SEE ALSO inetd(1M), select(3C), recvfrom(3SOCKET), sendto(3SOCKET), attributes(5), gld(7D),

DIAGNOSTICS

cannot dispatch request
The proxy cannot dispatch the request. The rest of the message indicates the cause of the failure.

select(3C) failed
A select(3C) call failed. The rest of the message indicates the cause of the failure.

sendto(3SOCKET) failed
A sendto(3SOCKET) call failed. The rest of the message indicates the cause of the failure.

recvfrom(3SOCKET) failed
A recvfrom(3SOCKET) call failed. The rest of the message indicates the cause of the failure.

no response from system
The SNMP agent on the target system does not respond to SNMP requests. This error might indicate that the SNMP agent is not running on the target system, the target system is down, or the network containing the target system is unreachable.

response too big
The agent could not fit the results of an operation into a single SNMP message. Split large groups or tables into smaller entities.

missing attribute
An attribute is missing from the requested group.

bad attribute type
An object attribute type received from the SNMP agent that does not match the attribute type specified by the proxy agent schema. The rest of the message indicates the expected type and received type.

cannot get sysUpTime
The proxy agent cannot get the variable *sysUpTime* from the SNMP agent.

sysUpTime type bad
The variable *sysUpTime* received from the SNMP agent has the wrong data type.

unknown SNMP error
An unknown SNMP error was received.

mibiisa(1M)

bad variable value

The requested specified an incorrect syntax or value for a set operation.

variable is read only

The SNMP agent did not perform the set request because a variable to set may not be written.

general error

A general error was received.

cannot make request PDU

An error occurred building a request PDU.

cannot make request varbind list

An error occurred building a request variable binding list.

cannot parse response PDU

An error occurred parsing a response PDU.

request ID - response ID mismatch

The response ID does not match the request ID.

string contains non-displayable characters

A displayable string contains non-displayable characters.

cannot open schema file

An error occurred opening the proxy agent schema file.

cannot parse schema file

The proxy agent couldn't parse the proxy agent schema file.

cannot open host file

An error occurred opening the file associated with the *na.snmp.hostfile* keyword in */etc/snmp/conf/snmpd.conf*

cannot parse host file

The proxy agent was unable to parse the file associated with the *na.snmp.hostfile* keyword in */etc/snmp/conf/snm.conf*.

attribute unavailable for set operations

The set could not be completed because the attribute was not available for set operations.

BUGS The mibiisa utility returns the wrong interface speed for the SBUS FDDI interface (for example, "bf0").

The mibiisa utility does not return a MAC address for the SBUS FDDI interface (for example, "bf0").

Process names retrieved from mibiisa contain a leading blank space.

When you change attribute values in the system group with an SNMP set request, the change is effective only as long as mibiisa is running. mibiisa does not save the changes to */etc/snmp/conf/snmpd.conf*.

NAME	mipagent – Mobile IP agent
SYNOPSIS	<code>/usr/lib/inet/mipagent</code>
DESCRIPTION	The <code>mipagent</code> utility implements the Mobile IP home agent and foreign agent functionality described in <i>RFC 2002, IP Mobility Support</i>. The term “mobility agent” is used to refer to the home agent and foreign agent functionality collectively. <code>mipagent</code> responds to Mobile IP registration and deregistration requests and router discovery solicitation messages from a mobile node. Besides responding to external messages, the <code>mipagent</code> utility also tasks on a periodic basis, such as aging the mobility bindings and visitor entries and sending agent advertisements. The mobility agent can also handle direct delivery style reverse tunneling as specified in <i>RFC 2344, Reverse Tunneling for Mobile IP</i>. Limited private address support for mobile nodes is also available. In addition, separate IPsec policies for registration requests, replies, and tunnel traffic can be configured to protect the datagrams associated with these between two mobility agents. Run the <code>mipagent</code> daemon as root using the start-up script, which has the following syntax: <pre>example# /etc/init.d/mipagent [start stop]</pre> <code>/etc/inet/mipagent.conf</code> must be present before you start-up the <code>mipagent</code> daemon. See <code>mipagent.conf(4)</code>. At start up, <code>mipagent</code> reads the configuration information from <code>/etc/inet/mipagent.conf</code>. The <code>mipagent</code> daemon records a continuous log of its activities by means of <code>syslog()</code>. See <code>syslog(3C)</code>. You can use the <i>LogVerbosity</i> parameter in <code>/etc/inet/mipagent.conf</code> to control the verbosity level of the log. The <code>mipagent</code> daemon can be terminated either by the script: <pre>example# /etc/init.d/mipagent stop</pre> or by the <code>kill</code> command. Periodically while running, or if terminated or shutdown, the <code>mipagent</code> daemon stores the following internal state information in <code>/var/inet/mipagent_state</code>: ■ a list of the mobile nodes supported as home agents; ■ their current care-of addresses; and ■ the remaining registration lifetimes. If the <code>mipagent</code> utility is terminated for maintenance and restarted, <code>mipagent_state</code> is used to recreate as much of the mobility agent’s internal state as possible. This minimizes service disruption for mobile nodes that may be visiting other networks. If <code>mipagent_state</code> exists, it is read immediately after <code>mipagent.conf</code> when <code>mipagent</code> is restarted. The format of <code>mipagent_state</code> is undocumented since it is likely to change and programs other than <code>mipagent</code> should not use it for any purpose. A separate utility program <code>mipagentstat</code> is provided for monitoring <code>mipagent</code>.

mipagent(1M)

EXIT STATUS The following exit values are returned:

0 The daemon started successfully.
-1 The daemon failed to start.

FILES /etc/inet/mipagent.conf
 Configuration file for Mobile IP mobility agent.

/var/inet/mipagent_state
 File where private state information from mipagent is stored.

/etc/init.d/mipagent [start|stop]
 mipagent start-up script.

Montenegro, G., editor. *RFC 2344, Reverse Tunneling for Mobile IP*. Network Working Group. May 1998.

Perkins, C. *RFC 2002, IP Mobility Support*. Network Working Group. October 1996.

DIAGNOSTICS The mipagent utility exits with an error if the configuration file, mipagent.conf, cannot be read successfully. Upon receiving a SIGTERM or SIGINT signal, mipagent cleans its internal state, including any changes to the routing and ARP tables, and exits.

NOTES The foreign agent adds host-specific local routes to its routing table for visiting mobile nodes after they are successfully registered. If a visiting mobile node departs without sending a de-registration message through the foreign agent, these routing entries persist until the mobile node's previous registration expires. Any packets that arrive at the foreign agent for the departed mobile node during this time, for example because the foreign agent is also a router for the foreign network, will be lost. System administrators can configure foreign agents to accept only short registration lifetimes. This will automatically restrict the maximum duration for which a departed mobile node will be temporarily unreachable.

Home and foreign agents dynamically add and delete IPsec policies configured with a mobility agent peer. Those pertaining to the tunnel are only added when the tunnel is plumbed. At this time, IPsec tunnel policies must be identical in the forward and reverse direction. IPsec policies pertaining to permitting registration requests on the home agent are added to the IPsec policy file at init time as it must be ready to receive

mipagent(1M)

these at any time. Otherwise, IPsec policies pertaining to registration request and reply messages with a mobility agent peer are added as soon as they are needed, and are not removed until all mobile nodes are no longer registered with the mobility agent peer, at which point the tunnels are torn down.

mipagentconfig(1M)

NAME	mipagentconfig – configure Mobility IP Agent
SYNOPSIS	<code>/sbin/mipagentconfig [-f <i>configfile</i>] <i>command dest</i> [<i>parameters...</i>]</code>
DESCRIPTION	The <code>mipagentconfig</code> utility is used to configure the Mobility IP Agent. It allows the user to change settings and to add and delete mobility clients, Pools, and SPIs in the mobility agent configuration file.
OPTIONS	The following options are supported: <code>-f <i>configfile</i></code> Use the specified configuration file instead of the system default, <code>/etc/inet/mipagent.conf</code>.
OPERANDS	The <i>command</i> operand, as well as the parameters for each command are described below. See <code>mipagent.conf(4)</code> for the default values of the configuration operands described here. <code>add</code> Depending on the destination <i>dest</i>, this command will add advertisement parameters, security parameters, SPIs, or addresses to the configuration file. <code>add Address <i>ipAddress attr_value</i></code> Add the specified <i>ipAddress</i> with the specified SPI. To add an NAI address, you must specify the <code>Pool</code>. <code>add adv <i>device</i></code> Enable home and foreign agent functionality on the specified interface. <code>add adv <i>device AdvLifetime seconds</i></code> Add <code>AdvLifetime</code> to the specified device. <code>add adv <i>device RegLifetime seconds</i></code> Add <code>RegLifetime</code> to the specified device. <code>add adv <i>device AdvFrequency seconds</i></code> Add <code>AdvFrequency</code> to the specified device. <code>add adv <i>device AdvInitCount count</i></code> Add initial unsolicited advertisement count. <i>count</i> should be a small integer. <code>add adv <i>device AdvLimitUnsolicited yes no</i></code> Enable limited or unlimited unsolicited advertisements for foreign agent. Accepted values are: <code>yes</code> Limit unsolicited advertisement to <code>AdvInitCount</code> initial advertisements. <code>no</code> Do not limit unsolicited advertisement. The advertisement should take place periodically at the frequency specified by <code>AdvFrequency</code>.

add adv *device* HomeAgent yes | no

Add the HomeAgent flag to the specified device.

add adv *device* ForeignAgent yes | no

Add the ForeignAgent flag to the specified device.

add adv *device* PrefixLengthExt yes | no

Add the PrefixLengthExt flag to the specified device.

add adv *device* NAIExt yes | no

Add the NAIExt flag to the specified device.

add adv *device* Challenge yes | no

Add the Challenge flag to the specified device.

add adv *device* ReverseTunnel no | neither fa ha yes | both

Add the level of ReverseTunnel support indicated to the specified device. Possible values include:

no Do not support ReverseTunnel as either a foreign agent or a home agent on this device. Does not advertise reverse tunneling nor accept a registration requesting reverse tunnel support on this device.

neither Do not support ReverseTunnel as either a foreign agent or a home agent on this device. Do not advertise reverse tunneling nor accept a registration requesting reverse tunnel support on this device.

fa When the foreign agent processes a registration request received on this device, check to see if the mobile node requests that a reverse tunnel be set up to its home agent. If so, perform the necessary encapsulation of datagrams to the mobile node's home agent as described in *RFC 2344*. This means that a mobile node must see the agent advertising reverse tunnel support, so the reverse tunnel bit is advertised in the agent advertisement on this device.

ha When the home agent processes a registration request received on this device, check to see if the mobile node requests that a reverse tunnel be set up from its care-of address. If so, perform the necessary decapsulation as described in *RFC 2344*. This does not mean the home agent is advertising support of reverse tunneling on

mipagentconfig(1M)

this device. Mobile nodes are only interested in the advertisement flags if they are going to use foreign agent services. Moreover, reverse tunnels by definition originate at the care-of address, and HA support is therefore only of interest to the owner of the care-of address.

yes Whenever the mobility agent is processing a registration request received on this device, check to see if the mobile node is requesting a reverse tunnel be set up. If so, apply RFC 2344 as appropriate, either as an encapsulating foreign agent, or a decapsulating home agent, depending on how this mobility agent is servicing the specific mobile node. As a result, the mobility agent will be advertising reverse tunnel support on this device.

both Whenever the mobility agent is processing a registration request received on this device, check to see if the mobile node is requesting a reverse tunnel be set up. If so, apply RFC 2344 as appropriate, either as an encapsulating foreign agent, or a decapsulating home agent, depending on how this mobility agent is servicing the specific mobile node. As a result, the mobility agent will be advertising reverse tunnel support on this device.

`add adv device ReverseTunnelRequired no | neither fa ha
yes | both yes | both`

Add the requirement that the ReverseTunnel flag be set in any registration request received on the indicated device.
Possible values include:

no Reverse tunneling is not required by the mipagent on this device.

neither Reverse tunneling is not required by the mipagent on this device.

fa The ReverseTunnel flag is required to be set in registration requests received by the foreign agent on this device.

mipagentconfig(1M)

	ha	The ReverseTunnel flag is required to be set in registration requests received by the home agent on this device.
	yes	The ReverseTunnel flag is required to be set in all registration requests received by either home and or foreign agents on this device.
	both	The ReverseTunnel flag is required to be set in all registration requests received by either home and or foreign agents on this device.
	add Pool <i>number startAddr length</i> Add the specified Pool with the specified start addresses and length.	
	add SPI <i>number replay Key</i> Add the specified SPI with the given replay type and key. The replay type can have a value of none or timestamps.	
	add HA-FAAuth yes no Add the HA-FAAuth flag.	
	add MN-FAAuth yes no Add the MN-FAAuth flag.	
	add MaxClockSkew <i>seconds</i> Add the MaxClockSkew.	
	add KeyDistribution <i>type</i> Add the KeyDistribution type. The only value for KeyDistribution that is supported at this time is file.	
change	Depending on the destination <i>dest</i> , this command will change advertisement parameters, security parameters, SPIs, or addresses in the configuration file. Any of the above destinations are valid.	
delete	Depending on the destination <i>dest</i> , this command will delete advertisement parameters, security parameters, SPIs, or addresses from the configuration file. Any destination discussed above is valid.	
get	Display all of the parameters associated with <i>dest</i> . Any destination discussed above is valid.	

mipagentconfig(1M)

EXAMPLES

EXAMPLE 1 Adding an SPI, a Pool, and a Mobile Node and Requiring Reverse Tunneling on a Device to the *configfile*

The following example adds an SPI, a Pool, a mobile node, and requires reverse tunneling for the foreign agent in the *configfile*. First, the SPI of 250 is added. Then, a Pool of 200 addresses starting at 192.168.168.1 is added. joe@mobile.com is added with an SPI of 250 and using Pool 1. Finally, reverse tunneling is required for the foreign agent on device le0.

```
example# mipagentconfig add SPI 250 ReplayMethod none
example# mipagentconfig add SPI 250 Key 00ff00ff00ff
example# mipagentconfig add Pool 1 192.168.168.1 200
example# mipagentconfig add Address joe@mobile.com 250 1
example# mipagentconfig add le0 reversetunnel fa
example# mipagentconfig add le0 reversetunnelrequired fa
```

EXAMPLE 2 Adding Dynamic Interface Mobility Support on PPP Interfaces

The following example adds dynamic interface mobility support on PPP interfaces. The backslash (\) escape character is used to type in device number *. The example also indicates that all the new ppp interfaces offer reverse tunnel service.

```
example# mipagentconfig add ppp\* reversetunnel yes
example# mipagentconfig add ppp\* AdvLimitUnsolicited yes
example# mipagentconfig add ppp\* AdvInitCount 3
example# mipagentconfig add ppp\* AdvFrequency 1
```

EXAMPLE 3 Adding IPsec Policies to an Agent-Peer Entry

The following example adds IPsec policies to an existing mobility agent entry, then displays the configuration for the mobility agent peer. The backslash (\) character denotes a line continuation for the formatting of this example.

```
example# mipagentconfig add Address 192.168.10.1 \
        IPsecRequest apply {auth_algs md5 sa shared}
example# mipagentconfig add Address 192.168.10.1 \
        IPsecReply permit {auth_algs md5}
example# mipagentconfig add Address 192.168.10.1 \
        IPsecTunnel permit {encr_auth_algs md5 encr_algs 3des}
example# mipagentconfig get Address 192.168.10.1
```

```
[Address 192.168.10.1]
  Type = agent
  SPI = 137
  IPsecRequest = apply {auth_algs md5 sa shared}
  IPsecReply = permit {auth_algs md5}
  IPsecTunnel = \
    permit {encr_auth_algs md5 encr_algs 3des}
```

EXAMPLE 4 Modifying an SPI

To modify the SPI associated with joe, first, use the command `get` to verify the existing settings, then change the SPI from 250 to 257.

```
example# mipagentconfig get Address joe@mobile.com
Address: joe@mobile.com
SPI: 250
Pool: 1
example# mipagentconfig change Address joe@mobile.com 257 1
```

EXAMPLE 5 Deleting a Pool

Use the following example to delete Pool 3:

```
example# mipagentconfig delete Pool 3
```

EXIT STATUS

The following exit values are returned:

0	Successful completion.
non-zero	An error occurred.

FILES

<code>/etc/inet/mipagent.conf</code>	Configuration file for Mobile IP mobility agent.
<code>/etc/inet/mipagent.conf-sample</code>	Sample configuration file for mobility agents.
<code>/etc/inet/mipagent.conf.ha-sample</code>	Sample configuration file for home agent functionality.
<code>/etc/inet/mipagent.conf.fa-sample</code>	Sample configuration file for foreign agent functionality.

mipagentstat(1M)

NAME	mipagentstat – show Mobile IP Mobility Agent status															
SYNOPSIS	mipagentstat [-fhp]															
DESCRIPTION	Use the mipagentstat utility to display the content of various Mobile-IP related data structures.															
Visitor Table (First Form)	The visitor table display lists information for all mobile nodes registered with the foreign agent, one mobile node per line. This list consists of the mobile node’s home address or Network Access Identifier (NAI), home agent address, total registration lifetime and the number of seconds remaining before the registration expires. The following command line shows the output from a foreign agent with two mobile nodes registered: <pre>example# mipagentstat -f</pre> <table><tr><th>Mobile Node</th><th>Foreign Agent</th><th>Time Granted (in secs)</th><th>Time Remaining (in secs)</th><th>Flags</th></tr><tr><td>foobar@xyz.com</td><td>fal@tuv.com</td><td>600</td><td>125</td><td></td></tr><tr><td>10.1.5.23</td><td>123.2.5.12</td><td>1000</td><td>10</td><td>R</td></tr></table> An “R” in the flags column indicates a reverse tunnel is present. No reverse tunnel is configured for the mobile node foobar@xyz.com. A reverse tunnel is configured from mobile node 10.1.5.23.	Mobile Node	Foreign Agent	Time Granted (in secs)	Time Remaining (in secs)	Flags	foobar@xyz.com	fal@tuv.com	600	125		10.1.5.23	123.2.5.12	1000	10	R
Mobile Node	Foreign Agent	Time Granted (in secs)	Time Remaining (in secs)	Flags												
foobar@xyz.com	fal@tuv.com	600	125													
10.1.5.23	123.2.5.12	1000	10	R												
Binding Table (Second Form)	The binding table display lists information for all mobile nodes registered with the home agent, one mobile node per line. This list consists of the mobile node’s home address or NAI, foreign agent address, total registration lifetime and the number of seconds remaining before the registration expires. Use the following command line to show the output from a home agent with two active mobile nodes: <pre>example# mipagentstat -h</pre> <table><tr><th>Mobile Node</th><th>Home Agent</th><th>Time Granted (in secs)</th><th>Time Remaining (in secs)</th><th>Flags</th></tr><tr><td>foobar@xyz.com</td><td>hal@xyz.com</td><td>600</td><td>125</td><td></td></tr><tr><td>10.1.5.23</td><td>10.1.5.1</td><td>1000</td><td>10</td><td>R</td></tr></table> An “R” in the flags column indicates a reverse tunnel is present. No reverse tunnel is configured for the mobile node foobar@xyz.com. A reverse tunnel is configured for mobile node 10.1.5.23.	Mobile Node	Home Agent	Time Granted (in secs)	Time Remaining (in secs)	Flags	foobar@xyz.com	hal@xyz.com	600	125		10.1.5.23	10.1.5.1	1000	10	R
Mobile Node	Home Agent	Time Granted (in secs)	Time Remaining (in secs)	Flags												
foobar@xyz.com	hal@xyz.com	600	125													
10.1.5.23	10.1.5.1	1000	10	R												
Agent Table (Third Form)	The agent table display lists information for all current mobility agent-peers, that is all mobility agents with which mobile-nodes we are servicing are trying to obtain service. Provided in this display are the IPsec protection mechanisms being used with registration requests, replies, and tunnels. Use the following command line to show the output from a home agent with two (foreign) mobility agent peers: <pre>example# mipagentstat -hp</pre>															

mipagentstat(1M)

```
Foreign      . . . . . Security Association(s) . . . . .
Agent        Requests Replies FTunnel RTunnel
-----
fa.eng.sun.com    AH,ESP  AH,ESP  AH,ESP  AH,ESP
fa.central.sun.com AH      AH      ESP    ESP
```

Use the following command line to show the output from a home agent with two (foreign) mobility agent peers:

```
example# mipagentstat -fp
Home      . . . . . Security Association(s) . . . . .
Agent     Requests Replies FTunnel RTunnel
-----
ha.eng.sun.com    AH,ESP  AH,ESP  AH,ESP  AH,ESP
ha.central.sun.com
```

Use of the `-p` option without specifying the agent results in both displays described above, that is one display for each agent.

An AH in any column indicates the IPsec AH mechanism is in place for those datagrams.

An ESP in any column indicates the IPsec ESP mechanism is in place for those datagrams.

OPTIONS The following options are supported:

- f Display the list of active mobile nodes in the foreign agent's visitor's list.
- h Display the list of active mobile nodes in the home agent's binding table.
- p Display the list of mobility agent peers, and the IPsec protection mechanisms currently in use for registration and tunnel traffic.

EXIT STATUS The following exit values are returned:

- 0 Successful completion.
- non-zero An error occurred.

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

mkdevalloc(1M)

NAME	mkdevalloc – Make device_allocate entries						
SYNOPSIS	/usr/sbin/mkdevalloc						
DESCRIPTION	The mkdevalloc command writes to standard out a set of device_allocate(4) entries describing the system's frame buffer, audio and removable media devices. The mkdevalloc command is used by the <code>init.d(4)</code> scripts to create or update the <code>/etc/security/device_allocate</code> file. Entries are generated based on the device special files found in <code>/dev</code>. For the different categories of devices, the mkdevalloc command checks for the following files under <code>/dev</code>: <pre> audio /dev/audio, /dev/audioc1, /dev/sound/... tape /dev/rst*, /dev/nrst*, /dev/rmt/... floppy /dev/diskette, /dev/fd*, /dev/rdiskette, /dev/rfd* removable disk /dev/sr*, /dev/nsr*, /dev/dsk/c0t?d0s?, /dev/rdisk/c0t?d0s? frame buffer /dev/fb </pre> All entries set the <i>device-minimum</i> and <i>device-maximum</i> fields to the hex representations of ADMIN_LOW and ADMIN_HIGH, respectively. The <i>device-authorization</i> field is set to <code>solaris.device.allocate</code>, except for the <code>framebuffer</code> entry, where it is set to <code>*</code>. The <i>device-name</i>, <i>device-type</i> and <i>device-clean</i> fields are set to the following values: <pre> device-name device-type device-clean audio audio audio audio_clean_wrapper tape mag_tape_0,1,... st st_clean floppy floppy_0,1,... fd disk_clean removable disk cdrom_0,1,... sr disk_clean frame buffer framebuffer fb /bin/true </pre>						
ATTRIBUTES	See attributes(5) for descriptions of the following attributes: <table border="1"> <thead> <tr> <th>ATTRIBUTE TYPE</th><th>ATTRIBUTE VALUE</th></tr> </thead> <tbody> <tr> <td>Availability</td><td>SUNWcsu</td></tr> <tr> <td>Interface Stability</td><td>Obsolete</td></tr> </tbody> </table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	Availability	SUNWcsu	Interface Stability	Obsolete

Availability	SUNWcsu						
Interface Stability	Obsolete						
SEE ALSO	allocate(1), bsmconv(1M), attributes(5)						
NOTES	mkdevalloc might not be supported in a future release of the Solaris Operating Environment.						

NAME	mkdevmaps – make device_maps entries						
SYNOPSIS	/usr/sbin/mkdevmaps						
DESCRIPTION	The mkdevmaps command writes to standard out a set of device_maps(4) entries describing the system's frame buffer, audio, and removable media devices. The mkdevmaps command is used by the <code>init.d(4)</code> scripts to create or update the <code>/etc/security/device_maps</code> file. Entries are generated based on the device special files found in <code>/dev</code>. For the different categories of devices, the mkdevmaps command checks for the following files under <code>/dev</code>: <pre> audio /dev/audio, /dev/audioctl, /dev/sound/... tape /dev/rst*, /dev/nrst*, /dev/rmt/... floppy /dev/diskette, /dev/fd*, /dev/rdiskette, /dev/rfd* removable disk /dev/dsk/c0t?d0s?, /dev/rdsk/c0t?d0s? frame buffer /dev/fb </pre>						
ATTRIBUTES	See attributes(5) for descriptions of the following attributes: <table border="1"> <thead> <tr> <th>ATTRIBUTE TYPE</th><th>ATTRIBUTE VALUE</th></tr> </thead> <tbody> <tr> <td>Availability</td><td>SUNWcsu</td></tr> <tr> <td>Interface Stability</td><td>Obsolete</td></tr> </tbody> </table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	Availability	SUNWcsu	Interface Stability	Obsolete
ATTRIBUTE TYPE	ATTRIBUTE VALUE						
Availability	SUNWcsu						
Interface Stability	Obsolete						
SEE ALSO	allocate(1), bsmconv(1M), attributes(5)						
NOTES	mkdevmaps might not be supported in a future release of the Solaris Operating Environment.						

mkfifo(1M)

NAME	mkfifo – make FIFO special file						
SYNOPSIS	<code>/usr/bin/mkfifo [-m <i>mode</i>] <i>path</i>...</code>						
DESCRIPTION	The <code>mkfifo</code> utility creates the FIFO special files named by its argument list. The arguments are taken sequentially, in the order specified; and each FIFO special file is either created completely or, in the case of an error or signal, not created at all. If errors are encountered in creating one of the special files, <code>mkfifo</code> writes a diagnostic message to the standard error and continues with the remaining arguments, if any. The <code>mkfifo</code> utility calls the library routine <code>mkfifo(3C)</code>, with the <i>path</i> argument is passed as the <i>path</i> argument from the command line, and <i>mode</i> is set to the equivalent of <code>a=rw</code>, modified by the current value of the file mode creation mask <code>umask(1)</code>.						
OPTIONS	The following option is supported: <code>-m <i>mode</i></code> Sets the file permission bits of the newly-created FIFO to the specified <i>mode</i> value. The <i>mode</i> option-argument will be the same as the <i>mode</i> operand defined for the <code>chmod(1)</code> command. In <i><symbolicmode></i> strings, the <i>op</i> characters <code>+</code> and <code>-</code> will be interpreted relative to an assumed initial mode of <code>a=rw</code>.						
OPERANDS	The following operand is supported: <i>file</i> A path name of the FIFO special file to be created.						
USAGE	See <code>largefile(5)</code> for the description of the behavior of <code>mkfifo</code> when encountering files greater than or equal to 2 Gbyte (2^{31} bytes).						
ENVIRONMENT VARIABLES	See <code>environ(5)</code> for descriptions of the following environment variables that affect the execution of <code>mkfifo</code> : <code>LANG</code> , <code>LC_ALL</code> , <code>LC_CTYPE</code> , <code>LC_MESSAGES</code> , and <code>NLSPATH</code> .						
EXIT STATUS	The following exit values are returned: 0 All the specified FIFO special files were created successfully. >0 An error occurred.						
ATTRIBUTES	See <code>attributes(5)</code> for descriptions of the following attributes: <table border="1"> <thead> <tr> <th>ATTRIBUTE TYPE</th><th>ATTRIBUTE VALUE</th></tr> </thead> <tbody> <tr> <td>Availability</td><td>SUNWesu</td></tr> <tr> <td>Interface Stability</td><td>Standard</td></tr> </tbody> </table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	Availability	SUNWesu	Interface Stability	Standard

NAME	mkfile – create a file				
SYNOPSIS	mkfile [-nv] <i>size</i> [g k b m] <i>filename...</i>				
DESCRIPTION	mkfile creates one or more files that are suitable for use as NFS-mounted swap areas, or as local swap areas. When a root user executes <code>mkfile()</code> , the sticky bit is set and the file is padded with zeros by default. When non-root users execute <code>mkfile()</code> , they must manually set the sticky bit using <code>chmod(1)</code> . The default <i>size</i> is in bytes, but it can be flagged as gigabytes, kilobytes, blocks, or megabytes, with the g, k, b, or m suffixes, respectively.				
OPTIONS	-n Create an empty <i>filename</i>. The size is noted, but disk blocks are not allocated until data is written to them. Files created with this option cannot be swapped over local UFS mounts. -v Verbose. Report the names and sizes of created files.				
USAGE	See <code>largefile(5)</code> for the description of the behavior of <code>mkfile</code> when encountering files greater than or equal to 2 Gbyte (2^{31} bytes).				
ATTRIBUTES	See <code>attributes(5)</code> for descriptions of the following attributes:				
	<table border="1"> <thead> <tr> <th>ATTRIBUTE TYPE</th><th>ATTRIBUTE VALUE</th></tr> </thead> <tbody> <tr> <td>Availability</td><td>SUNWcsu</td></tr> </tbody> </table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	Availability	SUNWcsu
ATTRIBUTE TYPE	ATTRIBUTE VALUE				
Availability	SUNWcsu				
SEE ALSO	<code>chmod(1)</code> , <code>swap(1M)</code> , <code>attributes(5)</code> , <code>largefile(5)</code>				

mkfs(1M)

NAME	mkfs – construct a file system	
SYNOPSIS	mkfs [-F <i>FSType</i>] [<i>generic_options</i>] [-o <i>FSType-specific_options</i>] <i>raw_device_file</i> [<i>operands</i>]	
DESCRIPTION	The mkfs utility constructs a file system on the <i>raw_device_file</i> by calling the specific mkfs module indicated by -F <i>FSType</i>. Note: ufs file systems are normally created with the newfs(1M) command. <i>generic_options</i> are independent of file system type. <i>FSType-specific_options</i> is a comma-separated list of <i>keyword=value</i> pairs (with no intervening spaces), which are <i>FSType</i>-specific. <i>raw_device_file</i> specifies the disk partition on which to write the file system. It is required and must be the first argument following the <i>specific_options</i> (if any). <i>operands</i> are <i>FSType</i>-specific. See the <i>FSType</i>-specific manual page of mkfs (for example, mkfs_ufs(1M)) for a detailed description.	
OPTIONS	The following are the generic options for mkfs: -F Specify the <i>FSType</i> to be constructed. If -F is not specified, the <i>FSType</i> is determined from <i>/etc/vfstab</i> by matching the <i>raw_device_file</i> with a <i>vfstab</i> entry, or by consulting the <i>/etc/default/fs</i> file. -V Echo the complete command line, but do not execute the command. The command line is generated by using the options and arguments provided and adding to them information derived from <i>/etc/vfstab</i> or <i>/etc/default/fs</i>. This option may be used to verify and validate the command line. -m Return the command line which was used to create the file system. The file system must already exist. This option provides a means of determining the command used in constructing the file system. -o Specify <i>FSType</i>-specific options. See the manual page for the mkfs module specific to the file system type.	
USAGE	See largefile(5) for the description of the behavior of mkfs when encountering files greater than or equal to 2 Gbyte (2^{31} bytes).	
FILES	<i>/etc/default/fs</i>	Default file system type. Default values can be set for the following flags in <i>/etc/default/fs</i> . For example: LOCAL=ufs
	LOCAL	The default partition for a command if no <i>FSType</i> is specified.
	<i>/etc/vfstab</i>	List of default parameters for each file system

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

SEE ALSO `mkfs_ufs(1M)`, `newfs(1M)`, `vfstab(4)`, `attributes(5)`, `largefile(5)`

Manual pages for the *FSType*-specific modules of `mkfs`.

NOTES This command might not be supported for all *FSTypes*.

You can use `lofiadm` to create a file that appears to a `mkfs` command as a raw device. You can then use a `mkfs` command to create a file system on that device. See `lofiadm(1M)` for examples of creating a UFS and a PC (FAT) file system (using `mkfs_ufs(1M)` and `mkfs_pcfs(1M)`) on a device created by `lofiadm`.

mkfs_pcfs(1M)

NAME	mkfs_pcfs – construct a FAT file system
SYNOPSIS	mkfs -F pcfs [<i>generic_options</i>] [-o <i>FSType_specific_options</i>] <i>raw_device_file</i>
DESCRIPTION	The pcfs-specific module of mkfs constructs a File Allocation Table (FAT) on removable media (diskette, JAZ disk, ZIP disk, PCMCIA card), a hard disk, or a file (see NOTES). FATs are the standard MS-DOS and Windows file system format. Note that you can use fdformat(1) to construct a FAT file system only on a diskette or PCMCIA card. mkfs for pcfs determines an appropriate FAT size for the medium, then it installs an initial boot sector and an empty FAT. A sector size of 512 bytes is used. mkfs for pcfs can also install the initial file in the file system (see the pcfs-specific -o i option). This first file can optionally be marked as read-only, system, and/or hidden. If you want to construct a FAT with mkfs for pcfs on a medium that is not formatted, you must first perform a low-level format on the medium with fdformat(1) or format(1M). Non-diskette media must also be partitioned with the fdisk(1M) utility. Note that all existing data on the diskette or disk partition, if any, is destroyed when a new FAT is constructed. <i>generic_options</i> are supported by the generic mkfs command. See mkfs(1M) for a description of these options. <i>raw_device_file</i> indicates the device on which to write unless the -o N option has been specified, or if the -V or -m generic options are passed from the generic mkfs module.
OPTIONS	See mkfs(1M) for the list of supported generic options. The following options are supported: -o <i>FSType_specific_options</i> Specify pcfs file system-specific options in a comma-separated list with no intervening spaces. If invalid options are specified, a warning message is printed and the invalid options are ignored. b=<i>label</i> Label the media with volume label. The volume label is restricted to 11 uppercase characters. B=<i>filename</i> Install <i>filename</i> as the boot loader in the file system's boot sector. If you don't specify a boot loader, an MS-DOS boot loader is installed. The MS-DOS boot loader requires specific MS-DOS system files to make the diskette bootable. See NOTES for more information. fat=<i>n</i> The size of a FAT entry. Currently, only 12 and 16 are valid values. The default is 12 for diskettes, 16 for larger media. h Mark the first file installed as a hidden file. The -i option must also be specified.

<code>hidden=<i>n</i></code>	Set the number of hidden sectors to <i>n</i> . This is the number of sectors on the physical disk preceding the start of the volume (which is the boot sector itself). This defaults to 0 for diskettes or a computed value (based on the fdisk table) for disks. This option may be used only in conjunction with the <code>nofdisk</code> option.
<code>i=<i>filename</i></code>	Install <i>filename</i> as the initial file in the new file system. The initial file's contents are guaranteed to occupy consecutive clusters at the start of the files area. When creating bootable media, a boot program should be specified as the initial file.
<code>nofdisk</code>	Do not attempt to find an fdisk table on the medium. Instead rely on the <code>size</code> option for determining the partition size. By default, the created FAT is 16 bits and begins at the first sector of the device. This origination sector can be modified with the <code>hidden</code> option (<code>-h</code>).
<code>nsect=<i>n</i></code>	The number of sectors per track on the disk. If not specified, the value is determined by using a <code>dkio(7I)</code> ioctl to get the disk geometry, or (for diskette) from the results of an <code>FDIOGCHAR</code> ioctl.
<code>ntrack=<i>n</i></code>	The number of tracks per cylinder on the disk. If not specified, the value is determined by using a <code>dkio(7I)</code> ioctl to get the disk geometry, or (for diskette) from the results of an <code>FDIOGCHAR</code> ioctl.
<code>N</code>	No execution mode. Print normal output, but do not actually write the file system to the medium. This is most useful when used in conjunction with the <code>verbose</code> option.
<code>r</code>	Mark the first file installed as read-only. The <code>-i</code> option must also be specified.
<code>reserve=<i>n</i></code>	Set the number of reserved sectors to <i>n</i> . This is the number of sectors in the volume, preceding the start of the first FAT, including the boot sector. The value should always be at least 1, and the default value is exactly 1.
<code>s</code>	Mark the first file installed as a system file. The <code>-i</code> option must also be specified.
<code>size=<i>n</i></code>	The number of sectors in the file system. If not specified, the value is determined from the size of the partition given in the fdisk table or (for diskette) by way of computation using the <code>FDIOGCHAR</code> ioctl.
<code>spc=<i>n</i></code>	The size of the allocation unit for space within the file system, expressed as a number of sectors. The default value depends on the FAT entry size and the size of the file system.

mkfs_pcfs(1M)

	v	Verbose output. Describe, in detail, operations being performed.
FILES	<i>raw_device_file</i>	The device on which to build the FAT. The device name for a diskette must be specified as <code>/dev/rdiskette0</code> for the first diskette drive, or <code>/dev/rdiskette1</code> for a second diskette drive. For non-diskette media, a disk device name must be qualified with a suffix to indicate the proper partition. For example, in the name <code>/dev/rdisk/c0t0d0p0:c</code>, the <code>:c</code> suffix indicates that the first partition on the disk should receive the new FAT. For a file, <i>raw_device_file</i> is the block device name returned by <code>lofiadm(1M)</code>.
EXAMPLES	The media in these examples must be formatted before running <code>mkfs</code> for <code>pcfs</code>. See DESCRIPTION for more details. EXAMPLE 1 Creating a FAT File System on a Diskette The following command creates a FAT file system on a diskette: <pre>mkfs -F pcfs /dev/rdiskette</pre> EXAMPLE 2 Creating a FAT File System on a Disk The following command creates a FAT file system on the second fdisk partition of a disk attached to an x86 based system: <pre>mkfs -F pcfs /dev/rdisk/c0d0p0:d</pre> EXAMPLE 3 Creating a FAT File System on a ZIP Disk The following command creates a FAT file system on a ZIP disk located on a SPARC based system: <pre>mkfs -F pcfs /dev/rdisk/c0t4d0s2:c</pre> EXAMPLE 4 Creating a FAT File System on a JAZ Disk The following command creates a FAT file system on a JAZ disk located on a SPARC based system and overrides the sectors/track and tracks/cylinder values obtained from the device's controller: <pre>mkfs -F pcfs -o nsect=32,ntrack=64 /dev/rdisk/c0t3d0s2:c</pre>	

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWesu
Interface Stability	Stable

SEE ALSO `fdformat(1)`, `fdisk(1M)`, `format(1M)`, `lofiadm(1M)`, `mkfs(1M)`, `attributes(5)`, `fd(7D)`, `dkio(7I)`, `fdio(7I)`

NOTES The default MS-DOS boot loader, which is installed by default if `-o B` is not specified, requires specific MS-DOS system files to make the diskette bootable. These MS-DOS files are not installed when you format a diskette with `mkfs` for `pcfs`, which makes a diskette formatted this way not bootable. Trying to boot from it on an x86 based system will result in the following message:

```
Non-System disk or disk error
Replace and strike any key when ready
```

You must format a diskette with the DOS `format` command to install the specific MS-DOS system files required by the default boot loader.

You can use `lofiadm` to create a file that appears to a `mkfs` command (for example, `mkfs_pcfs` or `mkfs_ufs`) as a raw device. You can then use a `mkfs` command to create a file system on that device. See `lofiadm(1M)` for examples of creating a UFS and a PC (FAT) file system on a device created by `lofiadm`.

mkfs_udfs(1M)

NAME	mkfs_udfs – construct a udfs file system				
SYNOPSIS	mkfs -F udfs [<i>generic_options</i>] [-o <i>specific_options</i>] <i>raw_device_file</i> [<i>size</i>]				
DESCRIPTION	This is the universal disk format file system (udfs) -specific module of the mkfs command. mkfs constructs a udfs file system with a root directory.				
OPTIONS	See mkfs(1M) for the list of supported <i>generic_options</i>. The following options are supported: -o <i>specific_options</i> Specify a udfs-specific option. Specify udfs file system specific options in a comma-separated list with no intervening spaces. If invalid options are specified, a warning message is printed and the invalid options are ignored. The following <i>specific_options</i> are available: N Print the file system parameters without actually creating the file system. label=<i>string</i> Specify the label to be written into the volume header structures. Specify <i>string</i> as the name of the label. If <i>string</i> is not specified, a default <i>string</i> is generated in the form of *NoLabel*.				
OPERANDS	The following operands are supported: <i>raw_device_file</i> Specify the disk partition on which to write. <i>size</i> Specify the number of 512-byte blocks in the file system.				
ATTRIBUTES	See attributes(5) for descriptions of the following attributes: <table border="1"> <thead> <tr> <th>ATTRIBUTE TYPE</th><th>ATTRIBUTE VALUE</th></tr> </thead> <tbody> <tr> <td>Availability</td><td>SUNWudf</td></tr> </tbody> </table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	Availability	SUNWudf
ATTRIBUTE TYPE	ATTRIBUTE VALUE				
Availability	SUNWudf				
SEE ALSO	fsck (1M), mkfs (1M), attributes (5)				
DIAGNOSTICS	not currently a valid file system The specified device does not contain a valid udfs file system. Invalid size: larger than the partition size Number of blocks given as parameter to create the file system is larger than the size of the device specified.				

mkfs_udfs(1M)

is mounted can't mkfs

Device is in use, cannot create file system when the device is in use.

preposterous size

Negative size parameter provided is invalid.

sector size must be between 512, 8192 bytes

Sector size given is not in the valid range.

Volume integrity sequence descriptors too long

File set descriptor too long.

Not enough space to create volume integrity sequence or file set descriptor.

mkfs: argument out of range

One of the arguments is out of range.

mkfs: bad numeric arg

One of the arguments is potentially a bad numeric.

NOTES You can use `lofiadm` to create a file that appears to a `mkfs` command (for example, `mkfs_pcfs` or `mkfs_ufs`) as a raw device. You can then use a `mkfs` command to create a file system on that device. See `lofiadm(1M)` for examples of creating a UFS and a PC (FAT) file system on a device created by `lofiadm`.

mkfs_ufs(1M)

NAME	mkfs_ufs – construct a UFS file system
SYNOPSIS	mkfs -F ufs [<i>generic_options</i>] [-o <i>FSType_specific_options</i>] <i>raw_device_file</i> [<i>size</i>]
DESCRIPTION	The UFS-specific module of mkfs builds a UFS file system with a root directory and a <code>lost+found</code> directory (see fsck(1M)). The UFS-specific mkfs is rarely run directly. Use the newfs(1M) command instead. <i>raw_device_file</i> indicates the disk partition on which to create the new file system. If the -o N, -V, or -m options are specified, the <i>raw_device_file</i> is not actually modified. <i>size</i> specifies the number of disk sectors in the file system, where a disk sector is usually 512 bytes. This argument must follow the <i>raw_device_file</i> argument and is required (even with -o N), unless the -V or -m generic options are specified. <i>generic_options</i> are supported by the generic mkfs command. See mkfs(1M) for a description of these options.
OPTIONS	The following generic options are supported: -m Print the command line that was used to create the existing file system. -V Print the current mkfs command line.
OPTIONS	The following UFS-specific options are supported: -o Use one or more of the following values separated by commas (with no intervening spaces) to specify UFS-specific options: - apc=<i>n</i> The number of alternate sectors per cylinder to reserve for bad block replacement for SCSI devices only. The default is 0. - This option is not applicable for disks with EFI labels and is ignored. - bsize=<i>n</i> The logical block size of the file system in bytes, either 4096 or 8192. The default is 8192. The sun4u architecture does not support the 4096 block size. - cgroupsize=<i>n</i> The number of cylinders per cylinder group, ranging from 16 to 256. The default is calculated by dividing the number of sectors in the file system by the number of sectors in a gigabyte. Then, the result is multiplied by 32. The default value is always between 16 and 256. - The per-cylinder-group meta data must fit in a space no larger than what is available in one logical file system block. If too large a cgroupsize is requested, it is changed by the minimum amount necessary.

fragsize= <i>n</i>	The smallest amount of disk space in bytes that can be allocated to a file. <i>fragsize</i> must be a power of 2 divisor of <i>bsize</i>, where: <i>bsize</i> / <i>fragsize</i> is 1, 2, 4, or 8. This means that if the logical block size is 4096, legal values for <i>fragsize</i> are 512, 1024, 2048, and 4096. When the logical block size is 8192, legal values are 1024, 2048, 4096, and 8192. The default value is 1024. For file systems greater than 1 terabyte or for file systems created with the <code>mtb=y</code> option, <i>fragsize</i> is forced to match block size (<i>bsize</i>).
free= <i>n</i>	The minimum percentage of free space to maintain in the file system between 0% and 99%, inclusively. This space is off-limits to users. Once the file system is filled to this threshold, only the superuser can continue writing to the file system. The default is ((64 Mbytes/partition size) * 100), rounded down to the nearest integer and limited between 1% and 10%, inclusively.
gap= <i>n</i>	This parameter can be subsequently changed using the <code>tunefs(1M)</code> command.
maxcontig= <i>n</i>	Rotational delay. This option is obsolete. The value is always set to 0, regardless of the input value. The maximum number of logical blocks, belonging to one file, that are allocated contiguously. The default is calculated as follows: $\text{maxcontig} = \text{disk drive maximum transfer size} / \text{disk block size}$ If the disk drive's maximum transfer size cannot be determined, the default value for <code>maxcontig</code> is calculated from kernel parameters as follows: If <code>maxphys</code> is less than <code>ufs_maxmaxphys</code>, which is typically 1 Mbyte, then <code>maxcontig</code> is set to <code>maxphys</code>. Otherwise, <code>maxcontig</code> is set to <code>ufs_maxmaxphys</code>. You can set <code>maxcontig</code> to any positive integer value. The actual value will be the lesser of what has been specified and what the hardware supports.

mkfs_ufs(1M)

	You can subsequently change this parameter by using <code>tunefs(1M)</code> .
<code>mtb=y</code>	Set the parameters of the file system to allow eventual growth to over a terabyte in total file system size. This option sets <i>fragsize</i> to be the same as <i>bsize</i> , and sets <i>nbpi</i> to 1 Mbyte, unless the <code>-i</code> option is used to make it even larger. If you explicitly set the <i>fragsize</i> or <i>nbpi</i> parameters to values that are incompatible with this option, the user-supplied value of <i>fragsize</i> or <i>nbpi</i> is ignored.
<code>N</code>	Print out the file system parameters that would be used to create the file system without actually creating the file system.
<code>nbpi=n</code>	The number of bytes per inode, which specifies the density of inodes in the file system. The number is divided into the total size of the file system to determine the number of inodes to create. This value should reflect the expected average size of files in the file system. If fewer inodes are desired, a larger number should be used. To create more inodes, a smaller number should be given. The default is 2048.
<code>nrpos=n</code>	The number of inodes can increase if the file system is expanded with the <code>growfs</code> command. The number of different rotational positions in which to divide a cylinder group. The default is 8.
<code>nsect=n</code>	This option is not applicable for disks with EFI labels and is ignored. The number of sectors per track on the disk. The default is 32.
<code>ntrack=n</code>	The number of tracks per cylinder on the disk. The default is 16.
<code>opt=s t</code>	This option is not applicable for disks with EFI labels and is ignored. The file system can either be instructed to try to minimize the <i>time</i> spent allocating blocks, or to try to minimize the <i>space</i> fragmentation on the disk. The default is <i>time</i> . This parameter can be subsequently changed with the <code>tunefs(1M)</code> command.

mkfs_ufs(1M)

`rps=n`

The rotational speed of the disk, in revolutions per second. The default is 60.

Note that you specify *rps* for `mkfs` and *rpm* for `newfs`.

This option is not applicable for disks with EFI labels and is ignored.

Alternatively, parameters can be entered as a list of space-separated values (without keywords) whose meaning is positional. In this case, the `-o` option is omitted and the list follows the size operand. This is the way `newfs` passes the parameters to `mkfs`.

OPERANDS The following operands are supported:

`raw_device_file` The disk partition on which to write.

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

SEE ALSO `fsck(1M)`, `mkfs(1M)`, `newfs(1M)`, `tunefs(1M)`, `dir_ufs(4)`, `attributes(5)`, `ufs(7FS)`

DIAGNOSTICS The following error message typically occurs with very high density disks. On such disks, the file system structure cannot encode the proper disk layout information. However, such disks have enough onboard intelligence to make up for any layout deficiencies, so there is no actual impact on performance. The warning that performance might be impaired can be safely ignored.

Warning: insufficient space in super block for rotational layout tables with nsect *sblock.fs_nsect* and ntrak *sblock.fs_ntrak*. (File system performance may be impaired.)

The following error message occurs when the disk geometry results in a situation where the last truncated cylinder group cannot contain the correct number of data blocks. Some disk space is wasted.

Warning: inode blocks/cyl group (*grp*) >= data blocks (*num*) in last cylinder

The following error message occurs when the best calculated file system layout is unable to include the last few sectors in the last cylinder group. This is due to the interaction between how much space is used for various pieces of meta data and the total blocks available in a cylinder group. Modifying *nbpi* and *cpb* might reduce this number, but it is rarely worth the effort.

Warning: *num* sector(s) in last cylinder group unallocated

mkfs_ufs(1M)

NOTES | You can use `lofiadm` to create a file that appears to the `mkfs` command (for example, `mkfs_pcfs` or `mkfs_ufs`) as a raw device. You can then use the `mkfs` command to create a file system on that device. See `lofiadm(1M)` for examples of creating a UFS and a PC (FAT) file system on a device created by `lofiadm`.

Both the block and character devices, such as devices in `/dev/dsk` and `/dev/rdisk`, must be available prior to running the `mkfs` command.

NAME	mknod – make a special file				
SYNOPSIS	mknod <i>name</i> <i>b</i> <i>major</i> <i>minor</i> mknod <i>name</i> <i>c</i> <i>major</i> <i>minor</i> mknod <i>name</i> <i>p</i>				
DESCRIPTION	mknod makes a directory entry for a special file.				
OPTIONS	The following options are supported: <i>b</i> Create a block-type special file. <i>c</i> Create a character-type special file. <i>p</i> Create a FIFO (named pipe).				
OPERANDS	The following operands are supported: <i>major</i> The <i>major</i> device number. <i>minor</i> The <i>minor</i> device number; can be either decimal or octal. The assignment of major device numbers is specific to each system. You must be the super-user to use this form of the command. <i>name</i> A special file to be created.				
USAGE	See <code>largefile(5)</code> for the description of the behavior of mknod when encountering files greater than or equal to 2 Gbyte (2^{31} bytes).				
ATTRIBUTES	See <code>attributes(5)</code> for descriptions of the following attributes: <table border="1"> <thead> <tr> <th>ATTRIBUTE TYPE</th><th>ATTRIBUTE VALUE</th></tr> </thead> <tbody> <tr> <td>Availability</td><td>SUNWcsu</td></tr> </tbody> </table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	Availability	SUNWcsu
ATTRIBUTE TYPE	ATTRIBUTE VALUE				
Availability	SUNWcsu				
SEE ALSO	<code>ftp(1)</code> , <code>in.ftpd(1M)</code> , <code>mknod(2)</code> , <code>symlink(2)</code> , <code>attributes(5)</code> , <code>largefile(5)</code>				
NOTES	If <code>mknod(2)</code> is used to create a device, the major and minor device numbers are always interpreted by the kernel running on that machine. With the advent of physical device naming, it would be preferable to create a symbolic link to the physical name of the device (in the <code>/devices</code> subtree) rather than using <code>mknod</code>.				

modinfo(1M)

NAME	modinfo – display information about loaded kernel modules								
SYNOPSIS	/usr/sbin/modinfo [-c] [-w] [-i <i>module-id</i>]								
DESCRIPTION	The modinfo utility displays information about the loaded modules. The format of the information is as follows: <i>Id Loadaddr Size Info Rev Module Name</i> where <i>Id</i> is the module ID, <i>Loadaddr</i> is the starting text address in hexadecimal, <i>Size</i> is the size of text, data, and bss in hexadecimal bytes, <i>Info</i> is module specific information, <i>Rev</i> is the revision of the loadable modules system, and <i>Module Name</i> is the filename and description of the module. The module specific information is the block and character major numbers for drivers, the system call number for system calls, or, for other module types, the index into the appropriate kernel table: <table> <tr> <td>fmodsw</td><td>for STREAMS modules</td></tr> <tr> <td>vfssw</td><td>for filesystems</td></tr> <tr> <td>class</td><td>for scheduling classes</td></tr> <tr> <td>execsw</td><td>for exec modules</td></tr> </table>	fmodsw	for STREAMS modules	vfssw	for filesystems	class	for scheduling classes	execsw	for exec modules
fmodsw	for STREAMS modules								
vfssw	for filesystems								
class	for scheduling classes								
execsw	for exec modules								
OPTIONS	The following options are supported: -c Displays the number of instances of the module loaded and the module's current state. -i <i>module-id</i> Displays information about this module only. -w Does not truncate module information at 80 characters.								
EXAMPLES	EXAMPLE 1 Using the modinfo command. The following example displays the status of module 3: <pre>example% modinfo -i 3 Id Loadaddr Size Info Rev Module Name 3 f5a7a000 3bc0 1 1 specfs (filesystem for specfs)</pre>								
ATTRIBUTES	See attributes(5) for descriptions of the following attributes: <table> <tr> <th>ATTRIBUTE TYPE</th><th>ATTRIBUTE VALUE</th></tr> <tr> <td>Availability</td><td>SUNWcsu</td></tr> </table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	Availability	SUNWcsu				
ATTRIBUTE TYPE	ATTRIBUTE VALUE								
Availability	SUNWcsu								
SEE ALSO	modload(1M), modunload(1M), attributes(5)								

NAME	modload – load a kernel module				
SYNOPSIS	modload [-p] [-e <i>exec_file</i>] <i>filename</i>				
DESCRIPTION	The modload command loads the loadable module <i>filename</i> into the running system. <i>filename</i> is an object file produced by <code>ld -r</code>. If <i>filename</i> is an absolute pathname then the file specified by that absolute path is loaded. If <i>filename</i> does not begin with a slash (/), then the path to load <i>filename</i> is relative to the current directory unless the -p option is specified. The kernel's modpath variable can be set using the <code>/etc/system</code> file. The default value of the kernel's modpath variable is set to the path where the operating system was loaded. Typically this is <code>/kernel /usr/kernel</code>. For example, the following command looks for <code>./drv/foo</code>: <pre>example# modload drv/foo</pre> The following command looks for <code>/kernel/drv/foo</code> and then <code>/usr/kernel/drv/foo</code>: <pre>example# modload -p drv/foo</pre>				
OPTIONS	The following options are supported: <table> <tr> <td>-e <i>exec_file</i></td><td>Specify the name of a shell script or executable image file that is executed after the module is successfully loaded. The first argument passed is the module ID (in decimal). The other argument is module specific. The module specific information is: the block and character major numbers for drivers, the system call number for system calls, or, for other module types, the index into the appropriate kernel table. See <code>modinfo(1M)</code></td></tr> <tr> <td>-p</td><td>Use the kernel's internal modpath variable as the search path for the module.</td></tr> </table>	-e <i>exec_file</i>	Specify the name of a shell script or executable image file that is executed after the module is successfully loaded. The first argument passed is the module ID (in decimal). The other argument is module specific. The module specific information is: the block and character major numbers for drivers, the system call number for system calls, or, for other module types, the index into the appropriate kernel table. See <code>modinfo(1M)</code>	-p	Use the kernel's internal modpath variable as the search path for the module.
-e <i>exec_file</i>	Specify the name of a shell script or executable image file that is executed after the module is successfully loaded. The first argument passed is the module ID (in decimal). The other argument is module specific. The module specific information is: the block and character major numbers for drivers, the system call number for system calls, or, for other module types, the index into the appropriate kernel table. See <code>modinfo(1M)</code>				
-p	Use the kernel's internal modpath variable as the search path for the module.				
ATTRIBUTES	See <code>attributes(5)</code> for descriptions of the following attributes: <table> <tr> <th>ATTRIBUTE TYPE</th><th>ATTRIBUTE VALUE</th></tr> <tr> <td>Availability</td><td>SUNWcsu</td></tr> </table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	Availability	SUNWcsu
ATTRIBUTE TYPE	ATTRIBUTE VALUE

NOTES	Use <code>add_drv(1M)</code> to add device drivers, not modload. See <i>Writing Device Drivers</i> for procedures on adding device drivers.				

modunload(1M)

NAME	modunload – unload a module				
SYNOPSIS	modunload -i <i>module_id</i> [-e <i>exec_file</i>]				
DESCRIPTION	modunload unloads a loadable module from the running system. The <i>module_id</i> is the ID of the module as shown by modinfo(1M). If ID is 0, all modules that were autoloaded which are unloadable, are unloaded. Modules loaded by modload(1M) are not affected.				
OPTIONS	The following options are supported: -e <i>exec_file</i> Specify the name of a shell script or executable image file to be executed before the module is unloaded. The first argument passed is the module id (in decimal). There are two additional arguments that are module specific. For loadable drivers, the second argument is the driver major number. For loadable system calls, the second argument is the system call number. For loadable exec classes, the second argument is the index into the <i>execsw</i> table. For loadable filesystems, the second argument is the index into the <i>vfs</i>sw table. For loadable streams modules, the second argument is the index into the <i>fmodsw</i> table. For loadable scheduling classes, the second argument is the index into the class array. Minus one is passed for an argument that does not apply. -i <i>module_id</i> Specify the module to be unloaded.				
ATTRIBUTES	See attributes(5) for descriptions of the following attributes: <table><thead><tr><th>ATTRIBUTE TYPE</th><th>ATTRIBUTE VALUE</th></tr></thead><tbody><tr><td>Availability</td><td>SUNWcsu</td></tr></tbody></table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	Availability	SUNWcsu
ATTRIBUTE TYPE	ATTRIBUTE VALUE				
Availability	SUNWcsu				
SEE ALSO	modinfo(1M), modload(1M), update_drv(1M), attributes(5)				
NOTES	The modunload command has often been used on driver modules to force the system to reread the associated driver configuration file. While this works in Solaris 9, this behavior might break in future releases. The supported way for rereading driver configuration file is through the update_drv(1M) command.				

NAME	mofcomp – compile MOF files into CIM classes										
SYNOPSIS	<pre>/usr/sadm/bin/mofcomp [-c <i>cimom_hostname</i>] [-h] [-j <i>filename</i>] [-n <i>namespace</i>] [-o <i>dirname</i>] [-p <i>password</i>] [-CIQ] [-u <i>username</i>] [-v] [-version] [-x] <i>file</i></pre>										
DESCRIPTION	The <code>mofcomp</code> utility is executed during installation to compile managed object format (MOF) files that describe the Common Information Model (CIM) and Solaris Schemas into the CIM Object Manager Repository, a central storage area for management data. The CIM Schema is a collection of class definitions used to represent managed objects that occur in every management environment. The Solaris Schema is a collection of class definitions that extend the CIM Schema and represent managed objects in a typical Solaris operating environment. The <code>mofcomp</code> utility must be run as root or as a user with write access to the namespace in which you are compiling. MOF is a language for defining CIM classes and instances. MOF files are ASCII text files that use the MOF language to describe CIM objects. A CIM object is a computer representation or model of a managed resource, such as a printer, disk drive, or CPU. Many sites store information about managed resources in MOF files. Because MOF can be converted to Java, Java applications that can run on any system with a Java Virtual Machine can interpret and exchange this information. You can also use the <code>mofcomp</code> utility to compile MOF files at any time after installation.										
OPTIONS	The following options are supported: <table> <tr> <td><code>-c <i>cimom_hostname</i></code></td><td>Specify a remote system running the CIM Object Manager.</td></tr> <tr> <td><code>-C</code></td><td>Run the compiler set with the class option, which updates a class if it exists, and returns an error if the class does not exist. If you do not specify this option, the compiler adds a CIM class to the connected namespace, and returns an error if the class already exists.</td></tr> <tr> <td><code>-h</code></td><td>List the arguments to the <code>mofcomp</code> utility.</td></tr> <tr> <td><code>-I</code></td><td>Run the compiler set with the instance option, which updates an instance if it exists, and returns an error if the instance does not exist. If you do not specify this option, the compiler adds a CIM instance to the connected namespace, and returns an error if the instance already exists.</td></tr> <tr> <td><code>-j <i>filename</i></code></td><td>Generate Java Beans and Java Interfaces to manage the CIM instances related to the CIM classes in the MOF being compiled.</td></tr> </table> The contents of <i>filename</i> are:	<code>-c <i>cimom_hostname</i></code>	Specify a remote system running the CIM Object Manager.	<code>-C</code>	Run the compiler set with the class option, which updates a class if it exists, and returns an error if the class does not exist. If you do not specify this option, the compiler adds a CIM class to the connected namespace, and returns an error if the class already exists.	<code>-h</code>	List the arguments to the <code>mofcomp</code> utility.	<code>-I</code>	Run the compiler set with the instance option, which updates an instance if it exists, and returns an error if the instance does not exist. If you do not specify this option, the compiler adds a CIM instance to the connected namespace, and returns an error if the instance already exists.	<code>-j <i>filename</i></code>	Generate Java Beans and Java Interfaces to manage the CIM instances related to the CIM classes in the MOF being compiled.
<code>-c <i>cimom_hostname</i></code>	Specify a remote system running the CIM Object Manager.										
<code>-C</code>	Run the compiler set with the class option, which updates a class if it exists, and returns an error if the class does not exist. If you do not specify this option, the compiler adds a CIM class to the connected namespace, and returns an error if the class already exists.										
<code>-h</code>	List the arguments to the <code>mofcomp</code> utility.										
<code>-I</code>	Run the compiler set with the instance option, which updates an instance if it exists, and returns an error if the instance does not exist. If you do not specify this option, the compiler adds a CIM instance to the connected namespace, and returns an error if the instance already exists.										
<code>-j <i>filename</i></code>	Generate Java Beans and Java Interfaces to manage the CIM instances related to the CIM classes in the MOF being compiled.										

mofcomp(1M)

	<pre> PACKAGE=<i>Java package name</i> IMPORTS=<i>import1:...:importN</i> <EXCEPTIONS=<i>exception1:...:exceptionN</i> </pre>
	PACKAGE is a valid Java package name to include in all generated Java source. IMPORTS is an optional colon separated list of valid Java classes to be imported in all generated Java source. EXCEPTIONS is an optional colon separated list of valid Java exceptions to be thrown by the methods in all generated Java source.
-n <i>namespace</i>	Requests that the compiler load the MOF file into the namespace specified as <i>namespace</i>. The default namespace (<code>root\cimv2</code>) is used unless this switch is used or a <code>#pragma namespace ("namespace")</code> statement appears in the MOF file. If both the -n <i>namespace</i> switch and the <code>#pragma namespace</code> construct are used, all namespaces are created, but the objects are created only in the <code>#pragma namespace</code>s.
-o <i>dirname</i>	Run compiler in standalone mode, without the CIM Object Manager. Specify <i>dirname</i> as the directory in which the compiler output is to be stored. In this mode, the CIM Object Manager need not be running.
-p <i>password</i>	Specify a password for connecting to the CIM Object Manager. Use this option for compilations that require privileged access to the CIM Object Manager. If you specify both -p and -u, you must type the password on the command line, which can pose a security risk. A more secure way to specify a password is to specify -u but not -p, so that the compiler will prompt for the password.
-Q	Run the compiler set with the qualifier types option, which updates a qualifier type if it exists, and returns an error if the qualifier type does not exist. If you do not specify this option, the compiler adds a CIM qualifier type to the connected namespace, and returns an error if the qualifier type already exists.
-u <i>username</i>	Specify user name for connecting to the CIM Object Manager. Use this option for compilations that require privileged access to the CIM Object Manager. If you specify both -p and -u, you must type the password on the command line, which can pose a security risk. A more secure way to specify a password is to specify -u but not -p, so that the compiler will prompt for the password.

mofcomp(1M)

- v Run the compiler in verbose mode, which displays compiler messages.
- version Display the version of the MOF compiler.
- x Generate XML documents for the CIM classes defined in the input MOF file.

OPERANDS The following operands are supported:

file The pathname of the file to be compiled.

EXIT STATUS The mofcomp utility exits with 0 upon success and a positive integer upon failure.

FILES MOF files are installed in /usr/sadm/mof.

mofreg(1M)

NAME	mofreg – register MOF classes with WBEM services		
SYNOPSIS	<pre>/usr/sadm/bin/mofreg -r tag file /usr/sadm/bin/mofreg -s /usr/sadm/bin/mofreg -u tag [file]</pre>		
DESCRIPTION	The <code>mofreg</code> command is used by package and patch install scripts, or by any applications that wish to register managed object format (MOF) classes with Sun The Web-Based Enterprise Management (WBEM) services. The WBEM services daemon (Common Information Model or CIM object manager) processes at start up the files that are specified by <code>mofreg</code> commands. Files are processed in the order that the individual <code>mofreg</code> commands are executed. As an alternative to using the <code>mofreg</code> command, MOFs can be registered or unregistered by manipulating directories in <code>/var/sadm/wbem/logr</code>. Instead of running the <code>mofreg -r tag file</code> version of the command you can create a directory named <code>tag</code> under <code>/var/sadm/wbem/logr/preReg</code> and copy <code>file</code> to the <code>tag</code> directory. Similarly, instead of running the <code>mofreg -u tag [file]</code> command, you can create a directory named <code>tag</code> under <code>/var/sadm/wbem/logr/preUnreg</code> and copy the optional <code>file</code> to the <code>tag</code> directory. The entries are processed in increasing order of last modification time of the <code>tag</code> directories. If you issue <code>mofreg</code> commands in rapid succession, the timestamps might be the same. If you have a situation where the timestamp order is critical, you can place appropriate sleeps between the successive registration or unregistration operations. As with the <code>mofreg</code> command, processing is done at next restart or by using the <code>-s</code> option. This alternative mechanism is typically used in package install scripts which do not have access to <code>/usr</code>, and therefore do not have access to the <code>mofreg</code> command. This case arises when packages are installed for diskless clients.		
OPTIONS	The following options are supported: <table><tr><td><code>-r tag file</code></td><td>The <i>file</i> argument is the actual MOF registration file. Its form is identical to the MOF syntax as defined by the Distributed Management Task Force (DMTF). The only difference is the addition of the following 3 new pseudo-pragmas, which are variations of the namespace pragma. The name of file cannot end in <code>.unreg</code>.</td></tr></table> <pre>#pragma namespace("__create") #pragma namespace("__delete") #pragma namespace("__modify")</pre>	<code>-r tag file</code>	The <i>file</i> argument is the actual MOF registration file. Its form is identical to the MOF syntax as defined by the Distributed Management Task Force (DMTF). The only difference is the addition of the following 3 new pseudo-pragmas, which are variations of the namespace pragma. The name of file cannot end in <code>.unreg</code> .
<code>-r tag file</code>	The <i>file</i> argument is the actual MOF registration file. Its form is identical to the MOF syntax as defined by the Distributed Management Task Force (DMTF). The only difference is the addition of the following 3 new pseudo-pragmas, which are variations of the namespace pragma. The name of file cannot end in <code>.unreg</code> .		

These three pragmas are used specify if the elements following the pragmas should be created, deleted, or modified by the CIM object manager. The `__delete` pragma can currently only be applied for a `mofreg -u` command.

The *tag* argument is a unique string that specifies the identity of the registry action. This tag can be set to the package name or the patch number if the `mofreg` script is being invoked through packages/patches, though any tag can be specified.

Errors and warnings that are encountered when the CIM object manager handles the `mofreg` script are logged. Processing of the `mofreg` script stops at the first error. Specific warnings include:

Element already defined - the element already exists and cannot be created.

Element not found - the element does not exist and cannot be modified.

The error conditions are:

Key modification - A class cannot be modified if its keys are being changed.

Other mod compilation errors.

-s Forces the CIM object manager to immediately process outstanding registry requests, instead of at the next restart. This currently requires Java.

-u tag [file] Undoes the operations performed during `mof` registry.

The *tag* argument must correspond to the value set during the original `mofreg` invocation. If no `mofreg` was done with the original *tag*, the command does not succeed.

If required, an *unreg* file can be specified. If no *unreg* file is specified, the CIM object manager automatically undoes the actions of the registry. Any class created by the registry process is removed and any classes modified by the registry revert to the old state.

The `mofreg` command does not take care of cases where packages and patches make conflicting changes to classes. This should be taken care of by the standard patch and package conflict resolution.

EXIT STATUS The following exit values are returned:

0	Successful completion.
1	An error occurred. The reason for error is displayed.

NAME	monitor – SPARC system PROM monitor
SYNOPSIS	STOP-A BREAK initial system power-on exit from a client program, e.g., the Operating System
DESCRIPTION	The CPU board of a workstation contains one or more EPROMs or EEPROMs. The program which executes from the PROMs is referred to as “the monitor”. Among other things, the monitor performs system initialization at power-on and provides a user interface.
Monitor Prompt	The monitor of earlier workstations was known as the SunMON monitor and displayed the > for its prompt. See the SunMON MONITOR USAGE section for further details. Existing workstations use a monitor which is known as the OpenBoot monitor. The OpenBoot monitor typically displays ok as its prompt, but it may also display the > prompt under certain circumstances. If the ‘auto-boot?’ NVRAM parameter is set to ‘false’ when the workstation is powered on, the system does not attempt to boot and the monitor issues its prompt. If ‘auto-boot’ is set to ‘true’, the system initiates the boot sequence. The boot sequence can be aborted by simultaneously pressing two keys on the system’s keyboard: L1 and A (on older keyboards), or Stop and A (on newer keyboards). Either a lower case a or an upper case A works for the keyboard abort sequence. If a console has been attached by way of one of the system’s serial ports then the abort sequence can be accomplished by sending a BREAK. See tip(1). When the NVRAM ‘security-mode’ parameter has been turned on, or when the value of the ‘sunmon-compat?’ parameter is true, then the OpenBoot monitor displays the message: Type b (boot), c (continue), or n (new command mode) and the > prompt appears.
OPENBOOT PROM USAGE	Some of the more useful commands that can be issued from OpenBoot’s ok prompt are described here. Refer to the <i>OpenBoot 2.x Command Reference Manual</i> book for a complete list of commands.
Help	Help for various functional areas of the OpenBoot monitor can be obtained by typing help. The help listing provides a number of other key words which can then be used in the help command to provide further details.
NVRAM Parameters	Each workstation contains one or more NVRAM devices which contains unique system ID information, as well as a set of user-configurable parameters. The NVRAM parameters allow the user a certain level of flexibility in configuring the system to act in a given manner under a specific set of circumstances.

monitor(1M)

See `eeeprom(1M)` for a description of the parameters and information regarding setting the parameters from the OS level.

The following commands can be used at the OpenBoot monitor to access the NVRAM parameters.

`printenv` Used to list the NVRAM parameters, along with their default values and current values.

`setenv pn pv` Used to set or modify a parameter. The *pn* represents the parameter name, and *pv* represents the parameter value.

`set-default pn` Used to set an individual parameter back to its default value.

`set-defaults` Used to reset all parameters to their default values. (Note that 'set-defaults' only affects parameters that have assigned default values.)

Security Parameters

Newer OpenBoot monitors contain user interfaces that support the storage and listing of keys for later use by client programs.

`list-security-keys`

Lists the names of keys currently stored on a machine.

`set-security-key keyname [ keydata ]`

Stores key data *keydata* in a key named *keyname*. Actual key data can be up to 32 bytes in length. The maximum length of *keyname* is 64 bytes, which allows for the hex-formatted ASCII used to present the key data. If *keydata* is not present, *keyname* and its corresponding data is deleted.

Hardware Checks and Diagnostics

The following commands are available for testing or checking the system's hardware. If the 'diag-switch?' NVRAM parameter is set to true when the system is powered on, then a Power-On Self Test (POST) diagnostic is run, if present, sending its results messages to the system's serial port A. Not all of the commands shown are available on all workstations.

`test-all` Run the diagnostic tests on each device which has provided a self-test.

`test floppy` Run diagnostics on the system's floppy device.

`test /memory` Run the main memory tests. If the NVRAM parameter 'diag-switch?' is set to true, then all of main memory is tested. If the parameter is false then only the amount of memory specified in the 'selftest-#megs' NVRAM parameter is tested.

`test net` Test the network connection for the on-board network controller.

`watch-net` Monitor the network attached to the on-board net controller.

`watch-net-all` Monitor the network attached to the on-board net controller, as well as the network controllers installed in SBus slots.

`watch-clock` Test the system's clock function.

System Information	The following commands are available for displaying information about the system. Not all commands are available on all workstations.	
	banner	Display the power-on banner.
	.enet-addr	Display the system's Ethernet address.
	.idprom	Display the formatted contents of the IDPROM.
	module-info	Display information about the system's processor(s).
	probe-scsi	Identify the devices attached to the on-board SCSI controller.
	probe-scsi-all	Identify the devices attached to the on-board SCSI controller as well as those devices which are attached to SBus SCSI controllers.
	show-disks	Display a list of the device paths for installed SCSI disk controllers.
	show-displays	Display a list of the device paths for installed display devices.
	show-nets	Display a list of the device paths for installed Ethernet controllers.
	show-sbus	Display list of installed SBus devices.
	show-tapes	Display a list of the device paths for installed SCSI tape controllers.
	show-ttys	Display a list of the device paths for tty devices.
	.traps	Display a list of the SPARC trap types.
	.version	Display the version and date of the OpenBoot PROM.
Emergency Commands	These commands must be typed from the keyboard, they do not work from a console which is attached by way of the serial ports. With the exception of the Stop-A command, these commands are issued by pressing and holding down the indicated keys on the keyboard immediately after the system has been powered on. The keys must be held down until the monitor has checked their status. The Stop-A command can be issued at any time after the console display begins, and the keys do not need to be held down once they've been pressed. The Stop-D, Stop-F and Stop-N commands are not allowed when one of the security modes has been set. Not all commands are available on all workstations.	
	Stop (L1)	Bypass the Power-On Self Test (POST). This is only effective if the system has been placed into the diagnostic mode.
	Stop-A (L1-A)	Abort the current operation and return to the monitor's default prompt.

monitor(1M)

Line Editor Commands

Stop-D (L1-D)	Set the system's 'diag-switch?' NVRAM parameter to 'true', which places the system in diagnostic mode. POST diagnostics, if present, are run, and the messages are displayed by way of the system's serial port A.
Stop-F (L1-F)	Enter the OpenBoot monitor before the monitor has probed the system for devices. Issue the 'fexit' command to continue with system initialization.
Stop-N (L1-N)	Causes the NVRAM parameters to be reset to their default values. Note that not all parameters have default values.
The following commands can be used while the monitor is displaying the ok prompt. Not all of these editing commands are available on all workstations.	
CTRL-A	Place the cursor at the start of line.
CTRL-B	Move the cursor backward one character.
ESC-B	Move the cursor backward one word.
CTRL-D	Erase the character that the cursor is currently highlighting.
ESC-D	Erase the portion of word from the cursor's present position to the end of the word.
CTRL-E	Place the cursor at the end of line.
CTRL-F	Move the cursor forward one character.
ESC-F	Move the cursor forward one word.
CTRL-H	Erase the character preceding the cursor (also use Delete or Back Space)
ESC-H	Erase the portion of the word which precedes the cursor (use also CTRL-W)
CTRL-K	Erase from the cursor's present position to the end of the line.
CTRL-L	Show the command history list.
CTRL-N	Recall the next command from the command history list
CTRL-P	Recall a previous command from the command history list.
CTRL-Q	Quote the next character (used to type a control character).
CTRL-R	Retype the current line.
CTRL-U	Erase from the cursor's present position to the beginning of the line.
CTRL-Y	Insert the contents of the memory buffer into the line, in front (to the left) of the cursor.

nvrampc	The nvrampc is an area of the system's NVRAM where users may store Forth programs. The programs which are stored in the nvrampc are executed each time the system is reset, provided that the 'use-nvrampc?' NVRAM parameter has been set to 'true'. Refer to the <i>OpenBoot 2.x Command Reference Manual</i> book for information on how to edit and use the nvrampc.												
Restricted Monitor	The command 'old-mode' is used to move OpenBoot into a restricted monitor mode, causing the > prompt to be displayed. Only three commands are allowed while in the restricted monitor; the 'go' command (to resume a program which was interrupted with the Stop-A command), the 'n' command (to return to the normal OpenBoot monitor), and boot commands. The restricted monitor's boot commands approximate the older SunMON monitor's boot command syntax. If a 'security-mode' has been turned on then the restricted monitor becomes the default monitor environment. The restricted monitor may also become the default environment if the 'sunmon-compat?' NVRAM parameter is set to true. Not all workstations have the 'sunmon-compat?' parameter.												
SunMON PROM USAGE	The following commands are available systems with older SunMON-based PROM: + - Increment or decrement the current address and display the contents of the new location. ^C <i>source destination n</i> (caret-C) Copy, byte-by-byte, a block of length <i>n</i> from the <i>source</i> address to the <i>destination</i> address. ^I <i>program</i> (caret-I) Display the compilation date and location of <i>program</i>. ^T <i>virtual_address</i> (caret-T) Display the physical address to which <i>virtual_address</i> is mapped. b [!] [<i>device</i> [(<i>c, u, p</i>)]] [<i>pathname</i>] [<i>arguments_list</i>] b[?] Reset appropriate parts of the system and bootstrap a program. A '!' (preceding the <i>device</i> argument) prevents the system reset from occurring. Programs can be loaded from various devices (such as a disk, tape, or Ethernet). 'b' with no arguments causes a default boot, either from a disk, or from an Ethernet controller. 'b?' displays all boot devices and their <i>devices</i>. <table> <tr> <td><i>device</i></td><td>one of</td></tr> <tr> <td>le</td><td>Lance Ethernet</td></tr> <tr> <td>ie</td><td>Intel Ethernet</td></tr> <tr> <td>sd</td><td>SCSI disk, CDROM</td></tr> <tr> <td>st</td><td>SCSI 1/4" or 1/2" tape</td></tr> <tr> <td>fd</td><td>Diskette</td></tr> </table>	<i>device</i>	one of	le	Lance Ethernet	ie	Intel Ethernet	sd	SCSI disk, CDROM	st	SCSI 1/4" or 1/2" tape	fd	Diskette
<i>device</i>	one of												
le	Lance Ethernet												
ie	Intel Ethernet												
sd	SCSI disk, CDROM												
st	SCSI 1/4" or 1/2" tape												
fd	Diskette												

monitor(1M)

	<i>id</i>	IPI disk
	<i>mt</i>	Tape Master 9-track 1/2" tape
	<i>xd</i>	Xylogics 7053 disk
	<i>xt</i>	Xylogics 1/2" tape
	<i>xy</i>	Xylogics 440/450 disk
<i>c</i>		A controller number (0 if only one controller),
<i>u</i>		A unit number (0 if only one driver), and
<i>p</i>		A partition.
<i>pathname</i>		A pathname for a program such as <i>/stand/diag</i> .
<i>arguments_list</i>		A list of up to seven arguments to pass to the program being booted.
c	[<i>virtual_address</i>]	Resume execution of a program. When given, <i>virtual_address</i> is the address at which execution resumes. The default is the current PC. Registers are restored to the values shown by the <i>d</i> , and <i>r</i> commands.
d	[<i>window_number</i>]	Display (dump) the state of the processor. The processor state is observable only after: ■ An unexpected trap was encountered. ■ A user program dropped into the monitor (by calling <i>abortent</i>). ■ The user manually entered the monitor by typing L1-A or BREAK. The display consists of the following: ■ The special registers: PSR, PC, nPC, TBR, WIM, and Y ■ Eight global registers ■ 24 window registers (8 <i>in</i>, 8 <i>local</i>, and 8 <i>out</i>), corresponding to one of the 7 available windows. If a Floating-Point Unit is on board, its status register along with 32 floating-point registers are also shown. <i>window_number</i> Display the indicated <i>window_number</i>, which can be any value between 0 and 6, inclusive. If no window is specified and the PSR's current window pointer contains a valid window number, registers from the window that was active just prior to entry into the monitor are displayed. Otherwise, registers from window 0 are displayed.
e	[<i>virtual_address</i>] [<i>action</i>] . . .	Open the 16-bit word at <i>virtual_address</i> (default zero). The address is interpreted in the address space defined by the <i>s</i> command. See the <i>a</i> command for a description of <i>action</i> .

f *virtual_address1 virtual_address2 pattern [size]*

Fill the bytes, words, or long words from *virtual_address1* (lower) to *virtual_address2* (higher) with the constant, *pattern*. The *size* argument can take one of the following values:

b	byte format (the default)
w	word format
l	long word format

For example, the following command fills the address block from 0x1000 to 0x2000 with the word pattern, 0xABCD:

```
f 1000 2000 ABCD W
```

g [*vector*] [*argument*]

g [*virtual_address*] [*argument*]

Goto (jump to) a predetermined or default routine (first form), or to a user-specified routine (second form). The value of *argument* is passed to the routine. If the *vector* or *virtual_address* argument is omitted, the value in the PC is used as the address to jump to.

To set up a predetermined routine to jump to, a user program must, prior to executing the monitor's **g** command, set the variable **romp->v_vector_cmd* to be equal to the virtual address of the desired routine. Predetermined routines need not necessarily return control to the monitor.

The default routine, defined by the monitor, prints the user-supplied *vector* according to the format supplied in *argument*. This format can be one of:

%x	hexadecimal
%d	decimal

g0

Force a panic and produce a crash dump when the monitor is running as a result of the system being interrupted,

g4

(Sun-4 systems only) Force a kernel stack trace when the monitor is running as a result of the system being interrupted,

h

Display the help menu for monitor commands and their descriptions. To return to the monitor's basic command level, press ESCAPE or **q** before pressing RETURN.

i [*cache_data_offset*] [*action*] . . .

Modify cache data RAM command. Display and/or modify one or more of the cache data addresses. See the **a** command for a description of *action*.

monitor(1M)

- j *[cache_tag_offset] [action] . . .*
Modify cache tag RAM command. Display and/or modify the contents of one or more of the cache tag addresses. See the a command for a description of *action*.
- k *[reset_level]*
Reset the system, where *reset_level* is:
 - 0 Reset VMEbus, interrupt registers, video monitor (Sun-4 systems). This is the default.
 - 1 Software reset.
 - 2 Power-on reset. Resets and clears the memory. Runs the EPROM-based diagnostic self test, which can take several minutes, depending upon how much memory is being tested.
- kb
Display the system banner.
- l *[virtual_address] [action] . . .*
Open the long word (32 bit) at memory address *virtual_address* (default zero). The address is interpreted in the address space defined by the s command (below). See the a command for a description of *action*.
- m *[virtual_address] [action] . . .*
Open the segment map entry that maps *virtual_address* (default zero). The address is interpreted in the address space defined by the s command. See the a command for a description of *action*.
- ne
- ni
Disable, enable, or invalidate the cache, respectively.
- o *[virtual_address] [action] . . .*
Open the byte location specified by *virtual_address* (default zero). The address is interpreted in the address space defined by the s command. See the a command for a description of *action*.
- p *[virtual_address] [action] . . .*
Open the page map entry that maps *virtual_address* (default zero) in the address space defined by the s command. See the a command for a description of *action*.
- q *[eprom_offset] [action] . . .*
Open the EEPROM *eprom_offset* (default zero) in the EEPROM address space. All addresses are referenced from the beginning or base of the EEPROM in physical address space, and a limit check is performed to insure that no address beyond the EEPROM physical space is accessed. This command is used to display or modify configuration parameters, such as: the amount of memory to test during self test, whether to display a standard or custom banner, if a serial port (A or B) is to be the system console, etc. See the a command for a description of *action*.
- r *[register_number]*
- r *[register_type]*

r [*w window_number*]

Display and/or modify one or more of the IU or FPU registers. A hexadecimal *register_number* can be one of:

0x00–0x0f	window(0,i0)–window(0,i7), window(0,i0)—window(0,i7)
0x10–0x1f	window(1,i0)–window(1,i7), window(1,i0)—window(1,i7)
0x20–0x2f	window(2,i0)–window(2,i7), window(2,i0)—window(2,i7)
0x30–0x3f	window(3,i0)–window(3,i7), window(3,i0)—window(3,i7)
0x40–0x4f	window(4,i0)–window(4,i7), window(4,i0)—window(4,i7)
0x50–0x5f	window(5,i0)–window(5,i7), window(5,i0)—window(5,i7)
0x60–0x6f	window(6,i0)–window(6,i7), window(6,i0)—window(6,i7)
0x70–0x77	g0, g1, g2, g3, g4, g5, g6, g7
0x78–0x7d	PSR, PC, nPC, WIM, TBR, Y.
0x7e–0x9e	FSR, f0–f31

Register numbers can only be displayed after an unexpected trap, a user program has entered the monitor using the *abortent* function, or the user has entered the monitor by manually typing L1–A or BREAK.

If a *register_type* is given, the first register of the indicated type is displayed. *register_type* can be one of:

f	floating-point
g	global
s	special

If *w* and a *window_number* (0–6) are given, the first *in*-register within the indicated window is displayed. If *window_number* is omitted, the window that was active just prior to entering the monitor is used. If the PSR's current window pointer is invalid, window 0 is used.

s [*asi*]

Set or display the Address Space Identifier. With no argument, *s* displays the current Address Space Identifier. The *asi* value can be one of:

0x2	control space

monitor(1M)

0x3	segment table
0x4	Page table
0x8	user instruction
0x9	supervisor instruction
0xa	user data
0xb	supervisor data
0xc	flush segment
0xd	flush page
0xe	flush context
0xf	cache data
u [echo]	
u [port] [options] [baud_rate]	
u [u] [virtual_address]	
With no arguments, display the current I/O device characteristics including: current input device, current output device, baud rates for serial ports A and B, an input-to-output echo indicator, and virtual addresses of mapped UART devices. With arguments, set or configure the current I/O device. With the u argument (uu. . .), set the I/O device to be the <i>virtual_address</i> of a UART device currently mapped.	
echo	Can be either e to enable input to be echoed to the output device, or ne, to indicate that input is not echoed.
port	Assign the indicated <i>port</i> to be the current I/O device. <i>port</i> can be one of:
a	serial port A
b	serial port B
k	the workstation keyboard
s	the workstation screen
baud_rate	Any legal baud rate.
options	can be any combination of:
i	input
o	output
u	UART
e	echo input to output
ne	do not echo input

monitor(1M)

r reset indicated serial port (a and b ports only)

If either a or b is supplied, and no *options* are given, the serial port is assigned for both input and output. If k is supplied with no options, it is assigned for input only. If s is supplied with no options, it is assigned for output only.

v *virtual_address1 virtual_address2 [size]*

Display the contents of *virtual_address1* (lower) *virtual_address2* (higher) in the format specified by *size*:

b byte format (the default)

w word format

l long word format

Enter return to pause for viewing; enter another return character to resume the display. To terminate the display at any time, press the space bar.

For example, the following command displays the contents of virtual address space from address 0x1000 to 0x2000 in word format:

v 1000 2000 W

w [*virtual_address*] [*argument*]

Set the execution vector to a predetermined or default routine. Pass *virtual_address* and *argument* to that routine.

To set up a predetermined routine to jump to, a user program must, prior to executing the monitor's w command, set the variable *romp->v_vector_cmd to be equal to the virtual address of the desired routine. Predetermined routines need not necessarily return control to the monitor.

The default routine, defined by the monitor, prints the user-supplied *vector* according to the format supplied in *argument*. This format can be one of:

%x hexadecimal

%d decimal

x

Display a menu of extended tests. These diagnostics permit additional testing of such things as the I/O port connectors, video memory, workstation memory and keyboard, and boot device paths.

y c *context_number*

y p | s *context_number virtual_address*

Flush the indicated context, context page, or context segment.

c flush context *context_number*

monitor(1M)

- p flush the page beginning at *virtual_address* within context *context_number*
- s flush the segment beginning at *virtual_address* within context *context_number*

OpenBoot 2.x Command Reference Manual

NAME	mount, umount – mount or unmount file systems and remote resources
SYNOPSIS	<pre> mount [-p -v] mount [-F <i>FSType</i>] [<i>generic_options</i>] [-o <i>specific_options</i>] [-O] <i>special</i> <i>mount_point</i> mount [-F <i>FSType</i>] [<i>generic_options</i>] [-o <i>specific_options</i>] [-O] <i>special</i> <i>mount_point</i> mount -a [-F <i>FSType</i>] [-V] [<i>current_options</i>] [-o <i>specific_options</i>] [<i>mount_point...</i>] umount [-f] [-V] [-o <i>specific_options</i>] <i>special</i> <i>mount_point</i> umount -a [-f] [-V] [-o <i>specific_options</i>] [<i>mount_point...</i>] </pre>
DESCRIPTION	mount attaches a file system to the file system hierarchy at the <i>mount_point</i>, which is the pathname of a directory. If <i>mount_point</i> has any contents prior to the mount operation, these are hidden until the file system is unmounted. umount unmounts a currently mounted file system, which may be specified either as a <i>mount_point</i> or as <i>special</i>, the device on which the file system resides. The table of currently mounted file systems can be found by examining the mounted file system information file. This is provided by a file system that is usually mounted on <i>/etc/mnttab</i>. The mounted file system information is described in <i>mnttab(4)</i>. Mounting a file system adds an entry to the mount table; a <i>umount</i> removes an entry from the table. When invoked with both the <i>special</i> and <i>mount_point</i> arguments and the <i>-F</i> option, mount validates all arguments except for <i>special</i> and invokes the appropriate <i>FSType</i>-specific mount module. If invoked with no arguments, mount lists all the mounted file systems recorded in the mount table, <i>/etc/mnttab</i>. If invoked with a partial argument list (with only one of <i>special</i> or <i>mount_point</i>, or with both <i>special</i> or <i>mount_point</i> specified but not <i>FSType</i>), mount will search <i>/etc/vfstab</i> for an entry that will supply the missing arguments. If no entry is found, and the <i>special</i> argument starts with <i>"/"</i>, the default local file system type specified in <i>/etc/default/fs</i> will be used. Otherwise the default remote file system type will be used. The default remote file system type is determined by the first entry in the <i>/etc/dfs/fstypes</i> file. After filling in missing arguments, mount will invoke the <i>FSType</i>-specific mount module. Only a super-user can mount or unmount file systems using <i>mount</i> and <i>umount</i>. However, any user can use <i>mount</i> to list mounted file systems and resources.
OPTIONS	<i>-F FSType</i> Used to specify the <i>FSType</i> on which to operate. The <i>FSType</i> must be specified or must be determinable from <i>/etc/vfstab</i>, or by consulting <i>/etc/default/fs</i> or <i>/etc/dfs/fstypes</i>. <i>-a [mount_points. . .]</i> Perform mount or umount operations in parallel, when possible.

mount(1M)

If mount points are not specified, mount will mount all file systems whose `/etc/vfstab` "mount at boot" field is "yes". If mount points are specified, then `/etc/vfstab` "mount at boot" field will be ignored.

If mount points are specified, umount will only umount those mount points. If none is specified, then umount will attempt to unmount all file systems in `/etc/mnttab`, with the exception of certain system required file systems: `/`, `/usr`, `/var`, `/var/adm`, `/var/run`, `/proc`, `/dev/fd` and `/tmp`.

-f

Forcibly unmount a file system.

Without this option, umount does not allow a file system to be unmounted if a file on the file system is busy. Using this option can cause data loss for open files; programs which access files after the file system has been unmounted will get an error (EIO).

-p

Print the list of mounted file systems in the `/etc/vfstab` format. Must be the only option specified. See BUGS.

-v

Print the list of mounted file systems in verbose format. Must be the only option specified.

-V

Echo the complete command line, but do not execute the command. umount generates a command line by using the options and arguments provided by the user and adding to them information derived from `/etc/mnttab`. This option should be used to verify and validate the command line.

generic_options

Options that are commonly supported by most *FSType*-specific command modules. The following options are available:

-m

Mount the file system without making an entry in `/etc/mnttab`.

-g

Globally mount the file system. On a clustered system, this globally mounts the file system on all nodes of the cluster. On a non-clustered system this has no effect.

-o

Specify *FSType*-specific options in a comma separated (without spaces) list of suboptions and keyword-attribute pairs for interpretation by the *FSType*-specific module of the command. (See `mount_ufs(1M)`.) When you use `-o` with a file system that has an entry in `/etc/vfstab`, any mount options entered for that file system in `/etc/vfstab` are ignored.

	-O Overlay mount. Allow the file system to be mounted over an existing mount point, making the underlying file system inaccessible. If a mount is attempted on a pre-existing mount point without setting this flag, the mount will fail, producing the error “device busy”.				
	-r Mount the file system read-only.				
USAGE	See largefile(5) for the description of the behavior of mount and umount when encountering files greater than or equal to 2 Gbyte (2 ³¹ bytes).				
FILES	/etc/mnttab Table of mounted file systems.				
	/etc/default/fs Default local file system type. Default values can be set for the following flags in /etc/default/fs. For example: LOCAL=ufs				
	LOCAL: The default partition for a command if no <i>FSType</i> is specified.				
	/etc/vfstab List of default parameters for each file system.				
ATTRIBUTES	See attributes(5) for descriptions of the following attributes:				
	<table><tr><th>ATTRIBUTE TYPE</th><th>ATTRIBUTE VALUE</th></tr><tr><td>Availability</td><td>SUNWcsu</td></tr></table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	Availability	SUNWcsu
ATTRIBUTE TYPE	ATTRIBUTE VALUE				
Availability	SUNWcsu				
SEE ALSO	mount_cachefs(1M), mount_hsfcs(1M), mount_nfs(1M), mount_pcfs(1M), mount_tmpfs(1M), mount_ufs(1M), mountall(1M), umountall(1M), mnttab(4), vfstab(4), attributes(5), largefile(5), lofs(7FS), pcfs(7FS)				
NOTES	If the directory on which a file system is to be mounted is a symbolic link, the file system is mounted on the directory to which the symbolic link refers, rather than on top of the symbolic link itself.				
BUGS	The mount -p output is incorrect for cachefs.				

mountall(1M)

NAME	mountall, umountall – mount, unmount multiple file systems
SYNOPSIS	mountall [-F <i>FSType</i>] [-l -r] [<i>file_system_table</i>] umountall [-k] [-s] [-F <i>FSType</i>] [-l -r] [-n] umountall [-k] [-s] [-h <i>host</i>] [-n]
DESCRIPTION	mountall is used to mount file systems specified in a file system table. The file system table must be in <i>vfstab</i>(4) format. If no <i>file_system_table</i> is specified, /etc/vfstab is used. If – is specified as <i>file_system_table</i>, mountall reads the file system table from the standard input. mountall mounts only those file systems with the mount at boot field set to yes in the <i>file_system_table</i>. For each file system in the file system table, the following logic is executed: if there exists a file /usr/lib/fs/<i>FSType</i>/fsckall, where <i>FSType</i> is the type of the file system, save that file system in a list to be passed later, and all at once, as arguments to the /usr/lib/fs/<i>FSType</i>/fsckall script. The /usr/lib/fs/<i>FSType</i>/fsckall script checks all of the file systems in its argument list to determine whether they can be safely mounted. If no /usr/lib/fs/<i>FSType</i>/fsckall script exists for the <i>FSType</i> of the file system, the file system is individually checked using fsck(1M). If the file system does not appear mountable, it is fixed using fsck before the mount is attempted. File systems with a – entry in the fsckdev field are mounted without first being checked. umountall causes all mounted file systems except root, /usr, /var, /var/adm, /var/run, /proc, and /dev/fd to be unmounted. If the <i>FSType</i> is specified, mountall and umountall limit their actions to the <i>FSType</i> specified. There is no guarantee that umountall unmounts <i>busy</i> file systems, even if the -k option is specified.
OPTIONS	The following options are supported: -F Specify the <i>FSType</i> of the file system to be mounted or unmounted. -h <i>host</i> Unmount all file systems listed in /etc/mnttab that are remote-mounted from host. -k Use the fuser -k <i>mount-point</i> command. See the fuser(1M) for details. The -k option sends the SIGKILL signal to each process using the file. As this option spawns kills for each process, the kill messages might not show up immediately. There is no guarantee that umountall unmounts <i>busy</i> file systems, even if the -k option is specified. -l Limit the action to local file systems. -n List the actions that would be performed for the specified options, but do not actually execute these actions. Repeating the command without the -n option executes the listed actions, assuming that the /etc/mnttab file has not changed in the interval prior to repeating the command.

