <code>char</code> and then compared against the integer constant <code>EOF</code> , the comparison may never succeed, because sign-extension of a variable of type <code>char</code> on widening to integer is implementation-dependent.	
	The <code>ferror(3C)</code> or <code>feof(3C)</code> functions must be used to distinguish between an error condition and an end-of-file condition.	
	Functions exist for the <code>getc()</code> , <code>getc_unlocked()</code> , <code>getchar()</code> , and <code>getchar_unlocked()</code> macros. To get the function form, the macro name must be undefined (for example, <code>#undef getc</code>).	
	When the macro forms are used, <code>getc()</code> and <code>getc_unlocked()</code> evaluate the <i>stream</i> argument more than once. In particular, <code>getc(*f++)</code> ; does not work sensibly. The <code>fgetc()</code> function should be used instead when evaluating the <i>stream</i> argument has side effects.	
	Because of possible differences in word length and byte ordering, files written using <code>getw()</code> are machine-dependent, and may not be read using <code>getw()</code> on a different processor.	

getw(3C)

The `getw()` function is inherently byte stream-oriented and is not tenable in the context of either multibyte character streams or wide-character streams. Application programmers are recommended to use one of the character-based input functions instead.

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
MT-Level	See NOTES below.

SEE ALSO `intro(3)`, `fclose(3C)`, `feof(3C)`, `fgets(3C)`, `fgetwc(3C)`, `fgetws(3C)`, `flockfile(3C)`, `fopen(3C)`, `fread(3C)`, `fscanf(3C)`, `gets(3C)`, `putc(3C)`, `scanf(3C)`, `stdio(3C)`, `ungetc(3C)`, `ungetwc(3C)`, `attributes(5)`

NOTES The `fgetc()`, `getc()`, `getchar()`, and `getw()` routines are MT-Safe in multithreaded applications. The `getc_unlocked()` and `getchar_unlocked()` routines are unsafe in multithreaded applications.

getwc(3C)

NAME	getwc – get wide character from a stream				
SYNOPSIS	<pre>#include <stdio.h> #include <wchar.h> wint_t getwc(FILE *stream) ;</pre>				
DESCRIPTION	The <code>getwc()</code> function is equivalent to <code>fgetwc(3C)</code> , except that if it is implemented as a macro it may evaluate <i>stream</i> more than once, so the argument should never be an expression with side effects.				
RETURN VALUES	Refer to <code>fgetwc(3C)</code> .				
ERRORS	Refer to <code>fgetwc(3C)</code> .				
USAGE	<p>This interface is provided to align with some current implementations and with possible future ISO standards.</p> <p>Because it may be implemented as a macro, <code>getwc()</code> may treat incorrectly a <i>stream</i> argument with side effects. In particular, <code>getwc(*f++)</code> may not work as expected. Therefore, use of this function is not recommended; <code>fgetwc(3C)</code> should be used instead.</p>				
ATTRIBUTES	See <code>attributes(5)</code> for descriptions of the following attributes:				
	<table border="1"><thead><tr><th>ATTRIBUTE TYPE</th><th>ATTRIBUTE VALUE</th></tr></thead><tbody><tr><td>MT-Level</td><td>MT-Safe</td></tr></tbody></table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	MT-Level	MT-Safe
ATTRIBUTE TYPE	ATTRIBUTE VALUE				
MT-Level	MT-Safe				
SEE ALSO	<code>fgetwc(3C)</code> , <code>attributes(5)</code>				

NAME	getwchar – get wide character from stdin stream				
SYNOPSIS	#include <wchar.h> wint_t getwchar (void);				
DESCRIPTION	The getwchar() function is equivalent to getwc(stdin).				
RETURN VALUES	Refer to fgetwc(3C).				
ERRORS	Refer to fgetwc(3C).				
USAGE	If the wint_t value returned by getwchar() is stored into a variable of type wchar_t and then compared against the wint_t macro WEOF, the comparison may never succeed because wchar_t is defined as unsigned.				
ATTRIBUTES	See attributes(5) for descriptions of the following attributes:				
	<table border="1"> <thead> <tr> <th>ATTRIBUTE TYPE</th> <th>ATTRIBUTE VALUE</th> </tr> </thead> <tbody> <tr> <td>MT-Level</td> <td>MT-Safe</td> </tr> </tbody> </table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	MT-Level	MT-Safe
ATTRIBUTE TYPE	ATTRIBUTE VALUE				
MT-Level	MT-Safe				
SEE ALSO	fgetwc(3C), getwc(3C), attributes(5)				

getwd(3C)

NAME	getwd – get current working directory pathname
SYNOPSIS	<pre>#include <unistd.h> char *getwd(char *path_name);</pre>
DESCRIPTION	<p>The <code>getwd()</code> function determines an absolute pathname of the current working directory of the calling process, and copies that pathname into the array pointed to by the <code>path_name</code> argument.</p> <p>If the length of the pathname of the current working directory is greater than <code>(PATH_MAX + 1)</code> including the null byte, <code>getwd()</code> fails and returns a null pointer.</p>
RETURN VALUES	Upon successful completion, a pointer to the string containing the absolute pathname of the current working directory is returned. Otherwise, <code>getwd()</code> returns a null pointer and the contents of the array pointed to by <code>path_name</code> are undefined.
ERRORS	No errors are defined.
USAGE	For portability to implementations conforming to versions of the X/Open Portability Guide prior to SUS, <code>getcwd(3C)</code> is preferred over this function.
SEE ALSO	<code>getcwd(3C)</code> , <code>standards(5)</code>

NAME	getwidth – get codeset information				
SYNOPSIS	<pre>#include <euc.h> #include <getwidth.h> void getwidth(eucwidth_t *ptr) ;</pre>				
DESCRIPTION	<p>The <code>getwidth()</code> function reads the character class table for the current locale to get information on the supplementary codesets. <code>getwidth()</code> sets this information into the struct <code>eucwidth_t</code>. This struct is defined in <code><euc.h></code> and has the following members:</p> <pre>short int _eucw1, _eucw2, _eucw3; short int _scrw1, _scrw2, _scrw3; short int _pcw; char _multibyte;</pre> <p>Codeset width values for supplementary codesets 1, 2, and 3 are set in <code>_eucw1</code>, <code>_eucw2</code>, and <code>_eucw3</code>, respectively. Screen width values for supplementary codesets 1, 2, and 3 are set in <code>_scrw1</code>, <code>_scrw2</code>, and <code>_scrw3</code>, respectively.</p> <p>The width of Extended Unix Code (EUC) Process Code is set in <code>_pcw</code>. The <code>_multibyte</code> entry is set to 1 if multibyte characters are used, and set to 0 if only single-byte characters are used.</p>				
ATTRIBUTES	<p>See <code>attributes(5)</code> for descriptions of the following attributes:</p> <table border="1" style="width: 100%; border-collapse: collapse;"> <thead> <tr> <th style="text-align: left;">ATTRIBUTE TYPE</th> <th style="text-align: left;">ATTRIBUTE VALUE</th> </tr> </thead> <tbody> <tr> <td>MT-Level</td> <td>MT-Safe with exceptions</td> </tr> </tbody> </table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	MT-Level	MT-Safe with exceptions
ATTRIBUTE TYPE	ATTRIBUTE VALUE				
MT-Level	MT-Safe with exceptions				
SEE ALSO	<code>euclen(3C)</code> , <code>setlocale(3C)</code> , <code>attributes(5)</code>				
NOTES	<p>The <code>getwidth()</code> function can be used safely in a multithreaded application, as long as <code>setlocale(3C)</code> is not being called to change the locale.</p> <p>The <code>getwidth()</code> function will only work with EUC locales.</p>				

getws(3C)

NAME	getws, fgetws – get a wide-character string from a stream				
SYNOPSIS	<pre>#include <stdio.h> #include <wchar.h> wchar_t *getws (wchar_t *ws); #include <stdio.h> #include <wchar.h> wchar_t *fgetws (wchar_t *ws, int n, FILE *stream);</pre>				
DESCRIPTION	<p>The <code>getws()</code> function reads a string of characters from the standard input stream, <code>stdin</code>, converts these characters to the corresponding wide-character codes, and writes them to the array pointed to by <code>ws</code>, until a newline character is read, converted and transferred to <code>ws</code> or an end-of-file condition is encountered. The wide-character string, <code>ws</code>, is then terminated with a null wide-character code.</p> <p>The <code>fgetws()</code> function reads characters from the <code>stream</code>, converts them to the corresponding wide-character codes, and places them in the <code>wchar_t</code> array pointed to by <code>ws</code> until <code>n-1</code> characters are read, or until a newline character is read, converted and transferred to <code>ws</code>, or an end-of-file condition is encountered. The wide-character string, <code>ws</code>, is then terminated with a null wide-character code.</p> <p>If an error occurs, the resulting value of the file position indicator for the stream is indeterminate.</p> <p>The <code>fgetws()</code> function may mark the <code>st_atime</code> field of the file associated with <code>stream</code> for update. The <code>st_atime</code> field will be marked for update by the first successful execution of <code>fgetc(3C)</code>, <code>fgets(3C)</code>, <code>fgetwc(3C)</code>, <code>fgetws()</code>, <code>fread(3C)</code>, <code>fscanf(3C)</code>, <code>getc(3C)</code>, <code>getchar(3C)</code>, <code>gets(3C)</code>, or <code>scanf(3C)</code> using <code>stream</code> that returns data not supplied by a prior call to <code>scanf(3C)</code> or <code>scanf(3C)</code>.</p>				
RETURN VALUES	Upon successful completion, <code>getws()</code> and <code>fgetws()</code> returns <code>ws</code> . If the stream is at end-of-file, the end-of-file indicator for the stream is set and <code>fgetws()</code> returns a null pointer. If a read error occurs, the error indicator for the stream is set, <code>fgetws()</code> returns a null pointer and sets <code>errno</code> to indicate the error.				
ERRORS	See <code>fgetwc(3C)</code> for the conditions that will cause <code>fgetws()</code> to fail.				
ATTRIBUTES	See <code>attributes(5)</code> for descriptions of the following attributes:				
	<table border="1"><thead><tr><th>ATTRIBUTE TYPE</th><th>ATTRIBUTE VALUE</th></tr></thead><tbody><tr><td>MT-Level</td><td>MT-Safe</td></tr></tbody></table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	MT-Level	MT-Safe
ATTRIBUTE TYPE	ATTRIBUTE VALUE				
MT-Level	MT-Safe				
SEE ALSO	<code>ferror(3C)</code> , <code>fgetwc(3C)</code> , <code>fread(3C)</code> , <code>getwc(3C)</code> , <code>putws(3C)</code> , <code>scanf(3C)</code> , <code>attributes(5)</code>				

NAME	glob, globfree – generate path names matching a pattern
SYNOPSIS	<pre>#include <glob.h> int glob(const char *pattern, int flags, int (*errfunc)(const char *epath, int errno), glob_t *pglob); void globfree(glob_t *pglob);</pre>
DESCRIPTION	<p>The glob() function is a path name generator.</p> <p>The globfree() function frees any memory allocated by glob() associated with <i>pglob</i>.</p>
pattern Argument	<p>The argument <i>pattern</i> is a pointer to a path name pattern to be expanded. The glob() function matches all accessible path names against this pattern and develops a list of all path names that match. In order to have access to a path name, glob() requires search permission on every component of a path except the last, and read permission on each directory of any filename component of <i>pattern</i> that contains any of the following special characters:</p> <p>* ? [</p>
pglob Argument	<p>The structure type glob_t is defined in the header <glob.h> and includes at least the following members:</p> <pre>size_t gl_pathc; /* count of paths matched by pattern */ char **gl_pathv; /* pointer to list of matched path names */ size_t gl_offs; /* slots to reserve at beginning of gl_pathv */</pre> <p>The glob() function stores the number of matched path names into <i>pglob->gl_pathc</i> and a pointer to a list of pointers to path names into <i>pglob->gl_pathv</i>. The path names are in sort order as defined by the current setting of the LC_COLLATE category. The first pointer after the last path name is a NULL pointer. If the pattern does not match any path names, the returned number of matched paths is set to 0, and the contents of <i>pglob->gl_pathv</i> are implementation-dependent.</p> <p>It is the caller's responsibility to create the structure pointed to by <i>pglob</i>. The glob() function allocates other space as needed, including the memory pointed to by <i>gl_pathv</i>. The globfree() function frees any space associated with <i>pglob</i> from a previous call to glob().</p>
flags Argument	<p>The <i>flags</i> argument is used to control the behavior of glob(). The value of <i>flags</i> is a bitwise inclusive OR of zero or more of the following constants, which are defined in the header <glob.h>:</p> <pre> GLOB_APPEND Append path names generated to the ones from a previous call to glob(). GLOB_DOOFFS Make use of pglob->gl_offs. If this flag is set, pglob->gl_offs is used to specify how many NULL pointers to add to the beginning of pglob->gl_pathv. In other words, pglob->gl_pathv will point</pre>

glob(3C)

	to <i>pglob</i> → <i>gl_offs</i> NULL pointers, followed by <i>pglob</i> → <i>gl_pathc</i> path name pointers, followed by a NULL pointer.
GLOB_ERR	Causes <code>glob()</code> to return when it encounters a directory that it cannot open or read. Ordinarily, <code>glob()</code> continues to find matches.
GLOB_MARK	Each path name that is a directory that matches <i>pattern</i> has a slash appended.
GLOB_NOCHECK	If <i>pattern</i> does not match any path name, then <code>glob()</code> returns a list consisting of only <i>pattern</i> , and the number of matched path names is 1.
GLOB_NOESCAPE	Disable backslash escaping.
GLOB_NOSORT	Ordinarily, <code>glob()</code> sorts the matching path names according to the current setting of the LC_COLLATE category. When this flag is used the order of path names returned is unspecified.

The GLOB_APPEND flag can be used to append a new set of path names to those found in a previous call to `glob()`. The following rules apply when two or more calls to `glob()` are made with the same value of *pglob* and without intervening calls to `globfree()`:

1. The first such call must not set GLOB_APPEND. All subsequent calls must set it.
2. All the calls must set GLOB_DOOFFS, or all must not set it.
3. After the second call, *pglob*→*gl_pathv* points to a list containing the following:
 - a. Zero or more NULL pointers, as specified by GLOB_DOOFFS and *pglob*→*gl_offs*.
 - b. Pointers to the path names that were in the *pglob*→*gl_pathv* list before the call, in the same order as before.
 - c. Pointers to the new path names generated by the second call, in the specified order.
4. The count returned in *pglob*→*gl_pathc* will be the total number of path names from the two calls.
5. The application can change any of the fields after a call to `glob()`. If it does, it must reset them to the original value before a subsequent call, using the same *pglob* value, to `globfree()` or `glob()` with the GLOB_APPEND flag.

errfunc and *epath* Arguments

If, during the search, a directory is encountered that cannot be opened or read and *errfunc* is not a NULL pointer, `glob()` calls (**errfunc*) with two arguments:

1. The *epath* argument is a pointer to the path that failed.
2. The *eerrno* argument is the value of *errno* from the failure, as set by the `opendir(3C)`, `readdir(3C)` or `stat(2)` functions. (Other values may be used to report other errors not explicitly documented for those functions.)

The following constants are defined as error return values for `glob()`:

<code>GLOB_ABORTED</code>	The scan was stopped because <code>GLOB_ERR</code> was set or (<i>*errfunc</i>) returned non-zero.
<code>GLOB_NOMATCH</code>	The pattern does not match any existing path name, and <code>GLOB_NOCHECK</code> was not set in flags.
<code>GLOB_NOSPACE</code>	An attempt to allocate memory failed.

If (**errfunc*) is called and returns non-zero, or if the `GLOB_ERR` flag is set in *flags*, `glob()` stops the scan and returns `GLOB_ABORTED` after setting `gl_pathc` and `gl_pathv` in *pglob* to reflect the paths already scanned. If `GLOB_ERR` is not set and either *errfunc* is a NULL pointer or (**errfunc*) returns 0, the error is ignored.

RETURN VALUES The following values are returned by `glob()`:

0	Successful completion. The argument <code>pglob->gl_pathc</code> returns the number of matched path names and the argument <code>pglob->gl_pathv</code> contains a pointer to a null-terminated list of matched and sorted path names. However, if <code>pglob->gl_pathc</code> is 0, the content of <code>pglob->gl_pathv</code> is undefined.
non-zero	An error has occurred. Non-zero constants are defined in <code><glob.h></code> . The arguments <code>pglob->gl_pathc</code> and <code>pglob->gl_pathv</code> are still set as defined above.

The `globfree()` function returns no value.

USAGE This function is not provided for the purpose of enabling utilities to perform path name expansion on their arguments, as this operation is performed by the shell, and utilities are explicitly not expected to redo this. Instead, it is provided for applications that need to do path name expansion on strings obtained from other sources, such as a pattern typed by a user or read from a file.

If a utility needs to see if a path name matches a given pattern, it can use `fnmatch(3C)`.

Note that `gl_pathc` and `gl_pathv` have meaning even if `glob()` fails. This allows `glob()` to report partial results in the event of an error. However, if `gl_pathc` is 0, `gl_pathv` is unspecified even if `glob()` did not return an error.

The `GLOB_NOCHECK` option could be used when an application wants to expand a path name if wildcards are specified, but wants to treat the pattern as just a string otherwise.

The new path names generated by a subsequent call with `GLOB_APPEND` are not sorted together with the previous path names. This mirrors the way that the shell handles path name expansion when multiple expansions are done on a command line.

glob(3C)

Applications that need tilde and parameter expansion should use the `wordexp(3C)` function.

EXAMPLES **EXAMPLE 1** Example of `glob_doofs` function.

One use of the `GLOB_DOOFFS` flag is by applications that build an argument list for use with the `execv()`, `execve()`, or `execvp()` functions (see `exec(2)`). Suppose, for example, that an application wants to do the equivalent of:

```
ls -l *.c
```

but for some reason:

```
system("ls -l *.c")
```

is not acceptable. The application could obtain approximately the same result using the sequence:

```
globbuf.gl_offs = 2;
glob (*.c", GLOB_DOOFFS, NULL, &globbuf);
globbuf.gl_pathv[0] = "ls";
globbuf.gl_pathv[1] = "-l";
execvp ("ls", &globbuf.gl_pathv[0]);
```

Using the same example:

```
ls -l *.c *.h
```

could be approximately simulated using `GLOB_APPEND` as follows:

```
globbuf.gl_offs = 2;
glob (*.c", GLOB_DOOFFS, NULL, &globbuf);
glob (*.h", GLOB_DOOFFS|GLOB_APPEND, NULL, &globbuf);
. . .
```

NAME	glob, globfree – generate path names matching a pattern
SYNOPSIS	<pre>#include <glob.h> int glob(const char *pattern, int flags, int (*errfunc)(const char *epath, int errno), glob_t *pglob); void globfree(glob_t *pglob);</pre>
DESCRIPTION	<p>The glob() function is a path name generator.</p> <p>The globfree() function frees any memory allocated by glob() associated with <i>pglob</i>.</p>
pattern Argument	<p>The argument <i>pattern</i> is a pointer to a path name pattern to be expanded. The glob() function matches all accessible path names against this pattern and develops a list of all path names that match. In order to have access to a path name, glob() requires search permission on every component of a path except the last, and read permission on each directory of any filename component of <i>pattern</i> that contains any of the following special characters:</p> <p>* ? [</p>
pglob Argument	<p>The structure type glob_t is defined in the header <glob.h> and includes at least the following members:</p> <pre>size_t gl_pathc; /* count of paths matched by pattern */ char **gl_pathv; /* pointer to list of matched path names */ size_t gl_offs; /* slots to reserve at beginning of gl_pathv */</pre> <p>The glob() function stores the number of matched path names into <i>pglob</i>→gl_pathc and a pointer to a list of pointers to path names into <i>pglob</i>→gl_pathv. The path names are in sort order as defined by the current setting of the LC_COLLATE category. The first pointer after the last path name is a NULL pointer. If the pattern does not match any path names, the returned number of matched paths is set to 0, and the contents of <i>pglob</i>→gl_pathv are implementation-dependent.</p> <p>It is the caller's responsibility to create the structure pointed to by <i>pglob</i>. The glob() function allocates other space as needed, including the memory pointed to by gl_pathv. The globfree() function frees any space associated with <i>pglob</i> from a previous call to glob().</p>
flags Argument	<p>The <i>flags</i> argument is used to control the behavior of glob(). The value of <i>flags</i> is a bitwise inclusive OR of zero or more of the following constants, which are defined in the header <glob.h>:</p> <pre> GLOB_APPEND Append path names generated to the ones from a previous call to glob(). GLOB_DOOFFS Make use of <i>pglob</i>→gl_offs. If this flag is set, <i>pglob</i>→gl_offs is used to specify how many NULL pointers to add to the beginning of <i>pglob</i>→gl_pathv. In other words, <i>pglob</i>→gl_pathv will point</pre>

globfree(3C)

	to <i>pglob</i> → <i>gl_offs</i> NULL pointers, followed by <i>pglob</i> → <i>gl_pathc</i> path name pointers, followed by a NULL pointer.
GLOB_ERR	Causes <code>glob()</code> to return when it encounters a directory that it cannot open or read. Ordinarily, <code>glob()</code> continues to find matches.
GLOB_MARK	Each path name that is a directory that matches <i>pattern</i> has a slash appended.
GLOB_NOCHECK	If <i>pattern</i> does not match any path name, then <code>glob()</code> returns a list consisting of only <i>pattern</i> , and the number of matched path names is 1.
GLOB_NOESCAPE	Disable backslash escaping.
GLOB_NOSORT	Ordinarily, <code>glob()</code> sorts the matching path names according to the current setting of the <code>LC_COLLATE</code> category. When this flag is used the order of path names returned is unspecified.

The `GLOB_APPEND` flag can be used to append a new set of path names to those found in a previous call to `glob()`. The following rules apply when two or more calls to `glob()` are made with the same value of *pglob* and without intervening calls to `globfree()`:

1. The first such call must not set `GLOB_APPEND`. All subsequent calls must set it.
2. All the calls must set `GLOB_DOOFFS`, or all must not set it.
3. After the second call, *pglob*→*gl_pathv* points to a list containing the following:
 - a. Zero or more NULL pointers, as specified by `GLOB_DOOFFS` and *pglob*→*gl_offs*.
 - b. Pointers to the path names that were in the *pglob*→*gl_pathv* list before the call, in the same order as before.
 - c. Pointers to the new path names generated by the second call, in the specified order.
4. The count returned in *pglob*→*gl_pathc* will be the total number of path names from the two calls.
5. The application can change any of the fields after a call to `glob()`. If it does, it must reset them to the original value before a subsequent call, using the same *pglob* value, to `globfree()` or `glob()` with the `GLOB_APPEND` flag.

errfunc and *epath* Arguments

If, during the search, a directory is encountered that cannot be opened or read and *errfunc* is not a NULL pointer, `glob()` calls (*errfunc*) with two arguments:

1. The *epath* argument is a pointer to the path that failed.
2. The *errno* argument is the value of *errno* from the failure, as set by the `opendir(3C)`, `readdir(3C)` or `stat(2)` functions. (Other values may be used to report other errors not explicitly documented for those functions.)

The following constants are defined as error return values for `glob()`:

<code>GLOB_ABORTED</code>	The scan was stopped because <code>GLOB_ERR</code> was set or (<i>*errfunc</i>) returned non-zero.
<code>GLOB_NOMATCH</code>	The pattern does not match any existing path name, and <code>GLOB_NOCHECK</code> was not set in flags.
<code>GLOB_NOSPACE</code>	An attempt to allocate memory failed.

If (**errfunc*) is called and returns non-zero, or if the `GLOB_ERR` flag is set in *flags*, `glob()` stops the scan and returns `GLOB_ABORTED` after setting `gl_pathc` and `gl_pathv` in *pglob* to reflect the paths already scanned. If `GLOB_ERR` is not set and either *errfunc* is a NULL pointer or (**errfunc*) returns 0, the error is ignored.

RETURN VALUES

The following values are returned by `glob()`:

0	Successful completion. The argument <code>pglob->gl_pathc</code> returns the number of matched path names and the argument <code>pglob->gl_pathv</code> contains a pointer to a null-terminated list of matched and sorted path names. However, if <code>pglob->gl_pathc</code> is 0, the content of <code>pglob->gl_pathv</code> is undefined.
non-zero	An error has occurred. Non-zero constants are defined in <code><glob.h></code> . The arguments <code>pglob->gl_pathc</code> and <code>pglob->gl_pathv</code> are still set as defined above.

The `globfree()` function returns no value.

USAGE

This function is not provided for the purpose of enabling utilities to perform path name expansion on their arguments, as this operation is performed by the shell, and utilities are explicitly not expected to redo this. Instead, it is provided for applications that need to do path name expansion on strings obtained from other sources, such as a pattern typed by a user or read from a file.

If a utility needs to see if a path name matches a given pattern, it can use `fnmatch(3C)`.

Note that `gl_pathc` and `gl_pathv` have meaning even if `glob()` fails. This allows `glob()` to report partial results in the event of an error. However, if `gl_pathc` is 0, `gl_pathv` is unspecified even if `glob()` did not return an error.

The `GLOB_NOCHECK` option could be used when an application wants to expand a path name if wildcards are specified, but wants to treat the pattern as just a string otherwise.

The new path names generated by a subsequent call with `GLOB_APPEND` are not sorted together with the previous path names. This mirrors the way that the shell handles path name expansion when multiple expansions are done on a command line.

globfree(3C)

Applications that need tilde and parameter expansion should use the `wordexp(3C)` function.

EXAMPLES **EXAMPLE 1** Example of `glob_doofs` function.

One use of the `GLOB_DOOFFS` flag is by applications that build an argument list for use with the `execv()`, `execve()`, or `execvp()` functions (see `exec(2)`). Suppose, for example, that an application wants to do the equivalent of:

```
ls -l *.c
```

but for some reason:

```
system("ls -l *.c")
```

is not acceptable. The application could obtain approximately the same result using the sequence:

```
globbuf.gl_offs = 2;
glob (*.c", GLOB_DOOFFS, NULL, &globbuf);
globbuf.gl_pathv[0] = "ls";
globbuf.gl_pathv[1] = "-l";
execvp ("ls", &globbuf.gl_pathv[0]);
```

Using the same example:

```
ls -l *.c *.h
```

could be approximately simulated using `GLOB_APPEND` as follows:

```
globbuf.gl_offs = 2;
glob (*.c", GLOB_DOOFFS, NULL, &globbuf);
glob (*.h", GLOB_DOOFFS|GLOB_APPEND, NULL, &globbuf);
. . .
```

NAME	ctime, ctime_r, localtime, localtime_r, gmtime, gmtime_r, asctime, asctime_r, tzset – convert date and time to string
SYNOPSIS	<pre>#include <time.h> char *ctime(const time_t *clock); struct tm *localtime(const time_t *clock); struct tm *gmtime(const time_t *clock); char *asctime(const struct tm *tm); extern time_t timezone, altzone; extern int daylight; extern char *tzname[2]; void tzset(void); char *ctime_r(const time_t *clock, char *buf, int buflen); struct tm *localtime_r(const time_t *clock, struct tm *res); struct tm *gmtime_r(const time_t *clock, struct tm *res); char *asctime_r(const struct tm *tm, char *buf, int buflen);</pre>
POSIX	<pre>cc [flag...] file... -D_POSIX_PTHREAD_SEMANTICS [library...] char *ctime_r(const time_t *clock, char *buf); char *asctime_r(const struct tm *tm, char *buf);</pre>
DESCRIPTION	<p>The <code>ctime()</code> function converts the time pointed to by <code>clock</code>, representing the time in seconds since the Epoch (00:00:00 UTC, January 1, 1970), to local time in the form of a 26-character string, as shown below. Time zone and daylight savings corrections are made before string generation. The fields are in constant width:</p> <pre>Fri Sep 13 00:00:00 1986\n\0</pre> <p>The <code>ctime()</code> function is equivalent to:</p> <pre>asctime(localtime(clock))</pre> <p>The <code>ctime()</code>, <code>asctime()</code>, <code>gmtime()</code>, and <code>localtime()</code> functions return values in one of two static objects: a broken-down time structure and an array of <code>char</code>. Execution of any of the functions can overwrite the information returned in either of these objects by any of the other functions.</p> <p>The <code>ctime_r()</code> function has the same functionality as <code>ctime()</code> except that the caller must supply a buffer <code>buf</code> with length <code>buflen</code> to store the result; <code>buf</code> must be at least 26 bytes. The POSIX <code>ctime_r()</code> function does not take a <code>buflen</code> parameter.</p>

gmtime(3C)

The `localtime()` and `gmtime()` functions return pointers to `tm` structures (see below). The `localtime()` function corrects for the main time zone and possible alternate (“daylight savings”) time zone; the `gmtime()` function converts directly to Coordinated Universal Time (UTC), which is what the UNIX system uses internally.

The `localtime_r()` and `gmtime_r()` functions have the same functionality as `localtime()` and `gmtime()` respectively, except that the caller must supply a buffer *res* to store the result.

The `asctime()` function converts a `tm` structure to a 26-character string, as shown in the previous example, and returns a pointer to the string.

The `asctime_r()` function has the same functionality as `asctime()` except that the caller must supply a buffer *buf* with length *buflen* for the result to be stored. The *buf* argument must be at least 26 bytes. The POSIX `asctime_r()` function does not take a *buflen* parameter. The `asctime_r()` function returns a pointer to *buf* upon success. In case of failure, `NULL` is returned and `errno` is set.

Declarations of all the functions and externals, and the `tm` structure, are in the `<time.h>` header. The members of the `tm` structure are:

```
int    tm_sec;    /* seconds after the minute - [0, 61] */
        /* for leap seconds */
int    tm_min;    /* minutes after the hour - [0, 59] */
int    tm_hour;   /* hour since midnight - [0, 23] */
int    tm_mday;   /* day of the month - [1, 31] */
int    tm_mon;    /* months since January - [0, 11] */
int    tm_year;   /* years since 1900 */
int    tm_wday;   /* days since Sunday - [0, 6] */
int    tm_yday;   /* days since January 1 - [0, 365] */
int    tm_isdst;  /* flag for alternate daylight savings time */
```

The value of `tm_isdst` is positive if daylight savings time is in effect, zero if daylight savings time is not in effect, and negative if the information is not available. Previously, the value of `tm_isdst` was defined as non-zero if daylight savings was in effect.

The external `time_t` variable `altzone` contains the difference, in seconds, between Coordinated Universal Time and the alternate time zone. The external variable `timezone` contains the difference, in seconds, between UTC and local standard time. The external variable `daylight` indicates whether time should reflect daylight savings time. Both `timezone` and `altzone` default to 0 (UTC). The external variable `daylight` is non-zero if an alternate time zone exists. The time zone names are contained in the external variable `tzname`, which by default is set to:

```
char *tzname[2] = { "GMT", "" };
```

These functions know about the peculiarities of this conversion for various time periods for the U.S. (specifically, the years 1974, 1975, and 1987). They start handling the new daylight savings time starting with the first Sunday in April, 1987.

The `tzset()` function uses the contents of the environment variable `TZ` to override the value of the different external variables. It is called by `asctime()` and can also be called by the user. See `environ(5)` for a description of the `TZ` environment variable.

Starting and ending times are relative to the current local time zone. If the alternate time zone start and end dates and the time are not provided, the days for the United States that year will be used and the time will be 2 AM. If the start and end dates are provided but the time is not provided, the time will be 2 AM. The effects of `tzset()` change the values of the external variables `timezone`, `altzone`, `daylight`, and `tzname`.

Note that in most installations, `TZ` is set to the correct value by default when the user logs on, using the local `/etc/default/init` file (see `TIMEZONE(4)`).

ERRORS The `ctime_r()` and `asctime_r()` functions will fail if:

ERANGE The length of the buffer supplied by the caller is not large enough to store the result.

USAGE These functions do not support localized date and time formats. The `strftime(3C)` function can be used when localization is required.

The `localtime()`, `localtime_r()`, `gmtime()`, `gmtime_r()`, `ctime()`, and `ctime_r()` functions assume Gregorian dates. Times before the adoption of the Gregorian calendar will not match historical records.

EXAMPLES **EXAMPLE 1** Examples of the `tzset()` function.

The `tzset()` function scans the contents of the environment variable and assigns the different fields to the respective variable. For example, the most complete setting for New Jersey in 1986 could be:

```
EST5EDT4,116/2:00:00,298/2:00:00
```

or simply

```
EST5EDT
```

An example of a southern hemisphere setting such as the Cook Islands could be

```
KDT9:30KST10:00,63/5:00,302/20:00
```

In the longer version of the New Jersey example of `TZ`, `tzname[0]` is `EST`, `timezone` is set to `5*60*60`, `tzname[1]` is `EDT`, `altzone` is set to `4*60*60`, the starting date of the alternate time zone is the 117th day at 2 AM, the ending date of the alternate time zone is the 299th day at 2 AM (using zero-based Julian days), and `daylight` is set positive. Starting and ending times are relative to the current local time zone. If the alternate time zone start and end dates and the time are not provided, the days for the United States that year will be used and the time will be 2 AM. If the start and end dates are provided but the time is not provided, the time will be 2 AM. The effects of `tzset()` are thus to change the values of the external variables `timezone`, `altzone`, `daylight`, and `tzname`. The `ctime()`, `localtime()`, `mktime()`, and `strftime()` functions also update these external variables as if they had called `tzset()` at the

gmtime(3C)

EXAMPLE 1 Examples of the `tzset()` function. (Continued)

time specified by the `time_t` or `struct tm` value that they are converting.

BUGS The `zoneinfo` timezone data files do not transition past Tue Jan 19 03:14:07 2038 UTC. Therefore for 64-bit applications using `zoneinfo` timezones, calculations beyond this date might not use the correct offset from standard time, and could return incorrect values. This affects the 64-bit version of `localtime()`, `localtime_r()`, `ctime()`, and `ctime_r()`.

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
MT-Level	MT-Safe with exceptions
CSI	Enabled

SEE ALSO `time(2)`, `Intro(3)`, `getenv(3C)`, `mktime(3C)`, `printf(3C)`, `putenv(3C)`, `setlocale(3C)`, `strftime(3C)`, `TIMEZONE(4)`, `attributes(5)`, `environ(5)`

NOTES When compiling multithreaded programs, see `Intro(3)`, *Notes On Multithreaded Applications*.

The return values for `ctime()`, `localtime()`, and `gmtime()` point to static data whose content is overwritten by each call.

Setting the time during the interval of change from `timezone` to `altzone` or vice versa can produce unpredictable results. The system administrator must change the Julian start and end days annually.

The `asctime()`, `ctime()`, `gmtime()`, and `localtime()` functions are unsafe in multithread applications. The `asctime_r()` and `gmtime_r()` functions are MT-Safe. The `ctime_r()`, `localtime_r()`, and `tzset()` functions are MT-Safe in multithread applications, as long as no user-defined function directly modifies one of the following variables: `timezone`, `altzone`, `daylight`, and `tzname`. These four variables are not MT-Safe to access. They are modified by the `tzset()` function in an MT-Safe manner. The `mktime()`, `localtime_r()`, and `ctime_r()` functions call `tzset()`.

Solaris 2.4 and earlier releases provided definitions of the `ctime_r()`, `localtime_r()`, `gmtime_r()`, and `asctime_r()` functions as specified in POSIX.1c Draft 6. The final POSIX.1c standard changed the interface for `ctime_r()` and `asctime_r()`. Support for the Draft 6 interface is provided for compatibility only and might not be supported in future releases. New applications and libraries should use the POSIX standard interface.

gmtime(3C)

For POSIX.1c-compliant applications, the `_POSIX_PTHREAD_SEMANTICS` and `_REENTRANT` flags are automatically turned on by defining the `_POSIX_C_SOURCE` flag with a value `>= 199506L`.

gmtime_r(3C)

NAME	<code>ctime, ctime_r, localtime, localtime_r, gmtime, gmtime_r, asctime, asctime_r, tzset</code> – convert date and time to string
SYNOPSIS	<pre>#include <time.h> char *ctime(const time_t *clock); struct tm *localtime(const time_t *clock); struct tm *gmtime(const time_t *clock); char *asctime(const struct tm *tm); extern time_t timezone, altzone; extern int daylight; extern char *tzname[2]; void tzset(void); char *ctime_r(const time_t *clock, char *buf, int buflen); struct tm *localtime_r(const time_t *clock, struct tm *res); struct tm *gmtime_r(const time_t *clock, struct tm *res); char *asctime_r(const struct tm *tm, char *buf, int buflen);</pre>
POSIX	<pre>cc [flag...] file... -D_POSIX_THREAD_SEMANTICS [library...] char *ctime_r(const time_t *clock, char *buf); char *asctime_r(const struct tm *tm, char *buf);</pre>
DESCRIPTION	<p>The <code>ctime()</code> function converts the time pointed to by <code>clock</code>, representing the time in seconds since the Epoch (00:00:00 UTC, January 1, 1970), to local time in the form of a 26-character string, as shown below. Time zone and daylight savings corrections are made before string generation. The fields are in constant width:</p> <pre>Fri Sep 13 00:00:00 1986\n\0</pre> <p>The <code>ctime()</code> function is equivalent to:</p> <pre>asctime(localtime(clock))</pre> <p>The <code>ctime()</code>, <code>asctime()</code>, <code>gmtime()</code>, and <code>localtime()</code> functions return values in one of two static objects: a broken-down time structure and an array of <code>char</code>. Execution of any of the functions can overwrite the information returned in either of these objects by any of the other functions.</p> <p>The <code>ctime_r()</code> function has the same functionality as <code>ctime()</code> except that the caller must supply a buffer <code>buf</code> with length <code>buflen</code> to store the result; <code>buf</code> must be at least 26 bytes. The POSIX <code>ctime_r()</code> function does not take a <code>buflen</code> parameter.</p>

The `localtime()` and `gmtime()` functions return pointers to `tm` structures (see below). The `localtime()` function corrects for the main time zone and possible alternate (“daylight savings”) time zone; the `gmtime()` function converts directly to Coordinated Universal Time (UTC), which is what the UNIX system uses internally.

The `localtime_r()` and `gmtime_r()` functions have the same functionality as `localtime()` and `gmtime()` respectively, except that the caller must supply a buffer *res* to store the result.

The `asctime()` function converts a `tm` structure to a 26-character string, as shown in the previous example, and returns a pointer to the string.

The `asctime_r()` function has the same functionality as `asctime()` except that the caller must supply a buffer *buf* with length *buflen* for the result to be stored. The *buf* argument must be at least 26 bytes. The POSIX `asctime_r()` function does not take a *buflen* parameter. The `asctime_r()` function returns a pointer to *buf* upon success. In case of failure, `NULL` is returned and `errno` is set.

Declarations of all the functions and externals, and the `tm` structure, are in the `<time.h>` header. The members of the `tm` structure are:

```
int    tm_sec;    /* seconds after the minute - [0, 61] */
                /* for leap seconds */
int    tm_min;    /* minutes after the hour - [0, 59] */
int    tm_hour;   /* hour since midnight - [0, 23] */
int    tm_mday;   /* day of the month - [1, 31] */
int    tm_mon;    /* months since January - [0, 11] */
int    tm_year;   /* years since 1900 */
int    tm_wday;   /* days since Sunday - [0, 6] */
int    tm_yday;   /* days since January 1 - [0, 365] */
int    tm_isdst;  /* flag for alternate daylight savings time */
```

The value of `tm_isdst` is positive if daylight savings time is in effect, zero if daylight savings time is not in effect, and negative if the information is not available. Previously, the value of `tm_isdst` was defined as non-zero if daylight savings was in effect.

The external `time_t` variable `altzone` contains the difference, in seconds, between Coordinated Universal Time and the alternate time zone. The external variable `timezone` contains the difference, in seconds, between UTC and local standard time. The external variable `daylight` indicates whether time should reflect daylight savings time. Both `timezone` and `altzone` default to 0 (UTC). The external variable `daylight` is non-zero if an alternate time zone exists. The time zone names are contained in the external variable `tzname`, which by default is set to:

```
char *tzname[2] = { "GMT", "" };
```

These functions know about the peculiarities of this conversion for various time periods for the U.S. (specifically, the years 1974, 1975, and 1987). They start handling the new daylight savings time starting with the first Sunday in April, 1987.

gmtime_r(3C)

The `tzset()` function uses the contents of the environment variable `TZ` to override the value of the different external variables. It is called by `asctime()` and can also be called by the user. See `environ(5)` for a description of the `TZ` environment variable.

Starting and ending times are relative to the current local time zone. If the alternate time zone start and end dates and the time are not provided, the days for the United States that year will be used and the time will be 2 AM. If the start and end dates are provided but the time is not provided, the time will be 2 AM. The effects of `tzset()` change the values of the external variables `timezone`, `altzone`, `daylight`, and `tzname`.

Note that in most installations, `TZ` is set to the correct value by default when the user logs on, using the local `/etc/default/init` file (see `TIMEZONE(4)`).

ERRORS The `ctime_r()` and `asctime_r()` functions will fail if:

ERANGE The length of the buffer supplied by the caller is not large enough to store the result.