FILES	-r	Limit the action to remote file system types.
	-s	Do not perform the umount operation in parallel.
	/etc/mnttab	Mounted file system table
	/etc/vfstab	Table of file system defaults
	/usr/lib/fs/ <i>FSType</i> /fsckall	Script called by mountall to perform the file system check of all file systems of type <i>FSType</i>

ATTRIBUTES See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

SEE ALSO fsck(1M), fuser(1M), mount(1M), mnttab(4), vfstab(4), attributes(5)

DIAGNOSTICS No messages are printed if the file systems are mountable and clean.
Error and warning messages come from fsck(1M) and mount(1M).

mount_cachefs(1M)

NAME	mount_cachefs – mount CacheFS file systems
SYNOPSIS	mount -F cachefs [<i>generic_options</i>] -o backfstype= <i>file_system_type</i> [<i>specific_options</i>] [-O] <i>special mount_point</i>
DESCRIPTION	The CacheFS-specific version of the mount command mounts a cached file system; if necessary, it NFS-mounts its back file system. It also provides a number of CacheFS-specific options for controlling the caching process. For more information regarding back file systems, refer to the <i>System Administration Guide: Basic Administration</i> .
OPTIONS	To mount a CacheFS file system, use the generic mount command with the -F option followed by the argument cachefs. See mount(1M) for a list of supported <i>generic_options</i>. -o <i>specific_options</i> Specify CacheFS file system specific options in a comma-separated list with no intervening spaces. acdirmax=<i>n</i> Specifies that cached attributes are held for no more than <i>n</i> seconds after directory update. After <i>n</i> seconds, all directory information is purged from the cache. The default value is 30 seconds. acdirmin=<i>n</i> Specifies that cached attributes are held for at least <i>n</i> seconds after directory update. After <i>n</i> seconds, CacheFS checks to see if the directory modification time on the back file system has changed. If it has, all information about the directory is purged from the cache and new data is retrieved from the back file system. The default value is 30 seconds. acregmax=<i>n</i> Specifies that cached attributes are held for no more than <i>n</i> seconds after file modification. After <i>n</i> seconds, all file information is purged from the cache. The default value is 30 seconds. acregmin=<i>n</i> Specifies that cached attributes are held for at least <i>n</i> seconds after file modification. After <i>n</i> seconds, CacheFS checks to see if the file modification time on the back file system has changed. If it has, all information about the file is purged from the cache and new data is retrieved from the back file system. The default value is 30 seconds. actimeo=<i>n</i> Sets acregmin, acregmax, acdirmin, and acdirmax to <i>n</i>. backfstype=<i>file_system_type</i> The file system type of the back file system (can be nfs or hsfs).

backpath=path

Specifies where the back file system is already mounted. If this argument is not supplied, CacheFS determines a mount point for the back file system. The back file system must be read-only.

cachedir=directory

The name of the cache directory.

cacheid=ID

ID is a string specifying a particular instance of a cache. If you do not specify a cache ID, CacheFS will construct one.

demandconst

Verifies cache consistency only when explicitly requested, rather than the periodic checking that is done by default. A consistency check is requested by using the *-s* option of the *cfsadmin(1M)* command. This option is useful for back file systems that change infrequently, for example, */usr/openwin*. *demandconst* and *noconst* are mutually exclusive.

local-access

Causes the front file system to interpret the mode bits used for access checking instead of having the back file system verify access permissions. Do not use this argument with secure NFS.

noconst

Disables cache consistency checking. By default, periodic consistency checking is enabled. Specify *noconst* only when you know that the back file system will not be modified. Trying to perform cache consistency check using *cfsadmin -s* will result in error. *demandconst* and *noconst* are mutually exclusive.

ro | rw

Read-only or read-write (default).

suid | nosuid

Allow (default) or disallow *setuid* execution.

write-around | non-shared

Write modes for CacheFS. The *write-around* mode (the default) handles writes the same as NFS does; that is, writes are made to the back file system, and the affected file is purged from the cache. You can use the *non-shared* mode when you are sure that no one else will be writing to the cached file system. In this mode, all writes are made to both the front and the back file system, and the file remains in the cache.

-O

Overlay mount. Allows the filesystem to be mounted over an existing mount point, making the underlying filesystem inaccessible. If a mount is attempted on a pre-existing mount point without setting this flag, mount will fail with the error: *mount -F cachefs: mount failed Device busy*.

mount_cachefs(1M)

EXAMPLES

EXAMPLE 1 CacheFS-mounting a File System

The following example CacheFS-mounts the file system `server1:/user2`, which is already NFS-mounted on `/usr/abc` as `/xyz`.

```
example# mount -F cachefs -o backfstype=nfs,backpath=/usr/abc,  
             cachedir=/cache1 server1:/user2 /xyz
```

The lines similar to the following appear in the `/etc/mnttab` file after the mount command is executed:

```
server1:/user2  /usr/abc      nfs  
/usr/abc       /cache1/xyz    cachefs      backfstype=nfs
```

ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

SEE ALSO

`cfsadmin(1M)`, `fsck_cachefs(1M)`, `mount(1M)`, `attributes(5)` *System Administration Guide: Basic Administration*

BUGS

The output for the *generic_option* `-p` output is incorrect for `cachefs`.

NAME	mountd – server for NFS mount requests and NFS access checks				
SYNOPSIS	<code>/usr/lib/nfs/mountd [-v] [-r]</code>				
DESCRIPTION	mountd is an RPC server that answers requests for NFS access information and file system mount requests. It reads the file <code>/etc/dfs/sharetab</code> to determine which file systems are available for mounting by which remote machines. See <code>sharetab(4)</code>. <code>nfsd</code> running on the local server will contact mountd the first time an NFS client tries to access the file system to determine whether the client should get read-write, read-only, or no access. This access can be dependent on the security mode used in the <code>remoted</code> procedure call from the client. See <code>share_nfs(1M)</code>. The command also provides information as to what file systems are mounted by which clients. This information can be printed using the <code>showmount(1M)</code> command. The mountd daemon is automatically invoked in run level 3. Only super user can run the mountd daemon.				
OPTIONS	The following options are supported: <code>-r</code> Reject mount requests from clients. Clients that have file systems mounted will not be affected. <code>-v</code> Run the command in verbose mode. Each time mountd determines what access a client should get, it will log the result to the console, as well as how it got that result.				
FILES	<code>/etc/dfs/sharetab</code> shared file system table				
ATTRIBUTES	See <code>attributes(5)</code> for descriptions of the following attributes:				
	<table border="1"> <thead> <tr> <th>ATTRIBUTE TYPE</th><th>ATTRIBUTE VALUE</th></tr> </thead> <tbody> <tr> <td>Availability</td><td>SUNWnfssu</td></tr> </tbody> </table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	Availability	SUNWnfssu
ATTRIBUTE TYPE	ATTRIBUTE VALUE				
Availability	SUNWnfssu				
SEE ALSO	<code>nfsd(1M)</code> , <code>share_nfs(1M)</code> , <code>showmount(1M)</code> , <code>sharetab(4)</code> , <code>attributes(5)</code>				
NOTES	If <code>nfsd</code> is running, mountd must also be running in order to be assured that the NFS server can respond to requests, otherwise, the NFS service can hang. Some routines that compare hostnames use case-sensitive string comparisons; some do not. If an incoming request fails, verify that the case of the hostname in the file to be parsed matches the case of the hostname called for, and attempt the request again.				

mount_hsf s(1M)

NAME	mount_hsf s – mount hsf s file systems
SYNOPSIS	mount -F hsf s [<i>generic_options</i>] [-o <i>FSType-specific_options</i>] [-O] <i>special</i> <i>mount_point</i> mount -F hsf s [<i>generic_options</i>] [-o <i>FSType-specific_options</i>] [-O] <i>special</i> <i>mount_point</i>
DESCRIPTION	mount attaches a High Sierra file system (hsf s) to the file system hierarchy at the <i>mount_point</i>, which is the pathname of a directory. If <i>mount_point</i> has any contents prior to the mount operation, these are hidden until the file system is unmounted. If mount is invoked with <i>special</i> or <i>mount_point</i> as the only arguments, mount will search /etc/vfstab to fill in the missing arguments, including the <i>FSType-specific_options</i>; see mount(1M) for more details. If the file system being mounted contains Rock Ridge extensions, by default they will be used, enabling support of features not normally available under High Sierra file systems such as symbolic links, and special files.
OPTIONS	<i>generic_options</i> See mount(1M) for the list of supported options. -o Specify hsf s file system specific options. If invalid options are specified, a warning message is printed and the invalid options are ignored. The following options are available: global noglobal If global is specified and supported on the file system, and the system in question is part of a cluster, the file system will be globally visible on all nodes of the cluster. If noglobal is specified, the mount will not be globally visible. The default behavior is noglobal. ro Mount the file system read-only. This option is required. nrr no Rock Ridge: if Rock Ridge extensions are present in the file system, ignore them; interpret it as a regular High Sierra file system. notraildot File names on High Sierra file systems consist of a proper name and an extension separated by a '.' (dot) character. By default, the separating dot is always considered part of the file's name for all file access operations, even if there is no extension present. Specifying notraildot makes it optional to specify the trailing dot to access a file whose name lacks an extension. <i>Exceptions:</i> This option is effective only on file systems for which Rock Ridge extensions are not active, either because they are not present on the CD-ROM, or they are explicitly ignored via the nrr option. If Rock Ridge extensions are active, hsf s quietly ignores this option.

nomaplcas

File names on High Sierra cdroms with no Rock Ridge extensions present should be uppercase characters only. By default, `hfs` maps file names read from a non-Rock Ridge disk to all lowercase characters. `nomaplcas` turns off this mapping. The exceptions for `notraildot` discussed above apply to `nomaplcas`.

nosuid

By default the file system is mounted with `setuid` execution allowed. Specifying `nosuid` causes the file system to be mounted with `setuid` execution disallowed.

-O

Overlay mount. Allow the file system to be mounted over an existing mount point, making the underlying file system inaccessible. If a mount is attempted on a pre-existing mount point without setting this flag, the mount will fail, producing the error device busy.

FILES `/etc/mnttab` table of mounted file systems

`/etc/vfstab` list of default parameters for each file system

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

SEE ALSO `mount(1M)`, `mountall(1M)`, `mount(2)`, `mnttab(4)`, `vfstab(4)`, `attributes(5)`

NOTES If the directory on which a file system is to be mounted is a symbolic link, the file system is mounted on the directory to which the symbolic link refers, rather than on top of the symbolic link itself.

mount_nfs(1M)

NAME	mount_nfs – mount remote NFS resources
SYNOPSIS	mount [-F nfs] [<i>generic_options</i>] [-o <i>specific_options</i>] [-O] <i>resource</i> mount [-F nfs] [<i>generic_options</i>] [-o <i>specific_options</i>] [-O] <i>mount_point</i> mount [-F nfs] [<i>generic_options</i>] [-o <i>specific_options</i>] [-O] <i>resource</i> <i>mount_point</i>
DESCRIPTION	The mount utility attaches a named <i>resource</i> to the file system hierarchy at the pathname location <i>mount_point</i>, which must already exist. If <i>mount_point</i> has any contents prior to the mount operation, the contents remain hidden until the <i>resource</i> is once again unmounted. If the resource is listed in the <i>/etc/vfstab</i> file, the command line can specify either <i>resource</i> or <i>mount_point</i>, and mount consults <i>/etc/vfstab</i> for more information. If the -F option is omitted, mount takes the file system type from <i>/etc/vfstab</i>. If the resource is not listed in the <i>/etc/vfstab</i> file, then the command line must specify both the <i>resource</i> and the <i>mount_point</i>. <i>host</i> can be an IPv4 or IPv6 address string. As IPv6 addresses already contain colons, enclose <i>host</i> in a pair of square brackets when specifying an IPv6 address string. Otherwise the first occurrence of a colon can be interpreted as the separator between the host name and path, for example, [1080::8:800:200C:417A]:tmp/file. See <i>inet(7P)</i> and <i>inet6(7P)</i>. <i>host:pathname</i> Where <i>host</i> is the name of the NFS server host, and <i>pathname</i> is the path name of the directory on the server being mounted. The path name is interpreted according to the server's path name parsing rules and is not necessarily slash-separated, though on most servers, this is the case. <i>nfs://host[:port]/pathname</i> This is an NFS URL and follows the standard convention for NFS URLs as described in <i>NFS URL Scheme</i>, RFC 2224. See the discussion of URL's and the public option under NFS FILE SYSTEMS for a more detailed discussion. A comma-separated list of <i>host:pathname</i> and/or <i>nfs://host[:port]/pathname</i> resources See the discussion of replicated file systems and failover under NFS FILE SYSTEMS for a more detailed discussion. A comma-separated list of hosts followed by a <i>:pathname</i> suffix See the discussion of replicated file systems and failover under NFS FILE SYSTEMS for a more detailed discussion. The mount command maintains a table of mounted file systems in <i>/etc/mnttab</i>, described in <i>mnttab(4)</i>.
OPTIONS	See <i>mount(1M)</i> for the list of supported <i>generic_options</i> .

-o *specific_options*

Set file system specific options according to a comma-separated list with no intervening spaces.

acdirmax=*n*

Hold cached attributes for no more than *n* seconds after directory update. The default value is 60.

acdirmin=*n*

Hold cached attributes for at least *n* seconds after directory update. The default value is 30.

acregmax=*n*

Hold cached attributes for no more than *n* seconds after file modification. The default value is 60.

acregmin=*n*

Hold cached attributes for at least *n* seconds after file modification. The default value is 3.

actimeo=*n*

Set *min* and *max* times for regular files and directories to *n* seconds.

bg | fg

If the first attempt fails, retry in the background, or, in the foreground. The default is fg.

forcedirectio | noforcedirectio

If **forcedirectio** is specified, then for the duration of the mount, forced direct I/O is used. If the filesystem is mounted using **forcedirectio**, data is transferred directly between client and server, with no buffering on the client. If the filesystem is mounted using **noforcedirectio**, data is buffered on the client. **forcedirectio** is a performance option that is of benefit only in large sequential data transfers. The default behavior is **noforcedirectio**.

grpuid

By default, the GID associated with a newly created file obeys the System V semantics; that is, the GID is set to the effective GID of the calling process. This behavior may be overridden on a per-directory basis by setting the set-GID bit of the parent directory; in this case, the GID of a newly created file is set to the GID of the parent directory (see **open(2)** and **mkdir(2)**). Files created on file systems that are mounted with the **grpuid** option obeys BSD semantics independent of whether the set-GID bit of the parent directory is set; that is, the GID is unconditionally inherited from that of the parent directory.

hard | soft

Continue to retry requests until the server responds (**hard**) or give up and return an error (**soft**). The default value is **hard**.

mount_nfs(1M)

`intr | nointr`

Allow (do not allow) keyboard interrupts to kill a process that is hung while waiting for a response on a hard-mounted file system. The default is `intr`, which makes it possible for clients to interrupt applications that may be waiting for a remote mount.

`noac`

Suppress data and attribute caching. The data caching that is suppressed is the write-behind. The local page cache is still maintained, but data copied into it is immediately written to the server.

`nocto`

Do not perform the normal close-to-open consistency. When a file is closed, all modified data associated with the file is flushed to the server and not held on the client. When a file is opened the client sends a request to the server to validate the client's local caches. This behavior ensures a file's consistency across multiple NFS clients. When `-nocto` is in effect, the client does not perform the flush on close and the request for validation, allowing the possibility of differences among copies of the same file as stored on multiple clients.

This option can be used where it can be guaranteed that accesses to a specified file system are made from only one client and only that client. Under such a condition, the effect of `-nocto` can be a slight performance gain.

`port=n`

The server IP port number. The default is `NFS_PORT`. If the `port` option is specified, and if the resource includes one or more NFS URLs, and if any of the URLs include a `port` number, then the `port` number in the option and in the URL must be the same.

`posix`

Request POSIX.1 semantics for the file system. Requires a mount Version 2 `mountd(1M)` on the server. See `standards(5)` for information regarding POSIX.

`proto=<netid>`

`<netid>` is a value of `network_id` field from entry in the `/etc/netconfig` file. By default, the transport protocol used for the NFS mount is the first available connection oriented transport supported on both the client and the server. If no connection oriented transport is found, then the first available connectionless transport is used. This default behavior can be overridden with the `proto=<netid>` option.

`public`

The `public` option forces the use of the public file handle when connecting to the NFS server. The resource specified may or may not have an NFS URL. See the discussion of URL's and the `public` option under `NFS FILE SYSTEMS` for a more detailed discussion.

quota | noquota

Enable or prevent quota(1M) to check whether the user is over quota on this file system; if the file system has quotas enabled on the server, quotas are still checked for operations on this file system.

remount

Remounts a read-only file system as read-write (using the *rw* option). This option cannot be used with other *-o* options, and this option works only on currently mounted read-only file systems.

retrans=*n*

Set the number of NFS retransmissions to *n*. The default value is 5. For connection-oriented transports, this option has no effect because it is assumed that the transport performs retransmissions on behalf of NFS.

retry=*n*

The number of times to retry the mount operation. The default for the mount command is 10000.

The default for the automounter is 0, in other words, do not retry. You might find it useful to increase this value on heavily loaded servers, where automounter traffic is dropped, causing unnecessary “server not responding” errors.

ro | rw

resource is mounted read-only or read-write. The default is *rw*.

rsize=*n*

Set the read buffer size to *n* bytes. The default value is 32768 when using Version 3 of the NFS protocol. The default can be negotiated down if the server prefers a smaller transfer size. When using Version 2, the default value is 8192.

sec=*mode*

Set the security *mode* for NFS transactions. If *sec=* is not specified, then the default action is to use *AUTH_SYS* over NFS Version 2 mounts, or to negotiate a *mode* over NFS Version 3 mounts. NFS Version 3 mounts negotiate a security mode when the server returns an array of security modes. The client picks the first mode in the array that is supported on the client. Only one mode can be specified with the *sec=* option. See *nfssec(5)* for the available *mode* options.

secure

This option has been deprecated in favor of the *sec=dh* option.

suid | nosuid

Allow or disallow *setuid* execution. The default is *suid*.

timeo=*n*

Set the NFS timeout to *n* tenths of a second. The default value is 11 tenths of a second for connectionless transports, and 600 tenths of a second for connection-oriented transports.

mount_nfs(1M)

NFS FILE SYSTEMS

`vers=<NFS version number>`

By default, the version of NFS protocol used between the client and the server is the highest one available on both systems. If the NFS server does not support NFS Version 3 protocol, then the NFS mount uses NFS Version 2 protocol.

`wsiz=n`

Set the write buffer size to *n* bytes. The default value is 32768 when using Version 3 of the NFS protocol. The default can be negotiated down if the server prefers a smaller transfer size. When using Version 2, the default value is 8192.

`xattr | noxattr`

Allow or disallow the creation and manipulation of extended attributes. The default is `xattr`. See `fsattr(5)` for a description of extended attributes.

`-O`

Overlay mount. Allow the file system to be mounted over an existing mount point, making the underlying file system inaccessible. If a mount is attempted on a pre-existing mount point without setting this flag, the mount fails, producing the error "device busy."

Background versus Foreground

File systems mounted with the `bg` option indicate that `mount` is to retry in the background if the server's mount daemon (`mountd(1M)`) does not respond. `mount` retries the request up to the count specified in the `retry=n` option. (Note that the default value for `retry` differs between `mount` and `automount`. See the description of `retry`, above.) Once the file system is mounted, each NFS request made in the kernel waits `timeo=n` tenths of a second for a response. If no response arrives, the time-out is multiplied by 2 and the request is retransmitted. When the number of retransmissions has reached the number specified in the `retrans=n` option, a file system mounted with the `soft` option returns an error on the request; one mounted with the `hard` option prints a warning message and continues to retry the request.

Hard versus Soft

File systems that are mounted read-write or that contain executable files should always be mounted with the `hard` option. Applications using `soft` mounted file systems may incur unexpected I/O errors, file corruption, and unexpected program core dumps. The `soft` option is not recommended.

Authenticated requests

The server may require authenticated NFS requests from the client. `sec=dh` authentication might be required. See `nfsssec(5)`.

URLs and the public option

If the `public` option is specified, or if the *resource* includes an NFS URL, `mount` attempts to connect to the server using the public file handle lookup protocol. See *WebNFS Client Specification*, RFC 2054. If the server supports the public file handle, the attempt is successful; `mount` does not need to contact the server's `rpcbind(1M)`, and the `mountd(1M)` daemons to get the port number of the mount server and the initial file handle of *pathname*, respectively. If the NFS client and server are separated by a firewall that allows all outbound connections through

specific ports, such as `NFS_PORT`, then this enables NFS operations through the firewall. The `public` option and the NFS URL can be specified independently or together. They interact as specified in the following matrix:

	resource style	
	<i>host:pathname</i>	NFS URL
public option	Force public file handle and fail mount if not supported. Use Native paths.	Force public file handle and fail mount if not supported. Use Canonical paths.
default	Use MOUNT protocol.	Try public file handle with Canonical paths. Fall back to MOUNT protocol if not supported.

A Native path is a path name that is interpreted according to conventions used on the native operating system of the NFS server. A Canonical path is a path name that is interpreted according to the URL rules. See *Uniform Resource Locators (URL)*, RFC 1738. See [EXAMPLES](#) for uses of Native and Canonical paths.

Replicated file systems and failover

resource can list multiple read-only file systems to be used to provide data. These file systems should contain equivalent directory structures and identical files. It is also recommended that they be created by a utility such as `rdist(1)`. The file systems may be specified either with a comma-separated list of *host:pathname* entries and/or NFS URL entries, or with a comma-separated list of hosts, if all file system names are the same. If multiple file systems are named and the first server in the list is down, failover uses the next alternate server to access files. If the read-only option is not chosen, replication is disabled. File access is blocked on the original if NFS locks are active for that file.

File Attributes

To improve NFS read performance, files and file attributes are cached. File modification times get updated whenever a write occurs. However, file access times may be temporarily out-of-date until the cache gets refreshed.

The attribute cache retains file attributes on the client. Attributes for a file are assigned a time to be flushed. If the file is modified before the flush time, then the flush time is extended by the time since the last modification (under the assumption that files that changed recently are likely to change soon). There is a minimum and maximum flush time extension for regular files and for directories. Setting `actimeo=n` sets flush time to *n* seconds for both regular files and directories.

Setting `actimeo=0` disables attribute caching on the client. This means that every reference to attributes is satisfied directly from the server though file data is still cached. While this guarantees that the client always has the latest file attributes from the server, it has an adverse effect on performance through additional latency, network load, and server load.

mount_nfs(1M)

Setting the noac option also disables attribute caching, but has the further effect of disabling client write caching. While this guarantees that data written by an application is written directly to a server, where it can be viewed immediately by other clients, it has a significant adverse effect on client write performance. Data written into memory-mapped file pages (mmap(2)) are not written directly to this server.

EXAMPLES

EXAMPLE 1 Mounting an NFS File System

To mount an NFS file system:

```
example# mount serv:/usr/src /usr/src
```

EXAMPLE 2 Mounting An NFS File System Read-Only With No suid Privileges

To mount an NFS file system read-only with no suid privileges:

```
example# mount -r -o nosuid serv:/usr/src /usr/src
```

EXAMPLE 3 Mounting An NFS File System Over Version 2, with the UDP Transport

To mount an NFS file system over Version 2, with the UDP transport:

```
example# mount -o vers=2,proto=udp serv:/usr/src /usr/src
```

EXAMPLE 4 Mounting an NFS File System Using An NFS URL

To mount an NFS file system using an NFS URL (a canonical path):

```
example# mount nfs://serv/usr/man /usr/man
```

EXAMPLE 5 Mounting An NFS File System Forcing Use Of The Public File Handle

To mount an NFS file system and force the use of the public file handle and an NFS URL (a canonical path) that has a non 7-bit ASCII escape sequence:

```
example# mount -o public nfs://serv/usr/%A0abc /mnt/test
```

EXAMPLE 6 Mounting an NFS File System Using a Native Path

To mount an NFS file system using a native path (where the server uses colons (":") as the component separator) and the public file handle:

```
example# mount -o public serv:C:doc:new /usr/doc
```

EXAMPLE 7 Mounting a Replicated Set of NFS File Systems with the Same Pathnames

To mount a replicated set of NFS file systems with the same pathnames:

```
example# mount serv-a,serv-b,serv-c:/usr/man /usr/man
```

EXAMPLE 8 Mounting a Replicated Set of NFS File Systems with Different Pathnames

To mount a replicated set of NFS file systems with different pathnames:

```
example# mount serv-x:/usr/man,serv-y:/var/man,nfs://serv-z/man /usr/man
```

Callaghan, Brent, *WebNFS Client Specification*, RFC 2054, October 1996.

Callaghan, Brent, *NFS URL Scheme*, RFC 2224, October 1997.

Berners-Lee, Masinter & McCahill, *Uniform Resource Locators (URL)*, RFC 1738, December 1994.

NOTES An NFS server should not attempt to mount its own file systems. See lofs(7FS).

If the directory on which a file system is to be mounted is a symbolic link, the file system is mounted on *the directory to which the symbolic link refers*, rather than being mounted on top of the symbolic link itself.

SunOS 4.x used the biod maintenance procedure to perform parallel read-ahead and write-behind on NFS clients. SunOS 5.x made biod obsolete with multi-threaded processing, which transparently performs parallel read-ahead and write-behind.

Since the root (/) file system is mounted read-only by the kernel during the boot process, only the remount option (and options that can be used in conjunction with remount) affect the root (/) entry in the /etc/vfstab file.

mount_pcfs(1M)

NAME	mount_pcfs – mount pcfs file systems				
SYNOPSIS	mount -F pcfs [<i>generic_options</i>] [-o <i>FSType-specific_options</i>] <i>special</i> <i>mount_point</i> mount -F pcfs [<i>generic_options</i>] [-o <i>FSType-specific_options</i>] <i>special mount_point</i>				
DESCRIPTION	mount attaches an MS-DOS file system (pcfs) to the file system hierarchy at the <i>mount_point</i>, which is the pathname of a directory. If <i>mount_point</i> has any contents prior to the mount operation, these are hidden until the file system is unmounted. If mount is invoked with <i>special</i> or <i>mount_point</i> as the only arguments, mount will search /etc/vfstab to fill in the missing arguments, including the <i>FSType-specific_options</i>; see mount(1M) for more details. The <i>special</i> argument can be one of two special device file types: ■ A floppy disk, such as /dev/diskette0 or /dev/diskette1. ■ A DOS logical drive on a hard disk expressed as <i>device-name:logical-drive</i>, where <i>device-name</i> specifies the special block device-file for the whole disk and <i>logical-drive</i> is either a drive letter (c through z) or a drive number (1 through 24). Examples are /dev/dsk/c0t0d0p0:c and /dev/dsk/c0t0d0p0:1. The <i>special</i> device file type must have a formatted MS-DOS file system with either a 12-bit, 16-bit, or 32-bit File Allocation Table.				
OPTIONS	<i>generic_options</i> See mount(1M) for the list of supported options. -o Specify pcfs file system specific options. The following options are available: rw ro Mount the file system read/write or read-only. The default is rw. foldcase nofoldcase Force uppercase characters in filenames to lowercase when reading them from the filesystem. This is for compatibility with the previous behavior of pcfs. The default is nofoldcase.				
FILES	/etc/mnttab table of mounted file systems /etc/vfstab list of default parameters for each file system

mount_pcfs(1M)

NOTES | If the directory on which a file system is to be mounted is a symbolic link, the file system is mounted on the directory to which the symbolic link refers, rather than on top of the symbolic link itself.

mount_tmpfs(1M)

NAME	mount_tmpfs – mount tmpfs file systems		
SYNOPSIS	mount [-F tmpfs] [-o <i>specific_options</i>] [-O] <i>special mount_point</i>		
DESCRIPTION	tmpfs is a memory based file system which uses kernel resources relating to the VM system and page cache as a file system. mount attaches a tmpfs file system to the file system hierarchy at the pathname location <i>mount_point</i>, which must already exist. If <i>mount_point</i> has any contents prior to the mount operation, these remain hidden until the file system is once again unmounted. The attributes (mode, owner, and group) of the root of the tmpfs filesystem are inherited from the underlying <i>mount_point</i>, provided that those attributes are determinable. If not, the root's attributes are set to their default values. The <i>special</i> argument is usually specified as <i>swap</i> but is in fact disregarded and assumed to be the virtual memory resources within the system.		
OPTIONS	-o <i>specific_options</i>	Specify tmpfs file system specific options in a comma-separated list with no intervening spaces. If invalid options are specified, a warning message is printed and the invalid options are ignored. The following options are available:	
	size=sz	The sz argument controls the size of this particular tmpfs file system. If the argument is has a 'k' suffix, the number will be interpreted as a number of kilobytes. An 'm' suffix will be interpreted as a number of megabytes. No suffix is interpreted as bytes. In all cases, the actual size of the file system is the number of bytes specified, rounded up to the physical pagesize of the system.	
	suid nosuid	Allow or disallow setuid execution. The default is suid.	
	xattr noxattr	Allow or disallow the creation and manipulation of extended attributes. The default is xattr. See fsattr(5) for a description of extended attributes.	
	-O	Overlay mount. Allow the file system to be mounted over an existing mount point, making the underlying file system inaccessible. If a mount is attempted on a pre-existing mount point without setting this flag, the mount will fail, producing the error device busy.	
FILES	/etc/mnttab	Table of mounted file systems

DIAGNOSTICS

not super user

The command is run by a non-root user. Run as root.

no such device

The device name specified does not exist.

not a directory

The specified mount point is not a directory.

is not an udfs file system

The device specified does not contain a udf 1.50 file system or the udfs file system module is not available.

is already mounted

The specified device is already in use.

not a block device

The device specified is not a block device. Use block device to mount.

write-protected

The device is read-only.

is corrupted. needs checking

The file system is in an inconsistent state. Run `fsck`.

NOTES

Copy-protected files can be stored on DVD-ROM media using Universal Disk Format (UDF). Reading these copy-protected files is not possible as this involves an authentication process. Unless an authentication process between the host and the drive is completed, reading these copy-protected files after mounting and before the authentication process, returns an error.

mount_ufs(1M)

NAME	mount_ufs – mount ufs file systems
SYNOPSIS	mount -F ufs [<i>generic_options</i>] [-o <i>specific_options</i>] [-O] <i>special</i> <i>mount_point</i> mount -F ufs [<i>generic_options</i>] [-o <i>specific_options</i>] [-O] <i>special mount_point</i>
DESCRIPTION	The mount utility attaches a <i>ufs</i> file system to the file system hierarchy at the <i>mount_point</i>, which is the pathname of a directory. If <i>mount_point</i> has any contents prior to the mount operation, these are hidden until the file system is unmounted. If mount is invoked with <i>special</i> or <i>mount_point</i> as the only arguments, mount will search <i>/etc/vfstab</i> to fill in the missing arguments, including the <i>specific_options</i>. See mount(1M). If <i>special</i> and <i>mount_point</i> are specified without any <i>specific_options</i>, the default is <i>rw</i>. If the directory on which a file system is to be mounted is a symbolic link, the file system is mounted on the directory to which the symbolic link refers, rather than on top of the symbolic link itself.
OPTIONS	See mount(1M) for the list of supported <i>generic_options</i>. The following options are supported: -o <i>specific_options</i> Specify <i>ufs</i> file system specific options in a comma-separated list with no intervening spaces. If invalid options are specified, a warning message is printed and the invalid options are ignored. The following options are available: dfratime nodfratime By default, writing access time updates to the disk may be deferred (<i>dfratime</i>) for the file system until the disk is accessed for a reason other than updating access times. <i>nodfratime</i> disables this behavior. If power management is enabled on the system, do not set <i>nodfratime</i> unless <i>noatime</i> is also set. If you set <i>nodfratime</i> without setting <i>noatime</i>, the disk is spun up every time a file within a file system on the disk is accessed - even if the file is not modified. forcedirectio noforcedirectio If <i>forcedirectio</i> is specified and supported by the file system, then for the duration of the mount, forced direct I/O will be used. If the filesystem is mounted using <i>forcedirectio</i>, data is transferred directly between user address space and the disk. If the filesystem is mounted using <i>noforcedirectio</i>, data is buffered in kernel address space when data is transferred between user address space and the disk. <i>forcedirectio</i> is a performance option that is of benefit only in large sequential data transfers. The default behavior is <i>noforcedirectio</i>. global noglobal If <i>global</i> is specified and supported on the file system, and the system in question is part of a cluster, the file system will be globally visible on all nodes of

mount_ufs(1M)

the cluster. If `noglobal` is specified, the mount will not be globally visible. The default behavior is `noglobal`. The `global` option is mutually exclusive of the `nbmand` option, described below.

`intr | nointr`

Allow (do not allow) keyboard interrupts to kill a process that is waiting for an operation on a locked file system. The default is `intr`.

`largefiles | nolargefiles`

If `nolargefiles` is specified and supported by the file system, then for the duration of the mount it is guaranteed that all regular files in the file system have a size that will fit in the smallest object of type `off_t` supported by the system performing the mount. The mount will fail if there are any files in the file system not meeting this criterion. If `largefiles` is specified, there is no such guarantee. The default behavior is `largefiles`.

If `nolargefiles` is specified, mount will fail for `ufs` if the file system to be mounted has contained a large file (a file whose size is greater than or equal to 2 Gbyte) since the last invocation of `fsck` on the file system. The large file need not be present in the file system at the time of the mount for the mount to fail; it could have been created previously and destroyed. Invoking `fsck` (see `fsck_ufs(1M)`) on the file system will reset the file system state if no large files are present. After invoking `fsck`, a successful mount of the file system with `nolargefiles` specified indicates the absence of large files in the file system; an unsuccessful mount attempt indicates the presence of at least one large file.

`logging | nologging`

If `logging` is specified, then logging is enabled for the duration of the mounted file system. Logging is the process of storing transactions (changes that make up a complete UFS operation) in a log before the transactions are applied to the file system. Once a transaction is stored, the transaction can be applied to the file system later. This prevents file systems from becoming inconsistent, therefore eliminating the need to run `fsck`. And, because `fsck` can be bypassed, logging reduces the time required to reboot a system if it crashes, or after an unclean halt.

The default behavior is `logging` for all UFS file systems.

The log is allocated from free blocks in the file system, and is sized approximately 1 Mbyte per 1 Gbyte of file system, up to a maximum of 64 Mbytes.

Logging is enabled on any UFS file system, including root (/), except under the following conditions:

- When logging is specifically disabled.
- If there is insufficient file system space for the log. In this case, the following message is displayed and file system is still mounted:

```
# mount /dev/dsk/c0t4d0s0 /mnt
/mnt: No space left on device
```

mount_ufs(1M)

Could not enable logging for /mnt on /dev/dsk/c0t4d0s0.

The log created by UFS logging is continually flushed as it fills up. The log is totally flushed when the file system is unmounted or as a result of the `lockfs -f` command.

m

Mount the file system without making an entry in `/etc/mnttab`.

nbmand | nonbmand

This option specifies that non-blocking mandatory locking semantics should be allowed on this file system. Non-blocking mandatory locking is disallowed by default. If the file system is mounted with the `nbmand` option, then applications can use the `fcntl(2)` interface to place non-blocking mandatory locks on files and the system will enforce those semantics. Enabling this option can cause standards conformant applications to see unexpected errors.

Do not use the `nbmand` option with `/`, `/var` and `/usr`.

The `remount` option should not be used to change the `nbmand` disposition of the file system. The `nbmand` option is mutually exclusive of the `global` option, described above.

noatime

By default, the file system is mounted with normal access time (`atime`) recording. If `noatime` is specified, the file system will ignore access time updates on files, except when they coincide with updates to the `ctime` or `mtime`. See `stat(2)`. This option reduces disk activity on file systems where access times are unimportant (for example, a Usenet news spool).

`noatime` turns off access time recording regardless of `dfratime` or `nodfratime`.

The POSIX standard requires that access times be marked on files. `-noatime` ignores them unless the file is also modified.

onerror = *action*

This option specifies the action that UFS should take to recover from an internal inconsistency on a file system. Specify *action* as `panic`, `lock`, or `umount`. These values cause a forced system shutdown, a file system lock to be applied to the file system, or the file system to be forcibly unmounted, respectively. The default is `panic`.

quota

Quotas are turned on for the file system.

remount

Remounts a file system with a new set of options. All options not explicitly set with `remount` revert to their default values.

rq

Read-write with quotas turned on. Equivalent to `rw`, `quota`.

ro | rw

Read-only or read-write. Default is rw.

suid | nosuid

Allow or disallow `setuid/setgid` execution. The default is `suid`. This option also allows/disallows opening any device-special entries that appear within the filesystem.

This option is highly recommended whenever the file system is shared via NFS with the `root=` option, because, without it, NFS clients could add `setuid` programs to the server, or create devices that could open security holes.

-O

Overlay mount. Allow the file system to be mounted over an existing mount point, making the underlying file system inaccessible. If a mount is attempted on a pre-existing mount point without setting this flag, the mount will fail, producing the error "device busy".

The `mount_ufs` command supports the `xattr` flag, to allow the creation and manipulation of extended attributes. See `fsattr(5)` for a description of extended attributes. The `xattr` flag is always on.

USAGE When a UFS file system is mounted with logging enabled, file system transactions that free blocks from files might not actually add those freed blocks to the file system's free list until some unspecified time in the future. This behavior improves file system performance but does not conform to the POSIX, Single UNIX Specification, SPARC Conformance Definition, System V Application Binary Interface, System V Interface Definition, and X/Open Portability Guide Standards, which require that freed space be available immediately. To enable standards conformance regarding file deletions or to address the problem of not being able to grow files on a relatively full UFS file system even after files have been deleted, disable UFS logging.

FILES `/etc/mnttab` table of mounted file systems
`/etc/vfstab` list of default parameters for each file system

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

SEE ALSO `fsck(1M)`, `fsck_ufs(1M)`, `mount(1M)`, `mountall(1M)`, `fcntl(2)`, `mount(2)`, `stat(2)`, `mnttab(4)`, `vfstab(4)`, `attributes(5)`, `fsattr(5)`, `largefile(5)`

NOTES Since the root (/) file system is mounted read-only by the kernel during the boot process, only the `remount` option (and options that can be used in conjunction with `remount`) affect the root (/) entry in the `/etc/vfstab` file.

mount_ufs(1M)

File system transactions that free blocks from files might not immediately add the freed blocks to the file system's free list. This behavior occurs in a system that has a UFS file system mounted with logging enabled.

This behavior improves file system performance, but does not conform to the following standards:

- POSIX, Single UNIX Specification
- SPARC Conformance Definition
- System V Application Binary Interface
- System V Interface Definition
- X/Open Portability Guide

These standards require that freed space be available immediately.

Consider disabling UFS logging under the following conditions:

- You want to enable standards conformance regarding file deletions.
- You encounter problems creating or growing files immediately after files have been deleted on a relatively full file system.

NAME	mount_xmemfs – mount xmemfs file systems		
SYNOPSIS	mount -F xmemfs [<i>generic_options</i>] -o[<i>largebsize</i> ,] <i>size=sz</i> [-O] <i>special mount_point</i>		
DESCRIPTION	xmemfs is an extended memory file system which provides file system semantics to manage and access large amounts of physical memory which can exceed 4 GB in size. mount attaches a xmemfs file system to the file system hierarchy at the pathname location <i>mount_point</i>, which must already exist. If <i>mount_point</i> has any contents prior to the mount operation, these remain hidden until the file system is once again unmounted. The attributes (mode, owner, and group) of the root of the xmemfs filesystem are inherited from the underlying <i>mount_point</i>, provided that those attributes are determinable. If not, the root's attributes are set to their default values. The special argument is not currently used by xmemfs but a placeholder, (such as <i>xmem</i>), needs to be specified nevertheless.		
OPTIONS	See mount(1M) for the list of supported <i>generic_options</i> .		
	-o <i>specific_options</i>	Specify xmemfs file system specific options in a comma-separated list with <i>no intervening spaces</i> . If invalid options are specified, a warning message is printed and the invalid options are ignored.	
		The <i>size=sz specific option</i> is required.	
		The following options are available:	
	size=sz	The <i>sz</i> argument specifies the desired size of this particular xmemfs file system. If the <i>sz</i> argument has a <i>k</i> suffix, the number is interpreted as kilobytes. An <i>m</i> suffix is interpreted as megabytes and <i>g</i> is interpreted as gigabytes. A <i>sz</i> specified with no suffix is interpreted as bytes.	
		In all cases, the actual size of the file system is the number of bytes specified, rounded up to the physical <i>pagesize</i> of the system or to the large page size if <i>largebsize</i> is specified.	
		This <i>specific_option</i> is required.	
	largebsize	If <i>largebsize</i> is specified, xmemfs uses the large memory page size as the file system block	

mount_xmemfs(1M)

size. On IA32, the large memory page size with mmu36 which supports PAE (Physical Address Extension) is 2 MB. The large memory page size without mmu36/PAE is 4 MB. If there is no large page support, the file system block size is `PAGESIZE`.

`-O` Overlay mount. Allow the file system to be mounted over an existing mount point, making the underlying file system inaccessible. If a mount is attempted on a pre-existing mount point without setting this flag, the mount fails, producing the error device busy.

FILES `/etc/mnttab` table of mounted file systems

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu
Architecture	i386
Interface Stability	Evolving

SEE ALSO `mount(1M)`, `mount(2)`, `mkdir(2)`, `open(2)`, `umount(2)`, `mnttab(4)`, `attributes(5)`, `xmemfs(7FS)`

NOTES If the directory on which a file system is to be mounted is a symbolic link, the file system is mounted on the directory to which the symbolic link refers, rather than on top of the symbolic link itself.

The only file types allowed on `xmemfs` are directories and regular files. The execution of object files resident in `xmemfs` is not supported. Execution is prevented by not allowing users to set execute permissions on regular files.

NAME	mpstat – report per-processor or per-processor-set statistics																																				
SYNOPSIS	<code>/usr/bin/mpstat [-a] [-p -P set] [interval [count]]</code>																																				
DESCRIPTION	mpstat reports processor statistics in tabular form. Each row of the table represents the activity of one processor. The first table summarizes all activity since boot; each subsequent table summarizes activity for the preceding interval. All values are rates (events per second) unless otherwise noted. During execution of this kernel status command, the "state" of the kernel can change. An example would be CPUs going online or offline. mpstat reports this as State change. mpstat reports the following information: <table> <tr> <td>CPU or SET</td><td>Without the -a option, mpstat reports CPU, the processor ID. With the -a option, mpstat reports SET, the processor set ID.</td></tr> <tr> <td>minf</td><td>minor faults</td></tr> <tr> <td>mjf</td><td>major faults</td></tr> <tr> <td>xcal</td><td>inter-processor cross-calls</td></tr> <tr> <td>intr</td><td>interrupts</td></tr> <tr> <td>ithr</td><td>interrupts as threads (not counting clock interrupt)</td></tr> <tr> <td>csw</td><td>context switches</td></tr> <tr> <td>icsw</td><td>involuntary context switches</td></tr> <tr> <td>migr</td><td>thread migrations (to another processor)</td></tr> <tr> <td>smtx</td><td>spins on mutexes (lock not acquired on first try)</td></tr> <tr> <td>srw</td><td>spins on readers/writer locks (lock not acquired on first try)</td></tr> <tr> <td>syscl</td><td>system calls</td></tr> <tr> <td>usr</td><td>percent user time</td></tr> <tr> <td>sys</td><td>percent system time</td></tr> <tr> <td>wt</td><td>percent wait time</td></tr> <tr> <td>idl</td><td>percent idle time</td></tr> </table> With the -a option, mpstat also reports: <table> <tr> <td>size</td><td>number of processors in the set</td></tr> </table> With the -p option, mpstat also reports: <table> <tr> <td>set</td><td>processor set membership of the CPU</td></tr> </table>	CPU or SET	Without the -a option, mpstat reports CPU, the processor ID. NOTES The sum of CPU utilization might vary slightly from 100 because of rounding errors in the production of a percentage figure.

NAME	msgid – generate message IDs				
SYNOPSIS	<code>/usr/sbin/msgid</code>				
DESCRIPTION	The <code>msgid</code> utility generates message IDs. A message ID is a numeric identifier that, with a high probability, uniquely identifies a message. The probability of two distinct messages having the same ID is about one in a million. Specifically, the message ID is a hash signature on the message's unexpanded format string, generated by <code>STRLOG_MAKE_MSGID()</code> as defined in <code><sys/strlog.h></code>. <code>syslogd(1M)</code> is a simple filter that takes strings as input and produces those same strings, preceded by their message IDs, as output. Every message logged by <code>syslogd(1M)</code> includes the message ID. The message ID is intended to serve as a small, language-independent identifier.				
EXAMPLES	EXAMPLE 1 Using the <code>msgid</code> command to generate a message ID The following example uses the <code>msgid</code> command to generate a message ID for the <code>echo</code> command. <pre>example# echo hello msgid205790 hello</pre> EXAMPLE 2 Using the <code>msgid</code> command to generate a message catalog The following example uses the <code>msgid</code> command to enumerate all of the messages in the binary <code>ufs</code>, to generate a message catalog. <pre>example# strings /kernel/fs/ufs msgid137713 free: freeing free frag, dev:0x%lx, blk:%ld, cg:%d, ino:%lu, fs:%s 567420 iallocg: block not in mapfs = %s 845546 alloc: %s: file system full ...</pre>				
ATTRIBUTES	See <code>attributes(5)</code> for descriptions of the following attributes: <table border="1"> <thead> <tr> <th>ATTRIBUTE TYPE</th><th>ATTRIBUTE VALUE</th></tr> </thead> <tbody> <tr> <td>Availability</td><td>SUNWcsu</td></tr> </tbody> </table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	Availability	SUNWcsu

mmdir(1M)

NAME	mvdір – move a directory					
SYNOPSIS	/usr/sbin/mvdір <i>dirname name</i>					
DESCRIPTION	mvdір moves directories within a file system. <i>dirname</i> must be a directory. If <i>name</i> does not exist, it will be created as a directory. If <i>name</i> does exist, and is a directory, <i>dirname</i> will be created as <i>name/dirname</i>. <i>dirname</i> and <i>name</i> may not be on the same path; that is, one may not be subordinate to the other. For example: <pre>example% mvdір x/y x/z</pre> is legal, but <pre>example% mvdір x/y x/y/z</pre> is not.					
OPERANDS	<i>dirname</i>	The name of the directory that is to be moved to another directory in the filesystem.				
	<i>name</i>	The name of the directory into which <i>dirname</i> is to be moved. If <i>name</i> does not exist, it will be created. It may not be on the same path as <i>dirname</i> .				
USAGE	See largefile(5) for the description of the behavior of <code>mvdір</code> when encountering files greater than or equal to 2 Gbyte (2 ³¹ bytes).					
EXIT STATUS	0	Successful operation.				
	>0	Operation failed.

named-xfer(1M)

NAME	named-xfer – ancillary agent for inbound zone transfers				
SYNOPSIS	named-xfer -z <i>zone_to_transfer</i> -f <i>db_file</i> -s <i>serial_no</i> [-d <i>debuglevel</i>] [-l <i>debug_log_file</i>] [-t <i>trace_file</i>] [-p <i>port#</i>] [-S] <i>nameserver...</i>				
DESCRIPTION	The named-xfer program is an ancillary program executed by <code>in.named</code> to perform an inbound zone transfer. It is rarely executed directly, and only by system administrators who are trying to debug a zone transfer problem. See RFC's 1033, 1034, and 1035 for more information on the Internet name-domain system.				
OPTIONS	-z Specifies the name of the zone to be transferred. -f Specifies the name of the file into which the zone should be dumped when it is received from the primary server. -s Specifies the serial number of the current copy of this zone. If the SOA RR from the primary server does not have a serial number higher than this, the transfer will be aborted. -d Print debugging information. A number after the "d" determines the level of messages printed. -l Specifies a log file for debugging messages. The default is system-dependent but is usually in <i>/var/tmp</i> or <i>/usr/tmp</i>. Note that this only applies if -d is also specified. -t Specifies a trace file which will contain a protocol trace of the zone transfer. This is probably only of interest to those debugging the name server itself. -p Use a different port number. The default is the standard port number as returned by <code>getservbyname(3SOCKET)</code> for service "domain". -S Perform a restricted transfer of only the SOA, NS records and glue A records for the zone. The SOA record will not be loaded by named but will be used to determine when to verify the NS records. See the "stubs" directive in <code>in.named(1M)</code> for more information. Additional arguments are taken as name server addresses in so-called "dotted-quad" syntax only; no host names are allowed. At least one address must be specified. If the first one fails to transfer successfully, the additional addresses will be tried in the order given.				
ATTRIBUTES	See <code>attributes(5)</code> for descriptions of the following attributes: <table border="1" data-bbox="444 1520 1417 1606"><thead><tr><th>ATTRIBUTE TYPE</th><th>ATTRIBUTE VALUE</th></tr></thead><tbody><tr><td>Availability</td><td>SUNWinamd</td></tr></tbody></table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	Availability	SUNWinamd

ncaconfd(1M)

NAME	ncaconfd – Solaris Network Cache and Accelerator (NCA) configuration daemon				
SYNOPSIS	/usr/lib/inet/ncaconfd				
DESCRIPTION	Use the <code>ncaconfd</code> utility to set up NCA on a system. At boot time, the <code>ncakmod</code> initialization script reads in <code>nca.if(4)</code> to determine on which interface(s) NCA should run. <code>ncaconfd</code> then sets up the interface. <code>ncaconfd</code> also operates as a daemon if the <code>nca_active</code> key is set to enabled in <code>ncakmod.conf(4)</code> file. In this case, <code>ncaconfd</code> will continue as a daemon after all the NCA interfaces have been set up, listening for routing changes. The changes are then passed to NCA to control which interface NCA should use to make active outgoing TCP connections.				
FILES	<code>/etc/nca/ncakmod.conf</code>				
ATTRIBUTES	See <code>attributes(5)</code> for descriptions of the following attributes:

NAME	ncheck – generate a list of path names versus i-numbers	
SYNOPSIS	ncheck [-F <i>FSType</i>] [-V] [<i>generic_options</i>] [-o <i>FSType-specific_options</i>] [<i>special...</i>]	
DESCRIPTION	ncheck with no options generates a path-name versus i-number list of all files on <i>special</i> . If <i>special</i> is not specified on the command line the list is generated for all <i>specials</i> in /etc/vfstab which have a numeric fsckpass. <i>special</i> is the raw device on which the file system exists.	
OPTIONS	-F Specify the <i>FSType</i> on which to operate. The <i>FSType</i> should either be specified here or be determinable from /etc/vfstab by finding an entry in the table that has a numeric fsckpass field and an fsckdev that matches <i>special</i>. -V Echo the complete command line, but do not execute the command. The command line is generated by using the options and arguments provided by the user and adding to them information derived from /etc/vfstab. This option may be used to verify and validate the command line. <i>generic_options</i> Options that are commonly supported by most <i>FSType</i>-specific command modules. The following options are available: -i <i>i-list</i> Limit the report to the files on the <i>i-list</i> that follows. The <i>i-list</i> must be separated by commas with no intervening spaces. -a Print the names “.” and “. .” which are ordinarily suppressed. -s Report only special files and files with set-user-ID mode. This option may be used to detect violations of security policy. -o Specify <i>FSType-specific_options</i> in a comma separated (without spaces) list of suboptions and keyword-attribute pairs for interpretation by the <i>FSType</i>-specific module of the command.	
USAGE	See largefile(5) for the description of the behavior of ncheck when encountering files greater than or equal to 2 Gbyte (2 ³¹ bytes).	
FILES	/etc/vfstab	list of default parameters for each file system

ncheck(1M)

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

Availability	SUNWcsu

SEE ALSO `vfstab(4)`, `attributes(5)`, `largefile(5)` Manual pages for the FSType-specific modules of `ncheck`

NOTES This command may not be supported for all *FSTypes*.

- NAME** ncheck_ufs – generate pathnames versus i-numbers for ufs file systems
- SYNOPSIS** **ncheck** -F ufs [*generic_options*] [-o m] [*special...*]
- DESCRIPTION** ncheck -F ufs generates a pathname versus i-number list of files for the ufs file system residing on *special*. Names of directory files are followed by '/.'.
- OPTIONS** See ncheck(1M) for the list of *generic_options* supported.
- o Specify ufs file system specific options. The available option is:
- m Print mode information.
- ATTRIBUTES** See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

- SEE ALSO** ff(1M), ncheck(1M), attributes(5)
- DIAGNOSTICS** When the file system structure is improper, '??' denotes the "parent" of a parentless file and a pathname beginning with './..' denotes a loop.

ndc(1M)

NAME	ndc – name daemon control program
SYNOPSIS	ndc [-c <i>channel</i>] [-l <i>localsock</i>] [-p <i>pidfile</i>] [-d] [-q] [-s] [-t] [<i>command</i>]
DESCRIPTION	System administrators use the <i>ndc</i> utility to control the operation of a name server. If the system administrator fails to list a command, <i>ndc</i> will prompt for one until it reads EOF.
OPTIONS	The <i>ndc</i> command supports the following options: -c <i>channel</i> Specify the rendezvous point for the control channel. The default value for <i>channel</i> is <i>/var/run/ndc</i>, a UNIX domain socket that is also the server's default control channel. If the desired control channel is a TCP/IP socket, then the format for the <i>channel</i> argument is <i>ipaddr/port</i>. For example, a value of <i>127.0.0.1/54</i> would be TCP port 54 on the local host. -d Turn on debugging mode. This option is mainly of interest to developers. -l <i>localsock</i> Bind the client side of the control channel to a specific address. Servers can be configured to reject connections that do not come from specific addresses. If the desired control channel is a TCP/IP socket, then the format for the <i>localsock</i> argument is <i>ipaddr/port</i>. -p <i>pidfile</i> Use for backwards compatibility with older name servers. It enables <i>ndc</i> to use UNIX signals for control communications. Optional with modern name servers, this capability may not be supported in future releases. The command set that is available is narrower when the signal interface is used. A likely value for the <i>pidfile</i> argument is <i>/var/run/named.pid</i>. -q Suppress prompt and result text. -s Suppress non-fatal error announcements. -t Turn on protocol and system tracing. Use this option in installation debugging.
COMMANDS	The following commands are built into the <i>ndc</i> utility. The full set of commands that the name server supports is dynamic. Use the <i>help</i> command for information on the available commands . /help Show help information for built in commands. /exit Exit from <i>ndc</i> command interpreter. /trace Toggle protocol and system tracing on and off. See -t. /debug Toggle debugging mode on and off. See -d. /quiet Toggle prompt and result information on and off. See -q.

ndc(1M)

/silent

Toggle announcement of non-fatal errors on and off.
See -s.

ATTRIBUTES See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu
Interface Stability	Standard, BIND 8.2.4

SEE ALSO in.named(1M), execvp(2), attributes(5)

NOTES When the ndc utility is running in *pidfile* mode, pass any arguments to start and restart commands to the new name server on the command line. If the ndc utility is running in *channel* mode, there is no start command, and the restart command just tells the name server to execvp(2) itself.

ndd(1M)

NAME	ndd – get and set driver configuration parameters				
SYNOPSIS	ndd [-set] <i>driver parameter</i> [<i>value</i>]				
DESCRIPTION	ndd gets and sets selected configuration parameters in some kernel drivers. Currently, ndd only supports the drivers that implement the TCP/IP Internet protocol family. Each driver chooses which parameters to make visible using ndd. Since these parameters are usually tightly coupled to the implementation, they are likely to change from release to release. Some parameters may be read-only. If the -set option is omitted, ndd queries the named <i>driver</i>, retrieves the value associated with the specified <i>parameter</i>, and prints it. If the -set option is given, ndd passes <i>value</i>, which must be specified, down to the named <i>driver</i> which assigns it to the named <i>parameter</i>. By convention, drivers that support ndd also support a special read-only <i>parameter</i> named “?” which can be used to list the parameters supported by the driver.				
EXAMPLES	EXAMPLE 1 Getting Parameters Supported By The TCP Driver To see which parameters are supported by the TCP driver, use the following command: <pre>example% ndd /dev/tcp \?</pre> The parameter name “?” may need to be escaped with a backslash to prevent its being interpreted as a shell meta character. The following command sets the value of the parameter <i>ip_forwarding</i> in the dual stack IP driver to zero. This disables IPv4 packet forwarding. <pre>example% ndd -set /dev/ip ip_forwarding 0</pre> Similarly, in order to disable IPv6 packet forwarding, the value of parameter <i>ip6_forwarding</i> <pre>example% ndd -set /dev/ip ip6_forwarding 0</pre> To view the current IPv4 forwarding table, use the following command: <pre>example% ndd /dev/ip ipv4_ire_status</pre> To view the current IPv6 forwarding table, use the following command: <pre>example% ndd /dev/ip ipv6_ire_status</pre>				
ATTRIBUTES	See attributes(5) for descriptions of the following attributes: <table border="1"> <thead> <tr> <th>ATTRIBUTE TYPE</th><th>ATTRIBUTE VALUE</th></tr> </thead> <tbody> <tr> <td>Availability</td><td>SUNWcsu</td></tr> </tbody> </table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	Availability	SUNWcsu
ATTRIBUTE TYPE	ATTRIBUTE VALUE				
Availability	SUNWcsu				

SEE ALSO nca(1), ioctl(2), attributes(5), arp(7P), ip(7P), ip6(7P), tcp(7P), udp(7P)

NOTES The parameters supported by each driver may change from release to release. Like programs that read /dev/kmem, user programs or shell scripts that execute ndd should be prepared for parameter names to change.

The `ioctl()` command that ndd uses to communicate with drivers is likely to change in a future release. User programs should avoid making dependencies on it.

The meanings of many ndd parameters make sense only if you understand how the driver is implemented.

netstat(1M)

NAME	netstat – show network status				
SYNOPSIS	<pre> netstat [-anv] [-f <i>address_family</i>] [-P <i>protocol</i>] netstat -g [-n] [-f <i>address_family</i>] netstat -p [-n] [-f <i>address_family</i>] netstat -s [-f <i>address_family</i>] [-P <i>protocol</i>] netstat -m [-v] netstat -i [-I <i>interface</i>] [-an] [-f <i>address_family</i>] [<i>interval</i> [<i>count</i>]] netstat -r [-anv] [-f <i>address_family</i> <i>filter</i>] netstat -M [-ns] [-f <i>address_family</i>] netstat -D [-I <i>interface</i>] [-f <i>address_family</i>] </pre>				
DESCRIPTION	The netstat command displays the contents of certain network-related data structures in various formats, depending on the options you select. The netstat command has the several forms shown in the SYNOPSIS section, above, listed as follows: ■ The first form of the command (with no required arguments) displays a list of active sockets for each protocol. ■ The second, third, and fourth forms (-g, -p, and -s options) display information from various network data structures. ■ The fifth form (-m option) displays STREAMS memory statistics. ■ The sixth form (-i option) shows the state of the interfaces. ■ The seventh form (-r option) displays the routing table. ■ The eighth form (-M option) displays the multicast routing table. ■ The ninth form (-D option) displays the state of DHCP on one or all interfaces. These forms are described in greater detail below. With no arguments (the first form), netstat displays connected sockets for PF_INET, PF_INET6, and PF_UNIX, unless modified otherwise by the -f option.				
OPTIONS	<table> <tr> <td>-a</td><td>Show the state of all sockets, all routing table entries, or all interfaces, both physical and logical. Normally, listener sockets used by server processes are not shown. Under most conditions, only interface, host, network, and default routes are shown and only the status of physical interfaces is shown.</td></tr> <tr> <td>-f <i>address_family</i></td><td>Limit all displays to those of the specified <i>address_family</i>. The value of <i>address_family</i> can be one of the following:</td></tr> </table>	-a	Show the state of all sockets, all routing table entries, or all interfaces, both physical and logical. Normally, listener sockets used by server processes are not shown. Under most conditions, only interface, host, network, and default routes are shown and only the status of physical interfaces is shown.	-f <i>address_family</i>	Limit all displays to those of the specified <i>address_family</i> . The value of <i>address_family</i> can be one of the following:
-a	Show the state of all sockets, all routing table entries, or all interfaces, both physical and logical. Normally, listener sockets used by server processes are not shown. Under most conditions, only interface, host, network, and default routes are shown and only the status of physical interfaces is shown.				
-f <i>address_family</i>	Limit all displays to those of the specified <i>address_family</i> . The value of <i>address_family</i> can be one of the following:				

netstat(1M)

-f *filter*

inet For the AF_INET address family showing IPv4 information.

inet6 For the AF_INET6 address family showing IPv6 information.

unix For the AF_UNIX address family.

With -r only, limit the display of routes to those matching the specified filter. A filter rule consists of a "keyword:value" pair. The known keywords and the value syntax are:

af:{inet|inet6|unix|*number*}

Selects an address family. This is identical to -f *address_family* and both syntaxes are supported.

{inif|outif}:{*name*|*ifIndex*|any|none}

Selects an input or output interface. You can specify the interface by name (such as hme0) or by *ifIndex* number (for example, 2). If any is used, the filter matches all routes having a specified interface (anything other than null). If none is used, the filter matches all routes having a null interface. Note that you can view the index number (*ifIndex*) for an interface with the -a option of ifconfig(1M).

{src|dst}:{*ip-address*[/*mask*]|any|none}

Selects a source or destination IP address. If specified with a mask length, then any routes with matching or longer (more specific) masks are selected. If any is used, then all but addresses but 0 are selected. If none is used, then address 0 is selected.

flags:[+ -]?[ABDGHLMUSU]+

Selects routes tagged with the specified flags. By default, the flags as specified must be set in order to match. With a leading +, the flags specified must be set but others are ignored. With a leading -, the flags specified must not be set and others are permitted.

You can specify multiple instances of -f to specify multiple filters. For example:

```
% netstat -nr -f outif:hme0 -f outif:hme1 -f dst:10.0.0.0/8
```

The preceding command displays routes within network 10.0.0.0/8, with mask length 8 or greater, and an output interface of either hme0 or hme1, and excludes all other routes.

netstat(1M)

	-g	Show the multicast group memberships for all interfaces. See DISPLAYS, below.
	-i	Show the state of the interfaces that are used for IP traffic. Normally this shows statistics for the physical interfaces. When combined with the -a option, this will also report information for the logical interfaces. See ifconfig(1M).
	-m	Show the STREAMS memory statistics.
	-n	Show network addresses as numbers. netstat normally displays addresses as symbols. This option may be used with any of the display formats.
	-p	Show the net to media tables. See DISPLAYS, below.
	-r	Show the routing tables. Normally, only interface, host, network, and default routes are shown, but when this option is combined with the -a option, all routes will be displayed, including cache.
	-s	Show per-protocol statistics. When used with the -M option, show multicast routing statistics instead. When used with the -a option, per-interface statistics will be displayed, when available, in addition to statistics global to the system. See DISPLAYS, below.
	-v	Verbose. Show additional information for the sockets, STREAMS memory statistics, and the routing table.
	-I <i>interface</i>	Show the state of a particular interface. <i>interface</i> can be any valid interface such as hme0 or le0. Normally, the status and statistics for physical interfaces are displayed. When this option is combined with the -a option, information for the logical interfaces is also reported.
	-M	Show the multicast routing tables. When used with the -s option, show multicast routing statistics instead.
	-P <i>protocol</i>	Limit display of statistics or state of all sockets to those applicable to <i>protocol</i> . The protocol can be one of ip, ipv6, icmp, icmpv6, igmp, udp, tcp, rawip. rawip can also be specified as raw. The command accepts protocol options only as all lowercase.
	-D	Show the status of DHCP configured interfaces.
OPERANDS	<i>interval</i>	Display interface statistics accumulated since last display every <i>interval</i> seconds, repeating forever, unless <i>count</i> is specified. When invoked with <i>interval</i> , the first row of netstat output shows statistics accumulated since last reboot.

	<i>count</i>	Display interface statistics the number of times specified by <i>count</i> , at the interval specified by <i>interval</i> .
DISPLAYS		
Active Sockets (First Form)	The display for each active socket shows the local and remote address, the send and receive queue sizes (in bytes), the send and receive windows (in bytes), and the internal state of the protocol.	
	The symbolic format normally used to display socket addresses is either <i>hostname.port</i> when the name of the host is specified, or <i>network.port</i> if a socket address specifies a network but no specific host.	
	The numeric host address or network number associated with the socket is used to look up the corresponding symbolic hostname or network name in the <i>hosts</i> or <i>networks</i> database.	
	If the network or hostname for an address is not known, or if the -n option is specified, the numerical network address is shown. Unspecified, or "wildcard", addresses and ports appear as "*". For more information regarding the Internet naming conventions, refer to <i>inet(7P)</i> and <i>inet6(7P)</i> .	
	TCP Sockets	The possible state values for TCP sockets are as follows:
	BOUND	Bound, ready to connect or listen.
	CLOSED	Closed. The socket is not being used.
	CLOSING	Closed, then remote shutdown; awaiting acknowledgment.
	CLOSE_WAIT	Remote shutdown; waiting for the socket to close.
	ESTABLISHED	Connection has been established.
	FIN_WAIT_1	Socket closed; shutting down connection.
	FIN_WAIT_2	Socket closed; waiting for shutdown from remote.
	IDLE	Idle, opened but not bound.
	LAST_ACK	Remote shutdown, then closed; awaiting acknowledgment.
	LISTEN	Listening for incoming connections.
	SYN_RECEIVED	Initial synchronization of the connection under way.
	SYN_SENT	Actively trying to establish connection.
	TIME_WAIT	Wait after close for remote shutdown retransmission.
Network Data Structures (Second Through Fifth Forms)	The form of the display depends upon which of the -g, -m, -p, or -s options you select.	

netstat(1M)

- g Displays the list of multicast group membership.
- m Displays the memory usage, for example, STREAMS mblks.
- p Displays the net to media mapping table. For IPv4, the address resolution table is displayed. See arp(1M). For IPv6, the neighbor cache is displayed.
- s Displays the statistics for the various protocol layers.

The statistics use the MIB specified variables. The defined values for ipForwarding are:

- forwarding (1) Acting as a gateway.
- not-forwarding (2) Not acting as a gateway.

The IPv6 and ICMPv6 protocol layers maintain per-interface statistics. If the -a option is specified with the -s option, then the per-interface statistics as well as the total sums are displayed. Otherwise, just the sum of the statistics are shown.

For the second, third, and fourth forms of the command, you must specify at least -g, -p, or -s. You can specify any combination of these options. You can also specify -m (the fifth form) with any set of the -g, -p, and -s options. If you specify more than one of these options, netstat displays the information for each one of them.

Interface Status (Sixth Form)

The interface status display lists information for all current interfaces, one interface per line. If an interface is specified using the -I option, it displays information for only the specified interface.

The list consists of the interface name, mtu (maximum transmission unit, or maximum packet size)(see ifconfig(1M)), the network to which the interface is attached, addresses for each interface, and counter associated with the interface. The counters show the number of input packets, input errors, output packets, output errors, and collisions, respectively. For Point-to-Point interfaces, the Net/Dest field is the name or address on the other side of the link.

If the -a option is specified with either the -i option or the -I option, then the output includes names of the physical interface(s), counts for input packets and output packets for each logical interface, plus additional information.

If the -n option is specified, the list displays the IP address instead of the interface name.

If an optional *interval* is specified, the output will be continually displayed in *interval* seconds until interrupted by the user or until *count* is reached. See OPERANDS.

The physical interface is specified using the -I option. When used with the *interval* operand, output for the -I option has the following format:

input	le0	output	input	(Total)	output
packets	errs	packets errs	packets	packets	errs
227681	0	659471 1	502	261331	0
				99597	1
					502

	netstat(1M)									
	10	0	0	0	0	10	0	0	0	0
	8	0	0	0	0	8	0	0	0	0
	10	0	2	0	0	10	0	2	0	0
Routing Table (Seventh Form)	If the input interface is not specified, the first interface of address family <code>inet</code> or <code>inet6</code> will be displayed.									
	The routing table display lists the available routes and the status of each. Each route consists of a destination host or network, and a gateway to use in forwarding packets. The <i>flags</i> column shows the status of the route (U if "up"), whether the route is to a gateway (G), whether it is a redundant route established with the <code>-multirt</code> option (M), whether the route was established using the <code>-setsrc</code> option (S), and whether the route was created dynamically by a redirect (D). If the <code>-a</code> option is specified, there will be routing entries with flags for combined routing and address resolution entries (A), broadcast addresses (B), and the local addresses for the host (L).									
	Interface routes are created for each interface attached to the local host; the gateway field for such entries shows the address of the outgoing interface.									
	The <code>use</code> column displays the number of packets sent using a combined routing and address resolution (A) or a broadcast (B) route. For a local (L) route, this count is the number of packets received, and for all other routes it is the number of times the routing entry has been used to create a new combined route and address resolution entry.									
	The <i>interface</i> entry indicates the network interface utilized for the route.									
Multicast Routing Tables (Eighth Form)	The multicast routing table consists of the virtual interface table and the actual routing table.									
DHCP Interface Information (Ninth Form)	The DHCP interface information consists of the interface name, its current state, lease information, packet counts, and a list of flags.									
	The states correlate with the specifications set forth in <i>RFC 2131</i> .									
	Lease information includes:									
	■ when the lease began; ■ when lease renewal will begin; and ■ when the lease will expire.									
	The flags currently defined include:									
	BOOTP					The interface has a lease obtained through BOOTP.				
	BUSY					The interface is busy with a DHCP transaction.				
	PRIMARY					The interface is the primary interface. See <code>dhcpinfo(1)</code> .				

netstat(1M)

FAILED The interface is in failure state and must be manually restarted.

Packet counts are maintained for the number of packets sent, the number of packets received, and the number of lease offers declined by the DHCP client. All three counters are initialized to zero and then incremented while obtaining a lease. The counters are reset when the period of lease renewal begins for the interface. Thus, the counters represent either the number of packets sent, received, and declined while obtaining the current lease, or the number of packets sent, received, and declined while attempting to obtain a future lease.

FILES /etc/default/inet_type DEFAULT_IP setting

ATTRIBUTES See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

SEE ALSO arp(1M), dhcpinfo(1), dhcpagent(1M), ifconfig(1M), iostat(1M), mibiisa(1M), savecore(1M), vmstat(1M), hosts(4), inet_type(4), networks(4), protocols(4), services(4), attributes(5), inet(7P), inet6(7P)

Droms, R., *RFC 2131, Dynamic Host Configuration Protocol*, Network Working Group, March 1997.

NOTES When displaying interface information, netstat honors the DEFAULT_IP setting in /etc/default/inet_type. If it is set to IP_VERSION4, then netstat will omit information relating to IPv6 interfaces, statistics, connections, routes and the like.

However, you can override the DEFAULT_IP setting in /etc/default/inet_type on the command-line. For example, if you have used the command-line to explicitly request IPv6 information by using the inet6 address family or one of the IPv6 protocols, it will override the DEFAULT_IP setting.

If you need to examine network status information following a kernel crash, use the mdb(1) utility on the savecore(1M) output.

The netstat utility obtains TCP statistics from the system by opening /dev/tcp and issuing queries. Because of this, netstat might display an extra, unused connection in IDLE state when reporting connection status.

NAME	newaliases – rebuild the data base for the mail aliases file																	
SYNOPSIS	newaliases																	
DESCRIPTION	newaliases rebuilds the random access data base for the mail aliases file /etc/mail/aliases. newaliases accepts all the flags that sendmail(1M) accepts. However, most of these flags have no effect, except for the -C option and three of the Processing Options that can be set from a configuration file with the -o option: <table><tr><td>-C /path/to/alt/config/file</td><td>Use alternate configuration file.</td></tr><tr><td>-oAfile</td><td>Specify possible alias files.</td></tr><tr><td>-oLn</td><td>Set the default log level to n. Defaults to 9.</td></tr><tr><td>-on</td><td>Validate the RHS of aliases when rebuilding the aliases(4) database.</td></tr></table> newaliases runs in verbose mode (-v option) automatically.		-C /path/to/alt/config/file	Use alternate configuration file.	-oAfile	Specify possible alias files.	-oLn	Set the default log level to n. Defaults to 9.	-on	Validate the RHS of aliases when rebuilding the aliases(4) database.								
-C /path/to/alt/config/file	Use alternate configuration file.																	
-oAfile	Specify possible alias files.																	
-oLn	Set the default log level to n. Defaults to 9.																	
-on	Validate the RHS of aliases when rebuilding the aliases(4) database.																	
EXAMPLES	EXAMPLE 1 Running the newaliases Command The following command runs newaliases on an alias file different from the /etc/mail/aliases default in sendmail(1M): <pre>example% newaliases -oA/path/to/alternate/alias/file</pre>																	
EXIT STATUS	newaliases returns an exit status describing what it did. The codes are defined in /usr/include/sysexits.h. <table><tr><td>EX_OK</td><td>Successful completion on all addresses.</td></tr><tr><td>EX_NOUSER</td><td>User name not recognized.</td></tr><tr><td>EX_UNAVAILABLE</td><td>Catchall. Necessary resources were not available.</td></tr><tr><td>EX_SYNTAX</td><td>Syntax error in address.</td></tr><tr><td>EX_SOFTWARE</td><td>Internal software error, including bad arguments.</td></tr><tr><td>EX_OSERR</td><td>Temporary operating system error, such as “cannot fork”.</td></tr><tr><td>EX_NOHOST</td><td>Host name not recognized.</td></tr><tr><td>EX_TEMPFAIL</td><td>Message could not be sent immediately, but was queued.</td></tr></table>		EX_OK	Successful completion on all addresses.	EX_NOUSER	User name not recognized.	EX_UNAVAILABLE	Catchall. Necessary resources were not available.	EX_SYNTAX	Syntax error in address.	EX_SOFTWARE	Internal software error, including bad arguments.	EX_OSERR	Temporary operating system error, such as “cannot fork”.	EX_NOHOST	Host name not recognized.	EX_TEMPFAIL	Message could not be sent immediately, but was queued.
EX_OK	Successful completion on all addresses.																	
EX_NOUSER	User name not recognized.																	
EX_UNAVAILABLE	Catchall. Necessary resources were not available.																	
EX_SYNTAX	Syntax error in address.																	
EX_SOFTWARE	Internal software error, including bad arguments.																	
EX_OSERR	Temporary operating system error, such as “cannot fork”.																	
EX_NOHOST	Host name not recognized.																	
EX_TEMPFAIL	Message could not be sent immediately, but was queued.																	
FILES	/etc/aliases	Symbolic link to /etc/mail/aliases																
	/etc/mail/aliases.pag

NAME	newfs – construct a UFS file system		
SYNOPSIS	newfs [-NTv] [<i>mkfs-options</i>] <i>raw-device</i>		
DESCRIPTION	newfs is a "friendly" front-end to the mkfs(1M) program for making UFS file systems on disk partitions. newfs calculates the appropriate parameters to use and calls mkfs. If run interactively (that is, standard input is a tty), newfs prompts for confirmation before making the file system. If the -N option is not specified and the inodes of the device are not randomized, newfs calls fsirand(1M). You must be super-user or have appropriate write privileges to use this command, except when creating a UFS file system on a <i>diskette</i>. See EXAMPLES. Keep the following limitations in mind when creating a multiterabyte UFS file system: ■ <i>nbpi</i> is set to 1 Mbyte unless you specifically set it higher. You cannot set <i>nbpi</i> lower than 1 Mbyte on a multiterabyte UFS file system. ■ <i>fragsize</i> is set equal to <i>bsize</i>.		
Creating a Multiterabyte UFS File System			
OPTIONS	The following options are supported:		
	-N	Print out the file system parameters that would be used to create the file system without actually creating the file system. fsirand(1M) is not called here.	
	-T	Set the parameters of the file system to allow eventual growth to over a terabyte in total file system size. This option sets <i>fragsize</i> to be the same as <i>bsize</i> , and sets <i>nbpi</i> to 1 Mbyte, unless the -i option is used to make it even larger. If you use the -f or -i options to specify a <i>fragsize</i> or <i>nbpi</i> that is incompatible with this option, the user-supplied value of <i>fragsize</i> or <i>nbpi</i> is ignored.	
	-v	Verbose. newfs prints out its actions, including the parameters passed to mkfs .	
	<i>mkfs-options</i>	Options that override the default parameters are:	
		-a <i>apc</i>	The number of alternate sectors per cylinder to reserve for bad block replacement for SCSI devices only. The default is 0.
			This option is not applicable for disks with EFI labels and is ignored.
		-b <i>bsize</i>	The logical block size of the file system in bytes, either 4096 or 8192. The default is 8192. The sun4u architecture does not support the 4096 block size.

newfs(1M)

<code>-c <i>cgsiz</i></code>	The number of cylinders per cylinder group, ranging from 16 to 256. The default is calculated by dividing the number of sectors in the file system by the number of sectors in a gigabyte. Then, the result is multiplied by 32. The default value is always between 16 and 256. <code>mkfs</code> can override this value. See <code>mkfs_ufs(1M)</code> for details. This option is not applicable for disks with EFI labels and is ignored.
<code>-C <i>maxcontig</i></code>	The maximum number of logical blocks, belonging to one file, that are allocated contiguously. The default is calculated as follows: $\text{maxcontig} = \text{disk drive maximum transfer size} / \text{disk block size}$ If the disk drive's maximum transfer size cannot be determined, the default value for <code>maxcontig</code> is calculated from kernel parameters as follows: If <code>maxphys</code> is less than <code>ufs_maxmaxphys</code>, which is typically 1 Mbyte, then <code>maxcontig</code> is set to <code>maxphys</code>. Otherwise, <code>maxcontig</code> is set to <code>ufs_maxmaxphys</code>. You can set <code>maxcontig</code> to any positive integer value. The actual value will be the lesser of what has been specified and what the hardware supports. You can subsequently change this parameter by using <code>tunefs(1M)</code>.
<code>-d <i>gap</i></code>	Rotational delay. This option is obsolete. The value is always set to 0, regardless of the input value.
<code>-f <i>fragsize</i></code>	The smallest amount of disk space in bytes that can be allocated to a file. <i>fragsize</i> must be a power of 2 divisor of <i>bsize</i>, where: $\text{bsize} / \text{fragsize} \text{ is } 1, 2, 4, \text{ or } 8.$

This means that if the logical block size is 4096, legal values for *fragsize* are 512, 1024, 2048, and 4096. When the logical block size is 8192, legal values are 1024, 2048, 4096, and 8192. The default value is 1024.

For file systems greater than 1 terabyte or for file systems created with the *-T* option, *fragsize* is forced to match block size (*bsize*).

-i nbpi

The number of bytes per inode, which specifies the density of inodes in the file system. The number is divided into the total size of the file system to determine the number of inodes to create.

This value should reflect the expected average size of files in the file system. If fewer inodes are desired, a larger number should be used. To create more inodes, a smaller number should be given. The default for *nbpi* is as follows:

Disk size	Density
Less than 1GB	2048
Less than 2GB	4096
Less than 3GB	6144
3GB to 1 Tbyte	8192
Greater than 1 Tbyte or created with <i>-T</i>	1048576

The number of inodes can increase if the file system is expanded with the *growfs* command.

-m free

The minimum percentage of free space to maintain in the file system, between 0% and 99%, inclusively. This space is off-limits to users. Once the file system is filled to this threshold, only the super-user can continue writing to the file system.

The default is ((64 Mbytes/partition size) * 100), rounded down to the nearest integer and limited between 1% and 10%, inclusively.

This parameter can be subsequently changed using the *tuneufs(1M)* command.

newfs(1M)

	-n <i>nrpos</i>	The number of different rotational positions in which to divide a cylinder group. The default is 8.
	-o <i>space</i> <i>time</i>	This option is not applicable for disks with EFI labels and is ignored. The file system can either be instructed to try to minimize the <i>time</i> spent allocating blocks, or to try to minimize the <i>space</i> fragmentation on the disk. The default is <i>time</i> .
	-r <i>rpm</i>	This parameter can subsequently be changed with the <code>tunefs(1M)</code> command. The rotational speed of the disk in revolutions per minute. The default is driver- or device-specific. Note that you specify <i>rpm</i> for <code>newfs</code> and <i>rps</i> for <code>mkfs</code> . This option is not applicable for disks with EFI labels and is ignored.
	-s <i>size</i>	The size of the file system in sectors. The default is to use the entire partition.
	-t <i>ntrack</i>	The number of tracks per cylinder on the disk. The default is taken from the disk label. This option is not applicable for disks with EFI labels and is ignored.
OPERANDS	The following operands are supported:	
	<i>raw-device</i>	The name of a raw special device residing in the <code>/dev</code> directory (for example, <code>/dev/rdisk/c0t0d0s6</code>) on which to create the file system.
USAGE	See <code>largefile(5)</code> for the description of the behavior of <code>newfs</code> when encountering files greater than or equal to 2 Gbyte (2^{31} bytes).	
EXAMPLES	EXAMPLE 1 Displaying the Parameters for the Raw Special Device The following example verbosely displays the parameters for the raw special device, <code>c0t0d0s6</code>. It does not actually create a new file system: <pre>example# newfs -Nv /dev/rdisk/c0t0d0s6 mkfs -F ufs -o N /dev/rdisk/c0t0d0s6 1112940 54 15 8192 1024 16 10 60 2048 t 0 -1 8 /dev/rdisk/c0t0d0s6: 1112940 sectors in 1374 cylinders of 15 tracks, 54 sectors 569.8MB in 86 cyl groups (16 c/g, 6.64MB/g, 3072 i/g) super-block backups</pre>	

EXAMPLE 1 Displaying the Parameters for the Raw Special Device (Continued)

```
(for fsck -b #) at:
32, 13056, 26080, 39104, 52128, 65152, 78176, 91200, 104224, . . .
```

EXAMPLE 2 Creating a UFS File System

The following example creates a UFS file system on a diskette that is managed by Volume Manager.

```
example% newfs /vol/dev/aliases/floppy0
newfs: construct a new file system /vol/dev/aliases/floppy0: (y/n)? y
/vol/dev/aliases/floppy0: 2880 sectors in 80 cylinders of 2 tracks,
18 sectors 1.4MB in 5 cyl groups (16 c/g, 0.28MB/g, 128 i/g)
super-block backups (for fsck -F ufs -o b=#) at:
32, 640, 1184, 1792, 2336, . . .
```

EXAMPLE 3 Creating a UFS File System That Will Eventually Be Grown to a Multiterabyte UFS File System

The following example creates a UFS file system that will eventually be grown to a multiterabyte UFS file system.

This command creates a 800-Gbyte file system on the volume, /dev/md/rdisk/d99.

```
# newfs -T /dev/md/rdisk/d99
newfs: construct a new file system /dev/md/rdisk/d99: (y/n)? y
/dev/md/rdisk/d99: 1677754368 sectors in 45512 cylinders of
144 tracks, 256 sectors
819216.0MB in 1821 cyl groups (25 c/g, 450.00MB/g, 448 i/g) . . .
```

Then, if you increase the volume size for this file system, you can use the `growfs` command to expand the file system. The file system is grown to 1.2 terabytes in this example:

```
# growfs -v /dev/md/rdisk/d99
/usr/lib/fs/ufs/mkfs -G /dev/md/rdisk/d99 2516631552 /dev/md/rdisk/d99:
2516631552 sectors in 68268 cylinders of 144 tracks, 256 sectors
1228824.0MB in 2731 cyl groups (25 c/g, 450.00MB/g, 448 i/g) . . .
```

EXIT STATUS

The following exit values are returned:

0	The operation was successful.
1, 10	Usage error or internal error. A message is output to <code>STDERR</code> explaining the error.

Other exit values may be returned by `mkfs(1M)`, which is called by `newfs`.

newfs(1M)

NAME	newkey – create a new Diffie-Hellman key pair in the publickey database				
SYNOPSIS	<pre>newkey -h <i>hostname</i> [-s nisplus nis files ldap]</pre> <pre>newkey -u <i>username</i> [-s nisplus nis files ldap]</pre>				
DESCRIPTION	newkey establishes new public keys for users and machines on the network. These keys are needed when using secure RPC or secure NFS service. newkey prompts for a password for the given <i>username</i> or <i>hostname</i> and then creates a new public/secret Diffie-Hellman 192 bit key pair for the user or host. The secret key is encrypted with the given password. The key pair can be stored in the <code>/etc/publickey</code> file, the NIS publickey map, or the NIS+ <code>cred.org_dir</code> table. newkey consults the publickey entry in the name service switch configuration file (see <code>nsswitch.conf(4)</code>) to determine which naming service is used to store the secure RPC keys. If the publickey entry specifies a unique name service, newkey will add the key in the specified name service. However, if there are multiple name services listed, newkey cannot decide which source to update and will display an error message. The user is required to specify the source explicitly with the <code>-s</code> option. In the case of NIS, newkey should be run by the superuser on the master NIS server for that domain. In the case of NIS+, newkey should be run by the superuser on a machine which has permission to update the <code>cred.org_dir</code> table of the new user/host domain. In the case of NIS+, <code>nisaddcred(1M)</code> should be used to add new keys. newkey cannot be used to create keys other than 192-bit Diffie-Hellman.				
OPTIONS	<pre>-h <i>hostname</i></pre> Create a new public/secret key pair for the privileged user at the given <i>hostname</i> . Prompts for a password for the given <i>hostname</i> . <pre>-u <i>username</i></pre> Create a new public/secret key pair for the given <i>username</i> . Prompts for a password for the given <i>username</i> . <pre>-s nisplus</pre> <pre>-s nis</pre> <pre>-s files</pre> <pre>-s ldap</pre> Update the database in the specified source: <code>nisplus</code> (for NIS+), <code>nis</code> (for NIS), <code>files</code> , or <code>ldap</code> (LDAP). Other sources may be available in the future.

NOTES NIS+ might not be supported in future releases of the Solaris™ Operating
Environment. Tools to aid the migration from NIS+ to LDAP are available in the
Solaris 9 operating environment. For more information, visit
<http://www.sun.com/directory/nisplus/transition.html>.

NAME	nfsd – NFS daemon
SYNOPSIS	/usr/lib/nfs/nfsd [-a] [-c <i>#_conn</i>] [-l <i>listen_backlog</i>] [-p <i>protocol</i>] [-t <i>device</i>] [<i>nservers</i>]
DESCRIPTION	nfsd is the daemon that handles client file system requests. Only the super-user can run this daemon. The nfsd daemon is automatically invoked in run level 3 with the -a option, described below. By default, nfsd starts over the TCP and UDP transports. You can change this with the -p option, described below. A previously invoked nfsd daemon started with or without options must be stopped before invoking another nfsd command. Administrators wanting to change startup parameters for nfsd should, as root, make changes in the /etc/default/nfs file rather than editing the /etc/init.d/nfs.server file. See nfs(4).
OPTIONS	The following options are supported: -a Start a NFS daemon over all available connectionless and connection-oriented transports, including UDP and TCP. Equivalent of setting the NFSD_PROTOCOL parameter to ALL in the nfs file. -c <i>#_conn</i> This sets the maximum number of connections allowed to the NFS server over connection-oriented transports. By default, the number of connections is unlimited. Equivalent of the NFSD_MAX_CONNECTIONS parameter in the nfs file. -l Set connection queue length for the NFS TCP over a connection-oriented transport. The default value is 32 entries. Equivalent of the NFSD_LISTEN_BACKLOG parameter in the nfs file. -p <i>protocol</i> Start a NFS daemon over the specified protocol. Equivalent of the NFSD_PROTOCOL parameter in the nfs file. -t <i>device</i> Start a NFS daemon for the transport specified by the given device. Equivalent of the NFSD_DEVICE parameter in the nfs file.
OPERANDS	The following operands are supported: <i>nservers</i> This sets the maximum number of concurrent NFS requests that the server can handle. This concurrency is achieved by up to <i>nservers</i> threads created as needed in the kernel. <i>nservers</i> should be based on the load expected on this server. 16 is the usual number of <i>nservers</i>. If <i>nservers</i> is not specified, the maximum number of concurrent NFS requests will default to 1. Equivalent of the

nfsd(1M)

	NFSD_MAX_CONNECTIONS parameter in the nfs file.					
USAGE	If the NFS_PORTMON variable is set in /etc/system, then clients are required to use privileged ports (ports < IPPORT_RESERVED) to get NFS services. This variable is equal to zero by default. This variable has been moved from the "nfs" module to the "nfssrv" module. To set the variable, edit the /etc/system file and add this entry: set nfssrv:nfs_portmon = 1					
EXIT STATUS	0 Daemon started successfully. 1 Daemon failed to start.					
FILES	.nfsXXX /etc/default/nfs /etc/init.d/nfs.server /etc/system	client machine pointer to an open-but-unlinked file contains startup parameters for nfsd shell script for starting nfsd system configuration information file				
ATTRIBUTES	See attributes(5) for descriptions of the following attributes: <table><tr><th>ATTRIBUTE TYPE</th><th>ATTRIBUTE VALUE</th></tr><tr><td>Availability</td><td>SUNWnfssu</td></tr></table>		ATTRIBUTE TYPE	ATTRIBUTE VALUE	Availability	SUNWnfssu
ATTRIBUTE TYPE	ATTRIBUTE VALUE					
Availability	SUNWnfssu					
SEE ALSO	ps(1), mountd(1M), nfs(4), sharetab(4), system(4), attributes(5) System Administration Guide: Naming and Directory Services (DNS, NIS, and LDAP)					
NOTES	Manually starting and restarting nfsd is not recommended. If it is necessary to do so, use the NFS server start/stop script (/etc/init.d/nfs.server). See System Administration Guide: Naming and Directory Services (DNS, NIS, and LDAP) for more information.					

NAME	nfslogd – nfs logging daemon
SYNOPSIS	<code>/usr/lib/nfs/nfslogd</code>
DESCRIPTION	The <code>nfslogd</code> daemon provides operational logging to the Solaris NFS server. It is the <code>nfslogd</code> daemon's job to generate the activity log by analyzing the RPC operations processed by the the NFS server. The log will only be generated for file systems exported with logging enabled. This is specified at file system export time by means of the <code>share_nfs(1M)</code> command. Each record in the log file includes a time stamp, the IP address (or hostname if it can be resolved) of the client system, the file or directory name the operation was performed on, and the type of operation. In the basic format, the operation can either be an input (i) or output (o) operation. The basic format of the NFS server log is compatible with the log format generated by the Washington University FTPd daemon. The log format can be extended to include directory modification operations, such as <code>mkdir</code>, <code>rmdir</code>, and <code>remove</code>. The extended format is not compatible with the Washington University FTPd daemon format. See <code>nfslog.conf(4)</code> for details. The NFS server logging mechanism is divided in two phases. The first phase is performed by the NFS kernel module, which records raw RPC requests and their results in work buffers backed by permanent storage. The location of the work buffers is specified in the <code>/etc/nfs/nfslog.conf</code> file. Refer to <code>nfslog.conf(4)</code> for more information. The second phase involves the <code>nfslogd</code> user-level daemon, which periodically reads the work buffers, interprets the raw RPC information, groups related RPC operations into single transaction records, and generates the output log. The <code>nfslogd</code> daemon then sleeps waiting for more information to be logged to the work buffers. The amount of time that the daemon sleeps can be configured by modifying the <code>IDLE_TIME</code> parameter in <code>/etc/default/nfslogd</code>. The work buffers are intended for internal consumption of the <code>nfslogd</code> daemon. NFS operations use file handles as arguments instead of path names. For this reason the <code>nfslogd</code> daemon needs to maintain a database of file handle to path mappings in order to log the path name associated with an operation instead of the corresponding file handle. A file handle entry is added to the database when a client performs a lookup or other NFS operation that returns a file handle to the client. Once an NFS client obtains a file handle from a server, it can hold on to it for an indefinite time, and later use it as an argument for an NFS operation on the file or directory. The NFS client can use the file handle even after the server reboots. Because the database needs to survive server reboots, it is backed by permanent storage. The location of the database is specified by the <code>htable</code> parameter in the <code>/etc/nfs/nfslog.conf</code> file. This database is intended for the internal use of the <code>nfslogd</code> daemon. In order to keep the size of the file handle mapping database manageable, <code>nfslogd</code> prunes the database periodically. It removes file handle entries that have not been accessed in more than a specified amount of time. The <code>PRUNE_TIMEOUT</code> configurable parameter in <code>/etc/default/nfslogd</code> specifies the interval length between

nfslogd(1M)

successive runs of the pruning process. A file handle record will be removed if it has not been used since the last time the pruning process was executed. Pruning of the database can effectively be disabled by setting the `PRUNE_TIMEOUT` as high as `INT_MAX`.

When pruning is enabled, there is always a risk that a client may have held on to a file handle longer than the `PRUNE_TIMEOUT` and perform an NFS operation on the file handle after the matching record in the mapping database had been removed. In such case, the pathname for the file handle will not be resolved, and the log will include the file handle instead of the pathname.

There are various configurable parameters that affect the behavior of the `nfslogd` daemon. These parameters are found in `/etc/default/nfslogd` and are described below:

<code>UMASK</code>	Sets the file mode for the log files, work buffer files and file handle mapping database.
<code>MIN_PROCESSING_SIZE</code>	Specifies the minimum size, in bytes, that the buffer file must reach before processing the work information and writing to the log file. The value of <code>MIN_PROCESSING_SIZE</code> must be between 1 and <code>ulimit</code> .
<code>IDLE_TIME</code>	Specifies the amount of time, in seconds, the daemon should sleep while waiting for more information to be placed in the buffer file. <code>IDLE_TIME</code> also determines how often the configuration file will be reread. The value of <code>IDLE_TIME</code> must be between 1 and <code>INT_MAX</code> .
<code>MAX_LOGS_PRESERVE</code>	The <code>nfslogd</code> periodically cycles its logs. <code>MAX_LOGS_PRESERVE</code> specifies the maximum number of log files to save. When <code>MAX_LOGS_PRESERVE</code> is reached, the oldest files will be overwritten as new log files are created. These files will be saved with a numbered extension, beginning with <code>filename.0</code> . The oldest file will have the highest numbered extension up to the value configured for <code>MAX_LOGS_PRESERVE</code> . The value of <code>MAX_LOGS_PRESERVE</code> must be between 1 and <code>INT_MAX</code> .
<code>CYCLE_FREQUENCY</code>	Specifies how often, in hours, the log files are cycled. <code>CYCLE_FREQUENCY</code> is used to insure that the log files do not get too large.