USAGE These functions do not support localized date and time formats. The `strftime(3C)` function can be used when localization is required.

The `localtime()`, `localtime_r()`, `gmtime()`, `gmtime_r()`, `ctime()`, and `ctime_r()` functions assume Gregorian dates. Times before the adoption of the Gregorian calendar will not match historical records.

EXAMPLES **EXAMPLE 1** Examples of the `tzset()` function.

The `tzset()` function scans the contents of the environment variable and assigns the different fields to the respective variable. For example, the most complete setting for New Jersey in 1986 could be:

```
EST5EDT4,116/2:00:00,298/2:00:00
```

or simply

```
EST5EDT
```

An example of a southern hemisphere setting such as the Cook Islands could be

```
KDT9:30KST10:00,63/5:00,302/20:00
```

In the longer version of the New Jersey example of `TZ`, `tzname[0]` is `EST`, `timezone` is set to `5*60*60`, `tzname[1]` is `EDT`, `altzone` is set to `4*60*60`, the starting date of the alternate time zone is the 117th day at 2 AM, the ending date of the alternate time zone is the 299th day at 2 AM (using zero-based Julian days), and `daylight` is set positive. Starting and ending times are relative to the current local time zone. If the alternate time zone start and end dates and the time are not provided, the days for the United States that year will be used and the time will be 2 AM. If the start and end dates are provided but the time is not provided, the time will be 2 AM. The effects of `tzset()` are thus to change the values of the external variables `timezone`, `altzone`, `daylight`, and `tzname`. The `ctime()`, `localtime()`, `mktime()`, and `strftime()` functions also update these external variables as if they had called `tzset()` at the

NOTES When compiling multithreaded programs, see Intro(3), *Notes On Multithreaded Applications*.

The return values for ctime (), localtime (), and gmtime () point to static data whose content is overwritten by each call.

Setting the time during the interval of change from timezone to altzone or vice versa can produce unpredictable results. The system administrator must change the Julian start and end days annually.

The asctime (), ctime (), gmtime (), and localtime () functions are unsafe in multithread applications. The asctime_r () and gmtime_r () functions are MT-Safe. The ctime_r (), localtime_r (), and tzset () functions are MT-Safe in multithread applications, as long as no user-defined function directly modifies one of the following variables: timezone, altzone, daylight, and tzname. These four variables are not MT-Safe to access. They are modified by the tzset () function in an MT-Safe manner. The mktime (), localtime_r (), and ctime_r () functions call tzset ().

Solaris 2.4 and earlier releases provided definitions of the ctime_r (), localtime_r (), gmtime_r (), and asctime_r () functions as specified in POSIX.1c Draft 6. The final POSIX.1c standard changed the interface for ctime_r () and asctime_r (). Support for the Draft 6 interface is provided for compatibility only and might not be supported in future releases. New applications and libraries should use the POSIX standard interface.

gmtime_r(3C)

For POSIX.1c-compliant applications, the `_POSIX_PTHREAD_SEMANTICS` and `_REENTRANT` flags are automatically turned on by defining the `_POSIX_C_SOURCE` flag with a value `>= 199506L`.

NAME	grantpt – grant access to the slave pseudo-terminal device						
SYNOPSIS	<pre>#include <stdlib.h> int grantpt(int <i>fildev</i>);</pre>						
DESCRIPTION	<p>The <code>grantpt()</code> function changes the mode and ownership of the slave pseudo-terminal device associated with its master pseudo-terminal counter part. <i>fildev</i> is the file descriptor returned from a successful open of the master pseudo-terminal device. A <i>setuid</i> root program (see <code>setuid(2)</code>) is invoked to change the permissions. The user ID of the slave is set to the real UID of the calling process and the group ID is set to a reserved group. The permission mode of the slave pseudo-terminal is set to readable and writable by the owner and writable by the group.</p>						
RETURN VALUES	Upon successful completion, <code>grantpt()</code> returns 0. Otherwise, it returns -1 and sets <code>errno</code> to indicate the error.						
ERRORS	<p>The <code>grantpt()</code> function may fail if:</p> <table border="0"> <tr> <td style="padding-right: 20px;">EBADF</td> <td>The <i>fildev</i> argument is not a valid open file descriptor.</td> </tr> <tr> <td>EINVAL</td> <td>The <i>fildev</i> argument is not associated with a master pseudo-terminal device.</td> </tr> <tr> <td>EACCES</td> <td>The corresponding slave pseudo-terminal device could not be accessed.</td> </tr> </table>	EBADF	The <i>fildev</i> argument is not a valid open file descriptor.	EINVAL	The <i>fildev</i> argument is not associated with a master pseudo-terminal device.	EACCES	The corresponding slave pseudo-terminal device could not be accessed.
EBADF	The <i>fildev</i> argument is not a valid open file descriptor.						
EINVAL	The <i>fildev</i> argument is not associated with a master pseudo-terminal device.						
EACCES	The corresponding slave pseudo-terminal device could not be accessed.						
USAGE	The <code>grantpt()</code> function will fail if it is unable to successfully invoke the <i>setuid</i> root program. It may also fail if the application has installed a signal handler to catch SIGCHLD signals.						
ATTRIBUTES	See <code>attributes(5)</code> for descriptions of the following attributes:						
	<table border="1" style="width: 100%; border-collapse: collapse;"> <thead> <tr> <th style="text-align: center;">ATTRIBUTE TYPE</th> <th style="text-align: center;">ATTRIBUTE VALUE</th> </tr> </thead> <tbody> <tr> <td>MT-Level</td> <td>Safe</td> </tr> </tbody> </table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	MT-Level	Safe

gsignal(3C)

NAME	ssignal, gsignal – software signals				
SYNOPSIS	<pre>#include <signal.h> void(*ssignal (int sig, int (*action) (int))) (int); int gsignal (int sig);</pre>				
DESCRIPTION	<p>The <code>ssignal()</code> and <code>gsignal()</code> functions implement a software facility similar to <code>signal(3C)</code>. This facility is made available to users for their own purposes.</p>				
ssignal()	<p>Software signals made available to users are associated with integers in the inclusive range 1 through 17. A call to <code>ssignal()</code> associates a procedure, <i>action</i>, with the software signal <i>sig</i>; the software signal, <i>sig</i>, is raised by a call to <code>gsignal()</code>. Raising a software signal causes the action established for that signal to be taken.</p> <p>The first argument to <code>ssignal()</code> is a number identifying the type of signal for which an action is to be established. The second argument defines the action; it is either the name of a (user-defined) <i>action function</i> or one of the manifest constants <code>SIG_DFL</code> (default) or <code>SIG_IGN</code> (ignore). The <code>ssignal()</code> function returns the action previously established for that signal type; if no action has been established or the signal number is illegal, <code>ssignal()</code> returns <code>SIG_DFL</code>.</p>				
gsignal()	<p>The <code>gsignal()</code> raises the signal identified by its argument, <i>sig</i>.</p> <p>If an action function has been established for <i>sig</i>, then that action is reset to <code>SIG_DFL</code> and the action function is entered with argument <i>sig</i>. The <code>gsignal()</code> function returns the value returned to it by the action function.</p> <p>If the action for <i>sig</i> is <code>SIG_IGN</code>, <code>gsignal()</code> returns the value 1 and takes no other action.</p> <p>If the action for <i>sig</i> is <code>SIG_DFL</code>, <code>gsignal()</code> returns the value 0 and takes no other action.</p> <p>If <i>sig</i> has an illegal value or no action was ever specified for <i>sig</i>, <code>gsignal()</code> returns the value 0 and takes no other action.</p>				
ATTRIBUTES	<p>See <code>attributes(5)</code> for descriptions of the following attributes:</p> <table border="1"><thead><tr><th>ATTRIBUTE TYPE</th><th>ATTRIBUTE VALUE</th></tr></thead><tbody><tr><td>MT-Level</td><td>Unsafe</td></tr></tbody></table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	MT-Level	Unsafe
ATTRIBUTE TYPE	ATTRIBUTE VALUE				
MT-Level	Unsafe				
SEE ALSO	<code>raise(3C)</code> , <code>signal(3C)</code> , <code>attributes(5)</code>				

NAME	getmntent, getmntany, getextmntent, hasmntopt, putmntent, resetmnttab – get mounted device information
SYNOPSIS	<pre>#include <stdio.h> #include <sys/mnttab.h> int getmntent(FILE *fp, struct mnttab *mp); int getmntany(FILE *fp, struct mnttab *mp, struct mnttab *mpref); int getextmntent(FILE *fp, struct extmnttab *mp, int len); char *hasmntopt(struct mnttab *mnt, char *opt); int putmntent(FILE *iop, struct mnttab *mp); void resetmnttab(FILE *fp);</pre>
getmntent() and getmntany()	<p>The <code>getmntent()</code> and <code>getmntany()</code> functions each fill in the structure pointed to by <code>mp</code> with the broken-out fields of a line in the <code>mnttab</code> file. Each line read from the file contains a <code>mnttab</code> structure, which is defined in the <code><sys/mnttab.h></code> header. The structure contains the following members, which correspond to the broken-out fields from a line in <code>/etc/mnttab</code> (see <code>mnttab(4)</code>).</p> <pre>char *mnt_special; /* name of mounted resource */ char *mnt_mountp; /* mount point */ char *mnt_fstype; /* type of file system mounted */ char *mnt_mntopts; /* options for this mount */ char *mnt_time; /* time file system mounted */</pre> <p>Each <code>getmntent()</code> call causes a new line to be read from the <code>mnttab</code> file. Successive calls can be used to search the entire list. The <code>getmntany()</code> function searches the file referenced by <code>fp</code> until a match is found between a line in the file and <code>mpref</code>. A match occurs if all non-null entries in <code>mpref</code> match the corresponding fields in the file. Note that these functions do not open, close, or rewind the file.</p>
getextmntent()	<p>The <code>getextmntent()</code> function is an extended version of the <code>getmntent()</code> function that returns, in addition to the information that <code>getmntent()</code> returns, the major and minor number of the mounted resource to which the line in <code>mnttab</code> corresponds. The <code>getextmntent()</code> function also fills in the <code>extmntent</code> structure defined in the <code><sys/mnttab.h></code> header. For <code>getextmntent()</code> to function properly, it must be notified when the <code>mnttab</code> file has been reopened or rewound since a previous <code>getextmntent()</code> call. This notification is accomplished by calling <code>resetmnttab()</code>. Otherwise, it behaves exactly as <code>getmntent()</code> described above.</p> <p>The data pointed to by the <code>mnttab</code> structure members are stored in a static area and must be copied to be saved between successive calls.</p>
hasmntopt()	<p>The <code>hasmntopt()</code> function scans the <code>mnt_mntopts</code> member of the <code>mnttab</code> structure <code>mnt</code> for a substring that matches <code>opt</code>. It returns the address of the substring if a match is found; otherwise it returns 0. Substrings are delimited by commas and the end of the <code>mnt_mntopts</code> string.</p>

hasmntopt(3C)

- `putmntent()` The `putmntent()` function is obsolete and no longer has any effect. Entries appear in `mnttab` as a side effect of a `mount(2)` call. The function name is still defined for transition purposes.
- `resetmnttab()` The `resetmnttab()` function notifies `getextmntent()` to reload from the kernel the device information that corresponds to the new snapshot of the `mnttab` information (see `mnttab(4)`). Subsequent `getextmntent()` calls then return correct `extmnttab` information. This function should be called whenever the `mnttab` file is either rewound or closed and reopened before any calls are made to `getextmntent()`.
- `getmntent()` and `getmntany()` If the next entry is successfully read by `getmntent()` or a match is found with `getmntany()`, 0 is returned. If an EOF is encountered on reading, these functions return -1. If an error is encountered, a value greater than 0 is returned. The following error values are defined in `<sys/mnttab.h>`:
- `MNT_TOOLONG` A line in the file exceeded the internal buffer size of `MNT_LINE_MAX`.
- `MNT_TOOMANY` A line in the file contains too many fields.
- `MNT_TOOFEW` A line in the file contains too few fields.
- `hasmntopt()` Upon successful completion, `hasmntopt()` returns the address of the substring if a match is found. Otherwise, it returns 0.
- `putmntent()` The `putmntent()` is obsolete and always returns -1.
- ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

NAME	hsearch, hcreate, hdestroy – manage hash search tables
SYNOPSIS	<pre>#include <search.h> ENTRY *hsearch(ENTRY item, ACTION action); int hcreate(size_t mekments); void hdestroy(void);</pre>
DESCRIPTION	<p>The <code>hsearch()</code> function is a hash-table search routine generalized from Knuth (6.4) Algorithm D. It returns a pointer into a hash table indicating the location at which an entry can be found. The comparison function used by <code>hsearch()</code> is <code>strcmp()</code> (see string(3C)). The <i>item</i> argument is a structure of type <code>ENTRY</code> (defined in the <code><search.h></code> header) containing two pointers: <code>item.key</code> points to the comparison key, and <code>item.data</code> points to any other data to be associated with that key. (Pointers to types other than <code>void</code> should be cast to pointer-to-void.) The <i>action</i> argument is a member of an enumeration type <code>ACTION</code> (defined in <code><search.h></code>) indicating the disposition of the entry if it cannot be found in the table. <code>ENTER</code> indicates that the item should be inserted in the table at an appropriate point. Given a duplicate of an existing item, the new item is not entered and <code>hsearch()</code> returns a pointer to the existing item. <code>FIND</code> indicates that no entry should be made. Unsuccessful resolution is indicated by the return of a null pointer.</p> <p>The <code>hcreate()</code> function allocates sufficient space for the table, and must be called before <code>hsearch()</code> is used. The <i>nel</i> argument is an estimate of the maximum number of entries that the table will contain. This number may be adjusted upward by the algorithm in order to obtain certain mathematically favorable circumstances.</p> <p>The <code>hdestroy()</code> function destroys the search table, and may be followed by another call to <code>hcreate()</code>.</p>
RETURN VALUES	<p>The <code>hsearch()</code> function returns a null pointer if either the action is <code>FIND</code> and the item could not be found or the action is <code>ENTER</code> and the table is full.</p> <p>The <code>hcreate()</code> function returns 0 if it cannot allocate sufficient space for the table.</p>
USAGE	<p>The <code>hsearch()</code> and <code>hcreate()</code> functions use <code>malloc(3C)</code> to allocate space.</p> <p>Only one hash search table may be active at any given time.</p>
EXAMPLES	<p>EXAMPLE 1 Example to read in strings.</p> <p>The following example will read in strings followed by two numbers and store them in a hash table, discarding duplicates. It will then read in strings and find the matching entry in the hash table and print it.</p> <pre>#include <stdio.h> #include <search.h> #include <string.h> #include <stdlib.h> struct info { /* this is the info stored in table */</pre>

hcreate(3C)

EXAMPLE 1 Example to read in strings. (Continued)

```
int age, room;                /* other than the key */
};
#define NUM_EMPL  5000        /* # of elements in search table */
main( )
{
    /* space to store strings */
    char string_space[NUM_EMPL*20];
    /* space to store employee info */
    struct info info_space[NUM_EMPL];
    /* next avail space in string_space */
    char *str_ptr = string_space;
    /* next avail space in info_space */
    struct info *info_ptr = info_space;
    ENTRY item, *found_item;
    /* name to look for in table */
    char name_to_find[30];
    int i = 0;

    /* create table */
    (void) hcreate(NUM_EMPL);
    while (scanf("%s%d%d", str_ptr, &info_ptr->age,
                &info_ptr->room) != EOF && i++ < NUM_EMPL) {
        /* put info in structure, and structure in item */
        item.key = str_ptr;
        item.data = (void *)info_ptr;
        str_ptr += strlen(str_ptr) + 1;
        info_ptr++;
        /* put item into table */
        (void) hsearch(item, ENTER);
    }

    /* access table */
    item.key = name_to_find;

hdestroy(3C)

NAME	hsearch, hcreate, hdestroy – manage hash search tables
SYNOPSIS	<pre>#include <search.h> ENTRY *hsearch(ENTRY item, ACTION action); int hcreate(size_t mekments); void hdestroy(void);</pre>
DESCRIPTION	<p>The <code>hsearch()</code> function is a hash-table search routine generalized from Knuth (6.4) Algorithm D. It returns a pointer into a hash table indicating the location at which an entry can be found. The comparison function used by <code>hsearch()</code> is <code>strcmp()</code> (see <code>string(3C)</code>). The <code>item</code> argument is a structure of type <code>ENTRY</code> (defined in the <code><search.h></code> header) containing two pointers: <code>item.key</code> points to the comparison key, and <code>item.data</code> points to any other data to be associated with that key. (Pointers to types other than <code>void</code> should be cast to <code>pointer-to-void</code>.) The <code>action</code> argument is a member of an enumeration type <code>ACTION</code> (defined in <code><search.h></code>) indicating the disposition of the entry if it cannot be found in the table. <code>ENTER</code> indicates that the item should be inserted in the table at an appropriate point. Given a duplicate of an existing item, the new item is not entered and <code>hsearch()</code> returns a pointer to the existing item. <code>FIND</code> indicates that no entry should be made. Unsuccessful resolution is indicated by the return of a null pointer.</p> <p>The <code>hcreate()</code> function allocates sufficient space for the table, and must be called before <code>hsearch()</code> is used. The <code>nel</code> argument is an estimate of the maximum number of entries that the table will contain. This number may be adjusted upward by the algorithm in order to obtain certain mathematically favorable circumstances.</p> <p>The <code>hdestroy()</code> function destroys the search table, and may be followed by another call to <code>hcreate()</code>.</p>
RETURN VALUES	<p>The <code>hsearch()</code> function returns a null pointer if either the action is <code>FIND</code> and the item could not be found or the action is <code>ENTER</code> and the table is full.</p> <p>The <code>hcreate()</code> function returns 0 if it cannot allocate sufficient space for the table.</p>
USAGE	<p>The <code>hsearch()</code> and <code>hcreate()</code> functions use <code>malloc(3C)</code> to allocate space.</p> <p>Only one hash search table may be active at any given time.</p>
EXAMPLES	<p>EXAMPLE 1 Example to read in strings.</p> <p>The following example will read in strings followed by two numbers and store them in a hash table, discarding duplicates. It will then read in strings and find the matching entry in the hash table and print it.</p> <pre>#include <stdio.h> #include <search.h> #include <string.h> #include <stdlib.h> struct info { /* this is the info stored in table */</pre>

EXAMPLE 1 Example to read in strings. (Continued)

iconv(3C)

NAME	iconv – code conversion function
SYNOPSIS	<pre>#include<iconv.h> size_t iconv(iconv_t cd, const char **inbuf, size_t *inbytesleft, char **outbuf, size_t *outbytesleft);</pre>
DESCRIPTION	<p>The <code>iconv()</code> function converts the sequence of characters from one code set, in the array specified by <code>inbuf</code>, into a sequence of corresponding characters in another code set, in the array specified by <code>outbuf</code>. The code sets are those specified in the <code>iconv_open()</code> call that returned the conversion descriptor, <code>cd</code>. The <code>inbuf</code> argument points to a variable that points to the first character in the input buffer and <code>inbytesleft</code> indicates the number of bytes to the end of the buffer to be converted. The <code>outbuf</code> argument points to a variable that points to the first available byte in the output buffer and <code>outbytesleft</code> indicates the number of the available bytes to the end of the buffer.</p> <p>For state-dependent encodings, the conversion descriptor <code>cd</code> is placed into its initial shift state by a call for which <code>inbuf</code> is a null pointer, or for which <code>inbuf</code> points to a null pointer. When <code>iconv()</code> is called in this way, and if <code>outbuf</code> is not a null pointer or a pointer to a null pointer, and <code>outbytesleft</code> points to a positive value, <code>iconv()</code> will place, into the output buffer, the byte sequence to change the output buffer to its initial shift state. If the output buffer is not large enough to hold the entire reset sequence, <code>iconv()</code> will fail and set <code>errno</code> to <code>E2BIG</code>. Subsequent calls with <code>inbuf</code> as other than a null pointer or a pointer to a null pointer cause the conversion to take place from the current state of the conversion descriptor.</p> <p>If a sequence of input bytes does not form a valid character in the specified code set, conversion stops after the previous successfully converted character. If the input buffer ends with an incomplete character or shift sequence, conversion stops after the previous successfully converted bytes. If the output buffer is not large enough to hold the entire converted input, conversion stops just prior to the input bytes that would cause the output buffer to overflow. The variable pointed to by <code>inbuf</code> is updated to point to the byte following the last byte successfully used in the conversion. The value pointed to by <code>inbytesleft</code> is decremented to reflect the number of bytes still not converted in the input buffer. The variable pointed to by <code>outbuf</code> is updated to point to the byte following the last byte of converted output data. The value pointed to by <code>outbytesleft</code> is decremented to reflect the number of bytes still available in the output buffer. For state-dependent encodings, the conversion descriptor is updated to reflect the shift state in effect at the end of the last successfully converted byte sequence.</p> <p>If <code>iconv()</code> encounters a character in the input buffer that is legal, but for which an identical character does not exist in the target code set, <code>iconv()</code> performs an implementation-defined conversion on this character.</p>
RETURN VALUES	The <code>iconv()</code> function updates the variables pointed to by the arguments to reflect the extent of the conversion and returns the number of non-identical conversions performed. If the entire string in the input buffer is converted, the value pointed to by

inbytesleft will be 0. If the input conversion is stopped due to any conditions mentioned above, the value pointed to by *inbytesleft* will be non-zero and *errno* is set to indicate the condition. If an error occurs *iconv()* returns (*size_t*) -1 and sets *errno* to indicate the error.

ERRORS The *iconv()* function will fail if:

EILSEQ	Input conversion stopped due to an input byte that does not belong to the input code set.
E2BIG	Input conversion stopped due to lack of space in the output buffer.
EINVAL	Input conversion stopped due to an incomplete character or shift sequence at the end of the input buffer.

The *iconv()* function may fail if:

EBADF	The <i>cd</i> argument is not a valid open conversion descriptor.
-------	---

EXAMPLES **EXAMPLE 1** Using the *iconv()* Functions

The following example uses the *iconv()* functions:

```
#include <stdio.h>
#include <errno.h>
#include <string.h>
#include <iconv.h>
#include <stdlib.h>

/*
 * For state-dependent encodings, changes the state of the conversion
 * descriptor to initial shift state. Also, outputs the byte sequence
 * to change the state to initial state.
 * This code is assuming the iconv call for initializing the state
 * won't fail due to lack of space in the output buffer.
 */
#define INIT_SHIFT_STATE(cd, fptr, ileft, tptr, oleft) \
{
    fptr = NULL; \
    ileft = 0; \
    tptr = to; \
    oleft = BUFSIZ; \
    (void) iconv(cd, &fptr, &ileft, &tptr, &oleft); \
    (void) fwrite(to, 1, BUFSIZ - oleft, stdout); \
}

int
main(int argc, char **argv)
{
    iconv_t cd;
    char    from[BUFSIZ], to[BUFSIZ];
    char    *from_code, *to_code;
    char    *tptr;
    const char *fptr;
    size_t  ileft, oleft, num, ret;
```

EXAMPLE 1 Using the iconv() Functions *(Continued)*

```

if (argc != 3) {
    (void) fprintf(stderr,
        "Usage: %s from_codeset to_codeset\\n", argv[0]);
    return (1);
}

from_code = argv[1];
to_code = argv[2];

cd = iconv_open((const char *)to_code, (const char *)from_code);
if (cd == (iconv_t)-1) {
    /*
     * iconv_open failed
     */
    (void) fprintf(stderr,
        "iconv_open(%s, %s) failed\\n", to_code, from_code);
    return (1);
}

ileft = 0;
while ((ileft +=
    (num = fread(from + ileft, 1, BUFSIZ - ileft, stdin)) > 0) {
    if (num == 0) {
        /*
         * Input buffer still contains incomplete character
         * or sequence.  However, no more input character.
         */

        /*
         * Initializes the conversion descriptor and outputs
         * the sequence to change the state to initial state.
         */
        INIT_SHIFT_STATE(cd, fptr, ileft, tptr, oleft);
        (void) iconv_close(cd);

        (void) fprintf(stderr, "Conversion error\\n");
        return (1);
    }

    fptr = from;
    for (;;) {
        tptr = to;
        oleft = BUFSIZ;

        ret = iconv(cd, &fptr, &ileft, &tptr, &oleft);
        if (ret != (size_t)-1) {
            /*
             * iconv succeeded
             */

            /*
             * Outputs converted characters
             */

```

EXAMPLE 1 Using the iconv() Functions (Continued)

```

        (void) fwrite(to, 1, BUFSIZ - oleft, stdout);
        break;
    }

    /*
     * iconv failed
     */
    if (errno == EINVAL) {
        /*
         * Incomplete character or shift sequence
         */

        /*
         * Outputs converted characters
         */
        (void) fwrite(to, 1, BUFSIZ - oleft, stdout);
        /*
         * Copies remaining characters in input buffer
         * to the top of the input buffer.
         */

NAME iconv_close – code conversion deallocation function

SYNOPSIS

```
#include <iconv.h>
int iconv_close(iconv_t cd);
```

DESCRIPTION The iconv_close() function deallocates the conversion descriptor *cd* and all other associated resources allocated by the iconv_open(3C) function.

If a file descriptor is used to implement the type iconv_t, that file descriptor will be closed.

For examples using the iconv_close() function, see iconv(3C).

RETURN VALUES Upon successful completion, iconv_close() returns 0; otherwise, it returns -1 and sets errno to indicate the error.

ERRORS The iconv_close() function may fail if:

EBADF The conversion descriptor is invalid.

iconv_open(3C)

NAME	iconv_open – code conversion allocation function								
SYNOPSIS	<pre>#include <iconv.h> iconv_t iconv_open(const char *<i>to</i>code, const char *<i>from</i>code);</pre>								
DESCRIPTION	<p>The <code>iconv_open()</code> function returns a conversion descriptor that describes a conversion from the codeset specified by the string pointed to by the <i>fromcode</i> argument to the codeset specified by the string pointed to by the <i>to</i>code argument. For state-dependent encodings, the conversion descriptor will be in a codeset-dependent initial shift state, ready for immediate use with the <code>iconv(3C)</code> function.</p> <p>Settings of <i>fromcode</i> and <i>to</i>code and their permitted combinations are implementation-dependent.</p> <p>The <code>iconv_open()</code> function supports the alias of the encoding name specified in <i>to</i>code and <i>fromcode</i>. The alias table of the encoding name is described in the file <code>/usr/lib/iconv/alias</code>. See <code>alias(4)</code>.</p> <p>A conversion descriptor remains valid in a process until that process closes it.</p> <p>For examples using the <code>iconv_open()</code> function, see <code>iconv(3C)</code>.</p>								
RETURN VALUES	Upon successful completion <code>iconv_open()</code> returns a conversion descriptor for use on subsequent calls to <code>iconv()</code> . Otherwise, <code>iconv_open()</code> returns <code>(iconv_t) -1</code> and sets <code>errno</code> to indicate the error.								
ERRORS	<p>The <code>iconv_open</code> function may fail if:</p> <table><tr><td>EMFILE</td><td>{OPEN_MAX} files descriptors are currently open in the calling process.</td></tr><tr><td>ENFILE</td><td>Too many files are currently open in the system.</td></tr><tr><td>ENOMEM</td><td>Insufficient storage space is available.</td></tr><tr><td>EINVAL</td><td>The conversion specified by <i>fromcode</i> and <i>to</i>code is not supported by the implementation.</td></tr></table>	EMFILE	{OPEN_MAX} files descriptors are currently open in the calling process.	ENFILE	Too many files are currently open in the system.	ENOMEM	Insufficient storage space is available.	EINVAL	The conversion specified by <i>fromcode</i> and <i>to</i> code is not supported by the implementation.
EMFILE	{OPEN_MAX} files descriptors are currently open in the calling process.								
ENFILE	Too many files are currently open in the system.								
ENOMEM	Insufficient storage space is available.

SEE ALSO	<code>exec(2)</code> , <code>iconv(3C)</code> , <code>iconv_close(3C)</code> , <code>malloc(3C)</code> , <code>alias(4)</code> , <code>attributes(5)</code>								

NOTES | The `iconv_open()` function uses `malloc(3C)` to allocate space for internal buffer areas. `iconv_open()` may fail if there is insufficient storage space to accommodate these buffers.

Portable applications must assume that conversion descriptors are not valid after a call to one of the `exec` functions (see `exec(2)`).

index(3C)

NAME	index, rindex – string operations
SYNOPSIS	<pre>#include <strings.h> char *index(const char *s, int c); char *rindex(const char *s, int c);</pre>
DESCRIPTION	<p>The <code>index()</code> and <code>rindex()</code> functions operate on null-terminated strings.</p> <p>The <code>index()</code> function returns a pointer to the first occurrence of character <code>c</code> in string <code>s</code>.</p> <p>The <code>rindex()</code> function returns a pointer to the last occurrence of character <code>c</code> in string <code>s</code>.</p> <p>Both <code>index()</code> and <code>rindex()</code> return a null pointer if <code>c</code> does not occur in the string. The null character terminating a string is considered to be part of the string.</p>
USAGE	<p>On most modern computer systems, you can <i>not</i> use a null pointer to indicate a null string. A null pointer is an error and results in an abort of the program. If you wish to indicate a null string, you must use a pointer that points to an explicit null string. On some machines and with some implementations of the C programming language, a null pointer, if dereferenced, would yield a null string. Though often used, this practice is not always portable. Programmers using a null pointer to represent an empty string should be aware of this portability issue. Even on machines where dereferencing a null pointer does not cause an abort of the program, it does not necessarily yield a null string.</p>

NAME	initgroups – initialize the supplementary group access list				
SYNOPSIS	<pre>#include <grp.h> #include <sys/types.h> int initgroups(const char *name, gid_t basegid);</pre>				
DESCRIPTION	<p>The <code>initgroups()</code> function reads the group database to get the group membership for the user specified by <i>name</i>, and initializes the supplementary group access list of the calling process (see <code>getgrnam(3C)</code> and <code>getgroups(2)</code>). The <i>basegid</i> group ID is also included in the supplementary group access list. This is typically the real group ID from the user database.</p> <p>While scanning the group database, if the number of groups, including the <i>basegid</i> entry, exceeds <code>NGROUPS_MAX</code>, subsequent group entries are ignored.</p>				
RETURN VALUES	Upon successful completion, 0 is returned. Otherwise, -1 is returned and <code>errno</code> is set to indicate the error.				
ERRORS	<p>The <code>initgroups()</code> function will fail and not change the supplementary group access list if:</p> <p><code>EPERM</code> The effective user ID is not super-user.</p>				
ATTRIBUTES	See <code>attributes(5)</code> for descriptions of the following attributes:

initstate(3C)

NAME	random, srandom, initstate, setstate – pseudorandom number functions
SYNOPSIS	<pre>#include <stdlib.h> long random(void); void srandom(unsigned int seed); char *initstate(unsigned int seed, char *state, size_t size); char *setstate(const char *state);</pre>
DESCRIPTION	<p>The <code>random()</code> function uses a nonlinear additive feedback random-number generator employing a default state array size of 31 long integers to return successive pseudo-random numbers in the range from 0 to $2^{31}-1$. The period of this random-number generator is approximately $16 \times (2^{31}-1)$. The size of the state array determines the period of the random-number generator. Increasing the state array size increases the period.</p> <p>The <code>srandom()</code> function initializes the current state array using the value of <i>seed</i>.</p> <p>The <code>random()</code> and <code>srandom()</code> functions have (almost) the same calling sequence and initialization properties as <code>rand()</code> and <code>srand()</code> (see <code>rand(3C)</code>). The difference is that <code>rand(3C)</code> produces a much less random sequence—in fact, the low dozen bits generated by <code>rand</code> go through a cyclic pattern. All the bits generated by <code>random()</code> are usable.</p> <p>The algorithm from <code>rand()</code> is used by <code>srandom()</code> to generate the 31 state integers. Because of this, different <code>srandom()</code> seeds often produce, within an offset, the same sequence of low order bits from <code>random()</code>. If low order bits are used directly, <code>random()</code> should be initialized with <code>setstate()</code> using high quality random values.</p> <p>Unlike <code>srand()</code>, <code>srandom()</code> does not return the old seed because the amount of state information used is much more than a single word. Two other routines are provided to deal with restarting/changing random number generators. With 256 bytes of state information, the period of the random-number generator is greater than 2^{69}, which should be sufficient for most purposes.</p> <p>Like <code>rand(3C)</code>, <code>random()</code> produces by default a sequence of numbers that can be duplicated by calling <code>srandom()</code> with 1 as the seed.</p> <p>The <code>initstate()</code> and <code>setstate()</code> functions handle restarting and changing random-number generators. The <code>initstate()</code> function allows a state array, pointed to by the <i>state</i> argument, to be initialized for future use. The <i>size</i> argument, which specifies the size in bytes of the state array, is used by <code>initstate()</code> to decide what type of random-number generator to use; the larger the state array, the more random the numbers. Values for the amount of state information are 8, 32, 64, 128, and 256 bytes. Other values greater than 8 bytes are rounded down to the nearest one of these values. For values smaller than 8, <code>random()</code> uses a simple linear congruential random number generator. The <i>seed</i> argument specifies a starting point for the random-number sequence and provides for restarting at the same point. The <code>initstate()</code> function returns a pointer to the previous state information array.</p>

If `initstate()` has not been called, then `random()` behaves as though `initstate()` had been called with `seed = 1` and `size = 128`.

If `initstate()` is called with `size < 8`, then `random()` uses a simple linear congruential random number generator.

Once a state has been initialized, `setstate()` allows switching between state arrays. The array defined by the `state` argument is used for further random-number generation until `initstate()` is called or `setstate()` is called again. The `setstate()` function returns a pointer to the previous state array.

RETURN VALUES

The `random()` function returns the generated pseudo-random number.

The `srandom()` function returns no value.

Upon successful completion, `initstate()` and `setstate()` return a pointer to the previous state array. Otherwise, a null pointer is returned.

ERRORS

No errors are defined.

USAGE

After initialization, a state array can be restarted at a different point in one of two ways:

- The `initstate()` function can be used, with the desired seed, state array, and size of the array.
- The `setstate()` function, with the desired state, can be used, followed by `srandom()` with the desired seed. The advantage of using both of these functions is that the size of the state array does not have to be saved once it is initialized.

EXAMPLES

EXAMPLE 1 Initialize an array.

The following example demonstrates the use of `initstate()` to initialize an array. It also demonstrates how to initialize an array and pass it to `setstate()`.

```
# include <stdlib.h>
static unsigned int state0[32];
static unsigned int state1[32] = {
    3,
    0x9a319039, 0x32d9c024, 0x9b663182, 0x5da1f342,
    0x7449e56b, 0xeb1dbb0, 0xab5c5918, 0x946554fd,
    0x8c2e680f, 0xeb3d799f, 0xb11ee0b7, 0x2d436b86,
    0xda672e2a, 0x1588ca88, 0xe369735d, 0x904f35f7,
    0xd7158fd6, 0x6fa6f051, 0x616e6b96, 0xac94efdc,
    0xde3b81e0, 0xdf0a6fb5, 0xf103bc02, 0x48f340fb,
    0x36413f93, 0xc622c298, 0xf5a42ab8, 0x8a88d77b,
    0xf5ad9d0e, 0x8999220b, 0x27fb47b9
};
main() {
    unsigned seed;
    int n;
    seed = 1;
    n = 128;
    (void)initstate(seed, (char *)state0, n);
    printf("random() = %d0\
```

initstate(3C)

EXAMPLE 1 Initialize an array. (Continued)

```
" , random());
    (void) setstate((char *)state1);
    printf("random() = %d\n",
    random());
}
```

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
MT-Level	See NOTES below.

SEE ALSO `drand48(3C)`, `rand(3C)`, `attributes(5)`

NOTES The `random()` and `srandom()` functions are unsafe in multithreaded applications.

Use of these functions in multithreaded applications is unsupported.

For `initstate()` and `setstate()`, the *state* argument must be aligned on an `int` boundary.

Newer and better performing random number generators such as `addrans()` and `lcrans()` are available with the SUNWspro package.

NAME	getnetgrent, getnetgrent_r, setnetgrent, endnetgrent, inetgr – get network group entry
SYNOPSIS	<pre>#include <netdb.h> int getnetgrent(char **<i>machinep</i>, char **<i>userp</i>, char **<i>domainp</i>); int getnetgrent_r(char **<i>machinep</i>, char **<i>userp</i>, char **<i>domainp</i>, char *<i>buffer</i>, int<i>buflen</i>); int setnetgrent(const char *<i>netgroup</i>); int endnetgrent(void); int inetgr(const char *<i>netgroup</i>, const char *<i>machine</i>, const char *<i>user</i>, const char *<i>domain</i>);</pre>
DESCRIPTION	<p>These functions are used to test membership in and enumerate members of “netgroup” network groups defined in a system database. Netgroups are sets of (machine,user,domain) triples (see netgroup(4)).</p> <p>These functions consult the source specified for netgroup in the /etc/nsswitch.conf file (see nsswitch.conf(4)).</p> <p>The function inetgr() returns 1 if there is a netgroup <i>netgroup</i> that contains the specified <i>machine</i>, <i>user</i>, <i>domain</i> triple as a member; otherwise it returns 0. Any of the supplied pointers <i>machine</i>, <i>user</i>, and <i>domain</i> may be NULL, signifying a “wild card” that matches all values in that position of the triple.</p> <p>The inetgr() function is safe for use in single-threaded and multithreaded applications.</p> <p>The functions setnetgrent(), getnetgrent(), and endnetgrent() are used to enumerate the members of a given network group.</p> <p>The function setnetgrent() establishes the network group specified in the parameter <i>netgroup</i> as the current group whose members are to be enumerated.</p> <p>Successive calls to the function getnetgrent() will enumerate the members of the group established by calling setnetgrent(); each call returns 1 if it succeeds in obtaining another member of the network group, or 0 if there are no further members of the group.</p> <p>When calling either getnetgrent() or getnetgrent_r(), addresses of the three character pointers are used as arguments, for example:</p> <pre>char *<i>mp</i>, *<i>up</i>, *<i>dp</i>; getnetgrent(&<i>mp</i>, &<i>up</i>, &<i>dp</i>);</pre>

innetgr(3C)

Upon successful return from `getnetgrent()`, the pointer `mp` points to a string containing the name of the machine part of the member triple, `up` points to a string containing the user name and `dp` points to a string containing the domain name. If the pointer returned for `mp`, `up`, or `dp` is `NULL`, it signifies that the element of the netgroup contains wild card specifier in that position of the triple.

The pointers returned by `getnetgrent()` point into a buffer allocated by `setnetgrent()` that is reused by each call. This space is released when an `endnetgrent()` call is made, and should not be released by the caller. This implementation is not safe for use in multi-threaded applications.

The function `getnetgrent_r()` is similar to `getnetgrent()` function, but it uses a buffer supplied by the caller for the space needed to store the results. The parameter `buffer` should be a pointer to a buffer allocated by the caller and the length of this buffer should be specified by the parameter `buflen`. The buffer must be large enough to hold the data associated with the triple. The `getnetgrent_r()` function is safe for use both in single-threaded and multi-threaded applications.

The function `endnetgrent()` frees the space allocated by the previous `setnetgrent()` call. The equivalent of an `endnetgrent()` implicitly performed whenever a `setnetgrent()` call is made to a new network group.

Note that while `setnetgrent()` and `endnetgrent()` are safe for use in multi-threaded applications, the effect of each is process-wide. Calling `setnetgrent()` resets the enumeration position for all threads. If multiple threads interleave calls to `getnetgrent_r()` each will enumerate a disjoint subset of the netgroup. Thus the effective use of these functions in multi-threaded applications may require coordination by the caller.

ERRORS The function `getnetgrent_r()` will return 0 and set `errno` to `ERANGE` if the length of the buffer supplied by caller is not large enough to store the result. See `Intro(2)` for the proper usage and interpretation of `errno` in multi-threaded applications.

The functions `setnetgrent()` and `endnetgrent()` return 0 upon success.

FILES `/etc/nsswitch.conf`

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
MT-Level	See <code>DESCRIPTION</code> section.

SEE ALSO `Intro(2)`, `Intro(3)`, `netgroup(4)`, `nsswitch.conf(4)`, `attributes(5)`

WARNINGS The function `getnetgrent_r()` is included in this release on an uncommitted basis only, and is subject to change or removal in future minor releases.

NOTES Only the Network Information Services, NIS and NIS+, are supported as sources for the `netgroup` database.

Programs that use the interfaces described in this manual page cannot be linked statically since the implementations of these functions employ dynamic loading and linking of shared objects at run time.