		The value of <code>CYCLE_FREQUENCY</code> must be between 1 and <code>INT_MAX</code> .				
	<code>MAPPING_UPDATE_INTERVAL</code>	Specifies the time interval, in seconds, between updates of the records in the file handle to path mapping tables. Instead of updating the <code>atime</code> of a record each time that record is accessed, it is only updated if it has aged based on this parameter. The record access time is used by the pruning routine to determine whether the record should be removed from the database. The value of this parameter must be between 1 and <code>INT_MAX</code> .				
	<code>PRUNE_TIMEOUT</code>	Specifies when a database record times out, in hours. If the time that elapsed since the record was last accessed is greater than <code>PRUNE_TIMEOUT</code> then the record can be pruned from the database. The default value for <code>PRUNE_TIMEOUT</code> is 168 hours (7 days). The value of <code>PRUNE_TIMEOUT</code> must be between 1 and <code>INT_MAX</code> .				
EXIT STATUS	The following exit values are returned: 0 Daemon started successfully. 1 Daemon failed to start.

nfsstat(1M)

NAME	nfsstat – NFS statistics						
SYNOPSIS	nfsstat [-cnrsmza]						
DESCRIPTION	nfsstat displays statistical information about the NFS and RPC (Remote Procedure Call), interfaces to the kernel. It can also be used to reinitialize this information. If no options are given the default is <pre>nfsstat -csnra</pre> That is, display everything, but reinitialize nothing.						
OPTIONS	-a Display NFS_ACL information. -c Display client information. Only the client side NFS, RPC, and NFS_ACL information is printed. Can be combined with the -n, -r, and -a options to print client side NFS, RPC, and NFS_ACL information only. -m Display statistics for each NFS mounted file system. This includes the server name and address, mount flags, current read and write sizes, the retransmission count, the attribute cache timeout values, failover information, and the timers used for dynamic retransmission. Note that the dynamic retransmission timers are displayed only where dynamic retransmission is in use. By default, NFS mounts over the TCP protocols and NFS Version 3 mounts over either TCP or UDP do not use dynamic retransmission. If you specify the -m option, this is the only option nfsstat uses. Any options specified in addition to -m are checked for validity, then ignored. -n Display NFS information. NFS information for both the client and server side will be printed. Can be combined with the -c and -s options to print client or server NFS information only. -r Display RPC information. -s Display server information. -z Zero (reinitialize) statistics. This option is for use by the super user only, and can be combined with any of the above options to zero particular sets of statistics after printing them.						
DISPLAYS	The server RPC display includes the following fields: <table> <tr> <td>calls</td><td>The total number of RPC calls received.</td></tr> <tr> <td>badcalls</td><td>The total number of calls rejected by the RPC layer (the sum of badlen and xdr call as defined below).</td></tr> <tr> <td>nullrecv</td><td>The number of times an RPC call was not available when it was thought to be received.</td></tr> </table>	calls	The total number of RPC calls received.	badcalls	The total number of calls rejected by the RPC layer (the sum of badlen and xdr call as defined below).	nullrecv	The number of times an RPC call was not available when it was thought to be received.
calls	The total number of RPC calls received.						
badcalls	The total number of calls rejected by the RPC layer (the sum of badlen and xdr call as defined below).						
nullrecv	The number of times an RPC call was not available when it was thought to be received.						

badlen	The number of RPC calls with a length shorter than a minimum-sized RPC call.
xdr call	The number of RPC calls whose header could not be XDR decoded.
dupchecks	The number of RPC calls that looked up in the duplicate request cache.
dupreqs	The number of RPC calls that were found to be duplicates.
The server NFS display shows the number of NFS calls received (<code>calls</code>) and rejected (<code>badcalls</code>), and the counts and percentages for the various calls that were made.	
The server NFS_ACL display shows the counts and percentages for the various calls that were made.	
The client RPC display includes the following fields:	
<code>calls</code>	The total number of RPC calls made.
<code>badcalls</code>	The total number of calls rejected by the RPC layer.
<code>badxids</code>	The number of times a reply from a server was received which did not correspond to any outstanding call.
<code>timeouts</code>	The number of times a call timed out while waiting for a reply from the server.
<code>newcreds</code>	The number of times authentication information had to be refreshed.
<code>badverfs</code>	The number of times the call failed due to a bad verifier in the response.
<code>timers</code>	The number of times the calculated time-out value was greater than or equal to the minimum specified time-out value for a call.
<code>cantconn</code>	The number of times the call failed due to a failure to make a connection to the server.
<code>nomem</code>	The number of times the call failed due to a failure to allocate memory.
<code>interrupts</code>	The number of times the call was interrupted by a signal before completing.
<code>retrans</code>	The number of times a call had to be retransmitted due to a timeout while waiting for a reply from the server. Applicable only to RPC over connection-less transports.
<code>cant send</code>	The number of times a client was unable to send an RPC request over a connectionless transport when it tried to do so.

nfsstat(1M)

The client NFS display shows the number of calls sent and rejected, as well as the number of times a CLIENT handle was received (`clgets`), the number of times the CLIENT handle cache had no unused entries (`cltoomany`), as well as a count of the various calls and their respective percentages.

The client NFS_ACL display shows the counts and percentages for the various calls that were made.

The `-m` option includes information about mount flags set by mount options, mount flags internal to the system, and other mount information. See `mount_nfs(1M)`.

The following mount flags are set by mount options:

<code>sec</code>	sec has one of the following values:
<code>none</code>	No authentication.
<code>sys</code>	UNIX-style authentication (UID, GID).
<code>short</code>	Short hand UNIX-style authentication.
<code>dh</code>	des-style authentication (encrypted timestamps).
<code>krb5</code>	kerberos v5-style authentication.
<code>krb5i</code>	kerberos v5-style authentication with integrity.
<code>krb5p</code>	kerberos v5-style authentication with privacy.
<code>hard</code>	Hard mount.
<code>soft</code>	Soft mount.
<code>intr</code>	Interrupts allowed on hard mount.
<code>nointr</code>	No interrupts allowed on hard mount.
<code>noac</code>	Client is not caching attributes.
<code>rsize</code>	Read buffer size in bytes.
<code>wsiz</code>	Write buffer size in bytes.
<code>retrans</code>	NFS retransmissions.
<code>timeo</code>	Initial NFS timeout, in tenths of a second.
<code>nocto</code>	No close-to-open consistency.
<code>llock</code>	Local locking being used (no lock manager).
<code>grp</code>	System V group id inheritance.
<code>rpctimesync</code>	RPC time sync.

The following mount flags are internal to the system:

<code>printed</code>	"Not responding" message printed.

down	Server is down.
dynamic	Dynamic transfer size adjustment.
link	Server supports links.
symlink	Server supports symbolic links.
readdir	Use readdir instead of readdirplus.
acl	Server supports NFS_ACL.

The following flags relate to additional mount information:

vers	NFS version.
proto	Protocol.

The -m option also provides attribute cache timeout values. The following fields in -m output provide timeout values for attribute cache:

acregmin	Minimum seconds to hold cached file attributes.
acregmax	Maximum seconds to hold cached file attributes.
acdirmin	Minimum seconds to hold cached directory attributes.
acdirmax	Maximum seconds to hold cached directory attributes.

The following fields in -m output provide failover information:

noresponse	How many times servers have failed to respond.
failover	How many times a new server has been selected.
remap	How many times files have been re-evaluated to the new server.
currserver	Which server is currently providing NFS service. See the <i>System Administration Guide: IP Services</i> for additional details.

The fields in -m output shown below provide information on dynamic retransmissions. Note that these items are displayed only where dynamic retransmission is in use.

srtt	The value for the smoothed round-trip time, in milliseconds.
dev	Estimated deviation, in milliseconds.
cur	Current backed-off retransmission value, in milliseconds.

EXIT STATUS The following exit values are returned:

0	Successful completion.
>0	An error occurred.

System Administration Guide: IP Services

NAME	nisaddcred – create NIS+ credentials																				
SYNOPSIS	nisaddcred [-p <i>principal</i>] [-P <i>nis_principal</i>] [-l <i>login_password</i>] <i>auth_type</i> [<i>domain_name</i>] nisaddcred -r [<i>nis_principal</i>] [<i>domain_name</i>]																				
DESCRIPTION	The nisaddcred command is used to create security credentials for NIS+ principals. NIS+ credentials serve two purposes. The first is to provide authentication information to various services; the second is to map the authentication service name into a NIS+ principal name. When the nisaddcred command is run, these credentials get created and stored in a table named cred.org_dir in the default NIS+ domain. If <i>domain_name</i> is specified, the entries are stored in the cred.org_dir of the specified domain. The specified domain must either be the one to which you belong, or one in which you are authenticated and authorized to create credentials, that is, a subdomain. Note that the credentials of normal users must be stored in the same domain as their passwords. It is simpler to add credentials using nisclient(1M), because it obtains the required information itself. nispopulate(1M) is used for “bulk” updates and can also be used to add credentials for entries in the hosts and the passwd NIS+ tables. NIS+ principal names are used in specifying clients that have access rights to NIS+ objects. For more details, refer to the “Principal Names” subsection of the nis+(1) manual page. See nischmod(1), nischown(1), nis_objects(3NSL), and nis_groups(3NSL). Various other services can also implement access control based on these principal names. The cred.org_dir table is organized as follows: <table><tr><th>cname</th><th>auth_type</th><th>auth_name</th><th>public_data</th><th>private_data</th></tr><tr><td>user1.foo.com.</td><td>LOCAL</td><td>2990</td><td>10,102,44</td><td></td></tr><tr><td>user1.foo.com.</td><td>DES</td><td>unix.2990@foo.com</td><td>098...819</td><td>3b8...ab2</td></tr><tr><td>user1.foo.com.</td><td>DHmmm-n</td><td>unix.2990@foo.com</td><td>248...428</td><td>a42...f32</td></tr></table> The cname column contains a canonical representation of the NIS+ principal name. By convention, this name is the login name of a user, or the host name of a machine, followed by a dot (‘.’) followed by the fully qualified “home” domain of that principal. For users, the home domain is defined to be the domain where their DES credentials are kept. For hosts, their home domain is defined to be the domain name returned by the domainname(1M) command executed on that host. There are two basic types of <i>auth_type</i> entries in the cred.org_dir table, those with authentication type LOCAL, and those with authentication type DES, <i>auth_type</i>, specified on the command line in upper or lower case, should be either <i>local</i> or <i>des</i>.	cname	auth_type	auth_name	public_data	private_data	user1.foo.com.	LOCAL	2990	10,102,44		user1.foo.com.	DES	unix.2990@foo.com	098...819	3b8...ab2	user1.foo.com.	DHmmm-n	unix.2990@foo.com	248...428	a42...f32
cname	auth_type	auth_name	public_data	private_data																	
user1.foo.com.	LOCAL	2990	10,102,44																		
user1.foo.com.	DES	unix.2990@foo.com	098...819	3b8...ab2																	
user1.foo.com.	DHmmm-n	unix.2990@foo.com	248...428	a42...f32																	

nisaddcred(1M)

However, the `cred.org_dir` table may also be used to hold data for other values of *auth_type*. Currently, this is limited to the mechanisms listed on the `nisauthconf(1M)` man page, for which the `nisaddcred auth_type` argument is the same as the name of the mechanism. These mechanisms use a modified form of Secure RPC, and they are similar to the DES authentication type.

If the *auth_type* is `des`, and other authentication mechanisms are configured with `nisauthconf(1M)`, then credential entries are added or updated for each mechanism configured. To only add or update 1992-bit Diffie Hellman credentials, that is, those with the *auth_type* of DES, use `dh192-0` on the command line. If there are no authentication mechanisms configured, using `des` on the command line will only add or update 192-bit Diffie Hellman credentials.

Entries of type LOCAL are used by the NIS+ service to determine the correspondence between fully qualified NIS+ principal names and users identified by UIDs in the domain containing the `cred.org_dir` table. This correspondence is required when associating requests made using the `AUTH_SYS` RPC authentication flavor (see `rpc_clnt_auth(3NSL)`) to a NIS+ principal name. It is also required for mapping a UID in one domain to its fully qualified NIS+ principal name whose home domain may be elsewhere. The principal's credentials for any authentication flavor may then be sought for within the `cred.org_dir` table in the principal's home domain (extracted from the principal name). The same NIS+ principal may have LOCAL credential entries in more than one domain. Only users, and not machines, have LOCAL credentials. In their home domain, users of NIS+ should have both types of credentials.

The *auth_name* associated with the LOCAL type entry is a UID that is valid for the principal in the domain containing the `cred.org_dir` table. This may differ from that in the principal's home domain. The public information stored in *public_data* for this type contains a list of GIDs for groups in which the user is a member. The GIDs also apply to the domain in which the table resides. There is no private data associated with this type. Neither a UID nor a principal name should appear more than once among the LOCAL entries in any one `cred.org_dir` table.

The DES *auth_type* is used for Secure RPC authentication (see `secure_rpc(3NSL)`).

The authentication name associated with the DES *auth_type* is a Secure RPC *netname*. A Secure RPC *netname* has the form `unix.id@domain.com`, where *domain* must be the same as the domain of the principal. For principals that are users the *id* must be the UID of the principal in the principal's home domain. For principals that are hosts, the *id* is the host's name. In Secure RPC, processes running under effective UID 0 (root) are identified with the host principal. Unlike LOCAL, there cannot be more than one DES credential entry for one NIS+ principal in the NIS+ namespace.

The public information in an entry of authentication type DES is the public key for the principal. The private information in this entry is the private key of the principal encrypted by the principal's network password.

User clients of NIS+ should have credentials of both types in their home domain. In addition, a principal must have a LOCAL entry in the `cred.org_dir` table of each domain from which the principal wishes to make authenticated requests. A client of NIS+ that makes a request from a domain in which it does not have a LOCAL entry will be unable to acquire DES credentials. A NIS+ service running at security level 2 or higher will consider such users unauthenticated and assign them the name *nobody* for determining access rights.

This command can only be run by those NIS+ principals who are authorized to add or delete the entries in the `cred` table.

If credentials are being added for the caller itself, `nisaddcred` automatically performs a keylogin for the caller.

You can list the `cred` entries for a particular principal with `nismatch(1)`.

The `cred.org_dir` NIS+ table replaces the maps *publickey.byname* and *netid.byname* used in NIS (YP).

OPTIONS The following options are supported:

`-p principal`

The name *principal* specifies the name of the principal as defined by the naming rules for that specific mechanism. For example, LOCAL credential names are supplied with this option by including a string specifying a UID. For DES credentials, the name should be a Secure RPC netname of the form `unix.id@domain.com`, as described earlier. If the `-p` option is not specified, the *auth_name* field is constructed from the effective UID of the current process and the name of the local domain.

`-P nis_principal`

Use the NIS+ principal name *nis_principal*. This option should be used when creating LOCAL or DES credentials for users whose home domain is different than the local machine's default domain.

Whenever the `-P` option is not specified, `nisaddcred` constructs a principal name for the entry as follows. When it is not creating an entry of type LOCAL, `nisaddcred` calls `nis_local_principal`, which looks for an existing LOCAL entry for the effective UID of the current process in the `cred.org_dir` table and uses the associated principal name for the new entry. When creating an entry of authentication type LOCAL, `nisaddcred` constructs a default NIS+ principal name by taking the login name of the effective UID for its

nisaddcred(1M)

	own process, and appending to it a dot ('.') followed by the local machine's default domain. If the caller is a superuser, the machine name is used instead of the login name.
<code>-l login_password</code>	Use the <i>login_password</i> specified as the password to encrypt the secret key for the credential entry. This overrides the prompting for a password from the shell. This option is intended for administration scripts only. Prompting guarantees not only that no one can see your password on the command line using <code>ps(1)</code> but it also checks to make sure you have not made any mistakes. <i>login_password</i> does not really have to be the user's password but if it is, it simplifies logging in.
<code>-r [nis_principal]</code>	Remove all credentials associated with the principal <i>nis_principal</i> from the <code>cred.org_dir</code> table. This option can be used when removing a client or user from the system. If <i>nis_principal</i> is not specified the default is to remove credentials for the current <i>user</i> . If <i>domain_name</i> is not specified, the operation is executed in the default NIS+ domain.

EXAMPLES

EXAMPLE 1 Adding the LOCAL and DES Credentials

The following examples illustrate how to add the LOCAL and DES credentials for some user, *user1*, with a UID of 2990, who is an NIS+ user principal in the *some.domain.com*. NIS+ domain:

```
example% nisaddcred -p 2990 -P user1.some.domain.com. local
```

Note that credentials are always added in the `cred.org_dir` table in the domain where `nisaddcred` is run, unless *domain_name* is specified as the last parameter on the command line. If credentials are being added from the domain server for its clients, then *domain_name* should be specified. The caller should have adequate permissions to create entries in the `cred.org_dir` table.

The system administrator can add a DES credential for the same user, using the following example:

```
example% nisaddcred -p unix.2990@some.domain.com -P user1.some.domain.com. des
```

Please note that DES credentials can be added only after the LOCAL credentials have been added. Also, if the system is configured to use more than one authentication mechanism, credentials will be made for each mechanism configured. See `nisauthconf(1M)`.

Note that the secure RPC netname does not end with a dot ('.') while the NIS+ principal name, specified with the `-P` option, does. This command should be executed from a machine in the same domain as is the user.

EXAMPLE 1 Adding the LOCAL and DES Credentials (Continued)

The following example shows how to add a machine's DES credentials in the same domain:

```
example% nisaddcred -p unix.foo@some.domain.com -P foo.some.domain.com. des
```

Please note that no LOCAL credentials are needed in this case.

The following example illustrates how to add a NIS+ workstation's principal DES credential:

```
example% nisaddcred -p unix.host1@sub.some.domain.com \
-P newhost.sub.some.domain.com. des sub.some.domain.com.
```

This format is particularly useful if you are running this command from a server which is in a higher domain than sub.some.domain.com. Without the last option for domain name, `nisaddcred` would fail because it would attempt to use the default domain of some.domain.com.

The following example illustrates adding DES credentials without being prompted for the root login password:

```
example% nisaddcred -p unix.2990@some.domain.com \
-P user1.some.domain.com. -l login_password des
```

The following example shows how to add a credential for a user using a specific authentication mechanism that was previously configured with `nisauthconf(1M)`. See `nisauthconf(1M)` for a list of the valid values of *auth_type*:

```
example% nisaddcred -p unix.2990@some.domain.com \
-P user.1.some.domain.com dh640-0
```

The password should be the same for all the credentials that belong to the user. Otherwise, only the credentials encrypted with the user's password will be used at login, and the user will have to run `chkey(1)` using the `-p` option.

The following example shows how to add a DES credential when other authentication mechanisms are configured on the system:

```
example% nisaddcred -p unix.2990@some.domain.com \
-P user1.some.domain.com dh192-0
```

EXIT STATUS

The following exit values are returned:

- 0 Successful operation.
- 1 Operation failed.

NAME	<code>nisaddent</code> – create NIS+ tables from corresponding <code>/etc</code> files or NIS maps
SYNOPSIS	<pre> /usr/lib/nis/nisaddent [-D defaults] [-Paorv] [-t table] type [nisdomain] /usr/lib/nis/nisaddent [-D defaults] [-Paprmov] -f file [-t table] type [nisdomain] /usr/lib/nis/nisaddent [-D defaults] [-Parmv] [-t table] -y ypdomain [-Y map] type [nisdomain] /usr/lib/nis/nisaddent -d [-AMoq] [-t table] type [nisdomain] </pre>
DESCRIPTION	<code>nisaddent</code> creates entries in NIS+ tables from their corresponding <code>/etc</code> files and NIS maps. This operation is customized for each of the standard tables that are used in the administration of Solaris systems. The <code>type</code> argument specifies the type of the data being processed. Legal values for this <code>type</code> are one of <code>aliases</code>, <code>bootparams</code>, <code>ethers</code>, <code>group</code>, <code>hosts</code>, <code>ipnodes</code>, <code>netid</code>, <code>netmasks</code>, <code>networks</code>, <code>passwd</code>, <code>protocols</code>, <code>publickey</code>, <code>rpc</code>, <code>services</code>, <code>shadow</code>, or <code>timezone</code> for the standard tables, or <code>key-value</code> for a generic two-column (key, value) table. For a site specific table, which is not of <code>key-value</code> type, one can use <code>nistbladm(1)</code> to administer it. The NIS+ tables should have already been created by <code>nistbladm(1)</code>, <code>nissetup(1M)</code>, or <code>nisserver(1M)</code>. It is easier to use <code>nispopulate(1M)</code> instead of <code>nisaddent</code> to populate the system tables. By default, <code>nisaddent</code> reads from the standard input and adds this data to the NIS+ table associated with the <code>type</code> specified on the command line. An alternate NIS+ table may be specified with the <code>-t</code> option. For type <code>key-value</code>, a table specification is required. Note that the <code>data</code> type can be different than the table name (<code>-t</code>). For example, the automounter tables have <code>key-value</code> as the table type. Although, there is a <code>shadow</code> data type, there is no corresponding <code>shadow</code> table. Both the <code>shadow</code> and the <code>passwd</code> data is stored in the <code>passwd</code> table itself. Files may be processed using the <code>-f</code> option, and NIS version 2 (YP) maps may be processed using the <code>-y</code> option. The merge option is not available when reading data from standard input. When a <code>ypdomain</code> is specified, the <code>nisaddent</code> command takes its input from the dbm files for the appropriate NIS map (<code>mail.aliases</code>, <code>bootparams</code>, <code>ethers.byaddr</code>, <code>group.byname</code>, <code>hosts.byaddr</code>, <code>hosts.byname</code>, <code>ipnodes.byaddr</code>, <code>ipnodes.byname</code>, <code>netid.byname</code>, <code>netmasks.byaddr</code>, <code>networks.byname</code>, <code>passwd.byname</code>, <code>protocols.byname</code>, <code>publickey.byname</code>, <code>rpc.bynumber</code>, <code>services.byname</code>, or <code>timezone.byname</code>). An alternate NIS map may be specified with the <code>-Y</code> option. For type <code>key-value</code>, a map specification is required. The map must be in the <code>/var/yp/ypdomain</code> directory on the local machine. Note that <code>ypdomain</code> is case sensitive. <code>ypxfr(1M)</code> can be used to get the NIS maps.

nisaddent(1M)

If a *nisdomain* is specified, *nisaddent* operates on the NIS+ table in that NIS+ domain, otherwise the default domain is used.

In terms of performance, loading up the tables is fastest when done through the dbm files (-y).

To accommodate other credential entries used by other authentication mechanisms stored in the *cred.org_dir* table, the *publickey* dump output has been modified to include a special *algorithm type* field. This format is incompatible with older versions of *nisaddent*. To produce dumps that can be read by older versions of *nisaddent*, or to load dumps created by such older versions, use the -o option.

OPTIONS

The following options are supported:

-a	Add the file or map to the NIS+ table without deleting any existing entries. This option is the default. Note that this mode only propagates additions and modifications, not deletions.						
-A	All data. This option specifies that the data within the table and all of the data in tables in the initial table's concatenation path be returned.						
-d	Dump the NIS+ table to the standard output in the appropriate format for the given <i>type</i> . For tables of type <i>key-value</i> , use <i>niscat(1)</i> instead. To dump the <i>cred</i> table, dump the <i>publickey</i> and the <i>netid</i> types.						
-D <i>defaults</i>	This option specifies a different set of defaults to be used during this operation. The <i>defaults</i> string is a series of tokens separated by colons. These tokens represent the default values to be used for the generic object properties. All of the legal tokens are described below. <table><tr><td><i>tth=time</i></td><td>This token sets the default time to live for objects that are created by this command. The value <i>time</i> is specified in the format as defined by the <i>nischttl(1)</i> command. The default is 12 hours.</td></tr><tr><td><i>owner=ownername</i></td><td>This token specifies that the NIS+ principal <i>ownername</i> should own the created object. The default for this value is the principal who is executing the command.</td></tr><tr><td><i>group=groupname</i></td><td>This token specifies that the group <i>groupname</i> should be the group owner for the object that is created. The default is NULL.</td></tr></table>	<i>tth=time</i>	This token sets the default time to live for objects that are created by this command. The value <i>time</i> is specified in the format as defined by the <i>nischttl(1)</i> command. The default is 12 hours.	<i>owner=ownername</i>	This token specifies that the NIS+ principal <i>ownername</i> should own the created object. The default for this value is the principal who is executing the command.	<i>group=groupname</i>	This token specifies that the group <i>groupname</i> should be the group owner for the object that is created. The default is NULL.
<i>tth=time</i>	This token sets the default time to live for objects that are created by this command. The value <i>time</i> is specified in the format as defined by the <i>nischttl(1)</i> command. The default is 12 hours.						
<i>owner=ownername</i>	This token specifies that the NIS+ principal <i>ownername</i> should own the created object. The default for this value is the principal who is executing the command.						
<i>group=groupname</i>	This token specifies that the group <i>groupname</i> should be the group owner for the object that is created. The default is NULL.						

	<code>access=rights</code>	This token specifies the set of access rights that are to be granted for the given object. The value <i>rights</i> is specified in the format as defined by the <code>nischmod(1)</code> command. The default is - - - -rmcdr - - -r - - -
<code>-f file</code>	Specify that <code>file</code> should be used as the source of input (instead of the standard input).	
<code>-m</code>	Merge the file or map with the NIS+ table. This is the most efficient way to bring an NIS+ table up to date with a file or NIS map when there are only a small number of changes. This option adds entries that are not already in the database, modifies entries that already exist (if changed), and deletes any entries that are not in the source. Use the <code>-m</code> option whenever the database is large and replicated, and the map being loaded differs only in a few entries. This option reduces the number of update messages that have to be sent to the replicas. Also see the <code>-r</code> option.	
<code>-M</code>	Master server only. This option specifies that lookups should be sent to the master server. This guarantees that the most up-to-date information is seen at the possible expense that the master server may be busy, or that it may be made busy by this operation.	
<code>-o</code>	Use strictly conforming <code>publickey</code> files. Dumps will not add the <code>algorithm type</code> field used by additional authentication mechanisms that might be configured using <code>nisauthconf(1M)</code> . 192-bit keys that are dumped using this option can be read by previous versions of <code>nisaddent</code> . However, the <code>algorithm</code> field will be lost and assumed to be "0" when read. Use the <code>-o</code> option when reading <code>publickey</code> files from previous versions of <code>nisaddent</code> to avoid warnings about the missing <code>algorithm</code> field.	
<code>-p</code>	Process the password field when loading password information from a file. By default, the password field is ignored because it is usually not valid (the actual password appears in a shadow file).	
<code>-P</code>	Follow concatenation path. This option specifies that lookups should follow the concatenation path of a table if the initial search is unsuccessful.	
<code>-q</code>	Dump tables in "quick" mode. The default method for dumping tables processes each entry individually. For some tables, for example, <code>hosts</code> , multiple entries must be combined into a single line, so extra requests to the server must be made. In "quick" mode, all of the entries for a table are retrieved in one call to the server, so the table can be dumped more quickly. However, for	

nisaddent(1M)

	large tables, there is a chance that the process will run out of virtual memory and the table will not be dumped.
-r	Replace the file or map in the existing NIS+ table by first deleting any existing entries, and then add the entries from the source (<code>/etc</code> files, or NIS+ maps). This option has the same effect as the -m option. The use of this option is <i>strongly</i> discouraged due to its adverse impact on performance, unless there are a large number of changes.
-t <i>table</i>	Specify that <i>table</i> should be the NIS+ table for this operation. This should be a relative name as compared to your default domain or the domainname if it has been specified.
-v	Verbose.
-y <i>ypdomain</i>	Use the dbm files for the appropriate NIS map, from the NIS domain <i>ypdomain</i> , as the source of input. The files are expected to be on the local machine in the <code>/var/yp/ypdomain</code> directory. If the machine is not an NIS server, use <code>ypxfr(1M)</code> to get a copy of the dbm files for the appropriate map.
-Y <i>map</i>	Use the dbm files for <i>map</i> as the source of input.

EXAMPLES

EXAMPLE 1 Using nisaddent

This example adds the contents of `/etc/passwd` to the `passwd.org_dir` table:

```
example% cat /etc/passwd | nisaddent passwd
```

The next example adds the shadow information. Note that the table type here is "shadow", not "passwd", even though the actual information is stored in the `passwd` table:

```
example% cat /etc/shadow | nisaddent shadow
```

This example replaces the `hosts.org_dir` table with the contents of `/etc/hosts` (in verbose mode):

```
example% nisaddent -rv -f /etc/hosts hosts
```

This example merges the `passwd` map from `ypdomain` with the `passwd.org_dir.nisdomain` table (in verbose mode). The example assumes that the `/var/yp/myypdomain` directory contains the `yppasswd` map.

```
example% nisaddent -mv -y myypdomain passwd nisdomain
```

This example merges the `auto.master` map from `myypdomain` with the `auto_master.org_dir` table:

```
example% nisaddent -m -y myypdomain -Y auto.master \
    -t auto_master.org_dir key-value
```

EXAMPLE 1 Using `nisaddent` (Continued)

This example dumps the `hosts.org_dir` table:

```
example% nisaddent -d hosts
```

This example dumps the `ipnodes.org_dir` table:

```
example% nisaddent -d ipnodes
```

ENVIRONMENT VARIABLES

NIS_DEFAULTS This variable contains a default string that will override the NIS+ standard defaults. If the `-D` switch is used, those values will then override both the `NIS_DEFAULTS` variable and the standard defaults. To avoid security accidents, the access rights in the `NIS_DEFAULTS` variable are ignored for the `passwd` table (but access rights specified with `-D` are used).

NIS_PATH If this variable is set, and neither the *nisdomain* nor the *table* are fully qualified, each directory specified in `NIS_PATH` will be searched until the table is found (see `nisdefaults(1)`).

EXIT STATUS

The following exit values are returned:

- 0 Successful operation.
- 1 Failure caused by an error other than parsing.
- 2 A parsing error occurred on an entry. A parsing error does not cause termination; the invalid entries are simply skipped.

nisauthconf(1M)

NAME	nisauthconf – configure NIS+ security								
SYNOPSIS	nisauthconf [-v] [<i>mechanism</i> , ...]								
DESCRIPTION	nisauthconf controls which authentication flavors NIS+ should use when communicating with other NIS+ clients and servers. If the command is not executed, then NIS+ will default to the AUTH_DES authentication flavor when running security level 2. See <code>rpc.nisd(1M)</code>. nisauthconf takes a list of authentication <i>mechanism</i>'s in order of preference. An authentication <i>mechanism</i> may use one or more authentication flavors listed below. If <code>des</code> is the only specified mechanism, then NIS+ only use AUTH_DES with other NIS+ clients and servers. If <code>des</code> is the first mechanism, then other authentication <i>mechanism</i>'s after <code>des</code> will be ignored by NIS+, except for <code>nisaddcred(1M)</code>. After changing the mechanism configuration, the <code>keyserv(1M)</code> daemon must be restarted. Note that doing so will remove encryption keys stored by the running <code>keyserv</code> process. This means that a <code>reboot</code> usually is the safest option when the mechanism configuration has been changed. The following mechanisms are available: <table><tr><th>Authentication <i>mechanism</i></th><th>Authentication Flavor</th></tr><tr><td>des</td><td>AUTH_DES</td></tr><tr><td>dh640-0</td><td>RPCSEC_GSS using 640-bit Diffie-Hellman keys</td></tr><tr><td>dh1024-0</td><td>RPCSEC_GSS using 1024-bit Diffie-Hellman keys</td></tr></table> If no mechanisms are specified, then a list of currently configured mechanisms is printed.	Authentication <i>mechanism</i>	Authentication Flavor	des	AUTH_DES	dh640-0	RPCSEC_GSS using 640-bit Diffie-Hellman keys	dh1024-0	RPCSEC_GSS using 1024-bit Diffie-Hellman keys
Authentication <i>mechanism</i>	Authentication Flavor								
des	AUTH_DES								
dh640-0	RPCSEC_GSS using 640-bit Diffie-Hellman keys								
dh1024-0	RPCSEC_GSS using 1024-bit Diffie-Hellman keys								
OPTIONS	-v Displays a verbose table listing the currently configured authentication mechanisms.								
EXAMPLES	EXAMPLE 1 Configuring a System with only RPCSEC_GSS Authentication Flavor To configure a system to use only the RPCSEC_GSS authentication flavor with 640-bit Diffie-Hellman keys, execute the following as root: <pre>example# /usr/lib/nis/nisauthconf dh640-0</pre> EXAMPLE 2 Configuring a System with both RPCSEC_GSS and AUTH_DES Authentication Flavors To configure a system to use both RPCSEC_GSS (with 640-bit Diffie-Hellman keys) and AUTH_DES authentication flavors: <pre>example# /usr/lib/nis/nisauthconf dh640-0 des</pre>								

EXAMPLE 3 Transitioning to Other Authentication Flavors

The following example can be used while adding credentials for a new mechanism before NIS+ is authenticating with the new mechanism:

```
example# /usr/lib/nis/nisauthconf des dh640-0
```

Note that except for nisaddcred(1M), NIS+ will not use mechanisms that follow 'des.'

EXIT STATUS The following exit values are returned:

0 Successful completion.
1 An error occurred.

FILES /etc/rpcsec/nisplussec.conf
NIS+ authentication configuration file. This file may change or be removed in future versions of Solaris.

NOTES A NIS+ client of a server that is configured for either dh640-0 or dh1024-0 must run Solaris 7 or later, even if the server is also configured with des.

NIS+ might not be supported in future releases of the Solaris™ Operating Environment. Tools to aid the migration from NIS+ to LDAP are available in the Solaris 9 operating environment. For more information, visit <http://www.sun.com/directory/nisplus/transition.html>.

nisbackup(1M)

NAME	<code>nisbackup</code> – backup NIS+ directories
SYNOPSIS	<code>nisbackup</code> [-v] <i>backup-dir</i> <i>directory...</i> <code>nisbackup</code> [-v] -a <i>backup-dir</i>
DESCRIPTION	<code>nisbackup</code> backs up a NIS+ directory object on a NIS+ master server. Updates to the NIS+ database will be temporarily disabled while <code>nisbackup</code> is running. The <i>backup-dir</i> is a UNIX directory that must exist prior to running <code>nisbackup</code>. The <code>nisbackup</code> command can be used to backup an individual NIS+ directory object or all (-a) of the NIS+ directory objects served by a master server. The NIS+ directory objects being backed up will be placed into subdirectories under the <i>backup-dir</i> directory. These subdirectories are named according to the NIS+ directory object they contain. <code>nisbackup</code> operates on individual NIS+ directory objects (for example, <code>org_dir.wiz.com</code>). This allows an administrator to selectively backup specific directories. The <code>rpc.nisd(1M)</code> process must be running on the master server with a stable NIS+ database for <code>nisbackup</code> to complete. <code>nisbackup</code> will not attempt to correct any corruption in the NIS+ database, so it is important that backups be done regularly as part of the NIS+ administration. The first synopsis is used to backup a single NIS+ directory object or a list of NIS+ directory objects. The objects can be partially qualified or fully qualified. The machine on which the command is executing must be the master for the NIS+ directory objects specified. The second synopsis will backup all of the NIS+ directory objects that are served by this master. The -a option is the recommended method of backing up a master server, since it will backup all NIS+ directory objects that are served by this master. If this server is a master server for more than one domain, the backup will include NIS+ directories that belong to all of the domains served. Individual NIS+ directory objects can be selected for restoring from a <i>backup-dir</i> created with the -a option. See <code>nisrestore(1M)</code>. The -a option only includes directory objects for which this server is the master. It is possible, but not recommended, to configure a master server as a replica for other domains. The objects belonging to those replicated domains will not be backed up with the -a option. The backup of replicated objects must be run on the master server for those objects. Do not use the same <i>backup-dir</i> to backup different master servers. Each master server must have its own <i>backup-dir</i>. <code>nisbackup</code> will set the <code>rpc.nisd(1M)</code> to read only mode, which will disable updates to the NIS+ database. This is necessary to ensure the consistency of the backup. For this reason, <code>nisbackup</code> should not be run while large numbers of updates are being applied to the NIS+ database. Update utilities such as <code>nisaddent(1M)</code> should not be run simultaneously with <code>nisbackup</code>.

OPTIONS	-a	Creates a backup of all NIS+ directory objects for which this server is a master.
	-v	Verbose option. Additional output will be produced and sent to syslog(3C) upon execution of the command (see syslog.conf(4)).
OPERANDS	<i>backup-dir</i>	The directory into which the subdirectories containing the backed up objects are placed. This must be created prior to running nisbackup.
	<i>directory</i>	The NIS+ directory object(s) being backed up.
EXAMPLES	EXAMPLE 1 Backup of the <i>org_dir</i> NIS+ directory object of the domain <i>foo.com</i> on a master server to a directory named <i>/backup</i> To backup the <i>org_dir</i> NIS+ directory object of the domain <i>foo.com</i> on a master server to a directory named <i>/backup</i>: <pre>master_server# nisbackup /backup org_dir.foo.com.</pre>	
	EXAMPLE 2 Backup of the entire NIS+ domain <i>foo.com</i> to a directory named <i>/backup</i> To backup the entire NIS+ domain <i>foo.com</i> to a directory named <i>/backup</i>: <pre>master_server# nisbackup /backup foo.com. \ org_dir.foo.com. groups_dir.foo.com. \ ctx_dir.foo.com.</pre>	
	EXAMPLE 3 Backup of an entire NIS+ database to a backup directory named <i>/backup</i> To backup an entire NIS+ database to a backup directory named <i>/backup</i>: <pre>master_server# nisbackup -a /backup</pre>	
EXIT STATUS	0	Successful completion.
	1	An error occurred.
FILES	<i>/backup-dir/backup_list</i> This ascii file contains a list of all the objects contained in this <i>backup-dir</i> directory.	
	<i>/backup-dir/directory-object</i> A subdirectory that is created in the <i>backup-dir</i> that contains the NIS+ directory-object backup.	
	<i>/backup-dir/directory-object/data</i> A subdirectory that contains the data files that are part of the NIS+ directory-object backup.	
	<i>/backup-dir/directory-object/last.upd</i> This data file contains timestamp information about the directory-object.	

nisbackup(1M)

/backup-dir/directory-object/data.dict

A NIS+ data dictionary for all of the objects contained in the NIS+ directory-object backup.

NAME	nis_cachemgr – NIS+ utility to cache location information about NIS+ servers		
SYNOPSIS	/usr/sbin/nis_cachemgr [-i] [-v]		
DESCRIPTION	The <code>nis_cachemgr</code> daemon maintains a cache of NIS+ directory objects and active servers for domains. It is responsible for locating servers for a domain on behalf of client processes. This improves performance because only one process has to search for servers. The cache contains location information necessary to contact the NIS+ servers. This includes transport addresses, information needed to authenticate the server, and a time to live field which gives a hint on how long the directory object can be cached. The cache helps to improve the performance of the clients that are traversing the NIS+ name space. <code>nis_cachemgr</code> should be running on all the machines that are using NIS+. However, it is not required that the <code>nis_cachemgr</code> program be running in order for NIS+ requests to be serviced. The cache maintained by this program is shared by all the processes that access NIS+ on a machine. The cache is maintained in a file that is memory mapped by all the processes. See <code>mmap(2)</code>. On start up, <code>nis_cachemgr</code> initializes the cache from the cold start file and preserves unexpired entries that already exist in the cache file. See <code>nisinit(1M)</code>. Thus, the cache survives machine reboots. The <code>nis_cachemgr</code> program is normally started from a system startup script. <code>nisshowcache(1M)</code> can be used to look at the cached objects and active servers. The <code>nisprefadm(1M)</code> command can be used to control which NIS+ servers the <code>nis_cachemgr</code> program will try to select. The <code>nis_cachemgr</code> program makes NIS+ requests under the NIS+ principal name of the host on which it runs. Before running <code>nis_cachemgr</code>, security credentials for the host should be added to the <code>cred.org_dir</code> table in the host's domain using <code>nisaddcred(1M)</code>. Credentials of type DES will be needed if the NIS+ service is operating at security level 2 (see <code>rpc.nisd(1M)</code>). See the DIAGNOSTICS section, below. Additionally, a "keylogin -r" should be done on the machine.		
OPTIONS	-i Force <code>nis_cachemgr</code> to ignore the previous cache file and reinitialize the cache from just the cold start file. By default, the cache manager initializes itself from both the cold start file and the old cache file, thereby maintaining the entries in the cache across machine reboots. -v This flag sets verbose mode. In this mode, the <code>nis_cachemgr</code> program logs not only errors and warnings, but also additional status messages. The additional messages are logged using <code>syslog(3C)</code> with a priority of <code>LOG_INFO</code>.		
FILES	<code>/var/nis/NIS_SHARED_DIRCACHE</code>	the shared cache file	
	<code>/var/nis/NIS_COLD_START</code>	the coldstart file	
	<code>/etc/init.d/rpc</code>	initialization scripts for NIS+	

nis_cachemgr(1M)

ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

SEE ALSO

`keylogin(1)`, `nisaddcred(1M)`, `nisinit(1M)`, `nisprefadm(1M)`, `nisshowcache(1M)`, `rpc.nisd(1M)`, `mmap(2)`, `rpc(3NSL)`, `syslog(3C)`, `nisfiles(4)`, `attributes(5)`

DIAGNOSTICS

The `nis_cachemgr` daemon logs error messages and warnings using `syslog(3C)`. Error messages are logged to the `DAEMON` facility with a priority of `LOG_ERR`. Warning messages are logged with a priority of `LOG_WARNING`. Additional status messages can be obtained using the `-v` option.

NOTES

NIS+ might not be supported in future releases of the Solaris™ Operating Environment. Tools to aid the migration from NIS+ to LDAP are available in the Solaris 9 operating environment. For more information, visit <http://www.sun.com/directory/nisplus/transition.html>.

NAME	nisclient – initialize NIS+ credentials for NIS+ principals
SYNOPSIS	<pre> /usr/lib/nis/nisclient -c [-x] [-o] [-v] [-l <network_password>] [-d <NIS+_domain>] client_name... /usr/lib/nis/nisclient -i [-x] [-v] -h <NIS+_server_host> [-a <NIS+_server_addr>] [-k <key_domain>] [-d <NIS+_domain>] [-s 0 2] /usr/lib/nis/nisclient -u [-x] [-v] /usr/lib/nis/nisclient -r [-x] </pre>
DESCRIPTION	The nisclient shell script can be used to: ■ create NIS+ credentials for hosts and users ■ initialize NIS+ hosts and users ■ restore the network service environment NIS+ credentials are used to provide authentication information of NIS+ clients to NIS+ service. Use the first synopsis (-c option) to create individual NIS+ credentials for hosts or users. You must be logged in as a NIS+ principal in the domain for which you are creating the new credentials. You must also have write permission to the local "cred" table. The <i>client_name</i> argument accepts any valid host or user name in the NIS+ domain (for example, the <i>client_name</i> must exist in the hosts or passwd table). nisclient verifies each <i>client_name</i> against both the host and passwd tables, then adds the proper NIS+ credentials for hosts or users. Note that if you are creating NIS+ credentials outside of your local domain, the host or user must exist in the host or passwd tables in both the local and remote domains. By default, nisclient will not overwrite existing entries in the credential table for the hosts and users specified. To overwrite, use the -o option. After the credentials have been created, nisclient will print the command that must be executed on the client machine to initialize the host or the user. The -c option requires a network password for the client which is used to encrypt the secret key for the client. You can either specify it on the command line with the -l option or the script will prompt you for it. You can change this network password later with passwd(1) or chkey(1). nisclient -c is not intended to be used to create NIS+ credentials for all users and hosts which are defined in the passwd and hosts tables. To define credentials for all users and hosts, use nispopulate(1M). Use the second synopsis (-i option) to initialize a NIS+ client machine. The -i option can be used to convert machines to use NIS+ or to change the machine's domainname. You must be logged in as super-user on the machine that is to become a NIS+ client. Your administrator must have already created the NIS+ credential for this host by using nisclient -c or nispopulate -C. You will need the network password your administrator created. nisclient will prompt you for the network password to decrypt your secret key and then for this machine's root login password to generate a

`nisclient(1M)`

new set of secret/public keys. If the NIS+ credential was created by your administrator using `nisclient -c`, then you can simply use the initialization command that was printed by the `nisclient` script to initialize this host instead of typing it manually.

To initialize an unauthenticated NIS+ client machine, use the `-i` option with `-s 0`. With these options, the `nisclient -i` option will not ask for any passwords.

During the client initialization process, files that are being modified are backed up as `files.no_nisplus`. The files that are usually modified during a client initialization are: `/etc/defaultdomain`, `/etc/nsswitch.conf`, `/etc/inet/hosts`, and, if it exists, `/var/nis/NIS_COLD_START`. Notice that a file will not be saved if a backup file already exists.

The `-i` option does not set up a NIS+ client to resolve hostnames using DNS. Please refer to the DNS documentation for information on setting up DNS. (See `resolv.conf(4)`).

It is not necessary to initialize either NIS+ root master servers or machines that were installed as NIS+ clients using `suninstall(1M)`.

Use the third synopsis (`-u` option) to initialize a NIS+ user. You must be logged in as the user on a NIS+ client machine in the domain where your NIS+ credentials have been created. Your administrator should have already created the NIS+ credential for your username using `nisclient -c` or `nispopulate(1M)`. You will need the network password your administrator used to create the NIS+ credential for your username. `nisclient` will prompt you for this network password to decrypt your secret key and then for your login password to generate a new set of secret/public keys.

Use the fourth synopsis (`-r` option) to restore the network service environment to whatever you were using before `nisclient -i` was executed. You must be logged in as super-user on the machine that is to be restored. The restore will only work if the machine was initialized with `nisclient -i` because it uses the backup files created by the `-i` option.

Reboot the machine after initializing a machine or restoring the network service.

OPTIONS The following options are supported:

<code>-a <NIS+_server_addr></code>	Specifies the IP address for the NIS+ server. This option is used <i>only</i> with the <code>-i</code> option.
<code>-c</code>	Adds DES credentials for NIS+ principals.
<code>-d <NIS+_domain></code>	Specifies the NIS+ domain where the credential should be created when used in conjunction with the <code>-c</code> option. It specifies the name for the new NIS+ domain when used in conjunction with the <code>-i</code> option. The default is your current domainname.

-h <NIS+_server_host>	Specifies the NIS+ server's hostname. This option is used <i>only</i> with the -i option.
-i	Initializes a NIS+ client machine.
-l <network_password>	Specifies the network password for the clients. This option is used <i>only</i> with the -c option. If this option is not specified, the script will prompt you for the network password.
-k <key_domain>	This option specifies the domain where root's credentials are stored. If a domain is not specified, then the system default domain is assumed.
-o	Overwrites existing credential entries. The default is not to overwrite. This is used <i>only</i> with the -c option.
-r	Restores the network service environment.
-s 0 2	Specifies the authentication level for the NIS+ client. Level 0 is for unauthenticated clients and level 2 is for authenticated (DES) clients. The default is to set up with level 2 authentication. This is used <i>only</i> with the -i option. <code>nisclient</code> always uses level 2 authentication (DES) for both -c and -u options. There is no need to run <code>nisclient</code> with -u and -c for level 0 authentication. To configure authentication mechanisms other than DES at security level 2, use <code>nisauthconf(1M)</code> before running <code>nisclient</code> .
-u	Initializes a NIS+ user.
-v	Runs the script in verbose mode.
-x	Turns the "echo" mode on. The script just prints the commands that it would have executed. Notice that the commands are not actually executed. The default is off.

EXAMPLES**EXAMPLE 1** Adding the DES Credential in the Local Domain

To add the DES credential for host `sunws` and user `fred` in the local domain:

```
example% /usr/lib/nis/nisclient -c sunws fred
```

EXAMPLE 2 Adding the DES Credential in a Specified Domain

To add the DES credential for host `sunws` and user `fred` in domain `xyz.sun.com.`:

```
example% /usr/lib/nis/nisclient -c -d xyz.sun.com. sunws fred
```

nisclient(1M)

EXAMPLE 3 Initializing the Host in a Specific Domain

To initialize host sunws as a NIS+ client in domain xyz.sun.com. where nisplus_server is a server for the domain xyz.sun.com.:

```
example# /usr/lib/nis/nisclient -i -h nisplus_server -d xyz.sun.com
```

The script will prompt you for the IP address of nisplus_server if the server is not found in the /etc/hosts file. The -d option is needed only if your current domain name is different from the new domain name.

EXAMPLE 4 Initializing the Host as an Unauthenticated Client in a Specific Domain

To initialize host sunws as an unauthenticated NIS+ client in domain xyz.sun.com. where nisplus_server is a server for the domain xyz.sun.com:

```
example# /usr/lib/nis/nisclient -i -S 0 \  
-h nisplus_server -d xyz.sun.com. -a 129.140.44.1
```

EXAMPLE 5 Initializing the User as a NIS+ principal

To initialize user fred as a NIS+ principal, log in as user fred on a NIS+ client machine.

```
example% /usr/lib/nis/nisclient -u
```

FILES	/var/nis/NIS_COLD_START	This file contains a list of servers, their transport addresses, and their Secure RPC public keys that serve the machines default domain.
	/etc/defaultdomain	The system default domainname.
	/etc/nsswitch.conf	Configuration file for the name-service switch.
	/etc/inet/hosts	Local host name database.

nisinit(1M)

NAME	nisinit – NIS+ client and server initialization utility
SYNOPSIS	nisinit -r nisinit -pY D N <i>parent_domain</i> <i>host</i>... nisinit -c [-k <<i>key_domain</i>>] -H <i>host</i> -B -C <i>coldstart</i>
DESCRIPTION	nisinit initializes a machine to be a NIS+ client or an NIS+ root master server. It may be easier to use nisclient(1M) or nisserver(1M) to accomplish this same task.
OPTIONS	-r Initialize the machine to be a NIS+ root server. This option creates the file /var/nis/data/root.object and initialize it to contain information about this machine. It uses the sysinfo(2) system call to retrieve the name of the default domain. To initialize the machine as an NIS+ root server, it is advisable to use the “-r” option of nisserver(1M), instead of using “nisinit -r”. -p Y D N <i>parent_domain</i> <i>host</i> ... This option is used on a root server to initialize a /var/nis/data/parent.object to make this domain a part of the namespace above it. Only root servers can have parent objects. A parent object describes the namespace “above” the NIS+ root. If this is an isolated domain, this option should not be used. The argument to this option tells the command what type of name server is serving the domain above the NIS+ domain. When clients attempt to resolve a name that is outside of the NIS+ namespace, this object is returned with the error NIS_FOREIGNNS indicating that a name space boundary has been reached. It is up to the client to continue the name resolution process. The parameter <i>parent_domain</i> is the name of the parent domain in a syntax that is native to that type of domain. The list of host names that follow the domain parameter are the names of hosts that serve the parent domain. If there is more than one server for a parent domain, the first host specified should be the master server for that domain. Y Specifies that the parent directory is a NIS version 2 domain. D Specifies that the parent directory is a DNS domain. N Specifies that the parent directory is another NIS+ domain. This option is useful for connecting a pre-existing NIS+ subtree into the global namespace. Note that in the current implementation, the NIS+ clients do not take advantage of the -p feature. Also, since the parent object is currently not replicated on root replica servers, it is recommended that this option not be used. -c Initializes the machine to be a NIS+ client. There are three initialization options available: initialize by coldstart, initialize by hostname, and initialize by broadcast.

The most secure mechanism is to initialize from a trusted coldstart file. The second option is to initialize using a hostname that you specify as a trusted host. The third method is to initialize by broadcast and it is the least secure method.

- C *coldstart* Causes the file *coldstart* to be used as a prototype coldstart file when initializing a NIS+ client. This coldstart file can be copied from a machine that is already a client of the NIS+ namespace. For maximum security, an administrator can encrypt and encode (with `uuencode(1C)`) the coldstart file and mail it to an administrator bringing up a new machine. The new administrator would then decode (with `uudecode`), decrypt, and then use this file with the `nisinit` command to initialize the machine as an NIS+ client. If the coldstart file is from another client in the same domain, the `nisinit` command may be safely skipped and the file copied into the `/var/nis` directory as `/var/nis/NIS_COLD_START`.
- H *hostname* Specifies that the host *hostname* should be contacted as a trusted NIS+ server. The `nisinit` command will iterate over each transport in the `NETPATH` environment variable and attempt to contact `rpcbind(1M)` on that machine. This *hostname* *must* be reachable from the client without the name service running. For IP networks this means that there must be an entry in `/etc/hosts` for this host when `nisinit` is invoked.
- B Specifies that the `nisinit` command should use an IP broadcast to locate a NIS+ server on the local subnet. Any machine that is running the NIS+ service may answer. No guarantees are made that the server that answers is a server of the organization's namespace. If this option is used, it is advisable to check with your system administrator that the server and domain served are valid. The binding information can be dumped to the standard output using the `nisshowcache(1M)` command.

Note that `nisinit -c` will just enable navigation of the NIS+ name space from this client. To make NIS+ your name service, modify the file `/etc/nsswitch.conf` to reflect that. See `nsswitch.conf(4)` for more details.

-k <*key_domain*>

This option specifies the domain where root's credentials are stored. If it is not specified, then the system default domain is assumed. This domain name is used to create the `/var/nis/NIS_COLD_START` file.

RETURN VALUES

`nisinit` returns 0 on success and 1 on failure.

nisinit(1M)

EXAMPLES

EXAMPLE 1 Initializing the Machine as a NIS+ Client using the Host *freddy* as a Trusted Server

This example initializes the machine as an NIS+ client using the host *freddy* as a trusted server.

```
example# nisinit -cH freddy
```

EXAMPLE 2 Setting up a Client using a Trusted Coldstart File

This example sets up a client using a trusted coldstart file.

```
example# nisinit -cC /tmp/colddata
```

EXAMPLE 3 Setting up a Client Using an IP Broadcast

This example sets up a client using an IP broadcast.

```
example# nisinit -cB
```

EXAMPLE 4 Setting up a Root Server

This example sets up a root server.

```
example# nisinit -r
```

ENVIRONMENT VARIABLES

NETPATH This environment variable may be set to the transports to try when contacting the NIS+ server (see `netconfig(4)`). The client library will only attempt to contact the server using connection oriented transports.

FILES

<code>/var/nis/NIS_COLD_START</code>	This file contains a list of servers, their transport addresses, and their Secure RPC public keys that serve the machine's default domain.
<code>/var/nis/data/root.object</code>	This file describes the root object of the NIS+ namespace. It is a standard XDR-encoded NIS+ directory object that can be modified by authorized clients using the <code>nis_modify()</code> interface.
<code>/var/nis/data/parent.object</code>	This file describes the namespace that is logically above the NIS+ namespace. The most common type of parent object is a DNS object. This object contains contact information for a server of that domain.
<code>/etc/hosts</code>	Internet host table.

nisinit(1M)

ATTRIBUTES See attributes(5) for descriptions of the following attributes:

nislmaptest(1M)

NAME	nislmaptest – test NIS+ and LDAP mapping configuration files
SYNOPSIS	nislmaptest [-s -r -d] [-l -t <i>object</i>] [-v] [-i] [-o] [-m <i>conf</i> file] [-x attr=val...] [col=val...]
DESCRIPTION	Use the nislmaptest utility to test NIS+ to LDAP mapping configuration files. See NIS+LDAPmapping(4). The nislmaptest utility uses much of the same internal interface as the rpc.nisd(1M) does to read, add, modify, or delete LDAP data, as specified by the column name and value operand pairs. nislmaptest does not read or modify any of the rpc.nisd(1M) database files. See NOTES for details on important differences between the ways that nislmaptest and rpc.nisd(1M) operate on LDAP data.
OPTIONS	The nislmaptest utility supports the following options: -d Delete data in LDAP. -i Ignore failures when obtaining information from the NIS+ server. This enables nislmaptest to work to some extent, even if the NIS+ server is unreachable, or if the system is not a NIS+ client. However, NIS+ lookups are still attempted, so there may be NIS+ error messages. -l Parse the configuration file into internal data structures, and then print out the configuration per those structures. Note that the printed data is not in configuration file format. -m <i>conf</i>file Specify the name of the NIS+LDAPmapping(4) configuration file. The default directory is /var/nis , and the default mapping file is NIS+LDAPmapping. -o For NIS+ tables, work on the NIS+ object itself, specified by means of the -t option, not on the table entries. -r Replace or add data in LDAP. -s Search for data in LDAP. This is the default. -t <i>object</i> Specify the NIS+ object on which to operate. If the object name is not fully qualified, that is, it does not end in a dot, the value of the nisplusLDAPbaseDomain attribute is appended.

	-v Set the verbose flag. This flag produces extra diagnostic information. -x attr=val... Specify mapping attribute and value pairs to override those obtained by means of the configuration file. Although any attributes defined on <code>NIS+LDAPmapping(4)</code> or <code>rpc.nisd(4)</code> can be specified, the ones that control <code>rpc.nisd(1M)</code> operation have no effect on <code>nisldapmaptest</code>.
OPERANDS	The following operands are supported: col=val... NIS+ column and value pairs used to specify which entries should be looked up, added, modified, or deleted. For additions and modifications, use <code>col=val</code> to specify the new values.
EXAMPLES	EXAMPLE 1 Searching for a User Use the following example to search for the user <code>xyzzy</code> in the LDAP container specified for the <code>passwd.org_dir</code> table. <pre>example% nisldapmaptest -t passwd.org_dir name=xyzzy</pre> EXAMPLE 2 Listing Table Entries Use the following example to list all entries in the container specified for the <code>services.org_dir</code> table. <pre>example% nisldapmaptest -t services.org_dir</pre> EXAMPLE 3 Listing an Object Use the following example to list the <code>services.org_dir</code> object itself, as it is stored in LDAP. <pre>example% nisldapmaptest -o -t services.org_dir</pre> EXAMPLE 4 Modifying a Table Entry Use the following example to modify the membership list of the group <code>grp</code>, in the container specified for the <code>group.org_dir</code> table, to be <code>mem1</code>, <code>mem2</code>, and <code>mem3</code>. <pre>example% nisldapmaptest -r -t group.org_dir name=grp \ members=mem1,mem2,mem3</pre> EXAMPLE 5 Deleting a Table Entry Use the following example to delete the host called <code>bad</code> from the container specified for the <code>hosts.org_dir</code> table. <pre>example% nisldapmaptest -d -t hosts.org_dir name=bad</pre>

`nisldapmaptest(1M)`

EXIT STATUS

The following exit values are returned:

- 0 The requested operation was successful.
- `!= 0` An error occurred.

FILES

`/var/nis/NIS+LDAPmapping.template`
`/etc/default/rpd.nisd`

ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWnisd
Interface Stability	Obsolete

SEE ALSO

`rpc.nisd(1M)`, `NIS+LDAPmapping(4)`, `rpc.nisd(4)`, `attributes(5)`

NOTES

There are several differences between the ways that `nisldapmaptest` and `rpc.nisd` operate:

1. `nisldapmaptest` obtains information about NIS+ by means of the NIS+ API calls, while `rpc.nisd` looks in its internal database. Thus, if the NIS+ server is not available, `nisldapmaptest` may be unable to determine NIS+ object types or table column information.
2. While `nisldapmaptest` can add, modify, or delete LDAP data, it does not modify any NIS+ data.
3. When operating on table entries, if `nisldapmaptest` is unable to obtain the entry from NIS+, it composes LDAP operations using only the supplied `col=val` operands. Depending on the mapping used, this can result in extra LDAP operations, for example, attempting to obtain a DN for add, modify, or delete.
4. The default value for `nisplusLDAPbaseDomain` is the system domain name per `sysinfo(2)` in `nisldapmaptest`, but the internal notion of the domain it serves in `rpc.nisd`. While the two usually are the same, this is not necessarily always the case.
5. When more than one NIS+ entry maps to a single LDAP entry, `nisldapmaptest` may be unable to perform a complete update, unless you make sure that the `col=val` specification picks up all relevant NIS+ entries. For example, if you have the `services.org_dir` NIS+ entries:

cname	name	proto	port
x	x	tcp	12345
x	y	tcp	12345
x	z	tcp	12345

`nisldapmaptest(1M)`

then specifying `cname=x` will pick up all three entries and create or modify the corresponding LDAP entry to have three CN values: `x`, `y`, and `z`. However, specifying `name=x` will match just the first NIS+ entry, and create or modify the LDAP entry to have just one CN: `x`.

nislog(1M)

NAME	nislog – display the contents of the NIS+ transaction log						
SYNOPSIS	/usr/sbin/nislog [-h <i>num</i> -t <i>num</i>] [-v] [<i>directory...</i>]						
DESCRIPTION	nislog displays the contents of the NIS+ server transaction log on the standard output. This command can be used to track changes in the namespace. The <code>/var/nis/trans.log</code> file contains the transaction log maintained by the NIS+ server. When updates occur, they are logged to this file and then propagated to replicas as log transactions. When the log is checkpointed, updates that have been propagated to the replicas are removed. The <code>nislog</code> command can only be run on an NIS+ server by superuser. It displays the log entries for that server only. If <i>directory</i> is not specified, the entire log is searched. Otherwise, only those logs entries that correspond to the specified directories are displayed.						
OPTIONS	<table><tr><td>-h <i>num</i></td><td>Display <i>num</i> transactions from the “head” of the log. If the numeric parameter is 0, only the log header is displayed.</td></tr><tr><td>-t <i>num</i></td><td>Display <i>num</i> transactions from the “tail” of the log. If the numeric parameter is 0, only the log header is displayed.</td></tr><tr><td>-v</td><td>Verbose mode.</td></tr></table>	-h <i>num</i>	Display <i>num</i> transactions from the “head” of the log. If the numeric parameter is 0, only the log header is displayed.	-t <i>num</i>	Display <i>num</i> transactions from the “tail” of the log. If the numeric parameter is 0, only the log header is displayed.	-v	Verbose mode.
-h <i>num</i>	Display <i>num</i> transactions from the “head” of the log. If the numeric parameter is 0, only the log header is displayed.						
-t <i>num</i>	Display <i>num</i> transactions from the “tail” of the log. If the numeric parameter is 0, only the log header is displayed.						
-v	Verbose mode.						
FILES	<code>/var/nis/trans.log</code> transaction log

NAME	nisping – send ping to NIS+ servers	
SYNOPSIS	<pre>/usr/lib/nis/nisping [-uf] [-H <i>hostname</i>] [-r <i>directory</i>] /usr/lib/nis/nisping -C [-a] [-H <i>hostname</i>] [<i>directory</i>]</pre>	
DESCRIPTION	In the first SYNOPSIS line, the <code>nisping</code> command sends a “ping” to all replicas of a NIS+ directory. Once a replica receives a ping, it will check with the master server for the directory to get updates. Prior to pinging the replicas, this command attempts to determine the last update “seen” by a replica and the last update logged by the master. If these two timestamps are the same, the ping is not sent. The <code>-f</code> (force) option will override this feature. Under normal circumstances, NIS+ replica servers get the new information from the master NIS+ server within a short time. Therefore, there should not be any need to use <code>nisping</code>. In the second SYNOPSIS line, the <code>nisping -C</code> command sends a checkpoint request to the servers. If no <i>directory</i> is specified, the home domain, as returned by <code>nisdefaults(1)</code>, is checkpointed. If all directories, served by a given server, have to be checkpointed, then use the <code>-a</code> option. On receiving a checkpoint request, the servers would commit all the updates for the given <i>directory</i> from the table log files to the database files. This command, if sent to the master server, will also send updates to the replicas if they are out of date. This option is needed because the database log files for NIS+ are not automatically checkpointed. <code>nisping</code> should be used at frequent intervals (such as once a day) to checkpoint the NIS+ database log files. This command can be added to the <code>crontab(1)</code> file. If the database log files are not checkpointed, their sizes will continue to grow. If the server specified by the <code>-H</code> option does not serve the directory, then no ping is sent. Per-server and per-directory access restrictions may apply; see <code>nisopaccess(1)</code>. <code>nisping</code> uses <code>NIS_CPTIME</code> and <code>NIS_PING</code> (resync (ping) of replicas), or <code>NIS_CHECKPOINT</code> (for checkpoint). Since the <code>NIS_PING</code> operation does not return a status, the <code>nisping</code> command is typically unable to indicate success or failure for resyncs.	
OPTIONS	-a Checkpoint all directories on the server. -C Send a request to checkpoint, rather than a ping, to each server. The servers schedule to commit all the transactions to stable storage. -H <i>hostname</i> Only the host <i>hostname</i> is sent the ping, checked for an update time, or checkpointed. -f Force a ping, even though the timestamps indicate there is no reason to do so. This option is useful for debugging.	

```
nisping(1M)
```

RETURN VALUES

EXAMPLE 1 Using `nisping`

```
example% nisping
```

This example pings the server *example* which is a replica of the *org_dir.foo.com*. directory:

```
example% nisping -H example org dir.foo.com.
```

This example checkpoints all servers of the *org_dir.bar.com.* directory.

```
example% nisping -C org dir.bar.com.
```

NIS_PATH	If this variable is set, and the NIS+ directory name is not fully qualified, each directory specified will be searched until the directory is found.

See `attributes(5)` for descriptions of the following attributes:

nispopulate(1M)

NAME	nispopulate – populate the NIS+ tables in a NIS+ domain
SYNOPSIS	<pre>/usr/lib/nis/nispopulate -Y [-x] [-f] [-n] [-u] [-v] [-S 0 2] [-l <network_passwd>] [-d <NIS+_domain>] -h <NIS_server_host> [-a <NIS_server_addr>] -y <NIS_domain> [table] ... /usr/lib/nis/nispopulate -F [-x] [-f] [-u] [-v] [-S 0 2] [-d <NIS+_domain>] [-l <network_passwd>] [-p <directory_path>] [table] ... /usr/lib/nis/nispopulate -C [-x] [-f] [-v] [-d <NIS+_domain>] [-l <network_passwd>] [hosts passwd]</pre>
DESCRIPTION	The nispopulate shell script can be used to populate NIS+ tables in a specified domain from their corresponding files or NIS maps. nispopulate assumes that the tables have been created either through nisserver(1M) or nissetup(1M). The table argument accepts standard names that are used in the administration of Solaris systems and non-standard <i>key-value</i> type tables. See nisaddent(1M) for more information on <i>key-value</i> type tables. If the table argument is not specified, nispopulate will automatically populate each of the standard tables. These standard (default) tables are: auto_master, auto_home, ethers, group, hosts, ipnodes, networks, passwd, protocols, services, rpc, netmasks, bootparams, netgroup, aliases and shadow. Note that the shadow table is only used when populating from files. The non-standard tables that nispopulate accepts are those of <i>key-value</i> type. These tables must first be created manually with the nistbladm(1) command. Use the first synopsis (-Y) to populate NIS+ tables from NIS maps. nispopulate uses ypxfrr(1M) to transfer the NIS maps from the NIS servers to the /var/yp/<NIS_domain> directory on the local machine. Then, it uses these files as the input source. Note that <NIS_domain> is case sensitive. Make sure there is enough disk space for that directory. Use the second synopsis (-F) to populate NIS+ tables from local files. nispopulate will use those files that match the table name as input sources in the current working directory or in the specified directory. Note that when populating the hosts, ipnodes, and passwd tables, nispopulate will automatically create the NIS+ credentials for all users and hosts (ipnodes) that are defined in the hosts, ipnodes, and passwd tables, respectively. A network passwd is required to create these credentials. This network password is used to encrypt the secret key for the new users and hosts. This password can be specified using the -l option or it will use the default password, "nisplus". nispopulate will not overwrite any existing credential entries in the credential table. Use nisclient(1M) to overwrite the entries in the cred table. It creates both LOCAL and DES credentials for users, and only DES credentials for hosts. To disable automatic credential creation, specify the "-S 0" option. The third synopsis (-C) is used to populate NIS+ credential table with level 2 authentication (DES) from the hosts, ipnodes and passwd tables of the specified domain. The valid table arguments for this operation are hosts, ipnodes and

passwd. If this argument is not specified then it will use `hosts`, `ipnodes` and `passwd` as the input source. If other authentication mechanisms are configured using `nisauthconf(1M)`, the NIS+ credential table will be loaded with credentials for those mechanisms.

If `nispopulate` was earlier used with `"-S 0"` option, then no credentials were added for the hosts or the users. If later the site decides to add credentials for all users and hosts, then this `(-C)` option can be used to add credentials.

OPTIONS

<code>-a <NIS_server_addr></code>	Specifies the IP address for the NIS server. This option is only used with the <code>-Y</code> option.
<code>-C</code>	Populate the NIS+ credential table from <code>hosts</code> , <code>ipnodes</code> , and <code>passwd</code> tables using DES authentication (security level 2). If other authentication mechanisms are configured using <code>nisauthconf(1M)</code> , the NIS+ credential table will be populated with credentials for those mechanisms.
<code>-d <NIS+_domain.></code>	Specifies the NIS+ domain. The default is the local domain.
<code>-F</code>	Populates NIS+ tables from files.
<code>-f</code>	Forces the script to populate the NIS+ tables without prompting for confirmation.
<code>-h <NIS_server_host></code>	Specifies the NIS server hostname from where the NIS maps are copied from. This is only used with the <code>-Y</code> option. This hostname must be present in the NIS+ <code>hosts</code> or <code>ipnodes</code> table, or in the <code>/etc/hosts</code> or <code>/etc/inet/ipnodes</code> file. If the hostname is not defined, the script will prompt you for its IP address, or you can use the <code>-a</code> option to specify the address manually.
<code>-l <network_passwd></code>	Specifies the network password for populating the NIS+ credential table. This is only used when you are populating the <code>hosts</code> , <code>ipnodes</code> , and <code>passwd</code> tables. The default <code>passwd</code> is <code>"nisplus"</code> .
<code>-n</code>	Does not overwrite local NIS maps in <code>/var/yp/<NISdomain></code> directory if they already exist. The default is to overwrite the existing NIS maps in the local <code>/var/yp/<NISdomain></code> directory. This is only used with the <code>-Y</code> option.
<code>-p <directory_path></code>	Specifies the directory where the files are stored. This is only used with the <code>-F</code> option. The default is the current working directory.

nispopulate(1M)

-s 0 2	Specifies the authentication level for the NIS+ clients. Level 0 is for unauthenticated clients and no credentials will be created for users and hosts in the specified domain. Level 2 is for authenticated (DES) clients and DES credentials will be created for users and hosts in the specified domain. The default is to set up with level 2 authentication (DES). There is no need to run <code>nispopulate</code> with <code>-C</code> for level 0 authentication. Also, if other authentication mechanisms are configured with <code>nisauthconf(1M)</code> , credentials for those mechanisms will also be populated for the NIS+ clients.
-u	Updates the NIS+ tables (ie., adds, deletes, modifies) from either files or NIS maps. This option should be used to bring an NIS+ table up to date when there are only a small number of changes. The default is to add to the NIS+ tables without deleting any existing entries. Also, see the <code>-n</code> option for updating NIS+ tables from existing maps in the <code>/var/yp</code> directory.
-v	Runs the script in verbose mode.
-x	Turns the "echo" mode on. The script just prints the commands that it would have executed. Note that the commands are not actually executed. The default is off.
-Y	Populate the NIS+ tables from NIS maps.
-y <NIS_domain>	Specifies the NIS domain to copy the NIS maps from. This is only used with the <code>-Y</code> option. The default domainname is the same as the local domainname.

EXAMPLES

EXAMPLE 1 Using `nispopulate`

To populate all the NIS+ standard tables in the domain *xyz.sun.com*. from NIS maps of the *yp.sun.COM* domain as input source where host *yp_host* is a YP server of *yp.sun.COM*:

```
nis_server# /usr/lib/nis/nispopulate -Y -y yp.sun.COM \  
-h yp_host -d xyz.sun.com.
```

To update all of the NIS+ standard tables from the same NIS domain and hosts shown above:

```
nis_server# /usr/lib/nis/nispopulate -Y -u -y yp.sun.COM -h yp_host \  
-d xyz.sun.com.
```

To populate the `hosts` table in domain *xyz.sun.com*. from the `hosts` file in the `/var/nis/files` directory and using "somepasswd" as the network password for key encryption:

EXAMPLE 1 Using nispopulate (Continued)

```
nis_server# /usr/lib/nis/nispopulate -F -p \
/var/nis/files -l somepasswd hosts
```

To populate the passwd table in domain *xyz.sun.com*. from the passwd file in the */var/nis/files* directory without automatically creating the NIS+ credentials:

```
nis_server# /usr/lib/nis/nispopulate -F -p /var/nis/files \
-d xys.sun.com. -S 0 passwd
```

To populate the credential table in *domain xyz.sun.com*. for all users defined in the passwd table.

```
nis_server# /usr/lib/nis/nispopulate -C -d xys.sun.com. passwd
```

To create and populate a non-standard key-value type NIS+ table, "private", from the file */var/nis/files/private*: (nispopulate assumes that the private.org_dirkey-value type table has already been created).

```
nis_server# /usr/bin/nistbladm -D access=og=rmcd,nw=r \
-c private key=S,nogw= value=,nogw= private.org.dir
nis_server# /usr/lib/nis/nispopulate -F -p /var/nis/files private
```

**ENVIRONMENT
VARIABLES**

nispopulate normally creates temporary files in the directory */tmp*. You may specify another directory by setting the environment variable *TMPDIR* to your chosen directory. If *TMPDIR* is not a valid directory, then nispopulate will use */tmp*.

FILES

<i>/etc/inet/hosts</i>	local host name database
<i>/etc/inet/ipnodes</i>	local database associating names of nodes with IP addresses
<i>/var/yp</i>	NIS (YP) domain directory
<i>/var/nis</i>	NIS+ domain directory
<i>/tmp</i>

NAME	<code>nisprefadm</code> – NIS+ utility to set server preferences for NIS+ clients
SYNOPSIS	<pre> /usr/bin/nisprefadm -a {-L -G} [-o <i>opt-string</i>] [-d <i>domain</i>] [-C <i>client</i>] <i>server...</i> /usr/bin/nisprefadm -m {-L -G} [-o <i>opt-string</i>] [-d <i>domain</i>] [-C <i>client</i>] <i>oldserver=newserver...</i> /usr/bin/nisprefadm -r {-L -G} [-o <i>opt-string</i>] [-d <i>domain</i>] [-C <i>client</i>] <i>server...</i> /usr/bin/nisprefadm -u {-L -G} [-o <i>opt-string</i>] [-d <i>domain</i>] [-C <i>client</i>] <i>server...</i> /usr/bin/nisprefadm -x {-L -G} [-d <i>domain</i>] [-C <i>client</i>] /usr/bin/nisprefadm -l {-L -G} [-d <i>domain</i>] [-C <i>client</i>] /usr/bin/nisprefadm -F </pre>
DESCRIPTION	<code>nisprefadm</code> defines which servers are to be preferred by NIS+ clients. This information is used by <code>nis_cachemgr</code>(1M) to control the order in which it selects which server to use for a particular domain. On a client system, the cache manager first looks for a local preferred server list in <code>/var/nis</code>. If it doesn't find one, it looks for an entry with its host name in the NIS+ table. Finally, if it doesn't find it there, it looks for an entry for its subnet. By default, <code>nis_cachemgr</code> puts all servers that are on the same subnet as the client system (that is, local servers) are on the preferred server list. In some cases this default preferred server list is inadequate. For example, if all of the servers for a domain are remote, but some are <i>closer</i> than others, the cache manager should try to select the closer one. Because the cache manager has no reliable way to determine the distance to remote servers, <code>nisprefadm</code> is used to provide this information. The preferred server information is stored either globally in a NIS+ table (with the <code>-G</code> option) or locally in a file, <code>/var/nis/client_info</code> (with the <code>-L</code> option). It is preferable to store the information globally so that it can be used by all clients on a subnet. The <code>nis_cachemgr</code> process on a client machine reloads the preferred server information periodically, depending on the machine's setup. If the local file is used, the information is reloaded every 12 hours. If the global table is used, the information is reloaded based on the TTL value of the client information table. This TTL value can be changed using <code>nischttl</code>(1). If you want your changes to take effect immediately, use the <code>nisprefadm -F</code> command. When changing local information (<code>-L</code>), <code>nisprefadm</code> automatically forces <code>nis_cachemgr</code> to reload the information. The cache manager assigns weights to all of the servers on the preferred list. By default, local servers (that is, servers on the same subnet) are given a weight of 0. Other servers are given the weight, "infinite". This can be changed by using the <code>nisprefadm</code> command and giving a weight in parentheses after the server name. When selecting a server for a domain, the cache manager first tries to contact the

`nisprefadm(1M)`

servers with the lowest weight. If it doesn't get a response, it tries the servers with the next lowest weight, and so on. If it fails to get a response from any of the preferred servers, it tries to contact the non-preferred servers.

The use of weights gives fine control over the server selection process, but care must be given to avoid assigning too many different weights. For example, if weights 0, 1, 2, and 3 are used, but all of the servers with weight 0, 1, and 2, are unavailable, then there will be a noticeable delay in selecting a server. This is because the cache manager waits 5 seconds for a response at each weight level before moving on to the next one. As a general rule, one or two weight levels provides a good balance of server selection control and performance.

When specifying a server name, it is not necessary to fully qualify the name. When the cache manager tries to access a domain, it compares the list of servers for the domain with the list of preferred servers. It will find a match if a preferred server name is a prefix of the name of a server for the domain. If a domain is served by two servers with the same prefix, the preferred server name must include enough of the domain name to distinguish the two.

The `nis_cachemgr(1M)` process automatically adds local servers (same subnet as the client) to the preferred server list with a weight of 0. Thus, it is not necessary to specify them, though it does no harm.

If you specify a weight for a server, you probably should quote the parentheses to avoid having the shell interpret them. The following command illustrates this:

```
example% nisprefadm -G -a -C client1 "srv1(2)"
```

In general, `nis_cachemgr` does a fairly good job of selecting servers on its own. Therefore, the use of `nisprefadm` is not usually necessary. Some situations in which it is recommended are:

No local servers, many remote servers

In this case, `nis_cachemgr` needs to choose one of the remote servers. Because it doesn't have information on which is closest, it sends a ping to all of them and then selects the one that responds fastest. This may not always select the best server. If some of the servers are closer to the client than the others, they should be listed as preferred servers so that `nis_cachemgr` will try them first. This reduces the amount of network traffic for selecting a server.

Very remote servers

In some networks there are NIS+ servers that are only reachable through very slow network connections. It is usually best to avoid unnecessary traffic over that connection. If the `pref_type=pref_only` option is set along with preferred servers, then only the preferred servers are contacted for domains they serve. The non-preferred servers are not tried at all; even if all of the preferred servers are unavailable. For domains that are not served by any of the preferred servers, the `pref_only` option is ignored.

OPTIONS	In the SYNOPSIS, when several options are surrounded by braces (that is, by '{' and '}') one of the options must be specified.
-a	Add the specified servers to the preferred server list.
-C <i>client</i>	Store the preferred server information with the key, <i>client</i> . The <i>client</i> can be either a hostname or a subnet number. When a hostname is specified, the preferred server information applies to that host only. When a subnet is specified, the preferred server information applies to all clients on that subnet. The cache manager searches for host specific entries first. It only searches for subnet entries if no host entry is found. If this option is not specified, then the hostname of the machine on which the command is run is used.
-d <i>domain</i>	Specify the <i>domain</i> to which the command is to apply.
-F	Tells <code>nis_cachemgr(1M)</code> to refresh its preferred server information. The program periodically does this anyway, but this option forces it to do the refresh immediately. When updating the local information, <code>nis_cachemgr</code> automatically refreshes the preferred server information.
	This option must be executed as <code>root</code> .
-l	List the current preferred server information.
-L -G	Store the preferred server information locally in the file, <code>/var/nis/client_info</code> (the <code>-L</code> option), or globally in a NIS+ table <code>client.info.org-dir.domain</code> (the <code>-G</code> option). If the information is stored locally, then it only applies to the system on which the command is run. If it is stored globally then it can apply to all systems on a subnet (depending on the value of the <code>-C</code> option).
	The <code>-L</code> option must be run as <code>root</code> .
-m	Modify the preferred server list. The server specified by <i>oldserver</i> is replaced by <i>newserver</i> . This is typically used to change the weight for a server.
-o	Specify additional options to control server selection. Currently the only valid option is <i>pref_type</i> , which can have a value of either <code>all</code> (the default) or <code>pref_only</code> . If the value is <code>all</code> , then the cache manager tries to contact non-preferred servers if all of the preferred servers fail to respond. If <code>pref_only</code> is specified, then it won't try non-preferred servers. The only exception to this is when a domain is not served by any of the preferred servers. In this case, the cache manager ignores the option. This is to avoid requiring that preferred servers be defined for every domain.
-r	Remove the specified servers from the preferred server list.

nisprefadm(1M)

- u Clear the list of preferred servers and then add the specified servers to the preferred server list.
- x Remove the preferred server information completely.

RETURN VALUES nisprefadm returns the following values:

- 0 On success.
- 1 On failure.

EXAMPLES

EXAMPLE 1 Using nisprefadm

This command sets the preferred server list for the system on which it is run:

```
example% nisprefadm -L -a srv1 srv2
```

The information is stored in a file, `/var/nis/client_info`, so it will only affect this one system.

The following command has the same effect, but the information is stored in a NIS+ table in the default domain.

```
example% nisprefadm -G -a srv1 srv2
```

As a system administrator, you might want to set the preferred server information for a client system other than the one you are running the command on. The following command sets the preferred server information for a client system named *client1*:

```
example% nisprefadm -G -a -C client1 srv1 srv2
```

It is common for all client systems on a subnet to use the same set of preferred servers. The following command sets a preferred server list that applies to all clients on subnet, 192.85.18.0:

```
example% nisprefadm -G -a -C 192.85.18.0 srv1 srv2
```

NAME	nisrestore – restore NIS+ directory backup
SYNOPSIS	nisrestore [-fv] <i>backup-dir</i> <i>directory...</i> nisrestore [-fv] -a <i>backup-dir</i> nisrestore -t <i>backup-dir</i>
DESCRIPTION	nisrestore restores an existing backup of a NIS+ directory object that was created using nisbackup(1M). The <i>backup-dir</i> is the UNIX directory that contains the NIS+ backup on the server being restored. The nisrestore command can be used to restore a NIS+ directory object or a complete NIS+ database. It also can be used as an "out of band" fast replication for a new replica server being initialized. The rpc.nisd(1M) daemon must be stopped before running nisrestore. The first synopsis is used to restore a single directory object or a specified list of directory objects. The directory can be partially qualified or fully qualified. The server being restored will be verified against the list of servers serving the directory. If this server is not configured to serve this object, nisrestore will exit with an error. The -f option will override this check and force the operation. The second synopsis will restore all of the directory objects contained in the <i>backup-dir</i>. Again, the server will be validated against the serving list for each of the directory objects in the <i>backup-dir</i>. If one of the objects in the <i>backup-dir</i> are not served by this server, nisrestore will exit with an error. The -f option will override this check and force the operation. The -a option will attempt to restore all NIS+ objects contained in the <i>backup-dir</i>. If any of these objects are not served by the server, nisrestore will exit with an error. If the <i>backup-dir</i> contains objects that are not served by the server, nisrestore must be executed without the -a option and the specific directory objects listed. The -f option will disable verification of the server being configured to serve the objects being restored. This option should be used with care, as data could be inadvertently restored to a server that doesn't serve the restored data. This option is required in the case of restoring a single server domain (master server only) or if the other NIS+ servers are unavailable for NIS+ lookups. The combination of options -f and -a should be used with caution, as no validation of the server serving the restored objects will be done. New replicas can be quickly added to a namespace with the nisrestore command. The steps are as follows. Configure the new replica on the master server (see nisserver(1M)): <pre>master# nisserver -R -h replica</pre> Kill the rpc.nisd server process on the new replica server: <pre>replica# kill rpc.nisd-pid</pre>

nisrestore(1M)

Create a backup of the NIS+ database on the master, which will include the new replica information. See `nisbackup(1M)`. The `/backup` will need to be exported to the new replica. See `share_nfs(1M)`.

```
master# nisbackup -a /backup
```

Restore the backup of the NIS+ database on the new replica. Use the `-f` option if `nisrestore` is unable to lookup the NIS+ objects being restored. The backup should be available through `nfs` or similar means. See `share_nfs(1M)`.

```
replica# nisrestore -f -a //nfs-mnt/backup
```

Restart the `rpc.nisd(1M)` process on the new replica, and the server will immediately be available for service.

OPTIONS	<code>-a</code>	Restores all directory objects included in the <i>backup-dir</i> partition.
	<code>-f</code>	Forces the restoration of a directory without the validation of the server in the directory object's serving list.
	<code>-t</code>	Lists all directory objects contained in <i>backup-dir</i> .
	<code>-v</code>	Verbose option. Additional output will be produced upon execution of the command.

OPERANDS	<i>backup-dir</i>	The UNIX directory that contains the data files for the NIS+ directory objects to be restored.
	<i>directory</i>	The NIS+ directory object(s) to be restored. This can be a fully or partially qualified name.

EXAMPLES **EXAMPLE 1** Restoring the Directory Object on a Replica Server from a Local UFS Partition

To restore the `org_dir` directory object of the domain `foo.com` on a replica server from a local `ufs` partition named `/var/backup`:

```
replica_server# nisrestore /var/backup org_dir.foo.com.
```

EXAMPLE 2 Forcing the Restore of a Backed up NIS+ Namespace to a Replica Server From the Backup Partition

To force the restore of an entire backed up NIS+ namespace to a replica server from the backup partition named `/var/backup`:

```
replica_server# nisrestore -f -a /var/backup
```

EXAMPLE 3 Restoring the Subdomain on a Master Server From a Backup that Includes Other Directory Objects

To restore the subdomain `sub.foo.com` on a master server, from a backup that includes other directory objects:

EXAMPLE 3 Restoring the Subdomain on a Master Server From a Backup that Includes Other Directory Objects (Continued)

```
master_server# nisrestore /var/backup sub.foo.com. \
    org_dir.sub.foo.com. groups_dir.sub.foo.com.
```

EXIT STATUS

0	Successful completion.
1	An error occurred.

FILES

- /backup-dir/backup_list*
This ASCII file contains a list of all the objects contained in this *backup-dir* directory. This information can be displayed with the *-t* option.
- /backup-dir/directory-object*
A subdirectory that is created in the *backup-dir* which contains the directory-object backup.
- /backup-dir/directory-object/data*
A subdirectory that contains the data files that are part of the directory-object backup.
- /backup-dir/directory-object/last.upd*
This data file contains timestamp information about the directory-object.
- /backup-dir/directory-object/data.dict*
A NIS+ data dictionary for all of the objects contained in this directory-object backup.

nisserver(1M)

NAME	nisserver – set up NIS+ servers	
SYNOPSIS	<pre> /usr/lib/nis/nisserver -r [-x] [-f] [-v] [-Y] [-d NIS+_domain] [-g NIS+_groupname] [-l network_password] /usr/lib/nis/nisserver -M [-x] [-f] [-v] [-Y] -d NIS+_domain [-g NIS+_groupname] [-h NIS+_server_host] /usr/lib/nis/nisserver -R [-x] [-f] [-v] [-Y] [-d NIS+_domain] [-h NIS+_server_host] </pre>	
DESCRIPTION	The nisserver shell script can be used to set up a root master, non-root master, and replica NIS+ server with level 2 security (DES). If other authentication mechanisms are configured with nisauthconf(1M), nisserver will set up a NIS+ server using those mechanisms. nisauthconf(1M) should be used before nisserver. When setting up a new domain, this script creates the NIS+ directories (including groups_dir and org_dir) and system table objects for the domain specified. It does not populate the tables. nispopulate(1M) must be used to populate the tables.	
OPTIONS	-d NIS+_domain	Specifies the name for the NIS+ domain. The default is your local domain.
	-f	Forces the NIS+ server setup without prompting for confirmation.
	-g NIS+_groupname	Specifies the NIS+ group name for the new domain. This option is not valid with -R option. The default group is admin.<domain>.
	-h NIS+_server_host	Specifies the hostname for the NIS+ server. It must be a valid host in the local domain. Use a fully qualified hostname (for example, hostx.xyz.sun.com.) to specify a host outside of your local domain. This option is <i>only</i> used for setting up non-root master or replica servers. The default for non-root master server setup is to use the same list of servers as the parent domain. The default for replica server setup is the local hostname.
	-l network_password	Specifies the network password with which to create the credentials for the root master server. This option is <i>only</i> used for master root server setup (-r option). If this option is not specified, the script prompts you for the login password.
	-M	Sets up the specified host as a master server. Make sure that rpc.nisd(1M) is running on the new master server before this command is executed.
	-R	Sets up the specified host as a replica server. Make sure that rpc.nisd is running on the new replica server.

<code>-r</code>	Sets up the server as a root master server. Use the <code>-R</code> option to set up a root replica server.
<code>-v</code>	Runs the script in verbose mode.
<code>-x</code>	Turns the echo mode on. The script just prints the commands that it would have executed. Note that the commands are not actually executed. The default is off.
<code>-Y</code>	Sets up a NIS+ server with NIS-compatibility mode. The default is to set up the server without NIS-compatibility mode.

USAGE Use the first synopsis of the command (`-r`) to set up a root master server. To run the command, you must be logged in as super-user on the server machine.

Use the second synopsis of the command (`-M`) to set up a non-root master server for the specified domain. To run the command, you must be logged in as a NIS+ principal on a NIS+ machine and have write permission to the parent directory of the domain that you are setting up. The new non-root master server machine must already be an NIS+ client (see `nisclient(1M)`) and have the `rpc.nisd(1M)` daemon running.

Use the third synopsis of the command (`-R`) to set up a replica server for both root and non-root domains. To run the command, you must be logged in as a NIS+ principal on a NIS+ machine and have write permission to the parent directory of the domain that you are replicating. The new non-root replica server machine must already be an NIS+ client and have the `rpc.nisd` daemon running.

EXAMPLES **EXAMPLE 1** Setting up Servers

To set up a root master server for domain `sun.com.`:

```
root_server# /usr/lib/nis/nisserver -r -d sun.com.
```

For the following examples make sure that the new servers are NIS+ clients and that `rpc.nisd` is running on these hosts before executing `nisserver`. To set up a replica server for the `sun.com.` domain on host *sunreplica*:

```
root_server# /usr/lib/nis/nisserver -R -d sun.com. -h sunrep
```

To set up a non-root master server for domain *xyz.sun.com.* on host *sunxyz* with the NIS+ groupname as *admin-mgr.xyz.sun.com.*:

```
root_server# /usr/lib/nis/nisserver -M -d xyz.sun.com. -h sunxyz \
-g admin-mgr.xyz.sun.com.
```

To set up a non-root replica server for domain *xyz.sun.com.* on host *sunabc*:

```
sunxyz# /usr/lib/nis/nisserver -R -d xyz.sun.com. -h sunabc
```

NAME	nissetup – initialize a NIS+ domain				
SYNOPSIS	<code>/usr/lib/nis/nissetup [-Y] [domain]</code>				
DESCRIPTION	nissetup is a shell script that sets up a NIS+ domain to service clients that wish to store system administration information in a domain named <i>domain</i>. This domain should already exist prior to executing this command. See <code>nismkdir(1)</code> and <code>nisinit(1M)</code>. A NIS+ domain consists of a NIS+ directory and its subdirectories: <code>org_dir</code> and <code>groups_dir</code>. <code>org_dir</code> stores system administration information and <code>groups_dir</code> stores information for group access control. nissetup creates the subdirectories <code>org_dir</code> and <code>groups_dir</code> in <i>domain</i>. Both subdirectories will be replicated on the same servers as the parent domain. After the subdirectories are created, nissetup creates the default tables that NIS+ serves. These are <code>auto_master</code>, <code>auto_home</code>, <code>bootparams</code>, <code>cred</code>, <code>ethers</code>, <code>group</code>, <code>hosts</code>, <code>mail_aliases</code>, <code>netmasks</code>, <code>networks</code>, <code>passwd</code>, <code>protocols</code>, <code>rpc</code>, <code>services</code>, and <code>timezone</code>. The nissetup script uses the <code>nistbladm(1)</code> command to create these tables. The script can be easily customized to add site specific tables that are created at setup time. This command is normally executed just once per domain. While this command creates the default tables, it does not initialize them with data. This is accomplished with the <code>nisaddent(1M)</code> command. It is easier to use the <code>nissERVER(1M)</code> script to create subdirectories and the default tables.				
OPTIONS	<code>-Y</code> Specify that the domain will be served as both a NIS+ domain as well as an NIS domain using the backward compatibility flag. This will set up the domain to be less secure by making all the system tables readable by unauthenticated clients as well.

nisshowcache(1M)

NAME	nisshowcache – NIS+ utility to print out the contents of the shared cache file				
SYNOPSIS	/usr/lib/nis/nisshowcache [-v]				
DESCRIPTION	nisshowcache prints out the contents of the per-machine NIS+ directory cache that is shared by all processes accessing NIS+ on the machine. By default, nisshowcache only prints out the directory names in the cache along with the list of active servers. The shared cache is maintained by nis_cachemgr(1M).				
OPTIONS	-v Verbose mode. Print out the contents of each directory object, including the information on the server name and its universal addresses.				
FILES	/var/nis/NIS_SHARED_DIRCACHE				
ATTRIBUTES	See attributes(5) for descriptions of the following attributes: <table><tr><th>ATTRIBUTE TYPE</th><th>ATTRIBUTE VALUE</th></tr><tr><td>Availability</td><td>SUNWcsu</td></tr></table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	Availability	SUNWcsu
ATTRIBUTE TYPE	ATTRIBUTE VALUE				
Availability	SUNWcsu				
SEE ALSO	nis_cachemgr(1M), syslogd(1M), nisfiles(4), attributes(5)				
DIAGNOSTICS	Error messages are sent to the syslogd(1M) daemon.				
NOTES	NIS+ might not be supported in future releases of the Solaris™ Operating Environment. Tools to aid the migration from NIS+ to LDAP are available in the Solaris 9 operating environment. For more information, visit http://www.sun.com/directory/nisplus/transition.html .				

NAME	nisstat – report NIS+ server statistics																
SYNOPSIS	<code>/usr/lib/nis/nisstat [-H <i>host</i>] [<i>directory</i>]</code>																
DESCRIPTION	The <code>nisstat</code> command queries a NIS+ server for various statistics about its operations. These statistics may vary between implementations and from release to release. Not all statistics are available from all servers. If you request a statistic from a server that does not support that statistic, it is never a fatal error. The message “unknown statistic” is returned. By default, statistics are fetched from the server(s) of the NIS+ directory for the default domain. If <i>directory</i> is specified, servers for that directory are queried. Supported statistics for this release are as follows: <table> <tr> <td><i>root server</i></td><td>This reports whether the server is a root server.</td></tr> <tr> <td><i>NIS compat mode</i></td><td>This reports whether the server is running in NIS compat mode.</td></tr> <tr> <td><i>DNS forwarding in NIS mode</i></td><td>This reports whether the server in NIS compat mode will forward host lookup calls to DNS.</td></tr> <tr> <td><i>security level</i></td><td>This reports the security level of this server.</td></tr> <tr> <td><i>serves directories</i></td><td>This lists the directories served by this server.</td></tr> <tr> <td><i>Operations</i></td><td> This statistic returns results in the form: <code>OP=<i>opname</i> : C=<i>calls</i> : E=<i>errors</i> : T=<i>micros</i></code> Where <i>opname</i> is replaced by the RPC procedure name or operation, <i>calls</i> is the number of calls to this procedure that have been made since the server started running. <i>errors</i> is the number of errors that have occurred while processing a call, and <i>micros</i> is the average time in microseconds to complete the last 16 calls. </td></tr> <tr> <td><i>Directory Cache</i></td><td>This statistic reports the number of calls to the internal directory object cache, the number of hits on that cache, the number of misses, and the hit rate percentage.</td></tr> <tr> <td><i>Group Cache</i></td><td>This statistic reports the number of calls to the internal NIS+ group object cache, the number of hits on that cache, the number of misses, and the hit rate percentage.</td></tr> </table>	<i>root server</i>	This reports whether the server is a root server.	<i>NIS compat mode</i>	This reports whether the server is running in NIS compat mode.	<i>DNS forwarding in NIS mode</i>	This reports whether the server in NIS compat mode will forward host lookup calls to DNS.	<i>security level</i>	This reports the security level of this server.	<i>serves directories</i>	This lists the directories served by this server.	<i>Operations</i>	This statistic returns results in the form: <code>OP=<i>opname</i> : C=<i>calls</i> : E=<i>errors</i> : T=<i>micros</i></code> Where <i>opname</i> is replaced by the RPC procedure name or operation, <i>calls</i> is the number of calls to this procedure that have been made since the server started running. <i>errors</i> is the number of errors that have occurred while processing a call, and <i>micros</i> is the average time in microseconds to complete the last 16 calls.	<i>Directory Cache</i>	This statistic reports the number of calls to the internal directory object cache, the number of hits on that cache, the number of misses, and the hit rate percentage.	<i>Group Cache</i>	This statistic reports the number of calls to the internal NIS+ group object cache, the number of hits on that cache, the number of misses, and the hit rate percentage.
<i>root server</i>	This reports whether the server is a root server.																
<i>NIS compat mode</i>	This reports whether the server is running in NIS compat mode.																
<i>DNS forwarding in NIS mode</i>	This reports whether the server in NIS compat mode will forward host lookup calls to DNS.																
<i>security level</i>	This reports the security level of this server.																
<i>serves directories</i>	This lists the directories served by this server.																
<i>Operations</i>	This statistic returns results in the form: <code>OP=<i>opname</i> : C=<i>calls</i> : E=<i>errors</i> : T=<i>micros</i></code> Where <i>opname</i> is replaced by the RPC procedure name or operation, <i>calls</i> is the number of calls to this procedure that have been made since the server started running. <i>errors</i> is the number of errors that have occurred while processing a call, and <i>micros</i> is the average time in microseconds to complete the last 16 calls.																
<i>Directory Cache</i>	This statistic reports the number of calls to the internal directory object cache, the number of hits on that cache, the number of misses, and the hit rate percentage.																
<i>Group Cache</i>	This statistic reports the number of calls to the internal NIS+ group object cache, the number of hits on that cache, the number of misses, and the hit rate percentage.																

nisstat(1M)

	<i>Static Storage</i>	This statistic reports the number of bytes the server has allocated for its static storage buffers.				
	<i>Dynamic Storage</i>	This statistic reports the amount of heap the server process is currently using.				
	<i>Uptime</i>	This statistic reports the time since the service has been running.				
	Per-server and per-directory access restrictions may apply. See <code>nisopaccess(1)</code> . <code>nisstat</code> uses <code>NIS_STATUS</code> .					
	OPTIONS	<code>-H host</code>	Normally all servers for the directory are queried. With this option, only the machine named <i>host</i> is queried. If the named machine does not serve the directory, no statistics are returned.			
ENVIRONMENT VARIABLES	<code>NIS_PATH</code>	If this variable is set, and the NIS+ directory name is not fully qualified, each directory specified will be searched until the directory is found. See <code>nisdefaults(1)</code> .				
ATTRIBUTES	See <code>attributes(5)</code> for descriptions of the following attributes:					
	<table><tr><th>ATTRIBUTE TYPE</th><th>ATTRIBUTE VALUE</th></tr><tr><td>Availability</td><td>SUNWnisu</td></tr></table>		ATTRIBUTE TYPE	ATTRIBUTE VALUE	Availability	SUNWnisu
ATTRIBUTE TYPE	ATTRIBUTE VALUE					
Availability	SUNWnisu					
SEE ALSO	<code>nisdefaults(1)</code> , <code>nisopaccess(1)</code> , <code>attributes(5)</code>					
NOTES	NIS+ might not be supported in future releases of the Solaris™ Operating Environment. Tools to aid the migration from NIS+ to LDAP are available in the Solaris 9 operating environment. For more information, visit http://www.sun.com/directory/nisplus/transition.html .					

NAME	nisupdkeys – update the public keys in a NIS+ directory object	
SYNOPSIS	<pre>/usr/lib/nis/nisupdkeys [-a -C] [-H <i>host</i>] [<i>directory</i>]</pre> <pre>/usr/lib/nis/nisupdkeys -s [-a -C] -H <i>host</i></pre>	
DESCRIPTION	This command updates the public keys in an NIS+ directory object. When the public key(s) for a NIS+ server are changed, <i>nisupdkeys</i> reads a directory object and attempts to get the public key data for each server of that directory. These keys are placed in the directory object and the object is then modified to reflect the new keys. If <i>directory</i> is present, the directory object for that directory is updated. Otherwise the directory object for the default domain is updated. The new key must be propagated to all directory objects that reference that server. On the other hand, <i>nisupdkeys -s</i> gets a list of all the directories served by <i>host</i> and updates those directory objects. This assumes that the caller has adequate permission to change all the associated directory objects. The list of directories being served by a given server can also be obtained by <i>nisstat</i>(1M). Before you do this operation, make sure that the new address/public key has been propagated to all replicas. If multiple authentication mechanisms are configured using <i>nisauthconf</i>(1M), then the keys for those mechanisms will also be updated or cleared. The user executing this command must have modify access to the directory object for it to succeed. The existing directory object can be displayed with the <i>niscat</i>(1) command using the <i>-o</i> option. This command does not update the directory objects stored in the <i>NIS_COLD_START</i> file on the NIS+ clients. If a server is also the root master server, then <i>nisupdkeys -s</i> cannot be used to update the root directory.	
OPTIONS	-a	Update the universal addresses of the NIS+ servers in the directory object. Currently, this only works for the TCP/IP family of transports. This option should be used when the IP address of the server is changed. The server's new address is resolved using <i>getipnodebyname</i> (3SOCKET) on this machine. The <i>/etc/nsswitch.conf</i> file must point to the correct source for <i>ipnodes</i> and <i>hosts</i> for this resolution to work.
	-C	Specify to clear rather than set the public key(s). Communication with a server that has no public key(s) does not require the use of secure RPC.
	-H <i>host</i>	Limit key changes only to the server named <i>host</i> . If the hostname is not a fully qualified NIS+ name, then it is assumed to be a host in the default domain. If the named host does not serve the directory, no action is taken.
	-s	Update all the NIS+ directory objects served by the specified server. This assumes that the caller has adequate access rights to

nisupdkeys(1M)

change all the associated directory objects. If the NIS+ principal making this call does not have adequate permissions to update the directory objects, those particular updates will fail and the caller will be notified. If the `rpc.nisd` on *host* cannot return the list of servers it serves, the command will print an error message. The caller would then have to invoke `nisupdkeys` multiple times (as in the first synopsis), once per NIS+ directory that it serves.

EXAMPLES

EXAMPLE 1 Using `nisupdkeys`

The following example updates the keys for servers of the *foo.bar.* domain.

```
example% nisupdkeys foo.bar.
```

This example updates the key(s) for host *fred* that serves the *foo.bar.* domain.

```
example% nisupdkeys -H fred foo.bar.
```

This example clears the public key(s) for host *wilma* in the *foo.bar.* directory.

```
example% nisupdkeys -CH wilma foo.bar.
```

This example updates the public key(s) in all directory objects that are served by the host *wilma*.

```
example% nisupdkeys -s -H wilma
```

NAME	nlsadmin – network listener service administration						
SYNOPSIS	<pre> /usr/sbin/nlsadmin -x /usr/sbin/nlsadmin [options] net_spec /usr/sbin/nlsadmin [options] -N port_monitor_tag /usr/sbin/nlsadmin -V /usr/sbin/nlsadmin -c cmd -o streamname [-p modules] [-A address -D] [-R prognum : versnum] </pre>						
DESCRIPTION	nlsadmin is the administrative command for the network listener process(es) on a machine. Each network has at least one instance of the network listener process associated with it; each instance (and thus, each network) is configured separately. The listener process “listens” to the network for service requests, accepts requests when they arrive, and invokes servers in response to those service requests. The network listener process may be used with any network (more precisely, with any connection-oriented transport provider) that conforms to the transport provider specification. nlsadmin can establish a listener process for a given network, configure the specific attributes of that listener, and start and kill the listener process for that network. nlsadmin can also report on the listener processes on a machine, either individually (per network) or collectively. <i>net_spec</i> represents a particular listener process. Specifically, <i>net_spec</i> is the relative path name of the entry under /dev for a given network (that is, a transport provider). <i>address</i> is a transport address on which to listen and is interpreted using a syntax that allows for a variety of address formats. By default, <i>address</i> is interpreted as the symbolic ASCII representation of the transport address. An <i>address</i> preceded by \x will let you enter an address in hexadecimal notation. Note that <i>address</i> must appear as a single word to the shell, thus it must be quoted if it contains any blanks. Changes to the list of services provided by the listener or the addresses of those services are put into effect immediately.						
OPTIONS	nlsadmin may be used with the following combinations of options and arguments: <table> <tr> <td>-x</td><td>Report the status of all of the listener processes installed on this machine.</td></tr> <tr> <td><i>net_spec</i></td><td>Print the status of the listener process for <i>net_spec</i>.</td></tr> <tr> <td>-q <i>net_spec</i></td><td>Query the status of the listener process for the specified network, and reflects the result of that query in its exit code. If a listener process is active, nlsadmin will exit with a status of 0; if no process is active, the exit</td></tr> </table>	-x	Report the status of all of the listener processes installed on this machine.	<i>net_spec</i>	Print the status of the listener process for <i>net_spec</i> .	-q <i>net_spec</i>	Query the status of the listener process for the specified network, and reflects the result of that query in its exit code. If a listener process is active, nlsadmin will exit with a status of 0; if no process is active, the exit
-x	Report the status of all of the listener processes installed on this machine.						
<i>net_spec</i>	Print the status of the listener process for <i>net_spec</i> .						
-q <i>net_spec</i>	Query the status of the listener process for the specified network, and reflects the result of that query in its exit code. If a listener process is active, nlsadmin will exit with a status of 0; if no process is active, the exit						

nlsadmin(1M)

	code will be 1; the exit code will be greater than 1 in case of error.
<code>-v net_spec</code>	Print a verbose report on the servers associated with <i>net_spec</i> , giving the service code, status, command, and comment for each. It also specifies the <code>uid</code> the server will run as and the list of modules to be pushed, if any, before the server is started.
<code>-z service_code net_spec</code>	Print a report on the server associated with <i>net_spec</i> that has service code <i>service_code</i> , giving the same information as in the <code>-v</code> option.
<code>-q -z service_code net_spec</code>	Query the status of the service with service code <i>service_code</i> on network <i>net_spec</i> , and exits with a status of 0 if that service is enabled, 1 if that service is disabled, and greater than 1 in case of error.
<code>-l address net_spec</code>	Change or set the transport address on which the listener listens (the general listener service). This address can be used by remote processes to access the servers available through this listener (see the <code>-a</code> option, below). If <i>address</i> is just a dash (" - "), <code>nlsadmin</code> reports the address currently configured, instead of changing it. A change of address takes effect immediately.
<code>-t address net_spec</code>	Change or set the address on which the listener listens for requests for terminal service but is otherwise similar to the <code>-l</code> option above. A terminal service address should not be defined unless the appropriate remote login software is available; if such software is available, it must be configured as service code 1 (see the <code>-a</code> option, below).
<code>-i net_spec</code>	Initialize an instance of the listener for the network specified by <i>net_spec</i> ; that is, create and initialize the files required by the listener as well as starting that instance of the listener. Note that a particular instance

`-a service_code`

of the listener should be initialized only once. The listener must be initialized before assigning addresses or services.

`[-p modules] [-w name] -c cmd -y
comment net_spec`

Add a new service to the list of services available through the indicated listener. *service_code* is the code for the service, *cmd* is the command to be invoked in response to that service code, comprised of the full path name of the server and its arguments, and *comment* is a brief (free-form) description of the service for use in various reports. Note that *cmd* must appear as a single word to the shell; if arguments are required, the *cmd* and its arguments must be enclosed in quotation marks. The *comment* must also appear as a single word to the shell. When a service is added, it is initially enabled (see the `-e` and `-d` options, below).

Service codes are alphanumeric strings, and are administered by AT&T. The numeric service codes 0 through 100 are reserved for internal use by the listener. Service code 0 is assigned to the nlps server, which is the service invoked on the general listening address. In particular, code 1 is assigned to the remote login service, which is the service automatically invoked for connections to the terminal login address.

If the `-p` option is specified, then *modules* will be interpreted as a list of STREAMS modules for the listener to push before starting the service being added. The modules are pushed in the order they are specified. *modules* should be a comma-separated list of modules, with no white space included.

If the `-w` option is specified, then *name* is interpreted as the user name from `/etc/passwd` that the listener should look up. From the user name, the listener obtains

the user ID, the group ID(s), and the home directory for use by the server. If `-w` is not specified, the default is to use the user name `listen`.

A service must explicitly be added to the listener for each network on which that service is to be available. This operation will normally be performed only when the service is installed on a machine, or when populating the list of services for a new network.

`-r service_code net_spec`

Remove the entry for the *service_code* from that listener's list of services. This is normally done only in conjunction with the de-installation of a service from a machine.

`-e service_code net_spec`

`-d service_code net_spec`

Enable or disable (respectively) the service indicated by *service_code* for the specified network. The service must previously have been added to the listener for that network (see the `-a` option, above). Disabling a service will cause subsequent service requests for that service to be denied, but the processes from any prior service requests that are still running will continue unaffected.

`-s net_spec`

`-k net_spec`

Start and kill (respectively) the listener process for the indicated network. These operations are normally performed as part of the system startup and shutdown procedures. Before a listener can be started for a particular network, it must first have been initialized (see the `-i` option, above). When a listener is killed, processes that are still running as a result of prior service requests will continue unaffected.

Under the Service Access Facility, it is possible to have multiple instances of the listener on a single *net_spec*. In any of the above commands, the option `-N port_monitor_tag` may be used in place of the *net_spec* argument. This argument specifies the tag by which an instance of the listener is identified by the Service Access Facility. If the `-N` option is not specified (that is, the *net_spec* is specified in the invocation), then it will be assumed that the last component of the *net_spec* represents

the tag of the listener for which the operation is destined. In other words, it is assumed that there is at least one listener on a designated *net_spec*, and that its tag is identical to the last component of the *net_spec*. This listener may be thought of as the primary, or default, listener for a particular *net_spec*.

nlsadmin is also used in conjunction with the Service Access Facility commands. In that capacity, the following combinations of options can be used:

-V

Write the current version number of the listener's administrative file to the standard output. It is used as part of the *sacadm* command line when *sacadm* adds a port monitor to the system.

-c *cmd* | -o *streamname* [-p *modules*] [-A *address* | -D] [-R *prognum* : *versnum*]

Format the port monitor-specific information to be used as an argument to *pmadm*(1M)

The -c option specifies the full path name of the server and its arguments. *cmd* must appear as a single word to the shell, and its arguments must therefore be surrounded by quotes.

The -o option specifies the full path name of a FIFO or named STREAM through which a standing server is actually receiving the connection.

If the -p option is specified, then *modules* will be interpreted as a list of STREAMS modules for the listener to push before starting the service being added. The modules are pushed in the order in which they are specified. *modules* must be a comma-separated list, with no white space included.

If the -A option is specified, then *address* will be interpreted as the server's private address. The listener will monitor this address on behalf of the service and will dispatch all calls arriving on this address directly to the designated service. This option may not be used in conjunction with the -D option.

If the -D option is specified, then the service is assigned a private address dynamically, that is, the listener will have the transport provider select the address each time the listener begins listening on behalf of this service. For RPC services, this option will be often be used in conjunction with the -R option to register the dynamically assigned address with the *rpcbinder*. This option may not be used in conjunction with the -A option.

When the -R option is specified, the service is an RPC service whose address, program number, and version number should be registered with the *rpcbinder* for this transport provider. This registration is performed each time the listener begins listening on behalf of the service. *prognum* and *versnum* are the program number and version number, respectively, of the RPC service.

nlsadmin may be invoked by any user to generate reports; all operations that affect a listener's status or configuration may only be run by a super-user.

nlsadmin(1M)

The options specific to the Service Access Facility may not be used together with any other options.

ERRORS If successful, nlsadmin exits with a status of 0. If nlsadmin fails for any reason, it exits with a status greater than or equal to 2. See -q option for a return status of 1.

NOTES Dynamically assigned addresses are not displayed in reports as statically assigned addresses are.

NAME	nscd – name service cache daemon									
SYNOPSIS	<code>/usr/sbin/nscd</code> [-f <i>configuration-file</i>] [-g] [-e <i>cachename</i> , yes no] [-i <i>cachename</i>]									
DESCRIPTION	nscd is a process that provides a cache for the most common name service requests. It starts up during multi-user boot. The default <i>configuration-file</i> <code>/etc/nscd.conf</code> determines the behavior of the cache daemon. See <code>nscd.conf(4)</code>. nscd provides caching for the <code>passwd(4)</code>, <code>group(4)</code>, <code>hosts(4)</code>, <code>ipnodes(4)</code>, <code>exec_attr(4)</code>, <code>prof_attr(4)</code>, and <code>user_attr(4)</code> databases through standard libc interfaces, such as <code>gethostbyname(3NSL)</code>, <code>getipnodebyname(3SOCKET)</code>, <code>gethostbyaddr(3NSL)</code>, and others. Each cache has a separate time-to-live for its data; modifying the local database (<code>/etc/hosts</code>, <code>/etc/resolv.conf</code>, and so forth) causes that cache to become invalidated upon the next call to nscd. The shadow file is specifically not cached. <code>getspnam(3C)</code> calls remain uncached as a result. nscd also acts as its own administration tool. If an instance of nscd is already running, commands are passed to the running version transparently. In order to preserve NIS+ security, the startup script for nscd (<code>/etc/init.d/nscd</code>) checks the permissions on the <code>passwd</code> table if NIS+ is being used. If this table cannot be read by unauthenticated users, then nscd will make sure that any encrypted password information returned from the NIS+ server is supplied only to the owner of that password.									
OPTIONS	Several of the options described below require a <i>cachename</i> specification. Supported values are <code>passwd</code>, <code>group</code>, <code>hosts</code>, <code>ipnodes</code>, <code>exec_attr</code>, <code>prof_attr</code>, and <code>user_attr</code>. <table><tr><td>-f <i>configuration-file</i></td><td>Causes nscd to read its configuration data from the specified file.</td></tr><tr><td>-g</td><td>Prints current configuration and statistics to standard output. This is the only option executable by non-root users.</td></tr><tr><td>-e <i>cachename</i>, yes no</td><td>Enables or disables the specified cache.</td></tr><tr><td>-i <i>cachename</i></td><td>Invalidate the specified cache.</td></tr></table>		-f <i>configuration-file</i>	Causes nscd to read its configuration data from the specified file.	-g	Prints current configuration and statistics to standard output. This is the only option executable by non-root users.	-e <i>cachename</i> , yes no	Enables or disables the specified cache.	-i <i>cachename</i>	Invalidate the specified cache.
-f <i>configuration-file</i>	Causes nscd to read its configuration data from the specified file.									
-g	Prints current configuration and statistics to standard output. This is the only option executable by non-root users.									
-e <i>cachename</i> , yes no	Enables or disables the specified cache.									
-i <i>cachename</i>	Invalidate the specified cache.									
EXAMPLES	EXAMPLE 1 Stopping and restarting the nscd daemon. <pre>example# /etc/init.d/nscd stop</pre> <pre>example# /etc/init.d/nscd start</pre>									
FILES	<code>/etc/nscd.conf</code>	Determines the behavior of the cache daemon

NAME	nslookup – query name servers interactively	
SYNOPSIS	nslookup [- option]... <i>host</i> [<i>server</i>] nslookup [- option]... - [<i>server</i>] nslookup	
DESCRIPTION	nslookup sends queries to Internet domain name servers. It has two modes: interactive and non-interactive. Interactive mode allows the user to contact servers for information about various hosts and domains or to display a list of hosts in a domain. Non-interactive mode is used to display just the name and requested information for a host or domain.	
OPTIONS	-option	Set the permissible options, as shown in the following list. These are the same options that the set command supports in interactive mode (see set in the Commands section for more complete descriptions). all List the current settings class= <i>classname</i> Restrict search according to the specified class d2 Set exhaustive debug mode on nod2 Set exhaustive debug mode off debug Set debug mode on nodebug Set debug mode off defname Set domain-appending mode on nodefname Set domain-appending mode off domain= <i>string</i> Establish the appendable domain ignoretc Set it to ignore packet truncation errors noignoretc Set it to acknowledge packet truncation errors
OPERANDS	<i>host</i>	Inquires about the specified <i>host</i> . In this non-interactive command format, nslookup Does not prompt for additional commands.
	-	Causes nslookup to prompt for more information, such as host names, before sending one or more queries.
	<i>server</i>	Directs inquiries to the name server specified here in the command line rather than the one read from the <code>/etc/resolv.conf</code> file (see <code>resolv.conf(4)</code>). <i>server</i> can be either a name or an Internet address. If the specified host cannot be reached, nslookup resorts to using the name server specified in <code>/etc/resolv.conf</code> .
USAGE		

nslookup(1M)

Non-interactive Mode	Non-interactive mode is selected when the name or Internet address of the host to be looked up is given as the first argument. Within non-interactive mode, space-separated options can be specified. They must be entered before the host name, to be queried. Each option must be prefixed with a hyphen. For example, to request extensive host information and to set the timeout to 10 seconds when inquiring about <i>gypsy</i>, enter: <pre>example% nslookup -query=hinfo -timeout=10 gypsy</pre> To avoid repeated entry of an option that you almost always use, place a corresponding <code>set</code> command in a <code>.nslookuprc</code> file located inside your home directory. (See Commands for more information about <code>set</code>.) The <code>.nslookuprc</code> file can contain several <code>set</code> commands if each is followed by a RETURN.
Entering and Leaving Interactive Mode	Interactive mode is selected when ■ No arguments are supplied. ■ A '-' (hyphen) character is supplied as the <i>host</i> argument. To exit from an interactive nslookup session, type <code>Control-d</code> or type the command <code>exit</code> followed by RETURN.
Supported Command Interactions	The commands associated with interactive mode are subject to various limitations and run-time conventions. The maximum length of a command line is 255 characters. When the RETURN key is pressed, command-line execution begins. While a command is running, its execution can be interrupted by typing <code>Control-c</code>. The first word entered on the command line must be the name of a nslookup command unless you wish to enter the name of a host to inquire about. Any unrecognized command is handled as a host name to inquire about. To force a command to be treated as a host name to be inquired about, precede it with a backslash character.
Commands	<code>exit</code> Exit the nslookup program. <code>help</code> <code>?</code> Display a brief summary of commands. <code>host [server]</code> Look up information for <i>host</i> using the current default server, or using <i>server</i> if it is specified.

If the *host* supplied is an Internet address and the query type is A or PTR, the name of the host is returned. If the *host* supplied is a name and it does not have a trailing period, the default domain name is appended to the name. (This behavior depends on the state of the set options domain, srchlist, defname, and search).

To look up a host that is not in the current domain, append a period to the name.

finger [*name*] [>> *filename*]

Connect with the finger server on the current host, which is defined by the most recent successful host lookup.

If no *name* value is specified, a list of login account names on the current host is generated.

Similar to a shell command interpreter, output can be redirected to a file using the usual redirection symbols: > and >>.

ls [-*options*] *domain* [>> *filename*]

List the information available for *domain*, optionally creating or appending to *filename*. The default output contains host names and their Internet addresses.

Output can be redirected to *filename* using the > and >> redirection symbols. When output is directed to a file, hash marks are shown for every 50 records received from the server. The permissible values for *options* are:

a	Lists aliases of hosts in the domain. This is a synonym for the command ls -t CNAME .
d	Lists all records for the domain. This is a synonym for the command ls -t ANY .
h	Lists CPU and operating system information for the domain. This is a synonym for the command ls -t HINFO .
s	Lists well-known services of hosts in the domain. This is a synonym for the command ls -t WKS .
t <i>querytype-value</i>	lists all records of the specified type (see <i>querytype</i> within the discussion of the set command).

set *token=value*

set *keyword*

Establish a preferred mode of search operation. Permissible *token* and *keyword* values are:

all	Display the current values of frequently-used options. Information about the current default server and host is also displayed.

nslookup(1M)

<code>cl[ass]=classname</code>	Limit the search according to the protocol group (<i>classname</i>) for which lookup information is desired. Permissible <i>classname</i> values are: ANY A wildcard selecting all classes IN The Internet class (the default) CHAOS The Chaos class. HESIOD The MIT Athena Hesiod class.
<code>d2</code> <code>nod2</code>	Enable or disable exhaustive debugging mode. Essentially all fields of every packet are displayed. By default, this option is disabled.
<code>deb[ug]</code> <code>nodeb[ug]</code>	Enable or disable debugging mode. When debugging mode is enabled, much more information is produced about the packet sent to the server and the resulting answer. By default, this option is disabled.
<code>def[name]</code> <code>nodef[name]</code>	Enable or disable appending the default domain name to a single-component lookup request (one that lacks a dot). By default, this option is enabled for <code>nslookup</code> . The default value for the domain name is the value given in <code>/etc/resolv.conf</code> , unless: there is an environmental value for <code>LOCALDOMAIN</code> when <code>nslookup</code> is run; a recent value has been specified through the <code>srchlist</code> command or the <code>set domain</code> command.
<code>do[main]=string</code>	Change the default domain name to be appended to all lookup requests to <i>string</i> . For this option to have any effect, the <code>defname</code> option must also be enabled and the <code>search</code> option must be set in a compatible way. The domain search list contains the parents of the default domain if it has at least two components in its name. For example, if the default domain is <code>CC.Berkeley.EDU</code> , the search list is <code>CC.Berkeley.EDU</code> and <code>Berkeley.EDU</code> . Use the <code>set srchlist</code> command to specify a different list. Use the <code>set all</code> command to display the list.
<code>ignoretc</code> <code>noignoretc</code>	Ignore packet truncation errors. By default, this option is disabled.

```
srch[list]=name1/name2/...
```

Change the default domain name to *name1* and the domain search list to *name1*, *name2*, etc. A maximum of 6 names can be specified, along with slash characters to separate them. For example,

```
example% set srchlist=lcs.MIT.EDU/ai.MIT.EDU/MIT.EDU
```

sets the domain to *lcs.MIT.EDU* and the search list to all three names. This command overrides the default domain name and search list of the `set domain` command. Use the `set all` command to display the list.

```
search
```

```
nosearch
```

Enable or disable having the domain names in the domain search list appended to the request, generating a series of lookup queries if necessary until an answer is received. To take effect, the lookup request must contain at least one dot (period); yet it must not contain a trailing period. By default, this option is enabled.

```
po[rt]=value
```

Specify the default TCP/UDP name server port. By default, this value is 53.

```
q[ue]rytype=value
```

```
ty[pe]=value
```

Change the type of information returned from a query to one of:

A	The Internet address of the host
CNAME	The canonical name for an alias
HINFO	The host CPU and operating system type
MD	The mail destination
MX	The mail exchanger
MB	The mailbox domain name
MG	The mail group member
MINFO	The mailbox or mail list information
NS	The name server
PTR	The host name if the query is in the form of an Internet address; otherwise the pointer to other information
SOA	The domain's start-of-authority information
TXT	The text information
UINFO	The user information
WKS	The supported well-known services

(Other types specified in the *RFC 1035* document are valid, but they are not as useful.)

nslookup(1M)

`recurse`
`norecurse`
Enable or disable having to query other name servers before abandoning a search. By default, this feature is enabled.

`ret[ry]=count`
Set the maximum number of times to retry a request before abandoning a search. When a reply to a request is not received within a certain amount of time (changed with `set timeout`), the timeout period is doubled and the request is resent. The retry value controls how many times a request is resent before the request is aborted. The default for *count* is 4.

`ro[ot]=host`
Change the name of the root server to *host*. This affects the `root` command. The default root server is `ns.internic.net`.

`t[timeout]=interval`
Change the amount of time to wait for a reply to *interval* seconds. Each retry doubles the timeout period. The default *interval* is 5 seconds.

`vc`
`novc`
Enable or disable the use of a virtual circuit when sending requests to the server. By default, this feature is disabled.

`root`
Change the default server to the server for the root of the domain name space. Currently, the host `ns.internic.net` is used; this command is a synonym for `server ns.internic.net`. The name of the root server can be changed with the `set root` command.

`server domain`
`lserver domain`
Change the default server to *domain*. `lserver` uses the initial server to look up information about *domain* while `server` uses the current default server. If an authoritative answer can not be found, the names of servers that might have the answer are returned.

EXAMPLES

EXAMPLE 1 Searching the Internet Domain Namespace

To effectively search the Internet domain namespace, it helps to know its structure. At present, the Internet domain name-space is tree-structured, with one top level domain for each country except the United States.. There are also some traditional top level domains, not explicitly tied to any particular country. These include:

COM	Commercial establishments
EDU	Educational institutions
ORG	Not-for-profit organizations
GOV	Government agencies
MIL	MILNET hosts

EXAMPLE 1 Searching the Internet Domain Namespace (Continued)

If you are looking for a specific host, you need to know something about the host's organization in order to determine the top-level domain that it belongs to. For instance, if you want to find the Internet address of a machine at UCLA, do the following:

- Connect with the root server using the `root` command. The root server of the name space has knowledge of the top-level domains.
- Since UCLA is a university, its domain name is `ucla.edu`. Connect with a server for the `ucla.edu` domain with the command `server ucla.edu`. The response produces the names of hosts that act as servers for that domain. Note: the root server does not have information about `ucla.edu`, but knows the names and addresses of hosts that do. Once located by the root server, all future queries will be sent to the UCLA name server.
- To request information about a particular host in the domain (for instance, `locus`), just type the host name. To request a listing of hosts in the UCLA domain, use the `ls` command. The `ls` command requires a domain name, (in this case, `ucla.edu`, as an argument.

If you are connected with a name server that handles more than one domain, all lookups for host names must be fully specified with its domain. For instance, the domain `harvard.edu` is served by `seismo.css.gov`, which also services the `css.gov` and `cornell.edu` domains. A lookup request for the host `aiken` in the `harvard.edu` domain must be specified as `aiken.harvard.edu`. However, the `set domain=name` and `set defname` commands can be used to automatically append a domain name to each request.

After a successful lookup of a host, use the `finger(1)` command to see who is on the system, or to finger a specific person. (`finger` requires the type to be A.)

To get other information about the host, use the `set querytype=value` command to change the type of information desired and request another lookup.

**ENVIRONMENT
VARIABLES**

`HOSTALIASES` References the file containing host aliases
`LOCALDOMAIN` Overrides default domain

EXIT STATUS

The process returns the following values:

0 On success.
 1 On failure.

Mockapetris, Paul. *RFC 1034, Domain Names - Concepts and Facilities*. Network Working Group. November 1987.

Mockapetris, Paul. *RFC 1035, Domain Names - Implementation and Specification*. Network Working Group. November 1987.

DIAGNOSTICS If the lookup request is successful, an error message is produced. Possible errors are:

Timed out	The server did not respond to a request after a certain amount of time (changed with <code>set timeout=value</code>) and a certain number of retries (changed with <code>set retry=value</code>).
No response from server	No name server is running on the server machine.
No records	The server does not have resource records of the current query type for the host, although the host name is valid. The query type is specified with the <code>set querytype</code> command.
Non-existent domain	The host or domain name does not exist.
Connection refused Network is unreachable	The connection to the name or finger server can not be made at the current time. This error commonly occurs with <code>ls</code> and <code>finger</code> requests.
Server failure	The name server found an internal inconsistency in its database and could not return a valid answer.
Refused	The name server refused to service the request.

nslookup(1M)

Format error

The name server found that the request packet was not in the proper format. This may indicate an error in `nslookup`.

nctest(1M)

NAME	nctest – DNS test shell		
SYNOPSIS	nctest [-d] [-i] [-r] [-v] [-p <i>port</i>] [<i>inet_addr</i> [<i>logfile</i>]]		
DESCRIPTION	nctest is an interactive DNS test program. Queries are formed and sent by user command; any reply received is printed on the standard output. <i>inet_addr</i> is the Internet address of the DNS resolver to which nctest should send its queries. If <i>inet_addr</i> is not included, nctest first tries to contact a DNS server on the local host; if that fails, it tries the servers listed in the <code>/etc/resolv.conf</code> file. If a <i>logfile</i> is supplied, nctest uses it to log the queries sent and replies received.		
OPTIONS	-d	Causes nctest to create a file named <code>ns_packet.dump</code> (if it does not exist) and write into it a raw (binary) copy of each packet sent. If <code>ns_packet.dump</code> does exist, nctest will truncate it.	
	-i	Sets the <code>RES_IGNTC</code> flag on the queries it makes. See <code>resolver(3RESOLV)</code> for a description of the <code>RES_IGNTC</code> flag.	
	-r	Turns off the <code>RES_RECURSE</code> flag on the queries it makes. See <code>resolver(3RESOLV)</code> for a description of the <code>RES_RECURSE</code> flag.	
	-v	Turns on the <code>RES_USEVC</code> and <code>RES_STAYOPEN</code> flags on the <code>res_send()</code> calls made. See <code>resolver(3RESOLV)</code> for a description of the <code>RES_USEVC</code> and <code>RES_STAYOPEN</code> flags.	
	-p	Causes nctest to use the supplied <i>port</i> instead of the default name server port.	
USAGE	When nctest starts, it prints a prompt (" > ") and waits for user input. DNS queries are formed by typing a <i>key letter</i> followed by the appropriate <i>argument</i> . Each <i>key letter</i> results in a call to <code>res_mkquery()</code> with <i>op</i> set to either <code>IQUERY</code> or <code>QUERY</code> and <i>type</i> set to one of the type values (defined in <code><arpa/nameser.h></code>). (Any other key letter than those listed below causes nctest to print a summary of the following table.)		
	Key Letter &		
	Argument	Op	Type
	<i>ahost</i>	QUERY	T_A
	<i>Aaddr</i>	IQUERY	T_A
	<i>Buser</i>	QUERY	T_MG
	<i>buser</i>	QUERY	T_MB
	<i>chost</i>	QUERY	T_CNAME
	<i>fhost</i>	QUERY	T_UINFO

<i>Ggid</i>	IQUERY	T_GID
<i>ghost</i>	QUERY	T_GID
<i>hhost</i>	QUERY	T_HINFO
<i>ihost</i>	QUERY	T_MINFO
<i>Mhost</i>	QUERY	T_MAILB
<i>mhost</i>	QUERY	T_MX
<i>nhost</i>	QUERY	T_NS
<i>phost</i>	QUERY	T_PTR
<i>rhost</i>	QUERY	T_MR
<i>shost</i>	QUERY	T_SOA
<i>Thost</i>	QUERY	T_TXT
<i>Uuid</i>	IQUERY	T_UID
<i>uhost</i>	QUERY	T_UID
<i>whost</i>	QUERY	T_WKS
<i>xhost</i>	QUERY	T_AXFR

After the query is successfully formed, `res_send()` is called to send it and wait for a reply. `nctest` then prints the following on the standard output:

- a summary of the request and reply packets, including the `HEADER` structure (defined in `<arpa/nameser.h>`) used in the request
- the question being asked of the name server
- an enumeration of the name server(s) being polled
- a summary of the `HEADER` structure received in the reply
- the question the name server answered
- the answer itself

EXAMPLES

EXAMPLE 1 Fetching the Address of a Host From the Sun Name Server

The following command fetches the address of host `playground.sun.com` from the Sun name server:

```
$ nctest 192.9.5.1
> aplayground.sun.com
```

The utility `nctest` returns the following:

```
res_mkquery(0, playground.sun.com, 1, 1)
res_send()
HEADER:
```

EXAMPLE 1 Fetching the Address of a Host From the Sun Name Server *(Continued)*

```
opcode = QUERY, id = 1, rcode = NOERROR
header flags:  rd
qdcount = 1, ancount = 0, nscount = 0, arcount = 0
```

QUESTIONS:

```
playground.sun.com, type = A, class = IN
```

Querying server (# 1) address = 192.9.5.1

got answer:

HEADER:

```
opcode = QUERY, id = 1, rcode = NOERROR
header flags:  qr aa rd ra
qdcount = 1, ancount = 1, nscount = 0, arcount = 0
```

QUESTIONS:

```
playground.sun.com, type = A, class = IN
```

ANSWERS:

```
playground.sun.com
type = A, class = IN, ttl = 1 day, dlen = 4
internet address = 192.9.5.5
```

EXAMPLE 2 Looking Up a PTR record

The following command looks up a PTR record:

```
$ nctest 192.9.5.1
> p5.5.9.192.in-addr.arpa
```

The utility nctest would return the following:

```
res_mkquery(0, 5.5.9.192.in-addr.arpa, 1, 12)
```

```
res_send()
```

HEADER:

```
opcode = QUERY, id = 2, rcode = NOERROR
header flags:  rd
qdcount = 1, ancount = 0, nscount = 0, arcount = 0
```

QUESTIONS:

```
5.5.9.192.in-addr.arpa, type = PTR, class = IN
```

Querying server (# 1) address = 192.9.5.1

got answer:

HEADER:

```
opcode = QUERY, id = 2, rcode = NOERROR
header flags:  qr aa rd ra
qdcount = 1, ancount = 1, nscount = 0, arcount = 0
```

QUESTIONS:

```
5.5.9.192.in-addr.arpa, type = PTR, class = IN
```

ANSWERS:

```
5.5.9.192.in-addr.arpa
type = PTR, class = IN, ttl = 7 hours 47 mins 2 secs, dlen = 23
domain name = playground.sun.com
```

nstest(1M)

nsupdate(1M)

NAME	nsupdate – update Internet name servers interactively
SYNOPSIS	nsupdate [-k <i>keydir:keyname</i>] [-d] [-v] [<i>filename</i>]
DESCRIPTION	The nsupdate program can be used to update Internet domain name servers that support dynamic update. nsupdate uses the DNS resolver library to pass messages to the DNS server requesting the addition or deletion of DNS resource records (RR's). nsupdate reads input from <i>filename</i> or from standard input.
OPTIONS	nsupdate supports the following options: -d Debug mode. -k Sign updates with Secret Key Transaction Authentication for DNS (TSIG). -v Virtual circuit. Make use of TCP to communicate with the server. The default is UDP.
USAGE	nsupdate reads input records, one per line. Each line contributes a resource record to an update request. All domain names used in a single update request must belong to the same DNS zone. Updates are sent to the master server as defined in the SOA MNAME field. A blank line causes the accumulated records to be formatted into a single update request and transmitted to the zone's authoritative name servers. Additional records may follow, which are formed into additional, but completely independent, update requests. End the input with a blank line in order to transmit the last request. Records take one of two general forms. Prerequisite records specify conditions that must be satisfied before the request will be processed. Update records specify changes to be made to the DNS database. An update request consists of zero or more prerequisites and one or more updates. Each update request is processed atomically. All prerequisites must be satisfied, then all updates will be performed. nsupdate understands the following input record formats: prereq nxdomain domain-name This format requires that no RR of any type exist with name <i>domain-name</i>. prereq yxdomain domain-name This format requires that at least one RR names <i>domain-name</i> must exist. prereq nxrrset domain-name [class] type This format requires that no RR exist of the specified type and <i>domain-name</i>. prereq yxrrset domain-name [class] type [data ...] This format requires that an RR exist of the specified type and <i>domain-name</i>. If data is specified, it must match exactly. update delete domain-name [class] [type [data ...]]

This format deletes RR's names *domain-name*. If *type* (and possibly *data*) are specified, only matching records will be deleted.

```
update add domain-name ttl [class] type data ...
```

This format adds a new RR of specified *ttl*, *type* and *data*.

EXAMPLES

EXAMPLE 1 Using nsupdate Interactively To Change an IP Address

The following example shows the interactive use of `nsupdate` to change an IP address. It deletes any existing A records for a domain name and then inserts a new address. Since no prerequisites are specified, the new record will be added even if there are no existing records to delete. A trailing blank line is required to process the request.

```
example$ nsupdate
>update delete test.example.com A
>update add test.example.com 3600 A 10.1.1.1
>
```

EXAMPLE 2 Using nsupdate Interactively to Add a CNAME (Alias)

In the following example, a CNAME (alias) is added to the database only if there are no existing A or CNAME records for the domain name.

```
example$ nsupdate
>prereq nxrrset www.example.com A
>prereq nxrrset www.example.com CNAME
>update add www.example.com 3600 CNAME test.test.com
>
```

EXAMPLE 3 Using nsupdate Interactively With a Key

In the following example, `nsupdate` is signed with the key `mykey`, which is located in the directory `/var/named/keys`.

```
example$ nsupdate -k /var/named/keys:mykey
>update add ftp.example.com 60 A 192.168.5.1
>
```

FILES `/etc/resolv.conf` Initial domain name and name server addresses.

DIAGNOSTICS

`Qq send error`

This message typically indicates that authoritative name servers could not be reached.

`Qq failed update packet`

This message typically indicates that the name server has rejected the update. Either the name server does not support dynamic update, or there was an authentication failure.

`Qq res_mkupdate: packet size = size`

If this is the only message sent, it indicates that the update was received and authenticated by the name server. However, the prerequisites may have prevented the update from being performed. Use debug mode (the `-d` option) to examine the status field in the name server's reply and determine if the update was performed.

NAME	ntpd – set the date and time by way of NTP
SYNOPSIS	/usr/sbin/ntpd [-bBdoqsuv] [-a <i>key#</i>] [-e <i>authdelay</i>] [-k <i>keyfile</i>] [-m] [-o <i>version</i>] [-p <i>samples</i>] [-t <i>timeout</i>] [-w] <i>server...</i>
DESCRIPTION	The <code>ntpd</code> utility sets the local date and time. To determine the correct time, it polls the Network Time Protocol (NTP) servers on the hosts given as arguments. This utility must be run as root on the local host. It obtains a number of samples from each of the servers and applies the standard NTP clock filter and selection algorithms to select the best of these. The reliability and precision of <code>ntpd</code> improve dramatically with a greater number of servers. While a single server may be used, better performance and greater resistance to inaccuracy on the part of any one server can be obtained by providing at least three or four servers, if not more. The <code>ntpd</code> utility makes time adjustments in one of two ways. If it determines that your clock is off by more than 0.5 seconds it simply steps the time by calling <code>gettimeofday(3C)</code>. If the error is less than 0.5 seconds, by default, it slews the clock's time with the offset, by way of a call to <code>adjtime(2)</code>. The latter technique is less disruptive and more accurate when the offset is small; it works quite well when <code>ntpd</code> is run by <code>cron</code> every hour or two. The adjustment made in the latter case is actually 50% larger than the measured offset. This adjustment tends to keep a badly drifting clock more accurate, at some expense to stability. This tradeoff is usually advantageous. At boot time, however, it is usually better to step the time. This can be forced in all cases by specifying the <code>-b</code> option on the command line. The <code>ntpd</code> utility declines to set the date if an NTP server daemon like <code>xntpd(1M)</code> is running on the same host. It can be run on a regular basis from <code>cron(1M)</code> as an alternative to running a daemon. Doing so once every one to two hours results in precise enough timekeeping to avoid stepping the clock.
OPTIONS	The following options are supported: -a <i>key#</i> Authenticate transactions, using the key number, <i>key#</i>. -b Step the time by calling <code>gettimeofday(3C)</code>. -B Force the time to always be slewed using the <code>adjtime(2)</code> system call, even if the measured offset is greater than +128 ms. The default is to step the time using <code>settimeofday(3C)</code> if the offset is greater than +128 ms. If the offset is much greater than +128 ms in this case, that it can take a long time (hours) to slew the clock to the correct value. During this time the host should not be used to synchronize clients. -d Display what will be done without actually doing it. Information useful for general debugging is also printed. -e <i>authdelay</i> Specify an authentication processing delay, <i>authdelay</i> in seconds. See <code>xntpd(1M)</code> for details. This number is usually small enough to

ntpdate(1M)

	be negligible for purposes of <code>ntpdate</code> . However, specifying a value may improve timekeeping on very slow CPU's.
<code>-k <i>keyfile</i></code>	Read keys from the file <i>keyfile</i> instead of the default file, <code>/etc/ntp.keys</code> . <i>keyfile</i> should be in the format described in <code>xntpd(1M)</code> .
<code>-m</code>	Join multicast group specified in <i>server</i> and synchronize to multicast NTP packets. The standard NTP group is 224.0.1.1.
<code>-o <i>version</i></code>	Force the program to poll as a version 1 or version 2 implementation. By default <code>ntpdate</code> claims to be an NTP version 3 implementation in its outgoing packets. However, some older software declines to respond to version 3 queries. This option can be used in these cases.
<code>-p <i>samples</i></code>	Set the number of samples <code>ntpdate</code> acquires from each server. <i>samples</i> can be between 1 and 8 inclusive. The default is 4.
<code>-q</code>	Query only. Do not set the clock.
<code>-s</code>	Log actions by way of the <code>syslog(3C)</code> facility rather than to the standard output — a useful option when running the program from <code>cron(1M)</code> .
<code>-t <i>timeout</i></code>	Set the time <code>ntpdate</code> spends, waiting for a response. <i>timeout</i> is rounded to a multiple of 0.2 seconds. The default is 1 second, a value suitable for polling across a LAN.
<code>-u</code>	Use an unprivileged port to send the packets from. This option is useful when you are behind a firewall that blocks incoming traffic to privileged ports, and you want to synchronize with hosts beyond the firewall. The <code>-d</code> option always uses unprivileged ports.
<code>-v</code>	Be verbose. This option causes <code>ntpdate</code> 's version identification string to be logged.
<code>-w</code>	Wait until able to synchronize with a server. When the <code>-w</code> option is used together with <code>-m</code> , <code>ntpdate</code> waits until able to join the group and synchronize.

FILES `/etc/inet/ntp.keys` Contains the encryption keys used by `ntpdate`.

NOTES The technique of compensating for clock oscillator errors to improve accuracy is inadequate. However, to further improve accuracy would require the program to save *state* from previous runs.

ntpq(1M)

NAME	ntpq – standard Network Time Protocol query program								
SYNOPSIS	/usr/sbin/ntpq [-inp] [-c <i>command</i>] [<i>host</i>] [...]								
DESCRIPTION	ntpq queries NTP servers which implement the recommended NTP mode 6 control message format, about current state. It can also request changes in that state. The program can be run in interactive mode; or it can be controlled using command line arguments. Requests to read and write arbitrary variables can be assembled, with raw and pretty-printed output options available. By sending multiple queries to the server, ntpq can also obtain and print a list of peers in a common format. If one or more request options are included on the command line, ntpq sends each of the requests to NTP servers running on each of the hosts given as command line arguments. By default, ntpq sends its requests to localhost, if hosts are not included on the command line. If no request options are given, ntpq attempts to read commands from the standard input and execute them on the NTP server running on the first host given on the command line. Again, ntpq defaults to localhost if no other host is specified. ntpq uses NTP mode 6 packets to communicate with an NTP server. Thus, it can be used to query any compatible server on the network that permits queries. Since NTP is a UDP protocol, this communication will be somewhat unreliable, especially over large distances. ntpq makes one attempt to retransmit requests; requests timeout if the remote host is not heard from within a suitable period.								
OPTIONS	Command line options are described below. Specifying a command line option other than -i or -n causes the specified query (queries) to be sent, immediately to the indicated host(s). Otherwise, ntpq attempts to read interactive format commands from standard input. <table><tr><td>-c</td><td>Interpret the next argument as an interactive format command and add it to the list of commands to be executed on the specified host(s). Multiple -c options may be given.</td></tr><tr><td>-i</td><td>Operate in interactive mode; write prompts to standard output and read commands from standard input.</td></tr><tr><td>-n</td><td>Output all host addresses in dotted-quad numeric format rather than converting them to canonical host names.</td></tr><tr><td>-p</td><td>Print a list of the peers known to the server as well as a summary of their state. This is equivalent to the peers interactive command. See USAGE below.</td></tr></table>	-c	Interpret the next argument as an interactive format command and add it to the list of commands to be executed on the specified host(s). Multiple -c options may be given.	-i	Operate in interactive mode; write prompts to standard output and read commands from standard input.	-n	Output all host addresses in dotted-quad numeric format rather than converting them to canonical host names.	-p	Print a list of the peers known to the server as well as a summary of their state. This is equivalent to the peers interactive command. See USAGE below.
-c	Interpret the next argument as an interactive format command and add it to the list of commands to be executed on the specified host(s). Multiple -c options may be given.								
-i	Operate in interactive mode; write prompts to standard output and read commands from standard input.								
-n	Output all host addresses in dotted-quad numeric format rather than converting them to canonical host names.								
-p	Print a list of the peers known to the server as well as a summary of their state. This is equivalent to the peers interactive command. See USAGE below.								
USAGE	Interactive format commands consist of a keyword followed by up to four arguments. Only enough characters of the full keyword to uniquely identify the command need be typed. Normally, the output of a command is sent to standard output; but this output may be written to a file by appending a '>', followed by a file name, to the command line.								

**Interactive
Commands**

A number of interactive format commands are executed entirely within the ntpq program itself. They do not result in NTP mode 6 requests being sent to a server. If no request options are included on the command line, and if the standard input is a terminal device, ntpq prompts for these commands. The interactive commands are described below:

? [*command_keyword*]

A '?' by itself prints a list of all the command keywords known to the current version of ntpq. A '?' followed by a command keyword prints function and usage information about the command.

timeout *milliseconds*

Specifies a time out period for responses to server queries. The default is about 5000 milliseconds. Since ntpq retries each query once after a time out, the total waiting time for a time out is twice the time out value that is set.

delay *milliseconds*

Specifies a time interval to be added to timestamps included in requests which require authentication. This command is used to enable (unreliable) server reconfiguration over long delay network paths or between machines whose clocks are unsynchronized. Currently, the server does not require time stamps in authenticated requests. Thus, this command may be obsolete.

host *hostname*

Set the name of the host to which future queries are to be sent. *Hostname* may be either a host name or a numeric address.

keyid #

Specify of a key number to be used to authenticate configuration requests. This number must correspond to a key number the server has been configured to use for this purpose.

passwd

Prompts the user to type in a password which will be used to authenticate configuration requests. If an authenticating key has been specified (see *keyid* above), this password must correspond to this key. ntpq does not echo the password as it is typed.

hostnames *yes* | *no*

If "yes" is specified, host names are printed in information displays. If "no" is given, numeric addresses are printed instead. The default is "yes" unless modified using the command line -n switch.

raw

Print all output from query commands exactly as it is received from the remote server. The only formatting/filtering done on the data is to transform non- ASCII data into printable form.

ntpq(1M)

`cooked`

Causes output from query commands to be “cooked”. The values of variables recognized by the server are reformatted, so that they can be more easily read. Variables which `ntpq` thinks should have a decodable value, but do not, are marked with a trailing ‘?’.

`ntpversion [ 1 | 2 | 3 ]`

Sets the NTP version number which `ntpq` claims in packets (defaults is 3). Note that mode 6 control messages (and modes, for that matter) did not exist in NTP version 1. There appear to be no servers left which demand version 1.

`authenticate [ yes | no ]`

The command `authenticate yes` instructs `ntpq` to send authentication with all requests it makes. Normally `ntpq` does not authenticate requests unless they are write requests. Authenticated requests cause some servers to handle requests slightly differently, and can occasionally cause a slowed response if you turn authentication on before doing a peer display. `addvars variable_name[=value] [ , ... ] rmvars variable_name [ , ... ] clearvars`

The data carried by NTP mode 6 messages consists of a list of items of the form

`variable_name=value` where the “`=value`” is ignored, and can be omitted, in requests to the server to read variables. `ntpq` maintains an internal list in which data to be included in control messages can be assembled, and sent. This is accomplished with the `readlist` and `writelist` commands described below. The `addvars` command allows variables and their optional values to be added to the list. If more than one variable is to be added, the list should be comma-separated, and it should not contain white space. The `rmvars` command can be used to remove individual variables from the list; the `clearlist` command removes all variables from the list.

`debug [ more | less | off ]`

Turns internal query program debugging on and off.

`quit`

Exit `ntpq`.

Control Message Commands

Each peer known to an NTP server has a 16 bit integer *association identifier* assigned to it. NTP control messages which carry peer variables must identify the peer that the values correspond to, by including its association ID. An association ID of 0 is special. It indicates the variables are system variables, whose names are drawn from a separate name space.

Control message commands send one or more NTP mode 6 messages to the server, and cause the data returned to be printed in some format. Most commands currently implemented send a single message and expect a single response. The current exceptions are the peers `mreadlist` and `mreadvar` commands. The `peers` command sends a preprogrammed series of messages to obtain the data it needs. The `mreadlist` and `mreadvar` commands, iterate over a range of associations.

Control message commands are described below:

`associations`

Obtains and prints a list of association identifiers and peer statuses for in-spec peers of the server being queried. The list is printed in columns. The first of these is an index that numbers the associations from 1, for internal use. The second column contains the actual association identifier returned by the server and the third the status word for the peer. This is followed by a number of columns containing data decoded from the status word. Note that the data returned by the `associations` command is cached internally in `ntp`. The index is then of use when dealing with “dumb” servers which use association identifiers that are hard for humans to type. For any subsequent commands which require an association identifier as an argument, the identifier can be specified by using the form, *&index*. Here *index* is taken from the previous list.

`lassociations`

Obtains and prints a list of association identifiers and peer statuses for all associations for which the server is maintaining *state*. This command differs from the `associations` command only for servers which retain *state* for out-of-spec client associations. Such associations are normally omitted from the display when the `associations` command is used, but are included in the output of `lassociations`.

`passociations`

Prints association data concerning in-spec peers from the internally cached list of associations. This command performs identically to the `associations` command except that it displays the internally stored data rather than making a new query.

`lpassociations`

Print data for all associations, including out-of-spec client associations, from the internally cached list of associations. This command differs from `passociations` only when dealing with servers which retain *state* for out-of-spec client associations.

`pstatus assocID`

Sends a read status request to the server for the given association. The names and values of the peer variables returned will be printed. Note that the status word from the header is displayed preceding the variables, both in hexadecimal and in pigeon English.

`readvar [ assoc ] [ variable_name[=value] [ , . . . ] ]`

Requests that the values of the specified variables be returned by the server by sending a read variables request. If the association ID is omitted or is given as zero the variables are system variables, otherwise they are peer variables and the values returned will be those of the corresponding peer. Omitting the variable list will send a request with no data which should induce the server to return a default display.

`rv [ assocID ] [ variable_name[=value] [ , . . . ] ]`

An easy-to-type short form for the `readvar` command.

`writevar assocID variable_name=value [ ,... ]`
 Like the `readvar` request, except the specified variables are written instead of read.

`readlist [ assocID ]`
 Requests that the values of the variables in the internal variable list be returned by the server. If the association ID is omitted or is 0 the variables are assumed to be system variables. Otherwise they are treated as peer variables. If the internal variable list is empty a request is sent without data, which should induce the remote server to return a default display.

`rl [ assocID ]`
 An easy-to-type short form of the `readlist` command.

`writelist [ assocID ]`
 Like the `readlist` request, except the internal list variables are written instead of read.

`mreadvar assocID assocID [ variable_name[=value] [ ,... ] ]`
 Like the `readvar` command except the query is done for each of a range of (nonzero) association IDs. This range is determined from the association list cached by the most recent `associations` command.

`mrvar assocID assocID [ variable_name[=value] [ ,... ] ]`
 An easy-to-type short form of the `mreadvar` command.

`mreadlist assocID assocID`
 Like the `readlist` command except the query is done for each of a range of (nonzero) association IDs. This range is determined from the association list cached by the most recent `associations` command.

`mrl assocID assocID`
 An easy-to-type short form of the `mreadlist` command.

`clockvar [ assocID ] [ variable_name[=value] [ ,... ] ]`
 Requests that a list of the server's clock variables be sent. Servers which have a radio clock or other external synchronization respond positively to this. If the association identifier is omitted or zero the request is for the variables of the "system clock". This request generally gets a positive response from all servers with a clock. Some servers may treat clocks as pseudo-peers and, hence, can possibly have more than one clock connected at once. For these servers, referencing the appropriate peer association ID shows the variables of a particular clock. Omitting the variable list causes the server to return a default variable display.

`cv [ assocID ] [ variable_name[=value] [ ,... ] ]`
 An easy-to-type short form of the `clockvar` command.

`peers`
 Obtains a list of in-spec peers of the server, along with a summary of each peer's state. Summary information includes:

- The address of the remote peer
- The reference ID (0.0.0.0 if the ref ID is unknown)

- The stratum of the remote peer
- The type of the peer (local, unicast, multicast or broadcast) when the last packet was received
- The polling interval in seconds
- The reachability register, in octal
- The current estimated delay offset and dispersion of the peer, all in milliseconds.

The character in the left margin indicates the fate of this peer in the clock selection process. The codes mean:

SPACE	Discarded due to high stratum and/or failed sanity checks.
x	Designated falsticker by the intersection algorithm.
.	Culled from the end of the candidate list.
–	Discarded by the clustering algorithm.
+	Included in the final selection set.
#	Selected for synchronization; but distance exceeds maximum.
*	Selected for synchronization.
o	Selected for synchronization, pps signal in use.

Since the `peers` command depends on the ability to parse the values in the responses it gets, it may fail to work from time to time with servers which poorly control the data formats.

The contents of the host field may be given in one of four forms. It may be a host name, an IP address, a reference clock implementation name with its parameter or, `REFCLK(implementation number, parameter)`. On “hostnames no” only IP-addresses will be displayed.

lpeers

Like `peers`, except a summary of all associations for which the server is maintaining state is printed. This can produce a much longer list of peers from inadequate servers.

opeers

An old form of the `peers` command with the reference ID replaced by the local interface address.

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWntpu

SEE ALSO `attributes(5)`

ntp(1M)

BUGS	The <code>peers</code> command is non-atomic. It may occasionally result in spurious error messages about invalid associations occurring and terminating the command. The timeout value is a fixed constant. As a result, it often waits a long time to timeout, since the fixed value assumes sort of a worst case. The program should improve the time out estimate as it sends queries to a particular host; but it does not.

NAME	ntptrace – trace a chain of NTP hosts back to their master time source				
SYNOPSIS	/usr/sbin/ntptrace [-vdm] [-r <i>retries</i>] [-t <i>timeout</i>] [<i>server</i>]				
DESCRIPTION	ntptrace determines where a given Network Time Protocol (NTP) server gets its time from, and follows the chain of NTP servers back to their master time source. If given no arguments, it starts with <i>localhost</i> .				
OPTIONS	The following options are supported: -d Turns on some debugging output. -n Turns off the printing of host names; instead, host IP addresses are given. This may be necessary if a nameserver is down. -r <i>retries</i> Sets the number of retransmission attempts for each host. -t <i>timeout</i> Sets the retransmission timeout (in seconds); default = 2. -v Prints verbose information about the NTP servers.				
EXAMPLES	EXAMPLE 1 Sample Output From the ntptrace Command The following example shows the output from the ntptrace command: <pre>% ntptrace localhost: stratum 4, offset 0.0019529, synch distance 0.144135 server2.bozo.com: stratum 2, offset 0.0124263, synch distance 0.115784 usndh.edu: stratum 1, offset 0.0019298, synch distance 0.011993, refid 'WWVB'</pre> On each line, the fields are (left to right): ■ The server's host name ■ The server's stratum ■ The time offset between that server and the local host (as measured by ntptrace; this is why it is not always zero for <i>localhost</i>) ■ The host's synchronization distance ■ The reference clock ID (only for stratum-1 servers) All times are given in seconds. Synchronization distance is a measure of the goodness of the clock's time.

ntptrace(1M)

BUGS	This program makes no attempt to improve accuracy by doing multiple samples.

NAME	obpsym – Kernel Symbolic Debugging for OpenBoot Firmware
SYNOPSIS	modload -p misc/obpsym
DESCRIPTION	obpsym is a kernel module that installs OpenBoot callback handlers that provide kernel symbol information to OpenBoot. OpenBoot firmware user interface commands use the callbacks to convert numeric <i>addresses</i> to kernel symbol names for display purposes, and to convert kernel symbol names to numeric <i>literals</i> allowing symbolic names to be used as input arguments to user interface commands. Once obpsym is installed, kernel symbolic names may be used anywhere at the OpenBoot firmware's user interface command prompt in place of a literal (numeric) string. For example, if obpsym is installed, the OpenBoot firmware commands <i>ctrace</i> and <i>dis</i> typically display symbolic names and offsets in the form <i>modname:symbolname + offset</i>. User interface Commands such as <i>dis</i> can be given a kernel symbolic name such as <i>ufs:ufs_mount</i> instead of a numeric address. Placing the command <pre>forceload: misc/obpsym</pre> into the <i>system(4)</i> file forces the kernel module <i>misc/obpsym</i> to be loaded and activates the kernel callbacks during the kernel startup sequence. obpsym may be useful as a kernel debugger in situations where other kernel debuggers are not useful. For example, on SPARC machines, if obpsym is loaded, you may be able to use the OpenBoot firmware's <i>ctrace</i> command to display symbolic names in the stack backtrace after a watchdog reset. The syntax for a kernel symbolic name is: <pre>[<i>module-name</i> :] <i>symbol-name</i></pre> Where <i>module-name</i> is the name of the kernel module that the symbol <i>symbol-name</i> appears in. A NULL module name is taken as "all modules, in no particular order" by obpsym. The module name <i>unix</i> is equivalent to a NULL module name, so that conflicts with words defined in the firmware's vocabulary can be avoided. Typically, OpenBoot firmware reads a word from the input stream and looks the word up in its internal <i>vocabulary</i> before checking if the word is a <i>literal</i>. Thus, kernel symbols, such as <i>reset</i> may be given as <i>unix:reset</i> to avoid the unexpected side effect of the firmware finding and executing a matching word in its vocabulary.
Kernel Symbolic Name Syntax

OpenBoot 2.x Command Reference Manual

WARNINGS Some OpenBoot firmware user interface commands may use system resources incompatibly with the way they are used by the Unix kernel. These commands and the use of this feature as a kernel debugger may cause interactions that the Unix kernel is not prepared to deal with. If this occurs, the Unix kernel and/or the OpenBoot firmware user interface commands may react unpredictably and may panic the system, or may hang or may cause other unpredictable results. For these reasons, the use of this feature is only minimally supported and recommended to be used only as a kernel debugger of "last resort".

If a breakpoint or watchpoint is triggered while the console frame buffer is powered off, the system can crash and be left in a state from which it is difficult to recover. If one of these is triggered while the monitor is powered off, you will not be able to see the debugger output.

NOTES *platform-name* can be found using the -i option of uname(1)

obpsym is supported only on architectures that support OpenBoot firmware.

On some systems, OpenBoot must be completely RAM resident so the obpsym symbol callback support can be added to the firmware, if the firmware doesn't include support for the symbol callbacks. On these systems, obpsym may complain that it requires that "you must use ramforth to use this module".

See the *OpenBoot 2.x Command Reference Manual* for details on how to use the *ramforth* command, how to place the command into *nvrnrc*, and how to set *use-nvrnrc?* to true. On systems with version 1.x OpenBoot firmware, *nvrnrc* doesn't exist, and the *ramforth* command must be typed manually after each reset, in order to use this module.

Once installed, the symbol table callbacks can be disabled by using the following OpenBoot firmware command:

```
0 0 set-symbol-lookup
```

NAME	ocfserv – OCF server				
SYNOPSIS	ocfserv [-D] [-p <i>path</i>]				
DESCRIPTION	The OCF server, <i>ocfserv</i>, is a per-host daemon that acts as the central point of communications with all smartcards connected to the host. Applications that need to use a smartcard can do so by using the APIs in <i>libsmartcard.so</i> or <i>smartcard.jar</i>. The internal implementation of these APIs communicates with <i>ocfserv</i> to perform the requested function. <i>inetd</i>(1M) automatically starts the <i>ocfserv</i> command when it is needed. Once started, <i>ocfserv</i> runs forever. If <i>ocfserv</i> is killed or crashes, it restarts automatically if necessary. Because <i>ocfserv</i> is run automatically, there really is not a reason to run it by manually. You must have root priveleges to execute this utility.				
OPTIONS	The following options are supported: -D Run <i>ocfserv</i> in debug mode. -p <i>path</i> Specify property file name.				
EXIT STATUS	The following exit values are returned: 0 Successful completion. >0 An error occurred.				
FILES	/etc/smartcard/opencard.properties File where server stores properties				
ATTRIBUTES	See <i>attributes</i>(5) for descriptions of the following attributes: <table border="1"> <thead> <tr> <th>ATTRIBUTE TYPE</th><th>ATTRIBUTE VALUE</th></tr> </thead> <tbody> <tr> <td>Availability</td><td>SUNWocf</td></tr> </tbody> </table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	Availability	SUNWocf

parse_dynamic_clustertoc(1M)

NAME	parse_dynamic_clustertoc – parse clustertoc file based on dynamic entries				
SYNOPSIS	<code>cdrom/export/exec/sparc.Solaris_2.x/sbin/install.d/parse_dynamic_clustertoc</code> <code>cdrom/export/exec/i386.Solaris_2.x/sbin/install.d/parse_dynamic_clustertoc</code>				
DESCRIPTION	This script parses the <code>clustertoc</code> file before the <code>suninstall(1M)</code> process is run. <code>parse_dynamic_clustertoc</code> is called by a modified <code>sysconfig</code> script on the install CD. When <code>parse_dynamic_clustertoc</code> runs, it reads the <code>clustertoc</code> and when it encounters <code>SUNW_CSRMBRIFF</code> lines, it either checks the platform using the script's builtin function, or calls an external script. The script exits with a 0 if the cluster entry is included, otherwise it will be ignored. If the cluster entry is to be included, the <code>SUNW_CSRMBRIFF = (test test_arg) cluster</code> line is converted to <code>SUNW_CSRMEMBER =cluster</code>.				
EXAMPLES	EXAMPLE 1 Checking For an SX Framebuffer The following is an example of a simple external test to check for an SX Framebuffer. The entry in the <code>clustertoc</code> file is shown and following that is the script that must be placed in the <code>install.d/dynamic_test</code> directory. <pre>SUNW_CSRMBRIFF=(smcc.dctoc sx)SUNWCsx #!/bin/sh # # Likewise, this file is expected to live under \$(TESTDIR). # case "\$1" in sx) prtconf -p grep 'SUNW,sx' 1> /dev/null;; esac</pre>				
FILES	<code>cdrom/Solaris_2.x/locale/C/.clustertoc.dynamic</code> Dynamic version of the <code>clustertoc</code> file <code>cdrom/export/exec/sparc.Solaris_2.x/sbin/install.d/dynamic_test</code> Directory that contains any additional tests <code>cdrom/export/exec/i386.Solaris_2.x/sbin/install.d/dynamic_test</code> Directory that contains any additional tests

NAME	passmgmt – password files management	
SYNOPSIS	passmgmt -a <i>options name</i> passmgmt -m <i>options name</i> passmgmt -d <i>name</i>	
DESCRIPTION	The passmgmt command updates information in the password files. This command works with both <code>/etc/passwd</code> and <code>/etc/shadow</code>. passmgmt -a adds an entry for user <i>name</i> to the password files. This command does not create any directory for the new user and the new login remains locked (with the string <code>*LK*</code> in the password field) until the <code>passwd(1)</code> command is executed to set the password. passmgmt -m modifies the entry for user <i>name</i> in the password files. The name field in the <code>/etc/shadow</code> entry and all the fields (except the password field) in the <code>/etc/passwd</code> entry can be modified by this command. Only fields entered on the command line will be modified. passmgmt -d deletes the entry for user <i>name</i> from the password files. It will not remove any files that the user owns on the system; they must be removed manually. passmgmt can be used only by the super-user.	
OPTIONS	-c <i>comment</i> A short description of the login, enclosed in quotes. It is limited to a maximum of 128 characters and defaults to an empty field. -h <i>homedir</i> Home directory of <i>name</i>. It is limited to a maximum of 256 characters and defaults to <code>/usr/name</code>. -u <i>uid</i> UID of the <i>name</i>. This number must range from 0 to the maximum non-negative value for the system. It defaults to the next available UID greater than 99. Without the -o option, it enforces the uniqueness of a UID. -o This option allows a UID to be non-unique. It is used only with the -u option. -g <i>gid</i> GID of <i>name</i>. This number must range from 0 to the maximum non-negative value for the system. The default is 1. -s <i>shell</i> Login shell for <i>name</i>. It should be the full pathname of the program that will be executed when the user logs in. The maximum size of <i>shell</i> is 256 characters. The default is for this field to be empty and to be interpreted as <code>/usr/bin/sh</code>. -l <i>logname</i> This option changes the <i>name</i> to <i>logname</i>. It is used only with the -m option. The total size of each login entry is limited to a maximum of 511 bytes in each of the password files.	
FILES	<code>/etc/passwd</code> <code>/etc/shadow</code>	

passmgmt(1M)

/etc/opasswd
/etc/oshadow

EXIT STATUS

The `passmgmt` command exits with one of the following values:

0	Success.
1	Permission denied.
2	Invalid command syntax. Usage message of the <code>passmgmt</code> command is displayed.
3	Invalid argument provided to option.
4	UID in use.
5	Inconsistent password files (for example, <i>name</i> is in the <code>/etc/passwd</code> file and not in the <code>/etc/shadow</code> file, or vice versa).
6	Unexpected failure. Password files unchanged.
7	Unexpected failure. Password file(s) missing.
8	Password file(s) busy. Try again later.
9	<i>name</i> does not exist (if <code>-m</code> or <code>-d</code> is specified), already exists (if <code>-a</code> is specified), or <code>logname</code> already exists (if <code>-m -l</code> is specified).

NOTES

Do not use a colon (:) or RETURN as part of an argument. It is interpreted as a field separator in the password file. The `passmgmt` command will be removed in a future release. Its functionality has been replaced and enhanced by `useradd`, `userdel`, and `usermod`. These commands are currently available.

This command only modifies password definitions in the local `/etc/passwd` and `/etc/shadow` files. If a network nameservice such as NIS or NIS+ is being used to supplement the local files with additional entries, `passmgmt` cannot change information supplied by the network nameservice.

NAME	patchadd – apply a patch package to a system running the Solaris operating environment
SYNOPSIS	patchadd [-dun] [-B <i>backout_dir</i>] [-k <i>keystore</i>] [-P <i>passwd</i>] [-x <i>proxy</i>] [<i>target</i>] <i>source</i> [<i>dest</i>] patchadd -p [<i>target</i>]
DESCRIPTION	patchadd applies a patch package to a system running the Solaris 2.x operating environment or later Solaris environments (such as Solaris 9) that are compatible with Solaris 2.x. This patch installation utility cannot be used to apply Solaris 1 patches. patchadd must be run as root. The patchadd command has the following forms: ■ The first form of patchadd installs one or more patches to a system, client, service, or to the miniroot of a Net Install Image. ■ The second form of patchadd displays installed patches on the client, service, or to the miniroot of a Net Install Image.
OPTIONS	The following options are supported: -B <i>backout_dir</i> Saves backout data to a directory other than the package database. Specify <i>backout_dir</i> as an absolute path name. -d Does not back up the files to be patched. <i>The patch cannot be removed.</i> -k <i>keystore</i> Use <i>keystore</i> as the location to get trusted certificate authority certificates when verifying digital signatures found in each patch. If no keystore is specified, then the default keystore locations are searched for valid trusted certificates. See KEY STORE LOCATIONS in pkgadd(1M) for more information. -n Tells patchadd to ignore the signature and not to validate it. This should be used only when the content of the patch is known and trusted, and is primarily included to allow patchadd to apply a patch on systems without the ability to verify the patch signature, such as Solaris 8. -p In the second form, displays a list of the patches currently applied. -P <i>passwd</i> Password to use to decrypt the keystore specified with -k, if required. See PASS PHRASE ARGUMENTS in pkgadd(1M) for more information about the format of this option's argument. -u Turns off file validation. Applies the patch even if some of the files to be patched have been modified since their original installation.

patchadd(1M)

	-x proxy Specify a HTTP[S] proxy to use when downloading packages. The format of proxy is <i>host:port</i>, where <i>host</i> is the hostname of the HTTP[S] proxy, and <i>port</i> is the port number associated with the proxy. This switch overrides all other methods of specifying a proxy. See ENVIRONMENT VARIABLES in pkgadd(1M) for more information on alternate methods of specifying a default proxy.
OPERANDS	The following operands are supported:
Sources	patchadd must be supplied a source for retrieving the patch. The following sources and their syntax are acceptable: patch The absolute path name to <i>patch_id</i> or a URI pointing to a signed patch. <i>/var/sadm/spool/patch/104945-02</i> is an example of a patch. <i>https://syrinx.eng:8887/patches/104945-02</i> is an example of a URI pointing to a signed patch. -M patch_dir patch_id [patch_id...] Specifies the patches to be installed by directory location or URL, and patch number. To use the directory location or URL and the patch number, specify <i>patch_dir</i> as the absolute path name of the directory that contains spooled patches. Specify a URL as the server and path name that contains the spooled patches. Specify <i>patch_id</i> as the patch number of a given patch. Specifying multiple <i>patch_id</i>'s is recommended. <i>patch_id</i> is the patch number of a given patch. <i>104945-02</i> is an example of a <i>patch_id</i>. -M patch_dir patch_list Specifies the patches to be installed by directory location or URL and the name of a file containing a patch list. To use the directory location or URL and a file containing a patch list, specify <i>patch_dir</i> as the absolute path name of the directory that contains spooled patches. Specify URL as the server and path name that contains the spooled patches. Specify <i>patch_list</i> as the name of the file containing the patches to be installed.
Destinations	By default, patchadd applies a patch to the specified destination. If no destination is specified, then the current system (the one with its root filesystem mounted at <i>/</i>) is assumed to be the destination for the patch. You can also specify a destination in the following ways: -C net_install_image Patches the files located on the miniroot on a Net Install Image created by <i>setup_install_server</i>. Specify <i>net_install_image</i> as the absolute path name to a Solaris 8 or compatible version boot directory. See EXAMPLES. You should use the -C option only to install patches that are recommended for installation to the miniroot. Patches that are recommended for installation to the miniroot usually include install-related patches such as package commands, and

**KEYSTORE
LOCATIONS
KEYSTORE AND
CERTIFICATE
EXAMPLES**

patchadd(1M)

Sun install and patch installation tools. If you apply too many patches to the miniroot it can grow too large to fit into memory during a net installation of Solaris. Use the -B option and the -C option together so the miniroot does not get too large. See -B, above.

-R *client_root_path*

Locates all patch files generated by patchadd under the directory *client_root_path*. *client_root_path* is the directory that contains the bootable root of a client from the server's perspective. Specify *client_root_path* as the absolute path name to the beginning of the directory tree under which all patch files generated by patchadd are to be located. -R cannot be specified with the -S option. See NOTES.

-S *service*

Specifies an alternate service (for example, Solaris_8). This service is part of the server and client model, and can only be used from the server's console. Servers can contain shared /usr file systems that are created by Host Manager. These service areas can then be made available to the clients they serve. -S cannot be specified with the -R option. See NOTES.

See KEYSTORE LOCATIONS in pkgadd(1M) for details.

See KEYSTORE AND CERTIFICATE FORMATS in pkgadd(1M) for details.

The examples in this section are all relative to the /usr/sbin directory.

EXAMPLE 1 Installing a Patch to a Standalone Machine

The following example installs a patch to a standalone machine:

```
example# patchadd /var/sadm/spool/104945-02
```

EXAMPLE 2 Installing a Patch to a Client From the Server's Console

The following example installs a patch to a client from the server's console:

```
example# patchadd -R /export/root/client1 /var/sadm/spool/104945-02
```

EXAMPLE 3 Installing a Patch to a Service From the Server's Console

The following example installs a patch to a service from the server's console:

```
example# patchadd -S Solaris_8 /var/sadm/spool/104945-02
```

EXAMPLE 4 Installing Multiple Patches in a Single Invocation

The following example installs multiple patches in a single patchadd invocation:

```
example# patchadd -M /var/sadm/spool 104945-02 104946-02 102345-02
```

EXAMPLE 5 Installing Multiple Patches Specifying List of Patches to Install

The following example installs multiple patches specifying a file with the list of patches to install:

patchadd(1M)

EXAMPLE 5 Installing Multiple Patches Specifying List of Patches to Install (Continued)

```
example# patchadd -M /var/sadm/spool patchlist
```

EXAMPLE 6 Installing Multiple Patches to a Client and Saving the Backout Data

The following example installs multiple patches to a client and saves the backout data to a directory other than the default:

```
example# patchadd -M /var/sadm/spool -R /export/root/client1 \  
-B /export/backoutrepository 104945-02 104946-02 102345-02
```

EXAMPLE 7 Installing a Patch to a Solaris 8 or Compatible Version Net Install Image

The following example installs a patch to a Solaris 8 or compatible version Net Install Image:

```
example# patchadd -C /export/Solaris_8/Tools/Boot \  
/var/sadm/spool/104945-02
```

EXAMPLE 8 Displaying the Patches Installed on a Client

The following example displays the patches installed on a client:

```
example# patchadd -R /export/root/client1 -p
```

EXAMPLE 9 Installing a Digitally Signed Set of Patches

The following example installs multiple patches, some of which have been signed, using the supplied keystore, password, and HTTP proxy.

```
example# patchadd -k /etc/mycerts -p pass:abcd -x webcache.eng:8080 \  
-M http://www.sun.com/solaris/patches/latest 101223-02 102323-02
```

EXIT STATUS The following exit values are returned:

0	Successful completion.
>0	An error occurred.

ATTRIBUTES See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWswmt, SUNWcsu
Interface Stability	Evolving

DIAGNOSTICS The following messages might help in determining some of the most common problems associated with installing a patch.

Patch Installation errors**Message**

The prepatch script exited with return code *retcode*.
patchadd is terminating.

Explanation and Recommended Action

The prepatch script supplied with the patch exited with a return code other than 0. Run a script trace of the prepatch script and find out why the prepatch had a bad return code. Add the `-x` option to the first line of the prepatch script to fix the problem and run patchadd again.

Message

The signature on patch *patch_id* was unable to be verified.
patchadd is terminating.

Explanation and Recommended Action

The digital signature on a patch was unable to be verified given the keystore in use and the signature on the patch. Check the keystore to make sure it has the requisite trust anchor(s) required to validate the signature on the package and that the package has not been tampered with.

Message

The postpatch script exited with return code *retcode*.
Backing out patch.

Explanation and Recommended Action

The postpatch script provided with the patch exited with an error code other than 0. This script is mostly used to cleanup files (that is, when a package is known to have ownership or permission problems) attributes that do not correspond to the patch package's objects. After the user has noted all validation errors and taken the appropriate action for each one, the user should re-run patchadd using the `-u` (unconditional) option. This time, the patch installation will ignore validation errors and install the patch anyway.

Message

Insufficient space in `/var/sadm/patch` to save old files.
(For 2.4 systems and previous)

Explanation and Recommended Action

There is insufficient space in the `/var/sadm/patch` directory to save old files. The user has three options for handling this problem: Use the `-B` option while invoking patchadd. This option will direct patchadd to: save the backout data to the user specified file system, generate additional disk space by deleting unneeded files, or override the saving of the old files by using the `-d` (do not save) option when running patchadd.

If the user elects not to save the old versions of the files to be patched, `patchrm` cannot be used. One way to regain space on a system is to remove the save area for previously applied patches. Once the user has decided that it is unlikely that a patch will be backed out, the user can remove the files that were saved by patchadd. The following commands should be executed to remove the saved files for *patchpatch_id*:

patchadd(1M)

```
cd /var/sadm/patch/patch_id
rm -r save/*
rm .oldfilessaved
```

After these commands have been executed, patch *patch_id* can no longer be backed out.

Message

```
Insufficient space in /var/sadm/pkg/PKG/save to save old files.
(For 2.5 systems and later)
```

Explanation and Recommended Action

There is insufficient space in the `/var/sadm/pkg/PKG/save` directory to save old files. The user has three options for handling this problem: (1) Use the `-B` option while invoking `patchadd`. This option will direct `patchadd` to save the backout data to the user specified file system. (See synopsis above.) (2) Generate additional disk space by deleting unneeded files, or (3) override the saving of the old files by using the `-d` (do not save) option when running `patchadd`.

However, if the user elects not to save the old versions of the files to be patched, `patchrm` *cannot* be used. One way to regain space on a system is to remove the save area for previously applied patches. Once the user has decided that it is unlikely that a patch will be backed out, the user can remove the files that were saved by `patchadd`. The following commands should be executed to remove the saved files for patch *patch_id*:

```
cd /var/sadm/pkg/pkgabbrev/save
rm -r patch_id
```

After these commands have been executed, patch *patch_id* can no longer be backed out.

Message

```
Save of old files failed.
(For 2.4 systems and previous)
```

Explanation and Recommended Action

Before applying the patch, the patch installation script uses `cpio` to save the old versions of the files to be patched. This error message means that the `cpio` failed. The output of the `cpio` would have been preceded this message. The user should take the appropriate action to correct the `cpio` failure. A common reason for failure will be insufficient disk space to save the old versions of the files. The user has two options for handling insufficient disk space: (1) generate additional disk space by deleting unneeded files, or (2) override the saving of the old files by using the `-d` option when running `patchadd`. However if the user elects not to save the old versions of the files to be patched, the patch *cannot* be backed out.

Message

```
Pkgadd of pkgname package failed with error code code.
See /tmp/log.patch_id for reason for failure.
```

Explanation and Recommended Action

The installation of one of the patch packages failed. `patchadd` will backout the patch to leave the system in its pre-patched state. See the log file for the reason for failure. Correct the problem and reapply the patch.

Message

```
Pkgadd of pkgname package failed with error code code.
Will not backout patch...patch re-installation.
Warning: The system may be in an unstable state!
See /tmp/log.patch_id for reason for failure.
```

Explanation and Recommended Action

The installation of one of the patch packages failed. `patchadd` will *not* backout the patch. You may manually backout the patch using `patchrm`, then re-apply the entire patch. Look in the log file for the reason `pkgadd` failed. Correct the problem and re-apply the patch.

Message

```
patchadd is unable to find the INST_RELEASE file. This file
must be present for patchadd to function correctly.
```

Explanation and Recommended Action

The `INST_RELEASE` file is missing from the system. This file is created during either initial installation or during an update.

Message

```
A previous installation of patch patch_id was invoked
that saved files that were to be patched. Since files
were saved, you must run this instance of patchadd
without the -d option.
```

Explanation and Recommended Action

If a patch was previously installed without using the `-d` option, then the re-installation attempt must also be invoked without the `-d` option. Execute `patchadd` without the `-d` option.

Message

```
A previous installation of patch patch_id was invoked
with the -d option. (i.e. Do not save files that would
be patched) Therefore, this invocation of patchadd
must also be run with the -d option.
```

Explanation and Recommended Action

If a patch was previously installed using the `-d` option, then the re-installation attempt must also be invoked with the `-d` option. Execute `patchadd` with the `-d` option.

**Diagnostic
Reference**

The patch installation messages listed below are not necessarily considered errors, as indicated in the explanations given. These messages are, however, recorded in the patch installation log for diagnostic reference.

patchadd(1M)

Message

```
Package not patched:
PKG=SUNxxxx
Original package not installed
```

Explanation and Recommended Action

One of the components of the patch would have patched a package that is not installed on your system. This is not necessarily an error. A patch may fix a related bug for several packages.

For example, suppose a patch fixes a bug in both the online-backup and `fddi` packages. If you had online-backup installed but didn't have `fddi` installed, you would get the message :

```
Package not patched:
PKG=SUNWbf
Original package not installed
```

This message only indicates an error if you thought the package was installed on your system. If this is the case, take the necessary action to install the package, backout the patch (if it installed other packages) and re-install the patch.

Message

```
Package not patched:
PKG=SUNxxx
ARCH=xxxxxxxx
VERSION=xxxxxxxx
Architecture mismatch
```

Explanation and Recommended Action

One of the components of the patch would have patched a package for an architecture different from your system. This is not necessarily an error. Any patch to one of the architecture-specific packages might contain one element for each of the possible architectures. For example, assume you are running on a `sun4u`. If you were to install a patch to package `SUNWcar`, you would see the following (or similar) messages:

```
Package not patched:
PKG=SUNWcar
ARCH=sparc.sun4c
VERSION=11.5.0,REV=2.0.18
Architecture mismatch
```

```
Package not patched:
PKG=SUNWcar
ARCH=sparc.sun4u
VERSION=11.5.0,REV=2.0.18
Architecture mismatch
```

```
Package not patched:
PKG=SUNWcar
ARCH=sparc.sun4e
VERSION=11.5.0,REV=2.0.18
```

```
Package not patched:
PKG=SUNWcar
ARCH=sparc.sun4
VERSION=11.5.0,REV=2.0.18
Architecture mismatch
```

These messages indicate an error condition only if patchadd does not correctly recognize your architecture.

Message

```
Package not patched:
PKG=SUNxxxx
ARCH=xxxx
VERSION=xxxxxxx
Version mismatch
```

Explanation and Recommended Action

The version of software to which the patch is applied is not installed on your system. For example, if you were running Solaris 8, and you tried to install a patch against Solaris 9, you would see the following (or similar) message:

```
Package not patched:
PKG=SUNWcsu
ARCH=sparc
VERSION=10.0.2
Version mismatch
```

This message does not necessarily indicate an error. If the version mismatch was for a package you needed patched, either get the correct patch version or install the correct package version. Then backout the patch (if necessary) and re-apply.

Message

```
Re-installing Patch.
```

Explanation and Recommended Action

The patch has already been applied, but there is at least one package in the patch that could be added. For example, if you applied a patch that had both Openwindows and Answerbook components, but your system did not have Answerbook installed, the Answerbook parts of the patch would not have been applied. If, at a later time, you pkgadd Answerbook, you could re-apply the patch, and the Answerbook components of the patch would be applied to the system.

Message

```
patchadd Interrupted.
patchadd is terminating.
```

Explanation and Recommended Action

patchadd was interrupted during execution (usually through pressing CTRL-c). patchadd will clean up its working files and exit.

Message

```
patchadd Interrupted.
Backing out Patch...
```

patchadd(1M)

	Explanation and Recommended Action patchadd was interrupted during execution (usually through pressing CTRL-c). patchadd will clean up its working files, backout the patch, and exit.
SEE ALSO	cpio(1), pkginfo(1), patchrm(1M), pkgadd(1M), pkgadm(1M), pkgchk(1M), pkgrm(1M), smpatch(1M), showrev(1M), attributes(5)
NOTES	To successfully install a patch to a client or server, patchadd must be issued twice, once with the -R option and once with the -S option. This guarantees that the patch is installed to both the /usr and root partitions. This is necessary if there are both /usr and root packages in the patch. pkgadd is invoked by patchadd and executes the installation scripts in the <i>pkg/install</i> directory. The checkinstall script is executed with its ownership set to user install, if there is no user install then pkgadd executes the checkinstall script as nobody. The SVR4 ABI states that the checkinstall shall only be used as an information gathering script. If the permissions for the checkinstall script are changed to something other than the initial settings, pkgadd may not be able to open the file for reading, thus causing the patch installation to abort with the following error: <pre>pkgadd: ERROR: checkinstall script did not complete successfully.</pre> The permission for the checkinstall script should not be changed. Contents of log file for a successful installation: patchadd redirects pkgadd's output to the patch installation log file. For a successful installation, pkgadd will produce the following message that gets inserted into the log file: <pre>This appears to be an attempt to install the same architecture and version of a package which is already installed. This installation will attempt to overwrite this package. This message does not indicate a failure, it represents the correct behavior by pkgadd when a patch installs correctly. This message does not indicate a failure, it represents the correct behavior by pkgadd when a patch installs correctly.</pre> On client server machines the patch package is <i>not</i> applied to existing clients or to the client root template space. Therefore, when appropriate, <i>all client machines will need the patch applied directly using this same patchadd method on the client</i>. See instructions above for applying patches to a client. A bug affecting a package utility (for example, pkgadd, pkgrm, pkgchk) could affect the reliability of patchadd or patchrm, which use package utilities to install and backout the patch package. It is recommended that any patch that fixes package utility problems be reviewed and, if necessary, applied before other patches are applied. Existing patches are: Solaris 2.5.1 Sparc Platform Edition: 104578 Solaris 2.5.1 Intel Platform Edition: 104579

patchadd(1M)

Solaris 2.6 Sparc Platform Edition:
106292

Solaris 2.6 Intel Platform Edition:
106293

patchrm(1M)

NAME	patchrm – remove a Solaris patch package and restore previously saved files
SYNOPSIS	patchrm [-f] [-B <i>backout_dir</i>] [-C <i>net_install_image</i> -R <i>client_root_path</i> -S <i>service</i>] <i>patch_id</i>
DESCRIPTION	patchrm removes a patch package and restores previously saved files to a system running the Solaris 2.x operating environment or later Solaris environments (such as Solaris 8) that are compatible with Solaris 2.x. patchrm cannot be used with Solaris 1 patches. patchrm must be run as root.
OPTIONS	The following options are supported: -B <i>backout_dir</i> Removes a patch whose backout data has been saved to a directory other than the package database. This option is only needed if the original backout directory, supplied to the patchadd command at installation time, has been moved. Specify <i>backout_dir</i> as an absolute path name. -C <i>net_install_image</i> Removes the patched files located on the mini root on a Net Install Image created by <i>setup_install_server</i>. Specify <i>net_install_image</i> as the absolute path name to a Solaris 2.6 or compatible version boot directory. See EXAMPLES. -f Forces the patch removal regardless of whether the patch was superseded by another patch. -R <i>client_root_path</i> Locates all patch files generated by patchrm under the directory <i>client_root_path</i>. <i>client_root_path</i> is the directory that contains the bootable root of a client from the server's perspective. Specify <i>client_root_path</i> as the absolute path name to the beginning of the directory tree under which all patch files generated from patchrm will be located. -R cannot be specified with the -S option. -S <i>service</i> Specifies an alternate service (for example, Solaris_2.3). This service is part of the server and client model, and can only be used from the server's console. Servers can contain shared /usr file systems that are created by Host Manager. These service areas can then be made available to the clients they serve. -S cannot be specified with the -R option..
OPERANDS	The following operands are supported: <i>patch_id</i> The patch number of a given patch. 104945-02 is an example of a <i>patch_id</i>.

EXAMPLES The examples in this section assume that patch 104945-02 has been installed to the system prior to removal. All of the examples are relative to the `/usr/sbin` directory.

EXAMPLE 1 Removing a Patch From a Stand-alone System

The following example removes a patch from a standalone system:

```
example# patchrm 104945-02
```

EXAMPLE 2 Removing a Patch From a Client's System From the Server's Console

The following example removes a patch from a client's system from the server's console:

```
example# patchrm -R /export/root/client1 104945-02
```

EXAMPLE 3 Removing a Patch From a Server's Service Area

The following example removes a patch from a server's service area:

```
example# patchrm -S Solaris_2.3 104945-02
```

EXAMPLE 4 Removing a Patch From a Net Install Image

The following example removes a patch from a Net Install Image:

```
example# patchrm -C /export/Solaris_2.6/Tools/Boot 104945-02
```

EXIT STATUS The following exit values are returned:

0 Successful completion.
>0 An error occurred.

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWswmt, SUNWcsu

DIAGNOSTICS The following messages may help in determining some of the most common problems associated with backing out a patch.

Message

```
prebackout patch exited with return code code.
patchrm exiting.
```

Explanation and Recommended Action

The prebackout script supplied with the patch exited with a return code other than 0. Generate a script trace of the prebackout script to determine why the

patchrm(1M)

prebackout script failed. Add the `-x` option to the first line of the prepatch script to fix the problem and run `patchadd` again.

Message

```
postbackout patch exited with return code code.
patchrm exiting.
```

Explanation and Recommended Action

The postbackout script supplied with the patch exited with a return code other than 0. Look at the postbackout script to determine why it failed. Add the `-x` option to the first line of the prepatch script to fix the problem, and, if necessary, *re-execute the postbackout script only*.

Message

```
Only one service may be defined.
```

Explanation and Recommended Action

You have attempted to specify more than one service from which to backout a patch. Different services must have their patches backed out with different invocations of `patchrm`.

Message

```
The -S and -R arguments are mutually exclusive.
```

Explanation and Recommended Action

You have specified both a non-native service and a *client_root_path* from which to backout a patch. These two arguments are mutually exclusive. If backing out a patch from a non-native `usr` partition, the `-S` option should be used. If backing out a patch from a client's root partition (either native or non-native), the `-R` option should be used.

Message

```
The service service cannot be found on this system
```

Explanation and Recommended Action

You have specified a non-native service from which to backout a patch, but the specified service is not installed on your system. Correctly specify the service when backing out the patch.

Message

```
Only one client_root_path may be defined.
```

Explanation and Recommended Action

You have specified more than one *client_root_path* using the `-R` option. The `-R` option may be used only once per invocation of `patchrm`.