When compiling multi-threaded applications, see `Intro(3)`, *Notes On Multithread Applications*, for information about the use of the `_REENTRANT` flag.

insque(3C)

NAME	insque, remque – insert/remove element from a queue				
SYNOPSIS	<pre>include <search.h> void insque(struct qelem *elem, struct qelem *pred); void remque(struct qelem *elem);</pre>				
DESCRIPTION	<p>The <code>insque()</code> and <code>remque()</code> functions manipulate queues built from doubly linked lists. Each element in the queue must be in the following form:</p> <pre>struct qelem { struct qelem *q_forw; struct qelem *q_back; char q_data[]; };</pre> <p>The <code>insque()</code> function inserts <i>elem</i> in a queue immediately after <i>pred</i>. The <code>remque()</code> function removes an entry <i>elem</i> from a queue.</p>

NAME	isaexec – invoke isa-specific executable						
SYNOPSIS	<pre>#include <unistd.h> int isaexec(const char *path, char *const argv[], char *const envp[]);</pre>						
DESCRIPTION	<p>The <code>isaexec()</code> function takes the path specified as <i>path</i> and breaks it into directory and file name components. It enquires from the running system the list of supported instruction set architectures; see <code>isalist(5)</code>. The function traverses the list for an executable file in named subdirectories of the original directory. When such a file is located, <code>execve()</code> is invoked with <i>argv</i> [] and <i>envp</i> []. See <code>exec(2)</code>.</p>						
RETURN VALUES	<p>If no file is located, <code>isaexec()</code> returns <code>ENOENT</code>. Other return values are the same as for <code>execve()</code>.</p>						
EXAMPLES	<p>EXAMPLE 1 Example of <code>isaexec()</code> function.</p> <p>On a system whose <code>isalist</code> is</p> <pre>sparcv7 sparc</pre> <p>the program</p> <pre>int main(int argc, char *argv[], char *envp[]) { return (isaexec("/bin/thing", argv, envp)); }</pre> <p>will look first for an executable file named <code>/bin/sparcv7/thing</code>, then for an executable file named <code>bin/sparc/thing</code>. It will invoke <code>execve()</code> on the first executable file it finds named <code>thing</code>.</p> <p>On that same system, a program called <code>/u/bin/tofu</code> can cause either <code>/u/bin/sparcv7/tofu</code> or <code>/u/bin/sparc/tofu</code> to be invoked using the following code:</p> <pre>int main(int argc, char *argv[], char *envp[]) { return (isaexec(getexecname(), argv, envp)); }</pre>						
ATTRIBUTES	<p>See <code>attributes(5)</code> for descriptions of the following attributes:</p> <table border="1" style="width: 100%; border-collapse: collapse;"> <thead> <tr> <th style="text-align: center;">ATTRIBUTE TYPE</th> <th style="text-align: center;">ATTRIBUTE VALUE</th> </tr> </thead> <tbody> <tr> <td>MT-Level</td> <td>Safe</td> </tr> <tr> <td>Interface Stability</td> <td>Stable</td> </tr> </tbody> </table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	MT-Level	Safe	Interface Stability	Stable

isalnum(3C)

NAME	ctype, isdigit, isxdigit, islower, isupper, isalpha, isalnum, isspace, iscntrl, ispunct, isprint, isgraph, isascii – character handling		
SYNOPSIS	<pre>#include <ctype.h> int isalpha(int c); int isupper(int c); int islower(int c); int isdigit(int c); int isxdigit(int c); int isalnum(int c); int isspace(int c); int ispunct(int c); int isprint(int c); int isgraph(int c); int iscntrl(int c); int isascii(int c);</pre>		
DESCRIPTION	<p>These macros classify character-coded integer values. Each is a predicate returning non-zero for true, 0 for false. The behavior of these macros, except <code>isascii()</code>, is affected by the current locale (see <code>setlocale(3C)</code>). To modify the behavior, change the <code>LC_TYPE</code> category in <code>setlocale()</code>, that is, <code>setlocale(LC_CTYPE, newlocale)</code>. In the "C" locale, or in a locale where character type information is not defined, characters are classified according to the rules of the US-ASCII 7-bit coded character set.</p> <p>The macro <code>isascii()</code> is defined on all integer values; the rest are defined only where the argument is an <code>int</code>, the value of which is representable as an unsigned char, or EOF, which is defined by the <code><stdio.h></code> header and represents end-of-file.</p> <p>Functions exist for all the macros defined below. To get the function form, the macro name must be undefined (for example, <code>#undef isdigit</code>).</p> <p>For macros described with Default and Standard conforming versions, standard-conforming behavior will be provided for standard-conforming applications (see <code>standards(5)</code>) and for applications that define <code>__XPG4_CHAR_CLASS__</code> before including <code><ctype.h></code>.</p>		
Default	<table border="0"> <tr> <td style="padding-right: 10px;"><code>isalpha()</code></td> <td>Tests for any character for which <code>isupper()</code> or <code>islower()</code> is true.</td> </tr> </table>	<code>isalpha()</code>	Tests for any character for which <code>isupper()</code> or <code>islower()</code> is true.
<code>isalpha()</code>	Tests for any character for which <code>isupper()</code> or <code>islower()</code> is true.		
Standard conforming	<table border="0"> <tr> <td style="padding-right: 10px;"><code>isalpha()</code></td> <td>Tests for any character for which <code>isupper()</code> or <code>islower()</code> is true, or any character that is one of the current locale-defined set of characters for which none of <code>iscntrl()</code>, <code>isdigit()</code>,</td> </tr> </table>	<code>isalpha()</code>	Tests for any character for which <code>isupper()</code> or <code>islower()</code> is true, or any character that is one of the current locale-defined set of characters for which none of <code>iscntrl()</code> , <code>isdigit()</code> ,
<code>isalpha()</code>	Tests for any character for which <code>isupper()</code> or <code>islower()</code> is true, or any character that is one of the current locale-defined set of characters for which none of <code>iscntrl()</code> , <code>isdigit()</code> ,		

		ispunct(), or isspace() is true. In "C" locale, isalpha() returns true only for the characters for which isupper() or islower() is true.
	isupper()	Tests for any character that is an upper-case letter or is one of the current locale-defined set of characters for which none of iscntrl(), isdigit(), ispunct(), isspace(), or islower() is true. In the "C" locale, isupper() returns true only for the characters defined as upper-case ASCII characters.
	islower()	Tests for any character that is a lower-case letter or is one of the current locale-defined set of characters for which none of iscntrl(), isdigit(), ispunct(), isspace(), or isupper() is true. In the "C" locale, islower() returns true only for the characters defined as lower-case ASCII characters.
	isdigit()	Tests for any decimal-digit character.
Default	isxdigit()	Tests for any hexadecimal-digit character ([0-9], [A-F], or [a-f]).
Standard conforming	isxdigit()	Tests for any hexadecimal-digit character ([0-9], [A-F], or [a-f] or the current locale-defined sets of characters representing the hexadecimal digits 10 to 15 inclusive). In the "C" locale, only 0 1 2 3 4 5 6 7 8 9 A B C D E F a b c d e f are included.
	isalnum()	Tests for any character for which isalpha() or isdigit() is true (letter or digit).
	isspace()	Tests for any space, tab, carriage-return, newline, vertical-tab or form-feed (standard white-space characters) or for one of the current locale-defined set of characters for which isalnum() is false. In the C locale, isspace() returns true only for the standard white-space characters.
	ispunct()	Tests for any printing character which is neither a space (" ") nor a character for which isalnum() or iscntrl() is true.
Default	isprint()	Tests for any character for which ispunct(), isupper(), islower(), isdigit(), and the space character (" ") is true.
Standard conforming	isprint()	Tests for any character for which iscntrl() is false, and isalnum(), isgraph(), ispunct(), the space character (" "), and the characters in the current locale-defined "print" class are true.
Default	isgraph()	Tests for any character for which ispunct(), isupper(), islower(), and isdigit() is true.

isalnum(3C)

Standard conforming

`isgraph()` Tests for any character for which `isalnum()` and `ispunct()` are true, or any character in the current locale-defined "graph" class which is neither a space (" ") nor a character for which `iscntrl()` is true.

`iscntrl()` Tests for any "control character" as defined by the character set.

`isascii()` Tests for any ASCII character, code between 0 and 0177 inclusive.

RETURN VALUES

If the argument to any of the character handling macros is not in the domain of the function, the result is undefined. Otherwise, the macro/function will return non-zero if the classification is TRUE, and 0 for FALSE.

USAGE

The `isdigit()`, `isxdigit()`, `islower()`, `isupper()`, `isalpha()`, `isalnum()`, `isspace()`, `iscntrl()`, `ispunct()`, `isprint()`, `isgraph()`, and `isascii()` macros can be used safely in multithreaded applications, as long as `setlocale(3C)` is not being called to change the locale.

In the "C" locale, islower() returns true only for the characters defined as lower-case ASCII characters.
	isdigit()	Tests for any decimal-digit character.
Default	isxdigit()	Tests for any hexadecimal-digit character ([0-9], [A-F], or [a-f]).
Standard conforming	isxdigit()	Tests for any hexadecimal-digit character ([0-9], [A-F], or [a-f] or the current locale-defined sets of characters representing the hexadecimal digits 10 to 15 inclusive). In the "C" locale, only 0 1 2 3 4 5 6 7 8 9 A B C D E F a b c d e f are included.
	isalnum()	Tests for any character for which isalpha() or isdigit() is true (letter or digit).
	isspace()	Tests for any space, tab, carriage-return, newline, vertical-tab or form-feed (standard white-space characters) or for one of the current locale-defined set of characters for which isalnum() is false. In the C locale, isspace() returns true only for the standard white-space characters.
	ispunct()	Tests for any printing character which is neither a space (" ") nor a character for which isalnum() or iscntrl() is true.
Default	isprint()	Tests for any character for which ispunct(), isupper(), islower(), isdigit(), and the space character (" ") is true.
Standard conforming	isprint()	Tests for any character for which iscntrl() is false, and isalnum(), isgraph(), ispunct(), the space character (" "), and the characters in the current locale-defined "print" class are true.
Default	isgraph()	Tests for any character for which ispunct(), isupper(), islower(), and isdigit() is true.

Standard conforming

`isgraph()` Tests for any character for which `isalnum()` and `ispunct()` are true, or any character in the current locale-defined "graph" class which is neither a space (" ") nor a character for which `iscntrl()` is true.

`iscntrl()` Tests for any "control character" as defined by the character set.

`isascii()` Tests for any ASCII character, code between 0 and 0177 inclusive.

RETURN VALUES

If the argument to any of the character handling macros is not in the domain of the function, the result is undefined. Otherwise, the macro/function will return non-zero if the classification is TRUE, and 0 for FALSE.

USAGE

The `isdigit()`, `isxdigit()`, `islower()`, `isupper()`, `isalpha()`, `isalnum()`, `isspace()`, `iscntrl()`, `ispunct()`, `isprint()`, `isgraph()`, and `isascii()` macros can be used safely in multithreaded applications, as long as `setlocale(3C)` is not being called to change the locale.

isascii(3C)

NAME	ctype, isdigit, isxdigit, islower, isupper, isalpha, isalnum, isspace, iscntrl, ispunct, isprint, isgraph, isascii – character handling
SYNOPSIS	<pre>#include <ctype.h> int isalpha(int c); int isupper(int c); int islower(int c); int isdigit(int c); int isxdigit(int c); int isalnum(int c); int isspace(int c); int ispunct(int c); int isprint(int c); int isgraph(int c); int iscntrl(int c); int isascii(int c);</pre>
DESCRIPTION	<p>These macros classify character-coded integer values. Each is a predicate returning non-zero for true, 0 for false. The behavior of these macros, except <code>isascii()</code>, is affected by the current locale (see <code>setlocale(3C)</code>). To modify the behavior, change the <code>LC_TYPE</code> category in <code>setlocale()</code>, that is, <code>setlocale(LC_CTYPE, newlocale)</code>. In the "C" locale, or in a locale where character type information is not defined, characters are classified according to the rules of the US-ASCII 7-bit coded character set.</p> <p>The macro <code>isascii()</code> is defined on all integer values; the rest are defined only where the argument is an <code>int</code>, the value of which is representable as an unsigned char, or EOF, which is defined by the <code><stdio.h></code> header and represents end-of-file.</p> <p>Functions exist for all the macros defined below. To get the function form, the macro name must be undefined (for example, <code>#undef isdigit</code>).</p> <p>For macros described with Default and Standard conforming versions, standard-conforming behavior will be provided for standard-conforming applications (see <code>standards(5)</code>) and for applications that define <code>__XPG4_CHAR_CLASS__</code> before including <code><ctype.h></code>.</p>
Default	<pre>isalpha()</pre> Tests for any character for which <code>isupper()</code> or <code>islower()</code> is true.
Standard conforming	<pre>isalpha()</pre> Tests for any character for which <code>isupper()</code> or <code>islower()</code> is true, or any character that is one of the current locale-defined set of characters for which none of <code>iscntrl()</code> , <code>isdigit()</code> ,

		ispunct(), or isspace() is true. In "C" locale, isalpha() returns true only for the characters for which isupper() or islower() is true.
	isupper()	Tests for any character that is an upper-case letter or is one of the current locale-defined set of characters for which none of iscntrl(), isdigit(), ispunct(), isspace(), or islower() is true. In the "C" locale, isupper() returns true only for the characters defined as upper-case ASCII characters.
	islower()	Tests for any character that is a lower-case letter or is one of the current locale-defined set of characters for which none of iscntrl(), isdigit(), ispunct(), isspace(), or isupper() is true. In the "C" locale, islower() returns true only for the characters defined as lower-case ASCII characters.
	isdigit()	Tests for any decimal-digit character.
Default	isxdigit()	Tests for any hexadecimal-digit character ([0-9], [A-F], or [a-f]).
Standard conforming	isxdigit()	Tests for any hexadecimal-digit character ([0-9], [A-F], or [a-f] or the current locale-defined sets of characters representing the hexadecimal digits 10 to 15 inclusive). In the "C" locale, only 0 1 2 3 4 5 6 7 8 9 A B C D E F a b c d e f are included.
	isalnum()	Tests for any character for which isalpha() or isdigit() is true (letter or digit).
	isspace()	Tests for any space, tab, carriage-return, newline, vertical-tab or form-feed (standard white-space characters) or for one of the current locale-defined set of characters for which isalnum() is false. In the C locale, isspace() returns true only for the standard white-space characters.
	ispunct()	Tests for any printing character which is neither a space (" ") nor a character for which isalnum() or iscntrl() is true.
Default	isprint()	Tests for any character for which ispunct(), isupper(), islower(), isdigit(), and the space character (" ") is true.
Standard conforming	isprint()	Tests for any character for which iscntrl() is false, and isalnum(), isgraph(), ispunct(), the space character (" "), and the characters in the current locale-defined "print" class are true.
Default	isgraph()	Tests for any character for which ispunct(), isupper(), islower(), and isdigit() is true.

isascii(3C)

Standard conforming

isgraph() Tests for any character for which isalnum() and ispunct() are true, or any character in the current locale-defined "graph" class which is neither a space (" ") nor a character for which iscntrl() is true.

iscntrl() Tests for any "control character" as defined by the character set.

isascii() Tests for any ASCII character, code between 0 and 0177 inclusive.

RETURN VALUES

If the argument to any of the character handling macros is not in the domain of the function, the result is undefined. Otherwise, the macro/function will return non-zero if the classification is TRUE, and 0 for FALSE.

USAGE

The isdigit(), isxdigit(), islower(), isupper(), isalpha(), isalnum(), isspace(), iscntrl(), ispunct(), isprint(), isgraph(), and isascii() macros can be used safely in multithreaded applications, as long as setlocale(3C) is not being called to change the locale.

NAME isastream – test a file descriptor

SYNOPSIS

```
#include <stropts.h>
int isastream(int fildev);
```

DESCRIPTION The `isastream()` function determines if a file descriptor represents a STREAMS file. The *fildev* argument refers to an open file descriptor.

RETURN VALUES Upon successful completion, `isastream()` returns 1 if *fildev* represents a STREAMS file, and 0 if it does not. Otherwise, `-1` is returned and `errno` is set to indicate the error.

ERRORS The `isastream()` function will fail if:
EBADF The *fildev* argument is not a valid file descriptor.

isatty(3C)

NAME	isatty – test for a terminal device				
SYNOPSIS	<pre>#include <unistd.h> int isatty(int <i>fildev</i>);</pre>				
DESCRIPTION	The <code>isatty()</code> function tests whether <i>fildev</i> , an open file descriptor, is associated with a terminal device.				
RETURN VALUES	The <code>isatty()</code> function returns 1 if <i>fildev</i> is associated with a terminal; otherwise it returns 0 and may set <code>errno</code> to indicate the error.				
ERRORS	The <code>isatty()</code> function may fail if: EBADF The <i>fildev</i> argument is not a valid open file descriptor. ENOTTY The <i>fildev</i> argument is not associated with a terminal.				
USAGE	The <code>isatty()</code> function does not necessarily indicate that a human being is available for interaction via <i>fildev</i> . It is quite possible that non-terminal devices are connected to the communications line.

Standard conforming	<table border="0"> <tr> <td style="padding-right: 20px;"><code>isalpha()</code></td> <td>Tests for any character for which <code>isupper()</code> or <code>islower()</code> is true, or any character that is one of the current locale-defined set of characters for which none of <code>iscntrl()</code>, <code>isdigit()</code>,</td> </tr> </table>	<code>isalpha()</code>	Tests for any character for which <code>isupper()</code> or <code>islower()</code> is true, or any character that is one of the current locale-defined set of characters for which none of <code>iscntrl()</code> , <code>isdigit()</code> ,
<code>isalpha()</code>	Tests for any character for which <code>isupper()</code> or <code>islower()</code> is true, or any character that is one of the current locale-defined set of characters for which none of <code>iscntrl()</code> , <code>isdigit()</code> ,		

isctrnl(3C)

		ispunct(), or isspace() is true. In "C" locale, isalpha() returns true only for the characters for which isupper() or islower() is true.
	isupper()	Tests for any character that is an upper-case letter or is one of the current locale-defined set of characters for which none of isctrnl(), isdigit(), ispunct(), isspace(), or islower() is true. In the "C" locale, isupper() returns true only for the characters defined as upper-case ASCII characters.
	islower()	Tests for any character that is a lower-case letter or is one of the current locale-defined set of characters for which none of isctrnl(), isdigit(), ispunct(), isspace(), or isupper() is true. In the "C" locale, islower() returns true only for the characters defined as lower-case ASCII characters.
	isdigit()	Tests for any decimal-digit character.
Default	isxdigit()	Tests for any hexadecimal-digit character ([0-9], [A-F], or [a-f]).
Standard conforming	isxdigit()	Tests for any hexadecimal-digit character ([0-9], [A-F], or [a-f] or the current locale-defined sets of characters representing the hexadecimal digits 10 to 15 inclusive). In the "C" locale, only 0 1 2 3 4 5 6 7 8 9 A B C D E F a b c d e f are included.
	isalnum()	Tests for any character for which isalpha() or isdigit() is true (letter or digit).
	isspace()	Tests for any space, tab, carriage-return, newline, vertical-tab or form-feed (standard white-space characters) or for one of the current locale-defined set of characters for which isalnum() is false. In the C locale, isspace() returns true only for the standard white-space characters.
	ispunct()	Tests for any printing character which is neither a space (" ") nor a character for which isalnum() or isctrnl() is true.
Default	isprint()	Tests for any character for which ispunct(), isupper(), islower(), isdigit(), and the space character (" ") is true.
Standard conforming	isprint()	Tests for any character for which isctrnl() is false, and isalnum(), isgraph(), ispunct(), the space character (" "), and the characters in the current locale-defined "print" class are true.
Default	isgraph()	Tests for any character for which ispunct(), isupper(), islower(), and isdigit() is true.

Standard conforming

`isgraph()` Tests for any character for which `isalnum()` and `ispunct()` are true, or any character in the current locale-defined "graph" class which is neither a space (" ") nor a character for which `iscntrl()` is true.

`iscntrl()` Tests for any "control character" as defined by the character set.

`isascii()` Tests for any ASCII character, code between 0 and 0177 inclusive.

RETURN VALUES

If the argument to any of the character handling macros is not in the domain of the function, the result is undefined. Otherwise, the macro/function will return non-zero if the classification is TRUE, and 0 for FALSE.

USAGE

The `isdigit()`, `isxdigit()`, `islower()`, `isupper()`, `isalpha()`, `isalnum()`, `isspace()`, `iscntrl()`, `ispunct()`, `isprint()`, `isgraph()`, and `isascii()` macros can be used safely in multithreaded applications, as long as `setlocale(3C)` is not being called to change the locale.

NAME	ctype, isdigit, isxdigit, islower, isupper, isalpha, isalnum, isspace, iscntrl, ispunct, isprint, isgraph, isascii – character handling		
SYNOPSIS	<pre>#include <ctype.h> int isalpha(int c); int isupper(int c); int islower(int c); int isdigit(int c); int isxdigit(int c); int isalnum(int c); int isspace(int c); int ispunct(int c); int isprint(int c); int isgraph(int c); int iscntrl(int c); int isascii(int c);</pre>		
DESCRIPTION	<p>These macros classify character-coded integer values. Each is a predicate returning non-zero for true, 0 for false. The behavior of these macros, except <code>isascii()</code>, is affected by the current locale (see <code>setlocale(3C)</code>). To modify the behavior, change the <code>LC_TYPE</code> category in <code>setlocale()</code>, that is, <code>setlocale(LC_TYPE, newlocale)</code>. In the "C" locale, or in a locale where character type information is not defined, characters are classified according to the rules of the US-ASCII 7-bit coded character set.</p> <p>The macro <code>isascii()</code> is defined on all integer values; the rest are defined only where the argument is an <code>int</code>, the value of which is representable as an unsigned <code>char</code>, or <code>EOF</code>, which is defined by the <code><stdio.h></code> header and represents end-of-file.</p> <p>Functions exist for all the macros defined below. To get the function form, the macro name must be undefined (for example, <code>#undef isdigit</code>).</p> <p>For macros described with Default and Standard conforming versions, standard-conforming behavior will be provided for standard-conforming applications (see <code>standards(5)</code>) and for applications that define <code>__XPG4_CHAR_CLASS__</code> before including <code><ctype.h></code>.</p>		
Default	<table border="0"> <tr> <td style="padding-right: 20px;"><code>isalpha()</code></td> <td>Tests for any character for which <code>isupper()</code> or <code>islower()</code> is true.</td> </tr> </table>	<code>isalpha()</code>	Tests for any character for which <code>isupper()</code> or <code>islower()</code> is true.
<code>isalpha()</code>	Tests for any character for which <code>isupper()</code> or <code>islower()</code> is true.		
Standard conforming	<table border="0"> <tr> <td style="padding-right: 20px;"><code>isalpha()</code></td> <td>Tests for any character for which <code>isupper()</code> or <code>islower()</code> is true, or any character that is one of the current locale-defined set of characters for which none of <code>iscntrl()</code>, <code>isdigit()</code>,</td> </tr> </table>	<code>isalpha()</code>	Tests for any character for which <code>isupper()</code> or <code>islower()</code> is true, or any character that is one of the current locale-defined set of characters for which none of <code>iscntrl()</code> , <code>isdigit()</code> ,
<code>isalpha()</code>	Tests for any character for which <code>isupper()</code> or <code>islower()</code> is true, or any character that is one of the current locale-defined set of characters for which none of <code>iscntrl()</code> , <code>isdigit()</code> ,		

isgraph(3C)

		ispunct(), or isspace() is true. In "C" locale, isalpha() returns true only for the characters for which isupper() or islower() is true.
	isupper()	Tests for any character that is an upper-case letter or is one of the current locale-defined set of characters for which none of iscntrl(), isdigit(), ispunct(), isspace(), or islower() is true. In the "C" locale, isupper() returns true only for the characters defined as upper-case ASCII characters.
	islower()	Tests for any character that is a lower-case letter or is one of the current locale-defined set of characters for which none of iscntrl(), isdigit(), ispunct(), isspace(), or isupper() is true. In the "C" locale, islower() returns true only for the characters defined as lower-case ASCII characters.
	isdigit()	Tests for any decimal-digit character.
Default	isxdigit()	Tests for any hexadecimal-digit character ([0-9], [A-F], or [a-f]).
Standard conforming	isxdigit()	Tests for any hexadecimal-digit character ([0-9], [A-F], or [a-f] or the current locale-defined sets of characters representing the hexadecimal digits 10 to 15 inclusive). In the "C" locale, only 0 1 2 3 4 5 6 7 8 9 A B C D E F a b c d e f are included.
	isalnum()	Tests for any character for which isalpha() or isdigit() is true (letter or digit).
	isspace()	Tests for any space, tab, carriage-return, newline, vertical-tab or form-feed (standard white-space characters) or for one of the current locale-defined set of characters for which isalnum() is false. In the C locale, isspace() returns true only for the standard white-space characters.
	ispunct()	Tests for any printing character which is neither a space (" ") nor a character for which isalnum() or iscntrl() is true.
Default	isprint()	Tests for any character for which ispunct(), isupper(), islower(), isdigit(), and the space character (" ") is true.
Standard conforming	isprint()	Tests for any character for which iscntrl() is false, and isalnum(), isgraph(), ispunct(), the space character (" "), and the characters in the current locale-defined "print" class are true.
Default	isgraph()	Tests for any character for which ispunct(), isupper(), islower(), and isdigit() is true.

Standard conforming

`isgraph()` Tests for any character for which `isalnum()` and `ispunct()` are true, or any character in the current locale-defined "graph" class which is neither a space (" ") nor a character for which `iscntrl()` is true.

`iscntrl()` Tests for any "control character" as defined by the character set.

`isascii()` Tests for any ASCII character, code between 0 and 0177 inclusive.

RETURN VALUES

If the argument to any of the character handling macros is not in the domain of the function, the result is undefined. Otherwise, the macro/function will return non-zero if the classification is TRUE, and 0 for FALSE.

USAGE

The `isdigit()`, `isxdigit()`, `islower()`, `isupper()`, `isalpha()`, `isalnum()`, `isspace()`, `iscntrl()`, `ispunct()`, `isprint()`, `isgraph()`, and `isascii()` macros can be used safely in multithreaded applications, as long as `setlocale(3C)` is not being called to change the locale.

islower(3C)

NAME	ctype, isdigit, isxdigit, islower, isupper, isalpha, isalnum, isspace, iscntrl, ispunct, isprint, isgraph, isascii – character handling
SYNOPSIS	<pre>#include <ctype.h> int isalpha(int c); int isupper(int c); int islower(int c); int isdigit(int c); int isxdigit(int c); int isalnum(int c); int isspace(int c); int ispunct(int c); int isprint(int c); int isgraph(int c); int iscntrl(int c); int isascii(int c);</pre>
DESCRIPTION	<p>These macros classify character-coded integer values. Each is a predicate returning non-zero for true, 0 for false. The behavior of these macros, except <code>isascii()</code>, is affected by the current locale (see <code>setlocale(3C)</code>). To modify the behavior, change the <code>LC_TYPE</code> category in <code>setlocale()</code>, that is, <code>setlocale(LC_CTYPE, newlocale)</code>. In the "C" locale, or in a locale where character type information is not defined, characters are classified according to the rules of the US-ASCII 7-bit coded character set.</p> <p>The macro <code>isascii()</code> is defined on all integer values; the rest are defined only where the argument is an <code>int</code>, the value of which is representable as an unsigned char, or EOF, which is defined by the <code><stdio.h></code> header and represents end-of-file.</p> <p>Functions exist for all the macros defined below. To get the function form, the macro name must be undefined (for example, <code>#undef isdigit</code>).</p> <p>For macros described with Default and Standard conforming versions, standard-conforming behavior will be provided for standard-conforming applications (see <code>standards(5)</code>) and for applications that define <code>__XPG4_CHAR_CLASS__</code> before including <code><ctype.h></code>.</p>
Default	<code>isalpha()</code> Tests for any character for which <code>isupper()</code> or <code>islower()</code> is true.
Standard conforming	<code>isalpha()</code> Tests for any character for which <code>isupper()</code> or <code>islower()</code> is true, or any character that is one of the current locale-defined set of characters for which none of <code>iscntrl()</code> , <code>isdigit()</code> ,

		ispunct(), or isspace() is true. In "C" locale, isalpha() returns true only for the characters for which isupper() or islower() is true.
	isupper()	Tests for any character that is an upper-case letter or is one of the current locale-defined set of characters for which none of iscntrl(), isdigit(), ispunct(), isspace(), or islower() is true. In the "C" locale, isupper() returns true only for the characters defined as upper-case ASCII characters.
	islower()	Tests for any character that is a lower-case letter or is one of the current locale-defined set of characters for which none of iscntrl(), isdigit(), ispunct(), isspace(), or isupper() is true. In the "C" locale, islower() returns true only for the characters defined as lower-case ASCII characters.
	isdigit()	Tests for any decimal-digit character.
Default	isxdigit()	Tests for any hexadecimal-digit character ([0-9], [A-F], or [a-f]).
Standard conforming	isxdigit()	Tests for any hexadecimal-digit character ([0-9], [A-F], or [a-f] or the current locale-defined sets of characters representing the hexadecimal digits 10 to 15 inclusive). In the "C" locale, only 0 1 2 3 4 5 6 7 8 9 A B C D E F a b c d e f are included.
	isalnum()	Tests for any character for which isalpha() or isdigit() is true (letter or digit).
	isspace()	Tests for any space, tab, carriage-return, newline, vertical-tab or form-feed (standard white-space characters) or for one of the current locale-defined set of characters for which isalnum() is false. In the C locale, isspace() returns true only for the standard white-space characters.
	ispunct()	Tests for any printing character which is neither a space (" ") nor a character for which isalnum() or iscntrl() is true.
Default	isprint()	Tests for any character for which ispunct(), isupper(), islower(), isdigit(), and the space character (" ") is true.
Standard conforming	isprint()	Tests for any character for which iscntrl() is false, and isalnum(), isgraph(), ispunct(), the space character (" "), and the characters in the current locale-defined "print" class are true.
Default	isgraph()	Tests for any character for which ispunct(), isupper(), islower(), and isdigit() is true.

islower(3C)

Standard conforming

`isgraph()` Tests for any character for which `isalnum()` and `ispunct()` are true, or any character in the current locale-defined "graph" class which is neither a space (" ") nor a character for which `iscntrl()` is true.

`iscntrl()` Tests for any "control character" as defined by the character set.

`isascii()` Tests for any ASCII character, code between 0 and 0177 inclusive.

RETURN VALUES

If the argument to any of the character handling macros is not in the domain of the function, the result is undefined. Otherwise, the macro/function will return non-zero if the classification is TRUE, and 0 for FALSE.

USAGE

The `isdigit()`, `isxdigit()`, `islower()`, `isupper()`, `isalpha()`, `isalnum()`, `isspace()`, `iscntrl()`, `ispunct()`, `isprint()`, `isgraph()`, and `isascii()` macros can be used safely in multithreaded applications, as long as `setlocale(3C)` is not being called to change the locale.

SYNOPSIS	<pre>#include <wchar.h> int iswalpha(wint_t <i>wc</i>);</pre>																		
DESCRIPTION	<p>These functions test whether <i>wc</i> is a wide-character code representing a character of a particular class defined in the LC_CTYPE category of the current locale.</p> <p>In all cases, <i>wc</i> is a wint_t, the value of which must be a wide-character code corresponding to a valid character in the current locale or must equal the value of the macro WEOF. If the argument has any other values, the behavior is undefined.</p> <table border="0" style="width: 100%;"> <tr> <td style="vertical-align: top; padding-right: 20px;">iswalpha(<i>wc</i>)</td> <td>Tests whether <i>wc</i> is a wide-character code representing a character of class "alpha" in the program's current locale.</td> </tr> <tr> <td style="vertical-align: top; padding-right: 20px;">iswupper(<i>wc</i>)</td> <td>Tests whether <i>wc</i> is a wide-character code representing a character of class "upper" in the program's current locale.</td> </tr> <tr> <td style="vertical-align: top; padding-right: 20px;">iswlower(<i>wc</i>)</td> <td>Tests whether <i>wc</i> is a wide-character code representing a character of class "lower" in the program's current locale.</td> </tr> <tr> <td style="vertical-align: top; padding-right: 20px;">iswdigit(<i>wc</i>)</td> <td>Tests whether <i>wc</i> is a wide-character code representing a character of class "digit" in the program's current locale.</td> </tr> <tr> <td style="vertical-align: top; padding-right: 20px;">iswxdigit(<i>wc</i>)</td> <td>Tests whether <i>wc</i> is a wide-character code representing a character of class "xdigit" in the program's current locale.</td> </tr> <tr> <td style="vertical-align: top; padding-right: 20px;">iswalnum(<i>wc</i>)</td> <td>Tests whether <i>wc</i> is a wide-character code representing a character of class "alpha" or "digit" in the program's current locale.</td> </tr> <tr> <td style="vertical-align: top; padding-right: 20px;">iswspace(<i>wc</i>)</td> <td>Tests whether <i>wc</i> is a wide-character code representing a character of class "space" in the program's current locale.</td> </tr> <tr> <td style="vertical-align: top; padding-right: 20px;">iswpunct(<i>wc</i>)</td> <td>Tests whether <i>wc</i> is a wide-character code representing a character of class "punct" in the program's current locale.</td> </tr> <tr> <td style="vertical-align: top; padding-right: 20px;">iswprint(<i>wc</i>)</td> <td>Tests whether <i>wc</i> is a wide-character code representing a character of class "print" in the program's current locale.</td> </tr> </table>	iswalpha(<i>wc</i>)	Tests whether <i>wc</i> is a wide-character code representing a character of class "alpha" in the program's current locale.	iswupper(<i>wc</i>)	Tests whether <i>wc</i> is a wide-character code representing a character of class "upper" in the program's current locale.	iswlower(<i>wc</i>)	Tests whether <i>wc</i> is a wide-character code representing a character of class "lower" in the program's current locale.	iswdigit(<i>wc</i>)	Tests whether <i>wc</i> is a wide-character code representing a character of class "digit" in the program's current locale.	iswxdigit(<i>wc</i>)	Tests whether <i>wc</i> is a wide-character code representing a character of class "xdigit" in the program's current locale.	iswalnum(<i>wc</i>)	Tests whether <i>wc</i> is a wide-character code representing a character of class "alpha" or "digit" in the program's current locale.	iswspace(<i>wc</i>)	Tests whether <i>wc</i> is a wide-character code representing a character of class "space" in the program's current locale.	iswpunct(<i>wc</i>)	Tests whether <i>wc</i> is a wide-character code representing a character of class "punct" in the program's current locale.	iswprint(<i>wc</i>)	Tests whether <i>wc</i> is a wide-character code representing a character of class "print" in the program's current locale.
iswalpha(<i>wc</i>)	Tests whether <i>wc</i> is a wide-character code representing a character of class "alpha" in the program's current locale.																		
iswupper(<i>wc</i>)	Tests whether <i>wc</i> is a wide-character code representing a character of class "upper" in the program's current locale.																		
iswlower(<i>wc</i>)	Tests whether <i>wc</i> is a wide-character code representing a character of class "lower" in the program's current locale.																		
iswdigit(<i>wc</i>)	Tests whether <i>wc</i> is a wide-character code representing a character of class "digit" in the program's current locale.																		
iswxdigit(<i>wc</i>)	Tests whether <i>wc</i> is a wide-character code representing a character of class "xdigit" in the program's current locale.																		
iswalnum(<i>wc</i>)	Tests whether <i>wc</i> is a wide-character code representing a character of class "alpha" or "digit" in the program's current locale.																		
iswspace(<i>wc</i>)	Tests whether <i>wc</i> is a wide-character code representing a character of class "space" in the program's current locale.																		
iswpunct(<i>wc</i>)	Tests whether <i>wc</i> is a wide-character code representing a character of class "punct" in the program's current locale.																		
iswprint(<i>wc</i>)	Tests whether <i>wc</i> is a wide-character code representing a character of class "print" in the program's current locale.																		

isnumber(3C)

<code>iswgraph(<i>wc</i>)</code>	Tests whether <i>wc</i> is a wide-character code representing a character of class "graph" in the program's current locale.
<code>iswcntrl(<i>wc</i>)</code>	Tests whether <i>wc</i> is a wide-character code representing a character of class "cntrl" in the program's current locale.
<code>iswascii(<i>wc</i>)</code>	Tests whether <i>wc</i> is a wide-character code representing an ASCII character.
<code>isphonogram(<i>wc</i>)</code>	Tests whether <i>wc</i> is a wide-character code representing a phonetic language character, excluding ASCII characters.
<code>isideogram(<i>wc</i>)</code>	Tests whether <i>wc</i> is a wide-character code representing an ideographic language character, excluding ASCII characters.
<code>isenglish(<i>wc</i>)</code>	Tests whether <i>wc</i> is a wide-character code representing an English language character, excluding ASCII characters.
<code>isnumber(<i>wc</i>)</code>	Tests whether <i>wc</i> is a wide-character code representing digit [0–9], excluding ASCII characters.
<code>isspecial(<i>wc</i>)</code>	Tests whether <i>wc</i> is a wide-character code representing a special language character, excluding ASCII characters.

iswalpha(<i>wc</i>)	Tests whether <i>wc</i> is a wide-character code representing a character of class "alpha" in the program's current locale.																		
iswupper(<i>wc</i>)	Tests whether <i>wc</i> is a wide-character code representing a character of class "upper" in the program's current locale.																		
iswlower(<i>wc</i>)	Tests whether <i>wc</i> is a wide-character code representing a character of class "lower" in the program's current locale.																		
iswdigit(<i>wc</i>)	Tests whether <i>wc</i> is a wide-character code representing a character of class "digit" in the program's current locale.																		
iswxdigit(<i>wc</i>)	Tests whether <i>wc</i> is a wide-character code representing a character of class "xdigit" in the program's current locale.																		
iswalnum(<i>wc</i>)	Tests whether <i>wc</i> is a wide-character code representing a character of class "alpha" or "digit" in the program's current locale.																		
iswspace(<i>wc</i>)	Tests whether <i>wc</i> is a wide-character code representing a character of class "space" in the program's current locale.																		
iswpunct(<i>wc</i>)	Tests whether <i>wc</i> is a wide-character code representing a character of class "punct" in the program's current locale.																		
iswprint(<i>wc</i>)	Tests whether <i>wc</i> is a wide-character code representing a character of class "print" in the program's current locale.																		

isphonogram(3C)

<code>iswgraph(<i>wc</i>)</code>	Tests whether <i>wc</i> is a wide-character code representing a character of class "graph" in the program's current locale.
<code>iswcntrl(<i>wc</i>)</code>	Tests whether <i>wc</i> is a wide-character code representing a character of class "cntrl" in the program's current locale.
<code>iswascii(<i>wc</i>)</code>	Tests whether <i>wc</i> is a wide-character code representing an ASCII character.
<code>isphonogram(<i>wc</i>)</code>	Tests whether <i>wc</i> is a wide-character code representing a phonetic language character, excluding ASCII characters.
<code>isideogram(<i>wc</i>)</code>	Tests whether <i>wc</i> is a wide-character code representing an ideographic language character, excluding ASCII characters.
<code>isenglish(<i>wc</i>)</code>	Tests whether <i>wc</i> is a wide-character code representing an English language character, excluding ASCII characters.
<code>isnumber(<i>wc</i>)</code>	Tests whether <i>wc</i> is a wide-character code representing digit [0–9], excluding ASCII characters.
<code>isspecial(<i>wc</i>)</code>	Tests whether <i>wc</i> is a wide-character code representing a special language character, excluding ASCII characters.