Message

```
The dir directory cannot be found on this system.
```

Explanation and Recommended Action

You have specified a directory using the -R option which is either not mounted, or does not exist on your system. Verify the directory name and re-backout the patch.

Message

Patch *patch_id* has not been successfully installed to this system.

Explanation and Recommended Action

You have attempted to backout a patch that is not installed on this system. If you must restore previous versions of patched files, you may have to restore the original files from the initial installation CD.

Message

Patch *patch_id* has not been successfully applied to this system.
Will remove directory *dir*.

Explanation and Recommended Action

You have attempted to back out a patch that is not applied to this system. While the patch has not been applied, a residual `/var/sadm/patch/patch_id` (perhaps from an unsuccessful `patchadd`) directory still exists. The patch cannot be backed out. If you must restore old versions of the patched files, you may have to restore them from the initial installation CD.

Message

This patch was obsoleted by patch *patch_id*.
Patches must be backed out in the reverse order in which they were installed. Patch backout aborted.

Explanation and Recommended Action

You are attempting to backout patches out of order. Patches should never be backed-out out of sequence. This could undermine the integrity of the more current patch.

Message

Patch *patch_id* is required to be installed by an already installed *patch_id*.
It cannot be backed out until the required patch is backed out first.

Explanation and Recommended Action

Backout the patch that is required to be installed then backout the desired patch.

Message

The installation of patch *patch_id* was interrupted.

Explanation and Recommended Action

A previous installation was interrupted. The interrupted patch needs to be installed before backing out the desired patch.

patchrm(1M)

Message

Patch *patch_id* was installed without backing up the original files. It cannot be backed out.

Explanation and Recommended Action

Either the `-d` option of `patchadd` was set when the patch was applied, or the save area of the patch was deleted to regain space. As a result, the original files are not saved and `patchrm` cannot be used. The original files can only be recovered from the original installation CD.

Message

`pkgadd` of *pkgname* package failed return code *code*.
See `/var/sadm/patch/patch_id/log` for reason for failure.

Explanation and Recommended Action

The installation of one of patch packages failed. See the log file for the reason for failure. Correct the problem and run the backout script again.

Message

Restore of old files failed.

Explanation and Recommended Action

The backout script uses the `cpio` command to restore the previous versions of the files that were patched. The output of the `cpio` command should have preceded this message. The user should take the appropriate action to correct the `cpio` failure. This is for Solaris 2.4 or previous versions.

SEE ALSO `cpio(1)`, `pkginfo(1)`, `patchadd(1M)`, `pkgadd(1M)`, `pkgchk(1M)`, `pkgrm(1M)`, `showrev(1M)`, `attributes(5)`

NOTES On client server machines the patch package is *not* removed from existing clients or from client root template space. Therefore, when appropriate, *all client machines will need the patch removed directly using this same patchrm method on the client*. A bug affecting a package utility (for example, `pkgadd`, `pkgrm`, `pkgchk`) could affect the reliability of `patchadd` or `patchrm` which use package utilities to install and backout the patch package. It is recommended that any patch that fixes package utility problems be reviewed and, if necessary, applied before other patches are applied. Existing patches are:

pbind(1M)

NAME	pbind – control and query bindings of processes to processors						
SYNOPSIS	pbind -b <i>processor_id</i> <i>pid</i>... pbind -u <i>pid</i>... pbind [-q] [<i>pid</i>...]						
DESCRIPTION	pbind controls and queries bindings of processes to processors. pbind binds all the LWPs (lightweight processes) of a process to a processor, or removes or displays the bindings. When an LWP is bound to a processor, it will be executed only by that processor except when the LWP requires a resource that is provided only by another processor. The binding is not exclusive, that is, the processor is free execute other LWPs as well. Bindings are inherited, so new LWPs and processes created by a bound LWP will have the same binding. Binding an interactive shell to a processor, for example, binds all commands executed by the shell. Superusers may bind or unbind any process, and other users can use pbind to bind or unbind any process for which the user has permission to signal, that is, any process that has the same effective user ID as the user.						
OPTIONS	The following options are supported: <table> <tr> <td>-b <i>processor_id</i></td><td>Binds all the LWPs of the specified processes to the processor <i>processor_id</i>. Specify <i>processor_id</i> as the processor ID of the processor to be controlled or queried. <i>processor_id</i> must be present and on-line. Use the <code>psrinfo</code> command to determine whether or not <i>processor_id</i> is present and on-line. See <code>psrinfo(1M)</code>.</td></tr> <tr> <td>-q</td><td>Displays the bindings of the specified processes, or of all processes. If a process is composed of multiple LWPs, which have different bindings, the bindings of only one of the bound LWPs will be displayed.</td></tr> <tr> <td>-u</td><td>Removes the bindings of all LWPs of the specified processes, allowing them to be executed on any on-line processor.</td></tr> </table>	-b <i>processor_id</i>	Binds all the LWPs of the specified processes to the processor <i>processor_id</i> . Specify <i>processor_id</i> as the processor ID of the processor to be controlled or queried. <i>processor_id</i> must be present and on-line. Use the <code>psrinfo</code> command to determine whether or not <i>processor_id</i> is present and on-line. See <code>psrinfo(1M)</code> .	-q	Displays the bindings of the specified processes, or of all processes. If a process is composed of multiple LWPs, which have different bindings, the bindings of only one of the bound LWPs will be displayed.	-u	Removes the bindings of all LWPs of the specified processes, allowing them to be executed on any on-line processor.
-b <i>processor_id</i>	Binds all the LWPs of the specified processes to the processor <i>processor_id</i> . Specify <i>processor_id</i> as the processor ID of the processor to be controlled or queried. <i>processor_id</i> must be present and on-line. Use the <code>psrinfo</code> command to determine whether or not <i>processor_id</i> is present and on-line. See <code>psrinfo(1M)</code> .						
-q	Displays the bindings of the specified processes, or of all processes. If a process is composed of multiple LWPs, which have different bindings, the bindings of only one of the bound LWPs will be displayed.						
-u	Removes the bindings of all LWPs of the specified processes, allowing them to be executed on any on-line processor.						
OPERANDS	The following operands are supported: <table> <tr> <td><i>pid</i></td><td>The process ID of the process to be controlled or queried.</td></tr> </table>	<i>pid</i>	The process ID of the process to be controlled or queried.				
<i>pid</i>	The process ID of the process to be controlled or queried.						
EXAMPLES	EXAMPLE 1 Binding Processes The following example binds processes 204 and 223 to processor 2: <pre>example% pbind -b 2 204 223 process id 204: was 2, now 2 process id 223: was 3, now 2</pre>						

EXAMPLE 2 Unbinding a Process

The following example unbinds process 204:

```
example% pbind -u 204
```

EXAMPLE 3 Querying Bindings

The following example queries bindings. It demonstrates that process 1 is bound to processor 0, process 149 has at least one LWP bound to CPU3, and process 101 has no bound LWPs.

```
example% pbind -q 1 149 101
process id 1: 0
process id 149: 3
process id 101: not bound
```

ATTRIBUTES See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

EXIT STATUS The following exit values are returned:

```
0          Successful completion.
>0         An error occurred.
```

SEE ALSO psradm(1M), psrinfo(1M), psrset(1M), processor_bind(2), processor_info(2), sysconf(3C), attributes(5)

DIAGNOSTICS

```
pbind: cannot query pid 31: No such process
    The process specified did not exist or has exited.

pbind: cannot bind pid 31: Not owner
    The user does not have permission to bind the process.

pbind: cannot bind pid 31: Invalid argument
    The specified processor is not on-line.
```

pcmcia(1M)

NAME	pcmcia – PCMCIA user daemon				
SYNOPSIS	/usr/lib/pcmcia				
DESCRIPTION	The PCMCIA user daemon provides user-level services for the PCMCIA nexus driver and PCMCIA card client drivers. There are no user-configurable options for this daemon.				
ATTRIBUTES	See attributes(5) for descriptions of the following attributes: <table><tr><th>ATTRIBUTE TYPE</th><th>ATTRIBUTE VALUE</th></tr><tr><td>Availability</td><td>SUNWpcmcu</td></tr></table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	Availability	SUNWpcmcu
ATTRIBUTE TYPE	ATTRIBUTE VALUE				
Availability	SUNWpcmcu				
SEE ALSO	pcmcia(4), attributes(5)				
DIAGNOSTICS	pcmcia: can't open /dev/pem: No such file or directory The user daemon could not communicate with the PCMCIA event management driver.				

NAME	pfinstall – tests installation profiles						
SYNOPSIS	<code>/usr/sbin/install.d/pfinstall -D -d disk_config [-c CDpath] profile</code>						
DESCRIPTION	After you create a profile, you can use the <code>pfinstall</code> command to test the profile and see if it does what you want before using it to install or upgrade a system. <code>pfinstall</code> enables you to test a profile against: ■ The system's disk configuration where <code>pfinstall</code> is being run. ■ Other disks by using a disk configuration file that represents a structure of a disk. See NOTES on how to create a disk configuration file. To successfully and accurately test a profile for a particular Solaris release, you must test a profile within the Solaris environment of the same release. For example, if you want to test a profile for Solaris 2.6, you have to run the <code>pfinstall</code> command on a system running Solaris 2.6. So, on a system running Solaris 2.6, you can test Solaris 2.6 initial installation profiles. However, if you want to test a Solaris 2.6 upgrade profile on a system running a previous version of Solaris, or if you don't have a Solaris 2.6 system installed yet to test Solaris 2.6 initial installation profiles, you have to boot a system from a Solaris 2.6 CD image and temporarily create a Solaris 2.6 install environment. Then, you can run <code>pfinstall</code> in the Solaris 2.6 install environment to test your profiles. To create a temporary Solaris 2.6 install environment, boot a system from a Solaris 2.6 CD image (just as you would to install), answer any system identification questions, choose the Solaris Interactive Installation program, and exit out of the first screen that is presented. Then, from the shell, you can execute the <code>pfinstall</code> command.						
OPTIONS	The following options are supported: <table> <tr> <td><code>-c CDpath</code></td><td>The path to the Solaris 2 installation image. This is required if the image is not mounted on <code>/cdrom</code>. (For example, use this option if you copied the installation image to disk or mounted the CD-ROM on a directory other than <code>/cdrom</code>.)</td></tr> <tr> <td><code>-d disk_config</code></td><td><code>pfinstall</code> uses a disk configuration file, <i>disk_config</i>, to test the profile. See NOTES on how to create a disk configuration file. You must specify either this option or the <code>-D</code> option to test the profile (see WARNINGS). This option cannot be used with an upgrade profile (<code>install_type upgrade</code>). You must always test an upgrade profile against a system's disk configuration (<code>-D</code> option).</td></tr> <tr> <td><code>-D</code></td><td><code>pfinstall</code> uses the system's disk configuration to test the profile. You must specify either this option or the <code>-d</code> option to test the profile (see WARNINGS).</td></tr> </table>	<code>-c CDpath</code>	The path to the Solaris 2 installation image. This is required if the image is not mounted on <code>/cdrom</code> . (For example, use this option if you copied the installation image to disk or mounted the CD-ROM on a directory other than <code>/cdrom</code> .)	<code>-d disk_config</code>	<code>pfinstall</code> uses a disk configuration file, <i>disk_config</i> , to test the profile. See NOTES on how to create a disk configuration file. You must specify either this option or the <code>-D</code> option to test the profile (see WARNINGS). This option cannot be used with an upgrade profile (<code>install_type upgrade</code>). You must always test an upgrade profile against a system's disk configuration (<code>-D</code> option).	<code>-D</code>	<code>pfinstall</code> uses the system's disk configuration to test the profile. You must specify either this option or the <code>-d</code> option to test the profile (see WARNINGS).
<code>-c CDpath</code>	The path to the Solaris 2 installation image. This is required if the image is not mounted on <code>/cdrom</code> . (For example, use this option if you copied the installation image to disk or mounted the CD-ROM on a directory other than <code>/cdrom</code> .)						
<code>-d disk_config</code>	<code>pfinstall</code> uses a disk configuration file, <i>disk_config</i> , to test the profile. See NOTES on how to create a disk configuration file. You must specify either this option or the <code>-D</code> option to test the profile (see WARNINGS). This option cannot be used with an upgrade profile (<code>install_type upgrade</code>). You must always test an upgrade profile against a system's disk configuration (<code>-D</code> option).						
<code>-D</code>	<code>pfinstall</code> uses the system's disk configuration to test the profile. You must specify either this option or the <code>-d</code> option to test the profile (see WARNINGS).						
OPERANDS	The following operands are supported: <table> <tr> <td><i>profile</i></td><td>The file name of the profile to test. If <i>profile</i> is not in the directory where <code>pfinstall</code> is being run, you must specify the path.</td></tr> </table>	<i>profile</i>	The file name of the profile to test. If <i>profile</i> is not in the directory where <code>pfinstall</code> is being run, you must specify the path.				
<i>profile</i>	The file name of the profile to test. If <i>profile</i> is not in the directory where <code>pfinstall</code> is being run, you must specify the path.						

EXAMPLES**EXAMPLE 1** Testing an Upgrade Profile

The following example tests an upgrade profile, `upgrade.prof`, on a system with a previous version of the Solaris software installed.

1. Boot the system to be upgraded from the Solaris image chosen for the upgrade, just as you would to install. The image can be located in the system's local CD-ROM or on an install server.
2. Answer the system configuration questions, if prompted.
3. If you are presented with a choice of installation options, choose the Solaris Interactive Installation program.
4. Exit from the first screen of the Solaris Interactive Installation program.
After the Solaris Interactive Installation program exits, a shell prompt is displayed.
5. Create a temporary mount point:

```
example# mkdir /tmp/mnt
```

6. Mount the directory that contains the profile(s) you want to test.

If you want to mount a remote NFS file system (for systems on the network), enter:

```
mount -F nfs server_name:path /tmp/mnt
```

If you want to mount a UFS-formatted diskette, enter:

```
mount -F ufs /dev/diskette /tmp/mnt
```

If you want to mount a PCFS-formatted diskette, enter:

```
mount -F pcfs /dev/diskette /tmp/mnt
```

7. Change directory to `/tmp/mnt` where the profile resides:

```
example# cd /tmp/mnt
```

8. Test the `upgrade.prof` profile:

```
/usr/sbin/install.d/pfinstall -D upgrade.prof
```

EXAMPLE 2 Testing the `basic.prof` Profile

The following example tests the `basic.prof` profile against the disk configuration on a Solaris 2.6 system where `pfinstall` is being run. The path to the Solaris CD image is specified because Volume Management is being used.

```
example# /usr/sbin/install.d/pfinstall -D -c /cdrom/cdrom0/s0 basic.prof
```

EXAMPLE 3 Testing the `basic.prof` Profile

The following example tests the `basic.prof` profile against the `535_test` disk configuration file. This example uses a Solaris CD image located in the `/export/install` directory, and `pfinstall` is being run on a Solaris 2.6 system.

```
example# /usr/sbin/install.d/pfinstall -d 535_test \
-c /export/install basic.prof
```

EXIT STATUS	0	Successful (system rebooted).
	1	Successful (system not rebooted).
	2	An error occurred.

ATTRIBUTES See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWinst

SEE ALSO fdisk(1M), prtvtoc(1M), attributes(5)

Solaris 9 9/04 Installation Guide

WARNINGS If the -d or -D option is not specified, pfinstall may perform an actual installation on the system by using the specified profile, and the data on the system may be overwritten.

NOTES You have to test a profile on a system with the same platform type for which the profile was created.

SPARC To create a disk configuration file (-d option) for a SPARC based system:

1. Locate a SPARC based system with a disk that you want to test.
2. Create a disk configuration file by redirecting the output of the prtvtoc(1M) command to a file.

```
example# prtvtoc /dev/rdisk/c0t3d0s2 > 535_disk
```

3. (Optional.) Concatenate disk configuration files into a single file to test a profile against multiple disks. The target numbers in the disk device names must be unique.

```
example# cat 535_disk 1G_disk > mult_disks
```

x86 To create a disk configuration file (-d option) for an x86 based system:

1. Locate an x86 based system with a disk that you want to test.
2. Create part of the disk configuration file by saving the output of the fdisk(1M) command to a file:

```
example# fdisk -R -W 535_disk /dev/rdisk/c0t3d0p0
```

3. Append the output of the prtvtoc(1M) command to the disk configuration file.

```
example# prtvtoc /dev/rdisk/c0t3d0s2 >> 535_disk
```

`pfinstall(1M)`

4. (Optional.) Concatenate disk configuration files into a single file to test a profile against multiple disks. The target numbers in the disk device names must be unique.

```
example# cat 535_disk 1G_disk > mult_disks
```

To test a profile with a specific system memory size, set `SYS_MEMSIZE` to the specific memory size (in Mbytes) before running `pfinstall`:

```
example# SYS_MEMSIZE=memory_size
```

```
example# export SYS_MEMSIZE
```

NAME	pgxconfig, GFXconfig, TSIfxconfig – configure the PGX32 (Raptor GFX) Graphics Accelerator
SYNOPSIS	<pre> /usr/sbin/pgxconfig [-dev <i>device-filename</i>] [-res <i>video-mode</i> [try noconfirm nocheck]] [-file machine system] [-depth 8 24] [-24only true false] [-cachedpixmap true false] [-defaults] /usr/sbin/pgxconfig [-propt] [-prconf] /usr/sbin/pgxconfig [-help] [-res ?] /usr/sbin/pgxconfig [-i] </pre>
DESCRIPTION	The <code>pgxconfig</code> utility configures the PGX32 (Raptor GFX) Graphics Accelerator and some of the X11 window system defaults for PGX32 (Raptor GFX). A previous version of this utility was named <code>GFXconfig</code>. The first form of <code>pgxconfig</code> shown in the synopsis above stores the specified options in the <code>OWconfig</code> file. These options are used to initialize the PGX32 (Raptor GFX) device the next time the window system is run on that device. Updating options in the <code>OWconfig</code> file provides persistence of these options across window system sessions and system reboots. The second, third, and fourth forms, which invoke only the <code>-prconf</code>, <code>-propt</code>, <code>-help</code>, and <code>-res ?</code> options, do not update the <code>OWconfig</code> file. For the third form all other options are ignored. The <code>-i</code> option starts <code>pgxconfig</code> in interactive mode. Options may be specified for only one PGX32 (Raptor GFX) device at a time. Only PGX32 (Raptor GFX)-specific options can be specified through <code>pgxconfig</code>. The normal window system options for specifying default depth, default visual class and so forth are still specified as device modifiers on the <code>openwin</code> command line. See the <code>Xsun(1)</code> manual page available with the <code>SUNWxwman</code> package. The user can also specify the <code>OWconfig</code> file that is to be updated. By default, the machine-specific file in the <code>/usr/openwin</code> directory tree is updated. The <code>-file</code> option can be used to specify an alternate file to use. For example, the system-global <code>OWconfig</code> file in the <code>/etc/openwin</code> directory tree can be updated instead. Both of these standard <code>OWconfig</code> files can only be written by root.
OPTIONS	The following options are supported: <code>-cachedpixmap true false</code> When set to <code>false</code>, it forces the PGX32 (Raptor GFX) device to use 24-bit only when running OpenWindows. The default value is <code>true</code>.

pgxconfig(1M)

Certain applications make use of a cached pixmap when writing to the display device. Such a technique can cause garbled output and can cause the X server to crash. If you experience such behavior, try setting the `-cachedpixmap` option to `false`.

`-defaults`

Reset all option values to their default values.

`-depth 8 | 24`

Sets the screen depth to 8 or 24 bits per pixel. 24 bits per pixel enables TrueColor graphics in the window system.

`-dev device-filename`

Specify the PGX32 (Raptor GFX) special file. The default is `/dev/fbs/gfxp0`, or `/dev/fbs/raptor0` if applicable.

`-file machine | system`

Specify which OWconfig file to update. If `machine`, the machine-specific OWconfig file in the `/etc/openwin` directory tree is used. If `system`, the global OWconfig file in the `/usr/openwin` directory tree is used. If the file does not exist, it is created.

`-help`

Print a list of the `pgxconfig` command line options, along with a brief explanation of each.

`-i`

Start `pgxconfig` in interactive mode.

`-prconf`

Print the PGX32 (Raptor GFX) hardware configuration. The following is a typical display:

```
--- Hardware Configuration for /dev/fbs/gfxp0 ---
DAC: version 0x0
Type:
Board:
PROM: version 0x0
PROM Information:
RAM:
EDID Data:
Monitor Sense ID:
Card possible resolutions:  640x480x60, 800x600x75, 1024x768x60

                             1024x768x87, 1024x768x60, 1024x768x70, 1024x768x75,
                             1280x1024x75, 1280x1024x76, 1152x900x66, 1152x900x76,
                             1280x1024x67, 960x680x112S, vga, svga, 1152, 1280
                             stereo
```

Current resolution setting: 1280x1024x76
Possible depths: 8, 24, 8+24
Current depth: 8

-propt
Print the current values of all PGX32 (Raptor GFX) options in the OWconfig file specified by the **-file** option for the device specified by the **-dev** option. Print the values of options as they would be in the OWconfig file after the call to pgxconfig would have completed. The following is a typical display:

```
--- OpenWindows Configuration for /dev/fbs/gfxp0 ---  
OWconfig: machine  
Video Mode: not set  
Depth: 8+24
```

-res *video-mode* [*try* | *noconfirm* | *nocheck*]
Specify the built-in video mode used to drive the monitor connected to the specified PGX32 (Raptor GFX) device.

The format for *video-mode* can be one of the following:

widthxheightxrate The *width* is the screen width in pixels, *height* is the screen height in pixels, and *rate* is the vertical frequency of the screen refresh. As a convenience, **-res** also accepts formats with **@** prepended to the refresh rate rather than **x**. For example: 1280x1024@76. The list can be obtained by running pgxconfig with the **-res ?** option (the third form shown in the command synopsis above). Note that not all resolutions are supported by both the video board and by the monitor. The pgxconfig utility will not permit you to set a resolution not supported by the board unless the **noconfirm** or **nocheck** option is specified. It will also request confirmation before setting a resolution not supported by the monitor if the **nocheck** option is not specified.

Symbolic names For convenience, the video modes listed below have symbolic names defined. Rather than the form *widthxheightxrate*, the symbolic name may be supplied as the argument to **-res**. If the symbolic name is **none**, the screen resolution will be the video mode that is currently programmed in the device when the window system is run.

svga	1024x768x60
1152	1152x900x76
1280	1280x1024x76
vga	640x480x60

pgxconfig(1M)

none default console resolution

The `-res` option also accepts additional, optional arguments immediately following the video mode specification. Any or all of these may be present.

noconfirm

Using the `-res` option, the user could put the system into an unusable state, a state where there is no video output. This can happen if there is ambiguity in the monitor sense codes for the particular code read. To reduce the chance of this occurring, the default behavior of `pgxconfig` is to print a warning message to this effect and to prompt the user to find out if it is okay to continue. The `noconfirm` option instructs `pgxconfig` to bypass this confirmation and to program the requested video mode anyway. This option is useful when `pgxconfig` is being run from a shell script.

nocheck

If present, normal error checking based on the monitor sense code is suspended. The video mode specified by the user will be accepted regardless of whether it is appropriate for the currently attached monitor. (This option is useful if a different monitor is to be connected to the PGX32 (Raptor GFX) device). Use of this option implies `noconfirm` as well.

try

This option allows the user to test the specified resolution before committing it. It displays a pattern on the screen with the specified resolution. If the test pattern appears correctly, the user may answer "y" to the query. The other permissible answer is "n".

-res ?

Print the list of possible resolutions supported by the PGX32 and the monitor.

-24only

Force the PGX32 (Raptor GFX) device to use 24 bit only when running Openwindows.

DEFAULTS

For a given invocation of `pgxconfig`, if an option does not appear on the command line, the corresponding `OWconfig` option is not updated; it retains its previous value, except for `-depth` and `-24only`.

A default value is used if a PGX32 (Raptor GFX) option has not been specified with `pgxconfig` when the window system is run. The option defaults are as follows:

<code>-dev</code>	<code>/dev/fbs/gfxp0</code>
<code>-file</code>	<code>system</code>
<code>-res</code>	<code>none</code>

The default of `none` for the `-res` option indicates that when the window system is run, the screen resolution will be the video mode that is currently programmed in the device.

EXAMPLES	EXAMPLE 1 Switching the Resolution on the Monitor Type
	The following example switches the monitor type to the resolution of 1280 x 1024 at 76 Hz: example# /usr/sbin/pgxconfig -res 1280x1024x76
FILES	/dev/fbs/gfxp0 device special file
	/usr/openwin/server/etc/OWconfig system configuration file
	/etc/openwin/server/etc/OWconfig machine configuration file
SEE ALSO	<i>PGX32 Installation Manual</i>

picld(1M)

NAME	picld – PICL daemon
SYNOPSIS	<code>/usr/lib/picl/picld</code>
DESCRIPTION	The Platform Information and Control Library (PICL) provides a mechanism to publish platform-specific information for clients to access in a platform-independent way. <code>picld</code> maintains and controls access to the PICL information from clients and plug-in modules. The daemon is started in both single-user and multi-user boot mode. Upon startup, the PICL daemon loads and initializes the plug-in modules. These modules use the <code>libpicltree(3PICLTREE)</code> interface to create nodes and properties in the PICL tree to publish platform configuration information. After the plug-in modules are initialized, the daemon opens the PICL daemon door to service client requests to access information in the PICL tree.
PICL Tree	The PICL tree is the repository of all the nodes and properties created by the plug-in modules to represent the platform configuration. Every node in the PICL tree is an instance of a well-defined PICL class. The name of the base PICL class is <code>picl</code>, which defines a basic set of properties that all nodes in the tree must possess. Two of those properties are <code>name</code> and <code>_class</code>, where <code>name</code> contains the name of the node, and the <code>_class</code> contains the PICL class name of the node. Certain nodes in the PICL tree have well-known names. For example, the name of the root node of the PICL tree is <code>/</code> and the name of the root node of the sub-tree containing platform device nodes is <code>platform</code>.
PICL plug-in Modules	The PICL plug-in modules are shared objects that publish platform-specific data in the PICL tree. They are located in well-known directories so that the daemon can locate and load them. Plug-in modules are located in one of the following plug-in directories depending on the platform-specific nature of the data that they collect and publish: <pre>/usr/platform/'uname -i'/lib/picl/plugins /usr/platform/'uname -m'/lib/picl/plugins</pre> A plug-in module can specify its dependency on another plug-in module using the <code>-l</code> or <code>-R</code> linker option. The plug-ins are loaded by the daemon using <code>dlopen(3DL)</code> according to the specified dependencies. Each plug-in module must define a <code>.init</code> section, which is executed when the plug-in module is loaded, to register themselves with the daemon. See <code>picld_plugin_register(3PICLTREE)</code> for additional information on plug-in registration. The plug-in modules use the <code>libpicltree(3PICLTREE)</code> interface to publish nodes and properties in the PICL tree so that clients can access them. When the PICL daemon invokes the initialization routine of the plug-in module, the plug-in collects the platform information and creates nodes and/or properties to represent the configuration in the PICL tree. A plug-in can create additional threads to monitor the platform configuration and update the PICL tree with any changes. This enables a PICL plug-in to operate as a daemon within the PICL framework.

An environmental monitor is an example of a plug-in module that uses a thread to monitor the temperatures and fan speeds of the platform, then publishes the environmental information in the PICL tree so clients can access them.

Clients use the `libpicl(3PICL)` interface to send requests to `picld` for accessing the PICL tree.

EXIT STATUS `picld` does not return an exit status.

FILES

<code>/var/run/picld_door</code>	PICL daemon door
<code>/usr/lib/picl/picld</code>	PICL daemon
<code>/etc/init.d/picld</code>	Start/stop script

ping(1M)

NAME	ping – send ICMP (ICMP6) ECHO_REQUEST packets to network hosts						
SYNOPSIS	<pre>/usr/sbin/ping host [timeout] /usr/sbin/ping -s [-l -U] [-adlLnRv] [-A addr_family] [-c traffic_class] [-g gateway [-g gateway...]] [-F flow_label] [-I interval] [-i interface] [-P tos] [-p port] [-t ttl] host [data_size] [npackets]</pre>						
DESCRIPTION	The utility <code>ping</code> utilizes the ICMP (ICMP6 in IPv6) protocol's ECHO_REQUEST datagram to elicit an ICMP (ICMP6) ECHO_RESPONSE from the specified <i>host</i> or network <i>gateway</i>. If <i>host</i> responds, <code>ping</code> will print: <pre>host is alive</pre> on the standard output and exit. Otherwise, after <i>timeout</i> seconds, it will write: <pre>no answer from host</pre> The default value of <i>timeout</i> is 20 seconds. When you specify the <code>s</code> flag, sends one datagram per second (adjust with <code>-I</code>) and prints one line of output for every ECHO_RESPONSE that it receives. <code>ping</code> produces no output if there is no response. In this second form, <code>ping</code> computes round trip times and packet loss statistics; it displays a summary of this information upon termination or timeout. The default <i>data_size</i> is 56 bytes, or you can specify a size with the <i>data_size</i> command-line argument. If you specify the optional <i>npackets</i>, <code>ping</code> sends <code>ping</code> requests until it either sends <i>npackets</i> requests or receives <i>npackets</i> replies. When using <code>ping</code> for fault isolation, first <code>ping</code> the local host to verify that the local network interface is running.						
OPTIONS	The following options are supported: <table><tr><td><code>-A addr_family</code></td><td>Specify the address family of the target host. <i>addr_family</i> can be either <code>inet</code> or <code>inet6</code>. Address family determines which protocol to use. For an argument of <code>inet</code>, IPv4 is used. For <code>inet6</code>, IPv6 is used.</td></tr><tr><td></td><td>By default, if the name of a host is provided, not the literal IP address, and a valid IPv6 address exists in the name service database, <code>ping</code> will use this address. Otherwise, if the name service database contains an IPv4 address, it will try the IPv4 address.</td></tr><tr><td></td><td>Specify the address family <code>inet</code> or <code>inet6</code> to override the default behavior. If the argument specified is <code>inet</code>, <code>ping</code> will use the IPv4 address associated with the host</td></tr></table>	<code>-A addr_family</code>	Specify the address family of the target host. <i>addr_family</i> can be either <code>inet</code> or <code>inet6</code> . Address family determines which protocol to use. For an argument of <code>inet</code> , IPv4 is used. For <code>inet6</code> , IPv6 is used.		By default, if the name of a host is provided, not the literal IP address, and a valid IPv6 address exists in the name service database, <code>ping</code> will use this address. Otherwise, if the name service database contains an IPv4 address, it will try the IPv4 address.		Specify the address family <code>inet</code> or <code>inet6</code> to override the default behavior. If the argument specified is <code>inet</code> , <code>ping</code> will use the IPv4 address associated with the host
<code>-A addr_family</code>	Specify the address family of the target host. <i>addr_family</i> can be either <code>inet</code> or <code>inet6</code> . Address family determines which protocol to use. For an argument of <code>inet</code> , IPv4 is used. For <code>inet6</code> , IPv6 is used.						
	By default, if the name of a host is provided, not the literal IP address, and a valid IPv6 address exists in the name service database, <code>ping</code> will use this address. Otherwise, if the name service database contains an IPv4 address, it will try the IPv4 address.						
	Specify the address family <code>inet</code> or <code>inet6</code> to override the default behavior. If the argument specified is <code>inet</code> , <code>ping</code> will use the IPv4 address associated with the host						

ping(1M)

	name. If none exists, <code>ping</code> will state that the host is unknown and exit. It does not try to determine if an IPv6 address exists in the name service database.
	If the specified argument is <code>inet6</code> , <code>ping</code> uses the IPv6 address that is associated with the host name. If none exists, <code>ping</code> states that the host is unknown and exits.
<code>-F flow_label</code>	Specify the flow label of probe packets. The value must be an integer in the range from 0 to 1048575. This option is valid only on IPv6.
<code>-I interval</code>	Turn on the statistics mode and specify the interval between successive transmissions. The default is one second. See the discussion of the <code>-s</code> option.
<code>-L</code>	Turn off loopback of multicast packets. Normally, members are in the host group on the outgoing interface, a copy of the multicast packets will be delivered to the local machine.
<code>-P tos</code>	Set the type of service (<i>tos</i>) in probe packets to the specified value. The default is zero. The value must be an integer in the range from 0 to 255. Gateways also in the path can route the probe packet differently, depending upon the value of <i>tos</i> that is set in the probe packet. This option is valid only on IPv4.
<code>-R</code>	Record route. Sets the IPv4 record route option, which stores the route of the packet inside the IPv4 header. The contents of the record route are only printed if the <code>-v</code> and <code>-s</code> options are given. They are only set on return packets if the target host preserves the record route option across echos, or the <code>-l</code> option is given. This option is valid only on IPv4.
<code>-U</code>	Send UDP packets instead of ICMP (ICMP6) packets. <code>ping</code> sends UDP packets to consecutive ports expecting to receive back ICMP (ICMP6) <code>PORT_UNREACHABLE</code> from the target host.
<code>-a</code>	<code>ping</code> all addresses, both IPv4 and IPv6, of the multihomed destination. The output appears as if <code>ping</code> has been run once for each IP address of the destination. If this option is used together with <code>-A</code> , <code>ping</code> probes only the addresses that are of the specified address family. When used with the <code>-s</code> option and <i>npackets</i> is not specified, <code>ping</code> continuously probes the destination addresses in a round robin

ping(1M)

	fashion. If <i>npackets</i> is specified, <i>ping</i> sends <i>npackets</i> number of probes to each IP address of the destination and then exits.
-c <i>traffic_class</i>	Specify the traffic class of probe packets. The value must be an integer in the range from 0 to 255. Gateways along the path can route the probe packet differently, depending upon the value of <i>traffic_class</i> set in the probe packet. This option is valid only on IPv6.
-d	Set the <code>SO_DEBUG</code> socket option.
-g <i>gateway</i>	Specify a loose source route gateway so that the probe packet goes through the specified host along the path to the target host. The maximum number of gateways is 8 for IPv4 and 127 for IPv6. Note that some factors such as the link MTU can further limit the number of gateways for IPv6.
-i <i>interface_address</i>	Specify the outgoing interface address to use for multicast packets for IPv4 and both multicast and unicast packets for IPv6. The default interface address for multicast packets is determined from the (unicast) routing tables. <i>interface_address</i> can be a literal IP address, for example, 10.123.100.99, or an interface name, for example, <code>le0</code> , or an interface index, for example 2.
-l	Use to send the probe packet to the given host and back again using loose source routing. Usually specified with the <code>-R</code> option. If any gateways are specified using <code>-g</code> , they are visited twice, both to and from the destination. This option is ignored if the <code>-U</code> option is used.
-n	Show network addresses as numbers. <i>ping</i> normally does a reverse name lookup on the IP addresses it extracts from the packets received. The <code>-n</code> option blocks the reverse lookup, so <i>ping</i> prints IP addresses instead of host names.
-p <i>port</i>	Set the base UDP <i>port</i> number used in probes. This option is used with the <code>-U</code> option. The default base <i>port</i> number is 33434. The <i>ping</i> utility starts setting the destination port number of UDP packets to this base and increments it by one at each probe.
-r	Bypass the normal routing tables and send directly to a host on an attached network. If the host is not on a directly attached network, an error is returned. This

		option can be used to ping a local host through an interface that has been dropped by the router daemon. See in.routed(1M).				
	-s	Send one datagram per second and collect statistics.				
	-t ttl	Specify the IPv4 time to live, or IPv6 hop limit, for unicast and multicast packets. The default time to live (hop limit) for unicast packets can be set with ndd(1M) using the icmp_ipv4_ttl variable for IPv4 and the icmp_ipv6_ttl variable for IPv6. The default time to live (hop limit) for multicast is one hop.				
	-v	Verbose output. List any ICMP (ICMP6) packets, other than replies from the target host.				
OPERANDS	host	The network host				
EXAMPLES	EXAMPLE 1 Using ping With IPv6 This example shows ping sending probe packets to all the IPv6 addresses of the host london, one at a time. It sends an ICMP6 ECHO_REQUEST every second until the user interrupts it. <pre>istanbul% ping -s -A inet6 -a london PING london: 56 data bytes 64 bytes from london (4::114:a00:20ff:ab3d:83ed): icmp_seq=0. time=2. ms 64 bytes from london (fec0::114:a00:20ff:ab3d:83ed): icmp_seq=1. time=1. ms 64 bytes from london (4::114:a00:20ff:ab3d:83ed): icmp_seq=2. time=1. ms 64 bytes from london (fec0::114:a00:20ff:ab3d:83ed): icmp_seq=3. time=1. ms 64 bytes from london (4::114:a00:20ff:ab3d:83ed): icmp_seq=4. time=1. ms 64 bytes from london (fec0::114:a00:20ff:ab3d:83ed): icmp_seq=5. time=1. ms ^C ----london PING Statistics---- 6 packets transmitted, 6 packets received, 0% packet loss round-trip (ms) min/avg/max = 1/1/2</pre>					
EXIT STATUS	The following exit values are returned: <table><tr><td>0</td><td>Successful operation; the machine is alive.</td></tr><tr><td>non-zero</td><td>An error has occurred. Either a malformed argument has been specified, or the machine was not alive.</td></tr></table>		0	Successful operation; the machine is alive.	non-zero	An error has occurred. Either a malformed argument has been specified, or the machine was not alive.

NAME	pkgadd – transfer software packages to the system
SYNOPSIS	<pre>pkgadd [-nvi] [-a <i>admin</i>] [-d <i>device</i>] [-x <i>proxy</i>] [[-M] -R <i>root_path</i>] [-r <i>response</i>] [-k <i>keystore</i>] [-P <i>passwd</i>] [-V <i>fs_file</i>] [<i>source</i>] [<i>instances</i>] pkgadd -s [<i>source</i>] [<i>instances</i>]</pre>
DESCRIPTION	pkgadd transfers the contents of a software package from the distribution medium or directory to install it onto the system. Used without the -d option, pkgadd looks in the default spool directory for the package (var/spool/pkg). Used with the -s option, it writes the package to a spool directory instead of installing it. The pkgadd utility requires an amount of temporary space the size of the package that is being installed. pkgadd determines which temporary directory to use by checking for the existence of the \$TMPDIR environment variable. If \$TMPDIR is not defined, pkgadd uses P_tmpdir from stdio.h. P_tmpdir has a default of /var/tmp/. Certain unbundled and third-party packages are no longer entirely compatible with the latest version of pkgadd. These packages require user interaction throughout the installation and not just at the very beginning. To install these older packages (released prior to Solaris 2.4), set the following environment variable: NONABI_SCRIPTS=TRUE pkgadd permits keyboard interaction throughout the installation as long as this environment variable is set.
OPTIONS	The following options are supported: -a <i>admin</i> Define an installation administration file, <i>admin</i>, to be used in place of the default administration file. The token none overrides the use of any <i>admin</i> file, and thus forces interaction with the user. Unless a full path name is given, pkgadd first looks in the current working directory for the administration file. If the specified administration file is not in the current working directory, pkgadd looks in the /var/sadm/install/admin directory for the administration file. -d <i>device</i> Install or copy a package from <i>device</i>. <i>device</i> can be a full path name to a directory or the identifiers for tape, floppy disk, or removable disk (for example, /var/tmp or /floppy/floppy_name). It can also be a device alias (for example, /floppy/floppy0) or a datastream created by pkgtrans (see pkgtrans(1)). -k <i>keystore</i> Use <i>keystore</i> as the location from which to get trusted certificate authority certificates when verifying digital signatures found in packages. If no keystore is specified, then the default keystore locations are searched for valid trusted certificates. See KEYSTORE LOCATIONS for more information. -M Instruct pkgadd not to use the \$root_path/etc/vfstab file for determining the client's mount points. This option assumes the

pkgadd(1M)

	mount points are correct on the server and it behaves consistently with Solaris 2.5 and earlier releases.
-n	Installation occurs in non-interactive mode. Suppress output of the list of installed files. The default mode is interactive.
-P <i>passwd</i>	Password to use to decrypt keystore specified with -k, if required. See PASS PHRASE ARGUMENTS for more information about the format of this option's argument.
-r <i>response</i>	Identify a file or directory which contains output from a previous pkgask(1M) session. This file supplies the interaction responses that would be requested by the package in interactive mode. <i>response</i> must be a full pathname.
-R <i>root_path</i>	Define the full path name of a directory to use as the <i>root_path</i> . All files, including package system information files, are relocated to a directory tree starting in the specified <i>root_path</i> . The <i>root_path</i> may be specified when installing to a client from a server (for example, /export/root/client1).
-s <i>spool</i>	Write the package into the directory <i>spool</i> instead of installing it.
-v	Trace all of the scripts that get executed by pkgadd, located in the <i>pkginst/install</i> directory. This option is used for debugging the procedural and non-procedural scripts.
-V <i>fs_file</i>	Specify an alternative <i>fs_file</i> to map the client's file systems. For example, used in situations where the <i>\$root_path/etc/vfstab</i> file is non-existent or unreliable.
-x <i>proxy</i>	Specify a HTTP[S] proxy to use when downloading packages. The format of proxy is <i>host:port</i> , where <i>host</i> is the hostname of the HTTP[S] proxy, and <i>port</i> is the port number associated with the proxy. This switch overrides all other methods of specifying a proxy. See ENVIRONMENT VARIABLES for more information on alternate methods of specifying a default proxy.
	When executed without options or operands, pkgadd uses /var/spool/pkg (the default spool directory).
OPERANDS	The following operands are supported:
Sources	By default, pkgadd looks in the /var/spool/pkg directory when searching for instances of a package to install or spool. Optionally, the source for the package instances to be installed or spooled can be specified using:
	-d <i>device</i> Install or copy a package from <i>device</i> . <i>device</i> can be a full path name to a directory or the identifiers for tape, floppy disk, or removable disk (for example, /var/tmp or /floppy/floppy_name). It can also be a device alias (for example, /floppy/floppy0) or a datastream created by pkgtrans (see pkgtrans(1)).

	<i>device</i> can also be a URL pointing to a datastream created by <code>pkgtrans</code>.
Instances	By default, <code>pkgadd</code> searches the specified source, and presents an interactive menu allowing the user to select which package instances found on the source are to be installed. As an alternative, the package instances to be installed can be specified using: <i>pkginst</i> The package instance or list of instances to be installed. The token <code>all</code> may be used to refer to all packages available on the source medium. The format <i>pkginst</i>. * can be used to indicate all instances of a package. The asterisk character (*) is a special character to some shells and may need to be escaped. In the C-Shell, the asterisk must be surrounded by single quotes (') or preceded by a backslash (\). -Y <i>category</i>[,<i>category</i>...] Install packages based on the value of the <code>CATEGORY</code> parameter stored in the package's <code>pkginfo(4)</code> file. All packages on the source medium whose <code>CATEGORY</code> matches one of the specified categories will be selected for installation or spooling.
KEYSTORE LOCATIONS	Package and patch tools such as <code>pkgadd</code> or <code>patchadd</code> use a set of trusted certificates to perform signature validation on any signatures found within the packages or patches. If there are no signatures included in the packages or patches then signature validation is skipped. The certificates can come from a variety of locations. If <code>-k keystore</code> is specified, and <i>keystore</i> is a directory, then <i>keystore</i> is assumed to be the base directory of the certificates to be used. If <i>keystore</i> is a file, then the file itself is assumed to have all required keys and certificates. When <code>-k</code> is not specified, then <code>/var/sadm/security</code> is used as the base directory. Within the specified base directory, the store locations to be searched are different based on the application doing the searching and the type of store being searched for. The following directories are searched in the specified order: 1. <code><store_dir>/<app_name>/<store_type></code> 2. <code><store_dir>/<store_type></code> Where <code><store_dir></code> is the directory specified by <code>-k</code>, <code><app_name></code> is the name of the application doing the searching, and <code><store_type></code> is one of <code>keystore</code> (for private keys), <code>certstore</code> (for untrusted public key certificates), or <code>truststore</code> (for trusted certificate authority certificates). For example, when <code>pkgadd</code> is run with <code>-k /export/certs</code>, then the following locations are successively searched to find the trust store: 1. <code>/export/certs/pkgadd/truststore</code> 2. <code>/export/certs/truststore</code> This searching order enables administrators to have a single location for most applications, and special certificate locations for certain applications.

pkgadd(1M)

KEYSTORE AND CERTIFICATE FORMATS

The packaging and patching utilities, such as `pkgtrans` and `patchadd`, require access to a set of keys and certificates in order to sign, and optionally verify, packages and patches.

The keystore files found by following the search pattern specified in `KEYSTORE LOCATIONS` must each be a self-contained PKCS#12-format file.

When signing a package with `pkgtrans`, if a `certstore` has more than one public key certificate, then each public key must have a `friendlyName` attribute in order to be identifiable and selectable with the `-a` option when signing packages or patches. In addition, the public key certificate selected with `-a` and found in the `certstore` must have an associated private key in the keystore.

Several browsers and utilities can be used to export and import certificates and keys into a PKCS#12 keystore. For example, a trusted certificate can be exported from Netscape, and then imported into a PKCS#12 keystore for use with `pkgadd` with the OpenSSL Toolkit.

PASS PHRASE ARGUMENTS

`pkgtrans` and `pkgadd` accept password arguments, typically using `-p` to specify the password. These allow the password to be obtained from a variety of sources. Both of these options take a single argument whose format is described below. If no password argument is given and a password is required then the user is prompted to enter one: this will typically be read from the current terminal with echoing turned off.

`pass:password`

The actual password is *password*. Because the password is visible to utilities such as `ps` this form should only be used where security is not important.

`env:var`

Obtain the password from the environment variable *var*. Because the environment of other processes is visible on certain platforms this option should be used with caution.

`file:pathname`

The first line contained within *pathname* is the password. *pathname* need not refer to a regular file: it could, for example, refer to a device or named pipe. For example, to read the password from standard input, use `file:/dev/stdin`.

`console`

Read the password from `/dev/tty`.

EXAMPLES

EXAMPLE 1 Installing a Package from a Solaris CD-ROM

The following example installs a package from a Solaris CD-ROM. You are prompted for the name of the package you want to install.

```
example% pkgadd -d /cdrom/cdrom0/s0/Solaris_2.6
```

EXIT STATUS

0	Successful completion
1	Fatal error.

**ENVIRONMENT
VARIABLES**

- 2 Warning.
- 3 Interruption.
- 4 Administration.
- 5 Administration. Interaction is required. Do not use `pkgadd -n`.
- 10 Reboot after installation of all packages.
- 20 Reboot after installation of this package.
- HTTPPROXY
Specifies an HTTP proxy host. Overrides administration file setting, and `http_proxy` environment variable.
- HTTPPROXYPORT
Specifies the port to use when contacting the host specified by HTTPPROXY. Ignored if HTTPPROXY is not set.
- `http_proxy`
URL format for specifying proxy host and port. Overrides administration file setting.

Application Packaging Developer's Guide

<http://www.openssl.org>

NOTES

When transferring a package to a spool directory, the `-r`, `-n`, and `-a` options cannot be used.

The `-r` option can be used to indicate a directory name as well as a filename. The directory can contain numerous response files, each sharing the name of the package with which it should be associated. This would be used, for example, when adding multiple interactive packages with one invocation of `pkgadd`. In this situation, each package would need a response file. If you create response files with the same name as the package (for example, `pkinst1` and `pkinst2`), then name the directory in which these files reside after the `-r`.

The `-n` option causes the installation to halt if any interaction is needed to complete it.

pkgadd(1M)

If the default *admin* file is too restrictive, the administration file may need to be modified to allow for total non-interaction during a package installation. See [admin\(4\)](#) for details.

If a package stream is specified with *-d*, and a digital signature is found in that stream, the default behavior is to attempt to validate the certificate and signature found. This behavior can be overridden with *admin* file settings. See [admin\(4\)](#) for more information.

NAME	pkgadm – manage packaging and patching system				
SYNOPSIS	<pre> pkgadm addcert [-ty] [-a <i>app</i>] [-k <i>keystore</i>] [-e <i>keyfile</i>] [-f <i>format</i>] [-n <i>name</i>] [-P <i>passarg</i>] [-p <i>import_passarg</i>] [-R <i>rootpath</i>] <i>certfile</i> pkgadm removecert [-a <i>app</i>] [-k <i>keystore</i>] -n <i>name</i> [-P <i>passarg</i>] [-R <i>rootpath</i>] pkgadm listcert [-a <i>app</i>] [-f <i>format</i>] [-k <i>keystore</i>] -n <i>name</i> [-P <i>passarg</i>] [-o <i>outfile</i>] [-R <i>rootpath</i>] pkgadm -V pkgadm -? </pre>				
DESCRIPTION	The pkgadm utility is used for managing the packaging and patching system. It has several subcommands that perform various operations relating to packaging. The pkgadm command includes subcommands for managing certificates and keys used.				
Managing Keys and Certificates	pkgadm maintains the packaging-system-wide keystore in <code>/var/sadm/security</code>, and individual user's certificates in <code>~/ .pkg/security</code>. The following subcommands operate on the package keystore database: addcert Add (import) a certificate into the database, with optional trust. Once added, trusted certificates can be used to verify signed packages and patches. Non-trusted user certificates and their associated keys can be used to sign packages and patches. Added user certificates are <i>not</i> used to build certificate chains during certificate verification. removecert Removes a user certificate/private key pair, or a trusted certificate authority certificate from the keystore. Once removed, the certificate and keys cannot be used. listcert Print details of one or more certificates in the keystore.				
OPTIONS	The following options are supported: -a <i>app</i> If this option is used, then the command only affects the keystore associated with a particular application. Otherwise, the global keystore is affected. -e <i>keyfile</i> When adding a non-trusted certificate/key combination, this option can be used to specify the file that contains the private key. If this option is not used, the private key must be in the same file as the certificate being added. -f <i>format</i> When adding certificates, this specifies the format to expect certificates and private keys in. Possible values when adding are: <table> <tr> <td>pem</td><td>Certificate and any private key uses PEM encoding.</td></tr> <tr> <td>der</td><td>Certificate and any private key uses DER encoding.</td></tr> </table>	pem	Certificate and any private key uses PEM encoding.	der	Certificate and any private key uses DER encoding.
pem	Certificate and any private key uses PEM encoding.				
der	Certificate and any private key uses DER encoding.				

pkgadm(1M)

When printing certificates, this specifies the output format used when printing. Acceptable values for format are:

<code>pem</code>	Output each certificate using PEM encoding.
<code>der</code>	Output each certificate using DER encoding.
<code>text</code>	Output each certificate in human-readable format.

`-k keystore`

Overrides the default location used when accessing the keystore.

`-n name`

Identifies the entity in the store on which you want to operate. When adding a user certificate, or removing certificates, this name is required. The name is associated with the certificate/key combination, and when adding, can be used later to reference the entity. When printing certificates, if no alias is supplied, then all keystore entities are printed.

`-o outfile`

Output the result of the command to *outfile*. Only used when examining (printing) certificates from the key store. Standard out is the default.

`-P passarg`

Password retrieval method to use to decrypt keystore specified with `-k`, if required. See `PASS PHRASE ARGUMENTS` in `pkgadd(1M)` for more information about the format of this option's argument. `console` is the default.

`-p import_passarg`

This option's argument is identical to `-P`, but is used for supplying the password used to decrypt the certificate and/or private key being added. `console` is the default.

`-R rootpath`

Defines the full name of a directory to use as the root (/) path. The default user location of the certificate operations is `${HOME}/.pkg`. If the `-R` option is supplied, the certificates and keys will be stored under `<altroot>/var/sadm/security`. Note that this operation fails if the user does not have sufficient permissions to access this directory. The `listcert` command requires read permission, while `addcert` and `removecert` require both read and write permission.

`-t`

Indicates the certificate being added is a trusted CA certificate. The details of the certificate (including the Subject Name, Validity Dates, and Fingerprints) are printed and the user is asked to verify the data. This verification step can be skipped with `-y`. When importing a trusted certificate, a private key should not be supplied, and will be rejected if supplied. Once a certificate is trusted, it can be used as a trust anchor when verifying future untrusted certificates.

`-V`

Print version associated with packaging tools.

	-y When adding a trusted certificate, the details of the certificate (Subject name, Issuer name, Validity dates, Fingerprints) are shown to the user and the user is asked to verify the correctness before proceeding. With -y, this additional verification step is skipped. -? Print help message.
OPERANDS	The following operand is supported: certfile File containing the certificate and optional private key, used when adding a trust anchor or certificate/key combination. Certificates must be encoded using PEM or binary DER.
KEYSTORE ALIASES	All keystore entries (user cert/key and trusted certificate entries) are accessed via unique aliases. Aliases are case-sensitive. An alias is specified when you add an entity to a keystore using the addcert or trustcert subcommand. If an alias is not supplied for a trust anchor, the trust anchor's Common Name is used as the alias. An alias is required when adding a signing certificate or chain certificate. Subsequent pkgcert or other package tool commands must use this same alias to refer to the entity.
KEYSTORE PASSWORDS	See pkgadd(1M) for a description of the passwords supplied to this utility.
EXAMPLES	EXAMPLE 1 Adding a Trust Anchor The following example adds a well-known and trusted certificate to be used when verifying signatures on packages. <pre>example% pkgadm addcert -t /tmp/certfile.pem</pre> EXAMPLE 2 Adding a Signing Certificate The following example adds a signing certificate and associated private key, each of which is in a separate file, which can then be used to sign packages. <pre>example% pkgadm addcert -a pkgtrans -e /tmp/keyfile.pem \ /tmp/certfile.pem</pre> EXAMPLE 3 Printing Certificates The following example prints all certificates in the root keystore. <pre>example% pkgadm listcert</pre>
EXIT STATUS	0 successful completion non-zero fatal error

pkgadm(1M)

Application Packaging Developer's Guide

NAME	pkgask – stores answers to a request script				
SYNOPSIS	pkgask [-d <i>device</i>] [-R <i>root_path</i>] -r <i>response</i> <i>pkginst...</i>				
DESCRIPTION	pkgask allows the administrator to store answers to an interactive package (one with a request script, that is, a user-created file that must be named <i>request</i>). Invoking this command generates a response file that is then used as input at installation time. The use of this response file prevents any interaction from occurring during installation since the file already contains all of the information the package needs.				
OPTIONS	The following options are supported -d <i>device</i> Run the request script for a package on <i>device</i>. <i>device</i> can be a directory pathname or the identifiers for tape, floppy disk or removable disk (for example, /var/tmp, /dev/diskette, and /dev/dsk/c1d0s0). The default device is the installation spool directory. -R <i>root_path</i> Define the full path name of a directory to use as the <i>root_path</i>. All files, including package system information files, are relocated to a directory tree starting in the specified <i>root_path</i>. -r <i>response</i> Identify a file or directory which should be created to contain the responses to interaction with the package. The name must be a full pathname. The file, or directory of files, can later be used as input to the pkgadd(1M) command.				
OPERANDS	The following operands are supported: <i>pkginst</i> Specify the package instance, or list of instances for which request scripts will be created. The token <i>all</i> may be used to refer to all packages available on the source medium.				
EXIT STATUS	0 Successful completion. >0 An error occurred.				
ATTRIBUTES	See attributes(5) for descriptions of the following attributes: <table border="1"> <thead> <tr> <th>ATTRIBUTE TYPE</th><th>ATTRIBUTE VALUE</th></tr> </thead> <tbody> <tr> <td>Availability</td><td>SUNWcsu</td></tr> </tbody> </table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	Availability	SUNWcsu
ATTRIBUTE TYPE	ATTRIBUTE VALUE				
Availability	SUNWcsu				
SEE ALSO	pkginfo(1), pkgmk(1), pkgparam(1), pkgproto(1), pkgtrans(1), installf(1M), pkgadd(1M), pkgchk(1M), pkgrm(1M), removef(1M), admin(4), attributes(5) <i>Application Packaging Developer's Guide</i>				
NOTES	The -r option can be used to indicate a directory name as well as a filename. The directory name is used to create numerous response files, each sharing the name of the package with which it should be associated. This would be used, for example, when				

pkgask(1M)

you will be adding multiple interactive packages with one invocation of `pkgadd(1M)`. Each package would need a response file. To create multiple response files with the same name as the package instance, name the directory in which the files should be created and supply multiple instance names with the `pkgask` command. When installing the packages, you will be able to identify this directory to the `pkgadd(1M)` command.

If the default `admin` file is too restrictive, the administration file may need to be modified to allow for total non-interaction during a package installation. See `admin(4)` for details.

NAME	pkgchk – check package installation accuracy
SYNOPSIS	pkgchk [-l -acfnqv] [-i <i>file</i>] [-p <i>path...</i>] [-R <i>root_path</i>] [[-m <i>pkgmap</i> [-e <i>envfile</i>]] pkginst... -Y <i>category,category...</i>] pkgchk -d <i>device</i> [-l -fv] [-i <i>file</i>] [-M] [-p <i>path...</i>] [-V <i>fs_file</i>] [pkginst... -Y <i>category[,category...]</i>]
DESCRIPTION	pkgchk checks the accuracy of installed files or, by using the -l option, displays information about package files. pkgchk checks the integrity of directory structures and files. Discrepancies are written to standard error along with a detailed explanation of the problem. The first synopsis defined above is used to list or check the contents and/or attributes of objects that are currently installed on the system, or in the indicated pkgmap. Package names may be listed on the command line, or by default, the entire contents of a machine will be checked. The second synopsis is used to list or check the contents of a package which has been spooled on the specified device, but not installed. Note that attributes cannot be checked for spooled packages.
OPTIONS	The following options are supported: -a Audit the file attributes only and do not check file contents. Default is to check both. -c Audit the file contents only and do not check file attributes. Default is to check both. -d <i>device</i> Specify the device on which a spooled package resides. <i>device</i> can be a directory path name or the identifiers for tape, floppy disk, or removable disk (for example, /var/tmp or /dev/diskette). -e <i>envfile</i> Request that the package information file named as <i>envfile</i> be used to resolve parameters noted in the specified pkgmap file. -f Correct file attributes if possible. If used with the -x option, this option removes hidden files. When pkgchk is invoked with this option, it creates directories, named pipes, links, and special devices if they do not already exist. If the -d option calls out an uninstalled package, the -f option will only take effect if the package is in directory (not stream) format. All file attributes will be set to agree with the entries in the pkgmap file except that setuid, setgid, and sticky bits will not be set in the mode. -i <i>file</i> Read a list of path names from <i>file</i> and compare this list against the installation software database or the indicated pkgmap file. Path names which are not contained in <i>file</i> are not checked. -l List information on the selected files that make up a package. This option is not compatible with the -a, -c, -f, -g, and -v options.

pkgchk(1M)

	-m pkgmap	Check the package against the package map file, pkgmap.
	-M	Instruct pkgchk not to use the <i>\$root_path/etc/vfstab</i> file for determining the client's mount points. This option assumes the mount points are correct on the server and it behaves consistently with Solaris 2.5 and earlier releases.
	-n	Do not check volatile or editable files' contents. This should be used for most post-installation checking.
	-p <i>path</i>	Only check the accuracy of the path name or path names listed. <i>path</i> can be one or more path names separated by commas (or by white space, if the list is quoted).
	-q	Quiet mode. Do not give messages about missing files.
	-R <i>root_path</i>	Define the full name of a directory to use as the <i>root_path</i> . All files, including package system information files, are relocated to a directory tree starting in the specified <i>root_path</i> . The <i>root_path</i> may be specified when installing to a client from a server (for example, <i>/export/root/client1</i>).
	-v	Verbose mode. Files are listed as processed.
	-V <i>fs_file</i>	Specify an alternative <i>fs_file</i> to map the client's file systems. For example, used in situations where the <i>\$root_path/etc/vfstab</i> file is non-existent or unreliable.
	-x	Search exclusive directories, looking for files which exist that are not in the installation software database or the indicated pkgmap file.
	-Y <i>category</i>	Check packages based on the value of the CATEGORY parameter stored in the installed or spooled package's pkginfo(4) file.
OPERANDS	<i>pkginst</i>	The package instance or instances to be checked. The format <i>pkginst</i> . * can be used to check all instances of a package. The default is to display all information about all installed packages. The asterisk character (*) is a special character to some shells and may need to be escaped. In the C-Shell, "*" must be surrounded by single quotes (') or preceded by a backslash (\);
EXAMPLES	EXAMPLE 1 Using pkgchk for Displaying Package Installation Information The following example displays package installation information for <i>/usr/bin/ls</i>: <pre>example% pkgchk -l -p /usr/bin/ls</pre>	
EXIT STATUS	0	Successful completion.
	>0	An error occurred.

pkgchk(1M)

ATTRIBUTES See attributes(5) for descriptions of the following attributes:

Application Packaging Developer's Guide

pkgrm(1M)

NAME	pkgrm – remove a package from the system
SYNOPSIS	<pre>pkgrm [-nv] [-a <i>admin</i>] [[-A -M] -R <i>root_path</i>] [-V <i>fs_file</i>] [pkginst... -Y <i>category</i> [, <i>category</i>...]] pkgrm -s <i>spool</i> [pkginst... -Y <i>category</i> [, <i>category</i>...]]</pre>
DESCRIPTION	pkgrm will remove a previously installed or partially installed package from the system. A check is made to determine if any other packages depend on the one being removed. If a dependency exists, the action taken is defined in the <i>admin</i> file. The default state for the command is in interactive mode, meaning that prompt messages are given during processing to allow the administrator to confirm the actions being taken. Non-interactive mode can be requested with the <i>-n</i> option. The <i>-s</i> option can be used to specify the directory from which spooled packages should be removed. Certain unbundled and third-party packages are no longer entirely compatible with the latest version of pkgrm. These packages require user interaction throughout the removal and not just at the very beginning. To remove these older packages (released prior to Solaris 2.4), set the following environment variable: <i>NONABI_SCRIPTS=TRUE</i> pkgrm permits keyboard interaction throughout the removal as long as this environment variable is set.
OPTIONS	The following options are supported: -a <i>admin</i> Use the installation administration file, <i>admin</i>, in place of the default <i>admin</i> file. pkgrm first looks in the current working directory for the administration file. If the specified administration file is not in the current working directory, pkgrm looks in the <i>/var/sadm/install/admin</i> directory for the administration file. -A Remove the package files from the client's file system, absolutely. If a file is shared with other packages, the default behavior is to not remove the file from the client's file system. -M Instruct pkgrm not to use the <i>\$root_path/etc/vfstab</i> file for determining the client's mount points. This option assumes the mount points are correct on the server and it behaves consistently with Solaris 2.5 and earlier releases. -n Non-interactive mode. If there is a need for interaction, the command will exit. Use of this option requires that at least one package instance be named upon invocation of the command. Certain conditions must exist for a package to be removed non-interactively or a non-restrictive <i>admin</i> file needs to be used.

	-R <i>root_path</i> Defines the full path name of a directory to use as the <i>root_path</i>. All files, including package system information files, are relocated to a directory tree starting in the specified <i>root_path</i>. -s <i>spool</i> Remove the specified package(s) from the directory <i>spool</i>. The default directory for spooled packages is <code>/var/sadm/pkg</code>. -v Trace all of the scripts that get executed by <code>pkgrm</code>, located in the <i>pkginst/install</i> directory. This option is used for debugging the procedural and non-procedural scripts. -V <i>fs_file</i> Specify an alternative <i>fs_file</i> to map the client's file systems. Used in situations where the <code>\$root_path/etc/vfstab</code> file is non-existent or unreliable. -Y <i>category</i> Remove packages based on the value of the <code>CATEGORY</code> parameter stored in the installed or spooled package's <code>pkginfo(4)</code> file. No package with the <code>CATEGORY</code> value of <code>system</code> can be removed from the file system with this option.														
OPERANDS	The following operand is supported: <i>pkginst</i> Specifies the package to be removed. The format <i>pkginst</i>.<code>*</code> can be used to remove all instances of a package. The asterisk character (<code>*</code>) is a special character to some shells and may need to be escaped. In the C-Shell, <code>"*"</code> must be surrounded by single quotes (<code>'</code>) or preceded by a backslash (<code>\</code>).														
EXAMPLES	EXAMPLE 1 Removing All instances of SUNWjunk From <code>client1</code> The following example removes all instances of SUNWjunk from <code>client1</code>: <pre>example% pkgrm -R /export/root/client1 SUNWjunk*</pre>														
EXIT STATUS	The following exit values are returned: <table> <tr> <td>0</td><td>Successful completion.</td></tr> <tr> <td>1</td><td>Fatal error.</td></tr> <tr> <td>2</td><td>Warning.</td></tr> <tr> <td>3</td><td>Interruption.</td></tr> <tr> <td>4</td><td>Administration.</td></tr> <tr> <td>10</td><td>Reboot after removal of all packages.</td></tr> <tr> <td>20</td><td>Reboot after removal of this package.</td></tr> </table>	0	Successful completion.	1	Fatal error.	2	Warning.	3	Interruption.	4	Administration.	10	Reboot after removal of all packages.	20	Reboot after removal of this package.
0	Successful completion.														
1	Fatal error.														
2	Warning.														
3	Interruption.														
4	Administration.														
10	Reboot after removal of all packages.														
20	Reboot after removal of this package.

Application Packaging Developer's Guide

NAME	pmadm – port monitor administration
SYNOPSIS	<pre>pmadm -a [-p <i>pmtag</i> -t <i>type</i>] -s <i>svctag</i> -i <i>id</i> -m <i>pmspecific</i> -v <i>ver</i> [-f <i>xu</i>] [-y <i>comment</i>] [-z <i>script</i>] pmadm -r -p <i>pmtag</i> -s <i>svctag</i> pmadm -e -p <i>pmtag</i> -s <i>svctag</i> pmadm -d -p <i>pmtag</i> -s <i>svctag</i> pmadm -l [-t <i>type</i> -p <i>pmtag</i>] [-s <i>svctag</i>] pmadm -L [-t <i>type</i> -p <i>pmtag</i>] [-s <i>svctag</i>] pmadm -g -p <i>pmtag</i> -s <i>svctag</i> [-z <i>script</i>] pmadm -g -s <i>svctag</i> -t <i>type</i> -z <i>script</i></pre>
DESCRIPTION	pmadm is the administrative command for the lower level of the Service Access Facility hierarchy, that is, for service administration. A port may have only one service associated with it although the same service may be available through more than one port. In order to uniquely identify an instance of a service, the pmadm command must identify both the port monitor or port monitors through which the service is available (-p or -t) and the service (-s). See OPTIONS. pmadm performs the following functions: ■ adds or removes a service ■ enables or disables a service ■ installs or replaces a per-service configuration script ■ prints requested service information Any user on the system may invoke pmadm to request service status (-l or -L) or to print per-service configuration scripts (-g without the -z option). pmadm with other options may be executed only by a privileged user.
OPTIONS	The following options are supported: -a Add a service. pmadm adds an entry for the new service to the port monitor's administrative file. Because of the complexity of the options and arguments that follow the -a option, it may be convenient to use a command script or the menu system to add services. -d Disable a service. Add x to the flag field in the entry for the service <i>svctag</i> in the port monitor's administrative file. This is the entry used by port monitor <i>pmtag</i>. See the -f option, below, for a description of the flags available. -e Enable a service. Remove x from the flag field in the entry for the service <i>svctag</i> in the port monitor administrative file. This is the entry used by port monitor <i>pmtag</i>. See the -f option, below, for a description of the flags available.

pmadm(1M)

-f xu	The -f option specifies one or both of the following two flags which are then included in the flag field of the entry for the new service in the port monitor's administrative file. If the -f option is not included, no flags are set and the default conditions prevail. By default, a new service is enabled and no utmpx entry is created for it. An -f option without a following argument is illegal. x Do not enable the service <i>svctag</i> available through port monitor <i>pmtag</i>. u Create a utmpx entry for service <i>svctag</i> available through port monitor <i>pmtag</i>.
-g	Print, install, or replace a per-service configuration script. The -g option with a -p option and a -s option prints the per-service configuration script for service <i>svctag</i> available through port monitor <i>pmtag</i>. The -g option with a -p option, a -s option, and a -z option installs the per-service configuration script contained in the file <i>script</i> as the per-service configuration script for service <i>svctag</i> available through port monitor <i>pmtag</i>. The -g option with a -s option, a -t option, and a -z option installs the file <i>script</i> as the per-service configuration script for service <i>svctag</i> available through any port monitor of type <i>type</i>. Other combinations of options with -g are invalid.
-i <i>id</i>	<i>id</i> is the identity that is to be assigned to service <i>svctag</i> when it is started. <i>id</i> must be an entry in <i>/etc/passwd</i>.
-l	The -l option requests service information. Used by itself and with the options described below, it provides a filter for extracting information in several different groupings. -l By itself, the -l option lists all services on the system. -l -p <i>pmtag</i> Lists all services available through port monitor <i>pmtag</i>. -l -s <i>svctag</i> Lists all services with tag <i>svctag</i>. -l -p <i>pmtag</i>-<i>svctag</i> Lists service <i>svctag</i>. -l -t <i>type</i> Lists all services available through port monitors of type <i>type</i>. -l -t <i>type</i>-<i>svctag</i> Lists all services with tag <i>svctag</i> available through a port monitor of type <i>type</i>. Other combinations of options with -l are invalid.
-L	The -L option is identical to the -l option except that output is printed in a condensed format.

-m <i>pmspecific</i>	<i>pmspecific</i> is the port monitor-specific portion of the port monitor administrative file entry for the service.
-p <i>pmtag</i>	Specifies the tag associated with the port monitor through which a service (specified as -s <i>svctag</i>) is available.
-r	Remove a service. When pmadm removes a service, the entry for the service is removed from the port monitor's administrative file.
-s <i>svctag</i>	Specifies the service tag associated with a given service. The service tag is assigned by the system administrator and is part of the entry for the service in the port monitor's administrative file.
-t <i>type</i>	Specifies the the port monitor type.
-v <i>ver</i>	Specifies the version number of the port monitor administrative file. The version number may be given as -v ' <i>pmspec</i> -V' where <i>pmspec</i> is the special administrative command for port monitor <i>pmtag</i> . This special command is ttyadm for ttymon and nlsadmin for listen. The version stamp of the port monitor is known by the command and is returned when <i>pmspec</i> is invoked with a -V option.
-y <i>comment</i>	Associate <i>comment</i> with the service entry in the port monitor administrative file.
-z <i>script</i>	Used with the -g option to specify the name of the file that contains the per-service configuration script. Modifying a configuration script is a three-step procedure. First a copy of the existing script is made (-g alone). Then the copy is edited. Finally, the copy is put in place over the existing script (-g with -z).

Options that request information write the requested information to the standard output. A request for information using the -l option prints column headers and aligns the information under the appropriate headings. In this format, a missing field is indicated by a hyphen. A request for information in the condensed format using the -L option prints the information in colon-separated fields; missing fields are indicated by two successive colons. # is the comment character.

EXAMPLES

EXAMPLE 1 Adding a Service to a Port Monitor with the Tag pmtag

The following command adds a service to a port monitor with tag pmtag and gives the service the tag svctag. The port monitor-specific information is generated by specpm. The service defined by svctag will be invoked with identity root.

```
pmadm -a -p pmtag -s svctag -i root -m 'specpm -a arg1 -b arg2' -v 'specpm -V'
```

pmadm(1M)

EXAMPLE 2 Adding a Service with Service Tab `svctag`

The following command adds a service with service tag `svctag`, identity `guest`, and port monitor-specific information generated by `specpm` to all port monitors of type `type`:

```
pmadm -a -s svctag -i guest -t type -m 'specpm -a arg1 -b arg2' -v 'specpm -V'
```

EXAMPLE 3 Removing a Service

The following command removes the service `svctag` from port monitor `pmtag`:

```
pmadm -r -p pmtag -s svctag
```

EXAMPLE 4 Enabling a Service

The following command enables the service `svctag` available through port monitor `pmtag`:

```
pmadm -e -p pmtag -s svctag
```

EXAMPLE 5 Disabling a Service

The following command disables the service `svctag` available through port monitor `pmtag`:

```
pmadm -d -p pmtag -s svctag
```

EXAMPLE 6 Listing Status Information

The following command lists status information for all services:

```
pmadm -l
```

EXAMPLE 7 Listing Status Information

The following command lists status information for all services available through the port monitor with tag `ports`:

```
pmadm -l -p ports
```

EXAMPLE 8 Listing Status Information in Condensed Format

The following command lists the status information for all services available through the port monitor with tag `ports` in condensed format:

```
pmadm -L -p ports
```

EXAMPLE 9 Listing Status Information for All Services

List status information for all services available through port monitors of type `listen`:

```
pmadm -l -t listen
```

EXAMPLE 10 Printing the per-service Configuration

The following command prints the per-service configuration script associated with the service `svctag` available through port monitor `pmtag`:

```
pmadm -g -p pmtag -s svctag
```

EXIT STATUS The following exit values are returned:

0 Successful operation.

>0 Operation failed.

FILES `/etc/saf/pmtag/_config`

`/etc/saf/pmtag/svctag`

`/var/saf/pmtag/*`

pmconfig(1M)

NAME	pmconfig – Configure the Power Management system									
SYNOPSIS	/usr/sbin/pmconfig [-r]									
DESCRIPTION	The pmconfig utility sets the Power Management and suspend-resume configuration. User has permission to change Power Management configuration using pmconfig only if he is allowed to do so according to PMCHANGEPERM keyword of /etc/default/power. User has permission to change the suspend-resume configuration using pmconfig only if he is allowed to do so according to the CPRCHANGEPERM keyword of /etc/default/power. See FILES section below for a description of the PMCHANGEPERM and CPRCHANGEPERM keywords of /etc/default/power. Based on user permissions, pmconfig first resets the Power Management and/or suspend-resume state back to its default and then reads the new Power Management and/or suspend-resume configuration from /etc/power.conf and issues the commands to activate the new configuration. The pmconfig utility is run at system boot. This utility can also be run from the command line after manual changes have been made to the /etc/power.conf file. For editing changes made to the /etc/power.conf file to take effect, users must run pmconfig. The preferred interface for changing Power Management and suspend-resume configuration is dtpower(1M).									
OPTIONS	The following options are supported: -r Reset Power Management and suspend-resume state to default and exit. User must have both Power Management and suspend-resume configuration permission for this option.									
EXIT STATUS	The following exit values are returned: <table><tr><td>0</td><td>Upon successful completion</td></tr><tr><td>>0</td><td>An error occurred</td></tr></table>		0	Upon successful completion	>0	An error occurred				
0	Upon successful completion									
>0	An error occurred									
FILES	<table><tr><td>/etc/power.conf</td><td>System Power Management configuration file</td></tr><tr><td>/etc/default/power</td><td>File that controls permissions for system’s Power Management and suspend-resume features. The PMCHANGEPERM keyword controls the Power Management configuration permissions, while the CPRCHANGEPERM keyword controls the suspend-resume configuration permissions.</td></tr></table> Allowed values are: <table><tr><td>all</td><td>Any user can change the configuration.</td></tr><tr><td>-</td><td>No one except super-user can change the configuration.</td></tr></table>	/etc/power.conf	System Power Management configuration file	/etc/default/power	File that controls permissions for system’s Power Management and suspend-resume features. The PMCHANGEPERM keyword controls the Power Management configuration permissions, while the CPRCHANGEPERM keyword controls the suspend-resume configuration permissions.	all	Any user can change the configuration.	-	No one except super-user can change the configuration.	
/etc/power.conf	System Power Management configuration file									
/etc/default/power	File that controls permissions for system’s Power Management and suspend-resume features. The PMCHANGEPERM keyword controls the Power Management configuration permissions, while the CPRCHANGEPERM keyword controls the suspend-resume configuration permissions.									
all	Any user can change the configuration.									
-	No one except super-user can change the configuration.									

`<user1, user2, ...>` A user in this user list or a super-user can change the configuration. The user list is a space and/or comma (,) separated list. You must enclose the list in `<` and `>` characters.

`console-owner` A user who owns the system console device node or a super-user can change the configuration.

The default values are `PMCHANGEPERM=console-owner` and `CPRCHANGEPERM=console-owner`.

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWpmu
Interface stability	Unstable

SEE ALSO `powerd(1M)`, `power.conf(4)`, `attributes(5)`, `cpr(7)`, `pm(7D)`

Using Power Management

DIAGNOSTICS If the program cannot open the configuration file, it prints an error message to standard error. If the program encounters a syntax error in the configuration file, it prints an error message and the line number of the error in the configuration file. It then skips the rest of the information on that line and processes the next line. Any configuration information already processed on the line containing the error is used. If user does not have permission to change Power Management and/or suspend-resume configuration, and configuration file has entries for which user doesn't have permission, it process the entries for which user has permissions and prints error on rest.

pntadm(1M)

NAME	pntadm – DHCP network table management utility
SYNOPSIS	pntadm -C [-r <i>resource</i>] [-p <i>path</i>] [-u <i>uninterpreted</i>] <i>network</i> pntadm -A <i>name_IP_address</i> [-c <i>comment</i>] [-e <i>mm/dd/yyyy</i>] [-f <i>num</i> <i>keywords</i>] [-h <i>client_hostname</i>] [-i [-a] <i>client_ID</i>] [-m [-y] <i>macro</i>] [-s <i>server</i>] [-r <i>resource</i>] [-p <i>path</i>] [-u <i>uninterpreted</i>] <i>network</i> pntadm -M <i>name_IP_address</i> [-c <i>comment</i>] [-e <i>mm/dd/yyyy</i>] [-f <i>num</i> <i>keywords</i>] [-h <i>client_hostname</i>] [-i [-a] <i>client_ID</i>] [-m [-y] <i>macro</i>] [-n <i>new_client_IP_address</i>] [-s <i>server</i>] [-r <i>resource</i>] [-p <i>path</i>] [-u <i>uninterpreted</i>] <i>network</i> pntadm -D <i>name_IP_address</i> [-y] [-r <i>resource</i>] [-p <i>path</i>] [-u <i>uninterpreted</i>] <i>network</i> pntadm -P [-v] [-x] [-r <i>resource</i>] [-p <i>path</i>] [-u <i>uninterpreted</i>] <i>network</i> pntadm -R [-r <i>resource</i>] [-p <i>path</i>] [-u <i>uninterpreted</i>] <i>network</i> pntadm -L [-r <i>resource</i>] [-p <i>path</i>] [-u <i>uninterpreted</i>] pntadm -B [-v] [<i>batchfile</i>]
DESCRIPTION	The pntadm command is used to manage the Dynamic Host Configuration Protocol (DHCP) network tables. It is used to add and remove networks under DHCP management, and add, delete, or modify IP address records within network tables, or to view tables. For a description of the format of DHCP network tables, see dhcp_network(4). pntadm can be run as root or by other users assigned to the DHCP Management profile. See rbac(5) and user_attr(4). If the networks you want to add are subnetted, you need to update the netmasks(4) table. One of the following options (function flags) must be specified with the pntadm command: -A, -B, -C, -D, -L, -M, -P, or -R.
OPTIONS	The following options are supported: -A <i>name_IP_address</i> Add a client entry with hostname or client IP address, <i>name_IP_address</i>, to the named DHCP network table. The following sub-options are optional: -c <i>comment</i> Comment text. The default is NULL. -e <i>mm/dd/yyyy</i> Absolute lease. The default is 0. -f <i>num</i> <i>keywords</i> Flag value. The default is 00.

The flag (*-f*) option can be specified either as a single number denoting the intended flag value, or as a series of the following keywords, combined using the plus (+) symbol:

DYNAMIC or 00

Server manager's assignment.

PERMANENT or 01

Lease on entry is permanent.

MANUAL or 02

Administrator managed assignment.

UNUSABLE or 04

Entry is not valid.

BOOTP or 08

Entry reserved for BOOTP clients.

For a more detailed description of the flag values, see `dhcp_network(4)`.

-h client_hostname

Client hostname. The default is NULL.

When the *-h* option is used in this mode, the *client_hostname* is added to the hosts table within the resource used for storing host names (files, NIS+ or DNS). The command will fail if this *client_hostname* is already present in the hosts table.

-i client_ID [-a]

Client identifier [-a]. The default is 00.

The *-i* option modified with *-a* specifies that the client identifier is in ASCII format, and thus needs to be converted to hexadecimal format before insertion into the table.

-m macro [-y]

Macro name. Default is UNKNOWN.

The *-m* option modified with *-y* verifies the existence of the named macro in the `dhcptab` table before adding the entry.

-s server

Server IP or name. Default is system name (`uname -n`).

-B

Activate batch mode. `pntadm` will read from the specified file or from standard input a series of `pntadm` commands and execute them within the same process. Processing many `pntadm` commands using this method is much faster than running an executable batchfile itself. Batch mode is recommended for using `pntadm` in scripts.

The following sub-option is optional:

- v
Display commands to standard output as they are processed.
- C
Create the DHCP network table for the network specified by *network*. See [OPERANDS](#). For details, see `dhcp_network(4)` and `networks(4)`.
- D *name_IP_address*
Delete the specified client entry with hostname or client IP address, *name_IP_address*, in the named DHCP network table. (See `dhcp_network(4)`.)

The following sub-option is optional:
 - Y
Remove associated host table entry. The -y option requests that all hostnames associated with the IP address in the hosts table in the resource be removed.
- L
List the DHCP network tables presently configured, one per line, on standard output. If none are found, no output is printed and an exit status of 0 is returned.
- M *name_IP_address*
Modify the specified client entry with hostname or client IP address, *name_IP_address*, in the named DHCP network table. See `dhcp_network(4)`. The default for the sub-options is what they currently are set to.

The following sub-options are optional.
 - c *comment*
New comment text.
 - e *mm/dd/yy*
New absolute lease expiration date. Time defaults to 12:00 AM of the day specified.
 - f *num* | *keyboard*
New flag value, see explanation following the description of the -A option.
 - h *host_name*
New client hostname.

The -h option allows you to change the current *hostname* associated with the IP address or to add a new *hostname* to the hosts table if an entry associated with this IP address does not exist.
 - i *client_ID*
New client identifier [-a].
 - m *macro* [-y]
Macro name defined in `dhcptab`.
 - n *new_client_IP_address*
New IP address.

-s *server*

New server IP or name.

For more detailed description of the sub-options and flag values, see `dhcp_network(4)`.

-P

Display the named DHCP network table.

The following sub-options are optional:

-v

Display lease time in full verbose format and resolve IP addresses for the clients and server to hostnames.

-x

Display lease time in raw format.

These flag codes are used with the **-P** sub-options:

-v	-x	Description
D	00	DYNAMIC
P	01	PERMANENT
M	02	MANUAL
U	04	UNUSABLE
B	08	BOOTP

See `dhcp_network(4)` for information on these sub-options and associated flag codes.

-p *path*

Override the `dhcpsvc.conf(4)` configuration value for data store resource path, *path* See `dhcpsvc.conf(4)`

-R

Remove the named DHCP network table. See `dhcp_network(4)`.

-r *data_store_resource*

Override the `/etc/inet/dhcpsvc.conf` configuration value for `RESOURCE=` with the *data_store_resource* specified. See the `dhcpsvc.conf(4)` man page for more details on resource type, and the *Solaris DHCP Service Developer's Guide* for more information about adding support for other data stores.

-u *uninterpreted*

Data which will be ignored by `pntadm`, but passed to the currently configured public module to be interpreted by the data store. This might be used for a database account name or other authentication or authorization parameters required by a

pntadm(1M)

particular data store.

OPERANDS The following operand is supported:

network

The network address or network name which corresponds to the dhcp network table. See dhcp_network(4).

EXAMPLES **EXAMPLE 1** Creating a Table for the 10.0.0.0 DHCP Network

The following command creates a table for the 10.0.0.0 (subnetted to class C) DHCP network table. Note that if you have an alias for this network in your networks(4) table, you can use that value rather than the dotted Internet Address notation.

```
example# pntadm -C 10.0.0.0
```

EXAMPLE 2 Adding an Entry to the 10.0.0.0 Table

The following command adds an entry to the 10.0.0.0 table in the files resource in the /var/mydhcp directory:

```
example# pntadm -r SUNWfiles -p /var/mydhcp -A 10.0.0.1 10.0.0.0
```

EXAMPLE 3 Modifying the 10.0.0.1 Entry of the 10.0.0.0 Table

The following command modifies the 10.0.0.1 entry of the 10.0.0.0 table, changing the macro name to Green, setting the flags field to MANUAL and PERMANENT:

```
example# pntadm -M 10.0.0.1 -m Green -f 'PERMANENT + MANUAL' 10.0.0.0
```

EXAMPLE 4 Changing the 10.0.0.1 Entry to 10.0.0.2

The following command changes the 10.0.0.1 entry to 10.0.0.2, making an entry in the hosts(4) table called myclient:

```
example# pntadm -M 10.0.0.1 -n 10.0.0.2 -h myclient 10.0.0.0
```

EXAMPLE 5 Setting the Client ID as ASCII

The following command sets the client ID as ASCII aruba.foo.com for the myclient entry:

```
example# pntadm -M myclient -i 'aruba.foo.com' -a 10.0.0.0
```

EXAMPLE 6 Deleting the myclientEntry from the 10.0.0.0 Table

The following command deletes the myclient (10.0.0.2) entry from the 10.0.0.0 table:

```
example# pntadm -D myclient 10.0.0.0
```

EXAMPLE 7 Removing the Named DHCP Network Table

The following command removes the named DHCP network table in the NIS+ directory specified:

```
example# pntadm -r SUNWnisplus -p Test.Nis.Plus. -R 10.0.0.0
```

EXAMPLE 8 Listing the Configured DHCP Network Tables

The following command lists the configured DHCP network tables:

```
example# pntadm -L
192.168.0.0
10.0.0.0
```

EXAMPLE 9 Executing pntadm Commands in Batch Mode

The following command runs a series of pntadm commands contained in a batch file:

```
example# pntadm -B addclients
```

EXIT STATUS

- 0 Successful completion.
- 1 Object already exists.
- 2 Object does not exist.
- 3 Non-critical error.
- 4 Critical error.

FILES

/etc/inet/dhcpsvc.conf
/etc/inet/hosts

NAME	pooladm – activate and deactivate the resource pools facility
SYNOPSIS	<code>/usr/sbin/pooladm [-n] [-c <i>filename</i>] -x]</code>
DESCRIPTION	The <code>pooladm</code> command provides administrative operations on pools and sets. <code>pooladm</code> reads the specified filename and attempts to activate the pool configuration contained in it. Before updating the current pool run-time configuration, <code>pooladm</code> validates the configuration for correctness. Without options, <code>pooladm</code> prints out the current running pools configuration.
OPTIONS	The following options are supported: <code>-c</code> Instantiate the configuration at the given location. If a filename is not specified, it defaults to <code>/etc/pooladm.conf</code>. <code>-n</code> Validate the configuration without actually updating the current active files. <code>-x</code> Remove the currently active pool configuration. Destroy all defined resources, and return all formerly partitioned components to their default resources.
OPERANDS	The following operands are supported: <i>filename</i> Use the configuration contained within this file.
EXAMPLES	EXAMPLE 1 Instantiating a Configuration The following command instantiates the configuration contained at <code>/home/admin/newconfig</code>: <pre>example# /usr/sbin/pooladm -c /home/admin/newconfig</pre> EXAMPLE 2 Validating the Configuration Without Instantiating It The following command attempts to instantiate the configuration contained at <code>/home/admin/newconfig</code>. It displays any error conditions that it encounters, but does not actually modify the active configuration. <pre>example# /usr/sbin/pooladm -n -c /home/admin/newconfig</pre> EXAMPLE 3 Removing the Current Configuration The following command removes the current pool configuration: <pre>example# /usr/sbin/pooladm -x</pre>
FILES	<code>/etc/pooladm.conf</code>

System Administration Guide: Resource Management and Network Services

NOTES Resource bindings that are not presented in the form of a binding to a partitionable resource, such as the scheduling class, are not necessarily be modified in a pooladm -x operation.

NAME	poolbind – bind processes, tasks, or projects or query binding of processes to resource pools
SYNOPSIS	<pre> /usr/sbin/poolbind -p poolname [-i idtype] id... /usr/sbin/poolbind -q pid... /usr/sbin/poolbind -Q pid... </pre>
DESCRIPTION	The poolbind command allows an authorized user to bind projects, tasks, and processes to pools. It can also allow a user to query a process to determine which pool the process is bound to.
OPTIONS	The following options are supported: <i>-i idtype</i> This option, together with the <i>idlist</i> arguments, specifies one or more processes to which the poolbind command is to apply. The interpretation of <i>idlist</i> depends on the value of <i>idtype</i>. The valid <i>idtype</i> arguments and corresponding interpretations of <i>idlist</i> are as follows: <i>pid</i> <i>idlist</i> is a list of process IDs. Binds the specified processes to the specified pool. This is the default behavior if no <i>idtype</i> is specified. <i>taskid</i> <i>idlist</i> is a list of task IDs. Bind all processes within the list of task IDs to the specified pool. <i>projid</i> <i>idlist</i> is a list of project IDs. Bind all processes within the list of projects to the specified pool. Each project ID can be specified as either a project name or a numerical project ID. See project(4). <i>-q pid ...</i> Queries the pool bindings for a given list of process IDs. If the collection of resources associated with the process does not correspond to any currently existing pool, or if there are multiple pools with the set of resources that the process is bound to, the query fails for that particular process ID. <i>-Q pid ...</i> Queries the resource bindings for a given list of process IDs. The resource bindings are each reported on a separate line.
OPERANDS	The following operands are supported: <i>poolname</i> The name of a pool to which the specified project, tasks or processes are to be bound.

poolbind(1M)

EXAMPLES

EXAMPLE 1 Binding All Processes

The following command binds all processes in projects 5 and 7 to pool web_app:

```
example# /usr/sbin/poolbind -p web_app -i projid 5 7
```

EXAMPLE 2 Binding the Running Shell

The following command binds the running shell to pool web_app:

```
example# /usr/sbin/poolbind -p web_app $$
```

EXAMPLE 3 Querying the Pool Bindings

The following command queries the bindings to verify that the shell is bound to the given pool:

```
example# /usr/sbin/poolbind -q $$
```

EXAMPLE 4 Querying the Resource Bindings

The following command queries the bindings to verify that the shell is bound to the given resources:

```
example# /usr/sbin/poolbind -Q $$
```

EXIT STATUS

The following exit values are returned:

- 0 Successful completion.
- 1 Requested operation could not be completed.
- 2 Invalid command line options were specified.

System Administration Guide: Resource Management and Network Services

NAME	poolcfg – create and modify resource pool configuration files
SYNOPSIS	<pre> /usr/sbin/poolcfg -c <i>command</i> <i>filename</i> /usr/sbin/poolcfg -f <i>command_file</i> <i>filename</i> /usr/sbin/poolcfg -h </pre>
DESCRIPTION	The <code>poolcfg</code> command provides configuration operations on pools and sets. These operations are performed upon an existing configuration and take the form of modifications to the specified configuration file. The special <code>discover</code> command does not require an existing configuration. Actual activation of the resulting configuration is achieved by way of the <code>pooladm(1M)</code> command. Pools configuration files are structured files that must have been constructed using <code>poolcfg</code> itself or <code>libpool(3LIB)</code> directly. The configurations which are created by this tool may be used by <code>pooladm</code> to instantiate the configuration upon a target host.
OPTIONS	The following options are supported: <code>-c <i>command</i></code> Specify <i>command</i> as an editing command. See USAGE. <code>-f <i>command_file</i></code> Take the commands from <i>command_file</i>. <i>command_file</i> consists of editing commands, one per line. <code>-h</code> Display extended information about the syntax of editing commands.
USAGE	
Scripts	A script consists of editing commands, one per line, of the following: <pre> info [<i>entity-name</i>] Display configuration (or specified portion) in human readable form to standard output. If no entity is specified, system information is displayed. Therefore, poolcfg -c 'info' afile is an equivalent invocation to poolcfg -c 'info system name' afile. create <i>entity-name</i> [<i>property-list</i>] Make an entity of the specified type and name. destroy <i>entity-name</i> Remove the specified entity. modify <i>entity-name</i> [<i>property-list</i>] Change the listed properties on the named entity. associate <i>pool-name</i> [<i>resource-list</i>] Connect one or more resources to a pool, or replace one or more existing connections. </pre>

poolcfg(1M)

	discover Create a system entity, with one pool entity and resources to match current system configuration. All discovered resources of each resource type are recorded in the file, with the single pool referring to the default resource for each resource type. rename <i>entity-name</i> to <i>new-name</i> Change the name of an entity on the system to its new name.										
Property Lists	The property list is specified by: <pre>(proptype name = value [; proptype name = value]*)</pre> where the last definition in the sequence for a given proptype, name pair is the one that holds. For property deletion, use ~ proptype name.										
Resource Lists	A resource list is specified by <pre>(resourcetype name [; resourcetype name]*)</pre> where the last specification in the sequence for a resource is the one that holds. There is no deletion syntax for resource lists.										
Recognized Entities	<table><tr><td>system</td><td>Machine level entity</td></tr><tr><td>pool</td><td>Named collection of resource associations</td></tr></table>	system	Machine level entity	pool	Named collection of resource associations						
system	Machine level entity										
pool	Named collection of resource associations										
Resource Types	<table><tr><td>pset</td><td>Processor set resource</td></tr></table>	pset	Processor set resource								
pset	Processor set resource										
Property Types	<table><tr><td>boolean</td><td>Takes one of two values true or false.</td></tr><tr><td>int</td><td>A 64-bit signed integer value.</td></tr><tr><td>uint</td><td>A 64-bit unsigned integer value.</td></tr><tr><td>string</td><td>Strings are delimited by quotes ("), and support the character escape sequences defined in <code>formats(5)</code>.</td></tr><tr><td>float</td><td>Scientific notation is not supported.</td></tr></table>	boolean	Takes one of two values true or false.	int	A 64-bit signed integer value.	uint	A 64-bit unsigned integer value.	string	Strings are delimited by quotes ("), and support the character escape sequences defined in <code>formats(5)</code> .	float	Scientific notation is not supported.
boolean	Takes one of two values true or false.										
int	A 64-bit signed integer value.										
uint	A 64-bit unsigned integer value.										
string	Strings are delimited by quotes ("), and support the character escape sequences defined in <code>formats(5)</code> .										
float	Scientific notation is not supported.										
EXAMPLES	EXAMPLE 1 Creating an Initial Configuration File The following command creates an initial configuration file for this host. By not supplying a file name, <code>/etc/pooladm.conf</code> is assumed. <pre>\$ poolcfg -c discover</pre> EXAMPLE 2 Creating an Initial Configuration File The following command creates an initial configuration file for this host and writes it to <code>/home/admin/new_config</code>: <pre>\$ poolcfg -c discover /home/admin/new_config</pre>										

EXAMPLE 3 Writing a poolcfg Script

The following `poolcfg` script creates a pool named `Accounting`, and a processor set, `small-1`. The processor set is created first, then the pool is created and associated with the set.

```
create pset small-1 ( uint pset.min = 1 ; uint pset.max = 4 )
create pool Accounting
associate pool Accounting ( pset small-1 )
```

EXAMPLE 4 Reporting on `pool_0`

The following command reports on `pool_0` to standard output in human readable form:

```
# poolcfg -c 'info pool pool_0' /etc/pooladm.conf
```

EXAMPLE 5 Destroying `pool_0` and Its Associations

The following command destroys `pool_0` and associations, but not the formerly associated resources:

```
# poolcfg -c 'destroy pool pool_0' /etc/pooladm.conf
```

EXAMPLE 6 Displaying the Current Configuration

The following command displays the current configuration:

```
$ poolcfg -c 'info' /etc/pooladm.conf
system muskoka
    int system.version 1
    boolean system.bind-default true
    string system.comment Discovered by libpool

    pool pool_default
        boolean pool.default true
        boolean pool.active true
        int pool.importance 5
        string pool.comment
        string pool.scheduler FSS
        pset pset_default

    pset pset_default
        int pset.sys_id -1
        string pset.units population
        boolean pset.default true
        uint pset.max 4294967295
        uint pset.min 1
        string pset.comment
        boolean pset.escapable false
        uint pset.load 0
        uint pset.size 2

    cpu
```

poolcfg(1M)

EXAMPLE 6 Displaying the Current Configuration *(Continued)*

```
int cpu.sys_id 0
string cpu.comment

cpu
int cpu.sys_id 2
string cpu.comment
```

System Administration Guide: Resource Management and Network Services

NAME	ports – creates /dev entries and inittab entries for serial lines
SYNOPSIS	/usr/sbin/ports [-r <i>rootdir</i>]
DESCRIPTION	devfsadm(1M) is now the preferred command for /dev and /devices and should be used instead of ports. The ports command creates symbolic links in the /dev/term and /dev/cua directories to the serial-port character device files in /devices and adds new entries in /etc/inittab for non-system ports found. System-board ports are given single lower-case letters for names (such as a and b) while other ports are named numerically. ports searches the kernel device tree to find the serial devices attached to the system. It also checks /dev/term and /dev/cua to see what symbolic links to serial devices already exist. ports then performs the following: 1. Assigns new numbers (or letters for system-board ports) to ports that are attached to the system but do not have /dev/term and /dev/cua entries. The numbers or letters assigned are the lowest-unused numbers or letters. 2. Removes dangling links: links from /dev/term and /dev/cua pointing to no-longer-existing ports. 3. Creates new /dev/term and /dev/cua links for new serial devices. 4. Invokes sacadm(1M) to make new port monitor entries for the new devices. This is not done automatically for on-board ports; on workstations these ports are often not used for dial-in sessions, so a port-monitor for one of these ports must be created explicitly. If the configuration has not changed, ports exits without doing anything. ports is run each time a reconfiguration-boot is performed, or when add_drv(1M) is executed. When invoking ports manually, first run drvconfig(1M) to ensure /devices is consistent with the current device configuration.
Notice to Driver Writers	ports considers devices with a node type of DDI_NT_SERIAL, DDI_NT_SERIAL_MB, DDI_NT_SERIAL_DO, or DDI_NT_SERIAL_MB_DO to be serial port devices. Devices with one of these node types must create minor device names that obey the following conventions when calling ddi_create_minor_node(9F). ■ The minor name for non-system port devices (DDI_NT_SERIAL) consists of an ASCII numeric string, where the first port on the device is named 0, the second named 1, the third named 2, up to the number of ports provided by the device. ■ The minor name for non-system dialout devices (DDI_NT_SERIAL_DO) is the ASCII numeric port name, concatenated with ,cu. For example, the minor name for the first dialout port on the serial board is 0,cu. ■ The minor name for system-board port devices (DDI_NT_SERIAL_MB) consists of a string containing a single ASCII lowercase character, where the first port on the device is named a, the second is named b, the third is named c, for all ports on the

ports(1M)

device (or up through port z).