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

NAME	ctype, isdigit, isxdigit, islower, isupper, isalpha, isalnum, isspace, iscntrl, ispunct, isprint, isgraph, isascii – character handling		
SYNOPSIS	<pre>#include <ctype.h> int isalpha(int c); int isupper(int c); int islower(int c); int isdigit(int c); int isxdigit(int c); int isalnum(int c); int isspace(int c); int ispunct(int c); int isprint(int c); int isgraph(int c); int iscntrl(int c); int isascii(int c);</pre>		
DESCRIPTION	<p>These macros classify character-coded integer values. Each is a predicate returning non-zero for true, 0 for false. The behavior of these macros, except <code>isascii()</code>, is affected by the current locale (see <code>setlocale(3C)</code>). To modify the behavior, change the <code>LC_TYPE</code> category in <code>setlocale()</code>, that is, <code>setlocale(LC_TYPE, newlocale)</code>. In the "C" locale, or in a locale where character type information is not defined, characters are classified according to the rules of the US-ASCII 7-bit coded character set.</p> <p>The macro <code>isascii()</code> is defined on all integer values; the rest are defined only where the argument is an <code>int</code>, the value of which is representable as an unsigned <code>char</code>, or <code>EOF</code>, which is defined by the <code><stdio.h></code> header and represents end-of-file.</p> <p>Functions exist for all the macros defined below. To get the function form, the macro name must be undefined (for example, <code>#undef isdigit</code>).</p> <p>For macros described with Default and Standard conforming versions, standard-conforming behavior will be provided for standard-conforming applications (see <code>standards(5)</code>) and for applications that define <code>__XPG4_CHAR_CLASS__</code> before including <code><ctype.h></code>.</p>		
Default	<table border="0"> <tr> <td style="padding-right: 20px;"><code>isalpha()</code></td> <td>Tests for any character for which <code>isupper()</code> or <code>islower()</code> is true.</td> </tr> </table>	<code>isalpha()</code>	Tests for any character for which <code>isupper()</code> or <code>islower()</code> is true.
<code>isalpha()</code>	Tests for any character for which <code>isupper()</code> or <code>islower()</code> is true.		
Standard conforming	<table border="0"> <tr> <td style="padding-right: 20px;"><code>isalpha()</code></td> <td>Tests for any character for which <code>isupper()</code> or <code>islower()</code> is true, or any character that is one of the current locale-defined set of characters for which none of <code>iscntrl()</code>, <code>isdigit()</code>,</td> </tr> </table>	<code>isalpha()</code>	Tests for any character for which <code>isupper()</code> or <code>islower()</code> is true, or any character that is one of the current locale-defined set of characters for which none of <code>iscntrl()</code> , <code>isdigit()</code> ,
<code>isalpha()</code>	Tests for any character for which <code>isupper()</code> or <code>islower()</code> is true, or any character that is one of the current locale-defined set of characters for which none of <code>iscntrl()</code> , <code>isdigit()</code> ,		

isprint(3C)

		ispunct(), or isspace() is true. In "C" locale, isalpha() returns true only for the characters for which isupper() or islower() is true.
	isupper()	Tests for any character that is an upper-case letter or is one of the current locale-defined set of characters for which none of iscntrl(), isdigit(), ispunct(), isspace(), or islower() is true. In the "C" locale, isupper() returns true only for the characters defined as upper-case ASCII characters.
	islower()	Tests for any character that is a lower-case letter or is one of the current locale-defined set of characters for which none of iscntrl(), isdigit(), ispunct(), isspace(), or isupper() is true. In the "C" locale, islower() returns true only for the characters defined as lower-case ASCII characters.
	isdigit()	Tests for any decimal-digit character.
Default	isxdigit()	Tests for any hexadecimal-digit character ([0-9], [A-F], or [a-f]).
Standard conforming	isxdigit()	Tests for any hexadecimal-digit character ([0-9], [A-F], or [a-f] or the current locale-defined sets of characters representing the hexadecimal digits 10 to 15 inclusive). In the "C" locale, only 0 1 2 3 4 5 6 7 8 9 A B C D E F a b c d e f are included.
	isalnum()	Tests for any character for which isalpha() or isdigit() is true (letter or digit).
	isspace()	Tests for any space, tab, carriage-return, newline, vertical-tab or form-feed (standard white-space characters) or for one of the current locale-defined set of characters for which isalnum() is false. In the C locale, isspace() returns true only for the standard white-space characters.
	ispunct()	Tests for any printing character which is neither a space (" ") nor a character for which isalnum() or iscntrl() is true.
Default	isprint()	Tests for any character for which ispunct(), isupper(), islower(), isdigit(), and the space character (" ") is true.
Standard conforming	isprint()	Tests for any character for which iscntrl() is false, and isalnum(), isgraph(), ispunct(), the space character (" "), and the characters in the current locale-defined "print" class are true.
Default	isgraph()	Tests for any character for which ispunct(), isupper(), islower(), and isdigit() is true.

isprint(3C)

Standard conforming

`isgraph()` Tests for any character for which `isalnum()` and `ispunct()` are true, or any character in the current locale-defined "graph" class which is neither a space (" ") nor a character for which `iscntrl()` is true.

`iscntrl()` Tests for any "control character" as defined by the character set.

`isascii()` Tests for any ASCII character, code between 0 and 0177 inclusive.

RETURN VALUES

If the argument to any of the character handling macros is not in the domain of the function, the result is undefined. Otherwise, the macro/function will return non-zero if the classification is TRUE, and 0 for FALSE.

USAGE

The `isdigit()`, `isxdigit()`, `islower()`, `isupper()`, `isalpha()`, `isalnum()`, `isspace()`, `iscntrl()`, `ispunct()`, `isprint()`, `isgraph()`, and `isascii()` macros can be used safely in multithreaded applications, as long as `setlocale(3C)` is not being called to change the locale.

Default	<code>isalpha()</code> Tests for any character for which <code>isupper()</code> or <code>islower()</code> is true.
Standard conforming	<code>isalpha()</code> Tests for any character for which <code>isupper()</code> or <code>islower()</code> is true, or any character that is one of the current locale-defined set of characters for which none of <code>iscntrl()</code> , <code>isdigit()</code> ,

		ispunct(), or isspace() is true. In "C" locale, isalpha() returns true only for the characters for which isupper() or islower() is true.
	isupper()	Tests for any character that is an upper-case letter or is one of the current locale-defined set of characters for which none of iscntrl(), isdigit(), ispunct(), isspace(), or islower() is true. In the "C" locale, isupper() returns true only for the characters defined as upper-case ASCII characters.
	islower()	Tests for any character that is a lower-case letter or is one of the current locale-defined set of characters for which none of iscntrl(), isdigit(), ispunct(), isspace(), or isupper() is true. In the "C" locale, islower() returns true only for the characters defined as lower-case ASCII characters.
	isdigit()	Tests for any decimal-digit character.
Default	isxdigit()	Tests for any hexadecimal-digit character ([0-9], [A-F], or [a-f]).
Standard conforming	isxdigit()	Tests for any hexadecimal-digit character ([0-9], [A-F], or [a-f] or the current locale-defined sets of characters representing the hexadecimal digits 10 to 15 inclusive). In the "C" locale, only 0 1 2 3 4 5 6 7 8 9 A B C D E F a b c d e f are included.
	isalnum()	Tests for any character for which isalpha() or isdigit() is true (letter or digit).
	isspace()	Tests for any space, tab, carriage-return, newline, vertical-tab or form-feed (standard white-space characters) or for one of the current locale-defined set of characters for which isalnum() is false. In the C locale, isspace() returns true only for the standard white-space characters.
	ispunct()	Tests for any printing character which is neither a space (" ") nor a character for which isalnum() or iscntrl() is true.
Default	isprint()	Tests for any character for which ispunct(), isupper(), islower(), isdigit(), and the space character (" ") is true.
Standard conforming	isprint()	Tests for any character for which iscntrl() is false, and isalnum(), isgraph(), ispunct(), the space character (" "), and the characters in the current locale-defined "print" class are true.
Default	isgraph()	Tests for any character for which ispunct(), isupper(), islower(), and isdigit() is true.

ispunct(3C)

Standard conforming

`isgraph()` Tests for any character for which `isalnum()` and `ispunct()` are true, or any character in the current locale-defined "graph" class which is neither a space (" ") nor a character for which `iscntrl()` is true.

`iscntrl()` Tests for any "control character" as defined by the character set.

`isascii()` Tests for any ASCII character, code between 0 and 0177 inclusive.

RETURN VALUES

If the argument to any of the character handling macros is not in the domain of the function, the result is undefined. Otherwise, the macro/function will return non-zero if the classification is TRUE, and 0 for FALSE.

USAGE

The `isdigit()`, `isxdigit()`, `islower()`, `isupper()`, `isalpha()`, `isalnum()`, `isspace()`, `iscntrl()`, `ispunct()`, `isprint()`, `isgraph()`, and `isascii()` macros can be used safely in multithreaded applications, as long as `setlocale(3C)` is not being called to change the locale.

isspace(3C)

		ispunct(), or isspace() is true. In "C" locale, isalpha() returns true only for the characters for which isupper() or islower() is true.
	isupper()	Tests for any character that is an upper-case letter or is one of the current locale-defined set of characters for which none of iscntrl(), isdigit(), ispunct(), isspace(), or islower() is true. In the "C" locale, isupper() returns true only for the characters defined as upper-case ASCII characters.
	islower()	Tests for any character that is a lower-case letter or is one of the current locale-defined set of characters for which none of iscntrl(), isdigit(), ispunct(), isspace(), or isupper() is true. In the "C" locale, islower() returns true only for the characters defined as lower-case ASCII characters.
	isdigit()	Tests for any decimal-digit character.
Default	isxdigit()	Tests for any hexadecimal-digit character ([0-9], [A-F], or [a-f]).
Standard conforming	isxdigit()	Tests for any hexadecimal-digit character ([0-9], [A-F], or [a-f] or the current locale-defined sets of characters representing the hexadecimal digits 10 to 15 inclusive). In the "C" locale, only 0 1 2 3 4 5 6 7 8 9 A B C D E F a b c d e f are included.
	isalnum()	Tests for any character for which isalpha() or isdigit() is true (letter or digit).
	isspace()	Tests for any space, tab, carriage-return, newline, vertical-tab or form-feed (standard white-space characters) or for one of the current locale-defined set of characters for which isalnum() is false. In the C locale, isspace() returns true only for the standard white-space characters.
	ispunct()	Tests for any printing character which is neither a space (" ") nor a character for which isalnum() or iscntrl() is true.
Default	isprint()	Tests for any character for which ispunct(), isupper(), islower(), isdigit(), and the space character (" ") is true.
Standard conforming	isprint()	Tests for any character for which iscntrl() is false, and isalnum(), isgraph(), ispunct(), the space character (" "), and the characters in the current locale-defined "print" class are true.
Default	isgraph()	Tests for any character for which ispunct(), isupper(), islower(), and isdigit() is true.

isspace(3C)

Standard conforming

isgraph() Tests for any character for which isalnum() and ispunct() are true, or any character in the current locale-defined "graph" class which is neither a space (" ") nor a character for which iscntrl() is true.

iscntrl() Tests for any "control character" as defined by the character set.

isascii() Tests for any ASCII character, code between 0 and 0177 inclusive.

RETURN VALUES

If the argument to any of the character handling macros is not in the domain of the function, the result is undefined. Otherwise, the macro/function will return non-zero if the classification is TRUE, and 0 for FALSE.

USAGE

The isdigit(), isxdigit(), islower(), isupper(), isalpha(), isalnum(), isspace(), iscntrl(), ispunct(), isprint(), isgraph(), and isascii() macros can be used safely in multithreaded applications, as long as setlocale(3C) is not being called to change the locale.

isupper(3C)

NAME	ctype, isdigit, isxdigit, islower, isupper, isalpha, isalnum, isspace, iscntrl, ispunct, isprint, isgraph, isascii – character handling
SYNOPSIS	<pre>#include <ctype.h> int isalpha(int c); int isupper(int c); int islower(int c); int isdigit(int c); int isxdigit(int c); int isalnum(int c); int isspace(int c); int ispunct(int c); int isprint(int c); int isgraph(int c); int iscntrl(int c); int isascii(int c);</pre>
DESCRIPTION	<p>These macros classify character-coded integer values. Each is a predicate returning non-zero for true, 0 for false. The behavior of these macros, except <code>isascii()</code>, is affected by the current locale (see <code>setlocale(3C)</code>). To modify the behavior, change the <code>LC_TYPE</code> category in <code>setlocale()</code>, that is, <code>setlocale(LC_CTYPE, newlocale)</code>. In the "C" locale, or in a locale where character type information is not defined, characters are classified according to the rules of the US-ASCII 7-bit coded character set.</p> <p>The macro <code>isascii()</code> is defined on all integer values; the rest are defined only where the argument is an <code>int</code>, the value of which is representable as an unsigned char, or EOF, which is defined by the <code><stdio.h></code> header and represents end-of-file.</p> <p>Functions exist for all the macros defined below. To get the function form, the macro name must be undefined (for example, <code>#undef isdigit</code>).</p> <p>For macros described with Default and Standard conforming versions, standard-conforming behavior will be provided for standard-conforming applications (see <code>standards(5)</code>) and for applications that define <code>__XPG4_CHAR_CLASS__</code> before including <code><ctype.h></code>.</p>
Default	<pre>isalpha()</pre> Tests for any character for which <code>isupper()</code> or <code>islower()</code> is true.
Standard conforming	<pre>isalpha()</pre> Tests for any character for which <code>isupper()</code> or <code>islower()</code> is true, or any character that is one of the current locale-defined set of characters for which none of <code>iscntrl()</code> , <code>isdigit()</code> ,

		ispunct(), or isspace() is true. In "C" locale, isalpha() returns true only for the characters for which isupper() or islower() is true.
	isupper()	Tests for any character that is an upper-case letter or is one of the current locale-defined set of characters for which none of iscntrl(), isdigit(), ispunct(), isspace(), or islower() is true. In the "C" locale, isupper() returns true only for the characters defined as upper-case ASCII characters.
	islower()	Tests for any character that is a lower-case letter or is one of the current locale-defined set of characters for which none of iscntrl(), isdigit(), ispunct(), isspace(), or isupper() is true. In the "C" locale, islower() returns true only for the characters defined as lower-case ASCII characters.
	isdigit()	Tests for any decimal-digit character.
Default	isxdigit()	Tests for any hexadecimal-digit character ([0-9], [A-F], or [a-f]).
Standard conforming	isxdigit()	Tests for any hexadecimal-digit character ([0-9], [A-F], or [a-f] or the current locale-defined sets of characters representing the hexadecimal digits 10 to 15 inclusive). In the "C" locale, only 0 1 2 3 4 5 6 7 8 9 A B C D E F a b c d e f are included.
	isalnum()	Tests for any character for which isalpha() or isdigit() is true (letter or digit).
	isspace()	Tests for any space, tab, carriage-return, newline, vertical-tab or form-feed (standard white-space characters) or for one of the current locale-defined set of characters for which isalnum() is false. In the C locale, isspace() returns true only for the standard white-space characters.
	ispunct()	Tests for any printing character which is neither a space (" ") nor a character for which isalnum() or iscntrl() is true.
Default	isprint()	Tests for any character for which ispunct(), isupper(), islower(), isdigit(), and the space character (" ") is true.
Standard conforming	isprint()	Tests for any character for which iscntrl() is false, and isalnum(), isgraph(), ispunct(), the space character (" "), and the characters in the current locale-defined "print" class are true.
Default	isgraph()	Tests for any character for which ispunct(), isupper(), islower(), and isdigit() is true.

isupper(3C)

Standard conforming

isgraph() Tests for any character for which isalnum() and ispunct() are true, or any character in the current locale-defined "graph" class which is neither a space (" ") nor a character for which iscntrl() is true.

iscntrl() Tests for any "control character" as defined by the character set.

isascii() Tests for any ASCII character, code between 0 and 0177 inclusive.

RETURN VALUES

If the argument to any of the character handling macros is not in the domain of the function, the result is undefined. Otherwise, the macro/function will return non-zero if the classification is TRUE, and 0 for FALSE.

USAGE

The isdigit(), isxdigit(), islower(), isupper(), isalpha(), isalnum(), isspace(), iscntrl(), ispunct(), isprint(), isgraph(), and isascii() macros can be used safely in multithreaded applications, as long as setlocale(3C) is not being called to change the locale.

SYNOPSIS	<pre>#include <wchar.h> int iswalpha(wint_t <i>wc</i>);</pre>																		
DESCRIPTION	<p>These functions test whether <i>wc</i> is a wide-character code representing a character of a particular class defined in the LC_CTYPE category of the current locale.</p> <p>In all cases, <i>wc</i> is a wint_t, the value of which must be a wide-character code corresponding to a valid character in the current locale or must equal the value of the macro WEOF. If the argument has any other values, the behavior is undefined.</p> <table border="0" style="width: 100%;"> <tr> <td style="vertical-align: top; padding-right: 20px;">iswalpha(<i>wc</i>)</td> <td>Tests whether <i>wc</i> is a wide-character code representing a character of class "alpha" in the program's current locale.</td> </tr> <tr> <td style="vertical-align: top; padding-right: 20px;">iswupper(<i>wc</i>)</td> <td>Tests whether <i>wc</i> is a wide-character code representing a character of class "upper" in the program's current locale.</td> </tr> <tr> <td style="vertical-align: top; padding-right: 20px;">iswlower(<i>wc</i>)</td> <td>Tests whether <i>wc</i> is a wide-character code representing a character of class "lower" in the program's current locale.</td> </tr> <tr> <td style="vertical-align: top; padding-right: 20px;">iswdigit(<i>wc</i>)</td> <td>Tests whether <i>wc</i> is a wide-character code representing a character of class "digit" in the program's current locale.</td> </tr> <tr> <td style="vertical-align: top; padding-right: 20px;">iswxdigit(<i>wc</i>)</td> <td>Tests whether <i>wc</i> is a wide-character code representing a character of class "xdigit" in the program's current locale.</td> </tr> <tr> <td style="vertical-align: top; padding-right: 20px;">iswalnum(<i>wc</i>)</td> <td>Tests whether <i>wc</i> is a wide-character code representing a character of class "alpha" or "digit" in the program's current locale.</td> </tr> <tr> <td style="vertical-align: top; padding-right: 20px;">iswspace(<i>wc</i>)</td> <td>Tests whether <i>wc</i> is a wide-character code representing a character of class "space" in the program's current locale.</td> </tr> <tr> <td style="vertical-align: top; padding-right: 20px;">iswpunct(<i>wc</i>)</td> <td>Tests whether <i>wc</i> is a wide-character code representing a character of class "punct" in the program's current locale.</td> </tr> <tr> <td style="vertical-align: top; padding-right: 20px;">iswprint(<i>wc</i>)</td> <td>Tests whether <i>wc</i> is a wide-character code representing a character of class "print" in the program's current locale.</td> </tr> </table>	iswalpha(<i>wc</i>)	Tests whether <i>wc</i> is a wide-character code representing a character of class "alpha" in the program's current locale.	iswupper(<i>wc</i>)	Tests whether <i>wc</i> is a wide-character code representing a character of class "upper" in the program's current locale.	iswlower(<i>wc</i>)	Tests whether <i>wc</i> is a wide-character code representing a character of class "lower" in the program's current locale.	iswdigit(<i>wc</i>)	Tests whether <i>wc</i> is a wide-character code representing a character of class "digit" in the program's current locale.	iswxdigit(<i>wc</i>)	Tests whether <i>wc</i> is a wide-character code representing a character of class "xdigit" in the program's current locale.	iswalnum(<i>wc</i>)	Tests whether <i>wc</i> is a wide-character code representing a character of class "alpha" or "digit" in the program's current locale.	iswspace(<i>wc</i>)	Tests whether <i>wc</i> is a wide-character code representing a character of class "space" in the program's current locale.	iswpunct(<i>wc</i>)	Tests whether <i>wc</i> is a wide-character code representing a character of class "punct" in the program's current locale.	iswprint(<i>wc</i>)	Tests whether <i>wc</i> is a wide-character code representing a character of class "print" in the program's current locale.
iswalpha(<i>wc</i>)	Tests whether <i>wc</i> is a wide-character code representing a character of class "alpha" in the program's current locale.																		
iswupper(<i>wc</i>)	Tests whether <i>wc</i> is a wide-character code representing a character of class "upper" in the program's current locale.																		
iswlower(<i>wc</i>)	Tests whether <i>wc</i> is a wide-character code representing a character of class "lower" in the program's current locale.																		
iswdigit(<i>wc</i>)	Tests whether <i>wc</i> is a wide-character code representing a character of class "digit" in the program's current locale.																		
iswxdigit(<i>wc</i>)	Tests whether <i>wc</i> is a wide-character code representing a character of class "xdigit" in the program's current locale.																		
iswalnum(<i>wc</i>)	Tests whether <i>wc</i> is a wide-character code representing a character of class "alpha" or "digit" in the program's current locale.																		
iswspace(<i>wc</i>)	Tests whether <i>wc</i> is a wide-character code representing a character of class "space" in the program's current locale.																		
iswpunct(<i>wc</i>)	Tests whether <i>wc</i> is a wide-character code representing a character of class "punct" in the program's current locale.																		
iswprint(<i>wc</i>)	Tests whether <i>wc</i> is a wide-character code representing a character of class "print" in the program's current locale.																		

iswascii(3C)

<code>iswgraph(wc)</code>	Tests whether <i>wc</i> is a wide-character code representing a character of class "graph" in the program's current locale.
<code>iswcntrl(wc)</code>	Tests whether <i>wc</i> is a wide-character code representing a character of class "cntrl" in the program's current locale.
<code>iswascii(wc)</code>	Tests whether <i>wc</i> is a wide-character code representing an ASCII character.
<code>isphonogram(wc)</code>	Tests whether <i>wc</i> is a wide-character code representing a phonetic language character, excluding ASCII characters.
<code>isideogram(wc)</code>	Tests whether <i>wc</i> is a wide-character code representing an ideographic language character, excluding ASCII characters.
<code>isenglish(wc)</code>	Tests whether <i>wc</i> is a wide-character code representing an English language character, excluding ASCII characters.
<code>isnumber(wc)</code>	Tests whether <i>wc</i> is a wide-character code representing digit [0–9], excluding ASCII characters.
<code>isspecial(wc)</code>	Tests whether <i>wc</i> is a wide-character code representing a special language character, excluding ASCII characters.

<i>iswalpha</i> (<i>wc</i>)	Tests whether <i>wc</i> is a wide-character code representing a character of class "alpha" in the program's current locale.																		
<i>iswupper</i> (<i>wc</i>)	Tests whether <i>wc</i> is a wide-character code representing a character of class "upper" in the program's current locale.																		
<i>iswlower</i> (<i>wc</i>)	Tests whether <i>wc</i> is a wide-character code representing a character of class "lower" in the program's current locale.																		
<i>iswdigit</i> (<i>wc</i>)	Tests whether <i>wc</i> is a wide-character code representing a character of class "digit" in the program's current locale.																		
<i>iswxdigit</i> (<i>wc</i>)	Tests whether <i>wc</i> is a wide-character code representing a character of class "xdigit" in the program's current locale.																		
<i>iswalnum</i> (<i>wc</i>)	Tests whether <i>wc</i> is a wide-character code representing a character of class "alpha" or "digit" in the program's current locale.																		
<i>iswspace</i> (<i>wc</i>)	Tests whether <i>wc</i> is a wide-character code representing a character of class "space" in the program's current locale.																		
<i>iswpunct</i> (<i>wc</i>)	Tests whether <i>wc</i> is a wide-character code representing a character of class "punct" in the program's current locale.																		
<i>iswprint</i> (<i>wc</i>)	Tests whether <i>wc</i> is a wide-character code representing a character of class "print" in the program's current locale.																		

iswcntrl(3C)

<code>iswgraph(<i>wc</i>)</code>	Tests whether <i>wc</i> is a wide-character code representing a character of class "graph" in the program's current locale.
<code>iswcntrl(<i>wc</i>)</code>	Tests whether <i>wc</i> is a wide-character code representing a character of class "cntrl" in the program's current locale.
<code>iswascii(<i>wc</i>)</code>	Tests whether <i>wc</i> is a wide-character code representing an ASCII character.
<code>isphonogram(<i>wc</i>)</code>	Tests whether <i>wc</i> is a wide-character code representing a phonetic language character, excluding ASCII characters.
<code>isideogram(<i>wc</i>)</code>	Tests whether <i>wc</i> is a wide-character code representing an ideographic language character, excluding ASCII characters.
<code>isenglish(<i>wc</i>)</code>	Tests whether <i>wc</i> is a wide-character code representing an English language character, excluding ASCII characters.
<code>isnumber(<i>wc</i>)</code>	Tests whether <i>wc</i> is a wide-character code representing digit [0–9], excluding ASCII characters.
<code>isspecial(<i>wc</i>)</code>	Tests whether <i>wc</i> is a wide-character code representing a special language character, excluding ASCII characters.

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE

SEE ALSO `localedef(1)`, `setlocale(3C)`, `stdio(3C)`, `ascii(5)`, `attributes(5)`

NAME	iswctype – test character for specified class
SYNOPSIS	<pre>#include <wchar.h> int iswctype(wint_t <i>wc</i>, wctype_t <i>charclass</i>);</pre>
DESCRIPTION	The <code>iswctype()</code> function determines whether the wide-character code <i>wc</i> has the character class <i>charclass</i> , returning TRUE or FALSE. The <code>iswctype()</code> function is defined on WEOF and wide-character codes corresponding to the valid character encodings in the current locale. If the <i>wc</i> argument is not in the domain of the function, the result is undefined. If the value of <i>charclass</i> is invalid (that is, not obtained by a call to <code>wctype(3C)</code> or <i>charclass</i> is invalidated by a subsequent call to <code>setlocale(3C)</code> that has affected category LC_CTYPE), the result is indeterminate.
RETURN VALUES	The <code>iswctype()</code> function returns 0 for FALSE and non-zero for TRUE.
USAGE	There are twelve strings that are reserved for the standard character classes:

"alnum"	"alpha"	"blank"
"cntrl"	"digit"	"graph"
"lower"	"print"	"punct"
"space"	"upper"	"xdigit"

In the table below, the functions in the left column are equivalent to the functions in the right column.

<code>iswalnum(<i>wc</i>)</code>	<code>iswctype(<i>wc</i>, wctype("alnum"))</code>
<code>iswalpha(<i>wc</i>)</code>	<code>iswctype(<i>wc</i>, wctype("alpha"))</code>
<code>iswcntrl(<i>wc</i>)</code>	<code>iswctype(<i>wc</i>, wctype("cntrl"))</code>
<code>iswdigit(<i>wc</i>)</code>	<code>iswctype(<i>wc</i>, wctype("digit"))</code>
<code>iswgraph(<i>wc</i>)</code>	<code>iswctype(<i>wc</i>, wctype("graph"))</code>
<code>iswlower(<i>wc</i>)</code>	<code>iswctype(<i>wc</i>, wctype("lower"))</code>
<code>iswprint(<i>wc</i>)</code>	<code>iswctype(<i>wc</i>, wctype("print"))</code>
<code>iswpunct(<i>wc</i>)</code>	<code>iswctype(<i>wc</i>, wctype("punct"))</code>
<code>iswspace(<i>wc</i>)</code>	<code>iswctype(<i>wc</i>, wctype("space"))</code>
<code>iswupper(<i>wc</i>)</code>	<code>iswctype(<i>wc</i>, wctype("upper"))</code>
<code>iswxdigit(<i>wc</i>)</code>	<code>iswctype(<i>wc</i>, wctype("xdigit"))</code>

The call

iswctype(3C)

`iswctype(wc, wctype("blank"))`

does not have an equivalent `isw*()` function.

iswdigit(<i>wc</i>)	Tests whether <i>wc</i> is a wide-character code representing a character of class "digit" in the program's current locale.																		
iswxdigit(<i>wc</i>)	Tests whether <i>wc</i> is a wide-character code representing a character of class "xdigit" in the program's current locale.																		
iswalnum(<i>wc</i>)	Tests whether <i>wc</i> is a wide-character code representing a character of class "alpha" or "digit" in the program's current locale.																		
iswspace(<i>wc</i>)	Tests whether <i>wc</i> is a wide-character code representing a character of class "space" in the program's current locale.																		
iswpunct(<i>wc</i>)	Tests whether <i>wc</i> is a wide-character code representing a character of class "punct" in the program's current locale.																		
iswprint(<i>wc</i>)	Tests whether <i>wc</i> is a wide-character code representing a character of class "print" in the program's current locale.																		

iswdigit(3C)

<code>iswgraph(<i>wc</i>)</code>	Tests whether <i>wc</i> is a wide-character code representing a character of class "graph" in the program's current locale.
<code>iswcntrl(<i>wc</i>)</code>	Tests whether <i>wc</i> is a wide-character code representing a character of class "cntrl" in the program's current locale.
<code>iswascii(<i>wc</i>)</code>	Tests whether <i>wc</i> is a wide-character code representing an ASCII character.
<code>isphonogram(<i>wc</i>)</code>	Tests whether <i>wc</i> is a wide-character code representing a phonetic language character, excluding ASCII characters.
<code>isideogram(<i>wc</i>)</code>	Tests whether <i>wc</i> is a wide-character code representing an ideographic language character, excluding ASCII characters.
<code>isenglish(<i>wc</i>)</code>	Tests whether <i>wc</i> is a wide-character code representing an English language character, excluding ASCII characters.
<code>isnumber(<i>wc</i>)</code>	Tests whether <i>wc</i> is a wide-character code representing digit [0–9], excluding ASCII characters.
<code>isspecial(<i>wc</i>)</code>	Tests whether <i>wc</i> is a wide-character code representing a special language character, excluding ASCII characters.

iswalpha(<i>wc</i>)	Tests whether <i>wc</i> is a wide-character code representing a character of class "alpha" in the program's current locale.																		
iswupper(<i>wc</i>)	Tests whether <i>wc</i> is a wide-character code representing a character of class "upper" in the program's current locale.																		
iswlower(<i>wc</i>)	Tests whether <i>wc</i> is a wide-character code representing a character of class "lower" in the program's current locale.																		
iswdigit(<i>wc</i>)	Tests whether <i>wc</i> is a wide-character code representing a character of class "digit" in the program's current locale.																		
iswxdigit(<i>wc</i>)	Tests whether <i>wc</i> is a wide-character code representing a character of class "xdigit" in the program's current locale.																		
iswalnum(<i>wc</i>)	Tests whether <i>wc</i> is a wide-character code representing a character of class "alpha" or "digit" in the program's current locale.																		
iswspace(<i>wc</i>)	Tests whether <i>wc</i> is a wide-character code representing a character of class "space" in the program's current locale.																		
iswpunct(<i>wc</i>)	Tests whether <i>wc</i> is a wide-character code representing a character of class "punct" in the program's current locale.																		
iswprint(<i>wc</i>)	Tests whether <i>wc</i> is a wide-character code representing a character of class "print" in the program's current locale.																		

iswgraph(3C)

<code>iswgraph(<i>wc</i>)</code>	Tests whether <i>wc</i> is a wide-character code representing a character of class "graph" in the program's current locale.
<code>iswcntrl(<i>wc</i>)</code>	Tests whether <i>wc</i> is a wide-character code representing a character of class "cntrl" in the program's current locale.
<code>iswascii(<i>wc</i>)</code>	Tests whether <i>wc</i> is a wide-character code representing an ASCII character.
<code>isphonogram(<i>wc</i>)</code>	Tests whether <i>wc</i> is a wide-character code representing a phonetic language character, excluding ASCII characters.
<code>isideogram(<i>wc</i>)</code>	Tests whether <i>wc</i> is a wide-character code representing an ideographic language character, excluding ASCII characters.
<code>isenglish(<i>wc</i>)</code>	Tests whether <i>wc</i> is a wide-character code representing an English language character, excluding ASCII characters.
<code>isnumber(<i>wc</i>)</code>	Tests whether <i>wc</i> is a wide-character code representing digit [0–9], excluding ASCII characters.
<code>isspecial(<i>wc</i>)</code>	Tests whether <i>wc</i> is a wide-character code representing a special language character, excluding ASCII characters.

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

SYNOPSIS	<pre>#include <wchar.h> int iswalpha(wint_t <i>wc</i>);</pre>																		
DESCRIPTION	<p>These functions test whether <i>wc</i> is a wide-character code representing a character of a particular class defined in the LC_CTYPE category of the current locale.</p> <p>In all cases, <i>wc</i> is a wint_t, the value of which must be a wide-character code corresponding to a valid character in the current locale or must equal the value of the macro WEOF. If the argument has any other values, the behavior is undefined.</p> <table border="0" style="width: 100%;"> <tr> <td style="vertical-align: top; padding-right: 20px;">iswalpha(<i>wc</i>)</td> <td>Tests whether <i>wc</i> is a wide-character code representing a character of class "alpha" in the program's current locale.</td> </tr> <tr> <td style="vertical-align: top; padding-right: 20px;">iswupper(<i>wc</i>)</td> <td>Tests whether <i>wc</i> is a wide-character code representing a character of class "upper" in the program's current locale.</td> </tr> <tr> <td style="vertical-align: top; padding-right: 20px;">iswlower(<i>wc</i>)</td> <td>Tests whether <i>wc</i> is a wide-character code representing a character of class "lower" in the program's current locale.</td> </tr> <tr> <td style="vertical-align: top; padding-right: 20px;">iswdigit(<i>wc</i>)</td> <td>Tests whether <i>wc</i> is a wide-character code representing a character of class "digit" in the program's current locale.</td> </tr> <tr> <td style="vertical-align: top; padding-right: 20px;">iswxdigit(<i>wc</i>)</td> <td>Tests whether <i>wc</i> is a wide-character code representing a character of class "xdigit" in the program's current locale.</td> </tr> <tr> <td style="vertical-align: top; padding-right: 20px;">iswalnum(<i>wc</i>)</td> <td>Tests whether <i>wc</i> is a wide-character code representing a character of class "alpha" or "digit" in the program's current locale.</td> </tr> <tr> <td style="vertical-align: top; padding-right: 20px;">iswspace(<i>wc</i>)</td> <td>Tests whether <i>wc</i> is a wide-character code representing a character of class "space" in the program's current locale.</td> </tr> <tr> <td style="vertical-align: top; padding-right: 20px;">iswpunct(<i>wc</i>)</td> <td>Tests whether <i>wc</i> is a wide-character code representing a character of class "punct" in the program's current locale.</td> </tr> <tr> <td style="vertical-align: top; padding-right: 20px;">iswprint(<i>wc</i>)</td> <td>Tests whether <i>wc</i> is a wide-character code representing a character of class "print" in the program's current locale.</td> </tr> </table>	iswalpha(<i>wc</i>)	Tests whether <i>wc</i> is a wide-character code representing a character of class "alpha" in the program's current locale.	iswupper(<i>wc</i>)	Tests whether <i>wc</i> is a wide-character code representing a character of class "upper" in the program's current locale.	iswlower(<i>wc</i>)	Tests whether <i>wc</i> is a wide-character code representing a character of class "lower" in the program's current locale.	iswdigit(<i>wc</i>)	Tests whether <i>wc</i> is a wide-character code representing a character of class "digit" in the program's current locale.	iswxdigit(<i>wc</i>)	Tests whether <i>wc</i> is a wide-character code representing a character of class "xdigit" in the program's current locale.	iswalnum(<i>wc</i>)	Tests whether <i>wc</i> is a wide-character code representing a character of class "alpha" or "digit" in the program's current locale.	iswspace(<i>wc</i>)	Tests whether <i>wc</i> is a wide-character code representing a character of class "space" in the program's current locale.	iswpunct(<i>wc</i>)	Tests whether <i>wc</i> is a wide-character code representing a character of class "punct" in the program's current locale.	iswprint(<i>wc</i>)	Tests whether <i>wc</i> is a wide-character code representing a character of class "print" in the program's current locale.
iswalpha(<i>wc</i>)	Tests whether <i>wc</i> is a wide-character code representing a character of class "alpha" in the program's current locale.																		
iswupper(<i>wc</i>)	Tests whether <i>wc</i> is a wide-character code representing a character of class "upper" in the program's current locale.																		
iswlower(<i>wc</i>)	Tests whether <i>wc</i> is a wide-character code representing a character of class "lower" in the program's current locale.																		
iswdigit(<i>wc</i>)	Tests whether <i>wc</i> is a wide-character code representing a character of class "digit" in the program's current locale.																		
iswxdigit(<i>wc</i>)	Tests whether <i>wc</i> is a wide-character code representing a character of class "xdigit" in the program's current locale.																		
iswalnum(<i>wc</i>)	Tests whether <i>wc</i> is a wide-character code representing a character of class "alpha" or "digit" in the program's current locale.																		
iswspace(<i>wc</i>)	Tests whether <i>wc</i> is a wide-character code representing a character of class "space" in the program's current locale.																		
iswpunct(<i>wc</i>)	Tests whether <i>wc</i> is a wide-character code representing a character of class "punct" in the program's current locale.																		
iswprint(<i>wc</i>)	Tests whether <i>wc</i> is a wide-character code representing a character of class "print" in the program's current locale.																		

iswlower(3C)

<code>iswgraph(<i>wc</i>)</code>	Tests whether <i>wc</i> is a wide-character code representing a character of class "graph" in the program's current locale.
<code>iswcntrl(<i>wc</i>)</code>	Tests whether <i>wc</i> is a wide-character code representing a character of class "cntrl" in the program's current locale.
<code>iswascii(<i>wc</i>)</code>	Tests whether <i>wc</i> is a wide-character code representing an ASCII character.
<code>isphonogram(<i>wc</i>)</code>	Tests whether <i>wc</i> is a wide-character code representing a phonetic language character, excluding ASCII characters.
<code>isideogram(<i>wc</i>)</code>	Tests whether <i>wc</i> is a wide-character code representing an ideographic language character, excluding ASCII characters.
<code>isenglish(<i>wc</i>)</code>	Tests whether <i>wc</i> is a wide-character code representing an English language character, excluding ASCII characters.
<code>isnumber(<i>wc</i>)</code>	Tests whether <i>wc</i> is a wide-character code representing digit [0–9], excluding ASCII characters.
<code>isspecial(<i>wc</i>)</code>	Tests whether <i>wc</i> is a wide-character code representing a special language character, excluding ASCII characters.

SYNOPSIS	<pre>#include <wchar.h> int iswalpha(wint_t <i>wc</i>);</pre>																		
DESCRIPTION	<p>These functions test whether <i>wc</i> is a wide-character code representing a character of a particular class defined in the LC_CTYPE category of the current locale.</p> <p>In all cases, <i>wc</i> is a wint_t, the value of which must be a wide-character code corresponding to a valid character in the current locale or must equal the value of the macro WEOF. If the argument has any other values, the behavior is undefined.</p> <table border="0" style="width: 100%;"> <tr> <td style="vertical-align: top; padding-right: 20px;">iswalpha(<i>wc</i>)</td> <td>Tests whether <i>wc</i> is a wide-character code representing a character of class "alpha" in the program's current locale.</td> </tr> <tr> <td style="vertical-align: top; padding-right: 20px;">iswupper(<i>wc</i>)</td> <td>Tests whether <i>wc</i> is a wide-character code representing a character of class "upper" in the program's current locale.</td> </tr> <tr> <td style="vertical-align: top; padding-right: 20px;">iswlower(<i>wc</i>)</td> <td>Tests whether <i>wc</i> is a wide-character code representing a character of class "lower" in the program's current locale.</td> </tr> <tr> <td style="vertical-align: top; padding-right: 20px;">iswdigit(<i>wc</i>)</td> <td>Tests whether <i>wc</i> is a wide-character code representing a character of class "digit" in the program's current locale.</td> </tr> <tr> <td style="vertical-align: top; padding-right: 20px;">iswxdigit(<i>wc</i>)</td> <td>Tests whether <i>wc</i> is a wide-character code representing a character of class "xdigit" in the program's current locale.</td> </tr> <tr> <td style="vertical-align: top; padding-right: 20px;">iswalnum(<i>wc</i>)</td> <td>Tests whether <i>wc</i> is a wide-character code representing a character of class "alpha" or "digit" in the program's current locale.</td> </tr> <tr> <td style="vertical-align: top; padding-right: 20px;">iswspace(<i>wc</i>)</td> <td>Tests whether <i>wc</i> is a wide-character code representing a character of class "space" in the program's current locale.</td> </tr> <tr> <td style="vertical-align: top; padding-right: 20px;">iswpunct(<i>wc</i>)</td> <td>Tests whether <i>wc</i> is a wide-character code representing a character of class "punct" in the program's current locale.</td> </tr> <tr> <td style="vertical-align: top; padding-right: 20px;">iswprint(<i>wc</i>)</td> <td>Tests whether <i>wc</i> is a wide-character code representing a character of class "print" in the program's current locale.</td> </tr> </table>	iswalpha(<i>wc</i>)	Tests whether <i>wc</i> is a wide-character code representing a character of class "alpha" in the program's current locale.	iswupper(<i>wc</i>)	Tests whether <i>wc</i> is a wide-character code representing a character of class "upper" in the program's current locale.	iswlower(<i>wc</i>)	Tests whether <i>wc</i> is a wide-character code representing a character of class "lower" in the program's current locale.	iswdigit(<i>wc</i>)	Tests whether <i>wc</i> is a wide-character code representing a character of class "digit" in the program's current locale.	iswxdigit(<i>wc</i>)	Tests whether <i>wc</i> is a wide-character code representing a character of class "xdigit" in the program's current locale.	iswalnum(<i>wc</i>)	Tests whether <i>wc</i> is a wide-character code representing a character of class "alpha" or "digit" in the program's current locale.	iswspace(<i>wc</i>)	Tests whether <i>wc</i> is a wide-character code representing a character of class "space" in the program's current locale.	iswpunct(<i>wc</i>)	Tests whether <i>wc</i> is a wide-character code representing a character of class "punct" in the program's current locale.	iswprint(<i>wc</i>)	Tests whether <i>wc</i> is a wide-character code representing a character of class "print" in the program's current locale.
iswalpha(<i>wc</i>)	Tests whether <i>wc</i> is a wide-character code representing a character of class "alpha" in the program's current locale.																		
iswupper(<i>wc</i>)	Tests whether <i>wc</i> is a wide-character code representing a character of class "upper" in the program's current locale.																		
iswlower(<i>wc</i>)	Tests whether <i>wc</i> is a wide-character code representing a character of class "lower" in the program's current locale.																		
iswdigit(<i>wc</i>)	Tests whether <i>wc</i> is a wide-character code representing a character of class "digit" in the program's current locale.																		
iswxdigit(<i>wc</i>)	Tests whether <i>wc</i> is a wide-character code representing a character of class "xdigit" in the program's current locale.																		
iswalnum(<i>wc</i>)	Tests whether <i>wc</i> is a wide-character code representing a character of class "alpha" or "digit" in the program's current locale.																		
iswspace(<i>wc</i>)	Tests whether <i>wc</i> is a wide-character code representing a character of class "space" in the program's current locale.																		
iswpunct(<i>wc</i>)	Tests whether <i>wc</i> is a wide-character code representing a character of class "punct" in the program's current locale.																		
iswprint(<i>wc</i>)	Tests whether <i>wc</i> is a wide-character code representing a character of class "print" in the program's current locale.																		

iswupper(3C)

<code>iswgraph(<i>wc</i>)</code>	Tests whether <i>wc</i> is a wide-character code representing a character of class "graph" in the program's current locale.
<code>iswcntrl(<i>wc</i>)</code>	Tests whether <i>wc</i> is a wide-character code representing a character of class "cntrl" in the program's current locale.
<code>iswascii(<i>wc</i>)</code>	Tests whether <i>wc</i> is a wide-character code representing an ASCII character.
<code>isphonogram(<i>wc</i>)</code>	Tests whether <i>wc</i> is a wide-character code representing a phonetic language character, excluding ASCII characters.
<code>isideogram(<i>wc</i>)</code>	Tests whether <i>wc</i> is a wide-character code representing an ideographic language character, excluding ASCII characters.
<code>isenglish(<i>wc</i>)</code>	Tests whether <i>wc</i> is a wide-character code representing an English language character, excluding ASCII characters.
<code>isnumber(<i>wc</i>)</code>	Tests whether <i>wc</i> is a wide-character code representing digit [0–9], excluding ASCII characters.
<code>isspecial(<i>wc</i>)</code>	Tests whether <i>wc</i> is a wide-character code representing a special language character, excluding ASCII characters.

NAME	ctype, isdigit, isxdigit, islower, isupper, isalpha, isalnum, isspace, iscntrl, ispunct, isprint, isgraph, isascii – character handling		
SYNOPSIS	<pre>#include <ctype.h> int isalpha(int c); int isupper(int c); int islower(int c); int isdigit(int c); int isxdigit(int c); int isalnum(int c); int isspace(int c); int ispunct(int c); int isprint(int c); int isgraph(int c); int iscntrl(int c); int isascii(int c);</pre>		
DESCRIPTION	<p>These macros classify character-coded integer values. Each is a predicate returning non-zero for true, 0 for false. The behavior of these macros, except <code>isascii()</code>, is affected by the current locale (see <code>setlocale(3C)</code>). To modify the behavior, change the <code>LC_TYPE</code> category in <code>setlocale()</code>, that is, <code>setlocale(LC_CTYPE, newlocale)</code>. In the "C" locale, or in a locale where character type information is not defined, characters are classified according to the rules of the US-ASCII 7-bit coded character set.</p> <p>The macro <code>isascii()</code> is defined on all integer values; the rest are defined only where the argument is an <code>int</code>, the value of which is representable as an unsigned <code>char</code>, or <code>EOF</code>, which is defined by the <code><stdio.h></code> header and represents end-of-file.</p> <p>Functions exist for all the macros defined below. To get the function form, the macro name must be undefined (for example, <code>#undef isdigit</code>).</p> <p>For macros described with Default and Standard conforming versions, standard-conforming behavior will be provided for standard-conforming applications (see <code>standards(5)</code>) and for applications that define <code>__XPG4_CHAR_CLASS__</code> before including <code><ctype.h></code>.</p>		
Default	<table border="0"> <tr> <td style="padding-right: 20px;"><code>isalpha()</code></td> <td>Tests for any character for which <code>isupper()</code> or <code>islower()</code> is true.</td> </tr> </table>	<code>isalpha()</code>	Tests for any character for which <code>isupper()</code> or <code>islower()</code> is true.
<code>isalpha()</code>	Tests for any character for which <code>isupper()</code> or <code>islower()</code> is true.		
Standard conforming	<table border="0"> <tr> <td style="padding-right: 20px;"><code>isalpha()</code></td> <td>Tests for any character for which <code>isupper()</code> or <code>islower()</code> is true, or any character that is one of the current locale-defined set of characters for which none of <code>iscntrl()</code>, <code>isdigit()</code>,</td> </tr> </table>	<code>isalpha()</code>	Tests for any character for which <code>isupper()</code> or <code>islower()</code> is true, or any character that is one of the current locale-defined set of characters for which none of <code>iscntrl()</code> , <code>isdigit()</code> ,
<code>isalpha()</code>	Tests for any character for which <code>isupper()</code> or <code>islower()</code> is true, or any character that is one of the current locale-defined set of characters for which none of <code>iscntrl()</code> , <code>isdigit()</code> ,		

isxdigit(3C)

		ispunct(), or isspace() is true. In "C" locale, isalpha() returns true only for the characters for which isupper() or islower() is true.
	isupper()	Tests for any character that is an upper-case letter or is one of the current locale-defined set of characters for which none of iscntrl(), isdigit(), ispunct(), isspace(), or islower() is true. In the "C" locale, isupper() returns true only for the characters defined as upper-case ASCII characters.
	islower()	Tests for any character that is a lower-case letter or is one of the current locale-defined set of characters for which none of iscntrl(), isdigit(), ispunct(), isspace(), or isupper() is true. In the "C" locale, islower() returns true only for the characters defined as lower-case ASCII characters.
	isdigit()	Tests for any decimal-digit character.
Default	isxdigit()	Tests for any hexadecimal-digit character ([0-9], [A-F], or [a-f]).
Standard conforming	isxdigit()	Tests for any hexadecimal-digit character ([0-9], [A-F], or [a-f] or the current locale-defined sets of characters representing the hexadecimal digits 10 to 15 inclusive). In the "C" locale, only 0 1 2 3 4 5 6 7 8 9 A B C D E F a b c d e f are included.
	isalnum()	Tests for any character for which isalpha() or isdigit() is true (letter or digit).
	isspace()	Tests for any space, tab, carriage-return, newline, vertical-tab or form-feed (standard white-space characters) or for one of the current locale-defined set of characters for which isalnum() is false. In the C locale, isspace() returns true only for the standard white-space characters.
	ispunct()	Tests for any printing character which is neither a space (" ") nor a character for which isalnum() or iscntrl() is true.
Default	isprint()	Tests for any character for which ispunct(), isupper(), islower(), isdigit(), and the space character (" ") is true.
Standard conforming	isprint()	Tests for any character for which iscntrl() is false, and isalnum(), isgraph(), ispunct(), the space character (" "), and the characters in the current locale-defined "print" class are true.
Default	isgraph()	Tests for any character for which ispunct(), isupper(), islower(), and isdigit() is true.

isxdigit(3C)

Standard conforming

`isgraph()` Tests for any character for which `isalnum()` and `ispunct()` are true, or any character in the current locale-defined "graph" class which is neither a space (" ") nor a character for which `iscntrl()` is true.

`iscntrl()` Tests for any "control character" as defined by the character set.

`isascii()` Tests for any ASCII character, code between 0 and 0177 inclusive.

RETURN VALUES

If the argument to any of the character handling macros is not in the domain of the function, the result is undefined. Otherwise, the macro/function will return non-zero if the classification is TRUE, and 0 for FALSE.

USAGE

The `isdigit()`, `isxdigit()`, `islower()`, `isupper()`, `isalpha()`, `isalnum()`, `isspace()`, `iscntrl()`, `ispunct()`, `isprint()`, `isgraph()`, and `isascii()` macros can be used safely in multithreaded applications, as long as `setlocale(3C)` is not being called to change the locale.

jrands48(3C)

NAME	drand48, erand48, lrand48, nrand48, mrand48, jrands48, srand48, seed48, lcong48 – generate uniformly distributed pseudo-random numbers
SYNOPSIS	<pre>#include <stdlib.h> double drand48(void); double erand48(unsigned short <i>x_i[3]</i>); long lrand48(void); long nrand48(unsigned short <i>x_i[3]</i>); long mrands48(void); long jrands48(unsigned short <i>x_i[3]</i>); void srand48(long <i>seedval</i>); unsigned short *seed48(unsigned short <i>seed16v[3]</i>); void lcong48(unsigned short <i>param[7]</i>);</pre>
DESCRIPTION	<p>This family of functions generates pseudo-random numbers using the well-known linear congruential algorithm and 48-bit integer arithmetic.</p> <p>Functions <code>drand48()</code> and <code>erand48()</code> return non-negative double-precision floating-point values uniformly distributed over the interval [0.0, 1.0).</p> <p>Functions <code>lrand48()</code> and <code>nrand48()</code> return non-negative long integers uniformly distributed over the interval $[0, 2^{31}]$.</p> <p>Functions <code>mrands48()</code> and <code>jrands48()</code> return signed long integers uniformly distributed over the interval $[-2^{31}, 2^{31}]$.</p> <p>Functions <code>srand48()</code>, <code>seed48()</code>, and <code>lcong48()</code> are initialization entry points, one of which should be invoked before either <code>drand48()</code>, <code>lrand48()</code>, or <code>mrands48()</code> is called. (Although it is not recommended practice, constant default initializer values will be supplied automatically if <code>drand48()</code>, <code>lrand48()</code>, or <code>mrands48()</code> is called without a prior call to an initialization entry point.) Functions <code>erand48()</code>, <code>nrand48()</code>, and <code>jrands48()</code> do not require an initialization entry point to be called first.</p> <p>All the routines work by generating a sequence of 48-bit integer values, X_i, according to the linear congruential formula</p> $X_{n+1} = (aX_n + c) \bmod m \quad n \geq 0.$ <p>The parameter $m = 2^{48}$; hence 48-bit integer arithmetic is performed. Unless <code>lcong48()</code> has been invoked, the multiplier value a and the addend value c are given by</p> $a = 5DEECE66D_{16} = 273673163155_8$

$c = B_{16} = 13_8$.

The value returned by any of the functions `drand48()`, `erand48()`, `lrand48()`, `nrand48()`, `mrnd48()`, or `jrand48()` is computed by first generating the next 48-bit X_i in the sequence. Then the appropriate number of bits, according to the type of data item to be returned, are copied from the high-order (leftmost) bits of X_i and transformed into the returned value.

The functions `drand48()`, `lrand48()`, and `mrnd48()` store the last 48-bit X_i generated in an internal buffer. X_i must be initialized prior to being invoked. The functions `erand48()`, `nrand48()`, and `jrand48()` require the calling program to provide storage for the successive X_i values in the array specified as an argument when the functions are invoked. These routines do not have to be initialized; the calling program must place the desired initial value of X_i into the array and pass it as an argument. By using different arguments, functions `erand48()`, `nrand48()`, and `jrand48()` allow separate modules of a large program to generate several *independent* streams of pseudo-random numbers, that is, the sequence of numbers in each stream will *not* depend upon how many times the routines have been called to generate numbers for the other streams.

The initializer function `srand48()` sets the high-order 32 bits of X_i to the 32 bits contained in its argument. The low-order 16 bits of X_i are set to the arbitrary value $330E_{16}$.

The initializer function `seed48()` sets the value of X_i to the 48-bit value specified in the argument array. In addition, the previous value of X_i is copied into a 48-bit internal buffer, used only by `seed48()`, and a pointer to this buffer is the value returned by `seed48()`. This returned pointer, which can just be ignored if not needed, is useful if a program is to be restarted from a given point at some future time — use the pointer to get at and store the last X_i value, and then use this value to reinitialize using `seed48()` when the program is restarted.

The initialization function `lcng48()` allows the user to specify the initial X_i , the multiplier value a , and the addend value c . Argument array elements `param[0-2]` specify X_i , `param[3-5]` specify the multiplier a , and `param[6]` specifies the 16-bit addend c . After `lcng48()` has been called, a subsequent call to either `srand48()` or `seed48()` will restore the “standard” multiplier and addend values, a and c , specified above.

killpg(3C)

NAME	killpg – send signal to a process group						
SYNOPSIS	<pre>#include <signal.h> int killpg(pid_t <i>pgrp</i>, int <i>sig</i>);</pre>						
DESCRIPTION	<p>The <code>killpg()</code> function sends the signal <i>sig</i> to the process group <i>pgrp</i>. See <code>signal(3HEAD)</code> for a list of signals.</p> <p>The real or effective user ID of the sending process must match the real or saved set-user ID of the receiving process, unless the effective user ID of the sending process is the privileged user. A single exception is the signal <code>SIGCONT</code>, which may always be sent to any descendant of the current process.</p>						
RETURN VALUES	Upon successful completion, 0 is returned. Otherwise, -1 is returned and <code>errno</code> is set to indicate the error.						
ERRORS	The <code>killpg()</code> function will fail and no signal will be sent if:						
	<table><tr><td><code>EINVAL</code></td><td>The <i>sig</i> argument is not a valid signal number.</td></tr><tr><td><code>EPERM</code></td><td>The effective user ID of the sending process is not privileged user, and neither its real nor effective user ID matches the real or saved set-user ID of one or more of the target processes.</td></tr><tr><td><code>ESRCH</code></td><td>No processes were found in the specified process group.</td></tr></table>	<code>EINVAL</code>	The <i>sig</i> argument is not a valid signal number.	<code>EPERM</code>	The effective user ID of the sending process is not privileged user, and neither its real nor effective user ID matches the real or saved set-user ID of one or more of the target processes.	<code>ESRCH</code>	No processes were found in the specified process group.
<code>EINVAL</code>	The <i>sig</i> argument is not a valid signal number.						
<code>EPERM</code>	The effective user ID of the sending process is not privileged user, and neither its real nor effective user ID matches the real or saved set-user ID of one or more of the target processes.						
<code>ESRCH</code>	No processes were found in the specified process group.

NAME a64l, l64a – convert between long integer and base-64 ASCII string

SYNOPSIS

```
#include <stdlib.h>
long a64l(const char *s);
char *l64a(long l);
```

DESCRIPTION These functions maintain numbers stored in base-64 ASCII characters that define a notation by which long integers can be represented by up to six characters. Each character represents a “digit” in a radix-64 notation.

The characters used to represent “digits” are as follows:

Character	Digit
.	0
/	1
0-9	2-11
A-Z	12-37
a-z	38-63

The `a64l()` function takes a pointer to a null-terminated base-64 representation and returns a corresponding `long` value. If the string pointed to by `s` contains more than six characters, `a64l()` uses the first six.

The `a64l()` function scans the character string from left to right with the least significant digit on the left, decoding each character as a 6-bit radix-64 number.

The `l64a()` function takes a `long` argument and returns a pointer to the corresponding base-64 representation. If the argument is 0, `l64a()` returns a pointer to a null string.

The value returned by `l64a()` is a pointer into a static buffer, the contents of which are overwritten by each call. In the case of multithreaded applications, the return value is a pointer to thread specific data.

labs(3C)

NAME abs, labs, llabs – return absolute value of integer

SYNOPSIS #include <stdlib.h>
int **abs**(int *val*);
long **labs**(long *lval*);
long long **llabs**(long long *llval*);

DESCRIPTION The `abs()` function returns the absolute value of its int operand.
The `labs()` function returns the absolute value of its long operand.
The `llabs()` function returns the absolute value of its long long operand.

USAGE In 2's-complement representation, the absolute value of the largest magnitude negative integral value is undefined.

NAME lckpwnf, ulckpwnf – manipulate shadow password database lock file

SYNOPSIS #include <shadow.h>

```
int lckpwnf(void);
int ulckpwnf(void);
```

DESCRIPTION The lckpwnf() and ulckpwnf() functions enable modification access to the password databases through the lock file. A process first uses lckpwnf() to lock the lock file, thereby gaining exclusive rights to modify the /etc/passwd or /etc/shadow password database. See passwd(4) and shadow(4). Upon completing modifications, a process should release the lock on the lock file using ulckpwnf(). This mechanism prevents simultaneous modification of the password databases. The lock file, /etc/.pwd.lock, is used to coordinate modification access to the password databases /etc/passwd and /etc/shadow.

RETURN VALUES If lckpwnf() is successful in locking the file within 15 seconds, it returns 0. If unsuccessful (for example, /etc/.pwd.lock is already locked), it returns -1.

If ulckpwnf() is successful in unlocking the file /etc/.pwd.lock, it returns 0. If unsuccessful (for example, /etc/.pwd.lock is already unlocked), it returns -1.

USAGE These routines are for internal use only; compatibility is not guaranteed.

FILES

/etc/passwd	password database
/etc/shadow	shadow password database
/etc/.pwd.lock	lock file

lcong48(3C)

NAME	drand48, erand48, lrand48, nrand48, mrand48, jrand48, srand48, seed48, lcong48 – generate uniformly distributed pseudo-random numbers
SYNOPSIS	<pre>#include <stdlib.h> double drand48(void); double erand48(unsigned short <i>x_i[3]</i>); long lrand48(void); long nrand48(unsigned short <i>x_i[3]</i>); long mrand48(void); long jrand48(unsigned short <i>x_i[3]</i>); void srand48(long <i>seedval</i>); unsigned short *seed48(unsigned short <i>seed16v[3]</i>); void lcong48(unsigned short <i>param[7]</i>);</pre>
DESCRIPTION	<p>This family of functions generates pseudo-random numbers using the well-known linear congruential algorithm and 48-bit integer arithmetic.</p> <p>Functions <code>drand48()</code> and <code>erand48()</code> return non-negative double-precision floating-point values uniformly distributed over the interval [0.0, 1.0).</p> <p>Functions <code>lrand48()</code> and <code>nrand48()</code> return non-negative long integers uniformly distributed over the interval $[0, 2^{31}]$.</p> <p>Functions <code>mrand48()</code> and <code>jrand48()</code> return signed long integers uniformly distributed over the interval $[-2^{31}, 2^{31}]$.</p> <p>Functions <code>srand48()</code>, <code>seed48()</code>, and <code>lcong48()</code> are initialization entry points, one of which should be invoked before either <code>drand48()</code>, <code>lrand48()</code>, or <code>mrand48()</code> is called. (Although it is not recommended practice, constant default initializer values will be supplied automatically if <code>drand48()</code>, <code>lrand48()</code>, or <code>mrand48()</code> is called without a prior call to an initialization entry point.) Functions <code>erand48()</code>, <code>nrand48()</code>, and <code>jrand48()</code> do not require an initialization entry point to be called first.</p> <p>All the routines work by generating a sequence of 48-bit integer values, X_i, according to the linear congruential formula</p> $X_{n+1} = (aX_n + c) \bmod m \quad n \geq 0.$ <p>The parameter $m = 2^{48}$; hence 48-bit integer arithmetic is performed. Unless <code>lcong48()</code> has been invoked, the multiplier value a and the addend value c are given by</p> $a = 5DEECE66D_{16} = 273673163155_8$

$c = B_{16} = 13_8$.

The value returned by any of the functions `drand48()`, `erand48()`, `lrand48()`, `nrand48()`, `rand48()`, or `jrand48()` is computed by first generating the next 48-bit X_i in the sequence. Then the appropriate number of bits, according to the type of data item to be returned, are copied from the high-order (leftmost) bits of X_i and transformed into the returned value.

The functions `drand48()`, `lrand48()`, and `rand48()` store the last 48-bit X_i generated in an internal buffer. X_i must be initialized prior to being invoked. The functions `erand48()`, `nrand48()`, and `jrand48()` require the calling program to provide storage for the successive X_i values in the array specified as an argument when the functions are invoked. These routines do not have to be initialized; the calling program must place the desired initial value of X_i into the array and pass it as an argument. By using different arguments, functions `erand48()`, `nrand48()`, and `jrand48()` allow separate modules of a large program to generate several *independent* streams of pseudo-random numbers, that is, the sequence of numbers in each stream will *not* depend upon how many times the routines have been called to generate numbers for the other streams.

The initializer function `srand48()` sets the high-order 32 bits of X_i to the 32 bits contained in its argument. The low-order 16 bits of X_i are set to the arbitrary value $330E_{16}$.

The initializer function `seed48()` sets the value of X_i to the 48-bit value specified in the argument array. In addition, the previous value of X_i is copied into a 48-bit internal buffer, used only by `seed48()`, and a pointer to this buffer is the value returned by `seed48()`. This returned pointer, which can just be ignored if not needed, is useful if a program is to be restarted from a given point at some future time — use the pointer to get at and store the last X_i value, and then use this value to reinitialize using `seed48()` when the program is restarted.

The initialization function `lcong48()` allows the user to specify the initial X_i , the multiplier value a , and the addend value c . Argument array elements `param[0-2]` specify X_i , `param[3-5]` specify the multiplier a , and `param[6]` specifies the 16-bit addend c . After `lcong48()` has been called, a subsequent call to either `srand48()` or `seed48()` will restore the “standard” multiplier and addend values, a and c , specified above.

NAME	div, ldiv, lldiv – compute the quotient and remainder				
SYNOPSIS	<pre>#include <stdlib.h> div_t div(int <i>numer</i>, int <i>denom</i>); ldiv_t ldiv(long int <i>numer</i>, long int <i>denom</i>); lldiv_t lldiv(long long <i>numer</i>, long long <i>denom</i>);</pre>				
DESCRIPTION	<p>The <code>div()</code> function computes the quotient and remainder of the division of the numerator <i>numer</i> by the denominator <i>denom</i>. It provides a well-defined semantics for the signed integral division and remainder operations, unlike the implementation-defined semantics of the built-in operations. The sign of the resulting quotient is that of the algebraic quotient, and if the division is inexact, the magnitude of the resulting quotient is the largest integer less than the magnitude of the algebraic quotient. If the result cannot be represented, the behavior is undefined; otherwise, <i>quotient * denom + remainder</i> will equal <i>numer</i>.</p> <p>The <code>ldiv()</code> and <code>lldiv()</code> functions are similar to <code>div()</code>, except that the arguments and the members of the returned structure are different. The <code>ldiv()</code> function returns a structure of type <code>ldiv_t</code> and has type <code>long int</code>. The <code>lldiv()</code> function returns a structure of type <code>lldiv_t</code> and has type <code>long long</code>.</p>				
RETURN VALUES	<p>The <code>div()</code> function returns a structure of type <code>div_t</code>, comprising both the quotient and remainder:</p> <pre>int quot; /*quotient*/ int rem; /*remainder*/</pre> <p>The <code>ldiv()</code> function returns a structure of type <code>ldiv_t</code> and <code>lldiv()</code> returns a structure of type <code>lldiv_t</code>, comprising both the quotient and remainder:</p> <pre>long int quot; /*quotient*/ long int rem; /*remainder*/</pre>

lfind(3C)

NAME	lsearch, lfind – linear search and update
SYNOPSIS	<pre>#include <search.h> void *lsearch(const void *key, void *base, size_t *nelp, size_t width, int (*compar) (const void *, const void *)); void *lfind(const void *key, const void *base, size_t *nelp, size_t width, int (*compar) (const void *, const void *));</pre>
DESCRIPTION	<p>The <code>lsearch()</code> function is a linear search routine generalized from Knuth (6.1) Algorithm S. (See <i>The Art of Computer Programming, Volume 3, Section 6.1, by Donald E. Knuth.</i>) It returns a pointer into a table indicating where a datum may be found. If the datum does not occur, it is added at the end of the table. The <code>key</code> argument points to the datum to be sought in the table. The <code>base</code> argument points to the first element in the table. The <code>nelp</code> argument points to an integer containing the current number of elements in the table. The integer is incremented if the datum is added to the table. The <code>width</code> argument is the size of an element in bytes. The <code>compar</code> argument is a pointer to the comparison function that the user must supply (<code>strcmp(3C)</code> for example). It is called with two arguments that point to the elements being compared. The function must return zero if the elements are equal and non-zero otherwise.</p> <p>The <code>lfind()</code> function is the same as <code>lsearch()</code> except that if the datum is not found, it is not added to the table. Instead, a null pointer is returned.</p> <p>It is important to note the following:</p> <ul style="list-style-type: none">■ the pointers to the key and the element at the base of the table may be pointers to any type.■ The comparison function need not compare every byte, so arbitrary data may be contained in the elements in addition to the values being compared.■ The value returned should be cast into type pointer-to-element.
RETURN VALUES	If the searched-for datum is found, both <code>lsearch()</code> and <code>lfind()</code> return a pointer to it. Otherwise, <code>lfind()</code> returns <code>NULL</code> and <code>lsearch()</code> returns a pointer to the newly added element.
USAGE	Undefined results can occur if there is not enough room in the table to add a new item.
EXAMPLES	<p>EXAMPLE 1 A sample code using the <code>lsearch()</code> function.</p> <p>This program will read in less than <code>TABSIZE</code> strings of length less than <code>ELSIZE</code> and store them in a table, eliminating duplicates, and then will print each entry.</p> <pre>#include <search.h> #include <string.h> #include <stdlib.h> #include <stdio.h> #define TABSIZE 50 #define ELSIZE 120</pre>

EXAMPLE 1 A sample code using the `lsearch()` function. (Continued)

```
main( )
{
    char line[ELSIZE];          /* buffer to hold input string */
    char tab[TABSIZE][ELSIZE]; /* table of strings */
    size_t nel = 0;            /* number of entries in tab */
    int i;

    while (fgets(line, ELSIZE, stdin) != NULL &&
           nel < TABSIZE)
        (void) lsearch(line, tab, &nel, ELSIZE, mycmp);
    for( i = 0; i < nel; i++ )
        (void) fputs(tab[i], stdout);
    return 0;
}
```

lfmt(3C)

NAME	lfmt – display error message in standard format and pass to logging and monitoring services
SYNOPSIS	<pre>#include <pfmt.h> int lfmt(FILE *stream, long flags, char *format, ... /* arg* */);</pre>
DESCRIPTION	<p>The <code>lfmt()</code> function retrieves a format string from a locale-specific message database (unless <code>MM_NOGET</code> is specified) and uses it for <code>printf(3C)</code> style formatting of <i>args</i>. The output is displayed on <i>stream</i>. If <i>stream</i> is <code>NULL</code> no output is displayed.</p> <p>The <code>lfmt()</code> function encapsulates the output in the standard error message format (unless <code>MM_NOSTD</code> is specified, in which case the output is like that of <code>printf()</code>). It forwards its output to the logging and monitoring facility, even if <i>stream</i> is <code>NULL</code>. Optionally, <code>lfmt()</code> displays the output on the console with a date and time stamp.</p> <p>If the <code>printf()</code> format string is to be retrieved from a message database, the <i>format</i> argument must have the following structure:</p> <pre><catalog> : <msgnum> : <defmsg>.</pre> <p>If <code>MM_NOGET</code> is specified, only the <i><defmsg></i> field must be specified.</p> <p>The <i><catalog></i> field indicates the message database that contains the localized version of the format string. This field is limited to 14 characters selected from a set of all characters values, excluding the null character (<code>\0</code>) and the ASCII codes for slash (<code>/</code>) and colon (<code>:</code>).</p> <p>The <i><msgnum></i> field is a positive number that indicates the index of the string into the message database.</p> <p>If the catalog does not exist in the locale (specified by the last call to <code>setlocale(3C)</code> using the <code>LC_ALL</code> or <code>LC_MESSAGES</code> categories), or if the message number is out of bound, <code>lfmt()</code> will attempt to retrieve the message from the C locale. If this second retrieval fails, <code>lfmt()</code> uses the <i><defmsg></i> field of the <i>format</i> argument.</p> <p>If <i><catalog></i> is omitted, <code>lfmt()</code> will attempt to retrieve the string from the default catalog specified by the last call to <code>setcat(3C)</code>. In this case, the <i>format</i> argument has the following structure:</p> <pre>: <msgnum> : <defmsg>.</pre> <p>The <code>lfmt()</code> function will output the message</p> <pre>Message not found!!\n</pre> <p>as the format string if <i><catalog></i> is not a valid catalog name, if no catalog is specified (either explicitly or with <code>setcat()</code>), if <i><msgnum></i> is not a valid number, or if no message could be retrieved from the message databases and <i><defmsg></i> was omitted.</p>

The *flags* argument determines the type of output (whether the `format` should be interpreted as it is or be encapsulated in the standard message format) and the access to message catalogs to retrieve a localized version of `format`.

The *flags* argument is composed of several groups, and can take the following values (one from each group):

Output format control

MM_NOSTD	Do not use the standard message format but interpret <code>format</code> as a <code>printf()</code> format. Only <i>catalog access control flags</i> , <i>console display control</i> and <i>logging information</i> should be specified if MM_NOSTD is used; all other flags will be ignored.
MM_STD	Output using the standard message format (default value is 0).

Catalog access control

MM_NOGET	Do not retrieve a localized version of <code>format</code> . In this case, only the <code><defmsg></code> field of <code>format</code> is specified.
MM_GET	Retrieve a localized version of <code>format</code> from <code><catalog></code> , using <code><msgid></code> as the index and <code><defmsg></code> as the default message (default value is 0).

Severity (standard message format only)

MM_HALT	Generate a localized version of HALT, but donot halt the machine.
MM_ERROR	Generate a localized version of ERROR (default value is 0).
MM_WARNING	Generate a localized version of WARNING.
MM_INFO	Generate a localized version of INFO.

Additional severities can be defined with the `addsev(3C)` function, using number-string pairs with numeric values in the range [5-255]. The specified severity is formed by the bitwise OR operation of the numeric value and other *flags* arguments.

If the severity is not defined, `lfmt()` uses the string `SEV=N` where `N` is the integer severity value passed in *flags*.

Multiple severities passed in *flags* will not be detected as an error. Any combination of severities will be summed and the numeric value will cause the display of either a severity string (if defined) or the string `SEV=N` (if undefined).

Action

MM_ACTION	Specify an action message. Any severity value is superseded and replaced by a localized version of TO FIX.
-----------	--

lfmt(3C)

Console display control

- MM_CONSOLE** Display the message to the console in addition to the specified *stream*.
- MM_NOCONSOLE** Do not display the message to the console in addition to the specified *stream* (default value is 0).

Logging information

Major classification

Identify the source of the condition. Identifiers are: **MM_HARD** (hardware), **MM_SOFT** (software), and **MM_FIRM** (firmware).

Message source subclassification

Identify the type of software in which the problem is spotted. Identifiers are: **MM_APPL** (application), **MM_UTIL** (utility), and **MM_OPYSYS** (operating system).

STANDARD ERROR MESSAGE FORMAT

The `lfmt()` function displays error messages in the following format:

label: *severity*: *text*

If no *label* was defined by a call to `setLabel(3C)`, the message is displayed in the format:

severity: *text*

If `lfmt()` is called twice to display an error message and a helpful *action* or recovery message, the output may appear as follows:

label: *severity*: *text*

label: TO FIX: *text*

RETURN VALUES

Upon successful completion, `lfmt()` returns the number of bytes transmitted. Otherwise, it returns a negative value:

- 1 Write the error to *stream*.
- 2 Cannot log and/or display at console.

USAGE

Since `lfmt()` uses `gettext(3C)`, it is recommended that `lfmt()` not be used.

EXAMPLES

EXAMPLE 1 The following example

```
setLabel("UX:test");
lfmt(stderr, MM_ERROR|MM_CONSOLE|MM_SOFT|MM_UTIL,
      "test:2:Cannot open file: %s\n", strerror(errno));
```

displays the message to `stderr` and to the console and makes it available for logging:

```
UX:test: ERROR: Cannot open file: No such file or directory
```

EXAMPLE 2 The following example

```
setLabel("UX:test");
lfmt(stderr, MM_INFO|MM_SOFT|MM_UTIL,
      "test:23:test facility is enabled\n");
```

EXAMPLE 2 The following example *(Continued)*

displays the message to `stderr` and makes it available for logging:

```
UX:test: INFO: test facility enabled
```

llabs(3C)

NAME abs, labs, llabs – return absolute value of integer

SYNOPSIS

```
#include <stdlib.h>
int abs(int val);
long labs(long lval);
long long llabs(long long llval);
```

DESCRIPTION The `abs()` function returns the absolute value of its `int` operand.
The `labs()` function returns the absolute value of its `long` operand.
The `llabs()` function returns the absolute value of its `long long` operand.

USAGE In 2's-complement representation, the absolute value of the largest magnitude negative integral value is undefined.

lltostr(3C)

NAME	strtol, strtoll, atol, atoll, atoi, lltostr, ulltostr – string conversion routines
SYNOPSIS	<pre>#include <stdlib.h> long strtol(const char *str, char **endptr, int base); long long strtoll(const char *str, char **endptr, int base); long atol(const char *str); long long atoll(const char *str); int atoi(const char *str); char *lltostr(long long value, char *endptr); char *ulltostr(unsigned long long value, char *endptr);</pre>
strtol() and strtoll()	<p>The <code>strtol()</code> function converts the initial portion of the string pointed to by <code>str</code> to a type long int representation.</p> <p>The <code>strtoll()</code> function converts the initial portion of the string pointed to by <code>str</code> to a type long long representation.</p> <p>Both functions first decompose the input string into three parts: an initial, possibly empty, sequence of white-space characters (as specified by <code>isspace(3C)</code>); a subject sequence interpreted as an integer represented in some radix determined by the value of <code>base</code>; and a final string of one or more unrecognized characters, including the terminating null byte of the input string. They then attempt to convert the subject sequence to an integer and return the result.</p> <p>If the value of <code>base</code> is 0, the expected form of the subject sequence is that of a decimal constant, octal constant or hexadecimal constant, any of which may be preceded by a + or – sign. A decimal constant begins with a non-zero digit, and consists of a sequence of decimal digits. An octal constant consists of the prefix 0 optionally followed by a sequence of the digits 0 to 7 only. A hexadecimal constant consists of the prefix 0x or 0X followed by a sequence of the decimal digits and letters a (or A) to f (or F) with values 10 to 15 respectively.</p> <p>If the value of <code>base</code> is between 2 and 36, the expected form of the subject sequence is a sequence of letters and digits representing an integer with the radix specified by <code>base</code>, optionally preceded by a + or – sign. The letters from a (or A) to z (or Z) inclusive are ascribed the values 10 to 35; only letters whose ascribed values are less than that of <code>base</code> are permitted. If the value of <code>base</code> is 16, the characters 0x or 0X may optionally precede the sequence of letters and digits, following the sign if present.</p> <p>The subject sequence is defined as the longest initial subsequence of the input string, starting with the first non-white-space character, that is of the expected form. The subject sequence contains no characters if the input string is empty or consists entirely of white-space characters, or if the first non-white-space character is other than a sign or a permissible letter or digit.</p>

If the subject sequence has the expected form and the value of *base* is 0, the sequence of characters starting with the first digit is interpreted as an integer constant. If the subject sequence has the expected form and the value of *base* is between 2 and 36, it is used as the base for conversion, ascribing to each letter its value as given above. If the subject sequence begins with a minus sign, the value resulting from the conversion is negated. A pointer to the final string is stored in the object pointed to by *endptr*, provided that *endptr* is not a null pointer.

In other than the POSIX locale, additional implementation-dependent subject sequence forms may be accepted.

If the subject sequence is empty or does not have the expected form, no conversion is performed; the value of *str* is stored in the object pointed to by *endptr*, provided that *endptr* is not a null pointer.

`atol()`, `atoll()`
and `atoi()`

Except for behavior on error, `atol()` is equivalent to: `strtol(str, (char **)NULL, 10)`.

Except for behavior on error, `atoll()` is equivalent to: `strtoll(str, (char **)NULL, 10)`.

Except for behavior on error, `atoi()` is equivalent to: `(int) strtol(str, (char **)NULL, 10)`.

`lltostr()` and
`ulltostr()`

The `lltostr()` function returns a pointer to the string represented by the long long *value*. The *endptr* argument is assumed to point to the byte following a storage area into which the decimal representation of *value* is to be placed as a string. The `lltostr()` function converts *value* to decimal and produces the string, and returns a pointer to the beginning of the string. No leading zeros are produced, and no terminating null is produced. The low-order digit of the result always occupies memory position *endptr*-1. The behavior of `lltostr()` is undefined if *value* is negative. A single zero digit is produced if *value* is 0.

The `ulltostr()` function is similar to `lltostr()` except that *value* is an unsigned long long.

RETURN VALUES

Upon successful completion, `strtol()`, `strtoll()`, `atol()`, `atoll()`, and `atoi()` return the converted value, if any. If no conversion could be performed, `strtol()` and `strtoll()` return 0 and `errno` may be set to `EINVAL`.

If the correct value is outside the range of representable values, `strtol()` returns `LONG_MAX` or `LONG_MIN` and `strtoll()` returns `LLONG_MAX` or `LLONG_MIN` (according to the sign of the value), and `errno` is set to `ERANGE`.

Upon successful completion, `lltostr()` and `ulltostr()` return a pointer to the converted string.

ERRORS

The `strtol()` and `strtoll()` functions will fail if:

`ERANGE` The value to be returned is not representable. The `strtol()` and `strtoll()` functions may fail if:

ltostr(3C)

EINVAL The value of *base* is not supported.

USAGE Because 0, LONG_MIN, LONG_MAX, LLONG_MIN, and LLONG_MAX are returned on error and are also valid returns on success, an application wishing to check for error situations should set `errno` to 0, call the function, then check `errno` and if it is non-zero, assume an error has occurred.

The `strtol()` function no longer accepts values greater than LONG_MAX or LLONG_MAX as valid input. Use `strtoul(3C)` instead.

NAME	localeconv – get numeric formatting information				
SYNOPSIS	<pre>#include <locale.h> struct lconv *localeconv(void);</pre>				
DESCRIPTION	<p>The <code>localeconv()</code> function sets the components of an object with type <code>struct lconv</code> (defined in <code><locale.h></code>) with the values appropriate for the formatting of numeric quantities (monetary and otherwise) according to the rules of the current locale (see <code>setlocale(3C)</code>). The definition of <code>struct lconv</code> is given below (the values for the fields in the “C” locale are given in comments).</p> <pre>char *decimal_point; /* "." */ char *thousands_sep; /* "" (zero length string) */ char *grouping; /* "" */ char *int_curr_symbol; /* "" */ char *currency_symbol; /* "" */ char *mon_decimal_point; /* "" */ char *mon_thousands_sep; /* "" */ char *mon_grouping; /* "" */ char *positive_sign; /* "" */ char *negative_sign; /* "" */ char int_frac_digits; /* CHAR_MAX */ char frac_digits; /* CHAR_MAX */ char p_cs_precedes; /* CHAR_MAX */ char p_sep_by_space; /* CHAR_MAX */ char n_cs_precedes; /* CHAR_MAX */ char n_sep_by_space; /* CHAR_MAX */ char p_sign_posn; /* CHAR_MAX */ char n_sign_posn; /* CHAR_MAX */</pre> <p>The members of the structure with type <code>char *</code> are strings, any of which (except <code>decimal_point</code>) can point to a null string (<code>""</code>), to indicate that the value is not available in the current locale or is of zero length. The members with type <code>char</code> are non-negative numbers, any of which can be <code>CHAR_MAX</code> (defined in the <code><limits.h></code> header) to indicate that the value is not available in the current locale. The members are the following:</p> <pre>char *decimal_point The decimal-point character used to format non-monetary quantities.</pre> <pre>char *thousands_sep The character used to separate groups of digits to the left of the decimal-point character in formatted non-monetary quantities.</pre> <pre>char *grouping A string in which each element is taken as an integer that indicates the number of digits that comprise the current group in a formatted non-monetary quantity. The elements of <code>grouping</code> are interpreted according to the following:</pre> <table border="0" style="margin-left: 20px;"> <tr> <td style="padding-right: 20px;"><code>CHAR_MAX</code></td> <td>No further grouping is to be performed.</td> </tr> <tr> <td><code>0</code></td> <td>The previous element is to be repeatedly used for the remainder of the digits.</td> </tr> </table>	<code>CHAR_MAX</code>	No further grouping is to be performed.	<code>0</code>	The previous element is to be repeatedly used for the remainder of the digits.
<code>CHAR_MAX</code>	No further grouping is to be performed.				
<code>0</code>	The previous element is to be repeatedly used for the remainder of the digits.				

localeconv(3C)

<i>other</i>	The value is the number of digits that comprise the current group. The next element is examined to determine the size of the next group of digits to the left of the current group.
<code>char *int_curr_symbol</code>	The international currency symbol applicable to the current locale, left-justified within a four-character space-padded field. The character sequences should match with those specified in <i>ISO 4217 Codes for the Representation of Currency and Funds</i> .
<code>char *currency_symbol</code>	The local currency symbol applicable to the current locale.
<code>char *mon_decimal_point</code>	The decimal point used to format monetary quantities.
<code>char *mon_thousands_sep</code>	The separator for groups of digits to the left of the decimal point in formatted monetary quantities.
<code>char *mon_grouping</code>	A string in which each element is taken as an integer that indicates the number of digits that comprise the current group in a formatted monetary quantity. The elements of <code>mon_grouping</code> are interpreted according to the rules described under grouping.
<code>char *positive_sign</code>	The string used to indicate a non-negative-valued formatted monetary quantity.
<code>char *negative_sign</code>	The string used to indicate a negative-valued formatted monetary quantity.
<code>char int_frac_digits</code>	The number of fractional digits (those to the right of the decimal point) to be displayed in an internationally formatted monetary quantity.
<code>char frac_digits</code>	The number of fractional digits (those to the right of the decimal point) to be displayed in a formatted monetary quantity.
<code>char p_cs_precedes</code>	Set to 1 or 0 if the <code>currency_symbol</code> respectively precedes or succeeds the value for a non-negative formatted monetary quantity.
<code>char p_sep_by_space</code>	Set to 1 or 0 if the <code>currency_symbol</code> respectively is or is not separated by a space from the value for a non-negative formatted monetary quantity.
<code>char n_cs_precedes</code>	Set to 1 or 0 if the <code>currency_symbol</code> respectively precedes or succeeds the value for a negative formatted monetary quantity.
<code>char n_sep_by_space</code>	Set to 1 or 0 if the <code>currency_symbol</code> respectively is or is not separated by a space from the value for a negative formatted monetary quantity.

char p_sign_posn

Set to a value indicating the positioning of the `positive_sign` for a non-negative formatted monetary quantity. The value of `p_sign_posn` is interpreted according to the following:

- 0 Parentheses surround the quantity and `currency_symbol`.
- 1 The sign string precedes the quantity and `currency_symbol`.
- 2 The sign string succeeds the quantity and `currency_symbol`.
- 3 The sign string immediately precedes the `currency_symbol`.
- 4 The sign string immediately succeeds the `currency_symbol`.

char n_sign_posn

Set to a value indicating the positioning of the `negative_sign` for a negative formatted monetary quantity. The value of `n_sign_posn` is interpreted according to the rules described under `p_sign_posn`.