- The minor name for system-board dialout devices (DDI_NT_SERIAL_MB_DO) consists of the lowercase character port name, concatenated with , cu. For example, the minor name for the first dialout port on the on-board serial device is a, cu.

To prevent disks from attempting to automatically generate links for a device, drivers must specify a private node type and refrain from using one of the above node types when calling `ddi_create_minor_node(9F)`.

OPTIONS The following options are supported:

`-r rootdir` Causes ports to presume that the `/dev/term`, `/dev/cua`, and `/devices` directories are found under *rootdir*, not directly under `/`. If this argument is specified, `sacadm(1M)` is not invoked, since it would update terminal administration files under `/etc` without regard to the *rootdir*.

EXAMPLES **EXAMPLE 1** Creating the Serial and Dialout Minor Device Nodes

The following example creates the serial and dialout minor device nodes from the `xkserial` driver's `attach(9E)` function:

```
/*
 * Create the minor number by combining the instance number
 * with the port number.
 */ #define XKNUMPORTS      8
#define XKMINORNUM(i, p)  ((i) << 4 | (p))
#define XKMINORNUM_DO(i, p) ((i) << 4 | (p) | 0x80)
int
xkserialattach(dev_info_t *dip, ddi_attach_cmd_t cmd)
{
    int instance, portnum;
    char name[8];
    /* other stuff in attach... */
    instance = ddi_get_instance(dip);
    for (portnum = 0; portnum < XKNUMPORTS; portnum++) {
        /*
         * create the serial port device
         */
        sprintf(name, "%d", portnum);
        ddi_create_minor_node(dip, name, S_IFCHR,
            XKMINORNUM(instance, portnum), DDI_NT_SERIAL, 0);

        /*
         * create the dialout device
         */
        sprintf(name, "%d,cu", portnum);
        ddi_create_minor_node(dip, name, S_IFCHR,
            XKMINORNUM_DO(instance, portnum), DDI_NT_SERIAL_DO, 0);
    }
}
```

EXAMPLE 2 Installing the xkserial Port Driver on a SPARCstation 20

The following example installs the xkserial port driver on a SPARCstation 20 (with the driver controlling the fictional XKSerial 8 port serial board) and performs a reconfiguration-boot. It creates the following special files in /devices.

```
# ls -l /devices/iommu@f,e0000000/sbus@f,e0001000/xkserial@f,800000/
crw-r----- 1 root sys 32, 16 Aug 29 00:02 xkserial@2000:0
crw-r----- 1 root sys 32, 144 Aug 29 00:02 xkserial@2000:0,cu
crw-r----- 1 root sys 32, 17 Aug 29 00:02 xkserial@2000:1

NAME	powerd – Power manager daemon						
SYNOPSIS	<code>/usr/lib/power/powerd [-n]</code>						
DESCRIPTION	The powerd daemon is started by pmconfig(1M) to monitor system activity and perform an automatic shutdown using the suspend-resume feature. When the system is suspended, complete current state is saved on the disk before power is removed. On reboot, the system automatically starts a resume operation and the system is restored to the same state it was in immediately prior to suspend. Immediately prior to system shutdown, the daemon notifies syslogd(1M) of the shutdown, which broadcasts a notification.						
OPTIONS	The following option is supported: <code>-n</code> No broadcast mode. The daemon silently shuts down the system without notifying syslogd(1M).						
FILES	<code>/etc/power.conf</code> Power Management configuration information file

pppd(1M)

NAME	pppd – point to point protocol daemon	
SYNOPSIS	pppd [<i>tty_name</i>] [<i>speed</i>] [<i>options</i>]	
DESCRIPTION	The point-to-point protocol (PPP) provides a method for transmitting datagrams over serial point-to-point links. PPP is composed of three components: a facility for encapsulating datagrams over serial links, an extensible link control protocol (LCP), and a family of network control protocols (NCP) for establishing and configuring different network-layer protocols. The encapsulation scheme is provided by driver code in the kernel. pppd provides the basic LCP authentication support and several NCPs for establishing and configuring the Internet Protocol (referred to as the IP Control Protocol or “IPCP”) and IPv6 (IPV6CP).	
OPTIONS	The following sections discuss the pppd options:	
Options Files	Options are taken from files and the command line. pppd reads options from the files <code>/etc/ppp/options</code>, <code>\$HOME/.ppprc</code> and <code>/etc/ppp/options.ttyname</code> (in that order) before processing the options on the command line. (Command-line options are scanned for the terminal name before the <code>options.ttyname</code> file is read.) To form the name of the <code>options.ttyname</code> file, the initial <code>/dev/</code> is removed from the terminal name, and any remaining forward slash characters (/) are replaced with dots. For example, with serial device <code>/dev/cua/a</code>, option file <code>/etc/ppp/options.cua.a</code> is read. An options file is parsed into a series of words that are delimited by whitespace. Whitespace can be included in a word by enclosing the word in double-quotes ("). A backslash (\) quotes the succeeding character. A hash (#) starts a comment, which continues until the end of the line. There is no restriction on using the <code>file</code> or <code>call</code> options within an options file.	
Frequently Used Options	<code><tty_name></code>	Communicate over the named device. The string <code>/dev/</code> is prepended if necessary. If no device name is given, or if the name of the terminal connected to the standard input is given, pppd uses that terminal and does not fork to put itself in the background. A value for this option from a privileged source cannot be overridden by a non-privileged user.
	<code><speed></code>	Set the baud rate to <code><speed></code> (a decimal number). The default is to leave the baud rate unchanged. This option is normally needed for dial-out only.
	<code>asyncmap <map></code>	Set the async character map to <code><map></code> . The map describes which control characters cannot be successfully received over the serial line. pppd asks the peer to send these characters as a 2-byte escape sequence. The argument is a 32 bit hex number, with each bit representing a character to escape. Bit 0

	(00000001) represents the character 0x00; bit 31 (80000000) represents the character 0x1f or ^_. If multiple <code>asynmap</code> options are given, the values are ORed together. If no <code>asynmap</code> option is given, <code>pppd</code> attempts to negotiate a value of 0. If the peer agrees, this disables escaping of the standard control characters. Use the <code>default-asynmap</code> option to disable negotiation and escape all control characters.
<code>auth</code>	Require the peer to authenticate itself before allowing network packets to be sent or received. This option is the default if the system has a default route. If the <code>auth</code> or the <code>noauth</code> option is not specified, <code>pppd</code> allows the peer to use only those IP addresses to which the system does not already have a route.
<code>call name</code>	Read options from the file <code>/etc/ppp/peers/name</code> . This file may contain privileged options, including <code>noauth</code> , even if <code>pppd</code> is not being run by root. The <i>name</i> string may not begin with a slash ("/") or include consecutive periods (" . . ") as a pathname component.
<code>callback number</code>	Request a callback to the given telephone number using Microsoft CBCP.
<code>connect script</code>	Use the executable or shell command specified by <i>script</i> to set up the serial line. This script would typically use the <code>chat(1M)</code> program to dial the modem and start the remote PPP session. A value for this option originating from a privileged source cannot be overridden by a non-privileged user.
<code>crtcts</code>	Use hardware flow control, that is, RTS/CTS, to control the flow of data on the serial port. If the <code>crtcts</code> , <code>nocrtcts</code> , <code>cdtrcts</code> or <code>nocdtrcts</code> option is not provided, the hardware flow control setting for the serial port is left unchanged. Some serial ports lack a true RTS output and use this mode to implement unidirectional flow control. The serial port suspends transmission when requested by the modem by means of CTS but cannot request the modem to stop sending to the computer. This mode allows the use of DTR as a modem control line.
<code>defaultroute</code>	Add a default route to the system routing tables when IPCP negotiation successfully completes, using the peer as the gateway. This entry is removed when the PPP connection is broken. This option is privileged if the <code>nodefaultroute</code> option is specified.

pppd(1M)

<i>disconnect script</i>	Run the executable or shell command specified by <i>script</i> after pppd terminates the link. Typically, this script is used to command the modem to hang up if hardware modem control signals are not available. <i>disconnect</i> is not run if the modem has already hung up. A value for this option originating from a privileged source cannot be overridden by a non-privileged user.
<i>escape xx,yy,...</i>	Specifies that certain characters be escaped on transmission regardless of whether the peer requests them to be escaped with its <i>async</i> control character map. The characters to be escaped are specified as a list of hex numbers separated by commas. Note that almost any character can be specified for the <i>escape</i> option, unlike the <i>asyncmap</i> option which allows only control characters to be specified. Characters that cannot be escaped are those containing hex values 0x20 through 0x3f and 0x5e.
<i>file name</i>	Read options from file <i>name</i> . If this option is used on the command line or in <i>\$HOME/.ppprc</i> , the file must be readable by the user invoking pppd. See Options Files for a list of files that pppd always reads, regardless of the use of this option.
<i>init script</i>	Run the executable or shell command specified by <i>script</i> to initialize the serial line. This script would typically use the <i>chat(1M)</i> program to configure the modem to enable auto-answer. A value for this option from a privileged source cannot be overridden by a non-privileged user.
<i>lock</i>	Directs pppd to create a UUCP-style lock file for the serial device to ensure exclusive access to the device.
<i>mru n</i>	Set the Maximum Receive Unit (MRU) value to <i>n</i> . pppd asks the peer to send packets of no more than <i>n</i> bytes. Minimum MRU value is 128. Default MRU value is 1500. A value of 296 is recommended for slow links (40 bytes for TCP/IP header + 256 bytes of data). For IPv6, MRU must be at least 1280.
<i>mtu n</i>	Set the Maximum Transmit Unit (MTU) value to <i>n</i> . Unless the peer requests a smaller value via MRU negotiation, pppd requests the kernel networking code to send data packets of no more than <i>n</i> bytes through the PPP network interface. For IPv6, MTU must be at least 1280.

Options

passive	Enables the "passive" option in the LCP. With this option, pppd attempts to initiate a connection; if no reply is received from the peer, pppd waits passively for a valid LCP packet instead of exiting, as it would without this option.
<local_IP_address>:<remote_IP_address>	Set the local and/or remote interface IP addresses. Either one may be omitted, but the colon is required. The IP addresses are specified with a host name or in decimal dot notation, for example: :10.1.2.3. The default local address is the first IP address of the system unless the <code>noipdefault</code> option is provided. The remote address is obtained from the peer if not specified in any option. Thus, in simple cases, this option is not required. If a local and/or remote IP address is specified with this option, pppd will not accept a different value from the peer in the IPCP negotiation unless the <code>ipcp-accept-local</code> and/or <code>ipcp-accept-remote</code> options are given, respectively.
allow-fcs <i>fcs-type</i>	Set allowable FCS type(s) for data sent to the peer. The <i>fcs-type</i> is a comma-separated list of "crc16", "crc32", "null", or integers. By default, all known types are allowed. If this option is specified and the peer requests a type not listed, a LCP Configure-Nak is sent to request only the listed types.
allow-ip <i>address(es)</i>	Allow peers to use the given IP address or subnet without authenticating themselves. The parameter is parsed in the same manner as each element of the list of allowed IP addresses is parsed in the secrets files. See the Authentication section more more details.
bsdcomp <i>nr,nt</i>	Request that the peer compress packets that it sends using the BSD-Compress scheme, with a maximum code size of <i>nr</i> bits, and agree to compress packets sent to the peer with a maximum code size of <i>nt</i> bits. If <i>nt</i> is not specified, it defaults to the value given for <i>nr</i> . Values in the range 9 to 15 may be used for <i>nr</i> and <i>nt</i> ; larger values provide better compression but consume more kernel memory for compression dictionaries. Alternatively, a value of 0 for <i>nr</i> or <i>nt</i> disables compression in the corresponding direction. Use <code>nobsdcomp</code> or <code>bsdcomp 0</code> to disable BSD-Compress compression entirely. If this option is read from a privileged source, a nonprivileged user may not specify a code size larger than the value from the privileged source.
cdtrcts	Use a non-standard hardware flow control such as DTR/CTS to control the flow of data on the serial port. If the <code>crtsets</code> , <code>nocrtsets</code> , <code>cdtrcts</code> or <code>nocdtrcts</code> option is not specified, the hardware flow control setting for the serial port is left unchanged. Some serial ports lack a true RTS output. Such serial ports use this mode to implement true bi-directional flow control. Note that this flow control mode does not permit using DTR as a modem control line.
chap-interval <i>n</i>	If this option is given, pppd will rechallenge the peer every <i>n</i> seconds.

pppd(1M)

`chap-max-challenge n`

Set the maximum number of CHAP challenge transmissions to *n* (default 10).

`chap-restart n`

Set the CHAP restart interval (retransmission timeout for challenges) to *n* seconds. The default is 3.

`connect-delay n`

Wait for up to *n* milliseconds after the connect script finishes for a valid PPP packet from the peer. When the wait period elapses or when a valid PPP packet is received from the peer, `pppd` begins negotiation by sending its first LCP packet. The default value is 1000 (1 second). A wait period applies only if the `connect` or `pty` option is used.

`datarate n`

Set maximum data rate to *n* (in bytes per second) when using the `pty`, `notty`, `record`, or `socket` options.

`debug`

Enables connection debugging facilities. If this option is given, `pppd` logs the contents of all control packets sent or received in a readable form. The packets are logged through `syslog` with facility `daemon` and level `debug`. This information can be directed to a file by configuring `/etc/syslog.conf` appropriately.

`default-asynctest`

Disable `asynctest` negotiation, forcing all control characters to be escaped for both the transmit and the receive direction.

`default-fcs`

Disable FCS Alternatives negotiation entirely. By default, no FCS Alternatives option is sent to the peer, but the option is accepted. If this option is specified by the peer, then LCP Configure-Reject is sent.

`default-mru`

Disable MRU [Maximum Receive Unit] negotiation. With this option, `pppd` uses the default MRU value of 1500 bytes for the transmit and receive directions.

`deflate nr,nt,e`

Request that the peer compress packets that it sends, using the `deflate` scheme, with a maximum window size of 2^{*nr} bytes, and agree to compress packets sent to the peer with a maximum window size of 2^{*nt} bytes and effort level of *e* (1 to 9). If *nt* is not specified, it defaults to the value given for *nr*. If *e* is not specified, it defaults to 6. Values in the range 9 to 15 may be used for *nr* and *nt*; larger values provide better compression but consume more kernel memory for compression dictionaries. (Value 8 is not permitted due to a `zlib` bug.) Alternatively, a value of 0 for *nr* or *nt* disables compression in the corresponding direction. Use `nodeflate` or `deflate 0` to disable `deflate` compression entirely. (Note: `pppd` requests `deflate` compression in preference to `BSD-Compress` if the peer can do either.) If this option is read from a privileged source, a nonprivileged user may not specify a code size larger than the value from the privileged source.

demand

Initiate the link only on demand, that is, when data traffic is present. With this option, the remote IP address must be specified by the user on the command line or in an options file. `pppd` initially configures and enables the interface for IP traffic without connecting to the peer. When traffic is available, `pppd` connects to the peer and performs negotiation, authentication and other actions. When completed, `pppd` passes data packets across the link. The `demand` option implies the `persist` option. If this behavior is not desired, use the `nopersist` option after the `demand` option. The `idle` and `holdoff` options can be used in conjunction with the `demand` option.

domain *d*

Append the domain name *d* to the local host name for authentication purposes. For example, if `gethostname()` returns the name `porsche`, but the fully qualified domain name is `porsche.Quotron.COM`, you could specify `domain Quotron.COM`. With this configuration, `pppd` uses the name `porsche.Quotron.COM` for accessing secrets in the secrets file and as the default name when authenticating to the peer. This option is privileged.

endpoint *endpoint-value*

Set the endpoint discriminator (normally used for RFC 1990 Multilink PPP operation). The *endpoint-value* consists of a class identifier and a class-dependent value. The class identifier is one of "null," "local," "IP," "MAC," "magic," "phone," or a decimal integer. If present, the class-dependent value is separated from the identifier by a colon (":") or period ("."). This value may be a standard dotted-decimal IP address for class "IP," an optionally colon-or-dot separated hex Ethernet address for class "MAC" (must have 6 numbers), or an arbitrary string of bytes specified in hex with optional colon or dot separators between bytes. Although this option is available, this implementation does not support multilink.

fcs *fcs-type*

Set FCS type(s) desired for data sent by the peer. The *fcs-type* is a comma-separated list of `crc16`, `crc32`, `null`, or integers. By default, an FCS Alternatives option is not specified, and the medium-dependent FCS type is used. If this option is specified and the peer sends an LCP Configure-Nak, only the listed types are used. If none are in common, the FCS Alternatives option is omitted from the next LCP Configure-Request to drop back to the default.

hide-password

When logging the contents of PAP packets, this option causes `pppd` to exclude the password string from the log. This is the default.

holdoff *n*

Specifies how many seconds to wait before re-initiating the link after it terminates. This option is effective only if the `persist` or `demand` option is used. The `holdoff` period is not applied if the link is terminated because it was idle.

ident *string*

Set the LCP Identification string. The default value is a version string similar to that displayed by the `--version` option.

pppd(1M)

`idle n`
Specifies that pppd must disconnect if the link is idle for *n* seconds. The link is idle when no data packets (i.e. IP packets) are being sent or received. Do not use this option with the `persist` option but without the `demand` option.

`ipcp-accept-local`
With this option, pppd accepts the peer's idea of the local IP address, even if the local IP address is specified in an option.

`ipcp-accept-remote`
With this option, pppd accepts the peer's idea of its remote IP address, even if the remote IP address is specified in an option.

`ipcp-max-configure n`
Set the maximum number of IPCP Configure-Request transmissions to *n* (default 10).

`ipcp-max-failure n`
Set the maximum number of IPCP Configure-NAKs sent before sending Configure-Rejects instead to *n* (default 10).

`ipcp-max-terminate n`
Set the maximum number of IPCP terminate-request transmissions to *n* (default 3).

`ipcp-restart n`
Set the IPCP restart interval (retransmission timeout) to *n* seconds (default 3).

`ipparam string`
Provides an extra parameter to the ip-up and ip-down scripts. When this option is given, the *string* supplied is given as the sixth parameter to those scripts. See the [Scripts](#) section.

`ipv6 <local_interface_identifier>, <remote_interface_identifier>`
Set the local and/or remote 64-bit interface identifier. Either one may be omitted. The identifier must be specified in standard ASCII notation of IPv6 addresses (for example: ::dead:beef). If the `ipv6cp-use-ipaddr` option is given, the local and remote identifiers are derived from the respective IPv4 addresses (see above). The `ipv6cp-use-persistent` option can be used instead of the `ipv6 <local>, <remote>` option.

`ipv6cp-accept-local`
Accept peer's interface identifier for the local link identifier.

`ipv6cp-max-configure n`
Set the maximum number of IPv6CP Configure-Request transmissions to *n* (default 10).

`ipv6cp-max-failure n`
Set the maximum number of IPv6CP Configure-NAKs sent before sending Configure-Rejects instead to *n* (default 10).

`ipv6cp-max-terminate n`
Set the maximum number of IPv6CP terminate-request transmissions to *n* (default 3).

ipv6cp-restart *n*

Set the IPv6CP restart interval (retransmission timeout) to *n* seconds (default 3).

ipv6cp-use-ipaddr

If either the local or remote IPv6 address is unspecified, use the corresponding configured IPv4 address as a default interface identifier. (This option uses the configured addresses, not the negotiated addresses. Do not use it with `ipcp-accept-local` if the local IPv6 identifier is unspecified or with `ipcp-accept-remote` if the remote IPv6 identifier is unspecified.)

ipv6cp-use-persistent

Use uniquely-available persistent value for link local address.

kdebug *n*

Enable debugging code in the kernel-level PPP driver. Argument *n* is the sum of the following values: 1 to enable general debug messages, 2 to request that contents of received packets be printed, and 4 to request contents of transmitted packets be printed. Messages printed by the kernel are logged by `syslogd(1M)` to a file directed in the `/etc/syslog.conf` configuration file. Do not use the `kdebug` option to debug failed links. Use the `debug` option instead.

lcp-echo-failure *n*

If this option is given, `pppd` presumes the peer to be dead if *n* LCP Echo-Requests are sent without receiving a valid LCP Echo-Reply. If this happens, `pppd` terminates the connection. This option requires a non-zero value for the `lcp-echo-interval` parameter. This option enables `pppd` to terminate after the physical connection is broken (for example, if the modem has hung up) in situations where no hardware modem control lines are available.

lcp-echo-interval *n*

If this option is given, `pppd` sends an LCP Echo-Request frame to the peer every *n* seconds. Normally the peer responds to the Echo-Request by sending an Echo-Reply. This option can be used with the `lcp-echo-failure` option to detect that the peer is no longer connected.

lcp-max-configure *n*

Set the maximum number of LCP Configure-Request transmissions to *n* (default 10).

lcp-max-failure *n*

Set the maximum number of LCP Configure-NAKs sent before starting to send Configure-Rejects instead to *n* (default 10).

lcp-max-terminate *n*

Set the maximum number of LCP Terminate-Request transmissions to *n* (default 3).

lcp-restart *n*

Set the LCP restart interval (retransmission timeout) to *n* seconds (default 3).

pppd(1M)

linkname *name*

Sets the logical name of the link to *name*. pppd creates a file named `ppp-name.pid` in `/var/run` containing its process ID. This is useful in determining which instance of pppd is responsible for the link to a given peer system. This is a privileged option.

local

Do not use modem control lines. With this option, pppd ignores the state of the CD (Carrier Detect) signal from the modem and does not change the state of the DTR (Data Terminal Ready) signal.

logfd *n*

Send log messages to file descriptor *n*. pppd sends log messages to (at most) one file or file descriptor (as well as sending the log messages to syslog), so this option and the `logfile` option are mutually exclusive. By default pppd sends log messages to `stdout` (file descriptor 1) unless the serial port is open on `stdout`.

logfile *filename*

Append log messages to the file *filename* (and send the log messages to syslog). The file is opened in append mode with the privileges of the user who invoked pppd.

login

Use the system password database for authenticating the peer using PAP, and record the user in the system `wtmp` file. Note that the peer must have an entry in the `/etc/ppp/pap-secrets` file and the system password database to be allowed access.

maxconnect *n*

Terminate the connection after it has been available for network traffic for *n* seconds (that is, *n* seconds after the first network control protocol starts). An LCP Time-Remaining message is sent when the first NCP starts, and again when 5, 2, and 0.5 minutes are remaining.

maxfail *n*

Terminate after *n* consecutive failed connection attempts. A value of 0 means no limit. The default value is 10.

modem

Use the modem control lines. This option is the default. With this option, pppd waits for the CD (Carrier Detect) signal from the modem to be asserted when opening the serial device (unless a connect script is specified), and drops the DTR (Data Terminal Ready) signal briefly when the connection is terminated and before executing the connect script.

ms-dns <*addr*>

If pppd is acting as a server for Microsoft Windows clients, this option allows pppd to supply one or two DNS (Domain Name Server) addresses to the clients. The first instance of this option specifies the primary DNS address; the second instance (if given) specifies the secondary DNS address. If the first instance specifies a name that resolves to multiple IP addresses, then the first two addresses are used. (This option is present in some older versions of pppd under the name `dns-addr`.)

ms-lanman

If pppd connects as a client to a Microsoft server and uses MS-CHAPv1 for authentication, this option selects the LAN Manager password style instead of Microsoft NT.

ms-wins <addr>

If pppd acts as a server for Microsoft Windows or Samba clients, this option allows pppd to supply one or two WINS (Windows Internet Name Services) server addresses to the clients. The first instance of this option specifies the primary WINS address; the second instance (if given) specifies the secondary WINS address. As with **ms-dns**, if the name specified resolves to multiple IP addresses, then the first two will be taken as primary and secondary.

name *name*

Set the name of the local system for authentication purposes to *name*. This is a privileged option. With this option, pppd uses lines in the secrets files that have *name* as the second field to look for a secret to use in authenticating the peer. In addition, unless overridden with the **user** option, *name* is used as the name to send to the peer when authenticating the local system. (Note that pppd does not append the domain name to *name*.)

no-accm-test

Disable use of **asynctest** (ACCM) checking using LCP Echo-Request messages. If the **lcp-echo-failure** is used on an asynchronous line, pppd includes all control characters in the first *n* LCP Echo-Request messages. If the **asynctest** is set incorrectly, the link drops rather than continue operation with random failures. This option disables that feature.

noaccomp

Disable HDLC Address/Control compression in both directions (send and receive).

noauth

Do not require the peer to authenticate itself. This option is privileged.

nobsdcomp

Disables BSD-Compress compression; pppd will not request or agree to compress packets using the BSD-Compress scheme. This option is not necessary if **noccp** is specified.

noccp

Disable CCP (Compression Control Protocol) negotiation. This option should only be required if the peer has bugs or becomes confused by requests from pppd for CCP negotiation. If CCP is disabled, then BSD and deflate compression do not need to be separately disabled.

nocrtscts

Disable hardware flow control (i.e. RTS/CTS) on the serial port. If the **crtscts**, **nocrtscts**, **cdtrcts** or **nocdtrcts** options are not given, the hardware flow control setting for the serial port is left unchanged.

pppd(1M)

`nocdtrcts`

This option is a synonym for `nocrtscts`. Either option will disable both forms of hardware flow control.

`nodefaultroute`

Disable the `defaultroute` option. You can prevent non-root users from creating default routes with `pppd` by placing this option in the `/etc/ppp/options` file.

`nodeflate`

Disables deflate compression; `pppd` will not request or agree to compress packets using the deflate scheme. This option is not necessary if `noccp` is specified.

`nodeflatedraft`

Do not use Internet Draft (incorrectly assigned) algorithm number for deflate compression. This option is not necessary if `noccp` is specified.

`nodetach`

Do not detach from the controlling terminal. Without this option, `pppd` forks to become a background process if a serial device other than the terminal on the standard input is specified.

`noendpoint`

Do not send or accept the Multilink Endpoint Discriminator option.

`noident`

Disable use of LCP Identification. LCP Identification messages will not be sent to the peer, but received messages will be logged. (Specify this option twice to completely disable LCP Identification. In this case, `pppd` sends LCP Code-Reject in response to received LCP Identification messages.)

`noip`

Disable IPCP negotiation and IP communication. Use this option only if the peer has bugs or becomes confused by requests from `pppd` for IPCP negotiation.

`noipv6`

Disable IPv6CP negotiation and IPv6 communication. IPv6 is not enabled by default.

`noipdefault`

Disables the default behavior when no local IP address is specified, which is to determine (if possible) the local IP address from the hostname. With this option, the peer must supply the local IP address during IPCP negotiation (unless it specified explicitly on the command line or in an options file).

`nolog`

Do not send log messages to a file or file descriptor. This option cancels the `logfd` and `logfile` options. `nologfd` acts as an alias for this option.

`nomagic`

Disable magic number negotiation. With this option, `pppd` cannot detect a looped-back line. Use this option only if the peer has bugs. Do not use this option to work around the "Serial line is looped back" error message.

nopam

This privileged option disables use of pluggable authentication modules. If this option is specified, pppd reverts to standard authentication mechanisms. The default is not to use PAM.

nopcomp

Disable protocol field compression negotiation in the receive and the transmit direction.

nopersist

Exit once a connection has been made and terminated. This is the default unless the **persist** or **demand** option is specified.

noplink

Cause pppd to use **L_LINK** instead of **L_PLINK**. This is the default. When **L_LINK** is used, the system cleans up terminated interfaces (even when **SIGKILL** is used) but does not allow **ifconfig(1M)** to unplumb PPP streams or insert or remove modules dynamically. Use the **plink** option if **ifconfig(1M)** **modinsert**, **modremove** or **unplumb** support is needed.

nopredictor1

Do not accept or agree to Predictor-1 compression. (This option is accepted for compatibility. The implementation does not support Predictor-1 compression.)

noproxyarp

Disable the **proxyarp** option. If you want to prevent users from creating proxy ARP entries with pppd, place this option in the `/etc/ppp/options` file.

notty

Normally, pppd requires a terminal device. With this option, pppd allocates itself a pseudo-tty master/slave pair and uses the slave as its terminal device. pppd creates a child process to act as a character shunt to transfer characters between the pseudo-tty master and its standard input and output. Thus, pppd transmits characters on its standard output and receives characters on its standard input even if they are not terminal devices. This option increases the latency and CPU overhead of transferring data over the ppp interface as all of the characters sent and received must flow through the character shunt process. An explicit device name may not be given if this option is used.

novj

Disable Van Jacobson style TCP/IP header compression in both the transmit and the receive direction.

novjccomp

Disable the connection-ID compression option in Van Jacobson style TCP/IP header compression. With this option, pppd does not omit the connection-ID byte from Van Jacobson compressed TCP/IP headers, nor does it ask the peer to do so. This option is unnecessary if **novj** is specified.

pppd(1M)

pam

This privileged option enables use of PAM. If this is specified, pppd uses the pam(3PAM) framework for user authentication with a service name of "ppp" if the login option and PAP authentication are used. The default is not to use PAM.

papcrypt

Indicates that pppd should not accept a password which, before encryption, is identical to the secret from the `/etc/ppp/pap-secrets` file. Use this option if the secrets in the `pap-secrets` file are in `crypt(3C)` format.

pap-max-authreq *n*

Set the maximum number of PAP authenticate-request transmissions to *n* (default 10).

pap-restart *n*

Set the PAP restart interval (retransmission timeout) to *n* seconds (default 3).

pap-timeout *n*

Set the maximum time that pppd waits for the peer to authenticate itself with PAP to *n* seconds (0= no limit). The default is 30 seconds.

password *string*

Password string for authentication to the peer.

persist

Do not exit after a connection is terminated; instead try to reopen the connection.

plink

Cause pppd to use `I_PLINK` instead of `I_LINK`. The default is to use `I_LINK`, which cleans up terminated interface (even if `SIGKILL` is used), but does not allow `ifconfig(1M)` to unplumb PPP streams or insert or remove modules dynamically. Use this option if `ifconfig(1M)` `modinsert/modremove/unplumb` support is needed. See also the `plumbed` option.

plugin *filename*

Load the shared library object file *filename* as a plugin. This is a privileged option. Unless the filename specifies an explicit path, `/etc/ppp/plugins` and `/usr/lib/inet/ppp` will be searched for the object to load in that order.

plumbed

This option indicates that pppd should find a plumbed interface and use that for the session. If IPv4 addresses or IPv6 interface IDs or link MTU are otherwise unspecified, they are copied from the interface selected. This mode mimics some of the functionality of the older `aspppd` implementation and may be helpful when pppd is used with external applications that use `ifconfig(1M)`.

pppmux *timer*

Enable PPP Multiplexing option negotiation and set transmit multiplexing timeout to *timer* microseconds.

privgroup *group-name*

Allows members of group *group-name* to use privileged options. This is a privileged option. Because there is no guarantee that members of *group-name* cannot use pppd

to become root themselves, you should be careful using this option. Consider it equivalent to putting the members of *group-name* in the *root* or *sys* group.

proxyarp

Add an entry to the system's Address Resolution Protocol (ARP) table with the IP address of the peer and the Ethernet address of this system. When you use this option, the peer appears to other systems to be on the local Ethernet. The remote address on the PPP link must be in the same subnet as assigned to an Ethernet interface.

pty *script*

Specifies that the command *script*, and not a specific terminal device is used for serial communication. pppd allocates itself a pseudo-tty master/slave pair and uses the slave as its terminal device. *script* runs in a child process with the pseudo-tty master as its standard input and output. An explicit device name may not be given if this option is used. (Note: if the *record* option is used in conjunction with the *pty* option, the child process will have pipes on its standard input and output.)

receive-all

With this option, pppd accepts all control characters from the peer, including those marked in the *receive asyncmap*. Without this option, pppd discards those characters as specified in *RFC 1662*. This option should be used only if the peer has bugs, as is often found with dial-back implementations.

record *filename*

Directs pppd to record all characters sent and received to a file named *filename*. *filename* is opened in append mode, using the user's user-ID and permissions. Because this option uses a pseudo-tty and a process to transfer characters between the pseudo-tty and the real serial device, it increases the latency and CPU overhead of transferring data over the PPP interface. Characters are stored in a tagged format with timestamps that can be displayed in readable form using the *pppdump(1M)* program. This option is generally used when debugging the kernel portion of pppd (especially CCP compression algorithms) and not for debugging link configuration problems. See the *debug* option.

remotename *name*

Set the assumed name of the remote system for authentication purposes to *name*. Microsoft WindowsNT does not provide a system name in its CHAP Challenge messages, and this option is often used to work around this problem.

refuse-chap

With this option, pppd will not agree to authenticate itself to the peer using standard Challenge Handshake Authentication Protocol (CHAP). (MS-CHAP is not affected.)

refuse-mschap

Do not agree to authenticate to peer with MS-CHAPv1. If this option is specified, requests for MS-CHAPv1 authentication from the peer are declined with LCP Configure-Nak. That option does not disable any other form of CHAP.

pppd(1M)

refuse-mschapv2

Do not agree to authenticate to peer with MS-CHAPv2. If specified, this option requests that MS-CHAPv2 authentication from the peer be declined with LCP Configure-Nak. That option does not disable any other form of CHAP.

refuse-pap

With this option, pppd will not agree to authenticate itself to the peer using Password Authentication Protocol (PAP).

require-chap

Require the peer to authenticate itself using standard CHAP authentication. MS-CHAP is not affected.

require-mschap

Require the peer to authenticate itself using MS-CHAPv1 authentication.

require-mschapv2

Require the peer to authenticate itself using MS-CHAPv2 authentication.

require-pap

Require the peer to authenticate itself using PAP authentication.

show-password

When logging contents of PAP packets, this option causes pppd to show the password string in the log message.

silent

With this option, pppd will not transmit LCP packets to initiate a connection until a valid LCP packet is received from the peer. This is like the “passive” option with older versions of pppd and is retained for compatibility, but the current *passive* option is preferred.

small-accm-test

When checking the *asynctest* (ACCM) setting, pppd uses all 256 possible values by default. See *no-accm-test*. This option restricts the test so that only the 32 values affected by standard ACCM negotiation are tested. This option is useful on very slow links.

socket *host:port*

Connect to given host and port using TCP and run PPP over this connection.

sync

Use synchronous HDLC serial encoding instead of asynchronous. The device used by pppd with this option must have sync support. Currently supports *zs*, *se*, and *hsi* drivers.

unit *n*

Set PPP interface unit number to *n*, if possible.

updetach

With this option, pppd detaches from its controlling terminal after establishing the PPP connection. When this is specified, messages sent to *stderr* by the connect script, usually *chat(1M)*, and debugging messages from the *debug* option are directed to pppd's standard output.

usehostname

Enforce the use of the hostname with domain name appended, if given, as the name of the local system for authentication purposes. This overrides the name option. Because the name option is privileged, this option is normally not needed.

usepeerdns

Ask the peer for up to two DNS server addresses. Addresses supplied by the peer, if any, are passed to the `/etc/ppp/ip-up` script in the environment variables DNS1 and DNS2. In addition, pppd creates an `/etc/ppp/resolv.conf` file containing one or two nameserver lines with the address(es) supplied by the peer.

user *name*

Sets the name used for authenticating the local system to the peer to *name*.

vj-max-slots *n*

Sets the number of connection slots to be used by the Van Jacobson TCP/IP header compression and decompression code to *n*, which must be between 2 and 16 (inclusive).

welcome *script*

Run the executable or shell command specified by *script* before initiating PPP negotiation, after the connect script, if any, has completed. A value for this option from a privileged source cannot be overridden by a non-privileged user.

xonxoff

Use software flow control, that is, XON/XOFF, to control the flow of data on the serial port.

Obsolete Options

The following options are obsolete:

+ua *name*

Read a PAP user name and password from the file *name*. This file must have two lines for name and password. Name and password are sent to the peer when the peer requests PAP authentication.

+ipv6

Enable IPv6 and IPv6CP without specifying interface identifiers.

--version

Show version number and exit.

--help

Show brief help message and exit.

**EXTENDED
DESCRIPTION**
Security

The following sections discuss miscellaneous features of pppd:

pppd allows system administrators to provide legitimate users with PPP access to a server machine without fear of compromising the security of the server or the network it runs on. Access control is provided by restricting IP addresses the peer may use based on its authenticated identity (if any), and through restrictions on options a non-privileged user may use. Options that permit potentially insecure configurations are privileged. Privileged options are accepted only in files that are under the control of the system administrator or when pppd is being run by root.

pppd(1M)

By default, `pppd` allows an unauthenticated peer to use a given IP address only if the system does not already have a route to that IP address. For example, a system with a permanent connection to the wider Internet will normally have a default route, meaning all peers must authenticate themselves to set up a connection. On such a system, the `auth` option is the default. Conversely, a system with a PPP link that comprises the only connection to the Internet probably does not possess a default route, so the peer can use virtually any IP address without authenticating itself.

Security-sensitive options are privileged and cannot be accessed by a non-privileged user running `pppd`, either on the command line, in the user's `$HOME/.ppprc` file, or in an options file read using the `file` option. Privileged options may be used in `/etc/ppp/options` file or in an options file read using the `call` option. If `pppd` is run by the root user, privileged options can be used without restriction. If the `/etc/ppp/options` file does not exist, then only root may invoke `pppd`. The `/etc/ppp/options` file must be created (but may be empty) to allow ordinary non-root users to access `pppd`.

When opening the device, `pppd` uses the invoking user's user ID or the root UID (that is, 0), depending if the device name was specified by the user or the system administrator. If the device name comes from a privileged source, that is, `/etc/ppp/options` or an options file read using the `call` option, `pppd` uses full root privileges when opening the device. Thus, by creating an appropriate file under `/etc/ppp/peers`, the system administrator can allow users to establish a PPP connection via a device that they would not normally have access to. Otherwise `pppd` uses the invoking user's real UID when opening the device.

Authentication

During the authentication process, one peer convinces the other of its identity by sending its name and some secret information to the other. During authentication, the first peer becomes the "client" and the second becomes the "server." Authentication names can (but are not required to) correspond to the peer's Internet hostnames.

`pppd` supports four authentication protocols: the Password Authentication Protocol (PAP) and three forms of the Challenge Handshake Authentication Protocol (CHAP). With the PAP protocol, the client sends its name and a cleartext password to the server to authenticate itself. With CHAP, the server initiates the authentication exchange by sending a challenge to the client who must respond with its name and a hash value derived from the shared secret and the challenge.

The PPP protocol is symmetrical, meaning that each peer may be required to authenticate itself to the other. Different authentication protocols and names can be used for each exchange.

By default, `pppd` authenticates if requested and does not require authentication from the peer. However, `pppd` does not authenticate itself with a specific protocol if it has no secrets that can do so.

pppd stores authentication secrets in the `/etc/ppp/pap-secrets` (for PAP), and `/etc/ppp/chap-secrets` (for CHAP) files. Both files use the same format. pppd uses secrets files to authenticate itself to other systems and to authenticate other systems to itself.

Secrets files contain one secret per line. Secrets are specific to a particular combination of client and server and can only be used by that client to authenticate itself to that server. Each line in a secrets file has a minimum of three fields that contain the client and server names followed by the secret. Often, these three fields are followed by IP addresses that are used by clients to connect to a server.

A secrets file is parsed into words, with client name, server name and secrets fields allocated one word each. Embedded spaces or other special characters within a word must be quoted or escaped. Case is significant in all three fields.

A secret beginning with an at sign ("`@`") is followed by the name of a file containing the secret. An asterisk (*) as the client or server name matches any name. When choosing a match, pppd selects the one with the fewest wildcards. Succeeding words on a line are interpreted by pppd as acceptable IP addresses for that client. IP Addresses are disallowed if they appear in lines that contain only three words or lines whose first word begins with a hyphen ("`-`"). To allow any address, use "`*`". An address starting with an exclamation point ("`!`") indicates that the specified address is not acceptable. An address may be followed by "`/`" and a number *n* to indicate a whole subnet (all addresses that have the same value in the most significant *n* bits). In this form, the address may be followed by a plus sign ("`+`") to indicate that one address from the subnet is authorized, based on the ppp network interface unit number in use. In this case, the host part of the address is set to the unit number, plus one.

When authenticating the peer, pppd chooses a secret with the peer's name in the first field of the secrets file and the name of the local system in the second field. The local system name defaults to the hostname, with the domain name appended if the `domain` option is used. The default can be overridden with the `name` option unless the `usehostname` option is used.

When authenticating to the peer, pppd first determines the name it will use to identify itself to the peer. This name is specified with the `user` option. If the `user` option is not used, the name defaults to the host name of the local system. pppd then selects a secret from the secrets file by searching for an entry with a local name in the first field and the peer's name in the second field. pppd will know the name of the peer if standard CHAP authentication is used because the peer will have sent it in the Challenge packet. However, if MS-CHAP or PAP is being used, pppd must determine the peer's name from the options specified by the user. The user can specify the peer's name directly with the `remotename` option. Otherwise, if the remote IP address was specified by a name, rather than in numeric form, that name will be used as the peer's name. If that fails, pppd uses the null string as the peer's name.

pppd(1M)

When authenticating the peer with PAP, the supplied password is compared with data in the secrets file. If the password and secret do not match, the password is encrypted using `crypt()` and checked against the secret again. If the `papcrypt` option is given, the first unencrypted comparison is omitted for better security, and entries must thus be in encrypted `crypt(3C)` form.

If the `login` option is specified, the username and password are also checked against the system password database. This allows you to set up the `pap-secrets` file to enable PPP access only to certain users, and to restrict the set of IP addresses available to users. Typically, when using the `login` option, the secret in `/etc/ppp/pap-secrets` would be `""`, which matches any password supplied by the peer. This makes having the same secret in two places unnecessary. When `login` is used, the `pam` option enables access control through `pam(3PAM)`.

Authentication must be completed before IPCP (or other network protocol) can be started. If the peer is required to authenticate itself and fails, `pppd` closes LCP and terminates the link. If IPCP negotiates an unacceptable IP address for the remote host, IPCP is closed. IP packets are sent or received only when IPCP is open.

To allow hosts that cannot authenticate themselves to connect and use one of a restricted set of IP addresses, add a line to the `pap-secrets` file specifying the empty string for the client name and secret.

Additional `pppd` options for a given peer may be specified by placing them at the end of the secrets entry, separated by two dashes (`—`). For example

```
peername servername secret ip-address -- novj
```

Routing

When IPCP negotiation is complete, `pppd` informs the kernel of the local and remote IP addresses for the PPP interface and creates a host route to the remote end of the link that enables peers to exchange IP packets. Communication with other machines generally requires further modification to routing tables and/or Address Resolution Protocol (ARP) tables. In most cases the `defaultroute` and/or `proxyarp` options are sufficient for this, but further intervention may be necessary. If further intervention is required, use the `/etc/ppp/ip-up` script or a routing protocol daemon.

To add a default route through the remote host, use the `defaultroute` option. This option is typically used for “client” systems; that is, end-nodes that use the PPP link for access to the general Internet.

In some cases it is desirable to use proxy ARP, for example on a server machine connected to a LAN, to allow other hosts to communicate with the remote host. `proxyarp` instructs `pppd` to look for a network interface on the same subnet as the remote host. That is, an interface supporting broadcast and ARP that is not a point-to-point or loopback interface and that is currently up. If found, `pppd` creates a permanent, published ARP entry with the IP address of the remote host and the hardware address of the network interface.

Scripts

When the demand option is used, the interface IP addresses are already set at the time when IPCP comes up. If pppd cannot negotiate the same addresses it used to configure the interface, it changes the interface IP addresses to the negotiated addresses. This may disrupt existing connections. Using demand dialing with peers that perform dynamic IP address assignment is not recommended.

pppd invokes scripts at various stages during processing that are used to perform site-specific ancillary processing. These scripts may be shell scripts or executable programs. pppd does not wait for the scripts to finish. The scripts are executed as root (with the real and effective user-id set to 0), enabling them to update routing tables, run privileged daemons, or perform other tasks. Be sure that the contents of these scripts do not compromise your system's security. pppd runs the scripts with standard input, output and error redirected to /dev/null, and with an environment that is empty except for some environment variables that give information about the link. The pppd environment variables are:

DEVICE	Name of the serial tty device.
IFNAME	Name of the network interface.
IPLOCAL	IP address for the link's local end. This is set only when IPCP has started.
IPREMOTE	IP address for the link's remote end. This is set only when IPCP has started.
PEERNAME	Authenticated name of the peer. This is set only if the peer authenticates itself.
SPEED	Baud rate of the tty device.
ORIG_UID	Real user-id of user who invoked pppd.
PPPLOGNAME	Username of the real user-id who invoked pppd. This is always set.

pppd also sets the following variables for the ip-down and auth-down scripts:

CONNECT_TIME	Number of seconds between the start of PPP negotiation and connection termination.
BYTES_SENT	Number of bytes sent at the level of the serial port during the connection.
BYTES_RCVD	Number of bytes received at the level of the serial port during the connection.
LINKNAME	Logical name of the link, set with the linkname option.

If they exist, pppd invokes the following scripts. It is not an error if they do not exist.

/etc/ppp/auth-up	Program or script executed after the remote system successfully authenticates itself. It is executed with five command-line arguments: interface-name

pppd(1M)

	peer-name user-name tty-device speed. Note that this script is not executed if the peer does not authenticate itself, for example, when the noauth option is used.
/etc/ppp/auth-down	Program or script executed when the link goes down if /etc/ppp/auth-up was previously executed. It is executed in the same manner with the same parameters as /etc/ppp/auth-up.
/etc/ppp/ip-up	A program or script that is executed when the link is available for sending and receiving IP packets (that is, IPCP has come up). It is executed with six command-line arguments: interface-name tty-device speed local-IP-address remote-IP-address ipparam.
/etc/ppp/ip-down	A program or script which is executed when the link is no longer available for sending and receiving IP packets. This script can be used for undoing the effects of the /etc/ppp/ip-up script. It is invoked in the same manner and with the same parameters as the ip-up script.
/etc/ppp/ipv6-up	Similar to /etc/ppp/ip-up, except that it is executed when the link is available for sending and receiving IPv6 packets. Executed with six command-line arguments: interface-name tty-device speed local-link-local-address remote-link-local-address ipparam.
/etc/ppp/ipv6-down	Similar to /etc/ppp/ip-down, but executed when IPv6 packets can no longer be transmitted on the link. Executed with the same parameters as the ipv6-up script.

EXAMPLES

EXAMPLE 1 Using the auth Option

The following examples assume that the /etc/ppp/options file contains the auth option.

pppd is commonly used to dial out to an ISP. You can do this using the “pppd call isp” command where the /etc/ppp/peers/isp file is set up to contain a line similar to the following:

```
cua/a 19200 crtscts connect '/usr/bin/chat -f /etc/ppp/chat-isp' noauth
```

For this example, chat(1M) is used to dial the ISP's modem and process any login sequence required. The /etc/ppp/chat-isp file is used by chat and could contain the following:

EXAMPLE 1 Using the auth Option (Continued)

```

ABORT "NO CARRIER"
ABORT "NO DIALTONE"
ABORT "ERROR"
ABORT "NO ANSWER"
ABORT "BUSY"
ABORT "Username/Password Incorrect"
" " "at"
OK "at&f&d2&c1"
OK "atdt2468135"
"name:" " ^Umyuserid"
"word:" " \qmypassword"
"ispts" " \q^Uppp"
"~~^Uppp~~"

```

See the chat(1M) man page for details of chat scripts.

EXAMPLE 2 Using pppd with proxyarp

pppd can also provide a dial-in ppp service for users. If the users already have login accounts, the simplest way to set up the ppp service is to let the users log in to their accounts and run pppd as shown in the following example:

```
example% pppd proxyarp
```

EXAMPLE 3 Providing a User with Access to PPP Facilities

To provide a user with access to the PPP facilities, allocate an IP address for the user's machine, create an entry in /etc/ppp/pap-secrets or /etc/ppp/chap-secrets. This enables the user's machine to authenticate itself. For example, to enable user "Joe" using machine "joespc" to dial in to machine "server" and use the IP address "joespc.my.net," add the following entry to the /etc/ppp/pap-secrets or /etc/ppp/chap-secrets files:

```
joespc      server      "joe's secret"      joespc.my.net
```

Alternatively, you can create another username, for example "ppp," whose login shell is /usr/bin/pppd and whose home directory is /etc/ppp. If you run pppd this way, add the options to the /etc/ppp/.ppprc file.

If your serial connection is complex, it may be useful to escape such control characters as XON (^Q) and XOFF (^S), using `asynmap a0000`. If the path includes a telnet, escape ^] (`asynmap 200a0000`). If the path includes a `rlogin` command, add escape `ff` option to the options, because `rlogin` removes the window-size-change sequence [0xff, 0xff, 0x73, 0x73, followed by any 8 bytes] from the stream.

EXIT STATUS

The pppd exit status indicates errors or specifies why a link was terminated. Exit status values are:

pppd(1M)

- 0 pppd has detached or the connection was successfully established and terminated at the peer's request.
- 1 An immediately fatal error occurred. For example, an essential system call failed.
- 2 An error was detected in the options given. For example, two mutually exclusive options were used, or `/etc/ppp/options` is missing and the user is not root.
- 3 pppd is not `setuid-root` and the invoking user is not root.
- 4 The kernel does not support PPP. For example, the PPP kernel driver is not included or cannot be loaded.
- 5 pppd terminated because it was sent a SIGINT, SIGTERM or SIGHUP signal.
- 6 The serial port could not be locked.
- 7 The serial port could not be opened.
- 8 The connect script failed and returned a non-zero exit status.
- 9 The command specified as the argument to the `pty` option could not be run.
- 10 The PPP negotiation failed because no network protocols were able to run.
- 11 The peer system failed or refused to authenticate itself.
- 12 The link was established successfully, but terminated because it was idle.
- 13 The link was established successfully, but terminated because the connect time limit was reached.
- 14 Callback was negotiated and an incoming call should arrive shortly.
- 15 The link was terminated because the peer is not responding to echo requests.
- 16 The link was terminated by the modem hanging up.
- 17 The PPP negotiation failed because serial loopback was detected.
- 18 The init script failed because a non-zero exit status was returned.
- 19 Authentication to the peer failed.

FILES	<code>/var/run/spppn.pid</code>	Process-ID for pppd process on PPP interface unit <i>n</i> .
	<code>/var/run/ppp-name.pid</code>	Process-ID for pppd process for logical link name (see the <code>linkname</code> option).
	<code>/etc/ppp/pap-secrets</code>	Username, passwords and IP addresses for PAP authentication. This file should be

	owned by root and not readable or writable by any other user, otherwise pppd will log a warning.
/etc/ppp/chap-secrets	Names, secrets and IP addresses for all forms of CHAP authentication. The /etc/ppp/pap-secrets file should be owned by root should not readable or writable by any other user, otherwise, pppd will log a warning.
/etc/ppp/options	System default options for pppd, read before user default options or command-line options.
\$HOME/.ppprc	User default options, read before /etc/ppp/options.ttyname.
/etc/ppp/options.ttyname	System default options for the serial port in use; read after \$HOME/.ppprc. The ttyname component of this filename is formed when the initial /dev/ is stripped from the port name (if present), and slashes (if any) are converted to dots.
/etc/ppp/peers	Directory with options files that may contain privileged options, even if pppd was invoked by a user other than root. The system administrator can create options files in this directory to permit non-privileged users to dial out without requiring the peer to authenticate, but only to certain trusted peers.

NOTES

These signals affect pppd behavior:

SIGINT, SIGTERM	Terminate the link, restore the serial device settings and exit.
SIGHUP	Terminate the link, restore the serial device settings and close the serial device. If the <code>persist</code> or <code>demand</code> option is specified, pppd attempts to reopen the serial device and start another connection after the holdoff period. Otherwise pppd exits. If received during the holdoff period, SIGHUP causes pppd to end the holdoff period immediately.
SIGUSR1	Toggles the state of the debug option and prints link status information to the log.
SIGUSR2	Causes pppd to renegotiate compression. This is useful to re-enable compression after it has been disabled as a result of a fatal decompression error. (Fatal decompression errors generally indicate a bug in an implementation.)

DIAGNOSTICS

Messages are sent to the syslog daemon using facility LOG_DAEMON. To see error and debug messages, edit the `/etc/syslog.conf` file to direct the messages to the desired output device or file, or use the `updetach` or `logfile` options.

The debug option causes the contents of all LCP, PAP, CHAP or IPCP control packets sent or received to be logged. This is useful if PPP negotiation does not succeed or if authentication fails.

Debugging can also be enabled or disabled by sending a SIGUSR1 signal, which acts as a toggle to the pppd process.

NAME	pppoe – PPPoE chat utility
SYNOPSIS	pppoe [-o<i>milliseconds</i>] [-s<i>milliseconds</i>] [-v] <i>device</i> [<i>service</i> [[<i>except</i>] <i>server</i>... [<i>only</i>]]] pppoe [-o<i>milliseconds</i>] [-v] -i [<i>device</i>]
DESCRIPTION	The pppoe utility implements the client-side negotiation of PPPoE. It is intended to be used with the pppd(1M) connect option, in the same manner as the chat(1M) utility is used for asynchronous dial-up PPP. When given with the -i flag, pppoe sends out a broadcast query on the given interface named by the <i>device</i> parameter. You can specify no other arguments in this mode. All responding PPPoE servers and the offered services are displayed on standard output. Otherwise, when given without the -i flag, pppoe does the full PPPoE client-side negotiation. The <i>device</i> parameter is the intended Ethernet interface, and must already be plumbed with sppptun(1M). The optional <i>service</i> parameter specifies a particular service desired; other offered services will be ignored. The optional <i>server</i> parameter specifies a specific server desired. You can specify <i>server</i> as an Ethernet address in the usual x:x:x:x:x:x format (with "*" in any of the six byte positions interpreted to mean "any"), or as a symbolic name resolved through /etc/ethers (or NIS), or as a PPPoE access concentrator name. The sense of the match (true or false) can be inverted by specifying the keyword <i>except</i> before this string. This parameter can be specified more than once, and the first match is taken. If you specify the <i>server</i> parameter, then the selected servers become "preferred." If no preferred server responds, then the first responding server is used instead. To exclude non-matching servers entirely, append the keyword <i>only</i>.
OPTIONS	The following options are supported: -i Sends out broadcast query over interface specified by <i>device</i>. -o Sets the initial wait time in milliseconds for PADO from the server before PADI is retried. The default is 500 milliseconds for normal operation, or 3000 milliseconds (3 seconds) for inquiry (-i) mode. -s Sets the initial wait time in milliseconds for PADS from the server before PADR is retried. The default is 2000 milliseconds (2 seconds). -v Displays verbose progress messages, including all PPPoE messages sent, and all state machine transitions. You normally do not need to adjust the parameters set with -o and -s. They are provided for coping with unusually slow servers.
OPERANDS	The following operands are supported: <i>device</i> plumbed Ethernet interface

pppoe(1M)

server preferred server or, if you specify only, the specified server

service desired service; other available services are ignored

EXAMPLES

EXAMPLE 1 Connecting to Any Service on hme0

The following command enables you to connect to any PPPoE service on hme0:

```
# /usr/bin/pppd sppptun plugin pppoe.so \
connect "/usr/lib/inet/pppoe hme0" debug
```

Often, a command such as the preceding is specified in an `/etc/ppp/peers` file instead. For example, enter the following in `/etc/ppp/peers/myisp`:

```
sppptun
plugin pppoe.so
connect "/usr/lib/inet/pppoe hme0"
debug
```

To invoke the PPP connection described in the file, enter:

```
% /usr/bin/pppd call myisp
```

Note that, because the `/etc/ppp/peers` files are considered privileged by `pppd`, you need not be root to invoke the preceding command.

EXAMPLE 2 Connecting to a Particular Service

A more complex example: on hme0, connect to only the internet service offered by PPPoE servers with access concentrator name `isp`, but not to any Ethernet addresses starting with `40:0:1a`.

```
# /usr/lib/inet/pppoe hme0 internet except 40:0:1a:*:*:* isp only
```

Note that the `except 40:0:1a:*:*:*` filter must come before `isp`, because the filters are first-match.

EXIT STATUS

The following exit values are returned:

```
0          Successful completion.
>0         An error occurred.
```

FILES

```
/usr/lib/inet/pppoe
    executable command

/dev/sppptun
    Solaris PPP tunneling device driver.

/etc/ppp/connect-errors
    usual location of error output (see DIAGNOSTICS, below)
```

ATTRIBUTES See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWpppdt

SEE ALSO pppd(1M), sppptun(1M), pppoed(1M), sppptun(7M)

RFC 2516, Method for Transmitting PPP Over Ethernet (PPPoE), Mamakos et al, February 1999

DIAGNOSTICS Error messages are written to standard error, which is normally redirected by pppd to /etc/ppp/connect-errors. The errors can also be redirected to pppd's standard output by using the updetach option.

If you specify the -v, verbose progress messages are displayed, including all PPPoE messages sent, and all state machine transitions. Specifying the updetach or nodetach pppd option is helpful when using verbose mode.

pppoed(1M)

NAME	pppoed – PPPoE server daemon				
SYNOPSIS	pppoed [<i>options</i>]				
DESCRIPTION	The pppoed daemon implements the server-side negotiation of PPPoE. When a client requests service from this daemon, a copy of pppd(1M) is invoked to handle the actual PPP communication. At startup, options are read from the command line and the <code>/etc/ppp/pppoe</code> file. After these options have been read, options in the per-device <code>/etc/ppp/pppoe.device</code> files are read, using the device names specified on the command line or in <code>/etc/ppp/pppoe</code>. Device names are not permitted in the per-device files. It is not an error if any of these files are absent; missing files are ignored. Options are reread in the same order on <code>SIGHUP</code>. Except for the possibility of short delays due to the processing time, <code>SIGHUP</code> does not interfere with any client operations. Current status, including options read, is dumped to <code>/tmp/pppoed.pid</code> on <code>SIGINT</code>. The options are used to set up a list of services to be offered to PPPoE clients on the broadcast domains (Ethernet subnets) specified by the named devices. Option parsing is always in one of two modes, either global mode or service mode. The initial mode at the beginning of each file (and the command line) is global mode. Options specified in global mode serve as default values for subsequently defined services. Service mode is entered by the <code>service name</code> option. In this mode, the named option is defined. Options that appear in this mode override any global mode definitions for the current service. The option parsing follows standard shell tokenizing rules, using whitespace to delimit tokens, quotes to enclose strings that can contain whitespace, and escape sequences for special characters. Environment variables are substituted using familiar <code>\$VAR</code> and <code>\${VAR}</code> syntax and set using <code>NEWVAR=string</code>. Variables are both usable in subsequent options and provided to the pppd(1M) processes spawned for each client, but they are interpreted as they are encountered during option processing. Thus, all set variables are seen by all processes spawned; position in the configuration files has no effect on this.				
OPTIONS	The pppoed daemon supports the following options: <table><tr><td><code>client [except] client-list</code></td><td>This option restricts the clients that may receive the service. If the <code>except</code> keyword is given, then the clients on the list cannot access the service, but others can. If this keyword is not given, then only the listed clients can access the service.</td></tr><tr><td></td><td>This option can be specified more than once for a given service. For a given client, first match among all listed options encountered specifies the handling. If it</td></tr></table>	<code>client [except] client-list</code>	This option restricts the clients that may receive the service. If the <code>except</code> keyword is given, then the clients on the list cannot access the service, but others can. If this keyword is not given, then only the listed clients can access the service.		This option can be specified more than once for a given service. For a given client, first match among all listed options encountered specifies the handling. If it
<code>client [except] client-list</code>	This option restricts the clients that may receive the service. If the <code>except</code> keyword is given, then the clients on the list cannot access the service, but others can. If this keyword is not given, then only the listed clients can access the service.				
	This option can be specified more than once for a given service. For a given client, first match among all listed options encountered specifies the handling. If it				

matches an option with `except` specified, then access is denied. Otherwise, it is granted. The `client` list within a service is prepended to any list specified in the global context.

If no `client` options are given or if all options are specified with `except`, then all clients are permitted by default. If any `client` options without `except` are specified, then no clients are permitted by default.

The *client-list* is a comma-separated list of client identifiers. The match is made if any client on the list matches; thus, these are logically "ORed" together. Each client identifier can be either a symbolic name (resolved through `/etc/ethers` or NIS, as defined by `/etc/nsswitch.conf`) or a hexadecimal Ethernet address in the format `x:x:x:x:x:x`. In the latter case, any byte of the address can be "*", which matches any value in that position. For example, `40:0:1a:*:*:` matches Ethernet adapters from the manufacturer assigned block `40:0:1a`.

debug	Increase debug logging detail level by one. The detail levels are 0 (no logging), 1 (errors only; the default), 2 (warnings), 3 (informational messages), and 4 (debug messages). Log messages are written by default to <code>syslog(3C)</code> using facility <i>daemon</i> (see the <code>log</code> option below). When specified on the command line or in the global context of the <code>/etc/ppp/pppoe</code> file, this option also sets the daemon's default (non-service-related) detail level.
device <i>device-list</i>	Specify the devices on which the service is available. The <i>device-list</i> is a comma-separated list of logical device names (without the leading <code>/dev/</code>), such as <code>hme0</code> . This option is ignored if encountered in the per-device <code>/etc/ppp/pppoe.device</code> files.
extra <i>string</i>	Specifies extra options to <code>pppd(1M)</code> . It defaults to <code>"plugin pppoe.so directtty"</code> and usually does not need to be overridden.
file <i>path</i>	Suspends parsing of the current file, returns to global mode, and reads options from <i>path</i> . This file must be present and readable; if it is not, an error is logged. When the end of that file is reached, processing returns to the current file and the mode is reset to global again.

pppoed(1M)

	The global mode options specified in files read by this command use the options set in the current file's global mode; this condition extends to any file included by those files. All files read are parsed as though the command line had specified this option, and thus inherit the command line's global modes. This option can be used to revert to global mode at any point in an option file by specifying <code>file /dev/null</code>.
<i>group name</i>	Specifies the group ID (symbolic or numeric) under which <code>pppd</code> is executed. If <code>pppoed</code> is not run as root, this option is ignored.
<i>log path</i>	Specifies an alternate debug logging file. Debug messages are sent to this file instead of <code>syslog</code> . The special name <code>syslog</code> is recognized to switch logging back to <code>syslog</code> . When specified on the command line or in the global context of the <code>/etc/ppp/pppoe</code> file, this option also sets the daemon's default (non-service-related) log file.
<i>nodebug</i>	Set debug logging detail level to 0 (no logging). When specified on the command line or in the global context of the <code>/etc/ppp/pppoe</code> file, this option also sets the daemon's default (non-service-related) detail level.
<i>nowildcard</i>	Specifies that the current service should not be included in response to clients requesting "any" service. The client must ask for this service by name. When specified on the command line or in the global context of the <code>/etc/ppp/pppoe</code> file, this option causes <code>pppoed</code> to ignore all wildcard service requests.
<i>path path</i>	Specifies the path to the <code>pppd</code> executable. Defaults to <code>/usr/bin/pppd</code> .
<i>pppd string</i>	Passes command-line arguments to <code>pppd</code> . It can be used to set the IP addresses or configure security for the session. The default value is the empty string.
<i>server string</i>	Specifies the PPPoE Access Concentrator name to be sent to the client. It defaults to "Solaris PPPoE".
<i>service name</i>	Closes any service being defined and begins definition of a new service. The same service name can be used without conflict on multiple devices. If the same service name is used on a single device, then the last definition encountered during parsing overrides all previous definitions.

<i>user name</i>	Specifies the user ID, symbolic or numeric, under which <code>pppd</code> is executed. If <code>pppoed</code> is not run as root, this option is ignored.
<i>wildcard</i>	Specifies that the service should be included in responses to client queries that request "any" service, which is done by requesting a service name of length zero. When specified on the command line or in the global context of the <code>/etc/ppp/pppoe</code> file, this option causes <code>pppoed</code> to ignore all wildcard service requests. This is the default.

EXAMPLES**EXAMPLE 1** Configuring for Particular Services

In the `/etc/ppp/pppoe` file:

```
service internet
    device $DEV
    pppd "proxyarp 192.168.1.1:"
service debugging
    device hme0,$DEV
    pppd "debug proxyarp 192.168.1.1:"
```

You then invoke the daemon with:

```
example% /usr/lib/inet/pppoed DEV=le0
```

The lines in `/etc/ppp/pppoe` and the preceding command result in offering services "internet" and "debugging" (and responding to wildcard queries) on interface `le0`, and offering only service "debugging" on interface `hme0`.

SIGNALS

The `pppoed` daemon responds to the following signals:

<code>SIGHUP</code>	Causes <code>pppoed</code> to reparse the original command line and all configuration files, and close and reopen any log files.
<code>SIGINT</code>	Causes a snapshot of the state of the <code>pppoed</code> daemon to be written to <code>/tmp/pppoed.pid</code> (where <i>pid</i> is the decimal process ID of the daemon).

FILES

<code>/usr/lib/inet/pppoed</code>	executable command
<code>/dev/sppptun</code>	Solaris PPP tunneling device driver
<code>/etc/ppp/pppoe</code>	main configuration option file
<code>/etc/ppp/pppoe.device</code>	per-device configuration option file
<code>/etc/ppp/pppoe-errors</code>	location of output from <code>pppd</code> 's stderr
<code>/etc/ppp/pppoe.if</code>	list of Ethernet interfaces to be plumbed at boot time

pppoed(1M)

/tmp/pppoed.pid ASCII text file containing dumped pppoed state information

ATTRIBUTES See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWpppdt

SEE ALSO pppd(1M), pppoec(1M), sppptun(1M), sppptun(7M)

Mamakos, L., et al. *RFC 2516, A Method for Transmitting PPP Over Ethernet (PPPoE)*. Network Working Group. February 1999

NOTES Because pppd is installed setuid root, this daemon need not be run as root. However, if it is not run as root, the user and group options are ignored.

The Ethernet interfaces to be used must be plumbed for PPPoE using the sppptun(1M) utility before services can be offered.

The daemon operate runs even if there are no services to offer. If you want to modify a configuration, it is not necessary to terminate the daemon. Simply use `kill -HUP pppoed` after updating the configuration files.

The PPPoE protocol is far from perfect. Because it runs directly over Ethernet, there is no possibility of security and the MTU is limited to 1492 (violating RFC 1661's default value of 1500). It is also not possible to run the client and the server of a given session on a single machine with a single Ethernet interface for testing purposes. The client and server portions of a single session must be run on separate Ethernet interfaces with different MAC addresses.

NAME	pppstats – print PPP statistics												
SYNOPSIS	pppstats [-a] [-v] [-r] [-z] [-c <count>] [-w <secs>] [<i>interface</i>]												
DESCRIPTION	The pppstats utility reports PPP-related statistics at regular intervals for the specified PPP interface. If the interface is unspecified, pppstats defaults to sppp0 . The display is split horizontally into input and output sections containing columns of statistics describing the properties and volume of packets received and transmitted by the interface.												
OPTIONS	The pppstats options are: -a Display absolute values rather than deltas. With this option, all reports show statistics for the time elapsed since the link was initiated. Without this option, the second and subsequent reports show statistics for the time since the last report. -c <i>count</i> Repeat the display <i>count</i> times. If this option is not specified, the default repeat count is 1 if the -w option is not specified, otherwise infinity. -r Display additional statistics summarizing the compression ratio achieved by the packet compression algorithm in use. -v Display additional statistics relating to the performance of the Van Jacobson TCP header compression algorithm. -w <i>wait</i> Pause <i>wait</i> seconds between each display. If this option is not specified, the default interval is five seconds. -z Instead of the standard display, show statistics indicating the performance of the packet compression algorithm in use.												
EXTENDED DESCRIPTION	The following fields are printed on the input side when the -z option is not used: <table> <tr> <td>IN</td><td>Total number of bytes received by this interface.</td></tr> <tr> <td>PACK</td><td>Total number of packets received by this interface.</td></tr> <tr> <td>VJCOMP</td><td>Number of header-compressed TCP packets received by this interface.</td></tr> <tr> <td>VJUNC</td><td>Number of header-uncompressed TCP packets received by this interface. Not reported when the -r option is specified.</td></tr> <tr> <td>VJERR</td><td>Number of corrupted or bogus header-compressed TCP packets received by this interface. Not reported when the -r option is specified.</td></tr> <tr> <td>VJTOSS</td><td>Number of VJ header-compressed TCP packets dropped on reception by this interface because of preceding errors. Only reported when the -v option is specified.</td></tr> </table>	IN	Total number of bytes received by this interface.	PACK	Total number of packets received by this interface.	VJCOMP	Number of header-compressed TCP packets received by this interface.	VJUNC	Number of header-uncompressed TCP packets received by this interface. Not reported when the -r option is specified.	VJERR	Number of corrupted or bogus header-compressed TCP packets received by this interface. Not reported when the -r option is specified.	VJTOSS	Number of VJ header-compressed TCP packets dropped on reception by this interface because of preceding errors. Only reported when the -v option is specified.
IN	Total number of bytes received by this interface.												
PACK	Total number of packets received by this interface.												
VJCOMP	Number of header-compressed TCP packets received by this interface.												
VJUNC	Number of header-uncompressed TCP packets received by this interface. Not reported when the -r option is specified.												
VJERR	Number of corrupted or bogus header-compressed TCP packets received by this interface. Not reported when the -r option is specified.												
VJTOSS	Number of VJ header-compressed TCP packets dropped on reception by this interface because of preceding errors. Only reported when the -v option is specified.												

pppstats(1M)

NON-VJ	Total number of non-TCP packets received by this interface. Only reported when the -v option is specified.
RATIO	Compression ratio achieved for received packets by the packet compression scheme in use, defined as the uncompressed size divided by the compressed size. Only reported when the -r option is specified.
UBYTE	Total number of bytes received, after decompression of compressed packets. Only reported when the -r option is specified.
The following fields are printed on the output side:	
OUT	Total number of bytes transmitted from this interface.
PACK	Total number of packets transmitted from this interface.
VJCOMP	Number of TCP packets transmitted from this interface with VJ-compressed TCP headers.
VJUNC	Number of TCP packets transmitted from this interface with VJ-uncompressed TCP headers. Not reported when the -r option is specified.
NON-VJ	Total number of non-TCP packets transmitted from this interface. Not reported when the -r option is specified.
VJSRCH	Number of searches for the cached header entry for a VJ header compressed TCP packet. Only reported when the -v option is specified.
VJMISS	Number of failed searches for the cached header entry for a VJ header compressed TCP packet. Only reported when the -v option is specified.
RATIO	Compression ratio achieved for transmitted packets by the packet compression scheme in use, defined as the size before compression divided by the compressed size. Only reported when the -r option is specified.
UBYTE	Total number of bytes to be transmitted before packet compression is applied. Only reported when the -r option is specified.
When the -z option is specified, pppstats displays the following fields relating to the packet compression algorithm currently in use. If packet compression is not in use, these fields display zeroes. The fields displayed on the input side are:	
COMPRESSED BYTE	Number of bytes of compressed packets received.
COMPRESSED PACK	Number of compressed packets received.

pppstats(1M)

INCOMPRESSIBLE BYTE	Number of bytes of incompressible packets (that is, those which were transmitted in uncompressed form) received.
INCOMPRESSIBLE PACK	Number of incompressible packets received.
COMP RATIO	Recent compression ratio for incoming packets, defined as the uncompressed size divided by the compressed size (including both compressible and incompressible packets).

The fields displayed on the output side are:

COMPRESSED BYTE	Number of bytes of compressed packets transmitted.
COMPRESSED PACK	Number of compressed packets transmitted.
INCOMPRESSIBLE BYTE	Number of bytes of incompressible packets received; that is, those that were transmitted by the peer in uncompressed form.
INCOMPRESSIBLE PACK	Number of incompressible packets transmitted.
COMP RATIO	Recent compression ratio for outgoing packets.

praudit(1M)

NAME	praudit – print contents of an audit trail file							
SYNOPSIS	praudit [-lrsx] [-ddel] [<i>filename</i> ...]							
DESCRIPTION	praudit reads the listed <i>filenames</i> (or standard input, if no <i>filename</i> is specified) and interprets the data as audit trail records as defined in <code>audit.log(4)</code> . By default, times, user and group IDs (UIDs and GIDs, respectively) are converted to their ASCII representation. Record type and event fields are converted to their ASCII representation. A maximum of 100 audit files can be specified on the command line.							
OPTIONS	The following options are supported: -ddel Use <i>del</i> as the field delimiter instead of the default delimiter, which is the comma. If <i>del</i> has special meaning for the shell, it must be quoted. The maximum size of a delimiter is three characters. The delimiter is not meaningful and is not used when the -x option is specified. -l Print one line per record. -r Print records in their raw form. Times, UIDs, GIDs, record types, and events are displayed as integers. This option and the -s option are exclusive. If both are used, a format usage error message is output. -s Print records in their short form. All numeric fields are converted to ASCII and displayed. The short ASCII representations for the record type and event fields are used. This option and the -r option are exclusive. If both are used, a format usage error message is output. -x Print records in XML form. Tags are included in the output to identify tokens and fields within tokens. Output begins with a valid XML prolog, which includes identification of the DTD which can be used to parse the XML.							
FILES	<code>/etc/security/audit_event</code>	Audit event definition and class mappings.						
	<code>/etc/security/audit_class</code>	Audit class definitions.						
	<code>/usr/share/lib/xml/dtd</code>	Directory containing the versioned DTD file referenced in XML output, for example, <code>adt_record.dtd.1</code> .						
	<code>/usr/share/lib/xml/style</code>	Directory containing the versioned XSL file referenced in XML output, for example, <code>adt_record.xsl.1</code> .

NOTES This functionality is available only if the Basic Security Module (BSM) has been enabled. See bsmconv(1M) for more information.

printmgr(1M)

NAME	printmgr – Solaris Print Manager is a graphical user interface for managing printers in a network
SYNOPSIS	<code>/usr/sadm/admin/bin/printmgr</code>
DESCRIPTION	Solaris Print Manager is a Java-based graphical user interface that enables you to manage local and remote printer access. This tool can be used in the following name service environments: LDAP, NIS, NIS+, NIS+ with Federated Naming Service (FNS), and files. You must be logged in as superuser to use this tool. Using Solaris Printer Manager is the preferred method for managing printer access instead of <code>admintool:printers</code> because Solaris Print Manager centralizes printer information when it is used in a name service environment. Adding printer information to a name service makes access to printers available to all systems on the network and generally makes printer administration easier because all the information about printers is centralized. Solaris Print Manager may be run on a remote system with the display sent to the local system. See the <i>System Administration Guide: Advanced Administration</i> for instructions on setting the <code>DISPLAY</code> environment variable. Using Solaris Print Manager to perform printer-related tasks automatically updates the appropriate printer databases. Solaris Print Manager also includes a command-line console that displays the <code>lp</code> command line for the add, modify, and delete printer operations. Errors and warnings may also be displayed when Printer Manager operations are performed. Help is available by clicking the Help button.
USAGE	Solaris Print Manager enables you to do the following tasks: - Select a Name Service Select a name service for retrieving or changing printer information. - Add Access to a Printer Add printer access on a printer client using Solaris Print Manager. - Add an Attached Printer After physically attaching the printer to a system, use Solaris Print Manager to install a local printer and make it available for printing. - Add a Network Printer After physically attaching the printer to a system, use Solaris Print Manager to install a local printer and make it available for printing. - Modify Printer Properties After adding access to a printer or adding an attached or network printer, you can modify certain printer attributes. - Delete a Printer Delete access to a printer from the print client or delete a printer from the print server or from the name service environment.

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWppm

SEE ALSO `ldap(1)`, `lpget(1M)`, `lpset(1M)`, `attributes(5)`

System Administration Guide: Advanced Administration

NOTES Be mindful of the following if the LDAP database is used as the name service.

1. Because the domain information for the printer being updated is extracted from the `ldapclient(1M)` configuration, the LDAP server being updated must host the same domain that is used by the current `ldapclient(1M)` server.
2. If the LDAP server being updated is a replica LDAP server, the updates will be referred to the master LDAP server and completed there. The updates might be out of sync and not appear immediately, as the replica server may not have been updated by the master server. For example, a printer that you deleted by using `lpset` may still appear in the printer list you display with `lpget` until the replica is updated from the master. Replica servers vary as to how often they are updated from the master. See *System Administration Guide: Advanced Administration* for information on LDAP server replication.
3. Although users can use the LDAP command line utilities `ldapadd(1)` and `ldapmodify(1)` to update printer entries in the directory, the preferred method is to use `lpset`. Otherwise, if the `lpadd` and `lpmodify` utilities are used, the administrator must ensure that the `printer-name` attribute value is unique within the `ou=printers` container on the LDAP server. If the value is not unique, the result of modifications done using `lpset` or the Solaris Print Manager, `printmgr(1M)` may be unpredictable.

privatepw(1M)

NAME	privatepw – administer FTP Server enhanced group access file												
SYNOPSIS	privatepw [-c] [-f <i>ftpgroups</i>] [-g <i>real_group_name</i>] <i>accessgroup</i> privatepw -d [-f <i>ftpgroups</i>] <i>accessgroup</i> privatepw -l [-f <i>ftpgroups</i>] privatepw -v												
DESCRIPTION	The privatepw utility is an administrative tool to add, delete and list enhanced access group information in the <i>ftpgroups</i> file. See <i>ftpgroups</i>(4). When privatepw is used without options, the help usage message is displayed. The privatepw utility prompts for a password when adding an enhanced access group entry or modifying an existing one.												
OPTIONS	The following options are supported by the privatepw utility: <table><tr><td>-c</td><td>Create a new <i>ftpgroups</i> file for the specified <i>accessgroup</i>.</td></tr><tr><td>-d</td><td>Delete information about the specified <i>accessgroup</i> from the <i>ftpgroups</i> file.</td></tr><tr><td>-f <i>ftpgroups</i></td><td>Use the specified <i>ftpgroups</i> file for all updates.</td></tr><tr><td>-g <i>group</i></td><td>Set the real system group to the <i>group</i> specified. <i>group</i> is a valid group name returned by <i>getgrnam</i>(3C). If the real system group is not supplied with the -g option when adding an enhanced access group entry, the privatepw utility prompts for it.</td></tr><tr><td>-l</td><td>List the contents of the <i>ftpgroups</i> file.</td></tr><tr><td>-v</td><td>Display program copyright and version information, then terminate.</td></tr></table>	-c	Create a new <i>ftpgroups</i> file for the specified <i>accessgroup</i> .	-d	Delete information about the specified <i>accessgroup</i> from the <i>ftpgroups</i> file.	-f <i>ftpgroups</i>	Use the specified <i>ftpgroups</i> file for all updates.	-g <i>group</i>	Set the real system group to the <i>group</i> specified. <i>group</i> is a valid group name returned by <i>getgrnam</i> (3C). If the real system group is not supplied with the -g option when adding an enhanced access group entry, the privatepw utility prompts for it.	-l	List the contents of the <i>ftpgroups</i> file.	-v	Display program copyright and version information, then terminate.
-c	Create a new <i>ftpgroups</i> file for the specified <i>accessgroup</i> .												
-d	Delete information about the specified <i>accessgroup</i> from the <i>ftpgroups</i> file.												
-f <i>ftpgroups</i>	Use the specified <i>ftpgroups</i> file for all updates.												
-g <i>group</i>	Set the real system group to the <i>group</i> specified. <i>group</i> is a valid group name returned by <i>getgrnam</i> (3C). If the real system group is not supplied with the -g option when adding an enhanced access group entry, the privatepw utility prompts for it.												
-l	List the contents of the <i>ftpgroups</i> file.												
-v	Display program copyright and version information, then terminate.												
OPERANDS	The following operands are supported: <table><tr><td><i>accessgroup</i></td><td>The name of the enhanced access group to create or update It consists of an arbitrary string of alphanumeric and punctuation characters. See <i>ftpgroups</i>(4).</td></tr></table>	<i>accessgroup</i>	The name of the enhanced access group to create or update It consists of an arbitrary string of alphanumeric and punctuation characters. See <i>ftpgroups</i> (4).										
<i>accessgroup</i>	The name of the enhanced access group to create or update It consists of an arbitrary string of alphanumeric and punctuation characters. See <i>ftpgroups</i> (4).												
EXIT STATUS	The following exit values are returned: <table><tr><td>0</td><td>Successful completion.</td></tr><tr><td>>0</td><td>An error occurred.</td></tr></table>	0	Successful completion.	>0	An error occurred.								
0	Successful completion.												
>0	An error occurred.												
FILES	/etc/ftpd/<i>ftpgroups</i> /etc/<i>group</i>

prodreg(1M)

NAME	prodreg – Solaris Product Registry administration
SYNOPSIS	prodreg [--help] [<i>subcommand operand ...</i>]
DESCRIPTION	The prodreg utility browses, unregisters, and uninstalls components in the Solaris Product Registry. Some installers make use of the libwsreg(3LIB) interface to register information. The Solaris Product Registry contains information about this installed software. The database associated with the Solaris Product Registry is relative to the root of the installed file system. Normally, this is the root of the file system (/). Sometimes, an alternate root, with a different Solaris Product Registry install database is used, as during live upgrade installation. See live_upgrade(5). The Registry database informs installers about installed software. The Registry and the prodreg utility do not directly perform installation or deinstallation. prodreg supports installers which are executed externally and launched by the prodreg utility or other means. Depending on the subcommand, the prodreg command offers equivalent functions from the command line or a GUI viewer. Two versions of the GUI viewer are available. The default is the Java Swing GUI. The other version, the Java awt GUI is provided for environments without Java Swing support. The only feature which exists in the CLI which is not present in the GUI is the unregister subcommand. It is possible for the product registry to become corrupted, if for example, some software is removed manually instead of by means of an uninstaller program. These entries can confuse installers which are run subsequently. The unregister subcommand allows stale entries to be removed, even forcefully. Care should be exercised when unregistering software with the recursive or force options so that valid entries in the registry are not removed by mistake. The prodreg command, whether it launches the GUI or the command line interface browser, displays the contents of the registry at that time only. If software is installed or uninstalled subsequent to or concurrent with launching either prodreg viewer, the view can be inconsistent with the Solaris Product Registry.
SUBCOMMANDS	You can specify options to the prodreg command without specifying a subcommand. If the subcommand is omitted, the swing subcommand is assumed. The following subcommands are supported: awt Launch the Java awt GUI. The awt subcommand has the following format: <pre>awt [-R <i>alt_root</i> --help]</pre>

browse

Display the Solaris Product Registry using a command line interface. The text output of this command displays identifying information of any component in the product registry tree, including its ancestors and children. If you repeatedly invoke this subcommand, you can interactively browse the product registry.

The database components are related as a tree. Components may have one or more children. Except for the root, components have one parent. This subcommand displays the ancestors and children for a given component in the Solaris Product Registry database.

Each time the `prodreg browse` subcommand is executed, one component in the Registry is shown, along with its ancestry to the root of the Registry, as well as the component's children. To browse in the `prodreg` GUI, a user selects a node to expand and clicks on it. The analogous activity using the command line interface is to browse on children of nodes successively, which effectively expands a view into the registry.

Start by browsing the root of the Registry with `prodreg browse`. Select components to expand the scope of the browsing activity. Use browse numbers as a convenience during this interactive browsing, but not in scripts. Browse numbers can change from one session to the next or on different systems. This is because browse numbers are generated as they are first used, by a given user on a particular system.

The browse subcommand has the following format:

```

browse [-R alt_root] [-u uuid [-i instance | -p location]]
browse [-R alt_root] -n bnum [-i instance | -p location]
browse [-R alt_root] -m name
browse --help

```

This following information is output for each component:

BROWSE #

This is the browse number associated with each component. This number can be used as an argument to either the `prodreg browse` or `info` subcommands as a convenience

+/-/.

The `+` indicates a component in the tree with children who are not shown. `-` indicates a component with children of which at least one child is being shown. The `.` indicates a component which has no children. This field is arranged so that each space (reading left to right) depicts a successive generation.

UUID

This is the component's unique identifier.

#

This is the instance number of the component. Software components can be installed multiple times. The software registry assigns a unique instance to each one.

prodreg(1M)

NAME

Each component in the Solaris Product Registry database has a localized name which is displayed in this field. It is possible that this name may not be unique in the registry since there could be another component that has the same name.

The `browse` subcommand provides four distinct options for viewing the registry database. If multiple instances are associated with the same component, then the output of the subcommand is the ambiguous list. The request must be made unambiguous. The instance or location operands can be used to disambiguate the `browse` subcommand when used with the `-u` or `-n` options.

- If no operand information is given, the root of the registry tree is displayed, as well as its children. This is the starting point for interactive browsing of the entire registry database.
- If the `browse` number is given, the component associated is output.
- If the `uuid` is given, the component associated with it is output.
- If the name is given, the component associated with it is output.

info

Display attributes for any component in the Solaris Product Registry by supplying identifying information for the component.

Components in the product registry are associated with attributes. These attributes are composed of a *name* and a single *value* string.

This subcommand outputs attribute information associated with components in the Solaris Product Registry. Individual components in the product registry are specified as for the `browse` subcommand, except that either the *uuid*, *name* or *bnum* must be specified.

If a component requested is ambiguous as it has more than one instance or the name is assigned to more than one component in the registry, the list of possibilities is output, not the attribute information.

The default output of this subcommand is a complete list of each attributes, each on a new line. The attribute name is followed by a colon (:) and a SPACE. The attribute value follows, after which a RETURN is appended. Other options include can be specified using `-a` and `-d`.

The `info` subcommand has the following format:

```
info --help
info [-R alt_root] -u uuid [-i instance | -p location]
info [-R alt_root] -n bnum [-i instance | -p location]
info [-R alt_root] -m name [-a attr | -d ]
```

`help | --help | -?`

Display help text.

The `help` subcommand has the following format:

```
help | --help | -?
```

swing

Launch the Java Swing GUI. If the Java Swing GUI is not available, this subcommand fails.

The swing subcommand has the following format:

```
swing [-R alt_root | --help]
```

version | --version | -V

Outputs a current version string.

The version subcommand has the following format:

```
version | --version | -V
```

unregister

Unregister an entry in the registry.

Remove a component from the Solaris Product Registry. The component corresponding to the *uuid* specified with the *-u* option must be a single instance. If it is not, the subcommand fails and returns the list of instances with the associated *uuid*. The subcommand must be reissued using either *-p* or *-i* to uniquely determine which component instance to unregister.

The unregister subcommand fails if there are components in the registry which depend on the component which is to be unregistered.

The unregister subcommand fails if the user does not have write access to the registry. See `wsreg_can_access_registry(3WSREG)`. The unregister subcommand fails if the user attempts to unregister a system component, instead of a component registered with the Solaris Product Registry. System components include those which include the attribute `PKG` and certain special Registry nodes including the following:

UUID	Name
=====	=====
root	System Registry
a01ee8dd-1dd1-11b2-a3f2-0800209a5b6b	Solaris System Software
8f64eabf-1dd2-11b2-a3f1-0800209a5b6b	Unclassified Software
b96ae9a9-1dd1-11b2-a3f2-0800209a5b6b	System Software Localizations
b1c43601-1dd1-11b2-a3f2-0800209a5b6b	Additional System Software
a8dcab4f-1dd1-11b2-a3f2-0800209a5b6b	Software Localizations

Before the unregister subcommand with the *-f* option is used, you should carefully review what components depend upon the component which is to be unregistered. The *-r* option is even more dangerous, since all children and software components depending upon the component are also deregistered. You can obtain the list of dependent components for a component with UUID *uuid* using :

```
prodreg info -u uuid -a "Dependent Components"
```

You can obtain a list of required components using:

```
prodreg info -u <uuid> -a "Required Components"
```

The output lists the name, UUID and instance of the component.

The `unregister` subcommand has the following format:

```
unregister [-R alt_root] [-fr] -u uuid [-p location | -i instance]
unregister --help
```

uninstall

Launch an uninstaller program.

Each component in the registry can have an uninstaller associated with it. This subcommand executes this associated installer, if there is one, for a component in the registry given by the `-u` option. If there is no uninstaller associated with the component, the subcommand fails. If the component given by the `-u` option is not unique (as there is more than one instance of the component installed), the subcommand outputs a list of all instances. The subcommand must then be reissued using `-i` or `-p` to disambiguate the `uuid` given with the `-u` option. Finally, if the component to uninstall is depended upon by other components, the command fails.

The command may also launch an uninstaller with a `-x` option. No checks for whether this uninstalls a component upon which other components depend in this case.

The `uninstall` command is not executed if the user does not have write access to the registry. See `wsreg_can_access_registry(3WSREG)`.

The `uninstall` command has the following format:

```
uninstall [-R alt_root] [-f] -u uuid -p location
uninstall [-R alt_root] -i instance [arguments ...]
uninstall --help
```

OPTIONS

The `awt` subcommand supports the following options:

- `--help` Display help text, do not launch the viewer.
 - `-R alt_root` Use the specified alternate root to locate the database to display with the GUI viewer.
- See OPERANDS for information regarding specification of *alt_root*.

The `browse` subcommand supports the following options:

- `-help` Display help text, do not execute the browse subcommand.
- `-i instance` Output the specified component instance.
- `-m name` Output the component instances associated with the name.
- `-n bnum` Output the component instances associated with the browse number.
- `-p location` Output the component instance installed in the specified location. The install location for a component can be obtained using the 'info' subcommand.

- R *alt_root* Use the specified alternate root to locate the database.
- u *uuid* Output the component instances associated with the *uuid*.

The `info` subcommand supports the following options:

- a *attr* Output only the attribute whose name is given by the operand '*attr*', instead of all attributes of the specified component.
- d Output only the attribute whose name is `isDamaged`, instead of all attributes of the specified component. If the value is set to `true`, this attribute indicates that the component in the registry
- help Output help text, do not execute the `browse` subcommand.
- i *instance* The instance operand distinguishes among multiple instances of components with the same *uuid* or browse number.
- m *name* The name operand indicates one or more components in the registry.
- n *bnum* Output the attributes of the component instance associated with the browse number *bnum*. If there is more than one instance, the command must be disambiguated using the `-i` or `-p` options.
- p *location* The install location indicated distinguishes among multiple instances of components with the same *uuid* or browse number.
- R *alt_root* Use the specified alternate root to locate the database.
- u *uuid* Output the attributes of the component instance associated with the *uuid*. If there is more than one instance, the subcommand must be disambiguated using the `-i` or `-p` options.

The `swing` subcommand supports the following options:

- help Output help text, do not execute the `install` subcommand.
- R *alt_root* Use the specified alternate root to locate the database.

The `uninstall` subcommand supports the following options:

- f Force the uninstall. A forced subcommand uninstalls all instances of a component, even if there are multiple ambiguous instances of the *uuid* operand.
- help Output help text, do not execute the `unregister` subcommand.
- i *instance* Disambiguate the *uuid* operand.
- p *location* Disambiguate the *uuid* operand. *location* corresponds to the where the software component was installed.
- R *alt_root* Use the specified alternate root to locate the database.

prodreg(1M)

	-u <i>uuid</i> Unregister the <i>uuid</i> component. If this component has been installed multiple times, the instance to unregister must be indicated unambiguously by using the -i or -p option. The <code>unregister</code> subcommand supports the following options: -f Force the unregistration. A forced subcommand unregisters a component even if there are other components which are dependent on this component. --help Output help text, do not execute the <code>unregister</code> subcommand. -i <i>instance</i> Disambiguate the <i>uuid</i> operand. -p <i>location</i> Disambiguate the <i>uuid</i> operand. The <i>location</i> corresponds to the where the software component was installed. -r Causes a recursive deregistration of a component as well as that component's children and dependencies. -R <i>alt_root</i> Use the specified alternate root to locate the database. -u <i>uuid</i> Unregister component <i>uuid</i> of the component to unregister. If this component has been installed multiple times, the instance to unregister must be indicated unambiguously by using the -i or -p option.
OPERANDS	The following operands are supported: <i>alt_root</i> Pathname to a file indicating an alternate root. The Solaris Product Registry database is located relative to the alternate root. If database relative to this location does not exist, it is created. <i>attr</i> Name of an attribute. This operand is used only with the <code>info</code> subcommand. If <i>attr</i> is associated with a component, the attribute name and value is displayed. <i>bnum</i> The browse number. Each component in the Solaris Product Registry is associated with a browse number. This number is generated for the convenience of an interactive user. The browse number can change if the system is rebooted or reinstalled. Do not store or use the browse number except to facilitate the <code>browse</code> and <code>info</code> subcommands. Browse numbers are always output by the <code>prodreg browse</code> subcommand. Only these values can be used as input values to the <code>browse</code> or <code>info</code> subcommand. <i>instance</i> Software can be installed in more than one location. The Solaris Product Registry associates a unique instance number for each. The <code>browse</code> subcommand shows the instance number associated

with each component in the registry. The instance operand is used to distinguish between installed, and possibly different, copies of software, when such exist.

<i>location</i>	A path to a specific file or directory in the file system. This operand indicates the installed location of registered software. For instance, if software is installed relative to <code>/usr/local</code> the value of this operand would be <code>/usr/local</code> . The install location is used to installer or to indicate the location of an installer or to diambiguate which instance is intended, of a software component which can have multiple instances.
<i>name</i>	Each software component in the Solaris Product Registry is associated with a name. This name is output by the <code>browse</code> subcommand. Some subcommands allow the user to input the software by name as an operand as a convenience. These names might not be unique. If the user supplies an ambiguous name, for which more than one components exist, the subcommand outputs a list of possible choices. The name can be localized; depending on the language setting the name can differ.
<i>uuid</i>	Each software component in the Solaris Product Registry is associated with a unique identifier. This identifier is a handle which accesses an entry in the registry database. The uuid corresponds to the componnet irrespective of how many instances of the component have been installed, and what the localized name of the component is.

EXAMPLES

EXAMPLE 1 Using the `prodreg` Command to Browse

Browsing is performed by means of the `prodreg browse` subcommand. Using these requests iteratively, one can peruse the tree, much as one would using a GUI by expanding components which are collections of other components. Browsing using browse numbers for convenience should be done only during this iterative browsing process, since the numbers are generated as a result of the browsing operation.

Evoking the `browse` subcommand without any arguments browses from the top of the registry. The output varies depending on the software installed on a particular system.