RETURN VALUES

The `localeconv()` function returns a pointer to the filled-in object. The structure pointed to by the return value may be overwritten by a subsequent call to `localeconv()`.

USAGE

The `localeconv()` function can be used safely in multithreaded applications, as long as `setlocale(3C)` is not being called to change the locale.

EXAMPLES

EXAMPLE 1 Rules used by four countries to format monetary quantities.

The following table illustrates the rules used by four countries to format monetary quantities.

Country	Positive format	Negative format	International format
Italy	L.1.234	-1.1.234	ITL.1.234
Netherlands	F 1.234,56	F -1.234,56	NLG 1.234,56
Norway	kr1.234,56	kr1.234,56-	NOK 1.234,56
Switzerland	SFrs.1,234.56	SFrs.1,234.56C	CHF 1,234.56

For these four countries, the respective values for the monetary members of the structure returned by `localeconv()` are as follows:

	Italy	Netherlands	Norway	Switzerland
<code>int_curr_symbol</code>	"ITL."	"NLG "	"NOK "	"CHF "
<code>currency_symbol</code>	"L."	"F"	"kr"	"SFrs."

localeconv(3C)

mon_decimal_point	","	","	":"
mon_thousands_sep	."	."	,"
mon_grouping	"\3"	"\3"	"\3"
positive_sign	""	""	""
negative_sign	"-"	"-"	"C"
int_frac_digits	2	2	2
frac_digits	0	2	2
p_cs_precedes	1	1	1
p_sep_by_space	0	0	0
n_cs_precedes	1	1	1
n_sep_by_space	0	0	0
p_sign_posn	1	1	1
n_sign_posn	1	2	2

NAME	ctime, ctime_r, localtime, localtime_r, gmtime, gmtime_r, asctime, asctime_r, tzset – convert date and time to string
SYNOPSIS	<pre>#include <time.h> char *ctime(const time_t *clock); struct tm *localtime(const time_t *clock); struct tm *gmtime(const time_t *clock); char *asctime(const struct tm *tm); extern time_t timezone, altzone; extern int daylight; extern char *tzname[2]; void tzset(void); char *ctime_r(const time_t *clock, char *buf, int buflen); struct tm *localtime_r(const time_t *clock, struct tm *res); struct tm *gmtime_r(const time_t *clock, struct tm *res); char *asctime_r(const struct tm *tm, char *buf, int buflen);</pre>
POSIX	<pre>cc [flag...] file... -D_POSIX_PTHREAD_SEMANTICS [library...] char *ctime_r(const time_t *clock, char *buf); char *asctime_r(const struct tm *tm, char *buf);</pre>
DESCRIPTION	<p>The <code>ctime()</code> function converts the time pointed to by <code>clock</code>, representing the time in seconds since the Epoch (00:00:00 UTC, January 1, 1970), to local time in the form of a 26-character string, as shown below. Time zone and daylight savings corrections are made before string generation. The fields are in constant width:</p> <pre>Fri Sep 13 00:00:00 1986\n\0</pre> <p>The <code>ctime()</code> function is equivalent to:</p> <pre>asctime(localtime(clock))</pre> <p>The <code>ctime()</code>, <code>asctime()</code>, <code>gmtime()</code>, and <code>localtime()</code> functions return values in one of two static objects: a broken-down time structure and an array of <code>char</code>. Execution of any of the functions can overwrite the information returned in either of these objects by any of the other functions.</p> <p>The <code>ctime_r()</code> function has the same functionality as <code>ctime()</code> except that the caller must supply a buffer <code>buf</code> with length <code>buflen</code> to store the result; <code>buf</code> must be at least 26 bytes. The POSIX <code>ctime_r()</code> function does not take a <code>buflen</code> parameter.</p>

localtime(3C)

The `localtime()` and `gmtime()` functions return pointers to `tm` structures (see below). The `localtime()` function corrects for the main time zone and possible alternate (“daylight savings”) time zone; the `gmtime()` function converts directly to Coordinated Universal Time (UTC), which is what the UNIX system uses internally.

The `localtime_r()` and `gmtime_r()` functions have the same functionality as `localtime()` and `gmtime()` respectively, except that the caller must supply a buffer *res* to store the result.

The `asctime()` function converts a `tm` structure to a 26-character string, as shown in the previous example, and returns a pointer to the string.

The `asctime_r()` function has the same functionality as `asctime()` except that the caller must supply a buffer *buf* with length *buflen* for the result to be stored. The *buf* argument must be at least 26 bytes. The POSIX `asctime_r()` function does not take a *buflen* parameter. The `asctime_r()` function returns a pointer to *buf* upon success. In case of failure, `NULL` is returned and `errno` is set.

Declarations of all the functions and externals, and the `tm` structure, are in the `<time.h>` header. The members of the `tm` structure are:

```
int    tm_sec;    /* seconds after the minute - [0, 61] */
        /* for leap seconds */
int    tm_min;    /* minutes after the hour - [0, 59] */
int    tm_hour;   /* hour since midnight - [0, 23] */
int    tm_mday;   /* day of the month - [1, 31] */
int    tm_mon;    /* months since January - [0, 11] */
int    tm_year;   /* years since 1900 */
int    tm_wday;   /* days since Sunday - [0, 6] */
int    tm_yday;   /* days since January 1 - [0, 365] */
int    tm_isdst;  /* flag for alternate daylight savings time */
```

The value of `tm_isdst` is positive if daylight savings time is in effect, zero if daylight savings time is not in effect, and negative if the information is not available. Previously, the value of `tm_isdst` was defined as non-zero if daylight savings was in effect.

The external `time_t` variable `altzone` contains the difference, in seconds, between Coordinated Universal Time and the alternate time zone. The external variable `timezone` contains the difference, in seconds, between UTC and local standard time. The external variable `daylight` indicates whether time should reflect daylight savings time. Both `timezone` and `altzone` default to 0 (UTC). The external variable `daylight` is non-zero if an alternate time zone exists. The time zone names are contained in the external variable `tzname`, which by default is set to:

```
char *tzname[2] = { "GMT", "" };
```

These functions know about the peculiarities of this conversion for various time periods for the U.S. (specifically, the years 1974, 1975, and 1987). They start handling the new daylight savings time starting with the first Sunday in April, 1987.

The `tzset()` function uses the contents of the environment variable `TZ` to override the value of the different external variables. It is called by `asctime()` and can also be called by the user. See `environ(5)` for a description of the `TZ` environment variable.

Starting and ending times are relative to the current local time zone. If the alternate time zone start and end dates and the time are not provided, the days for the United States that year will be used and the time will be 2 AM. If the start and end dates are provided but the time is not provided, the time will be 2 AM. The effects of `tzset()` change the values of the external variables `timezone`, `altzone`, `daylight`, and `tzname`.

Note that in most installations, `TZ` is set to the correct value by default when the user logs on, using the local `/etc/default/init` file (see `TIMEZONE(4)`).

ERRORS The `ctime_r()` and `asctime_r()` functions will fail if:

ERANGE The length of the buffer supplied by the caller is not large enough to store the result.

USAGE These functions do not support localized date and time formats. The `strftime(3C)` function can be used when localization is required.

The `localtime()`, `localtime_r()`, `gmtime()`, `gmtime_r()`, `ctime()`, and `ctime_r()` functions assume Gregorian dates. Times before the adoption of the Gregorian calendar will not match historical records.

EXAMPLES **EXAMPLE 1** Examples of the `tzset()` function.

The `tzset()` function scans the contents of the environment variable and assigns the different fields to the respective variable. For example, the most complete setting for New Jersey in 1986 could be:

```
EST5EDT4,116/2:00:00,298/2:00:00
```

or simply

```
EST5EDT
```

An example of a southern hemisphere setting such as the Cook Islands could be

```
KDT9:30KST10:00,63/5:00,302/20:00
```

In the longer version of the New Jersey example of `TZ`, `tzname[0]` is `EST`, `timezone` is set to `5*60*60`, `tzname[1]` is `EDT`, `altzone` is set to `4*60*60`, the starting date of the alternate time zone is the 117th day at 2 AM, the ending date of the alternate time zone is the 299th day at 2 AM (using zero-based Julian days), and `daylight` is set positive. Starting and ending times are relative to the current local time zone. If the alternate time zone start and end dates and the time are not provided, the days for the United States that year will be used and the time will be 2 AM. If the start and end dates are provided but the time is not provided, the time will be 2 AM. The effects of `tzset()` are thus to change the values of the external variables `timezone`, `altzone`, `daylight`, and `tzname`. The `ctime()`, `localtime()`, `mktime()`, and `strftime()` functions also update these external variables as if they had called `tzset()` at the

localtime(3C)

EXAMPLE 1 Examples of the `tzset()` function. (Continued)

time specified by the `time_t` or `struct tm` value that they are converting.

BUGS The `zoneinfo` timezone data files do not transition past Tue Jan 19 03:14:07 2038 UTC. Therefore for 64-bit applications using `zoneinfo` timezones, calculations beyond this date might not use the correct offset from standard time, and could return incorrect values. This affects the 64-bit version of `localtime()`, `localtime_r()`, `ctime()`, and `ctime_r()`.

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
MT-Level	MT-Safe with exceptions
CSI	Enabled

SEE ALSO `time(2)`, `Intro(3)`, `getenv(3C)`, `mktime(3C)`, `printf(3C)`, `putenv(3C)`, `setlocale(3C)`, `strftime(3C)`, `TIMEZONE(4)`, `attributes(5)`, `environ(5)`

NOTES When compiling multithreaded programs, see `Intro(3)`, *Notes On Multithreaded Applications*.

The return values for `ctime()`, `localtime()`, and `gmtime()` point to static data whose content is overwritten by each call.

Setting the time during the interval of change from `timezone` to `altzone` or vice versa can produce unpredictable results. The system administrator must change the Julian start and end days annually.

The `asctime()`, `ctime()`, `gmtime()`, and `localtime()` functions are unsafe in multithread applications. The `asctime_r()` and `gmtime_r()` functions are MT-Safe. The `ctime_r()`, `localtime_r()`, and `tzset()` functions are MT-Safe in multithread applications, as long as no user-defined function directly modifies one of the following variables: `timezone`, `altzone`, `daylight`, and `tzname`. These four variables are not MT-Safe to access. They are modified by the `tzset()` function in an MT-Safe manner. The `mktime()`, `localtime_r()`, and `ctime_r()` functions call `tzset()`.

Solaris 2.4 and earlier releases provided definitions of the `ctime_r()`, `localtime_r()`, `gmtime_r()`, and `asctime_r()` functions as specified in POSIX.1c Draft 6. The final POSIX.1c standard changed the interface for `ctime_r()` and `asctime_r()`. Support for the Draft 6 interface is provided for compatibility only and might not be supported in future releases. New applications and libraries should use the POSIX standard interface.

For POSIX.1c-compliant applications, the `_POSIX_PTHREAD_SEMANTICS` and `_REENTRANT` flags are automatically turned on by defining the `_POSIX_C_SOURCE` flag with a value `>= 199506L`.

localtime_r(3C)

NAME	<code>ctime, ctime_r, localtime, localtime_r, gmtime, gmtime_r, asctime, asctime_r, tzset</code> – convert date and time to string
SYNOPSIS	<pre>#include <time.h> char *ctime(const time_t *<i>clock</i>); struct tm *localtime(const time_t *<i>clock</i>); struct tm *gmtime(const time_t *<i>clock</i>); char *asctime(const struct tm *<i>tm</i>); extern time_t <i>timezone</i>, <i>altzone</i>; extern int <i>daylight</i>; extern char *<i>tzname</i>[2]; void tzset(void); char *ctime_r(const time_t *<i>clock</i>, char *<i>buf</i>, int <i>buflen</i>); struct tm *localtime_r(const time_t *<i>clock</i>, struct tm *<i>res</i>); struct tm *gmtime_r(const time_t *<i>clock</i>, struct tm *<i>res</i>); char *asctime_r(const struct tm *<i>tm</i>, char *<i>buf</i>, int <i>buflen</i>);</pre>
POSIX	<pre>cc [<i>flag...</i>] <i>file...</i> -D_POSIX_THREAD_SEMANTICS [<i>library...</i>] char *ctime_r(const time_t *<i>clock</i>, char *<i>buf</i>); char *asctime_r(const struct tm *<i>tm</i>, char *<i>buf</i>);</pre>
DESCRIPTION	<p>The <code>ctime()</code> function converts the time pointed to by <code>clock</code>, representing the time in seconds since the Epoch (00:00:00 UTC, January 1, 1970), to local time in the form of a 26-character string, as shown below. Time zone and daylight savings corrections are made before string generation. The fields are in constant width:</p> <pre>Fri Sep 13 00:00:00 1986\n\0</pre> <p>The <code>ctime()</code> function is equivalent to:</p> <pre>asctime(localtime(<i>clock</i>))</pre> <p>The <code>ctime()</code>, <code>asctime()</code>, <code>gmtime()</code>, and <code>localtime()</code> functions return values in one of two static objects: a broken-down time structure and an array of <code>char</code>. Execution of any of the functions can overwrite the information returned in either of these objects by any of the other functions.</p> <p>The <code>ctime_r()</code> function has the same functionality as <code>ctime()</code> except that the caller must supply a buffer <code>buf</code> with length <code>buflen</code> to store the result; <code>buf</code> must be at least 26 bytes. The POSIX <code>ctime_r()</code> function does not take a <code>buflen</code> parameter.</p>

The `localtime()` and `gmtime()` functions return pointers to `tm` structures (see below). The `localtime()` function corrects for the main time zone and possible alternate (“daylight savings”) time zone; the `gmtime()` function converts directly to Coordinated Universal Time (UTC), which is what the UNIX system uses internally.

The `localtime_r()` and `gmtime_r()` functions have the same functionality as `localtime()` and `gmtime()` respectively, except that the caller must supply a buffer *res* to store the result.

The `asctime()` function converts a `tm` structure to a 26-character string, as shown in the previous example, and returns a pointer to the string.

The `asctime_r()` function has the same functionality as `asctime()` except that the caller must supply a buffer *buf* with length *buflen* for the result to be stored. The *buf* argument must be at least 26 bytes. The POSIX `asctime_r()` function does not take a *buflen* parameter. The `asctime_r()` function returns a pointer to *buf* upon success. In case of failure, `NULL` is returned and `errno` is set.

Declarations of all the functions and externals, and the `tm` structure, are in the `<time.h>` header. The members of the `tm` structure are:

```
int    tm_sec;    /* seconds after the minute - [0, 61] */
        /* for leap seconds */
int    tm_min;    /* minutes after the hour - [0, 59] */
int    tm_hour;   /* hour since midnight - [0, 23] */
int    tm_mday;   /* day of the month - [1, 31] */
int    tm_mon;    /* months since January - [0, 11] */
int    tm_year;   /* years since 1900 */
int    tm_wday;   /* days since Sunday - [0, 6] */
int    tm_yday;   /* days since January 1 - [0, 365] */
int    tm_isdst;  /* flag for alternate daylight savings time */
```

The value of `tm_isdst` is positive if daylight savings time is in effect, zero if daylight savings time is not in effect, and negative if the information is not available. Previously, the value of `tm_isdst` was defined as non-zero if daylight savings was in effect.

The external `time_t` variable `altzone` contains the difference, in seconds, between Coordinated Universal Time and the alternate time zone. The external variable `timezone` contains the difference, in seconds, between UTC and local standard time. The external variable `daylight` indicates whether time should reflect daylight savings time. Both `timezone` and `altzone` default to 0 (UTC). The external variable `daylight` is non-zero if an alternate time zone exists. The time zone names are contained in the external variable `tzname`, which by default is set to:

```
char *tzname[2] = { "GMT", "" };
```

These functions know about the peculiarities of this conversion for various time periods for the U.S. (specifically, the years 1974, 1975, and 1987). They start handling the new daylight savings time starting with the first Sunday in April, 1987.

localtime_r(3C)

The `tzset()` function uses the contents of the environment variable `TZ` to override the value of the different external variables. It is called by `asctime()` and can also be called by the user. See `environ(5)` for a description of the `TZ` environment variable.

Starting and ending times are relative to the current local time zone. If the alternate time zone start and end dates and the time are not provided, the days for the United States that year will be used and the time will be 2 AM. If the start and end dates are provided but the time is not provided, the time will be 2 AM. The effects of `tzset()` change the values of the external variables `timezone`, `altzone`, `daylight`, and `tzname`.

Note that in most installations, `TZ` is set to the correct value by default when the user logs on, using the local `/etc/default/init` file (see `TIMEZONE(4)`).

ERRORS The `ctime_r()` and `asctime_r()` functions will fail if:

ERANGE The length of the buffer supplied by the caller is not large enough to store the result.

USAGE These functions do not support localized date and time formats. The `strftime(3C)` function can be used when localization is required.

The `localtime()`, `localtime_r()`, `gmtime()`, `gmtime_r()`, `ctime()`, and `ctime_r()` functions assume Gregorian dates. Times before the adoption of the Gregorian calendar will not match historical records.

EXAMPLES **EXAMPLE 1** Examples of the `tzset()` function.

The `tzset()` function scans the contents of the environment variable and assigns the different fields to the respective variable. For example, the most complete setting for New Jersey in 1986 could be:

```
EST5EDT4,116/2:00:00,298/2:00:00
```

or simply

```
EST5EDT
```

An example of a southern hemisphere setting such as the Cook Islands could be

```
KDT9:30KST10:00,63/5:00,302/20:00
```

In the longer version of the New Jersey example of `TZ`, `tzname[0]` is `EST`, `timezone` is set to `5*60*60`, `tzname[1]` is `EDT`, `altzone` is set to `4*60*60`, the starting date of the alternate time zone is the 117th day at 2 AM, the ending date of the alternate time zone is the 299th day at 2 AM (using zero-based Julian days), and `daylight` is set positive. Starting and ending times are relative to the current local time zone. If the alternate time zone start and end dates and the time are not provided, the days for the United States that year will be used and the time will be 2 AM. If the start and end dates are provided but the time is not provided, the time will be 2 AM. The effects of `tzset()` are thus to change the values of the external variables `timezone`, `altzone`, `daylight`, and `tzname`. The `ctime()`, `localtime()`, `mktime()`, and `strftime()` functions also update these external variables as if they had called `tzset()` at the

EXAMPLE 1 Examples of the `tzset()` function. (Continued)

time specified by the `time_t` or `struct tm` value that they are converting.

BUGS The `zoneinfo` timezone data files do not transition past Tue Jan 19 03:14:07 2038 UTC. Therefore for 64-bit applications using `zoneinfo` timezones, calculations beyond this date might not use the correct offset from standard time, and could return incorrect values. This affects the 64-bit version of `localtime()`, `localtime_r()`, `ctime()`, and `ctime_r()`.

SEE ALSO `time(2)`, `Intro(3)`, `getenv(3C)`, `mktime(3C)`, `printf(3C)`, `putenv(3C)`, `setlocale(3C)`, `strftime(3C)`, `TIMEZONE(4)`, `attributes(5)`, `environ(5)`

NOTES When compiling multithreaded programs, see `Intro(3)`, *Notes On Multithreaded Applications*.

The return values for `ctime()`, `localtime()`, and `gmtime()` point to static data whose content is overwritten by each call.

Setting the time during the interval of change from `timezone` to `altzone` or vice versa can produce unpredictable results. The system administrator must change the Julian start and end days annually.

The `asctime()`, `ctime()`, `gmtime()`, and `localtime()` functions are unsafe in multithread applications. The `asctime_r()` and `gmtime_r()` functions are MT-Safe. The `ctime_r()`, `localtime_r()`, and `tzset()` functions are MT-Safe in multithread applications, as long as no user-defined function directly modifies one of the following variables: `timezone`, `altzone`, `daylight`, and `tzname`. These four variables are not MT-Safe to access. They are modified by the `tzset()` function in an MT-Safe manner. The `mktime()`, `localtime_r()`, and `ctime_r()` functions call `tzset()`.

Solaris 2.4 and earlier releases provided definitions of the `ctime_r()`, `localtime_r()`, `gmtime_r()`, and `asctime_r()` functions as specified in POSIX.1c Draft 6. The final POSIX.1c standard changed the interface for `ctime_r()` and `asctime_r()`. Support for the Draft 6 interface is provided for compatibility only and might not be supported in future releases. New applications and libraries should use the POSIX standard interface.

localtime_r(3C)

For POSIX.1c-compliant applications, the `_POSIX_PTHREAD_SEMANTICS` and `_REENTRANT` flags are automatically turned on by defining the `_POSIX_C_SOURCE` flag with a value `>= 199506L`.

NAME	lockf – record locking on files
SYNOPSIS	<pre>#include <unistd.h> int lockf(int <i>fildes</i>, int <i>function</i>, off_t <i>size</i>);</pre>
DESCRIPTION	<p>The <code>lockf()</code> function allows sections of a file to be locked; advisory or mandatory write locks depending on the mode bits of the file (see <code>chmod(2)</code>). Locking calls from other processes that attempt to lock the locked file section will either return an error value or be put to sleep until the resource becomes unlocked. All the locks for a process are removed when the process terminates. See <code>fcntl(2)</code> for more information about record locking.</p> <p>The <i>fildes</i> argument is an open file descriptor. The file descriptor must have <code>O_WRONLY</code> or <code>O_RDWR</code> permission in order to establish locks with this function call.</p> <p>The <i>function</i> argument is a control value that specifies the action to be taken. The permissible values for <i>function</i> are defined in <code><unistd.h></code> as follows:</p> <pre>#define F_ULOCK 0 /* unlock previously locked section */ #define F_LOCK 1 /* lock section for exclusive use */ #define F_TLOCK 2 /* test & lock section for exclusive use */ #define F_TEST 3 /* test section for other locks */</pre> <p>All other values of <i>function</i> are reserved for future extensions and will result in an error if not implemented.</p> <p><code>F_TEST</code> is used to detect if a lock by another process is present on the specified section. <code>F_LOCK</code> and <code>F_TLOCK</code> both lock a section of a file if the section is available. <code>F_ULOCK</code> removes locks from a section of the file.</p> <p>The <i>size</i> argument is the number of contiguous bytes to be locked or unlocked. The resource to be locked or unlocked starts at the current offset in the file and extends forward for a positive <i>size</i> and backward for a negative <i>size</i> (the preceding bytes up to but not including the current offset). If <i>size</i> is zero, the section from the current offset through the largest file offset is locked (that is, from the current offset through the present or any future end-of-file). An area need not be allocated to the file in order to be locked as such locks may exist past the end-of-file.</p> <p>The sections locked with <code>F_LOCK</code> or <code>F_TLOCK</code> may, in whole or in part, contain or be contained by a previously locked section for the same process. Locked sections will be unlocked starting at the the point of the offset through <i>size</i> bytes or to the end of file if <i>size</i> is <code>(off_t) 0</code>. When this situation occurs, or if this situation occurs in adjacent sections, the sections are combined into a single section. If the request requires that a new element be added to the table of active locks and this table is already full, an error is returned, and the new section is not locked.</p> <p><code>F_LOCK</code> and <code>F_TLOCK</code> requests differ only by the action taken if the resource is not available. <code>F_LOCK</code> will cause the calling process to sleep until the resource is available. <code>F_TLOCK</code> will cause the function to return a <code>-1</code> and set <code>errno</code> to <code>EAGAIN</code> if the section is already locked by another process.</p>

lockf(3C)

File locks are released on first close by the locking process of any file descriptor for the file.

`F_ULOCK` requests may, in whole or in part, release one or more locked sections controlled by the process. When sections are not fully released, the remaining sections are still locked by the process. Releasing the center section of a locked section requires an additional element in the table of active locks. If this table is full, an `errno` is set to `EDEADLK` and the requested section is not released.

An `F_ULOCK` request in which `size` is non-zero and the offset of the last byte of the requested section is the maximum value for an object of type `off_t`, when the process has an existing lock in which `size` is 0 and which includes the last byte of the requested section, will be treated as a request to unlock from the start of the requested section with a size equal to 0. Otherwise, an `F_ULOCK` request will attempt to unlock only the requested section.

A potential for deadlock occurs if a process controlling a locked resource is put to sleep by requesting another process's locked resource. Thus calls to `lockf()` or `fcntl(2)` scan for a deadlock prior to sleeping on a locked resource. An error return is made if sleeping on the locked resource would cause a deadlock.

Sleeping on a resource is interrupted with any signal. The `alarm(2)` function may be used to provide a timeout facility in applications that require this facility.

RETURN VALUES

Upon successful completion, 0 is returned. Otherwise, -1 is returned and `errno` is set to indicate the error.

ERRORS

The `lockf()` function will fail if:

<code>EBADF</code>	The <i>fildevs</i> argument is not a valid open file descriptor; or <i>function</i> is <code>F_LOCK</code> or <code>F_TLOCK</code> and <i>fildevs</i> is not a valid file descriptor open for writing.
<code>EACCES</code> or <code>EAGAIN</code>	The <i>function</i> argument is <code>F_TLOCK</code> or <code>F_TEST</code> and the section is already locked by another process.
<code>EDEADLK</code>	The <i>function</i> argument is <code>F_LOCK</code> and a deadlock is detected.
<code>EINTR</code>	A signal was caught during execution of the function.
<code>ECOMM</code>	The <i>fildevs</i> argument is on a remote machine and the link to that machine is no longer active.
<code>EINVAL</code>	The <i>function</i> argument is not one of <code>F_LOCK</code> , <code>F_TLOCK</code> , <code>F_TEST</code> , or <code>F_ULOCK</code> ; or <i>size</i> plus the current file offset is less than 0.
<code>EOVERFLOW</code>	The offset of the first, or if <i>size</i> is not 0 then the last, byte in the requested section cannot be represented correctly in an object of type <code>off_t</code> .

The `lockf()` function may fail if:

EAGAIN	The function argument is <code>F_LOCK</code> or <code>F_TLOCK</code> and the file is mapped with <code>mmap(2)</code> .
EDEADLK or ENOLCK	The function argument is <code>F_LOCK</code> , <code>F_TLOCK</code> , or <code>F_ULOCK</code> , and the request would cause the number of locks to exceed a system-imposed limit.
EOPNOTSUPP or EINVAL	The locking of files of the type indicated by the <i>files</i> argument is not supported.

USAGE Record-locking should not be used in combination with the `fopen(3C)`, `fread(3C)`, `fwrite(3C)` and other `stdio` functions. Instead, the more primitive, non-buffered functions (such as `open(2)`) should be used. Unexpected results may occur in processes that do buffering in the user address space. The process may later read/write data which is/was locked. The `stdio` functions are the most common source of unexpected buffering.

The `alarm(2)` function may be used to provide a timeout facility in applications requiring it.

The `lockf()` function has a transitional interface for 64-bit file offsets. See `lf64(5)`.

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
MT-Level	MT-Safe

SEE ALSO `intro(2)`, `alarm(2)`, `chmod(2)`, `close(2)`, `creat(2)`, `fcntl(2)`, `mmap(2)`, `open(2)`, `read(2)`, `write(2)`, `attributes(5)`, `lf64(5)`

`_longjmp(3C)`

NAME	<code>_longjmp, _setjmp</code> – non-local goto
SYNOPSIS	<pre>#include <setjmp.h> void _longjmp(jmp_buf env, int val); int _setjmp(jmp_buf env);</pre>
DESCRIPTION	<p>The <code>_longjmp()</code> and <code>_setjmp()</code> functions are identical to <code>longjmp(3C)</code> and <code>setjmp(3C)</code>, respectively, with the additional restriction that <code>_longjmp()</code> and <code>_setjmp()</code> do not manipulate the signal mask.</p> <p>If <code>_longjmp()</code> is called even though <code>env</code> was never initialized by a call to <code>_setjmp()</code>, or when the last such call was in a function that has since returned, the results are undefined.</p>
RETURN VALUES	Refer to <code>longjmp(3C)</code> and <code>setjmp(3C)</code> .
ERRORS	No errors are defined.
USAGE	<p>If <code>_longjmp()</code> is executed and the environment in which <code>_setjmp()</code> was executed no longer exists, errors can occur. The conditions under which the environment of the <code>_setjmp()</code> no longer exists include exiting the function that contains the <code>_setjmp()</code> call, and exiting an inner block with temporary storage. This condition might not be detectable, in which case the <code>_longjmp()</code> occurs and, if the environment no longer exists, the contents of the temporary storage of an inner block are unpredictable. This condition might also cause unexpected process termination. If the function has returned, the results are undefined.</p> <p>Passing <code>longjmp()</code> a pointer to a buffer not created by <code>setjmp()</code>, passing <code>_longjmp()</code> a pointer to a buffer not created by <code>_setjmp()</code>, passing <code>siglongjmp(3C)</code> a pointer to a buffer not created by <code>sigsetjmp(3C)</code> or passing any of these three functions a buffer that has been modified by the user can cause all the problems listed above, and more.</p> <p>The <code>_longjmp()</code> and <code>_setjmp()</code> functions are included to support programs written to historical system interfaces. New applications should use <code>siglongjmp(3C)</code> and <code>sigsetjmp(3C)</code> respectively.</p>
SEE ALSO	<code>longjmp(3C)</code> , <code>setjmp(3C)</code> , <code>siglongjmp(3C)</code> , <code>sigsetjmp(3C)</code>

NAME	setjmp, sigsetjmp, longjmp, siglongjmp – non-local goto
SYNOPSIS	<pre>#include <setjmp.h> int setjmp(jmp_buf <i>env</i>); int sigsetjmp(sigjmp_buf <i>env</i>, int <i>savemask</i>); void longjmp(jmp_buf <i>env</i>, int <i>val</i>); void siglongjmp(sigjmp_buf <i>env</i>, int <i>val</i>);</pre>
DESCRIPTION	<p>These functions are useful for dealing with errors and interrupts encountered in a low-level subroutine of a program.</p> <p>The <code>setjmp()</code> function saves its stack environment in <i>env</i> for later use by <code>longjmp()</code>.</p> <p>The <code>sigsetjmp()</code> function saves the calling process's registers and stack environment (see <code>sigaltstack(2)</code>) in <i>env</i> for later use by <code>siglongjmp()</code>. If <i>savemask</i> is non-zero, the calling process's signal mask (see <code>sigprocmask(2)</code>) and scheduling parameters (see <code>prctl(2)</code>) are also saved.</p> <p>The <code>longjmp()</code> function restores the environment saved by the last call of <code>setjmp()</code> with the corresponding <i>env</i> argument. After <code>longjmp()</code> completes, program execution continues as if the corresponding call to <code>setjmp()</code> had just returned the value <i>val</i>. The caller of <code>setjmp()</code> must not have returned in the interim. The <code>longjmp()</code> function cannot cause <code>setjmp()</code> to return the value 0. If <code>longjmp()</code> is invoked with a second argument of 0, <code>setjmp()</code> will return 1. At the time of the second return from <code>setjmp()</code>, all external and static variables have values as of the time <code>longjmp()</code> is called (see <code>EXAMPLES</code>).</p> <p>The <code>siglongjmp()</code> function restores the environment saved by the last call of <code>sigsetjmp()</code> with the corresponding <i>env</i> argument. After <code>siglongjmp()</code> completes, program execution continues as if the corresponding call to <code>sigsetjmp()</code> had just returned the value <i>val</i>. The <code>siglongjmp()</code> function cannot cause <code>sigsetjmp()</code> to return the value 0. If <code>siglongjmp()</code> is invoked with a second argument of 0, <code>sigsetjmp()</code> will return 1. At the time of the second return from <code>sigsetjmp()</code>, all external and static variables have values as of the time <code>siglongjmp()</code> was called.</p> <p>If a signal-catching function interrupts <code>sleep(3C)</code> and calls <code>siglongjmp()</code> to restore an environment saved prior to the <code>sleep()</code> call, the action associated with <code>SIGALRM</code> and time it is scheduled to be generated are unspecified. It is also unspecified whether the <code>SIGALRM</code> signal is blocked, unless the process's signal mask is restored as part of the environment.</p> <p>The <code>siglongjmp()</code> function restores the saved signal mask if and only if the <i>env</i> argument was initialized by a call to the <code>sigsetjmp()</code> function with a non-zero <i>savemask</i> argument.</p>

longjmp(3C)

The values of register and automatic variables are undefined. Register or automatic variables whose value must be relied upon must be declared as volatile.

RETURN VALUES If the return is from a direct invocation, `setjmp()` and `sigsetjmp()` return 0. If the return is from a call to `longjmp()`, `setjmp()` returns a non-zero value. If the return is from a call to `siglongjmp()`, `sigsetjmp()` returns a non-zero value.

After `longjmp()` is completed, program execution continues as if the corresponding invocation of `setjmp()` had just returned the value specified by *val*. The `longjmp()` function cannot cause `setjmp()` to return 0; if *val* is 0, `setjmp()` returns 1.

After `siglongjmp()` is completed, program execution continues as if the corresponding invocation of `sigsetjmp()` had just returned the value specified by *val*. The `siglongjmp()` function cannot cause `sigsetjmp()` to return 0; if *val* is 0, `sigsetjmp()` returns 1.

EXAMPLES **EXAMPLE 1** Example of `setjmp()` and `longjmp()` functions.

The following example uses both `setjmp()` and `longjmp()` to return the flow of control to the appropriate instruction block:

```
#include <stdio.h>
#include <setjmp.h>
#include <signal.h>
#include <unistd.h>
jmp_buf env; static void signal_handler();

main() {
    int returned_from_longjump, processing = 1;
    unsigned int time_interval = 4;
    if ((returned_from_longjump = setjmp(env)) != 0)
        switch (returned_from_longjump) {
            case SIGINT:
                printf("longjumped from interrupt %d\n",SIGINT);
                break;
            case SIGALRM:
                printf("longjumped from alarm %d\n",SIGALRM);
                break;
        }
    (void) signal(SIGINT, signal_handler);
    (void) signal(SIGALRM, signal_handler);
    alarm(time_interval);
    while (processing) {
        printf(" waiting for you to INTERRUPT (cntrl-C) ...\n");
        sleep(1);
    }
    /* end while forever loop */
}

static void signal_handler(sig)
int sig; {
    switch (sig) {
        case SIGINT:    ... /* process for interrupt */
                        longjmp(env,sig);
                        /* break never reached */
        case SIGALRM:  ... /* process for alarm */
    }
}
```

EXAMPLE 1 Example of `setjmp()` and `longjmp()` functions. (Continued)

```

                                longjmp(env, sig);
                                /* break never reached */
                                exit(sig);
    default:
    }
}

```

When this example is compiled and executed, and the user sends an interrupt signal, the output will be:

```
longjumped from interrupt
```

Additionally, every 4 seconds the alarm will expire, signalling this process, and the output will be:

```
longjumped from alarm
```

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
MT-Level	Unsafe

SEE ALSO `getcontext(2)`, `prctl(2)`, `sigaction(2)`, `sigaltstack(2)`, `sigprocmask(2)`, `signal(3C)`, `attributes(5)`

WARNINGS If `longjmp()` or `siglongjmp()` are called even though `env` was never primed by a call to `setjmp()` or `sigsetjmp()`, or when the last such call was in a function that has since returned, the results are undefined.

`_longjmp(3UCB)`

NAME	<code>setjmp, longjmp, _setjmp, _longjmp</code> – non-local goto
SYNOPSIS	<pre><code>/usr/ucb/cc [flag ...] file ... #include <setjmp.h> int setjmp(env); jmp_buf env; void longjmp(env, val); jmp_buf env; int val; int _setjmp(env); jmp_buf env; void _longjmp(env, val); jmp_buf env; int val;</code></pre>
DESCRIPTION	<p>The <code>setjmp()</code> and <code>longjmp()</code> functions are useful for dealing with errors and interrupts encountered in a low-level subroutine of a program.</p> <p>The <code>setjmp()</code> function saves its stack environment in <code>env</code> for later use by <code>longjmp()</code>. A normal call to <code>setjmp()</code> returns zero. <code>setjmp()</code> also saves the register environment. If a <code>longjmp()</code> call will be made, the routine which called <code>setjmp()</code> should not return until after the <code>longjmp()</code> has returned control (see below).</p> <p>The <code>longjmp()</code> function restores the environment saved by the last call of <code>setjmp()</code>, and then returns in such a way that execution continues as if the call of <code>setjmp()</code> had just returned the value <code>val</code> to the function that invoked <code>setjmp()</code>; however, if <code>val</code> were zero, execution would continue as if the call of <code>setjmp()</code> had returned one. This ensures that a “return” from <code>setjmp()</code> caused by a call to <code>longjmp()</code> can be distinguished from a regular return from <code>setjmp()</code>. The calling function must not itself have returned in the interim, otherwise <code>longjmp()</code> will be returning control to a possibly non-existent environment. All memory-bound data have values as of the time <code>longjmp()</code> was called. The CPU and floating-point data registers are restored to the values they had at the time that <code>setjmp()</code> was called. But, because the <code>register</code> storage class is only a hint to the C compiler, variables declared as <code>register</code> variables may not necessarily be assigned to machine registers, so their values are unpredictable after a <code>longjmp()</code>. This is especially a problem for programmers trying to write machine-independent C routines.</p> <p>The <code>setjmp()</code> and <code>longjmp()</code> functions save and restore the signal mask while <code>_setjmp()</code> and <code>_longjmp()</code> manipulate only the C stack and registers.</p> <p>None of these functions save or restore any floating-point status or control registers.</p>

EXAMPLES **EXAMPLE 1** Examples of `setjmp()` and `longjmp()`.

The following example uses both `setjmp()` and `longjmp()` to return the flow of control to the appropriate instruction block:

```
#include <stdio.h>
#include <setjmp.h>
#include <signal.h>
#include <unistd.h>
jmp_buf env; static void signal_handler();
main() {
    int returned_from_longjump, processing = 1;
    unsigned int time_interval = 4;
    if ((returned_from_longjump = setjmp(env)) != 0)
        switch (returned_from_longjump) {
            case SIGINT:
                printf("longjumped from interrupt %d\n",SIGINT);
                break;
            case SIGALRM:
                printf("longjumped from alarm %d\n",SIGALRM);
                break;
        }
    (void) signal(SIGINT, signal_handler);
    (void) signal(SIGALRM, signal_handler);
    alarm(time_interval);
    while (processing) {
        printf(" waiting for you to INTERRUPT (cntrl-C) ...\n");
        sleep(1);
    } /* end while forever loop */
}

static void signal_handler(sig)
int sig; {
    switch (sig) {
        case SIGINT:
            ... /* process for interrupt */
            longjmp(env,sig);
            /* break never reached */
        case SIGALRM:
            ... /* process for alarm */
            longjmp(env,sig);
            /* break never reached */
        default:
            exit(sig);
    }
}
```

When this example is compiled and executed, and the user sends an interrupt signal, the output will be:

```
longjumped from interrupt
```

Additionally, every 4 seconds the alarm will expire, signalling this process, and the output will be:

```
longjumped from alarm
```

NOTES Use of these interfaces should be restricted to only applications written on BSD platforms. Use of these interfaces with any of the system libraries or in multi-thread applications is unsupported.

BUGS The `setjmp()` function does not save the current notion of whether the process is executing on the signal stack. The result is that a `longjmp()` to some place on the signal stack leaves the signal stack state incorrect.

On some systems `setjmp()` also saves the register environment. Therefore, all data that are bound to registers are restored to the values they had at the time that `setjmp()` was called. All memory-bound data have values as of the time `longjmp()` was called. However, because the `register` storage class is only a hint to the C compiler, variables declared as `register` variables may not necessarily be assigned to machine registers, so their values are unpredictable after a `longjmp()`. When using compiler options that specify automatic register allocation (see `cc(1B)`), the compiler will not attempt to assign variables to registers in routines that call `setjmp()`.

The `longjmp()` function never causes `setjmp()` to return 0, so programmers should not depend on `longjmp()` being able to cause `setjmp()` to return 0.

longjmp(3UCB)

EXAMPLES

EXAMPLE 1 Examples of `setjmp()` and `longjmp()`.