```
$ prodreg browse
BROWSE # +/-/.  UUID                                     #  NAME
===== =====
1          -      root                                     1  System
                                           Registry
2          +      a01ee8dd-1dd1-11b2-a3f2-0800209a5b6b  1  Solaris 9
                                           System
                                           Software
3          +      8f64eabf-1dd2-11b2-a3f1-0800209a5b6b  1  Unclassified
                                           Software
```

EXAMPLE 1 Using the prodreg Command to Browse (Continued)

The output of this command lists the browse number, UUID, instance number and name of the root component and its children. The ancestors of a component, each parent up to the root, are also shown. The +/-. column indicates whether the component in the tree is an expanded parent (-), a child with children (+) or a child without children (.).

EXAMPLE 2 Requesting Information About the Components in a Tree

The UUID, name and browse number fields can be used to request browsing information about components in the tree. The next example shows how a component can be browsed by UUID.

```
$ prodreg browse -u a01ee8dd-1dd1-11b2-a3f2-0800209a5b6b
BROWSE #  +/-.  UUID                                     #  NAME
=====  =====
1          -    root                                     1  System
                                           Registry
2          -    a01ee8dd-1dd1-11b2-a3f2-0800209a5b6b  1  Solaris 9
                                           System
                                           Software
4          +    b96ae9a9-1dd1-11b2-a3f2-0800209a5b6b  1  System
                                           Software
                                           Localizations
5          +    SUNWCall                                1  Entire
                                           Distribution
```

EXAMPLE 3 Browsing a Node by Name

The following example shows how a node can be browsed by name.

```
$ prodreg browse -m "System Software Localizations"
BROWSE #  +/-.  UUID                                     #  NAME
=====  =====
1          -    root                                     1  System
                                           Registry
2          -    a01ee8dd-1dd1-11b2-a3f2-0800209a5b6b  1  Solaris 9
                                           System
                                           Software
4          -    b96ae9a9-1dd1-11b2-a3f2-0800209a5b6b  1  System
                                           Software
                                           Localizations
316        .    SUNWceuw                                1  Central
                                           Europe OW
                                           Support
317        .    SUNWcsfw                                1  Simplified
                                           Chinese
                                           freeware
                                           message
318        .    SUNWceux                                1  Central
                                           Europe
                                           64-bit OS
```

EXAMPLE 3 Browsing a Node by Name (Continued)

Support

EXAMPLE 4 Browsing Iteratively

Additional output has been omitted. As a convenience, the browse number can be used for iterative browsing. This number should not be stored, as it differs depending on which system the prodreg command is run on, which user is running the command, and the log in session in which the command is run.

```
$ prodreg browse -n 3
```

BROWSE #	+/-/.	UUID	#	NAME
1	-	root	1	System Registry
2	-	a01ee8dd-1dd1-11b2-a3f2-0800209a5b6b	1	Solaris 9 System Software
5	-	SUNWCall	1	Entire Software Distribution
6	.	SUNWrsmo	1	RSMPI Operations Registration Module
7	+	SUNWCjvx	1	JavaVM (64-bit)
8	.	SUNWrsmx	1	Remote Shared Memory (64-bit)
9	+	SUNWCacc	1	System Accounting

EXAMPLE 5 Browsing Using an Ambiguous Value

If the requested value is ambiguous, the list of ambiguous instances are displayed. In the following example, there are two distinct software components with the same name.

```
$ ./prodreg browse -m JavaVM
```

The request failed because multiple components correspond to the criteria given. Use the list of possible components given below, select one and try again.

BROWSE #	+/-/.	UUID	#	NAME
12	.	org.spybeam.javavm	1	JavaVM
51	.	SUNWCjv	1	JavaVM

Issue one of the following requests again:

EXAMPLE 5 Browsing Using an Ambiguous Value (Continued)

```
$ prodreg browse -u SUNWCjv
```

or

```
$ prodreg browse -u org.spybeam.javavm
```

EXAMPLE 6 Browsing Multiple Installations of Software

Another possible ambiguous response arises when a particular software component is installed multiple times. In the example below Example software is registered three times.

```
$ prodreg browse -m Example
```

The request failed because multiple components correspond to the criteria given. Use the list of possible components given below, select one and try again.

BROWSE #	+/-/. UUID	#	NAME
7	. org.spybeam.example	2	Example
7	. org.spybeam.example	3	Example
7	. org.spybeam.example	1	Example

The component requested could not be found.

EXAMPLE 7 Browsing Using a Particular Instance

The request can be repeated specifying a particular instance to disambiguate it. It is also possible to disambiguate a request with the `-p` option, followed by the install location. In this case, to browse the first instance of the Example software, one would use the command:

```
$ prodreg browse -u org.spybeam.example -i 1
```

EXAMPLE 8 Using the `info` Subcommand

The install location, as well as other attributes of a component can be obtained with the `info` subcommand. The `info` subcommand accepts the same disambiguating options and returns all the attributes of a component, each on a single line.

```
$ prodreg info -m Example
```

The request failed because multiple components correspond to the criteria given. Use the list of possible components given below, select one and try again.

BROWSE #	+/-/. UUID	#	NAME
7	. org.spybeam.example	2	Example
7	. org.spybeam.example	3	Example
7	. org.spybeam.example	1	Example

The component requested could not be found.

EXAMPLE 8 Using the info Subcommand (Continued)

This variation of the info subcommand outputs all information associated with instance 1 of the Example component. The output from this variation is not displayed

```
$ prodreg info -u org.spybeam.example -i 1
```

EXAMPLE 9 Obtaining Information on the Install Location

You can use the info subcommand to obtain the install location and other attributes of a component. The info subcommand accepts the same disambiguating options as the browse subcommand. It returns all the attributes of a component, each on a single line. You can also request a single attribute.

The following command outputs the value of the install location attribute:

```
$ prodreg info -n 23 -a Location
```

EXAMPLE 10 Identifying and Unregistering Damaged Software

Removing installed software without using the associated uninstaller can damage the software in the registry. A damaged component indicates that certain software is installed, when in fact it is not present. A component can be damaged by removing files or packages directly, without running the associated uninstaller. The general rule to follow is: If software has been installed by an installer program, it should be uninstalled using the supplied uninstaller program.

This example shows how to identify and repair damaged software components so that software can be reinstalled.

Browsing for Examplesoft, produces the following:

```
$ prodreg browse -m Examplesoft
BROWSE # +/-/.  UUID                                     #  NAME
=====
1      -      root                                     1  System
                                           Registry
2      +      a01ee8dd-1dd1-11b2-a3f2-0800209a5b6b  1  Solaris 9
                                           System
                                           Software
3      +      8f64eabf-1dd2-11b2-a3f1-0800209a5b6b  1  Unclassified
                                           Software
4      -      95842091-725a-8501-ef29-0472985982be  1  ExampleSoft
233    .      90209809-9785-b89e-c821-0472985982be  1  Example Doc
234    .      EXSOzzt                                   1
235    .      EXSOblob                                  1  Example Data
```

The Examplesoft child EXSOzzt, representing a package component of registered software does not display its name. This is likely to be because the software Examplesoft is damaged. Verify this with the following command:

```
$ prodreg info -u 95842091-725a-8501-ef29-0472985982be \
-i 1 -d
```

EXAMPLE 10 Identifying and Unregistering Damaged Software (Continued)

```
isDamaged=TRUE
```

Since Damaged is TRUE, some part of Examplesoft is damaged. The following command lists the packages which make up Examplesoft:

```
$ prodreg info \
    -u 95842091-725a-8501-ef29-0472985982be\
    -i 1 -a PKGS pkgs:
EXSOzzt EXSOblob
```

Use the pkginfo command to verify if EXSO is installed:

```
$ pkginfo EXSOzzt
ERROR: information for "EXSOzzt" was not found
$ pkginfo EXSOblob
application EXSOblob      Example Data
```

The output of these commands shows that the package EXSOzzt has been removed, probably with the pkgrm command. The Examplesoft software will probably not function. To repair the software, one should run the uninstaller registered with Examplesoft. You probably need to run the uninstaller with root permissions, as it unregisters the software and runs pkgrm commands. Both of these operations require root permissions.

```
# prodreg uninstall -u 95842091-725a-8501-ef29-0472985982be -i 1
The install program requested could not be found.
```

Something is wrong, or else you would be able to access uninstall program to uninstall the software.. One possibility is that the uninstaller program has been removed manually. It is possible to determine where the uninstaller is located by requesting the uninstallprogram attribute:

```
$ prodreg info -m ExampleSoft -a uninstallprogram
uninstallprogram: /usr/bin/java -mx64m -classpath
/var/sadm/prod/org.example.ExampleSoft/987573587 uninstall_ExampleSoft
```

Check to see if there is an uninstaller in the registered location.

```
# ls /var/sadm/prod/org.example.ExampleSoft/987573587
/var/sadm/prod/org.example.ExampleSoft/987573587:
No such file or directory
```

Since there is no uninstaller at the desired location, you have two options. One is to load the uninstaller from back up storage and run it manually. Use the command line stored in the registry:

```
# /usr/bin/java -mx64m -classpath \
    /var/sadm/prod/org.example.ExampleSoft/987573587 \
    uninstall_ExampleSoft
```

If there is no other possibility, manually unregister the software.

```
# prodreg unregister -u 95842091-725a-8501-ef29-0472985982be -i 1
```

This does not remove the remaining package EXSOblob. You must do this manually.

```
# pkgrm EXSOblob
```

EXAMPLE 10 Identifying and Unregistering Damaged Software (Continued)**EXAMPLE 11** Removing Multiple Components

Component A has children B and C, and C has children D and E, and the you wish to remove all of the components at once. This is useful if the whole hierarchy has to be reinstalled and the uninstaller has been lost or cannot be run

```
$ prodreg browse -u UUID-of-C
BROWSE # +/-/. UUID # NAME
=====
1 - root 1 System
Registry
2 + a01ee8dd-1dd1-11b2-a3f2-0800209a5b6b 1 Solaris 9
System
Software
3 + 8f64eabf-1dd2-11b2-a3f1-0800209a5b6b 1 Unclassified
Software
1423 - UUID-of-A 1 Example A
1436 . UUID-of-B 1 Example B
1437 - UUID-of-C 1 Example C
1462 . UUID-of-D 1 Example D
1463 . UUID-of-E 1 Example E

# prodreg uninstall -u UUID-of-A -i 1
```

The `uninstall` subcommand can fail various ways, for example if the java classes have been removed, if the user has insufficient permissions or if Java software is not present on the system. The recursive unregistration subcommand is very powerful and dangerous. Not only does it unregister every child of a component, it also unregisters every component which depends upon the component to unregister. It is a good idea to view all information about the component to determine if any components will be unintentionally unregistered with `UUID-of-A`.

```
$ prodreg info -u UUID-of-A
Title: Example A Software
Version: 5.8.0.2001.11.02
Location: /usr
Vendor: Example Vendor
uninstallprogram: /usr/bin/java -mx64m -classpath
/var/sadm/prod/org.example.ExampleA/90820965 uninstall_ExampleA
vendorurl: http://www.example.org
description: Example A Software has many uses
Supported Languages: en
```

```
Child Components:
Name UUID #
-----
Example B UUID-of-B 1
Example C UUID-of-C 1

Required Components:
Name UUID #
-----
Example B UUID-of-B 1
```

EXAMPLE 11 Removing Multiple Components *(Continued)*

Example C	UUID-of-C	1

No software depends on Example A, or else an additional field, `Dependent Components` would be shown. To further ensure that there are no surprises, one should examine the dependent components and children of `UUID-of-B` and `UUID-of-C`, all the components which depend on `UUID-of-B`, `UUID-of-C` and their children, and so on.

If you examine the browse tree, you know the entire list of descendents of `UUID-of-A`. You can also examine the dependent component attributes of all of Example A's descendents.

```
$ prodreg info -u UUID-of-B -i 1 -a "Dependent Components"
Dependent Components:
Name                               UUID                               #
-----
Example A                          UUID-of-A                          1

$ prodreg info -u UUID-of-C -i 1 -a "Dependent Components"
Dependent Components:
Name                               UUID                               #
-----
Example A                          UUID-of-A                          1

$ prodreg info -u UUID-of-D -i 1 -a "Dependent Components"
Dependent Components:
Name                               UUID                               #
-----
Example C                          UUID-of-C                          1

$ prodreg info -u UUID-of-E -i 1 -a "Dependent Components"
Dependent Components:
Name                               UUID                               #
-----
Example C                          UUID-of-C                          1
```

A recursive unregistration of Example A only results in unregistering Example A and its descendents, as intended.

```
# prodreg unregister -r -u UUID-of-A -i 1
```

EXAMPLE 12 Reinstalling a Damaged Component

In this example, there is a component, `Software ZZZ` which is depended upon by other software. `Software ZZZ` has been damaged and you need to reinstall it. The reinstallation is impossible until `Software ZZZ` is unregistered.

First, you check what depends upon `Software ZZZ`:

```
$ prodreg info -m "Software ZZZ" -a "Dependent Components"
Dependent Components:
```

EXAMPLE 12 Reinstalling a Damaged Component *(Continued)*

Name	UUID	#
-----	-----	-
Software Foobar	d9723500-9823-1432-810c-0100e09832ff	1

Normally, you would have to uninstall Software Foobar before unregistering Software ZZZ, since Software Foobar depends on Software ZZZ. You decide that it is impossible or unreasonable to reinstall Software Foobar. Performing a recursive unregister of Software ZZZ is not an option as it would unregister Software Foobar as well. Instead you can do a forced unregister of Software ZZZ. The UUID of Software ZZZ is 90843fb1-9874-3a20-9b88-984b32098432.

```
# prodreg unregister -f -u 90843fb1-9874-3a20-9b88-984b32098432 -i 1
```

You can then reinstall Software ZZZ:

```
# /usr/bin/java -cp /usr/installers/org.example.softwarezzz
```

BUGS

The registry can become out of date because of software being manually removed, or removed using `pkgrm(1M)` directly. To avoid damaging the registry, use `uninstall programs` to remove software which was initially installed using an install program.

**ENVIRONMENT
VARIABLES**

The following environment variable affects the execution of `prodreg`:

<code>PKG_INSTALL_ROOT</code>	If present, defines the full path name of a directory to use as the system's <code>PKG_INSTALL_ROOT</code> path. All product and package information files are then looked for in the directory tree, starting with the specified <code>PKG_INSTALL_ROOT</code> path. If not present, the default system path of <code>/</code> is used.

EXIT STATUS

The following exit values are returned:

0	Successful completion.
>0	An error occurred.

ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWwsr2, SUNWwsrv
Interface Stability	Evolving

Application Packaging Developer's Guide

prodreg(1M)

NOTES	The prodreg GUI and command line interface view both the Solaris Product Registry and the package database. Both look like components in the registry, but some of these cannot be unregistered or uninstalled. Packages do not have an associated uninstaller, so they cannot be uninstalled using the <code>prodreg uninstall</code> subcommand. Solaris packages cannot be unregistered using the <code>prodreg unregister</code> subcommand. Packages are removed using the <code>pkgrm(1M)</code> command, after which time the packages do not appear in the GUI or CLI prodreg viewer. It is preferable to remove software using the uninstaller associated with the software installed than to remove individual packages using <code>pkgrm(1M)</code>, since the uninstaller software takes care of comprehensive removal of all resources associated with the installed software, including unregistering information in Registry and removing the appropriate packages. The <code>prodreg uninstall</code> subcommand launches an external program. The command line conventions of these programs have to be used to indicate the alternate root for the product registry. Another possibility is to use the <code>PKG_INSTALL_ROOT</code> environment variable for this purpose as the install program is executed in the same environment as prodreg. Uninstall programs are frequently java classes which require Java to be installed. If Java software has been removed or is missing from a Solaris distribution, it is impossible to run java based uninstallers. Only the <code>prodreg unregister</code> and <code>uninstall</code> subcommands can only be run with root permissions. This is because they modify the product registry in the case of <code>unregister</code>, and remove packages in the case of <code>uninstall</code>. The other operations merely read the registry and can be run with any user permissions. The <code>prodreg uninstall</code> subcommand might require root permissions as well, as installers can execute commands such as <code>pkgadd(1M)</code> or <code>pkgrm(1M)</code> which require root permissions to run. Attributes associated with components are documented in various places -primarily in the <i>Application Packaging Developer's Guide</i>. The attributes associated with the Solaris Product Registry itself are described in the following glossary. Dependent Components List of components upon which the component depends. Location The location relative to which software was installed. pkgs List of packages which correspond to the component. These packages are added with <code>pkgadd</code> after the component is registered. They are removed with <code>pkgrm</code> before the component is unregistered. Required Components List of components on which the component depends. Source Media from which the install was done. Supported Languages List of locales for which there are registered titles.

Title

Name given by the `prodreg browse` subcommand. This name can be localized to the locale in which the shell is running.

Unique Name

Name used by previous versions of the Solaris Product Registry. This value is often set to the package name corresponding to a given component in the registry.

Vendor

Vendor who produced the component.

Version

Version string associated with the component.

The Registry can contain components which do not correspond to software actually installed on the system. This can be detected several ways. The easiest is to check using the `info` subcommand if a component is damaged. Another way is to determine where software was installed using the `info` subcommand, and verify it is still there.

projadd(1M)

NAME	projadd – administer a new project on the system
SYNOPSIS	projadd [-c <i>comment</i>] [-U <i>user</i> [, <i>user</i> ...]] [-G <i>group</i> [, <i>group</i> ...]] [-p <i>projid</i> [<i>projid</i> ...]] <i>project</i>
DESCRIPTION	projadd adds a new project entry to the /etc/project file. If the files backend is being used for the project database, the new project is available for use immediately upon the completion of the projadd command.
OPTIONS	The following options are supported: -c <i>comment</i> Add a project comment. Comments are stored in the project's entry in the /etc/project file. Generally, comments contain a short description of the project and are used as the field for the project's full name. - Specify <i>comment</i> as a text string. <i>comment</i> cannot contain a colon (:) or NEWLINE. -G <i>group</i> Make <i>group</i> a member group of project. - Specify <i>group</i> as a group ID or name. -o Enable duplication of a project ID. -p <i>projid</i> Set the project ID of the new project. - Specify <i>projid</i> as a non-negative decimal integer below UID_MAX as defined in limits.h. <i>projid</i> defaults to the next available unique number above the highest number currently assigned. For example, if <i>projids</i> 100, 105, and 200 are assigned, the next default <i>projid</i> is 201. <i>projids</i> between 0-99 are reserved by SunOS. -U Add the existing users (as specified either by user ID or name), to member users of project.
OPERANDS	The following operands are supported: <i>project</i> The name of the project to create. The <i>project</i> operand is a string consisting of characters from the set of alphabetic characters, numeric characters, underline (_), and hyphen (-). The period ('.') is reserved for projects with special meaning to the operating system. The first character of the project name must be a letter. A warning message is displayed if these restrictions are not met.
EXIT STATUS	The following exit values are returned: 0 Successful completion. 2 The command syntax was invalid. A usage message for projadd is displayed. 3 An invalid argument was provided to an option.

- 4 The *projid* given with the *-p* option is already in use.
- 5 The project files contain an error. See *project*(4).
- 6 The project to be modified, group, or user does not exist.
- 9 The project is already in use.
- 10 Cannot update the */etc/project* file.

FILES */etc/project* System project file

ATTRIBUTES See *attributes*(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWesu

SEE ALSO *projects*(1), *groupadd*(1M), *groupdel*(1M), *groupmod*(1M), *grpchk*(1M), *projdel*(1M), *projmod*(1M), *useradd*(1M), *userdel*(1M), *usermod*(1M), *project*(4), *attributes*(5)

NOTES In case of an error, *projadd* prints an error message and exits with a non-zero status.

projadd adds a project definition only on the local system. If a network name service such as NIS or LDAP is being used to supplement the local */etc/project* file with additional entries, *projadd* cannot change information supplied by the network name service.

projdel(1M)

NAME	projdel – delete a project from the system				
SYNOPSIS	projdel <i>project</i>				
DESCRIPTION	The projdel utility deletes a project from the system and makes the appropriate changes to the system file.				
OPERANDS	The following operands are supported: <i>project</i> The name of the project to be deleted.				
EXIT STATUS	The following exit values are returned: 0 Successful completion. 2 The command syntax was invalid. A usage message for projdel is displayed. 3 An invalid argument was provided to an option. 4 The <i>projid</i> given with the -p option is already in use. 5 The project files contain an error. See project(4) . 6 The project to be modified, group, or user does not exist. 9 The project is already in use. 10 Cannot update the /etc/project file.				
FILES	/etc/project System project file				
ATTRIBUTES	See attributes(5) for descriptions of the following attributes: <table><thead><tr><th>ATTRIBUTE TYPE</th><th>ATTRIBUTE VALUE</th></tr></thead><tbody><tr><td>Availability</td><td>SUNWesu</td></tr></tbody></table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	Availability	SUNWesu
ATTRIBUTE TYPE	ATTRIBUTE VALUE				
Availability	SUNWesu				
SEE ALSO	projects(1) , groupadd(1M) , groupdel(1M) , groupmod(1M) , grpchk(1M) , logins(1M) , projadd(1M) , projmod(1M) , useradd(1M) , userdel(1M) , usermod(1M) , project(4) , attributes(5)				
DIAGNOSTICS	In case of an error, projdel prints an error message and exits with a non-zero status.				
NOTES	projdel deletes a project definition only on the local system. If a network name service such as NIS or LDAP is being used to supplement the local /etc/project file with additional entries, projdel cannot change information supplied by the network name service.				

NAME	projmod – modify a project’s information on the system
SYNOPSIS	projmod [-p <i>projid</i> [-o] [-a -r]] [-U <i>user</i> [, <i>user</i> ...]] [-G <i>group</i> [, <i>group</i> ...]] [-c <i>comment</i>] [-l <i>new_projectname</i>] <i>project</i>
DESCRIPTION	The projmod utility modifies a project’s definition on the system. projmod changes the definition of the specified project and makes the appropriate project-related system file and file system changes.
OPTIONS	The following options are supported: -c <i>comment</i> Specify <i>comment</i> as a text string. Generally, <i>comment</i> contains a short description of the project. This information is stored in the project’s <code>/etc/project</code> entry. -G <i>group</i> [,<i>group</i>...] Specify a replacement list of member groups of the project, or with -a or -r, a list of groups to be added or removed from the project. -l <i>new_projectname</i> Specify the new project name for the project. The <i>new_projectname</i> argument is a string consisting of characters from the set of alphabetic characters, numeric characters, period (.), underline (_), and hyphen (-). The first character should be alphabetic. A warning message is written if these restrictions are not met. -o This option allows the specified project ID to be duplicated (non-unique). -a This option specifies that the users or groups specified by the -U or -G flags should be added to the project, rather than replacing the existing member list. -r This option specifies that the users or groups specified by the -U or -G flags should be removed from the project, rather than replacing the existing member list. -p <i>projid</i> Specify a new project ID for the project. It must be a non-negative decimal integer less than MAXUID as defined in <code>param.h</code>. -U <i>user</i> [,<i>user</i>...] Specify a replacement list of member users of the project, or with -a or -r, a list of users to be added or removed from the project.
OPERANDS	The following operands are supported: <i>project</i> An existing project name to be modified.
EXIT STATUS	In case of an error, projmod prints an error message and exits with one of the following values:

projmod(1M)

The following exit values are returned:

0	Successful completion.
2	The command syntax was invalid. A usage message for projmod is displayed.
3	An invalid argument was provided to an option.
4	The <i>projid</i> given with the <i>-p</i> option is already in use.
5	The project files contain an error. See <i>project(4)</i> .
6	The project to be modified, group, or user does not exist.
9	The project is already in use.
10	Cannot update the <i>/etc/project</i> file.

FILES	<i>/etc/group</i>	System file containing group definitions
	<i>/etc/project</i>	System project file
	<i>/etc/passwd</i>	System password file
	<i>/etc/shadow</i>	System file containing users' encrypted passwords and related information

ATTRIBUTES See *attributes(5)* for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWesu

SEE ALSO *groupadd(1M)*, *groupdel(1M)*, *groupmod(1M)*, *projadd(1M)*, *projdel(1M)*, *useradd(1M)*, *userdel(1M)*, *usermod(1M)*, *passwd(4)*, *project(4)*, *attributes(5)*

NOTES The *projmod* utility modifies project definitions only in the local */etc/project* file. If a network name service such as NIS or LDAP is being used to supplement the local files with additional entries, *projmod* cannot change information supplied by the network name service. However *projmod* verifies the uniqueness of project name and project ID against the external name service.

NAME	prstat – report active process statistics
SYNOPSIS	prstat [-acJLmRtTv] [-C <i>psrsetlist</i>] [-j <i>projlist</i>] [-k <i>tasklist</i>] [-n <i>ntop</i> [, <i>nbottom</i>]] [-p <i>pidlist</i>] [-P <i>cpulist</i>] [-s <i>key</i> -S <i>key</i>] [-u <i>euidlist</i>] [-U <i>uidlist</i>] [<i>interval</i> [<i>count</i>]]
DESCRIPTION	The prstat utility iteratively examines all active processes on the system and reports statistics based on the selected output mode and sort order. prstat provides options to examine only processes matching specified PIDs, UIDs, CPU IDs, and processor set IDs. The -j, -k, -C, -p, -P, -u, and -U options accept lists as arguments. Items in a list can be either separated by commas or enclosed in quotes and separated by commas or spaces. If you do not specify an option, prstat examines all processes and reports statistics sorted by CPU usage.
OPTIONS	The following options are supported: -a Report information about processes and users. In this mode prstat displays separate reports about processes and users at the same time. -c Print new reports below previous reports instead of overprinting them. -C <i>psrsetlist</i> Report only processes or lwps that are bound to processor sets in the given list. Each processor set is identified by an integer as reported by psrset(1M). The load averages displayed are the sum of the load averages of the specified processor sets (see pset_getloadavg(3C)). -j <i>projlist</i> Report only processes or lwps whose project ID is in the given list. Each project ID can be specified as either a project name or a numerical project ID. See project(4). -J Report information about processes and projects. In this mode prstat displays separate reports about processes and projects at the same time. -k <i>tasklist</i> Report only processes or lwps whose task ID is in <i>tasklist</i>. -L Report statistics for each light-weight process (LWP). By default, prstat reports only the number of LWPs for each process. -m Report microstate process accounting information. In addition to all fields listed in -v mode, this mode also

prstat(1M)

	includes the percentage of time the process has spent processing system traps, text page faults, data page faults, waiting for user locks and waiting for CPU (latency time).
<code>-n ntop[,nbottom]</code>	Restrict number of output lines. The <i>ntop</i> argument determines how many lines of process or lwp statistics are reported, and the <i>nbottom</i> argument determines how many lines of user, task, or projects statistics are reported if the <code>-a</code> , <code>-t</code> , <code>-T</code> , or <code>-J</code> options are specified. By default, <code>prstat</code> displays as many lines of output that fit in a window or terminal. When you specify the <code>-c</code> option or direct the output to a file, the default values for <i>ntop</i> and <i>nbottom</i> are 15 and 5.
<code>-p pidlist</code>	Report only processes whose process ID is in the given list.
<code>-P cpulist</code>	Report only processes or lwps which have most recently executed on a CPU in the given list. Each CPU is identified by an integer as reported by <code>psrinfo(1M)</code> .
<code>-R</code>	Put <code>prstat</code> in the real time scheduling class. When this option is used, <code>prstat</code> is given priority over time-sharing and interactive processes. This option is available only for superuser.
<code>-s key</code>	Sort output lines (that is, processes, lwps, or users) by <i>key</i> in descending order. Only one <i>key</i> can be used as an argument. There are five possible key values: <code>cpu</code> Sort by process CPU usage. This is the default. <code>pri</code> Sort by process priority. <code>rss</code> Sort by resident set size. <code>size</code> Sort by size of process image. <code>time</code> Sort by process execution time.
<code>-S key</code>	Sort output lines by <i>key</i> in ascending order. Possible <i>key</i> values are the same as for the <code>-s</code> option. See <code>-s</code> .

	-t	Report total usage summary for each user. The summary includes the total number of processes or LWPs owned by the user, total size of process images, total resident set size, total cpu time, and percentages of recent cpu time and system memory.
	-T	Report information about processes and tasks. In this mode <code>prstat</code> displays separate reports about processes and tasks at the same time.
	-u <i>euidlist</i>	Report only processes whose effective user ID is in the given list. Each user ID may be specified as either a login name or a numerical user ID.
	-U <i>uidlist</i>	Report only processes whose real user ID is in the given list. Each user ID may be specified as either a login name or a numerical user ID.
	-v	Report verbose process usage. This output format includes the percentage of time the process has spent in user mode, in system mode, and sleeping. It also includes the number of voluntary and involuntary context switches, system calls and the number of signals received. Statistics that are not reported are marked with the - sign.
OUTPUT	The following list defines the column headings and the meanings of a <code>prstat</code> report:	
	PID	The process ID of the process.
	USERNAME	The real user (login) name or real user ID.
	SIZE	The total virtual memory size of the process, including all mapped files and devices, in kilobytes (K), megabytes (M), or gigabytes (G). The resident set size of the process (RSS), in kilobytes (K), megabytes (M), or gigabytes (G).
	STATE	The state of the process: cpuN Process is running on CPU N. sleep Sleeping: process is waiting for an event to complete. run Runnable: process in on run queue. zombie Zombie state: process terminated and parent not waiting.

prstat(1M)

	stop Process is stopped.
PRI	The priority of the process. Larger numbers mean higher priority.
NICE	Nice value used in priority computation. Only processes in certain scheduling classes have a nice value.
TIME	The cumulative execution time for the process.
CPU	The percentage of recent CPU time used by the process.
PROCESS	The name of the process (name of executed file).
LWPID	The lwp ID of the lwp being reported.
NLWP	The number of lwps in the process.
The following columns are displayed when the -v or -m option is specified	
USR	The percentage of time the process has spent in user mode.
SYS	The percentage of time the process has spent in system mode.
TRP	The percentage of time the process has spent in processing system traps.
TFL	The percentage of time the process has spent processing text page faults.
DFL	The percentage of time the process has spent processing data page faults.
LCK	The percentage of time the process has spent waiting for user locks.
SLP	The percentage of time the process has spent sleeping.
LAT	The percentage of time the process has spent waiting for CPU.
VCX	The number of voluntary context switches.
ICX	The number of involuntary context switches.
SCL	The number of system calls.
SIG	The number of signals received.
Under the -l option, one line is printed for each lwp in the process and some reporting fields show the values for the lwp, not the process.	
OPERANDS	The following operands are supported:

prstat(1M)

count Specifies the number of times that the statistics are repeated. By default, prstat reports statistics until a termination signal is received.

interval Specifies the sampling interval in seconds; the default interval is 5 seconds.

EXAMPLES

EXAMPLE 1 Reporting the Five Most Active Super-User Processes

The following command reports the five most active super-user processes running on CPU1 and CPU2:

```
example% prstat -u root -n 5 -P 1,2 1 1
```

PID	USERNAME	SIZE	RSS	STATE	PRI	NICE	TIME	CPU	PROCESS/LWP
306	root	3024K	1448K	sleep	58	0	0:00.00	0.3%	sendmail/1
102	root	1600K	592K	sleep	59	0	0:00.00	0.1%	in.rdisc/1
250	root	1000K	552K	sleep	58	0	0:00.00	0.0%	utmpd/1
288	root	1720K	1032K	sleep	58	0	0:00.00	0.0%	sac/1
1	root	744K	168K	sleep	58	0	0:00.00	0.0%	init/1
TOTAL: 25, load averages: 0.05, 0.08, 0.12									

EXAMPLE 2 Displaying Verbose Process Usage Information

The following command displays verbose process usage information about processes with lowest resident set sizes owned by users root and john.

```
example% prstat -S rss -n 5 -vc -u root,john
```

PID	USERNAME	USR	SYS	TRP	TFL	DFL	LCK	SLP	LAT	VCX	ICX	SCL	SIG	PROCESS/LWP
1	root	0.0	0.0	-	-	-	-	100	-	0	0	0	0	init/1
102	root	0.0	0.0	-	-	-	-	100	-	0	0	3	0	in.rdisc/1
250	root	0.0	0.0	-	-	-	-	100	-	0	0	0	0	utmpd/1
1185	john	0.0	0.0	-	-	-	-	100	-	0	0	0	0	csh/1
240	root	0.0	0.0	-	-	-	-	100	-	0	0	0	0	powerd/4
TOTAL: 71, load averages: 0.02, 0.04, 0.08														

EXIT STATUS

The following exit values are returned:

0 Successful completion.

1 An error occurred.

ATTRIBUTES

See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

prstat(1M)

SEE ALSO `proc(1)`, `psrinfo(1M)`, `psrset(1M)`, `sar(1M)`, `pset_getloadavg(3C)`, `proc(4)`, `project(4)`, `attributes(5)`

NOTES The snapshot of system usage displayed by `prstat` is true only for a split-second, and it may not be accurate by the time it is displayed. When the `-m` option is specified, `prstat` tries to turn on microstate accounting for each process; the original state is restored when `prstat` exits. See `proc(4)` for additional information about the microstate accounting facility.

NAME	prtconf – print system configuration
SYNOPSIS	
SPARC	<code>/usr/sbin/prtconf [-V] [-F] [-x] [-vpPD]</code>
x86	<code>/usr/sbin/prtconf [-V] [-x] [-vpPD]</code>
DESCRIPTION	The <code>prtconf</code> command prints the system configuration information. The output includes the total amount of memory, and the configuration of system peripherals formatted as a device tree.
OPTIONS	The following options are supported: -D For each system peripheral in the device tree, displays the name of the device driver used to manage the peripheral. -F Returns the device path name of the console frame buffer, if one exists. If there is no frame buffer, <code>prtconf</code> returns a non-zero exit code. This flag must be used by itself. It returns only the name of the console, frame buffer device or a non-zero exit code. For example, if the console frame buffer on a SPARCstation 1 is <code>cgthree</code> in SBus slot #3, the command returns: <code>/sbus@1, f80000000/cgthree@3, 0</code>. This option could be used to create a symlink for <code>/dev/fb</code> to the actual console device. -p Displays information derived from the device tree provided by the firmware (PROM) on SPARC platforms or the booting system on x86 platforms. The device tree information displayed using this option is a snapshot of the initial configuration and may not accurately reflect reconfiguration events that occur later. -P Includes information about pseudo devices. By default, information regarding pseudo devices is omitted. -v Specifies verbose mode. -V Displays platform-dependent PROM (on SPARC platforms) or booting system (on x86 platforms) version information. This flag must be used by itself. The output is a string. The format of the string is arbitrary and platform-dependent. -x Reports if the firmware on this system is 64-bit ready. Some existing platforms may need a firmware upgrade in order to run the 64-bit kernel. If the operation is not applicable to this platform or the firmware is already 64-bit ready, it exits silently with a return code of zero. If the operation is applicable to this platform and the firmware is not 64-bit ready, it displays a descriptive message on the standard output and exits with a non-zero return code. The hardware platform documentation contains more information about the platforms that may need a firmware upgrade in order to run the 64-bit kernel. This flag overrides all other flags and must be used by itself.

prtconf(1M)

EXIT STATUS The following exit values are returned:

0	No error occurred.
non-zero	With the -F option (SPARC only), a non-zero return value means that the output device is not a frame buffer. With the -x option, a non-zero return value means that the firmware is not 64-bit ready. In all other cases, a non-zero return value means that an error occurred.

ATTRIBUTES See attributes(5) for descriptions of the following attributes:

Sun Hardware Platform Guide

SPARC Only openprom(7D)

NOTES The output of the `prtconf` command is highly dependent on the version of the PROM installed in the system. The output will be affected in potentially all circumstances.

The `driver not attached` message means that no driver is currently attached to that instance of the device. In general, drivers are loaded and installed (and attached to hardware instances) on demand, and when needed, and may be uninstalled and unloaded when the device is not in use.

NAME	prtdiag – display system diagnostic information				
SYNOPSIS	<code>/usr/platform/platform-name/sbin/prtdiag [-v] [-l]</code>				
DESCRIPTION	prtdiag displays system configuration and diagnostic information on sun4u systems. The diagnostic information lists any failed field replaceable units (FRUs) in the system. The interface, output, and location in the directory hierarchy for prtdiag are uncommitted and subject to change in future releases. <i>platform-name</i> is the name of the platform implementation and can be found using the <code>-i</code> option of <code>uname(1)</code>. Note – prtdiag does not display diagnostic information and environmental status when executed on the Sun Enterprise 10000 server. See the <code>/var/opt/SUNWssp/adm/\${SUNW_HOSTNAME}/messages</code> file on the system service processor (SSP) to obtain such information for this server.				
OPTIONS	The following options are supported: -l Log output. If failures or errors exist in the system, output this information to <code>syslogd(1M)</code> only. -v Verbose mode. Displays the time of the most recent AC Power failure, and the most recent hardware fatal error information, and (if applicable) environmental status. The hardware fatal error information is useful to repair and manufacturing for detailed diagnostics of FRUs.				
EXIT STATUS	The following exit values are returned: 0 No failures or errors are detected in the system. 1 Failures or errors are detected in the system. 2 An internal prtdiag error occurred, for example, out of memory.				
ATTRIBUTES	See <code>attributes(5)</code> for descriptions of the following attributes: <table border="1"> <thead> <tr> <th>ATTRIBUTE TYPE</th><th>ATTRIBUTE VALUE</th></tr> </thead> <tbody> <tr> <td>Availability</td><td>SUNWkvm</td></tr> </tbody> </table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	Availability	SUNWkvm

prtfru(1M)

NAME	prtfru – print FRUID-specific information about the FRUs on a system or domain				
SYNOPSIS	<code>/usr/sbin/prtfru [-d] [-c x] [container]</code>				
DESCRIPTION	The <code>prtfru</code> utility is used to obtain FRUID data from the system or domain. Its output is that of a tree structure echoing the path in the FRU (Field-Replaceable Unit) tree to each container. When a container is found, the data from that container is printed in a tree-like structure as well. <code>prtfru</code> without any arguments will print the FRU hierarchy and all of the FRUID container data. <code>prtfru</code> prints to stdout which may be redirected to a file.				
OPTIONS	The following options are supported: -c Prints <i>only</i> the containers and their data. This option does not print the FRU tree hierarchy. -d Prints a DTD for the current registry to stdout. -l Prints <i>only</i> the FRU tree hierarchy. This option does not print the container data. -x Prints in XML format with a system identifier (SYSTEM) of <code>prtfrureg.dtd</code>. Options -c and -l can be used together to obtain a list of the containers.				
OPERANDS	The following operand is supported: <i>container</i> The name of a particular container in the FRU hierarchy, that is, either the name or path/name of a container as displayed in the -l option.				
EXIT STATUS	The following exit values are returned: 0 All information was found and printed successfully. >0 An error has occurred.				
ATTRIBUTES	See <code>attributes(5)</code> for descriptions of the following attributes: <table border="1"> <thead> <tr> <th>ATTRIBUTE TYPE</th><th>ATTRIBUTE VALUE</th></tr> </thead> <tbody> <tr> <td>Availability</td><td>SUNWfruid</td></tr> </tbody> </table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	Availability	SUNWfruid

Availability	SUNWfruid				
SEE ALSO	<code>fruadm(1M)</code> , <code>attributes(5)</code>				

NAME	prtpicl – print PICL tree				
SYNOPSIS	/usr/sbin/prtpicl [-c <i>picl_class</i>] [-v]				
DESCRIPTION	The <code>prtpicl</code> command prints the PICL tree maintained by the PICL daemon. The output of <code>prtpicl</code> includes the name and PICL class of the nodes.				
OPTIONS	The following options are supported: -c <i>picl_class</i> Print only the nodes of the named PICL class. -v Print in verbose mode. In verbose mode, <code>prtpicl</code> prints a list of properties and values for each node. Verbose mode is disabled by default.				
EXIT STATUS	The following exit values are returned: 0 Successful completion. non-zero An error occurred.				
ATTRIBUTES	See <code>attributes(5)</code> for descriptions of the following attributes: <table border="1"> <thead> <tr> <th>ATTRIBUTE TYPE</th><th>ATTRIBUTE VALUE</th></tr> </thead> <tbody> <tr> <td>Availability</td><td>SUNWpiclu</td></tr> </tbody> </table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	Availability	SUNWpiclu

Availability	SUNWpiclu				
SEE ALSO	<code>picld(1M)</code> , <code>attributes(5)</code>				

prvtoc(1M)

NAME	prvtoc – report information about a disk geometry and partitioning
SYNOPSIS	prvtoc [-fhs] [-t <i>vfstab</i>] [-m <i>mnttab</i>] <i>device</i>
DESCRIPTION	The prvtoc command allows the contents of the label to be viewed. The command can be used only by the super-user. The <i>device</i> name can be the file name of a raw device in the form of <code>/dev/rdisk/c?t?d?s2</code> or can be the file name of a block device in the form of <code>/dev/dsk/c?t?d?s2</code>.
OPTIONS	The following options are supported: -f Report on the disk free space, including the starting block address of the free space, number of blocks, and unused partitions. -h Omit the headers from the normal output. -m <i>mnttab</i> Use <i>mnttab</i> as the list of mounted filesystems, in place of <code>/etc/mnttab</code>. -s Omit all headers but the column header from the normal output. -t <i>vfstab</i> Use <i>vfstab</i> as the list of filesystem defaults, in place of <code>/etc/vfstab</code>.
EXAMPLES	EXAMPLE 1 Using the prvtoc Command The following example uses the prvtoc command on a 424-megabyte hard disk: <pre>example# prvtoc /dev/rdisk/c0t3d0s2 * /dev/rdisk/c0t3d0s2 partition map * * Dimension: * 512 bytes/sector * 80 sectors/track * 9 tracks/cylinder * 720 sectors/cylinder * 2500 cylinders * 1151 accessible cylinders * * Flags: * 1: unmountable * 10: read-only * * * Partition Tag Flags First Sector Last * Partition Tag Flags Sector Count Sector Mount Directory * 0 2 00 0 76320 76319 / * 1 3 01 76320 132480 208799 * 2 5 00 0 828720 828719 * 5 6 00 208800 131760 340559 /opt * 6 4 00 340560 447120 787679 /usr * 7 8 00 787680 41040 828719 /export/home example#</pre> The data in the Tag column above indicates the type of partition, as follows:

EXAMPLE 1 Using the prvtoc Command (Continued)

<i>Name</i>	<i>Number</i>
UNASSIGNED	0x00
BOOT	0x01
ROOT	0x02
SWAP	0x03
USR	0x04
BACKUP	0x05
STAND	0x06
VAR	0x07
HOME	0x08
ALTSCTR	0x09
CACHE	0x0a
RESERVED	0x0b

The data in the Flags column above indicates how the partition is to be mounted, as follows:

<i>Name</i>	<i>Number</i>
MOUNTABLE, READ AND WRITE	0x00
NOT MOUNTABLE	0x01
MOUNTABLE, READ ONLY	0x10

EXAMPLE 2 Using the prvtoc Command with the -f Option

The following example uses the prvtoc command with the -f option on a 424-megabyte hard disk:

```
example# prvtoc -f /dev/rdisk/c0t3d0s2
FREE_START=0 FREE_SIZE=0 FREE_COUNT=0 FREE_PART=34
```

EXAMPLE 3 Using the prvtoc Command on a Disk Over One Terabyte

The following example uses the prvtoc command on a disk over one terabyte:.

```
example# prvtoc /dev/rdisk/c1t1d0s2
* /dev/rdisk/c1t1d0s2 partition map
*
```

NAME	psradm – change processor operational status
SYNOPSIS	psradm -f -i -n [-v] <i>processor_id</i> ... psradm -a-f -i -n [-v]
DESCRIPTION	The psradm utility changes the operational status of processors. The legal states for the processor are <i>on-line</i>, <i>off-line</i>, and <i>no-intr</i>. An <i>on-line</i> processor processes LWPs (lightweight processes) and may be interrupted by I/O devices in the system. An <i>off-line</i> processor does not process any LWPs. Usually, an <i>off-line</i> processor is not interruptible by I/O devices in the system. On some processors or under certain conditions, it may not be possible to disable interrupts for an <i>off-line</i> processor. Thus, the actual effect of being <i>off-line</i> may vary from machine to machine. A <i>no-intr</i> processor processes LWPs but is not interruptible by I/O devices. A processor may not be taken <i>off-line</i> if there are LWPs that are bound to the processor. On some architectures, it might not be possible to take certain processors <i>off-line</i> if, for example, the system depends on some resource provided by the processor. At least one processor in the system must be able to process LWPs. At least one processor must also be able to be interrupted. Since an <i>off-line</i> processor may be interruptible, it is possible to have an operational system with one processor <i>no-intr</i> and all other processors <i>off-line</i> but with one or more accepting interrupts. If any of the specified processors are powered off, psradm may power on one or more processors. Only superusers can use the psradm utility.
OPTIONS	The following options are supported: -a Perform the action on all processors, or as many as possible. -f Take the specified processors <i>off-line</i>. -i Set the specified processors <i>no-intr</i>. -n Bring the specified processors <i>on-line</i>. -v Output a message giving the results of each attempted operation.
OPERANDS	The following operands are supported: <i>processor_id</i> The processor ID of the processor to be set <i>on-line</i> or <i>off-line</i> or <i>no-intr</i>. Specify <i>processor_id</i> as an individual processor number (for example, 3), multiple processor numbers separated by spaces (for example, 1 2 3), or a range of processor numbers (for example,

psradm(1M)

1-4). It is also possible to combine ranges and (individual or multiple) *processor_ids* (for example, 1-3 5 7-8 9).

EXAMPLES

EXAMPLE 1 Examples of psradm.

The following example sets processors 2 and 3 off-line.

```
psradm -f 2 3
```

The following example sets processors 1 and 2 no-intr.

```
psradm -i 1 2
```

The following example sets all processors on-line.

```
psradm -a -n
```

EXIT STATUS

The following exit values are returned:

0 Successful completion.
>0 An error occurred.

FILES

/etc/wtmpx records logging processor status changes

ATTRIBUTES

See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

SEE ALSO

psrinfo(1M), psrset(1M), p_online(2), attributes(5)

DIAGNOSTICS

psradm: processor 4: Invalid argument

The specified processor does not exist in the configuration.

psradm: processor 3: Device busy

The specified processor could not be taken off-line because it either has LWPs bound to it, is the last on-line processor in the system, or is needed by the system because it provides some essential service.

psradm: processor 3: Device busy

The specified processor could not be set no-intr because it is the last interruptible processor in the system, or or it is the only processor in the system that can service interrupts needed by the system.

psradm: processor 3: Device busy

The specified processor is powered off, and it cannot be powered on because some platform-specific resource is unavailable.

psradm: processor 0: Not owner

The user does not have permission to change processor status.

psradm(1M)

psradm: processor 2: Operation not supported

The specified processor is powered off, and the platform does not support power on of individual processors.

psrinfo(1M)

NAME	psrinfo – displays information about processors
SYNOPSIS	psrinfo [-p] [-v] [<i>processor_id</i>...] psrinfo [-p] -s <i>processor_id</i>
DESCRIPTION	psrinfo displays information about processors. Each physical processor may support multiple virtual processors. Each virtual processor is an entity with its own interrupt ID, capable of executing independent threads. Without the <i>processor_id</i> operand, psrinfo displays one line for each configured processor, displaying whether it is on-line, non-interruptible (designated by <i>no-intr</i>), off-line, or powered off, and when that status last changed. Use the <i>processor_id</i> operand to display information about a specific processor. See OPERANDS.
OPTIONS	The following options are supported: -s <i>processor_id</i> Silent mode. Displays 1 if the specified processor is fully on-line, and 0 if the specified processor is non-interruptible, off-line, or powered off. Use silent mode when using psrinfo in shell scripts. -p Display the number of physical processors in a system. When combined with the -v option, reports additional information about each physical processor. -v Verbose mode. Displays additional information about the specified processors, including: processor type, floating point unit type and clock speed. If any of this information cannot be determined, psrinfo displays unknown. When combined with the -p option, reports additional information about each physical processor.
OPERANDS	The following operands are supported: <i>processor_id</i> The processor ID of the processor about which information is to be displayed. Specify <i>processor_id</i> as an individual processor number (for example, 3), multiple processor numbers separated by spaces (for example, 1 2 3), or a range of processor numbers (for example, 1-4). It is also possible to combine ranges and (individual or multiple) <i>processor_ids</i> (for example, 1-3 5 7-8 9).
EXAMPLES	EXAMPLE 1 Displaying Information About All Configured Processors in Verbose Mode The following example displays information about all configured processors in verbose mode. <pre>psrinfo -v</pre>

EXAMPLE 2 Determining If a Processor is On-line

The following example uses `psrinfo` in a shell script to determine if a processor is on-line.

```
if [ "`psrinfo -s 3 2> /dev/null`" -eq 1 ]
then
    echo "processor 3 is up"
fi
```

EXAMPLE 3 Displaying Information About the Physical Processors in the System

With no additional arguments, the `-p` option displays a single integer: the number of physical processors in the system:

```
> psrinfo -p
      8
```

`psrinfo` also accepts command line arguments (processor IDs):

```
> psrinfo -p 0 512    # IDs 0 and 512 exist on the
1                    # same physical processor

> psrinfo -p 0 1      # IDs 0 and 1 exist on different
2                    # physical processors
```

In this example, virtual processors 0 and 512 exist on the same physical processor. Virtual processors 0 and 1 do not. This is specific to this example and is not a general rule.

EXIT STATUS The following exit values are returned:

```
0          Successful completion.
>0         An error occurred.
```

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

DIAGNOSTICS `psrinfo: processor 9: Invalid argument`
The specified processor does not exist.

psrset(1M)

NAME	psrset – creation and management of processor sets
SYNOPSIS	<pre>psrset -a <i>processor_set_id</i> <i>processor_id...</i> psrset -b <i>processor_set_id</i> <i>pid...</i> psrset -c [<i>processor_id...</i>] psrset -d <i>processor_set_id</i> psrset -e <i>processor_set_id</i> <i>command</i> [<i>argument(s)</i>] psrset -f <i>processor_set_id</i> psrset [-i] [<i>processor_set_id...</i>] psrset -n <i>processor_set_id</i> psrset -p [<i>processor_id...</i>] psrset -q [<i>pid...</i>] psrset -r <i>processor_id...</i> psrset -u <i>pid...</i></pre>
DESCRIPTION	The <code>psrset</code> utility controls the management of processor sets. Processor sets allow the binding of processes to groups of processors, rather than just a single processor. Processors assigned to processor sets can run only LWPs that have been bound to that processor set.
OPTIONS	The following options are supported: -a Assign the specified processors to the specified processor set. This option is restricted to use by the super-user. -b Bind all the LWPs of the specified processes to the specified processor set. LWPs bound to a processor set are restricted to run only on the processors in that set. Processes can only be bound to non-empty processor sets, that is, processor sets that have had processors assigned to them. Bindings are inherited, so new LWPs and processes created by a bound LWP have the same binding. Binding an interactive shell to a processor, for example, binds all commands executed by the shell. This option is restricted to use by the super-user. -c Create a new processor set and displays the new processor set ID. If a list of processors is given, it also attempts to assign those processors to the processor set. If this succeeds, the processors are idle until LWPs are bound to the processor set. This option is restricted to use by the super-user.

Only a limited number of processor sets can be active (created and not destroyed) at a given time. This limit is always be greater than the number of processors in the system. If the `-c` option is used when the maximum number of processor sets is already active, the command fails.

The following format is used for the first line of output of the `-c` option when the `LC_MESSAGES` locale category specifies the "C" locale. In other locales, the strings `created`, `processor`, and `set` can be replaced with more appropriate strings corresponding to the locale.

```
"created processor set %d\n" processor set ID
```

- d Remove the specified processor set, releasing all processors and processes associated with it.

This option is restricted to use by the super-user.
- e Execute a command (with optional arguments) in the specified processor set.

The command process and any child processes are executed only by processors in the processor set.

This option is restricted to use by the super-user.
- f Disables interrupts for all processors within the specified processor set. See `psradm(1M)`.

If some processors in the set cannot have their interrupts disabled, the other processors still have their interrupts disabled, and the command reports an error and return non-zero exit status.

This option is restricted to use by the super-user.
- i Display a list of processors assigned to each named processor set. If no argument is given, a list of all processor sets and the processors assigned to them is displayed. This is also the default operation if the `psrset` command is not given an option.
- n Enable interrupts for all processors within the specified processor set. See `psradm(1M)`.

This option is restricted to use by the super-user.
- p Display the processor set assignments for the specified list of processors. If no argument is given, the processor set assignments for all processors in the system is given.
- q Display the processor set bindings of the specified processes. If a process is composed of multiple LWPs, which have different bindings, the bindings of only one of the bound LWPs is shown. If no argument is given, the processor set bindings of all processes in the system is displayed.

psrset(1M)

- r** Remove a list of processors from their current processor sets. Processors that are removed return to the general pool of processors.
- Processors with LWPs bound to them using `pbind(1M)` cannot be assigned to or removed from processor sets.
- This option is restricted to use by the super-user.
- u** Remove the processor set bindings from all the LWPs of the specified processes, allowing them to be executed on any on-line processor if they are not bound to individual processors through `pbind`.
- The super-user can unbind any process from any active processor set. Other users can unbind processes from processor sets that do not have the `PSET_NOESCAPE` attribute set. In addition, the user must have permission to control the affected processes; the real or effective user ID of the user must match the real or saved user ID of the target processes.

OPERANDS The following operands are supported:

<i>pid</i>	Specify <i>pid</i> as a process ID.
<i>processor_id</i>	Specify <i>processor_id</i> as an individual processor number (for example, 3), multiple processor numbers separated by spaces (for example, 1 2 3), or a range of processor numbers (for example, 1-4). It is also possible to combine ranges and (individual or multiple) <i>processor_ids</i> (for example, 1-3 5 7-8 9).
<i>processor_set_id</i>	Specify <i>processor_set_id</i> as a processor set ID.

EXIT STATUS The following exit values are returned:

0	Successful completion.
non-0	An error occurred.

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu
Stability Level	Stable

SEE ALSO `pbind(1M)`, `psradm(1M)`, `psrinfo(1M)`, `processor_bind(2)`, `processor_info(2)`, `pset_bind(2)`, `pset_create(2)`, `pset_info(2)`, `sysconf(3C)`, `attributes(5)`

DIAGNOSTICS `psrset: cannot query pid 31: No such process`
The process specified did not exist or has exited.

psrset(1M)

psrset: cannot bind pid 31: Not owner

The user does not have permission to bind the process.

psrset: cannot assign processor 4: Not owner

The user does not have permission to assign the processor.

psrset: cannot assign processor 8: Invalid argument

The specified processor is not on-line, or the specified processor does not exist.

psrset: cannot bind pid 67: Device busy

An LWP in the specified process is bound to a processor and cannot be bound to a processor set that does not include that processor.

psrset: cannot assign processor 7: Device busy

The specified processor could not be added to the processor set. This can be due to bound LWPs on that processor, or because that processor cannot be combined in the same processor set with other processors in that set, or because the processor is the last one in its current processor set.

psrset: cannot execute in processor set 8: Invalid argument

The specified processor set does not exist.

psrset: cannot create processor set: Not enough space

The maximum number of processor sets allowed in the system is already active.

putdev(1M)

NAME	putdev – edits device table								
SYNOPSIS	putdev -a <i>alias</i> [<i>attribute=value</i> [...]] putdev -m <i>device attribute=value</i> [<i>attribute = value</i> [...]] putdev -d <i>device</i> [<i>attribute</i> [...]]								
DESCRIPTION	putdev adds a new device to the device table, modifies an existing device description or removes a device entry from the table. The first synopsis is used to add a device. The second synopsis is used to modify existing entries by adding or changing attributes. If a specified attribute is not defined, this option adds that attribute to the device definition. If a specified attribute is already defined, it modifies the attribute definition. The third synopsis is used to delete either an entire device entry or, if the attribute argument is used, to delete an attribute assignment for a device.								
OPTIONS	The following options are supported: -a Add a device to the device table using the specified attributes. The device must be referenced by its <i>alias</i>. -d Remove a device from the device table, when executed without the <i>attributes</i> argument. Used with the <i>attribute</i> argument, it deletes the given attribute specification for <i>device</i> from the table. -m Modify a device entry in the device table. If an entry already exists, it adds any specified attributes that are not defined. It also modifies any attributes which already have a value with the value specified by this command.								
OPERANDS	The following operands are supported: <table> <tr> <td><i>alias</i></td><td>Designates the alias of the device to be added.</td></tr> <tr> <td><i>attribute</i></td><td>Designates a device attribute to be added, modified, or deleted. Can be any of the device attributes described under DEVICE ATTRIBUTES except <i>alias</i>. This prevents an accidental modification or deletion of a device's alias from the table.</td></tr> <tr> <td><i>device</i></td><td>Designates the pathname or alias of the device whose attribute is to be added, modified, or removed.</td></tr> <tr> <td><i>value</i></td><td>Designates the value to be assigned to a device's attribute.</td></tr> </table>	<i>alias</i>	Designates the alias of the device to be added.	<i>attribute</i>	Designates a device attribute to be added, modified, or deleted. Can be any of the device attributes described under DEVICE ATTRIBUTES except <i>alias</i> . This prevents an accidental modification or deletion of a device's alias from the table.	<i>device</i>	Designates the pathname or alias of the device whose attribute is to be added, modified, or removed.	<i>value</i>	Designates the value to be assigned to a device's attribute.
<i>alias</i>	Designates the alias of the device to be added.								
<i>attribute</i>	Designates a device attribute to be added, modified, or deleted. Can be any of the device attributes described under DEVICE ATTRIBUTES except <i>alias</i> . This prevents an accidental modification or deletion of a device's alias from the table.								
<i>device</i>	Designates the pathname or alias of the device whose attribute is to be added, modified, or removed.								
<i>value</i>	Designates the value to be assigned to a device's attribute.								
DEVICE ATTRIBUTES	The following list shows the standard device attributes, used by applications such as <code>ufsdump(1M)</code> and <code>ufsrestore(1M)</code>, which can be defined for a device. You are not limited to this list, you can define any attribute you like. <table> <tr> <td><i>alias</i></td><td>The unique name by which a device is known. No two devices in the database may share the same alias name. The name is limited in length to 14 characters and should contain only alphanumeric characters and the following special characters if they are escaped with a backslash: underscore (_), dollar sign (\$), hyphen (-), and period (.).</td></tr> </table>	<i>alias</i>	The unique name by which a device is known. No two devices in the database may share the same alias name. The name is limited in length to 14 characters and should contain only alphanumeric characters and the following special characters if they are escaped with a backslash: underscore (_), dollar sign (\$), hyphen (-), and period (.).						
<i>alias</i>	The unique name by which a device is known. No two devices in the database may share the same alias name. The name is limited in length to 14 characters and should contain only alphanumeric characters and the following special characters if they are escaped with a backslash: underscore (_), dollar sign (\$), hyphen (-), and period (.).								

bdevice	The pathname to the block special device node associated with the device, if any. The associated major/minor combination should be unique within the database and should match that associated with the cdevice field, if any. (It is the administrator's responsibility to ensure that these major/minor numbers are unique in the database.)
capacity	The capacity of the device or of the typical volume, if removable.
cdevice	The pathname to the character special device node associated with the device, if any. The associated major/minor combination should be unique within the database and should match that associated with the bdevice field, if any. (It is the administrator's responsibility to ensure that these major/minor numbers are unique in the database.)
cyl	Used by the command specified in the mkfscmd attribute.
desc	A description of any instance of a volume associated with this device (such as floppy diskette).
dpartlist	The list of disk partitions associated with this device. Used only if type=disk. The list should contain device aliases, each of which must have type=dpart.
dparttype	The type of disk partition represented by this device. Used only if type=dpart. It should be either fs (for file system) or dp (for data partition).
erasescmd	The command string that, when executed, erases the device.
fmtcmd	The command string that, when executed, formats the device.
fsname	The file system name on the file system administered on this partition, as supplied to the /usr/sbin/labelit command. This attribute is specified only if type=dpart and dparttype=fs.
gap	Used by the command specified in the mkfscmd attribute.
mkfscmd	The command string that, when executed, places a file system on a previously formatted device.
mountpt	The default mount point to use for the device. Used only if the device is mountable. For disk partitions where type=dpart and dparttype=fs, this attribute should specify the location where the partition is normally mounted.
nblocks	The number of blocks in the file system administered on this partition. Used only if type=dpart and dparttype=fs.
ninodes	The number of inodes in the file system administered on this partition. Used only if type=dpart and dparttype=fs.

putdev(1M)

norewind	The name of the character special device node that allows access to the serial device without rewinding when the device is closed.
pathname	Defines the pathname to an i-node describing the device (used for non-block or character device pathnames, such as directories).
type	A token that represents inherent qualities of the device. Standard types include: 9-track, ctape, disk, directory, diskette, dpart, and qtape.
volname	The volume name on the file system administered on this partition, as supplied to the <code>/usr/sbin/labelit</code> command. Used only if <code>type=dpart</code> and <code>dparttype=fs</code> .
volume	A text string used to describe any instance of a volume associated with this device. This attribute should not be defined for devices which are not removable.

EXIT STATUS

The following exit values are returned:

0	Successful completion.
1	Command syntax was incorrect, an invalid option was used, or an internal error occurred.
2	The device table could not be opened for reading, or a new device table could not be created.
3	If executed with the <code>-a</code> option, indicates that an entry in the device table with the alias <code>alias</code> already exists. If executed with the <code>-m</code> or <code>-d</code> options, indicates that no entry exists for device <i>device</i> .
4	Indicates that <code>-d</code> was requested and one or more of the specified attributes were not defined for the device.

System Administration Guide: Basic Administration

NAME	putdgrp – edits device group table
SYNOPSIS	putdgrp [-d] <i>dgroup</i> [<i>device...</i>]
DESCRIPTION	putdgrp modifies the device group table. It performs two kinds of modification. It can modify the table by creating a new device group or removing a device group. It can also change group definitions by adding or removing a device from the group definition. When the command is invoked with only a <i>dgroup</i> specification, the command adds the specified group name to the device group table if it does not already exist. If the -d option is also used with only the <i>dgroup</i> specification, the command deletes the group from the table. When the command is invoked with both a <i>dgroup</i> and a <i>device</i> specification, it adds the given device name(s) to the group definition. When invoked with both arguments and the -d option, the command deletes the device name(s) from the group definition. When the command is invoked with both a <i>dgroup</i> and a <i>device</i> specification and the device group does not exist, it creates the group and adds the specified devices to that new group.
OPTIONS	The following options are supported: -d Delete the group or, if used with <i>device</i>, delete the device from a group definition.
OPERANDS	The following operands are supported: <i>dgroup</i> Specify a device group name. <i>device</i> Specify the pathname or alias of the device that is to be added to, or deleted from, the device group.
EXIT STATUS	The following exit values are returned: 0 Successful completion. 1 Command syntax was incorrect, an invalid option was used, or an internal error occurred. 2 Device group table could not be opened for reading or a new device group table could not be created. 3 If executed with the -d option, indicates that an entry in the device group table for the device group <i>dgroup</i> does not exist and so cannot be deleted. Otherwise, indicates that the device group <i>dgroup</i> already exists and cannot be added. 4 If executed with the -d option, indicates that the device group <i>dgroup</i> does not have as members one or more of the specified devices. Otherwise, indicates that the device group <i>dgroup</i> already has one or more of the specified devices as members.

putdgrp(1M)

EXAMPLES

EXAMPLE 1 Adding a new device group.

The following example adds a new device group:

```
example# putdgrp floppies
```

EXAMPLE 2 Adding a device to a device group.

The following example adds a device to a device group:

```
example# putdgrp floppies diskette2
```

EXAMPLE 3 Deleting a device group.

The following example deletes a device group:

```
example# putdgrp -d floppies
```

EXAMPLE 4 Deleting a device from a device group.

The following example deletes a device from a device group:

```
example# putdgrp -d floppies diskette2
```

NAME	pwck, grpck – password/group file checkers				
SYNOPSIS	<pre>/usr/sbin/pwck [filename]</pre> <pre>/usr/sbin/grpck [filename]</pre>				
DESCRIPTION	pwck scans the password file and notes any inconsistencies. The checks include validation of the number of fields, login name, user ID, group ID, and whether the login directory and the program-to-use-as-shell exist. The default password file is <code>/etc/passwd</code>. grpck verifies all entries in the group file. This verification includes a check of the number of fields, group name, group ID, whether any login names belong to more than NGROUPS_MAX groups, and that all login names appear in the password file. The default group file is <code>/etc/group</code>. All messages regarding inconsistent entries are placed on the <code>stderr</code> stream.				
FILES	<pre>/etc/group</pre> <pre>/etc/passwd</pre>				
ATTRIBUTES	See <code>attributes(5)</code> for descriptions of the following attributes: <table> <tr> <th>ATTRIBUTE TYPE</th><th>ATTRIBUTE VALUE</th></tr> <tr> <td>Availability</td><td>SUNWcsu</td></tr> </table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	Availability	SUNWcsu
ATTRIBUTE TYPE	ATTRIBUTE VALUE				
Availability	SUNWcsu				
SEE ALSO	<code>getpwent(3C)</code> , <code>group(4)</code> , <code>passwd(4)</code> , <code>attributes(5)</code>				
DIAGNOSTICS	Group entries in <code>/etc/group</code> with no login names are flagged. Group file '<i>filename</i>' is empty The <code>/etc/passwd</code> or <code>/etc/group</code> file is an empty file. cannot open file <i>filename</i>: No such file or directory The <code>/etc/passwd</code> or <code>/etc/group</code> file does not exist.				
NOTES	If no <code>filename</code> argument is given, <code>grpck</code> checks the local group file, <code>/etc/group</code> , and also makes sure that all login names encountered in the checked group file are known to the system <code>getpwent(3C)</code> routine. This means that the login names may be supplied by a network name service.				

pwconv(1M)

NAME	pwconv – installs and updates /etc/shadow with information from /etc/passwd				
SYNOPSIS	pwconv				
DESCRIPTION	The pwconv command creates and updates /etc/shadow with information from /etc/passwd. pwconv relies on a special value of 'x' in the password field of /etc/passwd. This value of 'x' indicates that the password for the user is already in /etc/shadow and should not be modified. If the /etc/shadow file does not exist, this command will create /etc/shadow with information from /etc/passwd. The command populates /etc/shadow with the user's login name, password, and password aging information. If password aging information does not exist in /etc/passwd for a given user, none will be added to /etc/shadow. However, the last changed information will always be updated. If the /etc/shadow file does exist, the following tasks will be performed: - Entries that are in the /etc/passwd file and not in the /etc/shadow file will be added to the /etc/shadow file. - Entries that are in the /etc/shadow file and not in the /etc/passwd file will be removed from /etc/shadow. - Password attributes (for example, password and aging information) that exist in an /etc/passwd entry will be moved to the corresponding entry in /etc/shadow. The pwconv command can only be used by the super-user.				
FILES	/etc/opasswd /etc/oshadow /etc/passwd /etc/shadow				
ATTRIBUTES	See attributes(5) for descriptions of the following attributes: <table><thead><tr><th>ATTRIBUTE TYPE</th><th>ATTRIBUTE VALUE</th></tr></thead><tbody><tr><td>Availability</td><td>SUNWcsu</td></tr></tbody></table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	Availability	SUNWcsu
ATTRIBUTE TYPE	ATTRIBUTE VALUE				
Availability	SUNWcsu				
SEE ALSO	passwd(1), passmgmt(1M), usermod(1M), passwd(4), attributes(5)				
DIAGNOSTICS	pwconv exits with one of the following values: <table><tbody><tr><td>0</td><td>SUCCESS.</td></tr><tr><td>1</td><td>Permission denied.</td></tr></tbody></table>	0	SUCCESS.	1	Permission denied.
0	SUCCESS.				
1	Permission denied.				

- 2 Invalid command syntax.
- 3 Unexpected failure. Conversion not done.
- 4 Unexpected failure. Password file(s) missing.
- 5 Password file(s) busy. Try again later.
- 6 Bad entry in `/etc/shadow` file.

quot(1M)

NAME	quot – summarize file system ownership
SYNOPSIS	quot [-acfhnv] <i>filesystem</i> . . . quot -a [-cfhnv]
DESCRIPTION	quot displays the number of blocks (1024 bytes) in the named <i>filesystem</i> (one or more) currently owned by each user. There is a limit of 2048 blocks. Files larger than this will be counted as a 2048 block file, but the total block count will be correct.
OPTIONS	The following options are supported: -a Generate a report for all mounted file systems. -c Display three columns giving a file size in blocks, the number of files of that size, and a cumulative total of blocks containing files of that size or a smaller size. -f Display three columns giving, for each user, the number of blocks owned, the count of number of files, and the user name. This option is incompatible with the -c and -v options. -h Estimate the number of blocks in the file. This does not account for files with holes in them. -n Attach names to the list of files read from standard input. quot -n cannot be used alone, because it expects data from standard input. For example, the pipeline ncheck myfilesystem sort +0n quot -n myfilesystem will produce a list of all files and their owners. This option is incompatible with all other options. -v In addition to the default output, display three columns containing the number of blocks not accessed in the last 30, 60, and 90 days.
OPERANDS	<i>filesystem</i> mount-point of the filesystem(s) being checked
USAGE	See <i>largefile</i> (5) for the description of the behavior of quot when encountering files greater than or equal to 2 Gbyte (2 ³¹ bytes).
EXIT STATUS	0 Successful operation. 32 Error condition (bad or missing argument, bad path, or other error).
FILES	/etc/mnttab Lists mounted file systems. /etc/passwd Used to obtain user names

quot(1M)

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

SEE ALSO `du(1)`, `mnttab(4)`, `passwd(4)`, `attributes(5)`, `largefile(5)`

NOTES This command can only be used by the super-user.

quota(1M)

NAME	quota – display a user’s ufs file system disk quota and usage
SYNOPSIS	quota [-v] [<i>username</i>]
DESCRIPTION	quota displays users’ ufs disk usage and limits. Only the super-user may use the optional <i>username</i> argument to view the limits of other users. quota without options only display warnings about mounted file systems where usage is over quota. Remotely mounted file systems which do not have quotas turned on are ignored. <i>username</i> can be the numeric UID of a user.
OPTIONS	-v Display user’s quota on all mounted file systems where quotas exist.
USAGE	See largefile(5) for the description of the behavior of quota when encountering files greater than or equal to 2 Gbyte (2 ³¹ bytes).
FILES	/etc/mnttab list of currently mounted filesystems
ATTRIBUTES	See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

SEE ALSO edquota(1M), quotaon(1M), quotacheck(1M), repquota(1M), rquotad(1M), attributes(5), largefile(5)

NOTES quota will also display quotas for NFS mounted ufs-based file systems if the rquotad daemon is running. See rquotad(1M).

quota may display entries for the same file system multiple times for multiple mount points. For example,

```
quota -v user1
```

may display identical quota information for user1 at the mount points /home/user1, /home/user2, and /home/user, if all three mount points are mounted from the same file system with quotas turned on.

NAME	quotacheck – ufs file system quota consistency checker				
SYNOPSIS	quotacheck [-fp] [-v] <i>filesystem...</i> quotacheck -a [-fpv]				
DESCRIPTION	quotacheck examines each mounted ufs file system, builds a table of current disk usage, and compares this table against the information stored in the file system's disk quota file. If any inconsistencies are detected, both the quota file and the current system copy of the incorrect quotas are updated. <i>filesystem</i> is either a file system mount point or the block device on which the file system resides. quotacheck expects each file system to be checked to have a quota file named <i>quotas</i> in the root directory. If none is present, quotacheck will not check the file system. quotacheck accesses the character special device in calculating the actual disk usage for each user. Thus, the file systems that are checked should be quiescent while quotacheck is running.				
OPTIONS	The following options are supported: -a Check the file systems which <i>/etc/mnttab</i> indicates are ufs file systems. These file systems must be read-write mounted with disk quotas enabled, and have an <i>rq</i> entry in the <i>mntopts</i> field in <i>/etc/vfstab</i>. -f Force check on file systems with logging enabled. Use in combination with the -p option. -p Check quotas of file systems in parallel. For file systems with logging enabled, no check is performed unless the -f option is also specified. -v Indicate the calculated disk quotas for each user on a particular file system. quotacheck normally reports only those quotas modified.				
USAGE	See <i>largefile(5)</i> for the description of the behavior of quotacheck when encountering files greater than or equal to 2 Gbyte (2^{31} bytes).				
FILES	<i>/etc/mnttab</i> Mounted file systems <i>/etc/vfstab</i> List of default parameters for each file system				
ATTRIBUTES	See <i>attributes(5)</i> for descriptions of the following attributes: <table border="1"> <thead> <tr> <th>ATTRIBUTE TYPE</th><th>ATTRIBUTE VALUE</th></tr> </thead> <tbody> <tr> <td>Availability</td><td>SUNWcsu</td></tr> </tbody> </table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	Availability	SUNWcsu
ATTRIBUTE TYPE	ATTRIBUTE VALUE				
Availability	SUNWcsu				
SEE ALSO	<i>edquota(1M)</i> , <i>quota(1M)</i> , <i>quotaon(1M)</i> , <i>repquota(1M)</i> , <i>attributes(5)</i> , <i>largefile(5)</i> , <i>quotactl(7I)</i> , <i>mount_ufs(1M)</i>				

quotaon(1M)

NAME	quotaon, quotaoff – turn ufs file system quotas on and off
SYNOPSIS	quotaon [-v] <i>filesystem...</i> quotaon -a [-v] quotaoff [-v] <i>filesystem...</i> quotaoff -a [-v]
DESCRIPTION	quotaon turns on disk quotas for one or more ufs file systems. Before a file system may have quotas enabled, a file named <i>quotas</i>, owned by root, must exist in the root directory of the file system. See <i>edquota(1M)</i> for details on how to modify the contents of this file. quotaoff turns off disk quotas for one or more ufs file systems. The file systems specified must already be mounted. These commands update the <i>mntopts</i> field of the appropriate entries in <i>/etc/mnttab</i> to indicate when quotas are on or off for each file system. If quotas are on, the string <i>quota</i> will be added to <i>mntopts</i>; if quotas are off, the <i>quota</i> string is not present. <i>filesystem</i> must be either the mount point of a file system, or the block device on which the file system resides.
OPTIONS	
quotaon	-a This option is normally used at boot time to enable quotas. It applies only to those file systems in <i>/etc/vfstab</i> which have “rq” in the <i>mntopts</i> field, are currently mounted “rw”, and have a <i>quotas</i> file in the root directory. -v Display a message for each file system after quotas are turned on.
quotaoff	-a Force all file systems in <i>/etc/mnttab</i> to have their quotas disabled. -v Display a message for each file system affected.
USAGE	See <i>largefile(5)</i> for the description of the behavior of <i>quotaon</i> and <i>quotaoff</i> when encountering files greater than or equal to 2 Gbyte (2 ³¹ bytes).
FILES	<i>/etc/mnttab</i> mounted file systems <i>/etc/vfstab</i> list of default parameters for each file system
ATTRIBUTES	See <i>attributes(5)</i> for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

raidctl(1M)

NAME	raidctl – RAID hardware utility																		
SYNOPSIS	<pre>raidctl -c disk1 disk2 raidctl -d disk1 raidctl [-f] -F filename controller... raidctl -l [controller...]</pre>																		
DESCRIPTION	The <code>raidctl</code> utility creates, deletes, or displays RAID volumes of the LSI1030 HW Raid controller. The <code>raidctl</code> utility requires privileges that are controlled by the underlying file-system permissions. Only privileged users can manipulate the RAID system configuration. If a non-privileged user attempts to create or delete a RAID volume, the command fails with <code>EPERM</code>. Without options, <code>raidctl</code> displays the current RAID configuration on all existing controllers.																		
OPTIONS	The following options are supported: <table> <tr> <td><code>-c disk1 disk2</code></td><td>Create a mirror using <i>disk1</i> and <i>disk2</i>. Replace the contents of <i>disk2</i> with the contents of <i>disk1</i>. Specify <i>disk1</i> and <i>disk2</i> in canonical form, for example, <code>c0t0d0</code>.</td></tr> <tr> <td></td><td>When you create a RAID volume, the RAID volume assumes the identity of the first target in the disk pair (<i>disk1</i>). The second target (<i>disk2</i>) disappears from the system. Therefore, the RAID volume appears as one disk.</td></tr> <tr> <td></td><td>To have a successful RAID creation, there must not already be a RAID configuration present on the specified controller. Additionally, the secondary disk must not be mounted, as it has all its data erased and replaced with the primary disk's data.</td></tr> <tr> <td><code>-d disk1</code></td><td>Delete the RAID volume specified as <i>disk1</i>.</td></tr> <tr> <td></td><td>Specify <i>disk1</i> in canonical form, for example, <code>c0t0d0</code>.</td></tr> <tr> <td><code>-f</code></td><td>Force an update. Do not prompt.</td></tr> <tr> <td><code>-F filename controller</code></td><td>Update the firmware running on the specified controller (<i>controller</i>).</td></tr> <tr> <td><code>-l [controller ...]</code></td><td>List the system's RAID configuration. If <i>controller</i> is specified, list RAID configurations for <i>controller</i>.</td></tr> <tr> <td></td><td>Output from the <code>-l</code> lists the following information:</td></tr> </table>	<code>-c disk1 disk2</code>	Create a mirror using <i>disk1</i> and <i>disk2</i> . Replace the contents of <i>disk2</i> with the contents of <i>disk1</i> . Specify <i>disk1</i> and <i>disk2</i> in canonical form, for example, <code>c0t0d0</code> .		When you create a RAID volume, the RAID volume assumes the identity of the first target in the disk pair (<i>disk1</i>). The second target (<i>disk2</i>) disappears from the system. Therefore, the RAID volume appears as one disk.		To have a successful RAID creation, there must not already be a RAID configuration present on the specified controller. Additionally, the secondary disk must not be mounted, as it has all its data erased and replaced with the primary disk's data.	<code>-d disk1</code>	Delete the RAID volume specified as <i>disk1</i> .		Specify <i>disk1</i> in canonical form, for example, <code>c0t0d0</code> .	<code>-f</code>	Force an update. Do not prompt.	<code>-F filename controller</code>	Update the firmware running on the specified controller (<i>controller</i>).	<code>-l [controller ...]</code>	List the system's RAID configuration. If <i>controller</i> is specified, list RAID configurations for <i>controller</i> .		Output from the <code>-l</code> lists the following information:
<code>-c disk1 disk2</code>	Create a mirror using <i>disk1</i> and <i>disk2</i> . Replace the contents of <i>disk2</i> with the contents of <i>disk1</i> . Specify <i>disk1</i> and <i>disk2</i> in canonical form, for example, <code>c0t0d0</code> .																		
	When you create a RAID volume, the RAID volume assumes the identity of the first target in the disk pair (<i>disk1</i>). The second target (<i>disk2</i>) disappears from the system. Therefore, the RAID volume appears as one disk.																		
	To have a successful RAID creation, there must not already be a RAID configuration present on the specified controller. Additionally, the secondary disk must not be mounted, as it has all its data erased and replaced with the primary disk's data.																		
<code>-d disk1</code>	Delete the RAID volume specified as <i>disk1</i> .																		
	Specify <i>disk1</i> in canonical form, for example, <code>c0t0d0</code> .																		
<code>-f</code>	Force an update. Do not prompt.																		
<code>-F filename controller</code>	Update the firmware running on the specified controller (<i>controller</i>).																		
<code>-l [controller ...]</code>	List the system's RAID configuration. If <i>controller</i> is specified, list RAID configurations for <i>controller</i> .																		
	Output from the <code>-l</code> lists the following information:																		

raidctl(1M)

RAID Volume	Displays logical RAID volume name.
RAID Status	Displays RAID status as either RESYNCING (disks are syncing), DEGRADED RAID is operating with reduced functionality), OK (operating optimally), or FAILED (non-functional).
RAID Disk	Displays RAID disk name.
Disk Status	Displays disk status as either OK or FAILED.

EXAMPLES **EXAMPLE 1** Creating the RAID Configuration

The following command creates the RAID configuration:

```
# raidctl -c c0t0d0 c0t1d0
RAID Volume 'c0t0d0' created
```

EXAMPLE 2 Displaying the RAID Configuration

The following command displays the RAID configuration:

```
# raidctl
RAID      RAID      RAID      Disk
Volume    Status    Disk      Status
-----
c0t0d0    RESYNCING  c0t0d0    OK
                  c0t1d0    OK
```

EXAMPLE 3 Deleting the RAID Configuration

The following command deletes the RAID configuration:

```
# raidctl -d c0t0d0
RAID Volume 'c0t0d0' deleted
```

EXAMPLE 4 Updating Flash Images on the Controller

The following command updates flash images on the controller:

```
# raidctl -F lsi1030.fw 0
Update flash image on controller 0? (y/N): y
Flash updated successfully
```

EXIT STATUS The following exit values are returned:

0 Successful completion.

raidctl(1M)

- 1 Invalid command line input.
- 2 Request operation failed.

System Administration Guide: Basic Administration

NAME	ramdiskadm – administer ramdisk pseudo device
SYNOPSIS	<pre>/usr/sbin/ramdiskadm -a <i>name size</i> [g m k b] /usr/sbin/ramdiskadm -d <i>name</i> /usr/sbin/ramdiskadm</pre>
DESCRIPTION	The ramdiskadm command administers ramdisk(7D), the ramdisk driver. Use ramdiskadm to create a new named ramdisk device, delete an existing named ramdisk, or list information about existing ramdisks. Ramdisks created using ramdiskadm are not persistent across reboots.
OPTIONS	The following options are supported: <i>-a name size</i> Create a ramdisk named <i>name</i> of size <i>size</i> and its corresponding block and character device nodes. <i>name</i> must be composed only of the characters a-z, A-Z, 0-9, _ (underbar), and - (hyphen), but it must not begin with a hyphen. It must be no more than 32 characters long. Ramdisk names must be unique. The size can be a decimal number, or, when prefixed with 0x, a hexadecimal number, and can specify the size in bytes (no suffix), 512-byte blocks (suffix b), kilobytes (suffix k), megabytes (suffix m) or gigabytes (suffix g). The size of the ramdisk actually created might be larger than that specified, depending on the hardware implementation. If the named ramdisk is successfully created, its block device path is printed on standard out. <i>-d name</i> Delete an existing ramdisk of the name <i>name</i>. This command succeeds only when the named ramdisk is not open. The associated memory is freed and the device nodes are removed. You can delete only ramdisks created using ramdiskadm. It is not possible to delete a ramdisk that was created during the boot process. Without options, ramdiskadm lists any existing ramdisks, their sizes (in decimal), and whether they can be removed by ramdiskadm (see the description of the -d option, above).
EXAMPLES	EXAMPLE 1 Creating a 2MB Ramdisk Named mydisk <pre># ramdiskadm -a mydisk 2m /dev/ramdisk/mydisk</pre> EXAMPLE 2 Listing All Ramdisks <pre># ramdiskadm Block Device Size Removable /dev/ramdisk/miniroot 134217728 No</pre>

ramdiskadm(1M)

EXAMPLE 2 Listing All Ramdisks (Continued)

```
/dev/ramdisk/certfs      1048576    No
/dev/ramdisk/mydisk      2097152    Yes
```

EXIT STATUS

ramdiskadm returns the following exit values:

0
Successful completion.

>0
An error occurred.

ATTRIBUTES

Interface Stability	Evolving

SEE ALSO

`attributes(5)`, `ramdisk(7D)`

NOTES

The abilities of `ramdiskadm` and the privilege level of the person who uses the utility are controlled by the permissions of `/dev/ramdiskctl`. Read access allows query operations, for example, listing device information. Write access is required to do any state-changing operations, for example, creating or deleting ramdisks.

As shipped, `/dev/ramdiskctl` is owned by `root`, in group `sys`, and mode `0644`, so all users can do query operations but only `root` can perform state-changing operations. An administrator can give write access to non-privileged users, allowing them to add or delete ramdisks. However, granting such ability entails considerable risk; such privileges should be given only to a trusted group.

NAME	rcapadm – configure resource capping daemon
SYNOPSIS	rcapadm rcapadm [[-n] -E -D] [-i <i>interval=value</i> , . . . , <i>interval=value</i>] [-c <i>percent</i>]
DESCRIPTION	The rcapadm command allows a user with the privileges described below to configure various attributes of the resource capping daemon. If used without arguments, rcapadm displays the current status of the resource capping daemon if it has been configured. See rcapd(1M) for more information. In Solaris 9, rcapadm is available to users who have the Process Management profile in their list of profiles. The System Administrator role includes the Process Management profile. The resource capping daemon (rcapd(1M)) is an optional feature.
OPTIONS	-n Do not affect the running state of the resource capping daemon when enabling or disabling it. -E Enable the resource capping daemon so that it will be started each time the system is booted. Also start the resource capping daemon now, if the -n option is not specified and it is not currently running. -D Disable the resource capping daemon so that it will not be started when the system is booted. Also stop the resource capping daemon now, if the -n option is not specified and it is currently running. -i <i>interval=value</i>,...,<i>interval=value</i> Set intervals for various periodic operations performed by rcapd. All intervals are specified in seconds. You can set the following intervals: scan The interval at which rcapd scans for new processes. The default scan interval is every 15 seconds. The minimum value is 1 second. sample The interval of process resident set size sampling. The default sample interval is every 5 seconds. The minimum value is 1 second. report The interval at which various paging statistics are updated by rcapd, in seconds. These statistics can be viewed by using rcapstat(1SRM). The default reporting interval is every 5 seconds. When the interval is set to 0, statistics will not be updated. Note – Paging refers to the act of relocating portions of memory, called pages, to or from physical memory. rcapd pages out the most infrequently used pages.

rcapadm(1M)

config

The reconfiguration interval, in seconds. At each reconfiguration event, `rcapd` checks its configuration file for updates, and scans the project databases for new project caps. The default reconfiguration interval is every 60 seconds. The minimum interval is 0. When the interval is set to 0, no periodic reconfiguration occurs, although the running daemon can still be reconfigured by sending it `SIGHUP`.

-c percent

Set the minimum physical memory utilization for memory cap enforcement. Caps will not be enforced until the physical memory available to processes is low. The *percent* value should be in the range 0 to 100. The minimum (and default) value is 0, which means that memory caps are always enforced.

EXAMPLES

EXAMPLE 1 Configuring the Resource Capping Daemon with Immediate Enforcement

```
# rcapadm -E -i scan=15,sample=5,report=5,config=60 -c 0
```

EXIT STATUS

The following exit values are returned:

- 0 Successful completion. The modifications to the current configuration were valid and made successfully.
- 1 An error occurred. A fatal error occurred either in obtaining or modifying the resource capping configuration.
- 2 Invalid command-line options were specified.

“Physical Memory Control Using the Resource Capping Daemon” in *System Administration Guide: Resource Management and Network Services*

NAME	rcapd – resource cap enforcement daemon
SYNOPSIS	rcapd [-d]
DESCRIPTION	The rcapd daemon enforces resource caps on collections of processes. Per-project physical memory caps are supported. For information about projects, see <code>project(4)</code>. When the resident set size (RSS) of a collection of processes exceeds its cap, rcapd takes action and reduces the RSS of the collection. The virtual memory system divides physical memory into segments known as pages. To read data from a file into memory, the virtual memory system reads in individual pages. To reduce resource consumption, the daemon can page out, or relocate, infrequently used pages to an area outside of physical memory. In the <code>project</code> file, caps are defined for projects that have positive values for the following project attribute: <pre>rcap.max-rss</pre> The total amount of physical memory, in bytes, that is available to the project's member processes See <code>project(4)</code> for a description of project attributes. You can configure rcapd through the use of <code>rcapadm(1M)</code>. The daemon can be monitored with <code>rcapstat(1)</code>. Configuration changes are incorporated into rcapd by sending it <code>SIGHUP</code> (see <code>kill(1)</code>), or according to the configuration interval (see <code>rcapadm(1M)</code>). rcapd is an optional feature.
OPTIONS	The following option is supported: -d Enable debug mode. Messages are displayed on the invoking user's terminal.
EXAMPLES	EXAMPLE 1 Setting Resident Set Size Cap Attribute The following line in the <code>/etc/project</code> database sets an RSS cap of 1073741824 bytes for a project named <code>foo</code>. <pre>foo:100::foo,root::rcap.max-rss=10737418240</pre>
EXIT STATUS	The following exit values are returned: 0 Successful completion. 1 An error occurred. 2 Invalid command-line options were specified.
FILES	<code>/etc/project</code> Project database.

rcapd(1M)

ATTRIBUTES See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWrcapu
Interface Stability	Evolving

SEE ALSO rcapstat(1), rcapadm(1M), project(4), attributes(5)

“Physical Memory Control Using the Resource Capping Daemon” in *System Administration Guide: Resource Management and Network Services*

NOTES If killed with SIGKILL, rcapd can leave processes in a stopped state. Use SIGTERM to cause rcapd to terminate properly.

A collection’s RSS can exceed its cap for some time before the cap is enforced, even if sufficient pageable memory is available. This period of time can be reduced by shortening the RSS sampling interval with rcapadm.

NAME	rctladm – display or modify global state of system resource controls
SYNOPSIS	rctladm [-lu] [-e <i>action</i>] [-d <i>action</i>] [<i>name</i> ...]
DESCRIPTION	The rctladm command allows the examination and modification of active resource controls on the running system. An instance of a resource control is referred to as an <i>rctl</i> . See setrctl(2) for further description of an rctl. Logging of rctl violations can be activated or deactivated system-wide and active rctls (and their state) can be listed.
OPTIONS	The following options are supported: -d <i>action</i> -e <i>action</i> Disable (-d) or enable (-e) the global action on the specified rctls. If no rctl is specified, no action is taken and an error status is returned. You can use the special token all with the disable option to deactivate all global actions on a resource control. - You can set the syslog action to a specific degree by assigning a severity level. To do this, specify <i>syslog=level</i>, where <i>level</i> is one of the string tokens given as valid severity levels in syslog(3C). You can omit the common LOG_ prefix on the severity level. -l List available rctls with event status. This option displays the global event actions available for each rctl, and by the action name used with the enable (-e) and disable (-d) options below. The global flag values for the control are also displayed. If one or more name operands are specified, only those rctls matching the given names is displayed. - This is the default action if no options are specified. -u Configure resource controls based on the contents of /etc/rctladm.conf. Any name operands are ignored.
OPERANDS	The following operands are supported: <i>name</i> The name of the rctl to operate on. You can specify multiple rctl names may be specified. If no names are specified, and the list action has been specified, then all rctls are listed. If the enable or disable action is specified, one or more rctl names must be specified.
EXAMPLES	EXAMPLE 1 Activating System Logging for Specific Violations The following command activates system logging of all violations of task.max-lwps. <pre>example# rctladm -e syslog task.max-lwps example#</pre>

rctladm(1M)

EXAMPLE 2 Examining Current Status of a Specific Resource

The following command examines the current status of the `task.max-lwps` resource.