The following example uses both `setjmp()` and `longjmp()` to return the flow of control to the appropriate instruction block:

```
#include <stdio.h>
#include <setjmp.h>
#include <signal.h>
#include <unistd.h>
jmp_buf env; static void signal_handler();
main() {
    int returned_from_longjump, processing = 1;
    unsigned int time_interval = 4;
    if ((returned_from_longjump = setjmp(env)) != 0)
        switch (returned_from_longjump) {
            case SIGINT:
                printf("longjumped from interrupt %d\n",SIGINT);
                break;
            case SIGALRM:
                printf("longjumped from alarm %d\n",SIGALRM);
                break;
        }
    (void) signal(SIGINT, signal_handler);
    (void) signal(SIGALRM, signal_handler);
    alarm(time_interval);
    while (processing) {
        printf(" waiting for you to INTERRUPT (cntrl-C) ...\n");
        sleep(1);
    } /* end while forever loop */
}

static void signal_handler(sig)
int sig; {
    switch (sig) {
        case SIGINT:
            ... /* process for interrupt */
            longjmp(env,sig);
            /* break never reached */
        case SIGALRM:
            ... /* process for alarm */
            longjmp(env,sig);
            /* break never reached */
        default:
            exit(sig);
    }
}
```

When this example is compiled and executed, and the user sends an interrupt signal, the output will be:

```
longjumped from interrupt
```

Additionally, every 4 seconds the alarm will expire, signalling this process, and the output will be:

```
longjumped from alarm
```

SEE ALSO `cc(1B)`, `sigvec(3UCB)`, `setjmp(3C)`, `signal(3C)`

- NOTES** Use of these interfaces should be restricted to only applications written on BSD platforms. Use of these interfaces with any of the system libraries or in multi-thread applications is unsupported.
- BUGS** The `setjmp()` function does not save the current notion of whether the process is executing on the signal stack. The result is that a `longjmp()` to some place on the signal stack leaves the signal stack state incorrect.
- On some systems `setjmp()` also saves the register environment. Therefore, all data that are bound to registers are restored to the values they had at the time that `setjmp()` was called. All memory-bound data have values as of the time `longjmp()` was called. However, because the `register` storage class is only a hint to the C compiler, variables declared as `register` variables may not necessarily be assigned to machine registers, so their values are unpredictable after a `longjmp()`. When using compiler options that specify automatic register allocation (see `cc(1B)`), the compiler will not attempt to assign variables to registers in routines that call `setjmp()`.
- The `longjmp()` function never causes `setjmp()` to return 0, so programmers should not depend on `longjmp()` being able to cause `setjmp()` to return 0.

lrand48(3C)

NAME	drand48, erand48, lrand48, nrand48, mrand48, jrand48, srand48, seed48, lcong48 – generate uniformly distributed pseudo-random numbers
SYNOPSIS	<pre>#include <stdlib.h> double drand48(void); double erand48(unsigned short <i>x_i[3]</i>); long lrand48(void); long nrand48(unsigned short <i>x_i[3]</i>); long mrnd48(void); long jrnd48(unsigned short <i>x_i[3]</i>); void srand48(long <i>seedval</i>); unsigned short *seed48(unsigned short <i>seed16v[3]</i>); void lcong48(unsigned short <i>param[7]</i>);</pre>
DESCRIPTION	<p>This family of functions generates pseudo-random numbers using the well-known linear congruential algorithm and 48-bit integer arithmetic.</p> <p>Functions <code>drand48()</code> and <code>erand48()</code> return non-negative double-precision floating-point values uniformly distributed over the interval [0.0, 1.0).</p> <p>Functions <code>lrand48()</code> and <code>nrand48()</code> return non-negative long integers uniformly distributed over the interval $[0, 2^{31}]$.</p> <p>Functions <code>mrnd48()</code> and <code>jrnd48()</code> return signed long integers uniformly distributed over the interval $[-2^{31}, 2^{31}]$.</p> <p>Functions <code>srand48()</code>, <code>seed48()</code>, and <code>lcong48()</code> are initialization entry points, one of which should be invoked before either <code>drand48()</code>, <code>lrand48()</code>, or <code>mrnd48()</code> is called. (Although it is not recommended practice, constant default initializer values will be supplied automatically if <code>drand48()</code>, <code>lrand48()</code>, or <code>mrnd48()</code> is called without a prior call to an initialization entry point.) Functions <code>erand48()</code>, <code>nrand48()</code>, and <code>jrnd48()</code> do not require an initialization entry point to be called first.</p> <p>All the routines work by generating a sequence of 48-bit integer values, X_i, according to the linear congruential formula</p> $X_{n+1} = (aX_n + c) \bmod m \quad n \geq 0.$ <p>The parameter $m = 2^{48}$; hence 48-bit integer arithmetic is performed. Unless <code>lcong48()</code> has been invoked, the multiplier value a and the addend value c are given by</p> $a = 5DEECE66D_{16} = 273673163155_8$

$c = B_{16} = 13_8$.

The value returned by any of the functions `drand48()`, `erand48()`, `lrand48()`, `nrand48()`, `mrnd48()`, or `jrnd48()` is computed by first generating the next 48-bit X_i in the sequence. Then the appropriate number of bits, according to the type of data item to be returned, are copied from the high-order (leftmost) bits of X_i and transformed into the returned value.

The functions `drand48()`, `lrand48()`, and `mrnd48()` store the last 48-bit X_i generated in an internal buffer. X_i must be initialized prior to being invoked. The functions `erand48()`, `nrand48()`, and `jrnd48()` require the calling program to provide storage for the successive X_i values in the array specified as an argument when the functions are invoked. These routines do not have to be initialized; the calling program must place the desired initial value of X_i into the array and pass it as an argument. By using different arguments, functions `erand48()`, `nrand48()`, and `jrnd48()` allow separate modules of a large program to generate several *independent* streams of pseudo-random numbers, that is, the sequence of numbers in each stream will *not* depend upon how many times the routines have been called to generate numbers for the other streams.

The initializer function `srand48()` sets the high-order 32 bits of X_i to the 32 bits contained in its argument. The low-order 16 bits of X_i are set to the arbitrary value $330E_{16}$.

The initializer function `seed48()` sets the value of X_i to the 48-bit value specified in the argument array. In addition, the previous value of X_i is copied into a 48-bit internal buffer, used only by `seed48()`, and a pointer to this buffer is the value returned by `seed48()`. This returned pointer, which can just be ignored if not needed, is useful if a program is to be restarted from a given point at some future time — use the pointer to get at and store the last X_i value, and then use this value to reinitialize using `seed48()` when the program is restarted.

The initialization function `lcg48()` allows the user to specify the initial X_i , the multiplier value a , and the addend value c . Argument array elements `param[0-2]` specify X_i , `param[3-5]` specify the multiplier a , and `param[6]` specifies the 16-bit addend c . After `lcg48()` has been called, a subsequent call to either `srand48()` or `seed48()` will restore the “standard” multiplier and addend values, a and c , specified above.

lsearch(3C)

NAME	lsearch, lfind – linear search and update
SYNOPSIS	<pre>#include <search.h> void *lsearch(const void *key, void *base, size_t *nelp, size_t width, int (*compar) (const void *, const void *)); void *lfind(const void *key, const void *base, size_t *nelp, size_t width, int (*compar) (const void *, const void *));</pre>
DESCRIPTION	<p>The <code>lsearch()</code> function is a linear search routine generalized from Knuth (6.1) Algorithm S. (See <i>The Art of Computer Programming, Volume 3, Section 6.1, by Donald E. Knuth.</i>) It returns a pointer into a table indicating where a datum may be found. If the datum does not occur, it is added at the end of the table. The <i>key</i> argument points to the datum to be sought in the table. The <i>base</i> argument points to the first element in the table. The <i>nelp</i> argument points to an integer containing the current number of elements in the table. The integer is incremented if the datum is added to the table. The <i>width</i> argument is the size of an element in bytes. The <i>compar</i> argument is a pointer to the comparison function that the user must supply (<code>strcmp(3C)</code> for example). It is called with two arguments that point to the elements being compared. The function must return zero if the elements are equal and non-zero otherwise.</p> <p>The <code>lfind()</code> function is the same as <code>lsearch()</code> except that if the datum is not found, it is not added to the table. Instead, a null pointer is returned.</p> <p>It is important to note the following:</p> <ul style="list-style-type: none">■ the pointers to the key and the element at the base of the table may be pointers to any type.■ The comparison function need not compare every byte, so arbitrary data may be contained in the elements in addition to the values being compared.■ The value returned should be cast into type pointer-to-element.
RETURN VALUES	If the searched-for datum is found, both <code>lsearch()</code> and <code>lfind()</code> return a pointer to it. Otherwise, <code>lfind()</code> returns <code>NULL</code> and <code>lsearch()</code> returns a pointer to the newly added element.
USAGE	Undefined results can occur if there is not enough room in the table to add a new item.
EXAMPLES	<p>EXAMPLE 1 A sample code using the <code>lsearch()</code> function.</p> <p>This program will read in less than <code>TABSIZE</code> strings of length less than <code>ELSIZE</code> and store them in a table, eliminating duplicates, and then will print each entry.</p> <pre>#include <search.h> #include <string.h> #include <stdlib.h> #include <stdio.h> #define TABSIZE 50 #define ELSIZE 120</pre>

EXAMPLE 1 A sample code using the `lsearch()` function. (Continued)

```
main( )
{
    char line[ELSIZE];          /* buffer to hold input string */
    char tab[TABSIZE][ELSIZE]; /* table of strings */
    size_t nel = 0;            /* number of entries in tab */
    int i;

    while (fgets(line, ELSIZE, stdin) != NULL &&
           nel < TABSIZE)
        (void) lsearch(line, tab, &nel, ELSIZE, mycmp);
    for( i = 0; i < nel; i++ )
        (void) fputs(tab[i], stdout);
    return 0;
}
```

madvise(3C)

NAME	madvise – provide advice to VM system
SYNOPSIS	<pre>#include <sys/types.h> #include <sys/mman.h> int madvise(caddr_t <i>addr</i>, size_t <i>len</i>, int <i>advice</i>);</pre>
DESCRIPTION	<p>The <code>madvise()</code> function advises the kernel that a region of user mapped memory in the range <code>[addr, addr + len)</code> will be accessed following a type of pattern. The kernel uses this information to optimize the procedure for manipulating and maintaining the resources associated with the specified mapping range.</p> <p>Values for <i>advice</i> are defined in <code><sys/mman.h></code> as:</p> <pre>#define MADV_NORMAL 0x0 /* No further special treatment */ #define MADV_RANDOM 0x1 /* Expect random page references */ #define MADV_SEQUENTIAL 0x2 /* Expect sequential page references */ #define MADV_WILLNEED 0x3 /* Will need these pages */ #define MADV_DONTNEED 0x4 /* Don't need these pages */ #define MADV_FREE 0x5 /* Contents can be freed */ #define MADV_ACCESS_DEFAULT 0x6 /* default access */ #define MADV_ACCESS_LWP 0x7 /* next LWP to access heavily */ #define MADV_ACCESS_MANY 0x8 /* many processes to access heavily */</pre> <p>MADV_NORMAL The default system characteristic where accessing memory within the address range causes the system to read data from the mapped file. The kernel reads all data from files into pages which are retained for a period of time as a “cache.” System pages can be a scarce resource, so the kernel steals pages from other mappings when needed. This is a likely occurrence, but adversely affects system performance only if a large amount of memory is accessed.</p> <p>MADV_RANDOM Tells the kernel to read in a minimum amount of data from a mapped file on any single particular access. If MADV_NORMAL is in effect when an address of a mapped file is accessed, the system tries to read in as much data from the file as reasonable, in anticipation of other accesses within a certain locality.</p> <p>MADV_SEQUENTIAL Tells the system that addresses in this range are likely to be accessed only once, so the system will free the resources mapping the address range as quickly as possible. This is used in the <code>cat(1)</code> and <code>cp(1)</code> utilities.</p> <p>MADV_WILLNEED Tells the system that a certain address range is definitely needed so the kernel will start reading the specified range into memory. This can benefit programs wanting to minimize the time needed to access memory the first time, as the kernel would need to read in from the file.</p>

MADV_DONTNEED	Tells the kernel that the specified address range is no longer needed, so the system starts to free the resources associated with the address range.
MADV_FREE	Tells the kernel that contents in the specified address range are no longer important and the range will be overwritten. When there is demand for memory, the system will free pages associated with the specified address range. In this instance, the next time a page in the address range is referenced, it will contain all zeroes. Otherwise, it will contain the data that was there prior to the MADV_FREE call. References made to the address range will not make the system read from backing store (swap space) until the page is modified again. This value cannot be used on mappings that have underlying file objects.
MADV_ACCESS_LWP	Tells the kernel that the next LWP to touch the specified address range will access it most heavily, so the kernel should try to allocate the memory and other resources for this range and the LWP accordingly.
MADV_ACCESS_MANY	Tells the kernel that many processes and/or LWPs will access the specified address range randomly across the machine, so the kernel should try to allocate the memory and other resources for this range accordingly.
MADV_ACCESS_DEFAULT	Resets the kernel's expectation for how the specified range will be accessed to the default.

The `madvise()` function should be used by applications with specific knowledge of their access patterns over a memory object, such as a mapped file, to increase system performance.

RETURN VALUES

Upon successful completion, `madvise()` returns 0; otherwise, it returns -1 and sets `errno` to indicate the error.

ERRORS

EAGAIN	Some or all mappings in the address range [<i>addr</i> , <i>addr + len</i>) are locked for I/O.
EBUSY	Some or all of the addresses in the range [<i>addr</i> , <i>addr + len</i>) are locked and <code>MS_SYNC</code> with the <code>MS_INVALIDATE</code> option is specified.
EFAULT	Some or all of the addresses in the specified range could not be read into memory from the underlying object when performing <code>MADV_WILLNEED</code> .

madvise(3C)

- EINVAL The *addr* argument is not a multiple of the page size as returned by *sysconf*(3C), the length of the specified address range is equal to 0, or the *advice* argument was invalid.
- EIO An I/O error occurred while reading from or writing to the file system.
- ENOMEM Addresses in the range [*addr*, *addr + len*) are outside the valid range for the address space of a process, or specify one or more pages that are not mapped.
- ESTALE Stale NFS file handle.

makecontext(3C)

NAME	makecontext, swapcontext – manipulate user contexts				
SYNOPSIS	<pre>cc -D__MAKECONTEXT_V2_SOURCE [flag...] file... [library...] #include <ucontext.h> void makecontext (ucontext_t *ucp, void(*func)(), int argc, ...); int swapcontext (ucontext_t *oucp, const ucontext_t *ucp);</pre>				
DESCRIPTION	<p>These functions are useful for implementing user-level context switching between multiple threads of control within a process.</p> <p>The <code>makecontext()</code> function modifies the context specified by <code>ucp</code>, which has been initialized using <code>getcontext(2)</code>. When this context is resumed using <code>swapcontext()</code> or <code>setcontext(2)</code>, program execution continues by calling the function <code>func</code>, passing it the arguments that follow <code>argc</code> in the <code>makecontext()</code> call. The value of <code>argc</code> must match the number of pointer-sized integer arguments passed to <code>func</code>. Otherwise the behavior is undefined.</p> <p>Before a call is made to <code>makecontext()</code>, the context being modified should have a stack allocated for it. The value of <code>argc</code> must match the number of integer arguments passed to <code>func</code>, otherwise the behavior is undefined.</p> <p>The <code>uc_link</code> member is used to determine the context that will be resumed when the context being modified by <code>makecontext()</code> returns. The <code>uc_link</code> member should be initialized prior to the call to <code>makecontext()</code>. If the <code>uc_link</code> member is initialized to <code>NULL</code>, the thread executing <code>func</code> will exit when <code>func</code> returns. See <code>pthread_exit(3THR)</code>.</p> <p>The <code>swapcontext()</code> function saves the current context in the context structure pointed to by <code>oucp</code> and sets the context to the context structure pointed to by <code>ucp</code>.</p> <p>If the <code>ucp</code> or <code>oucp</code> argument points to an illegal address, the behavior is undefined and <code>errno</code> may be set to <code>EFAULT</code>.</p>				
RETURN VALUES	Upon successful completion, <code>swapcontext()</code> returns 0. Otherwise, <code>-1</code> is returned and <code>errno</code> is set to indicate the error.				
ERRORS	<p>The <code>swapcontext()</code> function will fail if:</p> <table><tr><td><code>ENOMEM</code></td><td>The <code>ucp</code> argument does not have enough stack left to complete the operation.</td></tr></table> <p>The <code>swapcontext()</code> function may fail if:</p> <table><tr><td><code>EFAULT</code></td><td>The <code>ucp</code> or <code>oucp</code> argument points to an invalid address.</td></tr></table>	<code>ENOMEM</code>	The <code>ucp</code> argument does not have enough stack left to complete the operation.	<code>EFAULT</code>	The <code>ucp</code> or <code>oucp</code> argument points to an invalid address.
<code>ENOMEM</code>	The <code>ucp</code> argument does not have enough stack left to complete the operation.				
<code>EFAULT</code>	The <code>ucp</code> or <code>oucp</code> argument points to an invalid address.				
EXAMPLES	<p>EXAMPLE 1 Alternate execution context on a stack whose memory was allocated using <code>mmap(2)</code>.</p> <pre>#include <stdio.h> #include <ucontext.h> #include <sys/mman.h></pre>				

EXAMPLE 1 Alternate execution context on a stack whose memory was allocated using `mmap(2)`. (Continued)

```

void
assign(long a, int *b)
{
    *b = (int)a;
}

int
main(int argc, char **argv)
{
    ucontext_t uc, back;
    size_t sz = 0x10000;
    int value = 0;

    getcontext (&uc);

    uc.uc_stack.ss_sp = mmap(0, sz,
        PROT_READ | PROT_WRITE | PROT_EXEC,
        MAP_PRIVATE | MAP_ANON, -1, 0);
    uc.uc_stack.ss_size = sz;
    uc.uc_stack.ss_flags = 0;

    uc.uc_link = &back

    makecontext (&uc, assign, 2, 100L, &value);
    swapcontext (&back, &uc);

    printf("done %d\n", value);

    return (0);
}

```

USAGE These functions are useful for implementing user-level context switching between multiple threads of control within a process (co-processing). More effective multiple threads of control can be obtained by using native support for multithreading. See `threads(3THR)`.

makecontext(3C)

NOTES | The legacy implementation of `makecontext()` for `sparc` and `sparcv9` was in violation of the standard. To use the updated version with the corrected behavior, specify `-D__MAKECONTEXT_V2_SOURCE` when invoking the compiler. See the **EXAMPLES** section for the correct usage.

Future releases of Solaris will enable the corrected behavior by default, thereby eliminating the need to define `__MAKECONTEXT_V2_SOURCE`.

NAME	makedev, major, minor – manage a device number

mallinfo(3MALLOC)

NAME	<code>malloc, free, realloc, calloc, malloc, mallinfo</code> – memory allocator				
SYNOPSIS	<pre>cc [<i>flag</i> ...] <i>file</i> ... -lmalloc [<i>library</i> ...] #include <stdlib.h> void *malloc(size_t <i>size</i>); void free(void *<i>ptr</i>); void *realloc(void *<i>ptr</i>, size_t <i>size</i>); void *calloc(size_t <i>nelem</i>, size_t <i>elsize</i>); #include <malloc.h> int mallopt(int <i>cmd</i>, int <i>value</i>); struct mallinfo mallinfo(void);</pre>				
DESCRIPTION	<p>The <code>malloc()</code> and <code>free()</code> functions provide a simple general-purpose memory allocation package.</p> <p>The <code>malloc()</code> function returns a pointer to a block of at least <i>size</i> bytes suitably aligned for any use.</p> <p>The argument to <code>free()</code> is a pointer to a block previously allocated by <code>malloc()</code>. After <code>free()</code> is performed, this space is made available for further allocation, and its contents have been destroyed. See <code>mallopt()</code> below for a way to change this behavior. If <i>ptr</i> is a null pointer, no action occurs.</p> <p>Undefined results occur if the space assigned by <code>malloc()</code> is overrun or if some random number is handed to <code>free()</code>.</p> <p>The <code>realloc()</code> function changes the size of the block pointed to by <i>ptr</i> to <i>size</i> bytes and returns a pointer to the (possibly moved) block. The contents are unchanged up to the lesser of the new and old sizes. If <i>ptr</i> is a null pointer, <code>realloc()</code> behaves like <code>malloc()</code> for the specified size. If <i>size</i> is 0 and <i>ptr</i> is not a null pointer, the object it points to is freed.</p> <p>The <code>calloc()</code> function allocates space for an array of <i>nelem</i> elements of size <i>elsize</i>. The space is initialized to zeros.</p> <p>The <code>mallopt()</code> function provides for control over the allocation algorithm. The available values for <i>cmd</i> are:</p> <table><tr><td><code>M_MXFAST</code></td><td>Set <i>maxfast</i> to <i>value</i>. The algorithm allocates all blocks below the size of <i>maxfast</i> in large groups and then does them out very quickly. The default value for <i>maxfast</i> is 24.</td></tr><tr><td><code>M_NLBLKS</code></td><td>Set <i>numlblks</i> to <i>value</i>. The above mentioned “large groups” each contain <i>numlblks</i> blocks. <i>numlblks</i> must be greater than 0. The default value for <i>numlblks</i> is 100.</td></tr></table>	<code>M_MXFAST</code>	Set <i>maxfast</i> to <i>value</i> . The algorithm allocates all blocks below the size of <i>maxfast</i> in large groups and then does them out very quickly. The default value for <i>maxfast</i> is 24.	<code>M_NLBLKS</code>	Set <i>numlblks</i> to <i>value</i> . The above mentioned “large groups” each contain <i>numlblks</i> blocks. <i>numlblks</i> must be greater than 0. The default value for <i>numlblks</i> is 100.
<code>M_MXFAST</code>	Set <i>maxfast</i> to <i>value</i> . The algorithm allocates all blocks below the size of <i>maxfast</i> in large groups and then does them out very quickly. The default value for <i>maxfast</i> is 24.				
<code>M_NLBLKS</code>	Set <i>numlblks</i> to <i>value</i> . The above mentioned “large groups” each contain <i>numlblks</i> blocks. <i>numlblks</i> must be greater than 0. The default value for <i>numlblks</i> is 100.				

M_GRAIN	Set <i>grain</i> to <i>value</i> . The sizes of all blocks smaller than <i>maxfast</i> are considered to be rounded up to the nearest multiple of <i>grain</i> . <i>grain</i> must be greater than 0. The default value of <i>grain</i> is the smallest number of bytes that will allow alignment of any data type. Value will be rounded up to a multiple of the default when <i>grain</i> is set.
M_KEEP	Preserve data in a freed block until the next <code>malloc()</code> , <code>realloc()</code> , or <code>calloc()</code> . This option is provided only for compatibility with the old version of <code>malloc()</code> , and it is not recommended.

These values are defined in the `<malloc.h>` header.

The `mallopt()` function can be called repeatedly, but cannot be called after the first small block is allocated.

The `mallinfo()` function provides instrumentation describing space usage. It returns the `mallinfo` structure with the following members:

```

unsigned long arena;      /* total space in arena */
unsigned long ordblks;   /* number of ordinary blocks */
unsigned long smlbks;    /* number of small blocks */
unsigned long hblkhd;    /* space in holding block headers */
unsigned long hblks;     /* number of holding blocks */
unsigned long usmlbks;   /* space in small blocks in use */
unsigned long fsmblks;   /* space in free small blocks */
unsigned long uordblks;  /* space in ordinary blocks in use */
unsigned long fordblks;  /* space in free ordinary blocks */
unsigned long keepcost;  /* space penalty if keep option */
                        /* is used */

```

The `mallinfo` structure is defined in the `<malloc.h>` header.

Each of the allocation routines returns a pointer to space suitably aligned (after possible pointer coercion) for storage of any type of object.

RETURN VALUES

The `malloc()`, `realloc()`, and `calloc()` functions return a null pointer if there is not enough available memory. When `realloc()` returns `NULL`, the block pointed to by *ptr* is left intact. If `mallopt()` is called after any allocation or if *cmd* or *value* are invalid, a non-zero value is returned. Otherwise, it returns 0.

ERRORS

If `malloc()`, `calloc()`, or `realloc()` returns unsuccessfully, `errno` is set to indicate the error:

ENOMEM	<i>size</i> bytes of memory exceeds the physical limits of your system, and cannot be allocated.
EAGAIN	There is not enough memory available at this point in time to allocate <i>size</i> bytes of memory; but the application could try again later.

mallinfo(3MALLOC)

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
MT-Level	Safe

SEE ALSO `brk(2)`, `bsdmalloc(3MALLOC)`, `libmtmalloc(3LIB)`, `malloc(3C)`, `mapmalloc(3MALLOC)`, `mtmalloc(3MALLOC)`, `watchmalloc(3MALLOC)`, `attributes(5)`

NOTES Note that unlike `malloc(3C)`, this package does not preserve the contents of a block when it is freed, unless the `M_KEEP` option of `mallopt()` is used.

Undocumented features of `malloc(3C)` have not been duplicated.

Function prototypes for `malloc()`, `realloc()`, `calloc()`, and `free()` are also defined in the `<malloc.h>` header for compatibility with old applications. New applications should include `<stdlib.h>` to access the prototypes for these functions. Comparative Features of these `malloc` routines, `bsdmalloc(3MALLOC)`, and `malloc(3C)`

- These `malloc` routines are space-efficient but have slower performance.
- The `bsdmalloc(3MALLOC)` routines afford better performance but are space-inefficient.
- The standard, fully SCD-compliant `malloc(3C)` routines are a trade-off between performance and space-efficiency.

The `free()` function does not set `errno`.

NAME	malloc, calloc, free, memalign, realloc, valloc, alloca – memory allocator
SYNOPSIS	<pre>#include <stdlib.h> void *malloc(size_t size); void *calloc(size_t nelem, size_t elsize); void free(void *ptr); void *memalign(size_t alignment, size_t size); void *realloc(void *ptr, size_t size); void *valloc(size_t size); #include <alloca.h> void *alloca(size_t size);</pre>
DESCRIPTION	<p>The <code>malloc()</code> and <code>free()</code> functions provide a simple, general-purpose memory allocation package. The <code>malloc()</code> function returns a pointer to a block of at least <i>size</i> bytes suitably aligned for any use. If the space assigned by <code>malloc()</code> is overrun, the results are undefined.</p> <p>The argument to <code>free()</code> is a pointer to a block previously allocated by <code>malloc()</code>, <code>calloc()</code>, or <code>realloc()</code>. After <code>free()</code> is executed, this space is made available for further allocation by the application, though not returned to the system. Memory is returned to the system only upon termination of the application. If <i>ptr</i> is a null pointer, no action occurs. If a random number is passed to <code>free()</code>, the results are undefined.</p> <p>The <code>calloc()</code> function allocates space for an array of <i>nelem</i> elements of size <i>elsize</i>. The space is initialized to zeros.</p> <p>The <code>memalign()</code> function allocates <i>size</i> bytes on a specified alignment boundary and returns a pointer to the allocated block. The value of the returned address is guaranteed to be an even multiple of <i>alignment</i>. The value of <i>alignment</i> must be a power of two and must be greater than or equal to the size of a word.</p> <p>The <code>realloc()</code> function changes the size of the block pointed to by <i>ptr</i> to <i>size</i> bytes and returns a pointer to the (possibly moved) block. The contents will be unchanged up to the lesser of the new and old sizes. If <i>ptr</i> is NULL, <code>realloc()</code> behaves like <code>malloc()</code> for the specified size. If <i>size</i> is 0 and <i>ptr</i> is not a null pointer, the space pointed to is made available for further allocation by the application, though not returned to the system. Memory is returned to the system only upon termination of the application.</p> <p>The <code>valloc()</code> function has the same effect as <code>malloc()</code>, except that the allocated memory will be aligned to a multiple of the value returned by <code>sysconf(_SC_PAGESIZE)</code>.</p>

malloc(3C)

The `alloca()` function allocates *size* bytes of space in the stack frame of the caller, and returns a pointer to the allocated block. This temporary space is automatically freed when the caller returns. If the allocated block is beyond the current stack limit, the resulting behavior is undefined.

RETURN VALUES Upon successful completion, each of the allocation functions returns a pointer to space suitably aligned (after possible pointer coercion) for storage of any type of object.

If there is no available memory, `malloc()`, `realloc()`, `memalign()`, `valloc()`, and `calloc()` return a null pointer. When `realloc()` is called with *size* > 0 and returns `NULL`, the block pointed to by *ptr* is left intact. If *size*, *nelem*, or *elsize* is 0, either a null pointer or a unique pointer that can be passed to `free()` is returned.

If `malloc()`, `calloc()`, or `realloc()` returns unsuccessfully, `errno` will be set to indicate the error. The `free()` function does not set `errno`.

ERRORS The `malloc()`, `calloc()`, and `realloc()` functions will fail if:

- | | |
|---------------------|--|
| <code>ENOMEM</code> | The physical limits of the system are exceeded by <i>size</i> bytes of memory which cannot be allocated. |
| <code>EAGAIN</code> | There is not enough memory available to allocate <i>size</i> bytes of memory; but the application could try again later. |

USAGE Portable applications should avoid using `valloc()` but should instead use `malloc()` or `mmap(2)`. On systems with a large page size, the number of successful `valloc()` operations might be 0.

Comparative features of `malloc(3C)`, `bsdmalloc(3MALLOC)`, and `malloc(3MALLOC)` are as follows:

- The `bsdmalloc(3MALLOC)` routines afford better performance, but are space-inefficient.
- The `malloc(3MALLOC)` routines are space-efficient, but have slower performance.
- The standard, fully SCD-compliant `malloc` routines are a trade-off between performance and space-efficiency.

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Interface Stability	<code>malloc()</code> , <code>calloc()</code> , <code>free()</code> , <code>realloc()</code> , <code>valloc()</code> are Standard; <code>memalign()</code> and <code>alloca()</code> are Stable.
MT-Level	Safe

SEE ALSO `brk(2)`, `getrlimit(2)`, `bsdmalloc(3MALLOC)`, `malloc(3MALLOC)`, `mapmalloc(3MALLOC)`, `watchmalloc(3MALLOC)`, `attributes(5)`

WARNINGS Undefined results will occur if the size requested for a block of memory exceeds the maximum size of a process's heap, which can be obtained with `getrlimit(2)`

The `alloca()` function is machine-, compiler-, and most of all, system-dependent. Its use is strongly discouraged.

malloc(3MALLOC)

NAME	malloc, free, realloc, calloc, malloc, mallinfo – memory allocator				
SYNOPSIS	<pre>cc [<i>flag</i> ...] <i>file</i> ... -lmalloc [<i>library</i> ...] #include <stdlib.h> void *malloc(size_t <i>size</i>); void free(void *<i>ptr</i>); void *realloc(void *<i>ptr</i>, size_t <i>size</i>); void *calloc(size_t <i>nelem</i>, size_t <i>elsize</i>); #include <malloc.h> int mallot(int <i>cmd</i>, int <i>value</i>); struct mallinfo mallinfo(void);</pre>				
DESCRIPTION	<p>The malloc() and free() functins provide a simple general-purpose memory allocation package.</p> <p>The malloc() function returns a pointer to a block of at least <i>size</i> bytes suitably aligned for any use.</p> <p>The argument to free() is a pointer to a block previously allocated by malloc(). After free() is performed, this space is made available for further allocation, and its contents have been destroyed See mallot() below for a way to change this behavior. If <i>ptr</i> is a null pointer, no action occurs.</p> <p>Undefined results occur if the space assigned by malloc() is overrun or if some random number is handed to free().</p> <p>The realloc() function changes the size of the block pointed to by <i>ptr</i> to <i>size</i> bytes and returns a pointer to the (possibly moved) block. The contents are unchanged up to the lesser of the new and old sizes. If <i>ptr</i> is a null pointer, realloc() behaves like malloc() for the specified size. If <i>size</i> is 0 and <i>ptr</i> is not a null pointer, the object it points to is freed.</p> <p>The calloc() function allocates space for an array of <i>nelem</i> elements of size <i>elsize</i>. The space is initialized to zeros.</p> <p>The mallot() function provides for control over the allocation algorithm. The available values for <i>cmd</i> are:</p> <table><tr><td>M_MXFAST</td><td>Set <i>maxfast</i> to <i>value</i>. The algorithm allocates all blocks below the size of <i>maxfast</i> in large groups and then doles them out very quickly. The default value for <i>maxfast</i> is 24.</td></tr><tr><td>M_NLBLKS</td><td>Set <i>numlblks</i> to <i>value</i>. The above mentioned “large groups” each contain <i>numlblks</i> blocks. <i>numlblks</i> must be greater than 0. The default value for <i>numlblks</i> is 100.</td></tr></table>	M_MXFAST	Set <i>maxfast</i> to <i>value</i> . The algorithm allocates all blocks below the size of <i>maxfast</i> in large groups and then doles them out very quickly. The default value for <i>maxfast</i> is 24.	M_NLBLKS	Set <i>numlblks</i> to <i>value</i> . The above mentioned “large groups” each contain <i>numlblks</i> blocks. <i>numlblks</i> must be greater than 0. The default value for <i>numlblks</i> is 100.
M_MXFAST	Set <i>maxfast</i> to <i>value</i> . The algorithm allocates all blocks below the size of <i>maxfast</i> in large groups and then doles them out very quickly. The default value for <i>maxfast</i> is 24.				
M_NLBLKS	Set <i>numlblks</i> to <i>value</i> . The above mentioned “large groups” each contain <i>numlblks</i> blocks. <i>numlblks</i> must be greater than 0. The default value for <i>numlblks</i> is 100.				

M_GRAIN	Set <i>grain</i> to <i>value</i> . The sizes of all blocks smaller than <i>maxfast</i> are considered to be rounded up to the nearest multiple of <i>grain</i> . <i>grain</i> must be greater than 0. The default value of <i>grain</i> is the smallest number of bytes that will allow alignment of any data type. Value will be rounded up to a multiple of the default when <i>grain</i> is set.
M_KEEP	Preserve data in a freed block until the next <code>malloc()</code> , <code>realloc()</code> , or <code>calloc()</code> . This option is provided only for compatibility with the old version of <code>malloc()</code> , and it is not recommended.

These values are defined in the `<malloc.h>` header.

The `mallopt()` function can be called repeatedly, but cannot be called after the first small block is allocated.

The `mallinfo()` function provides instrumentation describing space usage. It returns the `mallinfo` structure with the following members:

```

unsigned long arena;      /* total space in arena */
unsigned long ordblks;   /* number of ordinary blocks */
unsigned long smlbks;   /* number of small blocks */
unsigned long hblkhd;   /* space in holding block headers */
unsigned long hblks;    /* number of holding blocks */
unsigned long usmlbks;  /* space in small blocks in use */
unsigned long fsmblks;  /* space in free small blocks */
unsigned long uordblks; /* space in ordinary blocks in use */
unsigned long fordblks; /* space in free ordinary blocks */
unsigned long keepcost; /* space penalty if keep option */
                       /* is used */

```

The `mallinfo` structure is defined in the `<malloc.h>` header.

Each of the allocation routines returns a pointer to space suitably aligned (after possible pointer coercion) for storage of any type of object.

RETURN VALUES

The `malloc()`, `realloc()`, and `calloc()` functions return a null pointer if there is not enough available memory. When `realloc()` returns `NULL`, the block pointed to by *ptr* is left intact. If `mallopt()` is called after any allocation or if *cmd* or *value* are invalid, a non-zero value is returned. Otherwise, it returns 0.

ERRORS

If `malloc()`, `calloc()`, or `realloc()` returns unsuccessfully, `errno` is set to indicate the error:

ENOMEM	<i>size</i> bytes of memory exceeds the physical limits of your system, and cannot be allocated.
EAGAIN	There is not enough memory available at this point in time to allocate <i>size</i> bytes of memory; but the application could try again later.

malloc(3MALLOC)

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
MT-Level	Safe

NOTES Note that unlike `malloc(3C)`, this package does not preserve the contents of a block when it is freed, unless the `M_KEEP` option of `mallopt()` is used.

Undocumented features of `malloc(3C)` have not been duplicated.

Function prototypes for `malloc()`, `realloc()`, `calloc()`, and `free()` are also defined in the `<malloc.h>` header for compatibility with old applications. New applications should include `<stdlib.h>` to access the prototypes for these functions. Comparative Features of these `malloc` routines, `bsdmalloc(3MALLOC)`, and `malloc(3C)`

- These `malloc` routines are space-efficient but have slower performance.
- The `bsdmalloc(3MALLOC)` routines afford better performance but are space-inefficient.
- The standard, fully SCD-compliant `malloc(3C)` routines are a trade-off between performance and space-efficiency.

The `free()` function does not set `errno`.

NAME	mtmalloc, mallocctl – MT hot memory allocator
SYNOPSIS	<pre>#include <mtmalloc.h> cc -o a.out -pthread -lmtmalloc void *malloc(size_t size); void *calloc(size_t nelem, size_t elsize); void free(void *ptr); void *memalign(size_t alignment, size_t size); void *realloc(void *ptr, size_t size); void *valloc(size_t size); void mallocctl(int cmd, long value);</pre>
DESCRIPTION	<p>The <code>malloc()</code> and <code>free()</code> functions provide a simple general-purpose memory allocation package that is suitable for use in high performance multithreaded applications. The suggested use of this library is in multithreaded applications; it can be used for single threaded applications, but there is no advantage in doing so. This library cannot be dynamically loaded via <code>dlopen()</code> during runtime because there must be only one manager of the process heap.</p> <p>The <code>malloc()</code> function returns a pointer to a block of at least <i>size</i> bytes suitably aligned for any use.</p> <p>The argument to <code>free()</code> is a pointer to a block previously allocated by <code>malloc()</code>, <code>calloc()</code> or <code>realloc()</code>. After <code>free()</code> is performed this space is available for further allocation. If <i>ptr</i> is a null pointer, no action occurs.</p> <p>Undefined results will occur if the space assigned by <code>malloc()</code> is overrun or if a random number is handed to <code>free()</code>. A freed pointer that is passed to <code>free()</code> will send a SIGABRT signal to the calling process. This behavior is controlled by <code>mallocctl()</code>.</p> <p>The <code>calloc()</code> function allocates a zero-initialized space for an array of <i>nelem</i> elements of size <i>elsize</i>.</p> <p>The <code>memalign()</code> function allocates <i>size</i> bytes on a specified alignment boundary and returns a pointer to the allocated block. The value of the returned address is guaranteed to be an even multiple of <i>alignment</i>. Note that the value of <i>alignment</i> must be a power of two, and must be greater than or equal to the size of a word.</p> <p>The <code>realloc()</code> function changes the size of the block pointed to by <i>ptr</i> to <i>size</i> bytes and returns a pointer to the (possibly moved) block. The contents will be unchanged up to the lesser of the new and old sizes. If <i>ptr</i> is NULL, <code>realloc()</code> behaves like <code>malloc()</code> for the specified size. If <i>size</i> is 0 and <i>ptr</i> is not a null pointer, the object pointed to is freed.</p>

mallocctl(3MALLOC)

The `valloc()` function has the same effect as `malloc()`, except that the allocated memory will be aligned to a multiple of the value returned by `sysconf(_SC_PAGESIZE)`.

After possible pointer coercion, each allocation routine returns a pointer to a space that is suitably aligned for storage of any type of object.

The `malloc()`, `realloc()`, `calloc()`, `memalign()`, and `valloc()` functions will fail if there is not enough available memory.

The `mallocctl()` function controls the behavior of the `malloc` library. The options fall into two general classes, debugging options and performance options.

MTDOUBLEFREE	Allows double free of a pointer. Setting <i>value</i> to 1 means yes and 0 means no. The default behavior of double free results in a core dump.
MTDEBUGPATTERN	Writes misaligned data into the buffer after <code>free()</code> . When the buffer is reallocated, the contents are verified to ensure that there was no access to the buffer after the free. If the buffer has been dirtied, a SIGABRT signal is delivered to the process. Setting <i>value</i> to 1 means yes and 0 means no. The default behavior is to <i>not</i> write misaligned data. The pattern used is <code>0xdeadbeef</code> . Use of this option results in a performance penalty.
MTINITBUFFER	Writes misaligned data into the newly allocated buffer. This option is useful for detecting some accesses before initialization. Setting <i>value</i> to 1 means yes and 0 means no. The default behavior is to <i>not</i> write misaligned data to the newly allocated buffer. The pattern used is <code>0xbaddcafe</code> . Use of this option results in a performance penalty.
MTCHUNKSIZE	This option changes the size of allocated memory when a pool has exhausted all available memory in the buffer. Increasing this value allocates more memory for the application. A substantial performance gain can occur because the library makes fewer calls to the OS for more memory. Acceptable number <i>values</i> are between 9 and 256; the default value is 9. This value is multiplied by 8192.

RETURN VALUES

If there is no available memory, `malloc()`, `realloc()`, `memalign()`, `valloc()`, and `calloc()` return a null pointer. When `realloc()` is called with *size* > 0 and returns `NULL`, the block pointed to by *ptr* is left intact. If *size*, *nelem*, or *elsize* is 0, either a null pointer or a unique pointer that can be passed to `free()` is returned.

If `malloc()`, `calloc()`, or `realloc()` returns unsuccessfully, `errno` will be set to indicate the error.

mallocctl(3MALLOC)

ERRORS The `malloc()`, `calloc()`, and `realloc()` functions will fail if:

- ENOMEM The physical limits of the system are exceeded by *size* bytes of memory which cannot be allocated.
- EAGAIN There is not enough memory available to allocate *size* bytes of memory; but the application could try again later.

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
MT-Level	Safe

SEE ALSO `brk(2)`, `getrlimit(2)`, `bsdmalloc(3MALLOC)`, `dlopen(3DL)`, `malloc(3C)`, `malloc(3MALLOC)`, `mapmalloc(3MALLOC)`, `signal(3HEAD)`, `watchmalloc(3MALLOC)`, `attributes(5)`

WARNINGS Undefined results will occur if the size requested for a block of memory exceeds the maximum size of a process's heap. This information may be obtained using `getrlimit()`.

NOTES Comparative Features of `malloc(3C)`, `bsdmalloc(3MALLOC)`, `malloc(3MALLOC)`, and `mtmalloc`.

- The `bsdmalloc(3MALLOC)` routines afford better performance, but are space-inefficient.
- The `malloc(3MALLOC)` routines are space-efficient, but have slower performance.
- The standard, fully SCD-compliant `malloc` routines are a trade-off between performance and space-efficiency.
- The `mtmalloc` routines provide fast, concurrent `malloc()` implementation that is space-inefficient.

The `free()` function does not set `errno`.

malloc(3MALLOC)

NAME	malloc, free, realloc, calloc, malloc, mallinfo – memory allocator				
SYNOPSIS	<pre>cc [flag ...] file ... -lmalloc [library ...] #include <stdlib.h> void *malloc(size_t size); void free(void *ptr); void *realloc(void *ptr, size_t size); void *calloc(size_t nelem, size_t elsize); #include <malloc.h> int mallopt(int cmd, int value); struct mallinfo mallinfo(void);</pre>				
DESCRIPTION	<p>The malloc() and free() functins provide a simple general-purpose memory allocation package.</p> <p>The malloc() function returns a pointer to a block of at least <i>size</i> bytes suitably aligned for any use.</p> <p>The argument to free() is a pointer to a block previously allocated by malloc(). After free() is performed, this space is made available for further allocation, and its contents have been destroyed See mallopt() below for a way to change this behavior. The above mentioned “large groups” each contain <i>numlblks</i> blocks. <i>numlblks</i> must be greater than 0. The default value for <i>numlblks</i> is 100.</td></tr></table>	M_MXFAST	Set <i>maxfast</i> to <i>value</i> . The algorithm allocates all blocks below the size of <i>maxfast</i> in large groups and then doles them out very quickly. The default value for <i>maxfast</i> is 24.	M_NLBLKS	Set <i>numlblks</i> to <i>value</i> . The above mentioned “large groups” each contain <i>numlblks</i> blocks. <i>numlblks</i> must be greater than 0. The default value for <i>numlblks</i> is 100.
M_MXFAST	Set <i>maxfast</i> to <i>value</i> . The algorithm allocates all blocks below the size of <i>maxfast</i> in large groups and then doles them out very quickly. The default value for <i>maxfast</i> is 24.				
M_NLBLKS	Set <i>numlblks</i> to <i>value</i> . The above mentioned “large groups” each contain <i>numlblks</i> blocks. <i>numlblks</i> must be greater than 0. The default value for <i>numlblks</i> is 100.				

malloc(3MALLOC)

<code>M_GRAIN</code>	Set <i>grain</i> to <i>value</i> . The sizes of all blocks smaller than <i>maxfast</i> are considered to be rounded up to the nearest multiple of <i>grain</i> . <i>grain</i> must be greater than 0. The default value of <i>grain</i> is the smallest number of bytes that will allow alignment of any data type. Value will be rounded up to a multiple of the default when <i>grain</i> is set.
<code>M_KEEP</code>	Preserve data in a freed block until the next <code>malloc()</code> , <code>realloc()</code> , or <code>calloc()</code> . This option is provided only for compatibility with the old version of <code>malloc()</code> , and it is not recommended.

These values are defined in the `<malloc.h>` header.

The `malloc()` function can be called repeatedly, but cannot be called after the first small block is allocated.

The `mallinfo()` function provides instrumentation describing space usage. It returns the `mallinfo` structure with the following members:

```
unsigned long arena;      /* total space in arena */
unsigned long ordblks;    /* number of ordinary blocks */
unsigned long smlbks;    /* number of small blocks */
unsigned long hblkhd;    /* space in holding block headers */
unsigned long hblks;     /* number of holding blocks */
unsigned long usmlbks;   /* space in small blocks in use */
unsigned long fsmblks;   /* space in free small blocks */
unsigned long uordblks;  /* space in ordinary blocks in use */
unsigned long fordblks;  /* space in free ordinary blocks */
unsigned long keepcost;  /* space penalty if keep option */
                        /* is used */
```

The `mallinfo` structure is defined in the `<malloc.h>` header.

Each of the allocation routines returns a pointer to space suitably aligned (after possible pointer coercion) for storage of any type of object.

RETURN VALUES

The `malloc()`, `realloc()`, and `calloc()` functions return a null pointer if there is not enough available memory. When `realloc()` returns `NULL`, the block pointed to by *ptr* is left intact. If `malloc()` is called after any allocation or if *cmd* or *value* are invalid, a non-zero value is returned. Otherwise, it returns 0.

ERRORS

If `malloc()`, `calloc()`, or `realloc()` returns unsuccessfully, `errno` is set to indicate the error:

<code>ENOMEM</code>	<i>size</i> bytes of memory exceeds the physical limits of your system, and cannot be allocated.
<code>EAGAIN</code>	There is not enough memory available at this point in time to allocate <i>size</i> bytes of memory; but the application could try again later.

NAME	mblen – get number of bytes in a character						
SYNOPSIS	<pre>#include <stdlib.h> int mblen(const char *s, size_t n);</pre>						
DESCRIPTION	<p>If <i>s</i> is not a null pointer, <code>mblen()</code> determines the number of bytes constituting the character pointed to by <i>s</i>. It is equivalent to:</p> <pre>mbtowc((wchar_t *)0, s, n);</pre> <p>A call with <i>s</i> as a null pointer causes this function to return 0. The behavior of this function is affected by the <code>LC_CTYPE</code> category of the current locale.</p>						
RETURN VALUES	<p>If <i>s</i> is a null pointer, <code>mblen()</code> returns 0. If <i>s</i> is not a null pointer, <code>mblen()</code> returns 0 (if <i>s</i> points to the null byte), the number of bytes that constitute the character (if the next <i>n</i> or fewer bytes form a valid character), or -1 (if they do not form a valid character) and may set <code>errno</code> to indicate the error. In no case will the value returned be greater than <i>n</i> or the value of the <code>MB_CUR_MAX</code> macro.</p>						
ERRORS	<p>The <code>mblen()</code> function may fail if:</p> <p><code>EILSEQ</code> Invalid character sequence is detected.</p>						
USAGE	<p>The <code>mblen()</code> function can be used safely in multithreaded applications, as long as <code>setlocale(3C)</code> is not being called to change the locale.</p>						
ATTRIBUTES	<p>See <code>attributes(5)</code> for descriptions of the following attributes:</p> <table border="1"> <thead> <tr> <th>ATTRIBUTE TYPE</th> <th>ATTRIBUTE VALUE</th> </tr> </thead> <tbody> <tr> <td>MT-Level</td> <td>MT-Safe with exceptions</td> </tr> <tr> <td>CSI</td> <td>Enabled</td> </tr> </tbody> </table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	MT-Level	MT-Safe with exceptions	CSI	Enabled

mbrlen(3C)

NAME	mbrlen – get number of bytes in a character (restartable)								
SYNOPSIS	<pre>#include <wchar.h> size_t mbrlen(const char *s, size_t n, mbstate_t *ps);</pre>								
DESCRIPTION	<p>If <i>s</i> is not a null pointer, <code>mbrlen()</code> determines the number of bytes constituting the character pointed to by <i>s</i>. It is equivalent to:</p> <pre>mbstate_t internal; mbrtowc(NULL, s, n, ps != NULL ? ps : &internal);</pre> <p>If <i>ps</i> is a null pointer, the <code>mbrlen()</code> function uses its own internal <code>mbstate_t</code> object, which is initialized at program startup to the initial conversion state. Otherwise, the <code>mbstate_t</code> object pointed to by <i>ps</i> is used to completely describe the current conversion state of the associated character sequence. Solaris will behave as if no function defined in the Solaris Reference Manual calls <code>mbrlen()</code>.</p> <p>The behavior of this function is affected by the <code>LC_CTYPE</code> category of the current locale. See <code>environ(5)</code>.</p>								
RETURN VALUES	<p>The <code>mbrlen()</code> function returns the first of the following that applies:</p> <table><tr><td>0</td><td>If the next <i>n</i> or fewer bytes complete the character that corresponds to the null wide-character.</td></tr><tr><td>positive</td><td>If the next <i>n</i> or fewer bytes complete a valid character; the value returned is the number of bytes that complete the character.</td></tr><tr><td>(size_t)-2</td><td>If the next <i>n</i> bytes contribute to an incomplete but potentially valid character, and all <i>n</i> bytes have been processed. When <i>n</i> has at least the value of the <code>MB_CUR_MAX</code> macro, this case can only occur if <i>s</i> points at a sequence of redundant shift sequences (for implementations with state-dependent encodings).</td></tr><tr><td>(size_t)-1</td><td>If an encoding error occurs, in which case the next <i>n</i> or fewer bytes do not contribute to a complete and valid character. In this case, <code>EILSEQ</code> is stored in <code>errno</code> and the conversion state is undefined.</td></tr></table>	0	If the next <i>n</i> or fewer bytes complete the character that corresponds to the null wide-character.	positive	If the next <i>n</i> or fewer bytes complete a valid character; the value returned is the number of bytes that complete the character.	(size_t)-2	If the next <i>n</i> bytes contribute to an incomplete but potentially valid character, and all <i>n</i> bytes have been processed. When <i>n</i> has at least the value of the <code>MB_CUR_MAX</code> macro, this case can only occur if <i>s</i> points at a sequence of redundant shift sequences (for implementations with state-dependent encodings).	(size_t)-1	If an encoding error occurs, in which case the next <i>n</i> or fewer bytes do not contribute to a complete and valid character. In this case, <code>EILSEQ</code> is stored in <code>errno</code> and the conversion state is undefined.
0	If the next <i>n</i> or fewer bytes complete the character that corresponds to the null wide-character.								
positive	If the next <i>n</i> or fewer bytes complete a valid character; the value returned is the number of bytes that complete the character.								
(size_t)-2	If the next <i>n</i> bytes contribute to an incomplete but potentially valid character, and all <i>n</i> bytes have been processed. When <i>n</i> has at least the value of the <code>MB_CUR_MAX</code> macro, this case can only occur if <i>s</i> points at a sequence of redundant shift sequences (for implementations with state-dependent encodings).								
(size_t)-1	If an encoding error occurs, in which case the next <i>n</i> or fewer bytes do not contribute to a complete and valid character. In this case, <code>EILSEQ</code> is stored in <code>errno</code> and the conversion state is undefined.								
ERRORS	<p>The <code>mbrlen()</code> function may fail if:</p> <table><tr><td><code>EINVAL</code></td><td>The <i>ps</i> argument points to an object that contains an invalid conversion state.</td></tr><tr><td><code>EILSEQ</code></td><td>Invalid character sequence is detected.</td></tr></table>	<code>EINVAL</code>	The <i>ps</i> argument points to an object that contains an invalid conversion state.	<code>EILSEQ</code>	Invalid character sequence is detected.				
<code>EINVAL</code>	The <i>ps</i> argument points to an object that contains an invalid conversion state.								
<code>EILSEQ</code>	Invalid character sequence is detected.

ATTRIBUTE TYPE	ATTRIBUTE VALUE
MT-Level	See NOTES below

SEE ALSO mbrtowc(3C), mbsinit(3C), setlocale(3C), attributes(5), environ(5)

NOTES If *ps* is not a null pointer, `mbrlen()` uses the `mbstate_t` object pointed to by *ps* and the function can be used safely in multithreaded applications, as long as `setlocale(3C)` is not being called to change the locale. If *ps* is a null pointer, `mbrlen()` uses its internal `mbstate_t` object and the function is Unsafe in multithreaded applications.

mbrtowc(3C)

NAME	mbrtowc – convert a character to a wide-character code (restartable)								
SYNOPSIS	<pre>#include <wchar.h> size_t mbrtowc(wchar_t *pwc, const char *s, size_t n, mbstate_t *ps);</pre>								
DESCRIPTION	<p>If <i>s</i> is a null pointer, the <code>mbrtowc()</code> function is equivalent to the call:</p> <pre>mbrtowc(NULL, '', 1, ps)</pre> <p>In this case, the values of the arguments <i>pwc</i> and <i>n</i> are ignored.</p> <p>If <i>s</i> is not a null pointer, the <code>mbrtowc()</code> function inspects at most <i>n</i> bytes beginning at the byte pointed to by <i>s</i> to determine the number of bytes needed to complete the next character (including any shift sequences). If the function determines that the next character is completed, it determines the value of the corresponding wide-character and then, if <i>pwc</i> is not a null pointer, stores that value in the object pointed to by <i>pwc</i>. If the corresponding wide-character is the null wide-character, the resulting state described is the initial conversion state.</p> <p>If <i>ps</i> is a null pointer, the <code>mbrtowc()</code> function uses its own internal <code>mbstate_t</code> object, which is initialized at program startup to the initial conversion state. Otherwise, the <code>mbstate_t</code> object pointed to by <i>ps</i> is used to completely describe the current conversion state of the associated character sequence. Solaris will behave as if no function defined in the Solaris Reference Manual calls <code>mbrtowc()</code>.</p> <p>The behavior of this function is affected by the <code>LC_CTYPE</code> category of the current locale. See <code>environ(5)</code>.</p>								
RETURN VALUES	<p>The <code>mbrtowc()</code> function returns the first of the following that applies:</p> <table><tr><td>0</td><td>If the next <i>n</i> or fewer bytes complete the character that corresponds to the null wide-character (which is the value stored).</td></tr><tr><td>positive</td><td>If the next <i>n</i> or fewer bytes complete a valid character (which is the value stored); the value returned is the number of bytes that complete the character.</td></tr><tr><td>(size_t)-2</td><td>If the next <i>n</i> bytes contribute to an incomplete but potentially valid character, and all <i>n</i> bytes have been processed (no value is stored). When <i>n</i> has at least the value of the <code>MB_CUR_MAX</code> macro, this case can only occur if <i>s</i> points at a sequence of redundant shift sequences (for implementations with state-dependent encodings).</td></tr><tr><td>(size_t)-1</td><td>If an encoding error occurs, in which case the next <i>n</i> or fewer bytes do not contribute to a complete and valid character (no value is stored). In this case, <code>EILSEQ</code> is stored in <code>errno</code> and the conversion state is undefined.</td></tr></table>	0	If the next <i>n</i> or fewer bytes complete the character that corresponds to the null wide-character (which is the value stored).	positive	If the next <i>n</i> or fewer bytes complete a valid character (which is the value stored); the value returned is the number of bytes that complete the character.	(size_t)-2	If the next <i>n</i> bytes contribute to an incomplete but potentially valid character, and all <i>n</i> bytes have been processed (no value is stored). When <i>n</i> has at least the value of the <code>MB_CUR_MAX</code> macro, this case can only occur if <i>s</i> points at a sequence of redundant shift sequences (for implementations with state-dependent encodings).	(size_t)-1	If an encoding error occurs, in which case the next <i>n</i> or fewer bytes do not contribute to a complete and valid character (no value is stored). In this case, <code>EILSEQ</code> is stored in <code>errno</code> and the conversion state is undefined.
0	If the next <i>n</i> or fewer bytes complete the character that corresponds to the null wide-character (which is the value stored).								
positive	If the next <i>n</i> or fewer bytes complete a valid character (which is the value stored); the value returned is the number of bytes that complete the character.								
(size_t)-2	If the next <i>n</i> bytes contribute to an incomplete but potentially valid character, and all <i>n</i> bytes have been processed (no value is stored). When <i>n</i> has at least the value of the <code>MB_CUR_MAX</code> macro, this case can only occur if <i>s</i> points at a sequence of redundant shift sequences (for implementations with state-dependent encodings).								
(size_t)-1	If an encoding error occurs, in which case the next <i>n</i> or fewer bytes do not contribute to a complete and valid character (no value is stored). In this case, <code>EILSEQ</code> is stored in <code>errno</code> and the conversion state is undefined.								
ERRORS	The <code>mbrtowc()</code> function may fail if:								

EINVAL The *ps* argument points to an object that contains an invalid conversion state.

EILSEQ Invalid character sequence is detected.

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
MT-Level	See NOTES below

SEE ALSO `mbsinit(3C)`, `setlocale(3C)`, `attributes(5)`, `environ(5)`

NOTES If *ps* is not a null pointer, `mbrtowc()` uses the `mbstate_t` object pointed to by *ps* and the function can be used safely in multithreaded applications, as long as `setlocale(3C)` is not being called to change the locale. If *ps* is a null pointer, `mbrtowc()` uses its internal `mbstate_t` object and the function is Unsafe in multithreaded applications.

mbsinit(3C)

NAME	mbsinit – determine conversion object status				
SYNOPSIS	<pre>#include <wchar.h> int mbsinit(const mbstate_t *ps);</pre>				
DESCRIPTION	If <i>ps</i> is not a null pointer, the <code>mbsinit()</code> function determines whether the object pointed to by <i>ps</i> describes an initial conversion state.				
RETURN VALUES	The <code>mbsinit()</code> function returns non-zero if <i>ps</i> is a null pointer, or if the pointed-to object describes an initial conversion state; otherwise, it returns 0. If an <code>mbstate_t</code> object is altered by any of the functions described as "restartable", and is then used with a different character sequence, or in the other conversion direction, or with a different <code>LC_CTYPE</code> category setting than on earlier function calls, the behavior is undefined. See <code>environ(5)</code> .				
ERRORS	No errors are defined.				
USAGE	The <code>mbstate_t</code> object is used to describe the current conversion state from a particular character sequence to a wide-character sequence (or vice versa) under the rules of a particular setting of the <code>LC_CTYPE</code> category of the current locale. The initial conversion state corresponds, for a conversion in either direction, to the beginning of a new character sequence in the initial shift state. A zero-valued <code>mbstate_t</code> object is at least one way to describe an initial conversion state. A zero-valued <code>mbstate_t</code> object can be used to initiate conversion involving any character sequence, in any <code>LC_CTYPE</code> category setting.

NOTES	The <code>mbsinit()</code> function can be used safely in multithreaded applications, as long as <code>setlocale(3C)</code> is not being called to change the locale.				

NAME	mbsrtowcs – convert a character string to a wide-character string (restartable)				
SYNOPSIS	<pre>#include <wchar.h> size_t mbsrtowcs(wchar_t *dst, const char **src, size_t len, mbstate_t *ps);</pre>				
DESCRIPTION	<p>The <code>mbsrtowcs()</code> function converts a sequence of characters, beginning in the conversion state described by the object pointed to by <code>ps</code>, from the array indirectly pointed to by <code>src</code> into a sequence of corresponding wide-characters. If <code>dst</code> is not a null pointer, the converted characters are stored into the array pointed to by <code>dst</code>. Conversion continues up to and including a terminating null character, which is also stored. Conversion stops early in either of the following cases:</p> <ul style="list-style-type: none"> ■ When a sequence of bytes is encountered that does not form a valid character. ■ When <code>len</code> codes have been stored into the array pointed to by <code>dst</code> (and <code>dst</code> is not a null pointer). <p>Each conversion takes place as if by a call to the <code>mbrtowc()</code> function.</p> <p>If <code>dst</code> is not a null pointer, the pointer object pointed to by <code>src</code> is assigned either a null pointer (if conversion stopped due to reaching a terminating null character) or the address just past the last character converted (if any). If conversion stopped due to reaching a terminating null character, and if <code>dst</code> is not a null pointer, the resulting state described is the initial conversion state.</p> <p>If <code>ps</code> is a null pointer, the <code>mbsrtowcs()</code> function uses its own internal <code>mbstate_t</code> object, which is initialized at program startup to the initial conversion state. Otherwise, the <code>mbstate_t</code> object pointed to by <code>ps</code> is used to completely describe the current conversion state of the associated character sequence. Solaris will behave as if no function defined in the Solaris Reference Manual calls <code>mbsrtowcs()</code>.</p> <p>The behavior of this function is affected by the <code>LC_CTYPE</code> category of the current locale. See <code>environ(5)</code>.</p>				
RETURN VALUES	<p>If the input conversion encounters a sequence of bytes that do not form a valid character, an encoding error occurs. In this case, the <code>mbsrtowcs()</code> function stores the value of the macro <code>EILSEQ</code> in <code>errno</code> and returns <code>(size_t)-1</code>; the conversion state is undefined. Otherwise, it returns the number of characters successfully converted, not including the terminating null (if any).</p>				
ERRORS	<p>The <code>mbsrtowcs()</code> function may fail if:</p> <table border="0" style="width: 100%;"> <tr> <td style="padding-right: 20px;"><code>EINVAL</code></td> <td>The <code>ps</code> argument points to an object that contains an invalid conversion state.</td> </tr> <tr> <td><code>EILSEQ</code></td> <td>Invalid character sequence is detected.</td> </tr> </table>	<code>EINVAL</code>	The <code>ps</code> argument points to an object that contains an invalid conversion state.	<code>EILSEQ</code>	Invalid character sequence is detected.
<code>EINVAL</code>	The <code>ps</code> argument points to an object that contains an invalid conversion state.				
<code>EILSEQ</code>	Invalid character sequence is detected.				

mbsrtowcs(3C)

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
MT-Level	See NOTES below

SEE ALSO `mbrtowc(3C)`, `mbsinit(3C)`, `setlocale(3C)`, `attributes(5)`, `environ(5)`

NOTES If *ps* is not a null pointer, `mbsrtowcs()` uses the `mbstate_t` object pointed to by *ps* and the function can be used safely in multithreaded applications, as long as `setlocale(3C)` is not being called to change the locale. If *ps* is a null pointer, `mbsrtowcs()` uses its internal `mbstate_t` object and the function is Unsafe in multithreaded applications.

NAME	mbstowcs – convert a character string to a wide-character string						
SYNOPSIS	<pre>#include <stdlib.h> size_t mbstowcs(wchar_t *pwcs, const char *s, size_t n);</pre>						
DESCRIPTION	<p>The <code>mbstowcs()</code> function converts a sequence of characters from the array pointed to by <code>s</code> into a sequence of corresponding wide-character codes and stores not more than <code>n</code> wide-character codes into the array pointed to by <code>pwcs</code>. No characters that follow a null byte (which is converted into a wide-character code with value 0) will be examined or converted. Each character is converted as if by a call to <code>mbtowlc(3C)</code>.</p> <p>No more than <code>n</code> elements will be modified in the array pointed to by <code>pwcs</code>. If copying takes place between objects that overlap, the behavior is undefined.</p> <p>The behavior of this function is affected by the <code>LC_CTYPE</code> category of the current locale. If <code>pwcs</code> is a null pointer, <code>mbstowcs()</code> returns the length required to convert the entire array regardless of the value of <code>n</code>, but no values are stored.</p>						
RETURN VALUES	<p>If an invalid character is encountered, <code>mbstowcs()</code> returns <code>(size_t)-1</code> and may set <code>errno</code> to indicate the error. Otherwise, <code>mbstowcs()</code> returns the number of the array elements modified (or required if <code>pwcs</code> is <code>NULL</code>), not including a terminating 0 code, if any. The array will not be zero-terminated if the value returned is <code>n</code>.</p>						
ERRORS	<p>The <code>mbstowcs()</code> function may fail if:</p> <p><code>EILSEC</code> Invalid byte sequence is detected.</p>						
ATTRIBUTES	<p>See <code>attributes(5)</code> for descriptions of the following attributes:</p> <table border="1" style="width: 100%; border-collapse: collapse;"> <thead> <tr> <th style="text-align: left;">ATTRIBUTE TYPE</th> <th style="text-align: left;">ATTRIBUTE VALUE</th> </tr> </thead> <tbody> <tr> <td>MT-Level</td> <td>MT-Safe</td> </tr> <tr> <td>CSI</td> <td>Enabled</td> </tr> </tbody> </table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	MT-Level	MT-Safe	CSI	Enabled

mbtowc(3C)

NAME	mbtowc – convert a character to a wide-character code						
SYNOPSIS	<pre>#include <stdlib.h> int mbtowc(wchar_t *pwc, const char *s, size_t n);</pre>						
DESCRIPTION	<p>If <i>s</i> is not a null pointer, <code>mbtowc()</code> determines the number of the bytes that constitute the character pointed to by <i>s</i>. It then determines the wide-character code for the value of type <code>wchar_t</code> that corresponds to that character. (The value of the wide-character code corresponding to the null byte is 0.) If the character is valid and <i>pwc</i> is not a null pointer, <code>mbtowc()</code> stores the wide-character code in the object pointed to by <i>pwc</i>.</p> <p>A call with <i>s</i> as a null pointer causes this function to return 0. The behavior of this function is affected by the <code>LC_CTYPE</code> category of the current locale. At most <i>n</i> bytes of the array pointed to by <i>s</i> will be examined.</p>						
RETURN VALUES	<p>If <i>s</i> is a null pointer, <code>mbtowc()</code> returns 0. If <i>s</i> is not a null pointer, <code>mbtowc()</code> returns 0 (if <i>s</i> points to the null byte), the number of bytes that constitute the converted character (if the next <i>n</i> or fewer bytes form a valid character), or -1 and may set <code>errno</code> to indicate the error (if they do not form a valid character).</p> <p>In no case will the value returned be greater than <i>n</i> or the value of the <code>MB_CUR_MAX</code> macro.</p>						
ERRORS	<p>The <code>mbtowc()</code> function may fail if:</p> <table><tr><td><code>EILSEQ</code></td><td>Invalid character sequence is detected.</td></tr></table>	<code>EILSEQ</code>	Invalid character sequence is detected.				
<code>EILSEQ</code>	Invalid character sequence is detected.						
USAGE	The <code>mbtowc()</code> function can be used safely in multithreaded applications, as long as <code>setlocale(3C)</code> is not being called to change the locale.

SEE ALSO	<code>mblen(3C)</code> , <code>mbstowcs(3C)</code> , <code>setlocale(3C)</code> , <code>wcstombs(3C)</code> , <code>wctomb(3C)</code> , <code>attributes(5)</code>						

NAME	mctl – memory management control
SYNOPSIS	<pre> /usr/ucb/cc[flag ...] file ... #include <sys/types.h> #include <sys/mman.h> int mctl(addr, len, function, arg); caddr_t addr; size_t len; int function; int arg; </pre>
DESCRIPTION	<p>mctl() applies a variety of control functions over pages identified by the mappings established for the address range [addr, addr + len). The function to be performed is identified by the argument <i>function</i>. Valid functions are defined in <code>mman.h</code> as follows:</p> <p>MC_LOCK Lock the pages in the range in memory. This function is used to support <code>mlock()</code>. See <code>mlock(3C)</code> for semantics and usage. <i>arg</i> is ignored.</p> <p>MC_LOCKAS Lock the pages in the address space in memory. This function is used to support <code>mlockall()</code>. See <code>mlockall(3C)</code> for semantics and usage. <i>addr</i> and <i>len</i> are ignored. <i>arg</i> is an integer built from the flags:</p> <p style="padding-left: 40px;">MCL_CURRENT Lock current mappings</p> <p style="padding-left: 40px;">MCL_FUTURE Lock future mappings</p> <p>MC_SYNC Synchronize the pages in the range with their backing storage. Optionally invalidate cache copies. This function is used to support <code>msync()</code>. See <code>msync(3C)</code> for semantics and usage. <i>arg</i> is used to represent the <i>flags</i> argument to <code>msync()</code>. It is constructed from an OR of the following values:</p> <p style="padding-left: 40px;">MS_SYNC Synchronized write</p> <p style="padding-left: 40px;">MS_ASYNC Return immediately</p> <p style="padding-left: 40px;">MS_INVALIDATE Invalidate mappings</p> <p style="padding-left: 40px;">MS_ASYNC returns after all I/O operations are scheduled. MS_SYNC does not return until all I/O operations are complete. Specify exactly one of MS_ASYNC or MS_SYNC. MS_INVALIDATE invalidates all cached copies of data from memory, requiring them to be re-obtained from the object's permanent storage location upon the next reference.</p> <p>MC_UNLOCK Unlock the pages in the range. This function is used to support <code>munlock()</code>. <i>arg</i> is ignored.</p> <p>MC_UNLOCKAS Remove address space memory lock, and locks on all current mappings. This function is used to support <code>munlockall()</code>. <i>addr</i></p>

mctl(3UCB)

and *len* must have the value 0. *arg* is ignored.

RETURN VALUES mctl() returns 0 on success, -1 on failure.

ERRORS mctl() fails if:

- EAGAIN Some or all of the memory identified by the operation could not be locked due to insufficient system resources.
- EBUSY MS_INVALIDATE was specified and one or more of the pages is locked in memory.
- EINVAL *addr* is not a multiple of the page size as returned by `getpagesize()`.
- EINVAL *addr* and/or *len* do not have the value 0 when MC_LOCKAS or MC_UNLOCKAS are specified.
- EINVAL *arg* is not valid for the function specified.
- EIO An I/O error occurred while reading from or writing to the file system.
- ENOMEM Addresses in the range [*addr*, *addr* + *len*) are invalid for the address space of a process, or specify one or more pages which are not mapped.
- EPERM The process's effective user ID is not super-user and one of MC_LOCK, MC_LOCKAS, MC_UNLOCK, or MC_UNLOCKAS was specified.

SEE ALSO mmap(2), memcntl(2), getpagesize(3C), mlock(3C), mlockall(3C), msync(3C)

NOTES Use of these interfaces should be restricted to only applications written on BSD platforms. Use of these interfaces with any of the system libraries or in multi-thread applications is unsupported.

NAME	malloc, calloc, free, memalign, realloc, valloc, alloca – memory allocator
SYNOPSIS	<pre>#include <stdlib.h> void *malloc(size_t size); void *calloc(size_t nelem, size_t elsize); void free(void *ptr); void *memalign(size_t alignment, size_t size); void *realloc(void *ptr, size_t size); void *valloc(size_t size); #include <alloca.h> void *alloca(size_t size);</pre>
DESCRIPTION	<p>The <code>malloc()</code> and <code>free()</code> functions provide a simple, general-purpose memory allocation package. The <code>malloc()</code> function returns a pointer to a block of at least <i>size</i> bytes suitably aligned for any use. If the space assigned by <code>malloc()</code> is overrun, the results are undefined.</p> <p>The argument to <code>free()</code> is a pointer to a block previously allocated by <code>malloc()</code>, <code>calloc()</code>, or <code>realloc()</code>. After <code>free()</code> is executed, this space is made available for further allocation by the application, though not returned to the system. Memory is returned to the system only upon termination of the application. If <i>ptr</i> is a null pointer, no action occurs. If a random number is passed to <code>free()</code>, the results are undefined.</p> <p>The <code>calloc()</code> function allocates space for an array of <i>nelem</i> elements of size <i>elsize</i>. The space is initialized to zeros.</p> <p>The <code>memalign()</code> function allocates <i>size</i> bytes on a specified alignment boundary and returns a pointer to the allocated block. The value of the returned address is guaranteed to be an even multiple of <i>alignment</i>. The value of <i>alignment</i> must be a power of two and must be greater than or equal to the size of a word.</p> <p>The <code>realloc()</code> function changes the size of the block pointed to by <i>ptr</i> to <i>size</i> bytes and returns a pointer to the (possibly moved) block. The contents will be unchanged up to the lesser of the new and old sizes. If <i>ptr</i> is <code>NULL</code>, <code>realloc()</code> behaves like <code>malloc()</code> for the specified size. If <i>size</i> is 0 and <i>ptr</i> is not a null pointer, the space pointed to is made available for further allocation by the application, though not returned to the system. Memory is returned to the system only upon termination of the application.</p> <p>The <code>valloc()</code> function has the same effect as <code>malloc()</code>, except that the allocated memory will be aligned to a multiple of the value returned by <code>sysconf(_SC_PAGESIZE)</code>.</p>

memalign(3C)

The `alloca()` function allocates *size* bytes of space in the stack frame of the caller, and returns a pointer to the allocated block. This temporary space is automatically freed when the caller returns. If the allocated block is beyond the current stack limit, the resulting behavior is undefined.

RETURN VALUES Upon successful completion, each of the allocation functions returns a pointer to space suitably aligned (after possible pointer coercion) for storage of any type of object.

If there is no available memory, `malloc()`, `realloc()`, `memalign()`, `valloc()`, and `calloc()` return a null pointer. When `realloc()` is called with *size* > 0 and returns `NULL`, the block pointed to by *ptr* is left intact. If *size*, *nelem*, or *elsize* is 0, either a null pointer or a unique pointer that can be passed to `free()` is returned.

If `malloc()`, `calloc()`, or `realloc()` returns unsuccessfully, `errno` will be set to indicate the error. The `free()` function does not set `errno`.

ERRORS The `malloc()`, `calloc()`, and `realloc()` functions will fail if:

- | | |
|---------------------|--|
| <code>ENOMEM</code> | The physical limits of the system are exceeded by <i>size</i> bytes of memory which cannot be allocated. |
| <code>EAGAIN</code> | There is not enough memory available to allocate <i>size</i> bytes of memory; but the application could try again later. |

USAGE Portable applications should avoid using `valloc()` but should instead use `malloc()` or `mmap(2)`. On systems with a large page size, the number of successful `valloc()` operations might be 0.

Comparative features of `malloc(3C)`, `bsdmalloc(3MALLOC)`, and `malloc(3MALLOC)` are as follows:

- The `bsdmalloc(3MALLOC)` routines afford better performance, but are space-inefficient.
- The `malloc(3MALLOC)` routines are space-efficient, but have slower performance.
- The standard, fully SCD-compliant `malloc` routines are a trade-off between performance and space-efficiency.

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Interface Stability	<code>malloc()</code> , <code>calloc()</code> , <code>free()</code> , <code>realloc()</code> , <code>valloc()</code> are Standard; <code>memalign()</code> and <code>alloca()</code> are Stable.
MT-Level	Safe

SEE ALSO `brk(2)`, `getrlimit(2)`, `bsdmalloc(3MALLOC)`, `malloc(3MALLOC)`, `mapmalloc(3MALLOC)`, `watchmalloc(3MALLOC)`, `attributes(5)`

WARNINGS Undefined results will occur if the size requested for a block of memory exceeds the maximum size of a process's heap, which can be obtained with `getrlimit(2)`

The `alloca()` function is machine-, compiler-, and most of all, system-dependent. Its use is strongly discouraged.

memalign(3MALLOC)

NAME	watchmalloc, cfree, memalign, valloc – debugging memory allocator
SYNOPSIS	<pre>#include <stdlib.h> void *malloc(size_t size); void free(void *ptr); void *realloc(void *ptr, size_t size); void *memalign(size_t alignment, size_t size); void *valloc(size_t size); void *calloc(size_t nelem, size_t elsize); void cfree(void *ptr, size_t nelem, size_t elsize); #include <malloc.h> int mallopt(int cmd, int value); struct mallinfo mallinfo(void);</pre>
DESCRIPTION	<p>The collection of <code>malloc()</code> functions in this shared object are an optional replacement for the standard versions of the same functions in the system C library. See <code>malloc(3C)</code>. They provide a more strict interface than the standard versions and enable enforcement of the interface through the watchpoint facility of <code>/proc</code>. See <code>proc(4)</code>.</p> <p>Any dynamically linked application can be run with these functions in place of the standard functions if the following string is present in the environment (see <code>ld.so.1(1)</code>):</p> <pre>LD_PRELOAD=watchmalloc.so.1</pre> <p>The individual function interfaces are identical to the standard ones as described in <code>malloc(3C)</code>. However, laxities provided in the standard versions are not permitted when the watchpoint facility is enabled (see <code>WATCHPOINTS</code> below):</p> <ul style="list-style-type: none">■ Memory may not be freed more than once.■ A pointer to freed memory may not be used in a call to <code>realloc()</code>.■ A call to <code>malloc()</code> immediately following a call to <code>free()</code> will not return the same space.■ Any reference to memory that has been freed yields undefined results. <p>To enforce these restrictions partially, without great loss in speed as compared to the watchpoint facility described below, a freed block of memory is overwritten with the pattern <code>0xdeadbeef</code> before returning from <code>free()</code>. The <code>malloc()</code> function returns with the allocated memory filled with the pattern <code>0xbaddcafe</code> as a precaution against applications incorrectly expecting to receive back unmodified memory from the last <code>free()</code>. The <code>calloc()</code> function always returns with the memory zero-filled.</p>

memalign(3MALLOC)

WATCHPOINTS

Entry points for `malloc()` and `mallinfo()` are provided as empty routines, and are present only because some `malloc()` implementations provide them.

The watchpoint facility of `/proc` can be applied by a process to itself. The functions in `watchmalloc.so.1` use this feature if the following string is present in the environment:

```
MALLOC_DEBUG=WATCH
```

This causes every block of freed memory to be covered with `WA_WRITE` watched areas. If the application attempts to write any part of freed memory, it will trigger a watchpoint trap, resulting in a `SIGTRAP` signal, which normally produces an application core dump.

A header is maintained before each block of allocated memory. Each header is covered with a watched area, thereby providing a red zone before and after each block of allocated memory (the header for the subsequent memory block serves as the trailing red zone for its preceding memory block). Writing just before or just after a memory block returned by `malloc()` will trigger a watchpoint trap.

Watchpoints incur a large performance penalty. Requesting `MALLOC_DEBUG=WATCH` can cause the application to run 10 to 100 times slower, depending on the use made of allocated memory.

Further options are enabled by specifying a comma-separated string of options:

```
MALLOC_DEBUG=WATCH,RW,STOP
```

WATCH	Enables <code>WA_WRITE</code> watched areas as described above.
RW	Enables both <code>WA_READ</code> and <code>WA_WRITE</code> watched areas. An attempt either to read or write freed memory or the red zones will trigger a watchpoint trap. This incurs even more overhead and can cause the application to run up to 1000 times slower.
STOP	The process will stop showing a <code>FLTWATCH</code> machine fault if it triggers a watchpoint trap, rather than dumping core with a <code>SIGTRAP</code> signal. This allows a debugger to be attached to the live process at the point where it underwent the watchpoint trap. Also, the various <code>/proc</code> tools described in <code>proc(1)</code> can be used to examine the stopped process.

One of `WATCH` or `RW` must be specified, else the watchpoint facility is not engaged. `RW` overrides `WATCH`. Unrecognized options are silently ignored.

memalign(3MALLOC)

LIMITATIONS Sizes of memory blocks allocated by `malloc()` are rounded up to the the worst-case alignment size, 8 bytes for 32-bit processes and 16 bytes for 64-bit processes. Accessing the extra space allocated for a memory block is technically a memory violation but is in fact innocuous. Such accesses are not detected by the watchpoint facility of `watchmalloc`.

Interposition of `watchmalloc.so.1` fails innocuously if the target application is statically linked with respect to its `malloc()` functions.

mkfifo(3C)

NAME	mkfifo – make a FIFO special file																
SYNOPSIS	<pre>#include <sys/types.h> #include <sys/stat.h> int mkfifo(const char *path, mode_t mode);</pre>																
DESCRIPTION	<p>The <code>mkfifo()</code> function creates a new FIFO special file named by the pathname pointed to by <i>path</i>. The file permission bits of the new FIFO are initialized from <i>mode</i>. The file permission bits of the <i>mode</i> argument are modified by the process's file creation mask (see <code>umask(2)</code>). Bits other than the file permission bits in <i>mode</i> are ignored.</p> <p>If <i>path</i> names a symbolic link, <code>mkfifo()</code> fails and sets <code>errno</code> to <code>EEXIST</code>.</p> <p>The FIFO's user ID is set to the process's effective user ID. The FIFO's group ID is set to the group ID of the parent directory or to the effective group ID of the process.</p> <p>The <code>mkfifo()</code> function calls <code>mknod(2)</code> to create the file.</p> <p>Upon successful completion, <code>mkfifo()</code> marks for update the <code>st_atime</code>, <code>st_ctime</code>, and <code>st_mtime</code> fields of the file. Also, the <code>st_ctime</code> and <code>st_mtime</code> fields of the directory that contains the new entry are marked for update.</p>																
RETURN VALUES	Upon successful completion, 0 is returned. Otherwise, -1 is returned and <code>errno</code> is set to indicate the error.