```
example$ rctladm -l task.max-lwps
task.max-lwps          syslog=DEBUG
example$
```

EXIT STATUS The following exit values are returned:

- 0 Successful completion.
- 1 Fatal error occurred.
- 2 Invalid command line options were specified

FILES `/etc/rctladm.conf` Each time `rctladm` is executed, it updates the contents of `rctladm.conf` with the current configuration.

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWesu

SEE ALSO `setrctl(2)`, `getrctl(2)`, `prctl(1)`, `rctlblk_get_global_flags(3C)`, `rctlblk_get_global_action(3C)`, `attributes(5)`

NOTES The base operating system provides a variety of controls by default:

```
process.max-address-space
process.max-file-descriptor
process.max-core-size
process.max-stack-size
process.max-data-size
process.max-file-size
process.max-cpu-time
```

```
task.max-cpu-time
task.max-lwps
```

```
project.cpu-shares
```

The default properties of the process resource controls are described on `setrlimit(2)`. Task and project resource controls are unenforced by default.

By default, there is no global logging of `rctl` violations.

NAME	rdate – set system date from a remote host				
SYNOPSIS	rdate <i>hostname</i>				
DESCRIPTION	rdate sets the local date and time from the <i>hostname</i> given as an argument. You must have the authorization <code>solaris.system.date</code> on the local system. Typically, rdate is used in a startup script. The inetd daemon responds to rdate requests. To enable inetd response, the lines invoking the time command in <code>inetd.conf</code> must not be commented out.				
USAGE	The rdate command is IPv6-enabled. See <code>ip6(7P)</code> .				
ATTRIBUTES	See <code>attributes(5)</code> for descriptions of the following attributes:				
	<table> <tr> <th>ATTRIBUTE TYPE</th><th>ATTRIBUTE VALUE</th></tr> <tr> <td>Availability</td><td>SUNWrcmdc</td></tr> </table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	Availability	SUNWrcmdc

reboot(1M)

NAME	reboot – restart the operating system
SYNOPSIS	<code>/usr/sbin/reboot</code> [-dlnq] [<i>boot_arguments</i>]
DESCRIPTION	The <code>reboot</code> utility restarts the kernel. The kernel is loaded into memory by the PROM monitor, which transfers control to the loaded kernel. Although <code>reboot</code> can be run by the super-user at any time, <code>shutdown(1M)</code> is normally used first to warn all users logged in of the impending loss of service. See <code>shutdown(1M)</code> for details. The <code>reboot</code> utility performs a <code>sync(1M)</code> operation on the disks, and then a multi-user reboot is initiated. See <code>init(1M)</code> for details. The <code>reboot</code> utility normally logs the reboot to the system log daemon, <code>syslogd(1M)</code>, and places a shutdown record in the login accounting file <code>/var/adm/wtmpx</code>. These actions are inhibited if the <code>-n</code> or <code>-q</code> options are present. Normally, the system reboots itself at power-up or after crashes.
OPTIONS	The following options are supported: <code>-d</code> Force a system crash dump before rebooting. See <code>dumpadm(1M)</code> for information on configuring system crash dumps. <code>-l</code> Suppress sending a message to the system log daemon, <code>syslogd(1M)</code> about who executed <code>reboot</code>. <code>-n</code> Avoid calling <code>sync(2)</code> and do not log the reboot to <code>syslogd(1M)</code> or to <code>/var/adm/wtmpx</code>. The kernel still attempts to sync filesystems prior to reboot, except if the <code>-d</code> option is also present. If <code>-d</code> is used with <code>-n</code>, the kernel does not attempt to sync filesystems. <code>-q</code> Quick. Reboot quickly and ungracefully, without shutting down running processes first.
OPERANDS	The following operands are supported: <i>boot_arguments</i> An optional <i>boot_arguments</i> string can be used to specify arguments to the <code>uadmin(2)</code> function that will be passed to the boot program and kernel upon restart. The form and list of arguments is described in the <code>boot(1M)</code> and <code>kernel(1M)</code> man pages. If multiple arguments are specified, they must be quoted for the shell, as shown in the <code>EXAMPLES</code> section. If the <i>boot_arguments</i> begin with a hyphen, they must be preceded by the <code>--</code> delimiter (two hyphens) to denote the end of the <code>reboot</code> argument list.
EXAMPLES	EXAMPLE 1 Passing the <code>-r</code> and <code>-v</code> Arguments to <code>boot</code> In the following example, the delimiter <code>--</code> (two hyphens) must be used to separate the options of <code>reboot</code> from the arguments of <code>boot(1M)</code>.

EXAMPLE 1 Passing the -r and -v Arguments to boot (Continued)

```
example# reboot -dl -- -rv
```

EXAMPLE 2 Rebooting Using a Specific Disk and Kernel

The following example reboots using a specific disk and kernel. Note that multiple boot arguments are quoted.

```
example# reboot "disk1 kernel.test/unix"
```

FILES /var/adm/wtmpx login accounting file

ATTRIBUTES See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

NOTES The reboot utility does not execute the scripts in /etc/rcnum.d or execute shutdown actions in inittab(4). To ensure a complete shutdown of system services, use shutdown(1M) or init(1M) to reboot a Solaris system.

rem_drv(1M)

NAME	rem_drv – remove a device driver from the system				
SYNOPSIS	rem_drv [-b <i>basedir</i>] <i>device_driver</i>				
DESCRIPTION	The rem_drv command informs the system that the device driver <i>device_driver</i> is no longer valid. If possible, rem_drv unloads <i>device_driver</i> from memory. Entries for the device in the /devices namespace are removed. rem_drv also updates the system driver configuration files. If rem_drv has been executed, the next time the system is rebooted it automatically performs a reconfiguration boot (see kernel(1M)).				
OPTIONS	The following options are supported: -b <i>basedir</i> Sets the path to the root directory of the diskless client. Used on the server to execute rem_drv for a client. The client machine must be rebooted to unload the driver.				
EXAMPLES	EXAMPLE 1 Removing the sd Driver The following example removes the sd driver from use: <pre>example% rem_drv sd</pre> EXAMPLE 2 Removing a Diskless Client The next example removes the driver from the sun1 diskless client. The driver is not uninstalled or unloaded until the client machine is rebooted. <pre>example% rem_drv -b /export/root/sun1 sd</pre>				
ATTRIBUTES	See attributes(5) for descriptions of the following attributes: <table><thead><tr><th>ATTRIBUTE TYPE</th><th>ATTRIBUTE VALUE</th></tr></thead><tbody><tr><td>Availability</td><td>SUNWcsu</td></tr></tbody></table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	Availability	SUNWcsu
ATTRIBUTE TYPE	ATTRIBUTE VALUE				
Availability	SUNWcsu				
SEE ALSO	add_drv(1M) , drvconfig(1M) , kernel(1M) , attributes(5)				

NAME	removef – remove a file from software database
SYNOPSIS	<pre>removef [[-M] -R <i>root_path</i>] [-V <i>fs_file</i>] <i>pkginst path...</i> removef [[-M] -R <i>root_path</i>] [-V <i>fs_file</i>] -f <i>pkginst</i></pre>
DESCRIPTION	removef informs the system that the user, or software, intends to remove a pathname. Output from removef is the list of input pathnames that may be safely removed (no other packages have a dependency on them).
OPTIONS	The following options are supported: -f After all files have been processed, removef should be invoked with the -f option to indicate that the removal phase is complete. -M Instruct removef not to use the <i>\$root_path/etc/vfstab</i> file for determining the client's mount points. This option assumes the mount points are correct on the server and it behaves consistently with Solaris 2.5 and earlier releases. -R <i>root_path</i> Define the full path name of a directory to use as the <i>root_path</i>. All files, including package system information files, are relocated to a directory tree starting in the specified <i>root_path</i>. The <i>root_path</i> may be specified when installing to a client from a server (for example, <i>/export/root/client1</i>). -V <i>fs_file</i> Specify an alternative <i>fs_file</i> to map the client's file systems. For example, used in situations where the <i>\$root_path/etc/vfstab</i> file is non-existent or unreliable.
OPERANDS	The following operands are supported: <i>path</i> The pathname to be removed. <i>pkginst</i> The package instance from which the pathname is being removed.
EXAMPLES	EXAMPLE 1 Using removef The following example uses the removef command in an optional pre-install script: <pre>echo "The following files are no longer part of this package and are being removed." removef \$PKGINST /dev/xt[0-9][0-9][0-9] while read pathname do echo "\$pathname" rm -f \$pathname done removef -f \$PKGINST exit 2</pre>
EXIT STATUS	0 Successful completion. >0 An error occurred.

NAME	repquota – summarize quotas for a ufs file system				
SYNOPSIS	repquota [-v] <i>filesystem</i> ... repquota -a [-v]				
DESCRIPTION	repquota prints a summary of the disk usage and quotas for the specified ufs file systems. The current number of files and amount of space (in kilobytes) is printed for each user along with any quotas created with edquota(1M). The <i>filesystem</i> must have the file quotas in its root directory. Only the super-user may view quotas which are not their own.				
OPTIONS	The following options are supported: -a Report on all mounted ufs file systems that have <i>rq</i> in the <i>mntopts</i> field of the <i>/etc/vfstab</i> file. -v Report quotas for all users, even those who do not consume resources.				
USAGE	See largefile(5) for the description of the behavior of repquota when encountering files greater than or equal to 2 Gbyte (2^{31} bytes).				
ATTRIBUTES	See attributes(5) for descriptions of the following attributes: <table border="1"> <thead> <tr> <th>ATTRIBUTE TYPE</th><th>ATTRIBUTE VALUE</th></tr> </thead> <tbody> <tr> <td>Availability</td><td>SUNWcsu</td></tr> </tbody> </table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	Availability	SUNWcsu

re-preinstall(1M)

NAME	re-preinstall – installs the JumpStart software on a system				
SYNOPSIS	<i>cdrom-mnt-pt/Solaris_XX/Tools/Boot/usr/sbin/install.d/re-preinstall</i> [-m <i>Solaris_boot_dir</i>] [-k <i>platform_name</i>] <i>target-slice</i>				
DESCRIPTION	re-preinstall installs the JumpStart software (preinstall boot image) on a system, so you can power-on the system and have it automatically install the Solaris software (perform a JumpStart installation on the system). When you turn on a re-preinstalled system, the system looks for the JumpStart software on the system's default boot disk. All new SPARC systems have the JumpStart software already preinstalled. The XX in Solaris_XX is the version number of the Solaris release being used. You can use the re-preinstall command in several ways. The most common way is to run re-preinstall on a system to install the JumpStart software on its own default boot disk. This is useful if you want to restore a system to its original factory conditions. (See the first procedure described in EXAMPLES.) You can also run re-preinstall on a system to install JumpStart software on any attached disk (non-boot disk). After you install the JumpStart software on a disk, you can move the disk to a different system and perform a JumpStart installation on the different system. (See the second procedure described in EXAMPLES.) re-preinstall creates a standard file system on the specified <i>target-slice</i> (usually slice 0), and re-preinstall makes sure there is enough space on the <i>target-slice</i> for the JumpStart software. If sufficient space is not available, re-preinstall fails with the following message: <pre>re-preinstall: target-slice too small xx Megabytes required</pre> You can use the format(1M) command to create sufficient space on the <i>target-slice</i> for the JumpStart software.				
OPTIONS	The following options are supported: <table> <tr> <td>-k <i>platform_name</i></td><td>Platform name of the system that will use the disk with the JumpStart software. The default is the platform name of the system running re-preinstall. (Use the uname(1) command (-i option) to determine a system's platform name.)</td></tr> <tr> <td>-m <i>Solaris_boot_dir</i></td><td>Absolute path to the Solaris_XX/Tools/Boot subdirectory of a mounted Solaris CD or a Solaris CD copied to disk that re-preinstall uses to install the JumpStart software. The default is root (/), which is where the Solaris CD is mounted in single-user mode.</td></tr> </table>	-k <i>platform_name</i>	Platform name of the system that will use the disk with the JumpStart software. The default is the platform name of the system running re-preinstall. (Use the uname(1) command (-i option) to determine a system's platform name.)	-m <i>Solaris_boot_dir</i>	Absolute path to the Solaris_XX/Tools/Boot subdirectory of a mounted Solaris CD or a Solaris CD copied to disk that re-preinstall uses to install the JumpStart software. The default is root (/), which is where the Solaris CD is mounted in single-user mode.
-k <i>platform_name</i>	Platform name of the system that will use the disk with the JumpStart software. The default is the platform name of the system running re-preinstall. (Use the uname(1) command (-i option) to determine a system's platform name.)				
-m <i>Solaris_boot_dir</i>	Absolute path to the Solaris_XX/Tools/Boot subdirectory of a mounted Solaris CD or a Solaris CD copied to disk that re-preinstall uses to install the JumpStart software. The default is root (/), which is where the Solaris CD is mounted in single-user mode.				
OPERANDS	The following operands are supported: <table> <tr> <td><i>target-slice</i></td><td>Device name of the disk slice where the JumpStart software will be installed (usually slice 0), for example, c0t3d0s0.</td></tr> </table>	<i>target-slice</i>	Device name of the disk slice where the JumpStart software will be installed (usually slice 0), for example, c0t3d0s0.		
<i>target-slice</i>	Device name of the disk slice where the JumpStart software will be installed (usually slice 0), for example, c0t3d0s0.				

EXAMPLES**EXAMPLE 1** Installing the JumpStart Software on a System's Own Default Boot Disk

The following procedure installs the JumpStart software on a system's own default boot disk:

1. From the `ok` prompt, boot the system from the Solaris media CD or DVD in single-user mode:

```
ok boot cdrom -s
```

2. The following command installs the Jumpstart software on the System default boot disk, `c0t0d0s0` on a Solaris 9 system:

```
example# /usr/sbin/install.d/re-preinstall c0t0d0s1
```

3. Reboot the slice:

```
example# reboot disk:b
```

EXAMPLE 2 Installing the JumpStart Software on a System's Attached (non-boot) Disk

The following procedure installs the JumpStart software on a system's attached (non-boot) disk:

1. Mount the Solaris CD or DVD if `vold(1M)` is not running or CD or DVD is not mounted.
2. Use the `format(1M)` command to determine the target-slice where JumpStart will be installed.
3. Use the `uname(1)` command (`-i` option) to determine the platform name of the system that will use the re-preinstalled disk
4. Run `re-preinstall` with the `-m Solaris_boot_dir` option if the Solaris CD or DVD is not mounted on `/cdrom`.

The following command installs the JumpStart software on the system's attached disk for a system with a Sun4u kernel architecture, and it uses the Solaris CD or DVD mounted with `vold(1M)` on a Solaris 9 system:

```
example# /cdrom/cdrom/s1/usr/bin/install.d/re-preinstall -m
/cdrom/cdrom/s1 -k sun4u c0t2d0s0
```

EXIT STATUS

The following exit values are returned:

0	Successful completion.
1	An error has occurred.

Solaris 9 9/04 Installation Guide

NAME	rmmount – removable media mounter for CD-ROM, floppy, Jaz drive, and others
SYNOPSIS	<code>/usr/sbin/rmmount [-D]</code>
DESCRIPTION	The rmmount utility is a removable media mounter that is executed by Volume Management whenever a removable medium, such as a CD-ROM or a floppy, is inserted. The Volume Management daemon, <code>vold(1M)</code>, manages removable media. rmmount can also be called by using <code>volrmmount(1)</code>. Upon insertion of a medium and following invocation of the <code>volcheck(1)</code> command, rmmount determines what type of file system (if any) is on that medium. If a file system is present, rmmount mounts the file system in one of the locations listed below. For a diskette (floppy): <code>/floppy/floppy0</code> symbolic link to mounted floppy in local floppy drive <code>/floppy/floppy_name</code> mounted named floppy <code>/floppy/unnamed_floppy</code> mounted unnamed floppy For a CD-ROM or a DVD-ROM: <code>/cdrom/cdrom0</code> symbolic link to mounted CD-ROM in local CD-ROM drive <code>/cdrom/CD-ROM_name</code> mounted named CD-ROM <code>/cdrom/CD-ROM_name/partition</code> mounted named CD-ROM with partitioned file system <code>/cdrom/unnamed_cdrom</code> mounted unnamed CD-ROM For a Zip drive: <code>/rmdisk/zip0</code> symbolic link to mounted Zip medium in local Zip drive <code>/rmdisk/Zip_name</code> mounted named Zip medium <code>/rmdisk/Zip_name/partition</code> mounted named Zip medium with partitioned file system <code>/rmdisk/unnamed_zip</code> mounted unnamed Zip medium For a Jaz drive:

rmmount(1M)

`/rmdisk/jaz0`
symbolic link to mounted Jaz medium in local Jaz drive

`/rmdisk/Jaz_name`
mounted named Jaz medium

`/rmdisk/Jaz_name/partition`
mounted named Jaz medium with partitioned file system

`/rmdisk/unnamed_Jaz`
mounted unnamed Jaz medium

For a generic “rmdisk” drive:

`/rmdisk/rmdisk0`
symbolic link to mounted removable medium in local removable medium drive

`/rmdisk/rmdisk_name`
mounted named removable medium

`/rmdisk/rmdisk_name/partition`
mounted named removable medium with partitioned file system

`/rmdisk/unnamed_rmdisk`
mounted unnamed removable medium

If the media is read-only (for example, a CD-ROM or a floppy with write-protect tab set), the file system is mounted read-only.

If a file system is not identified, `rmmount` does not mount a file system. See the *System Administration Guide: Basic Administration* for more information on the location of CD-ROM, floppy, and other media without file systems. Also see `volfs(7FS)`.

If a file system type has been determined, it is then checked to see that it is “clean.” If the file system is “dirty,” `fsck -p` (see `fsck(1M)`) is run in an attempt to clean it. If `fsck` fails, the file system is mounted read-only.

After the mount is complete, “actions” associated with the media type are executed. These actions allow for the notification to other programs that new media are available. These actions are shared objects and are described in the configuration file, `/etc/rmmount.conf`. See `rmmount.conf(4)`.

Actions are executed in the order in which they appear in the configuration file. The action function can return either 1 or 0. If it returns 0, no further actions will be executed. This allows the function to control which applications are executed.

In order to execute an action, `rmmount` performs a `dlopen(3DL)` on the shared object and calls the action function defined within it. The definition of the interface to actions can be found in `/usr/include/rmmount.h`.

File systems mounted by `rmmount` are always mounted with the `nosuid` flag set, thereby disabling `setuid` programs and access to block or character devices in that file system. Upon ejection, `rmmount` unmounts mounted file systems and executes actions associated with the media type. If a file system is “busy” (that is, it contains the current working directory of a live process), the ejection will fail.

OPTIONS `-D` Turn on the debugging output from the `rmmount` `dprintf` calls.

FILES `/etc/rmmount.conf` removable media mounter configuration file
 `/usr/lib/rmmount/*.so.1` shared objects used by `rmmount`.

System Administration Guide: Basic Administration

rmt(1M)

NAME	rmt – remote magtape protocol module												
SYNOPSIS	<code>/usr/sbin/rmt</code>												
DESCRIPTION	rmt is a program used by the remote dump and restore programs in manipulating a magnetic tape drive through an interprocess communication connection. rmt is normally started up with an <code>rexec(3SOCKET)</code> or <code>rcmd(3SOCKET)</code> call. The rmt program accepts requests that are specific to the manipulation of magnetic tapes, performs the commands, then responds with a status indication. All responses are in ASCII and in one of two forms. Successful commands have responses of: <i>A</i><code>number</code><code>\n</code> where <i>number</i> is an ASCII representation of a decimal number. Unsuccessful commands are responded to with: <i>E</i><code>error-number</code><code>\n</code><i>e</i><code>error-message</code><code>\n</code> where <i>error-number</i> is one of the possible error numbers described in <code>intro(3)</code>, and <i>error-message</i> is the corresponding error string as printed from a call to <code>perror(3C)</code>. The protocol consists of the following commands: <table><tr><td><i>S</i><code>\n</code></td><td>Return the status of the open device, as obtained with a <code>MTIOCGET</code> <code>ioctl</code> call. If the operation was successful, an “ack” is sent with the size of the status buffer, then the status buffer is sent (in binary).</td></tr><tr><td><i>C</i><code>device</code><code>\n</code></td><td>Close the currently open device. The <i>device</i> specified is ignored.</td></tr><tr><td><i>I</i><code>operation</code><code>\n</code><i>c</i><code>ount</code><code>\n</code></td><td>Perform a <code>MTIOCOP</code> <code>ioctl</code>(2) command using the specified parameters. The parameters are interpreted as the ASCII representations of the decimal values to place in the <i>mt_op</i> and <i>mt_count</i> fields of the structure used in the <code>ioctl</code> call. When the operation is successful the return value is the <i>count</i> parameter.</td></tr><tr><td><i>L</i><code>ffset</code><code>\n</code><i>w</i><code>hence</code><code>\n</code></td><td>Perform an <code>lseek</code>(2) operation using the specified parameters. The response value is returned from the <code>lseek</code> call.</td></tr><tr><td><i>O</i><code>device</code><code>\n</code><i>m</i><code>ode</code><code>\n</code></td><td>Open the specified <i>device</i> using the indicated <i>mode</i>. <i>device</i> is a full pathname, and <i>mode</i> is an ASCII representation of a decimal number suitable for passing to <code>open</code>(9E). If a device is already open, it is closed before a new open is performed.</td></tr><tr><td><i>R</i><code>count</code><code>\n</code></td><td>Read <i>count</i> bytes of data from the open device. rmt performs the requested <code>read</code>(9E) and responds with <i>A</i><code>count-read</code><code>\n</code> if the read was successful; otherwise an</td></tr></table>	<i>S</i> <code>\n</code>	Return the status of the open device, as obtained with a <code>MTIOCGET</code> <code>ioctl</code> call. If the operation was successful, an “ack” is sent with the size of the status buffer, then the status buffer is sent (in binary).	<i>C</i> <code>device</code> <code>\n</code>	Close the currently open device. The <i>device</i> specified is ignored.	<i>I</i> <code>operation</code> <code>\n</code> <i>c</i> <code>ount</code> <code>\n</code>	Perform a <code>MTIOCOP</code> <code>ioctl</code> (2) command using the specified parameters. The parameters are interpreted as the ASCII representations of the decimal values to place in the <i>mt_op</i> and <i>mt_count</i> fields of the structure used in the <code>ioctl</code> call. When the operation is successful the return value is the <i>count</i> parameter.	<i>L</i> <code>ffset</code> <code>\n</code> <i>w</i> <code>hence</code> <code>\n</code>	Perform an <code>lseek</code> (2) operation using the specified parameters. The response value is returned from the <code>lseek</code> call.	<i>O</i> <code>device</code> <code>\n</code> <i>m</i> <code>ode</code> <code>\n</code>	Open the specified <i>device</i> using the indicated <i>mode</i> . <i>device</i> is a full pathname, and <i>mode</i> is an ASCII representation of a decimal number suitable for passing to <code>open</code> (9E). If a device is already open, it is closed before a new open is performed.	<i>R</i> <code>count</code> <code>\n</code>	Read <i>count</i> bytes of data from the open device. rmt performs the requested <code>read</code> (9E) and responds with <i>A</i> <code>count-read</code> <code>\n</code> if the read was successful; otherwise an
<i>S</i> <code>\n</code>	Return the status of the open device, as obtained with a <code>MTIOCGET</code> <code>ioctl</code> call. If the operation was successful, an “ack” is sent with the size of the status buffer, then the status buffer is sent (in binary).												
<i>C</i> <code>device</code> <code>\n</code>	Close the currently open device. The <i>device</i> specified is ignored.												
<i>I</i> <code>operation</code> <code>\n</code> <i>c</i> <code>ount</code> <code>\n</code>	Perform a <code>MTIOCOP</code> <code>ioctl</code> (2) command using the specified parameters. The parameters are interpreted as the ASCII representations of the decimal values to place in the <i>mt_op</i> and <i>mt_count</i> fields of the structure used in the <code>ioctl</code> call. When the operation is successful the return value is the <i>count</i> parameter.												
<i>L</i> <code>ffset</code> <code>\n</code> <i>w</i> <code>hence</code> <code>\n</code>	Perform an <code>lseek</code> (2) operation using the specified parameters. The response value is returned from the <code>lseek</code> call.												
<i>O</i> <code>device</code> <code>\n</code> <i>m</i> <code>ode</code> <code>\n</code>	Open the specified <i>device</i> using the indicated <i>mode</i> . <i>device</i> is a full pathname, and <i>mode</i> is an ASCII representation of a decimal number suitable for passing to <code>open</code> (9E). If a device is already open, it is closed before a new open is performed.												
<i>R</i> <code>count</code> <code>\n</code>	Read <i>count</i> bytes of data from the open device. rmt performs the requested <code>read</code> (9E) and responds with <i>A</i> <code>count-read</code> <code>\n</code> if the read was successful; otherwise an												

rmt(1M)

error in standard format is returned. If the read was successful, the data read is sent.

wcount \n

Write data onto the open device. *rmt* reads *count* bytes from the connection, aborting if a premature EOF is encountered. The response value is returned from the *write(9E)* call.

Any other command causes *rmt* to exit.

ATTRIBUTES See *attributes(5)* for descriptions of the following attributes:

SEE ALSO *ufsdump(1M)*, *ufsrestore(1M)*, *intro(3)*, *ioctl(2)*, *lseek(2)*, *perror(3C)*, *rcmd(3SOCKET)*, *rexec(3SOCKET)*, *attributes(5)*, *mtio(7I)*, *open(9E)*, *read(9E)*, *write(9E)*

DIAGNOSTICS All responses are of the form described above.

BUGS Do not use this for a remote file access protocol.

roleadd(1M)

NAME	roleadd – administer a new role account on the system
SYNOPSIS	<pre> roleadd [-c <i>comment</i>] [-d <i>dir</i>] [-e <i>expire</i>] [-f <i>inactive</i>] [-g <i>group</i>] [-G <i>group</i> [, <i>group</i>...]] [-m [-k <i>skel_dir</i>]] [-u <i>uid</i> [-o]] [-s <i>shell</i>] [-A <i>authorization</i> [, <i>authorization</i>...]] <i>role</i> roleadd -D [-b <i>base_dir</i>] [-e <i>expire</i>] [-f <i>inactive</i>] [-g <i>group</i>] [-A <i>authorization</i> [, <i>authorization</i>...]] [-P <i>profile</i> [, <i>profile</i>...]] </pre>
DESCRIPTION	roleadd adds a role entry to the <code>/etc/passwd</code> and <code>/etc/shadow</code> and <code>/etc/user_attr</code> files. The <code>-A</code> and <code>-P</code> options respectively assign authorizations and profiles to the role. Roles cannot be assigned to other roles. roleadd also creates supplementary group memberships for the role (<code>-G</code> option) and creates the home directory (<code>-m</code> option) for the role if requested. The new role account remains locked until the <code>passwd(1)</code> command is executed. Specifying <code>roleadd -D</code> with the <code>-g</code>, <code>-b</code>, <code>-f</code>, or <code>-e</code> option (or any combination of these option) sets the default values for the respective fields. See the <code>-D</code> option. Subsequent <code>roleadd</code> commands without the <code>-D</code> option use these arguments. The system file entries created with this command have a limit of 512 characters per line. Specifying long arguments to several options can exceed this limit. The role (<code>role</code>) field accepts a string of no more than eight bytes consisting of characters from the set of alphabetic characters, numeric characters, period (<code>.</code>), underscore (<code>_</code>), and hyphen (<code>-</code>). The first character should be alphabetic and the field should contain at least one lower case alphabetic character. A warning message will be written if these restrictions are not met. A future Solaris release may refuse to accept role fields that do not meet these requirements. The <code>role</code> field must contain at least one character and must not contain a colon (<code>:</code>) or a newline (<code>\n</code>).
OPTIONS	The following options are supported: <code>-A <i>authorization</i></code> One or more comma separated authorizations defined in <code>auth_attr(4)</code>. Only a user or role who has grant rights to the authorization can assign it to an account <code>-b <i>base_dir</i></code> The default base directory for the system if <code>-d <i>dir</i></code> is not specified. <i>base_dir</i> is concatenated with the account name to define the home directory. If the <code>-m</code> option is not used, <i>base_dir</i> must exist. <code>-c <i>comment</i></code> Any text string. It is generally a short description of the role. This information is stored in the role's <code>/etc/passwd</code> entry. <code>-d <i>dir</i></code> The home directory of the new role. It defaults to <i>base_dir/account_name</i>, where <i>base_dir</i> is the base directory for new login home directories and <i>account_name</i> is the new role name.

-D	Display the default values for <i>group</i>, <i>base_dir</i>, <i>skel_dir</i>, <i>shell</i>, <i>inactive</i>, and <i>expire</i>. When used with the <i>-g</i>, <i>-b</i>, or <i>-f</i> options, the <i>-D</i> option sets the default values for the specified fields. The default values are: <table> <tr> <td><i>group</i></td><td>other (GID of 1)</td></tr> <tr> <td><i>base_dir</i></td><td>/home</td></tr> <tr> <td><i>skel_dir</i></td><td>/etc/skel</td></tr> <tr> <td><i>shell</i></td><td>/bin/sh</td></tr> <tr> <td><i>inactive</i></td><td>0</td></tr> <tr> <td><i>expire</i></td><td>Null</td></tr> <tr> <td><i>auths</i></td><td>Null</td></tr> <tr> <td><i>profiles</i></td><td>Null</td></tr> </table>	<i>group</i>	other (GID of 1)	<i>base_dir</i>	/home	<i>skel_dir</i>	/etc/skel	<i>shell</i>	/bin/sh	<i>inactive</i>	0	<i>expire</i>	Null	<i>auths</i>	Null	<i>profiles</i>	Null
<i>group</i>	other (GID of 1)																
<i>base_dir</i>	/home																
<i>skel_dir</i>	/etc/skel																
<i>shell</i>	/bin/sh																
<i>inactive</i>	0																
<i>expire</i>	Null																
<i>auths</i>	Null																
<i>profiles</i>	Null																
-e <i>expire</i>	Specify the expiration date for a role. After this date, no user will be able to access this role. The <i>expire</i> option argument is a date entered using one of the date formats included in the template file <i>/etc/datemsk</i>. See <i>getdate(3C)</i>. If the date format that you choose includes spaces, it must be quoted. For example, you can enter <i>10/6/90</i> or <i>"October 6, 1990"</i>. A null value (<i>" "</i>) defeats the status of the expired date. This option is useful for creating temporary roles.																
-f <i>inactive</i>	The maximum number of days allowed between uses of a role ID before that ID is declared invalid. Normal values are positive integers. A value of 0 defeats the status.																
-g <i>group</i>	An existing group's integer ID or character-string name. Without the <i>-D</i> option, it defines the new role's primary group membership and defaults to the default group. You can reset this default value by invoking <i>roleadd -D -g group</i>.																
-G <i>group</i>	An existing group's integer ID or character-string name. It defines the new role's supplementary group membership. Duplicates between <i>group</i> with the <i>-g</i> and <i>-G</i> options are ignored. No more than <i>NGROUPS_MAX</i> groups can be specified.																
-k <i>skel_dir</i>	A directory that contains skeleton information (such as <i>.profile</i>) that can be copied into a new role's home directory. This directory must already exist. The system provides the <i>/etc/skel</i> directory that can be used for this purpose.																
-m	Create the new role's home directory if it does not already exist. If the directory already exists, it must have read, write, and execute permissions by <i>group</i>, where <i>group</i> is the role's primary group.																

roleadd(1M)

- o This option allows a UID to be duplicated (non-unique).
- P *profile* One or more comma-separated execution profiles defined in `prof_attr(4)`.
- s *shell* Full pathname of the program used as the user's shell on login. It defaults to an empty field causing the system to use `/bin/sh` as the default. The value of *shell* must be a valid executable file.
- u *uid* The UID of the new role. This UID must be a non-negative decimal integer below `MAXUID` as defined in `<sys/param.h>`. The UID defaults to the next available (unique) number above the highest number currently assigned. For example, if UIDs 100, 105, and 200 are assigned, the next default UID number will be 201. (UIDs from 0-99 are reserved for possible use in future applications.)

FILES

- `/etc/datemsk`
- `/etc/passwd`
- `/etc/shadow`
- `/etc/group`
- `/etc/skel`
- `/usr/include/limits.h`
- `/etc/user_attr`

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

SEE ALSO `passwd(1)`, `profiles(1)`, `roles(1)`, `users(1B)`, `groupadd(1M)`, `groupdel(1M)`, `groupmod(1M)`, `grpck(1M)`, `logins(1M)`, `pwck(1M)`, `userdel(1M)`, `usermod(1M)`, `getdate(3C)`, `auth_attr(4)`, `passwd(4)`, `prof_attr(4)`, `user_attr(4)`, `attributes(5)`

DIAGNOSTICS In case of an error, `roleadd` prints an error message and exits with a non-zero status.

The following indicates that login specified is already in use:

UX: `roleadd: ERROR: login is already in use. Choose another.`

The following indicates that the *uid* specified with the `-u` option is not unique:

UX: `roleadd: ERROR: uid uid is already in use. Choose another.`

The following indicates that the *group* specified with the *-g* option is already in use:

```
UX: roleadd: ERROR: group group does not exist. Choose another.
```

The following indicates that the *uid* specified with the *-u* option is in the range of reserved UIDs (from 0-99):

```
UX: roleadd: WARNING: uid uid is reserved.
```

The following indicates that the *uid* specified with the *-u* option exceeds MAXUID as defined in *<sys/param.h>*:

```
UX: roleadd: ERROR: uid uid is too big. Choose another.
```

The following indicates that the */etc/passwd* or */etc/shadow* files do not exist:

```
UX: roleadd: ERROR: Cannot update system files - login cannot be created.
```

NOTES If a network nameservice such as NIS or NIS+ is being used to supplement the local */etc/passwd* file with additional entries, *roleadd* cannot change information supplied by the network nameservice.

roledel(1M)

NAME	roledel – delete a role’s login from the system					
SYNOPSIS	roledel [-r] <i>role</i>					
DESCRIPTION	The roledel utility deletes a role account from the system and makes the appropriate account-related changes to the system file and file system. roledel also removes the role from each user’s list of assumable roles.					
OPTIONS	The following options are supported: -r Remove the role’s home directory from the system. This directory must exist. The files and directories under the home directory will no longer be accessible following successful execution of the command.					
OPERANDS	The following operands are supported: <i>role</i> An existing role name to be deleted.					
EXIT STATUS	The following exit values are returned: 0 Successful completion. 2 Invalid command syntax. A usage message for the roledel command is displayed. 6 The account to be removed does not exist. 8 The account to be removed is in use. 10 Cannot update the <i>/etc/group</i> or <i>/etc/user_attr</i> file but the login is removed from the <i>/etc/passwd</i> file. 12 Cannot remove or otherwise modify the home directory.					
FILES	<i>/etc/passwd</i>	system password file				
	<i>/etc/shadow</i>	system file containing roles’ encrypted passwords and related information				
	<i>/etc/group</i>	system file containing group definitions				
	<i>/etc/user_attr</i>	system file containing additional role attributes				
ATTRIBUTES	See attributes(5) for descriptions of the following attributes:					
	<table><tr><th>ATTRIBUTE TYPE</th><th>ATTRIBUTE VALUE</th></tr><tr><td>Availability</td><td>SUNWcsu</td></tr></table>		ATTRIBUTE TYPE	ATTRIBUTE VALUE	Availability	SUNWcsu
ATTRIBUTE TYPE	ATTRIBUTE VALUE					
Availability	SUNWcsu					

roledel(1M)

SEE ALSO auths(1), passwd(1), profiles(1), roles(1), users(1B), groupadd(1M), groupdel(1M), groupmod(1M), logins(1M), roleadd(1M), rolemod(1M), useradd(1M), userdel(1M), usermod(1M), passwd(4), prof_attr(4), user_attr(4), attributes(5)

NOTES The roledel utility only deletes an account definition that is in the local /etc/group, /etc/passwd, /etc/shadow, and /etc/user_attr file. If a network name service such as NIS or NIS+ is being used to supplement the local /etc/passwd file with additional entries, roledel cannot change information supplied by the network name service.

rolemod(1M)

NAME	rolemod – modify a role’s login information on the system
SYNOPSIS	rolemod [<i>-u uid</i> [<i>-o</i>]] [<i>-g group</i>] [<i>-G group</i> [<i>,</i> <i>group...</i>]] [<i>-d dir</i> [<i>-m</i>]] [<i>-s shell</i>] [<i>-c comment</i>] [<i>-l new_name</i>] [<i>-f inactive</i>] [<i>-e expire</i>] [<i>-A authorization</i> [<i>,</i> <i>authorization</i>]] [<i>-P profile</i> [<i>,</i> <i>profile</i>]] <i>role</i>
DESCRIPTION	The rolemod utility modifies a role’s login information on the system. It changes the definition of the specified login and makes the appropriate login-related system file and file system changes. The system file entries created with this command have a limit of 512 characters per line. Specifying long arguments to several options may exceed this limit.
OPTIONS	The following options are supported: <i>-A authorization</i> One or more comma separated authorizations as defined in <code>auth_attr(4)</code>. Only role with grant rights to the <i>authorization</i> can assign it to an account. This replaces any existing authorization setting. <i>-c comment</i> Specify a comment string. <i>comment</i> can be any text string. It is generally a short description of the login, and is currently used as the field for the user’s full name. This information is stored in the user’s <code>/etc/passwd</code> entry. <i>-d dir</i> Specify the new home directory of the role. It defaults to <i>base_dir/login</i>, where <i>base_dir</i> is the base directory for new login home directories, and <i>login</i> is the new login. <i>-e expire</i> Specify the expiration date for a role. After this date, no role will be able to access this login. The expire option argument is a date entered using one of the date formats included in the template file <code>/etc/datemsk</code>. See <code>getdate(3C)</code>. - For example, you may enter <code>10/6/90</code> or <code>October 6, 1990</code>. A value of <code>''''</code> defeats the status of the expired date. <i>-f inactive</i> Specify the maximum number of days allowed between uses of a login ID before that login ID is declared invalid. Normal values are positive integers. A value of 0 defeats the status. <i>-g group</i> Specify an existing group’s integer ID or character-string name. It redefines the role’s primary group membership. <i>-G group</i> Specify an existing group’s integer "ID" <i>,</i> or character string name. It redefines the role’s supplementary

	group membership. Duplicates between <i>group</i> with the -g and -G options are ignored. No more than NGROUPS_UMAX groups may be specified as defined in <param.h>.
-l <i>new_logname</i>	Specify the new login name for the role. The <i>new_logname</i> argument is a string no more than eight bytes consisting of characters from the set of alphabetic characters, numeric characters, period (.), underline (_), and hyphen (-). The first character should be alphabetic and the field should contain at least one lower case alphabetic character. A warning message will be written if these restrictions are not met. A future Solaris release may refuse to accept login fields that do not meet these requirements. The <i>new_logname</i> argument must contain at least one character and must not contain a colon (:) or NEWLINE (\n).
-m	Move the role's home directory to the new directory specified with the -d option. If the directory already exists, it must have permissions read/write/execute by <i>group</i> , where <i>group</i> is the role's primary group.
-o	This option allows the specified UID to be duplicated (non-unique).
-P <i>profile</i>	One or more comma-separated execution profiles defined in <code>auth_attr(4)</code> . This replaces any existing profile setting.
-s <i>shell</i>	Specify the full pathname of the program that is used as the role's shell on login. The value of <i>shell</i> must be a valid executable file.
-u <i>uid</i>	Specify a new UID for the role. It must be a non-negative decimal integer less than MAXUID as defined in <param.h>. The UID associated with the role's home directory is not modified with this option; a role will not have access to their home directory until the UID is manually reassigned using <code>chown(1M)</code> .
OPERANDS	The following operands are supported: login An existing login name to be modified.
EXIT STATUS	In case of an error, <code>rolemod</code> prints an error message and exits with one of the following values: 2 The command syntax was invalid. A usage message for the <code>rolemod</code> command is displayed. 3 An invalid argument was provided to an option.

rolemod(1M)

- 4 The *uid* given with the *-u* option is already in use.
- 5 The password files contain an error. *pwconv*(1M) can be used to correct possible errors. See *passwd*(4).
- 6 The login to be modified does not exist, the *group* does not exist, or the login shell does not exist.
- 8 The login to be modified is in use.
- 9 The *new_logname* is already in use.
- 10 Cannot update the */etc/group* or */etc/user_attr* file. Other update requests will be implemented.
- 11 Insufficient space to move the home directory (*-m* option). Other update requests will be implemented.
- 12 Unable to complete the move of the home directory to the new home directory.

FILES	<i>/etc/group</i>	system file containing group definitions
	<i>/etc/datmsk</i>	system file of date formats
	<i>/etc/passwd</i>	system password file
	<i>/etc/shadow</i>	system file containing users' and roles' encrypted passwords and related information
	<i>/etc/usr_attr</i>	system file containing additional user and role attributes

NAME	route – manually manipulate the routing tables
SYNOPSIS	<pre> route [-fnvq] <i>sub-command</i> [[<i>modifiers</i>] <i>args</i>] route [-fnvq] add delete [<i>modifiers</i>] <i>destination gateway</i> [<i>args</i>] route [-fnvq] change get [<i>modifiers</i>] <i>destination</i> [<i>gateway</i> [<i>args</i>]] route [-fn] monitor [<i>modifiers</i>] route [-fnvq] flush [<i>modifiers</i>] </pre>
DESCRIPTION	route manually manipulates the network routing tables. These tables are normally maintained by the system routing daemon, such as <code>in.routed(1M)</code> and <code>in.ripngd(1M)</code>. route supports a limited number of general options, but a rich command language. Users can specify an arbitrary request that can be delivered by means of the programmatic interface discussed in <code>route(7P)</code>. route uses a routing socket and the new message types RTM_ADD, RTM_DELETE, RTM_GET, and RTM_CHANGE. Only superusers can modify routing tables.
OPTIONS	<pre> -f Flush the routing tables of all gateway entries. If you use the -f option in conjunction with any of the route sub-commands, route flushes the gateways before performing the sub-command. Specify the table to flush by placing the -inet or -inet6 modifier immediately after the -f option. If unspecified, flushing IPv4 (-inet) routes is the default. -n Prevent attempts to print host and network names symbolically when reporting actions. This option is useful when name servers are unavailable. -v Print additional details in verbose mode. -q Suppress all output. </pre>
Sub-commands	The following sub—commands are supported: <pre> add Add a route. change Change aspects of a route (such as its gateway). delete Delete a specific route. flush Remove all gateway entries from the routing table. get Look up and display the route for a destination. monitor Continuously report any changes to the routing information base, routing lookup misses, or suspected network partitionings. </pre> The add and delete sub-commands have the following syntax: <pre> route [-fnvq] cmd <i>destination gateway</i> [metric/netmask] </pre>

route(1M)

where *cmd* is `add` or `delete`, *destination* is the destination host or network, and *gateway* is the next-hop intermediary through which packets should be routed. Modifiers described in OPERANDS can be placed anywhere on the command line.

The `get` and `change` sub-commands have the following syntax:

```
route [ -fnvq ] cmd destination [gateway [metric/netmask]]
```

where *cmd* is `get` or `change`, *destination* is the destination host or network, and *gateway* is the next-hop intermediary through which packets should be routed. Modifiers described in OPERANDS can be placed anywhere on the command line.

The `monitor` sub-command has the following syntax:

```
route monitor [ -inet | -inet6 ]
```

OPERANDS

`route` executes its sub-commands on routes to destinations by way of gateways.

Destinations and Gateways

By default, destination and gateway addresses are interpreted as IPv4 addresses. All symbolic names are tried first as a host name, using `getipnodebyname(3SOCKET)`. If this lookup fails in the `AF_INET` case, `getnetbyname(3SOCKET)` interprets the name as that of a network.

Including an optional modifier on the command line before the address changes how the `route` sub-command interprets it.

The following modifiers are supported:

<code>-inet</code>	Force the address to be interpreted as an IPv4 address, that is, under the <code>AF_INET</code> address family.
<code>-inet6</code>	Force the address to be interpreted as an IPv6 address, that is, under the <code>AF_INET6</code> address family.

For IPv4 addresses, routes to a particular host are by default distinguished from those to a network by interpreting the Internet address specified as the destination. If the destination has a *local address part* (that is, the portion not covered by the netmask) of 0, or if the destination is resolved as the symbolic name of a network, then the route is assumed to be to a network; otherwise, it is presumed to be a route to a host.

You can force this selection by using one of the following modifiers:

<code>-host</code>	Force the destination to be interpreted as a host.
<code>-net</code>	Force the destination to be interpreted as a network.

For example:

Destination	Destination Equivalent
128.32	-host 128.0.0.32

Destination	Destination Equivalent
128.32.130	- host 128.32.0.130
-net 128.32	128.32.0.0
-net 128.32.130	128.32.130.0

Two modifiers avoid confusion between addresses and keywords (for example., *host* used as a symbolic host name). You can distinguish a *destination* by preceding it with the `-dst` modifier. You can distinguish a gateway address by using the `-gateway` modifier. If the destination is directly reachable by way of an interface requiring no intermediary IP router to act as a gateway, this can be indicated by using the `-interface` or `-iface` modifier.

In the following example, the route does not refer to an external gateway (router), but rather to one of the machine's interfaces. Packets with IP destination addresses matching the destination and mask on such a route are sent out on the interface identified by the gateway address. For interfaces using the ARP protocol, this type of route is used to specify that all matching destinations are local to the physical link. That is, a host could be configured to ARP for all addresses, without regard to the configured interface netmask, by adding a default route using this command. For example:

```
example# route add default hostname -interface
```

where gateway address *hostname* is the name or IP address associated with the network interface over which all matching packets should be sent. On a host with a single network interface, *hostname* is usually the same as the *nodename* returned by the `uname -n` command. See `uname(1)`.

For backward compatibility with older systems, directly reachable routes can also be specified by placing a 0 after the gateway address:

```
example# route add default hostname 0
```

This value was once a route metric, but this metric is no longer used. If the value is specified as 0, then the destination is directly reachable (equivalent to specifying `-interface`). If it is non-zero but cannot be interpreted as a subnet mask, then a gateway is used (default).

With the `AF_INET` address family or an IPv4 address, a separate subnet mask can be specified. This can be specified in one of the following ways:

- IP address following the gateway address . This is typically specified in *decimal dot* notation as for `inet_addr(3SOCKET)` rather than in symbolic form.
- IP address following the `-netmask` qualifier.
- Slash character and a decimal length appended to the destination address.

route(1M)

If a subnet mask is not specified, the mask used is the subnet mask of the output interface selected by the gateway address, if the classful network of the destination is the same as the classful network of the interface. Otherwise, the classful network mask for the destination address is used.

Each of the following examples creates an IPv4 route to the destination 192.0.2.32 subnet with a subnet mask of 255.255.255.224:

```
example# route add 192.0.2.32/27 somegateway
example# route add 192.0.2.32 -netmask 255.255.255.224 somegateway
example# route add 192.0.2.32 somegateway 255.255.255.224
```

For IPv6, only the slash format is accepted. The following example creates an IPv6 route to the destination 33fe:: with a netmask of 16 one-bits followed by 112 zero-bits.

```
example# route add -inet6 3ffe::/16 somegateway
```

In cases where the gateway does not uniquely identify the output interface (for example, when several interfaces have the same address), you can use the `-ifp ifname` modifier to specify the interface by name. For example, `-ifp lo0` associates the route with the `lo0` interface.

Routing Flags

Routes have associated flags that influence operation of the protocols when sending to destinations matched by the routes. These flags can be set (and in some cases cleared, indicated by `~`) by including the following modifiers on the command line:

Modifier	Flag	Description
<code>-interface</code>	<code>~RTF_GATEWAY</code>	Destination is directly reachable
<code>-iface</code>	<code>~RTF_GATEWAY</code>	Alias for interface modifier
<code>-static</code>	<code>RTF_STATIC</code>	Manually added route
<code>-nostatic</code>	<code>~RTF_STATIC</code>	Pretend route was added by kernel or routing daemon
<code>-reject</code>	<code>RTF_REJECT</code>	Emit an ICMP unreachable when matched
<code>-blackhole</code>	<code>RTF_BLACKHOLE</code>	Silently discard packets during updates
<code>-proto1</code>	<code>RTF_PROTO1</code>	Set protocol specific routing flag #1
<code>-proto2</code>	<code>RTF_PROTO2</code>	Set protocol specific routing flag #2
<code>-private</code>	<code>RTF_PRIVATE</code>	Do not advertise this route
<code>-multirt</code>	<code>RTF_MULTIRT</code>	Creates the specified redundant route
<code>-setsrc</code>	<code>RTF_SETSRC</code>	Assigns the default source address

The optional modifiers `-rtt`, `-rttvar`, `-sendpipe`, `-recvpipe`, `-mtu`, `-hopcount`, `-expire`, and `-sssthresh` provide initial values to quantities maintained in the routing entry by transport level protocols, such as TCP. These can be individually locked either by preceding each modifier to be locked by the `-lock` meta-modifier, or by specifying that all ensuing metrics can be locked by the `-lockrest` meta-modifier.

Some transport layer protocols can support only some of these metrics. The following optional modifiers are supported:

<code>-expire</code>	Lifetime for the entry. This optional modifier is not currently supported.
<code>-hopcount</code>	Maximum hop count. This optional modifier is not currently supported.
<code>-mtu</code>	Maximum MTU in bytes.
<code>-recvpipe</code>	Receive pipe size in bytes.
<code>-rtt</code>	Round trip time in microseconds.
<code>-rttvar</code>	Round trip time variance in microseconds.
<code>-sendpipe</code>	Send pipe size in bytes.
<code>-sssthresh</code>	Send pipe size threshold in bytes.

Compatibility

The modifiers `host` and `net` are taken to be equivalent to `-host` and `-net`. To specify a symbolic address that matches one of these names, use the `dst` or `gateway` keyword to distinguish it. For example: `-dst host`

The following two flags are also accepted for compatibility with older systems, but have no effect.

Modifier	Flag
<code>-cloning</code>	RTF_CLONING
<code>-xresolve</code>	RTF_XRESOLVE

The `-ifa hostname` modifier is also accepted, but has no effect.

FILES

<code>/etc/defaultrouter</code>	List of default routers
<code>/etc/hosts</code>	List of host names and net addresses
<code>/etc/networks</code>	List of network names and addresses

route(1M)

ATTRIBUTES

See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

SEE ALSO

uname(1), in.ripngd(1M), in.routed(1M), netstat(1M), routed(1M), ioctl(2), getipnodebyname(3SOCKET), getnetbyname(3SOCKET), inet_addr(3SOCKET), defaultrouter(4), hosts(4), networks(4), attributes(5), ARP(7P), ip(7P), route(7P), routing(7P)

DIAGNOSTICS

`add [ host | network ] destination:gateway flags`

The specified route is being added to the tables. The values printed are from the routing table entry supplied in the `ioctl(2)` call. If the gateway address used was not the primary address of the gateway (the first one returned by `getipnodebyname(3SOCKET)`) the gateway address is printed numerically as well as symbolically.

`delete [ host | network ] destination:gateway flags`

`change [ host | network ] destination:gateway flags`

As `add`, but when deleting or changing an entry.

destination done

When the `-f` flag is specified, or the `flush` sub-command is used, each routing table entry deleted is indicated with a message of this form.

Network is unreachable

An attempt to add a route failed because the gateway listed was not on a directly-connected network. Give the next-hop gateway instead.

not in table

A `delete` operation was attempted for an entry that is not in the table.

entry exists

An `add` operation was attempted for a route that already exists in the kernel.

routing table overflow

An operation was attempted, but the system was unable to allocate memory to create the new entry.

NOTES

Specifying that destinations are local (with the `-interface` modifier) assumes that the routers implement proxy ARP, meaning that they respond to ARP queries for all reachable destinations. Normally, using either router discovery or RIP is more reliable and scalable than using proxy ARP. See `in.routed(1M)` for information related to RIP.

Combining the all destinations are local route with subnet or network routes can lead to unpredictable results. The search order as it relates to the all destinations are local route are undefined and can vary from release to release.

NAME	rpcbind – universal addresses to RPC program number mapper				
SYNOPSIS	rpcbind [-d] [-w]				
DESCRIPTION	rpcbind is a server that converts RPC program numbers into universal addresses. It must be running on the host to be able to make RPC calls on a server on that machine. When an RPC service is started, it tells rpcbind the address at which it is listening, and the RPC program numbers it is prepared to serve. When a client wishes to make an RPC call to a given program number, it first contacts rpcbind on the server machine to determine the address where RPC requests should be sent. rpcbind should be started before any other RPC service. Normally, standard RPC servers are started by port monitors, so rpcbind must be started before port monitors are invoked. When rpcbind is started, it checks that certain name-to-address translation-calls function correctly. If they fail, the network configuration databases may be corrupt. Since RPC services cannot function correctly in this situation, rpcbind reports the condition and terminates. rpcbind can only be started by the super-user.				
OPTIONS	The following options are supported: -d Run in debug mode. In this mode, rpcbind will not fork when it starts, will print additional information during operation, and will abort on certain errors. With this option, the name-to-address translation consistency checks are shown in detail. -w Do a warm start. If rpcbind aborts or terminates on SIGINT or SIGTERM, it will write the current list of registered services to /tmp/portmap.file and /tmp/rpcbind.file. Starting rpcbind with the -w option instructs it to look for these files and start operation with the registrations found in them. This allows rpcbind to resume operation without requiring all RPC services to be restarted.				
FILES	/tmp/portmap.file /tmp/rpcbind.file				
ATTRIBUTES	See attributes(5) for descriptions of the following attributes: <table> <tr> <th>ATTRIBUTE TYPE</th><th>ATTRIBUTE VALUE</th></tr> <tr> <td>Availability</td><td>SUNWcsu</td></tr> </table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	Availability	SUNWcsu
ATTRIBUTE TYPE	ATTRIBUTE VALUE				
Availability	SUNWcsu				
SEE ALSO	rpcinfo(1M), rpcbind(3NSL), attributes(5)				
NOTES	Terminating rpcbind with SIGKILL will prevent the warm-start files from being written.				

rpcbind(1M)

All RPC servers must be restarted if the following occurs: `rpcbind` crashes (or is killed with `SIGKILL`) and is unable to write the warm-start files; `rpcbind` is started without the `-w` option after a graceful termination; or, the warm-start files are not found by `rpcbind`.

NAME	rpc.bootparamd, bootparamd – boot parameter server				
SYNOPSIS	/usr/sbin/rpc.bootparamd [-d]				
DESCRIPTION	rpc.bootparamd is a server process that provides information from a bootparams database to diskless clients at boot time. See bootparams(4). The source for the bootparams database is determined by the nsswitch.conf(4) file (on the machine running the rpc.bootparamd process). The rpc.bootparamd program can be invoked either by inetd(1M) or directly from the command line.				
OPTIONS	-d Display debugging information.				
FILES	/etc/bootparams boot parameter data base /etc/nsswitch.conf configuration file for the name-service switch				
ATTRIBUTES	See attributes(5) for descriptions of the following attributes:				
	<table> <tr> <th>ATTRIBUTE TYPE</th><th>ATTRIBUTE VALUE</th></tr> <tr> <td>Availability</td><td>SUNWbsu</td></tr> </table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	Availability	SUNWbsu
ATTRIBUTE TYPE	ATTRIBUTE VALUE				
Availability	SUNWbsu				
SEE ALSO	inetd(1M), bootparams(4), nsswitch.conf(4), attributes(5)				
NOTES	A diskless client requires service from at least one rpc.bootparamd process running on a server that is on the same IP subnetwork as the diskless client. Some routines that compare hostnames use case-sensitive string comparisons; some do not. If an incoming request fails, verify that the case of the hostname in the file to be parsed matches the case of the hostname called for, and attempt the request again.				

rpcinfo(1M)

NAME	rpcinfo – report RPC information
SYNOPSIS	rpcinfo [-m -s] [<i>host</i>] rpcinfo -p [<i>host</i>] rpcinfo -T <i>transport</i> <i>host</i> <i>prognum</i> [<i>versnum</i>] rpcinfo -l [-T <i>transport</i>] <i>host</i> <i>prognum</i> <i>versnum</i> rpcinfo [-n <i>portnum</i>] -u <i>host</i> <i>prognum</i> [<i>versnum</i>] rpcinfo [-n <i>portnum</i>] -t <i>host</i> <i>prognum</i> [<i>versnum</i>] rpcinfo -a <i>serv_address</i> -T <i>transport</i> <i>prognum</i> [<i>versnum</i>] rpcinfo -b [-T <i>transport</i>] <i>prognum</i> <i>versnum</i> rpcinfo -d [-T <i>transport</i>] <i>prognum</i> <i>versnum</i>
DESCRIPTION	rpcinfo makes an RPC call to an RPC server and reports what it finds. In the first synopsis, <i>rpcinfo</i> lists all the registered RPC services with <i>rpcbind</i> on <i>host</i>. If <i>host</i> is not specified, the local host is the default. If -s is used, the information is displayed in a concise format. In the second synopsis, <i>rpcinfo</i> lists all the RPC services registered with <i>rpcbind</i>, version 2. Note that the format of the information is different in the first and the second synopsis. This is because the second synopsis is an older protocol used to collect the information displayed (version 2 of the <i>rpcbind</i> protocol). The third synopsis makes an RPC call to procedure 0 of <i>prognum</i> and <i>versnum</i> on the specified <i>host</i> and reports whether a response was received. <i>transport</i> is the transport which has to be used for contacting the given service. The remote address of the service is obtained by making a call to the remote <i>rpcbind</i>. The <i>prognum</i> argument is a number that represents an RPC program number (see <i>rpc(4)</i>). If a <i>versnum</i> is specified, <i>rpcinfo</i> attempts to call that version of the specified <i>prognum</i>. Otherwise, <i>rpcinfo</i> attempts to find all the registered version numbers for the specified <i>prognum</i> by calling version 0, which is presumed not to exist; if it does exist, <i>rpcinfo</i> attempts to obtain this information by calling an extremely high version number instead, and attempts to call each registered version. Note that the version number is required for -b and -d options. The EXAMPLES section describe other ways of using <i>rpcinfo</i>.
OPTIONS	-T <i>transport</i> Specify the transport on which the service is required. If this option is not specified, <i>rpcinfo</i> uses the transport specified in the NETPATH environment variable, or if that is unset or NULL, the transport in the <i>netconfig(4)</i> database is used. This is a generic

	option, and can be used in conjunction with other options as shown in the SYNOPSIS.
-a <i>serv_address</i>	Use <i>serv_address</i> as the (universal) address for the service on <i>transport</i> to ping procedure 0 of the specified <i>prognum</i> and report whether a response was received. The -T option is required with the -a option. If <i>versnum</i> is not specified, <i>rpcinfo</i> tries to ping all available version numbers for that program number. This option avoids calls to remote <i>rpcbind</i> to find the address of the service. The <i>serv_address</i> is specified in universal address format of the given transport.
-b	Make an RPC broadcast to procedure 0 of the specified <i>prognum</i> and <i>versnum</i> and report all hosts that respond. If <i>transport</i> is specified, it broadcasts its request only on the specified transport. If broadcasting is not supported by any transport, an error message is printed. Use of broadcasting should be limited because of the potential for adverse effect on other systems.
-d	Delete registration for the RPC service of the specified <i>prognum</i> and <i>versnum</i> . If <i>transport</i> is specified, unregister the service on only that transport, otherwise unregister the service on all the transports on which it was registered. Only the owner of a service can delete a registration, except the superuser, who can delete any service.
-l	Display a list of entries with a given <i>prognum</i> and <i>versnum</i> on the specified <i>host</i> . Entries are returned for all transports in the same protocol family as that used to contact the remote <i>rpcbind</i> .
-m	Display a table of statistics of <i>rpcbind</i> operations on the given <i>host</i> . The table shows statistics for each version of <i>rpcbind</i> (versions 2, 3 and 4), giving the number of times each procedure was requested and successfully serviced, the number and type of remote call requests that were made, and information about RPC address lookups that were handled. This is useful for monitoring RPC activities on <i>host</i> .
-n <i>portnum</i>	Use <i>portnum</i> as the port number for the -t and -u options instead of the port number given by <i>rpcbind</i> . Use of this option avoids a call to the remote <i>rpcbind</i> to find out the address of the service. This option is made obsolete by the -a option.

rpcinfo(1M)

-p	Probe rpcbind on <i>host</i> using version 2 of the rpcbind protocol, and display a list of all registered RPC programs. If <i>host</i> is not specified, it defaults to the local host. This option is not useful for IPv6; use -s (see below) instead. Note that version 2 of the rpcbind protocol was previously known as the portmapper protocol.
-s	Display a concise list of all registered RPC programs on <i>host</i> . If <i>host</i> is not specified, it defaults to the local host.
-t	Make an RPC call to procedure 0 of <i>prognum</i> on the specified <i>host</i> using TCP, and report whether a response was received. This option is made obsolete by the -T option as shown in the third synopsis.
-u	Make an RPC call to procedure 0 of <i>prognum</i> on the specified <i>host</i> using UDP, and report whether a response was received. This option is made obsolete by the -T option as shown in the third synopsis.

EXAMPLES

EXAMPLE 1 RPC services.

To show all of the RPC services registered on the local machine use:

```
example% rpcinfo
```

To show all of the RPC services registered with rpcbind on the machine named klaxon use:

```
example% rpcinfo klaxon
```

The information displayed by the above commands can be quite lengthy. Use the -s option to display a more concise list:

```
example% rpcinfo -s klaxon
```

program	vrns	netid(s)	service	owner
100000	2,3,4	tcp,udp,ticlts,ticots,ticotsord	rpcbind	superuser
100008	1	ticotsord,ticots,ticlts,udp,tcp	walld	superuser
100002	2,1	ticotsord,ticots,ticlts,udp,tcp	rusersd	superuser
100001	2,3,4	ticotsord,ticots,tcp,ticlts,udp	rstatd	superuser
100012	1	ticotsord,ticots,ticlts,udp,tcp	sprayd	superuser
100007	3	ticotsord,ticots,ticlts,udp,tcp	ypbind	superuser
100029	1	ticotsord,ticots,ticlts	keyserv	superuser

EXAMPLE 1 RPC services. (Continued)

100078	4	ticotsord,ticots,ticlts	-	superuser
100024	1	ticotsord,ticots,ticlts,udp,tcp	status	superuser
100021	2,1	ticotsord,ticots,ticlts,udp,tcp	nlockmgr	superuser
100020	1	ticotsord,ticots,ticlts,udp,tcp	llockmgr	superuser

To show whether the RPC service with program number *prognum* and version *versnum* is registered on the machine named *klaxon* for the transport TCP use:

```
example% rpcinfo -T tcp klaxon prognum versnum
```

To show all RPC services registered with version 2 of the *rpcbind* protocol on the local machine use:

```
example% rpcinfo -p
```

To delete the registration for version 1 of the *walld* (program number 100008) service for all transports use:

```
example# rpcinfo -d 100008 1
```

or

```
example# rpcinfo -d walld 1
```

rpc.nisd(1M)

NAME	rpc.nisd, nisd – NIS+ service daemon
SYNOPSIS	/usr/sbin/rpc.nisd [-ACDFhlv] [-Y [-B [-t <i>netid</i>]]] [-d <i>dictionary</i>] [-L <i>load</i>] [-S <i>level</i>] [-m <i>mappingfile</i>] [-x <i>attribute=value</i>]... [-z <i>number</i>]
DESCRIPTION	The <code>rpc.nisd</code> daemon is an RPC service that implements the NIS+ service. This daemon must be running on all machines that serve a portion of the NIS+ namespace. <code>rpc.nisd</code> is usually started from a system startup script. The <code>-B</code> option causes <code>rpc.nisd</code> to start an auxiliary process, <code>rpc.nisd_resolv</code>, which provides yperv compatible DNS forwarding for NIS host requests. <code>rpc.nisd_resolv</code> can also be started independently. See <code>rpc.nisd_resolv(1M)</code> for more information on using <code>rpc.nisd_resolv</code> independently. The <code>/etc/default/rpc.nisd</code> file contains the following default parameter settings. See FILES. ENABLE_NIS_YP_EMULATION Specifies whether the server is put into NIS (YP) compatibility mode. <code>ENABLE_NIS_YP_EMULATION=YES</code> is equivalent to the <code>-Y</code> command-line option. The default value for <code>ENABLE_NIS_YP_EMULATION</code> is NO.
OPTIONS	-A Authentication verbose mode. The daemon logs all the authentication related activities to <code>syslogd(1M)</code> with <code>LOG_INFO</code> priority. -B Provide yperv compatible DNS forwarding for NIS host requests. The DNS resolving process, <code>rpc.nisd_resolv</code>, is started and controlled by <code>rpc.nisd</code>. This option requires that the <code>/etc/resolv.conf</code> file be setup for communication with a DNS nameserver. The <code>nslookup</code> utility can be used to verify communication with a DNS nameserver. See <code>resolv.conf(4)</code> and <code>nslookup(1M)</code>. -C Open diagnostic channel on <code>/dev/console</code>. -D Debug mode. Do not fork. -d <i>dictionary</i> Specify an alternate dictionary for the NIS+ database. The primary use of this option is for testing. Note that the string is not interpreted, rather it is simply passed to the <code>db_initialize</code> function.> -F Force the server to do a checkpoint of the database when it starts up. Forced checkpoints may be required when the server is low on disk space. This option removes updates from the transaction log that have propagated to all of the replicas.

-h	Print list of options.				
-L <i>number</i>	Specify the “load” the NIS+ service is allowed to place on the server. The load is specified in terms of the <i>number</i> of child processes that the server may spawn. The value of <i>number</i> must be at least 1 for the callback functions to work correctly. The default is 128.				
-m <i>mappingfile</i>	Specify the name of a configuration file that maps NIS+ objects (especially tables and columns) to LDAP (entries and attributes). See NIS+LDAPmapping(4). The default path is <code>/var/nis</code>. The default mapping file is <code>NIS+LDAPmapping</code>. If this file exists, the <code>rpc.nisd</code> daemon will map data to and from LDAP. A template mapping file that covers the normal NIS+ directories and tables is installed as <code>/var/nis/NIS+LDAPmapping.template</code>. A NIS+ object must have a valid mapping entry in the mapping file in order to have data for that table read from or written to the LDAP repository. The <code>rpc.nisd(4)</code> file contains specifications for LDAP server addresses, LDAP authentication method, and the like. See NIS+LDAPmapping(4) for an overview of the setup you need to map NIS+ data to or from LDAP.				
-S <i>level</i>	Set the authorization security level of the service. The argument is a number between 0 and 2. By default, the daemon runs at security level 2. <table> <tr> <td>0</td><td>Security level 0 is designed to be used for testing and initial setup of the NIS+ namespace. When running at level 0, the daemon does not enforce any access controls. Any client is allowed to perform any operation, including updates and deletions.</td></tr> <tr> <td>1</td><td>At security level 1, the daemon accepts both <code>AUTH_SYS</code> and <code>AUTH_DES</code> credentials for authenticating clients and authorizing them to perform NIS+ operations. This is not a secure mode of operation since <code>AUTH_SYS</code> credentials are easily forged. It should not be used on networks in which any untrusted users may potentially have access.</td></tr> </table>	0	Security level 0 is designed to be used for testing and initial setup of the NIS+ namespace. When running at level 0, the daemon does not enforce any access controls. Any client is allowed to perform any operation, including updates and deletions.	1	At security level 1, the daemon accepts both <code>AUTH_SYS</code> and <code>AUTH_DES</code> credentials for authenticating clients and authorizing them to perform NIS+ operations. This is not a secure mode of operation since <code>AUTH_SYS</code> credentials are easily forged. It should not be used on networks in which any untrusted users may potentially have access.
0	Security level 0 is designed to be used for testing and initial setup of the NIS+ namespace. When running at level 0, the daemon does not enforce any access controls. Any client is allowed to perform any operation, including updates and deletions.				
1	At security level 1, the daemon accepts both <code>AUTH_SYS</code> and <code>AUTH_DES</code> credentials for authenticating clients and authorizing them to perform NIS+ operations. This is not a secure mode of operation since <code>AUTH_SYS</code> credentials are easily forged. It should not be used on networks in which any untrusted users may potentially have access.				

rpc.nisd(1M)

	2	At security level 2, the daemon only accepts authentication using the security mechanisms configured by <code>nisauthconf(1M)</code> . The default security mechanism is <code>AUTH_DES</code> . Security level 2 is the default if the <code>-S</code> option is not used.
<code>-t netid</code>		Use <i>netid</i> as the transport for communication between <code>rpc.nisd</code> and <code>rpc.nisd_resolv</code> . The default transport is <code>ticots(7D)</code> (<code>tcp</code> on SunOS 4.x systems).
<code>-v</code>		Verbose. With this option, the daemon sends a running narration of what it is doing to the syslog daemon (see <code>syslogd(1M)</code>) at <code>LOG_INFO</code> priority. This option is most useful for debugging problems with the service. See also <code>-A</code> option.
<code>-x attribute=value</code>		Specify the value of the named <i>attribute</i> . Attributes that control the NIS+ to LDAP mapping operation are derived as follows: 1. Retrieve from LDAP. 2. Override with values from the <i>mappingfile</i>, if any. See the <code>-m</code> option. 3. Override with values from the command line <code>-x</code> options. See <code>NIS+LDAPmapping(4)</code> and <code>rpc.nisd(4)</code> for the recognized attributes and their syntax. As a special case, you can use the <code>nisplusLdapConfig*</code> attributes to derive additional information from LDAP. You can only specify the <code>nisplusLdapConfig*</code> attributes in <code>rpc.nisd(4)</code> or by means of the command line.
<code>-Y</code>		Put the server into NIS (YP) compatibility mode. When operating in this mode, the NIS+ server will respond to NIS Version 2 requests using the version 2 protocol. Because the YP protocol is not authenticated, only those items that have read access to nobody (the unauthenticated request) will be visible through the V2 protocol. It supports only the standard Version 2 maps in this mode (see <code>-B</code> option and <code>NOTES</code> in <code>ypfiles(4)</code>). See <code>FILES</code> .
<code>-z number</code>		Specify the maximum RPC record size that can be used over connection oriented transports. The default is 9000 bytes. If you specify a size less than the default value, the default value will be used instead.

EXAMPLES	EXAMPLE 1 Setting up the NIS+ Service	
	The following example sets up the NIS+ service.	
	example% rpc.nisd	
	EXAMPLE 2 Setting Up NIS+ Service Emulating YP With DNS Forwarding	
	The following example sets up the NIS+ service, emulating YP with DNS forwarding.	
	example% rpc.nisd -YB	
	EXAMPLE 3 Specifying NIS+ and LDAP Mapping Information	
	The following example shows how to specify that all additional NIS+ and LDAP mapping information should be retrieved from DN “dc=x,dc=y,dc=z”, from the LDAP server at IP address 1.2.3.4, port 389. The examples uses the simple authentication method and the cn=nisplusAdmin,ou=People, proxy user. The -m option is omitted for clarity in this example..	
	<pre>-x nisplusLDAPconfigDN=dc=x,dc=y,dc=z \ -x nisplusLDAPconfigPreferredServerList=127.0.0.1:389 \ -x nisplusLDAPconfigAuthenticationMethod=simple \ -x nisplusLDAPconfigProxyUser=cn=nisplusAdmin,ou=People, \ -x nisplusLDAPconfigProxyPassword=xyzzzy</pre>	
ENVIRONMENT VARIABLES	NETPATH	The transports that the NIS+ service will use can be limited by setting this environment variable. See netconfig(4).
	FILES	
	/var/nis/data/parent.object	This file describes the namespace that is logically above the NIS+ namespace. The most common type of parent object is a DNS object. This object contains contact information for a server of that domain.
	/var/nis/data/root.object	This file describes the root object of the NIS+ namespace. It is a standard XDR-encoded NIS+ directory object that can be modified by authorized clients using the nis_modify(3NSL) interface.
	/etc/init.d/rpc	Initialization script for NIS+.
	/etc/default/rpc.nisd	LDAP connection and general rpc.nisd configuration. You can override some of the settings by command-line options.
	/var/nis/nis+LDAPmapping	Default path for LDAP mapping file. See the discussion of the -m option.

NAME	rpc.nisd_resolv, nisd_resolv – NIS+ service daemon				
SYNOPSIS	rpc.nisd_resolv [-v -V] [-F [-C <i>fd</i>]] [-t <i>xx</i>] [-p <i>yy</i>]				
DESCRIPTION	rpc.nisd_resolv is an auxiliary process which provides DNS forwarding service for NIS hosts requests to both yperv and rpc.nisd that are running in the NIS compatibility mode. It is generally started by invoking rpc.nisd(1M) with the -B option or yperv(1M) with the -d option. Although it is not recommended, rpc.nisd_resolv can also be started independently with the following options. This command requires that the <code>/etc/resolv.conf</code> file be setup for communication with a DNS nameserver. The <code>nslookup</code> utility can be used to verify communication with a DNS nameserver. See <code>resolv.conf(4)</code> and <code>nslookup(1M)</code>.				
OPTIONS	-F Run in foreground. -C <i>fd</i> Use <i>fd</i> for service xprt (from nisd). -v Verbose. Send output to the syslog daemon. -V Verbose. Send output to stdout. -t <i>xx</i> Use transport <i>xx</i>. -p <i>yy</i> Use transient program# <i>yy</i>.				
ATTRIBUTES	See <code>attributes(5)</code> for descriptions of the following attributes: <table border="1"> <thead> <tr> <th>ATTRIBUTE TYPE</th><th>ATTRIBUTE VALUE</th></tr> </thead> <tbody> <tr> <td>Availability</td><td>SUNWnisu</td></tr> </tbody> </table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	Availability	SUNWnisu

rpc.nispasswd(1M)

NAME	rpc.nispasswd, nispasswd – NIS+ password update daemon	
SYNOPSIS	/usr/sbin/rpc.nispasswd [-a <i>attempts</i>] [-c <i>minutes</i>] [-D] [-g] [-v]	
DESCRIPTION	rpc.nispasswd daemon is an ONC+ RPC service that services password update requests from nispasswd(1) and yppasswd(1). It updates password entries in the NIS+ passwd table. rpc.nispasswd is normally started from a system startup script after the NIS+ server (rpc.nisd(1M)) has been started. rpc.nispasswd will determine whether it is running on a machine that is a master server for one or more NIS+ directories. If it discovers that the host is not a master server, then it will promptly exit. It will also determine if rpc.nisd(1M) is running in NIS (YP) compatibility mode (the -Yoption) and will register as yppasswd for NIS (YP) clients as well. rpc.nispasswd will syslog all failed password update attempts, which will allow an administrator to determine whether someone was trying to "crack" the passwords. rpc.nispasswd has to be run by a superuser.	
OPTIONS	-a <i>attempts</i>	Set the maximum number of attempts allowed to authenticate the caller within a password update request session. Failed attempts are syslogged(1M) and the request is cached by the daemon. After the maximum number of allowed attempts the daemon severs the connection to the client. The default value is set to 3.
	-c <i>minutes</i>	Set the number of minutes a failed password update request should be cached by the daemon. This is the time during which if the daemon receives further password update requests for the same user and authentication of the caller fails, then the daemon will simply not respond. The default value is set to 30minutes.
	-D	Debug. Run in debugging mode.
	-g	Generate DES credential. By default the DES credential is not generated for the user if they do not have one. By specifying this option, if the user does not have a credential, then one will be generated for them and stored in the NIS+ cred table.
	-v	Verbose. With this option, the daemon sends a running narration of what it is doing to the syslog daemon. This option is useful for debugging problems.
EXIT STATUS	0	success
	1	an error has occurred.
FILES	/etc/init.d/rpc	initialization script for NIS+

rpc.rexd(1M)

NAME	rpc.rexd, rexd – RPC-based remote execution server				
SYNOPSIS	<code>/usr/sbin/rpc.rexd [-s]</code>				
DESCRIPTION	<code>rpc.rexd</code> is the Sun RPC server for remote program execution. This daemon is started by <code>inetd(1M)</code> whenever a remote execution request is made. For non-interactive programs, the standard file descriptors are connected directly to TCP connections. Interactive programs involve pseudo-terminals, in a fashion that is similar to the login sessions provided by <code>rlogin(1)</code>. This daemon may use NFS to mount file systems specified in the remote execution request.				
OPTIONS	The following options are supported: <code>-s</code> Secure. When specified, requests must have valid DES credentials. If the request does not have a DES credential it is rejected. The default publickey credential is rejected. Only newer <code>on(1)</code> commands send DES credentials. If access is denied with an authentication error, you may have to set your publickey with the <code>chkey(1)</code> command. Specifying the <code>-s</code> option without presenting secure credentials will result in an error message: <code>Unix too weak auth (DesOnly)!</code>				
SECURITY	<code>rpc.rexd</code> uses <code>pam(3PAM)</code> for account and session management. The PAM configuration policy, listed through <code>/etc/pam.conf</code>, specifies the modules to be used for <code>rpc.rexd</code>. Here is a partial <code>pam.conf</code> file with <code>rpc.rexd</code> entries for account and session management using the UNIX module. <pre>rpc.rexd account requisite pam_roles.so.1 rpc.rexd account required pam_projects.so.1 rpc.rexd account required pam_unix_account.so.1 rpc.rexd session required pam_unix_session.so.1</pre> If there are no entries for the <code>rpc.rexd</code> service, then the entries for the "other" service will be used. <code>rpc.rexd</code> uses the <code>getpwnuid()</code> call to determine whether the given user is a legal user.				
FILES	<code>/dev/pts/n</code> Pseudo-terminals used for interactive mode <code>/etc/passwd</code> Authorized users <code>/tmp_rex/rexd?????</code> Temporary mount points for remote file systems				
ATTRIBUTES	See <code>attributes(5)</code> for descriptions of the following attributes: <table border="1"> <thead> <tr> <th>ATTRIBUTE TYPE</th><th>ATTRIBUTE VALUE</th></tr> </thead> <tbody> <tr> <td>Availability</td><td>SUNWnisu</td></tr> </tbody> </table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	Availability	SUNWnisu

Availability	SUNWnisu				

rpc.rexd(1M)

SEE ALSO chkey(1), on(1), rlogin(1), inetd(1M), pam(3PAM), inetd.conf(4), pam.conf(4), publickey(4), attributes(5), pam_authtok_check(5), pam_authtok_get(5), pam_authtok_store(5), pam_dhkeys(5), pam_passwd_auth(5), pam_unix(5), pam_unix_account(5), pam_unix_auth(5), pam_unix_session(5)

DIAGNOSTICS Diagnostic messages are normally printed on the console, and returned to the requestor.

NOTES Root cannot execute commands using rexd client programs such as on(1).

The pam_unix(5) module might not be supported in a future release. Similar functionality is provided by pam_authtok_check(5), pam_authtok_get(5), pam_authtok_store(5), pam_dhkeys(5), pam_passwd_auth(5), pam_unix_account(5), pam_unix_auth(5), and pam_unix_session(5).

rpc.rstatd(1M)

NAME	rpc.rstatd, rstatd – kernel statistics server
SYNOPSIS	/usr/lib/netsvc/rstat/rpc.rstatd
DESCRIPTION	rpc.rstatd is a server which returns performance statistics obtained from the kernel. rup(1) uses rpc.rstatd to collect the uptime information that it displays. rpc.rstatd is an RPC service.
ATTRIBUTES	See attributes(5) for descriptions of the following attributes:

rpc.rwalld(1M)

NAME rpc.rwalld, rwalld – network rwall server

SYNOPSIS `/usr/lib/netsvc/rwall/rpc.rwalld`

DESCRIPTION `rpc.rwalld` is a server that handles `rwall(1M)` requests. It is implemented by calling `wall(1M)` on all the appropriate network machines. The `rpc.rwalld` daemon may be started by `inetd(1M)` or `listen(1M)`.

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWrcmds

SEE ALSO `inetd(1M)`, `listen(1M)`, `rwall(1M)`, `wall(1M)`, `attributes(5)`

NAME	rpc.smserverd – removable media device server				
SYNOPSIS	<code>/usr/lib/smedia/rpc.smserverd</code>				
DESCRIPTION	<code>rpc.smserverd</code> is a server that handles requests from client applications, including the Volume Management daemon (<code>vold(1M)</code>), for access to removable media devices. In addition to <code>vold</code>, <code>rmformat(1)</code> and the CDE Filemanager (when performing removable media operations) are <code>rpc.smserverd</code> clients. The <code>rpc.smserverd</code> daemon is started by <code>inetd(1M)</code> when a client makes a call to a Solaris-internal library to access a SCSI, IDE, or USB device. The daemon is not started if a client attempts to access a floppy or PCMCIA device. Once started, the daemon remains active until such time as it is idle for three minutes or more. The <code>rpc.smserverd</code> daemon is provided for the exclusive use of the client applications mentioned above. It has no external, customer-accessible interfaces, including no configuration file.				
ATTRIBUTES	See <code>attributes(5)</code> for descriptions of the following attributes:

rpc.sprayd(1M)

NAME	rpc.sprayd, sprayd – spray server				
SYNOPSIS	/usr/lib/netsvc/spray/rpc.sprayd				
DESCRIPTION	rpc.sprayd is a server that records the packets sent by spray(1M). The rpc.sprayd daemon may be started by inetd(1M) or listen(1M). The service provided by rpc.sprayd is not useful as a networking benchmark as it uses unreliable connectionless transports, (udp for example). It can report a large number of packets dropped when the drops were caused by the program sending packets faster than they can be buffered locally (before the packets get to the network medium).				
ATTRIBUTES	See attributes(5) for descriptions of the following attributes: <table><tr><th>ATTRIBUTE TYPE</th><th>ATTRIBUTE VALUE</th></tr><tr><td>Availability</td><td>SUNWrcmds</td></tr></table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	Availability	SUNWrcmds
ATTRIBUTE TYPE	ATTRIBUTE VALUE

NAME	rpc.yppasswdd, yppasswdd – server for modifying NIS password file
SYNOPSIS	<pre> /usr/lib/netsvc/yp/rpc.yppasswdd [-D <i>directory</i>] [-nogecos] [-noshell] [-nopw] [-m <i>argument1 argument2...</i>] /usr/lib/netsvc/yp/rpc.yppasswdd [<i>passwordfile</i> [<i>adjunctfile</i>]] [-nogecos] [-noshell] [-nopw] [-m <i>argument1 argument2...</i>] </pre>
DESCRIPTION	rpc.yppasswdd is a server that handles password change requests from yppasswd(1). It changes a password entry in the passwd, shadow, and security/passwd.adjunct files. The passwd and shadow files provide the basis for the passwd.byname and passwd.byuid maps. The passwd.adjunct file provides the basis for the passwd.adjunct.byname and passwd.adjunct.byuid maps. Entries in the passwd, shadow or passwd.adjunct files are changed only if the password presented by yppasswd(1) matches the encrypted password of the entry. All password files are located in the PWDIR directory. If the -D option is given, the passwd, shadow, or passwd.adjunct files are placed under the directory path that is the argument to -D. If the -noshell, -nogecos or -nopw options are given, these fields cannot be changed remotely using chfn, chsh, or passwd(1). If the -m option is given, a make(1) is performed in /var/yp after any of the passwd, shadow, or passwd.adjunct files are modified. All arguments following the flag are passed to make. The second of the listed syntaxes is provided only for backward compatibility. If the second syntax is used, the passwordfile is the full pathname of the password file and adjunctfile is the full pathname of the optional passwd.adjunct file. If a shadow file is found in the same directory as passwordfile, the shadowfile is used as described above. Use of this syntax and the discovery of a shadowfile file generates diagnostic output. The daemon, however, starts normally. The first and second syntaxes are mutually exclusive. You cannot specify the full pathname of the passwd, passwd.adjunct files and use the -D option at the same time. The daemon is started automatically on the master server of the passwd map by ypstart(1M), which is invoked at boot time by the /etc/init.d/rpc script. The server does not insist on the presence of a shadow file unless there is no -D option present or the directory named with the -D option is /etc. In addition, a passwd.adjunct file is not necessary. If the -D option is given, the server attempts to find a passwd.adjunct file in the security subdirectory of the named directory. For example, in the presence of -D /var/yp the server checks for a /var/yp/security/passwd.adjunct file.

rpc.yppasswdd(1M)

If only a `passwd` file exists, then the encrypted password is expected in the second field. If both a `passwd` and a `passwd.adjunct` file exist, the encrypted password is expected in the second field of the adjunct file with `##username` in the second field of the `passwd` file. If all three files are in use, the encrypted password is expected in the shadow file. Any deviation causes a password update to fail.

If you remove or add a shadow or `passwd.adjunct` file after `rpc.yppasswdd` has started, you must stop and restart the daemon to enable it to recognize the change. See `ypstart(1m)` for information on restarting the daemon.

The `rpc.yppasswdd` daemon considers a shell that has a name that begins with 'r' to be a restricted shell. By default, the daemon does not check whether a shell begins with an 'r'. However, you can tell it to do so by uncommenting the `check_restricted_shell_name=1` line in `/etc/default/yppasswdd`. The result will be to restrict a user's ability to change from his default shell. See `yppasswdd(4)`.

On start up, `yppasswdd` checks for the existence of a NIS to LDAP (N2L) configuration file, `/var/yp/NISLDAPmapping`. If the configuration file is present, the daemon runs in N2L mode. If the file is not present, `yppasswdd` runs in traditional, non-N2L mode.

In N2L mode, changes are written directly to the Directory Information Tree (DIT). If the changes are written successfully, the NIS map is updated. The NIS source files, `passwd`, `shadow`, and `passwd.adjunct`, for example, are not updated. Thus, in N2L mode, the `-D` option is meaningless. In N2L mode, `yppasswdd` propagates changes by calling `yppush(1M)` instead of `ypmake(1M)`. The `-m` option is thus unused.

ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWypu

SEE ALSO

`make(1)`, `passwd(1)`, `yppasswd(1)`, `inetd(1M)`, `ypmake(1M)`, `yppush(1M)`, `NISLDAPmapping(4)`, `passwd(4)`, `shadow(4)`, `ypfiles(4)`, `yppasswdd(4)`, `ypserv(4)`, `attributes(5)`

NOTES

If `make` has not been installed and the `-m` option is given, the daemon outputs a warning and proceeds, effectively ignoring the `-m` flag.

When using the `-D` option, you should make sure that the `PWDIR` of the `/var/yp/Makefile` is set accordingly.

The second listed syntax is supplied only for backward compatibility and might be removed in a future release of this daemon.

rpc.yppasswdd(1M)

The Network Information Service (NIS) was formerly known as Sun Yellow Pages (YP). The functionality of the two remains the same; only the name has changed. The name Yellow Pages is a registered trademark in the United Kingdom of British Telecommunications PLC, and cannot be used without permission.

rpc.yppupdated(1M)

NAME	rpc.yppupdated, yppupdated – server for changing NIS information						
SYNOPSIS	/usr/lib/netsvc/yp/rpc.yppupdated [-is]						
DESCRIPTION	yppupdated is a daemon that updates information in the Network Information Service (NIS). yppupdated consults the updaters(4) file in the /var/yp directory to determine which NIS maps should be updated and how to change them. By default, the daemon requires the most secure method of authentication available to it, either DES (secure) or UNIX (insecure). On start up, yppupdated checks for the existence of a NIS to LDAP (N2L) configuration file, /var/yp/NISLDAPmapping. If the file is present, yppupdated generates an informational message and exits. yppupdated is not supported in N2L mode.						
OPTIONS	-i Accept RPC calls with the insecure AUTH_UNIX credentials. This allows programmatic updating of the NIS maps in all networks. -s Accept only calls authenticated using the secure RPC mechanism (AUTH_DES authentication). This disables programmatic updating of the NIS maps unless the network supports these calls.						
FILES	/var/yp/updaters Configuration file for rpc.updated command. /var/yp/NISLDAPmapping Configuration file for N2L

NOTES	The Network Information Service (NIS) was formerly known as Sun Yellow Pages (YP). The functionality of the two services remains the same. Only the name has changed. The name Yellow Pages is a registered trademark in the United Kingdom of British Telecommunications PLC, and it must not be used without permission.						

NAME	rpld – x86 Network Booting RPL (Remote Program Load) Server
SYNOPSIS	<pre>/usr/sbin/rpld [-fdMblgz] interface /usr/sbin/rpld -a [-fdMblgz]</pre>
DESCRIPTION	The RPL server provides network booting functionality to x86 clients by listening to boot requests from them according to the RPL protocol specifications. Boot requests can be generated by clients using the boot floppy supplied in the x86 distribution. Once the request has been received, the server validates the client and adds it to its internal service list. Subsequent requests from the client to download bootfiles will result in the sending of data frames from the server to the client specifying where to load the boot program in memory. When all the bootfiles have been downloaded, the server specifies where to start execution to initiate the boot process. In the first synopsis, the interface parameter names the network interface upon which rpld is to listen for requests. For example: <pre>/usr/sbin/rpld /dev/le0 /usr/sbin/rpld /dev/smc0</pre> In the second synopsis, rpld locates all of the network interfaces present on the system and starts a daemon process for each one. The server starts by reading the default configuration file, or an alternate configuration file if one is specified. If no configuration file can be found, internal default values will be used. Alternatively, command line options are available to override any of the values in the configuration file. After the configuration options are set, it then opens the network interface as specified in the command line and starts listening to RPL boot requests. Network boot x86 clients have to have information pre-configured on a server for the RPL server to validate and serve them. This involves putting configuration information in both the ethers(4) and the bootparams(4) databases. The ethers database contains a translation from the physical node address to the IP address of the clients and is normally used by the RARP server. The bootparams database stores all other information needed for booting off this client, such as the number of bootfiles and the file names of the various boot components. Both databases can be looked up by the RPL server through NIS. See the sub-section Client Configuration for information on how to set up these databases. To assist in the administration and maintenance of the network boot activity, there are two run-time signals that the server will accept to change some run-time parameters and print out useful status information. See the sub-section Signals for details. The RPL server is not limited to the ability to boot only x86 clients. If properly configured, the server should be able to download any bootfiles to the clients. Client Configuration The following configuration information is specific to booting x86 clients.

rpld(1M)

In order to allow clients to boot x86 from across the network, the client's information has to be pre-configured in two databases: `ethers(4)` and `bootparams(4)`. Both databases can be accessed through NIS. Refer to *Solaris 9 9/04 Installation Guide* for information on how to configure a diskless x86 client. The discussion contained in the rest of this section is provided for your information only and should not be performed manually.

The `ethers` database contains a translation table to convert the physical node address to the IP address of the client. Therefore, an IP address must be assigned to the client (if this has not been done already), the node address of the client must be obtained, and then this information needs to be entered in the `ethers` database.

The bulk of the configuration is done in the `bootparams` database. This is a free-format database that essentially contains a number of keyword-value string pairs. A number of keywords have been defined for specific purposes, like the `bootparams` RPC in `bootparamd(1M)`. Three more keywords have been defined for the RPL server. They are `numbootfiles`, `bootfile`, and `bootaddr`. All three keywords must be in lowercase letters with no spaces before or after the equals symbol following the keyword.

`numbootfiles` Specifies the number of files to be downloaded to the network boot client. The format of this option is:

```
numbootfiles=n
```

Always use `numbootfiles=3` to boot x86 across the network.

`bootfile` Specifies the path name of the bootfile to be downloaded and where in memory to start loading the bootfile. A complete path name should be used. For example, assuming the client's IP address is 129.181.32.15:

```
bootfile=/rplboot/129.181.32.15.hw.com:45000
bootfile=/rplboot/129.181.32.15.glue.com:35000
bootfile=/rplboot/129.181.32.15.inetboot=8000
```

The path name following the equals symbol specifies the bootfile to be downloaded, and the hex address following the colon (:) is the absolute address of the memory location to start loading that bootfile. These addresses should be in the range of 7c00 to a0000 (i.e., the base 640K range excluding the interrupt vector and BIOS data areas). Address 45000 for this `hw.com` bootfile is also a suggested value and if possible should not be changed. The address of 35000 for `glue.com` is a suggested value that, if possible, should not be changed. The address of 8000 for `inetboot` is an absolute requirement and should never be changed.

These files, when created following the procedures in the *Solaris 9 9/04 Installation Guide* are actually symbolic links to the real file to be downloaded to the client. `hw.com` is linked to a special driver that corresponds to the network interface card of the client. `glue.com` and `inetboot` are generic to all network boot clients.

The order of these bootfile lines is not significant, but because problems have been found with certain boot PROMs, it is highly recommended that the bootfile lines be ordered in descending order of the load addresses.

`bootaddr` The absolute address in memory to start executing after all the bootfiles have been downloaded. This address should always correspond to the address where `glue.com` is being loaded. If possible, always use:

`bootaddr=35000`

OPTIONS The following options are supported:

- `-b background_mode` Specify 1 to run the server in the background and relinquish the controlling terminal, or 0 to run in the foreground without relinquishing the controlling terminal. This option corresponds to the *BackGround* setting in the configuration file. If you have specified that the error or warning messages be sent to standard output in the configuration file or by using the `-D` option above, the server cannot be run in background mode. Doing so will cause the server to exit after announcing the error.
- `-d debug_level` Specify a level of 0 if you do not want any error or warning messages to be generated, or a level from 1 to 9 for increasing amounts of messages. This option corresponds to the *DebugLevel* setting in the configuration file. The default value is 0. Note that it is best to limit the level to 8 or below; use of level 9 may generate so many debug messages that the performance of the RPL server may be impacted.
- `-D debug_destination` Specify 0 to send error or warning messages to standard output, 1 to `syslogd`, and 2 to the log file. This option corresponds to the *DebugDest* setting in the configuration file. The default value is 2.
- `-f config_filename` Use this to specify a configuration file name other than the system default `/etc/rpld.conf` file.
- `-g delay_granularity` This corresponds to the *DelayGran* setting in the configuration file. If retransmission requests from clients do occur, the delay granularity factor will be used to adjust the delay count for this client upwards

rpld(1M)

	or downwards. If the retransmission request is caused by data overrun, the delay count will be incremented by delay granularity units to increase the delay between data frames. If the retransmission request is caused by sending data too slowly, this will be used to adjust the delay count downwards to shorten the delay. Eventually the server will settle at the delay count value that works best with the speed of the client and no retransmission request will be needed. The default value is 2.
<code>-l log_filename</code>	Specify an alternate log file name to hold the error or warning messages in connection with the <code>-D 2</code> option or the configuration file <code>DebugDest = 2</code> setting. This option corresponds to the <code>LogFile</code> setting in the configuration file. The default is <code>/var/spool/rpld.log</code>.
<code>-M maximum_clients</code>	Specify the maximum number of simultaneous network boot clients to be served. This option corresponds to the <code>MaxClients</code> setting in the configuration file. A value of <code>-1</code> means unlimited, and the actual number will depend on available system resources. The default value is <code>-1</code>.
<code>-s start_delay_count</code>	This option corresponds to the <code>StartDelay</code> setting in the configuration file. Specify the number of delay units between outgoing data frames sent to clients to avoid retransmission requests from them. Using the LLC type 1 protocol, data transfer is a one-way, best-effort delivery mechanism. The server, without any type of delay mechanism, can overrun the client by sending data frames too quickly. Therefore, a variable delay is built into the server to limit the speed of sending data to the clients, thus avoiding the clients sending back retransmission requests. This value should be machine environment specific. If you have a fast server machine but slow client machines, you may want to set a large start delay count. If you have comparable server and client machines, the delay count may be set to 1. The delay is only approximate and should not be taken as an accurate measure of time. There is no specific correlation between the delay unit and the actual time of delay. The default value is 20.
<code>-z frame_size</code>	This option corresponds to the <code>FrameSize</code> setting in the configuration file. This specifies the size of the data frames used to send data to the clients. This is limited by the underlying physical medium. For

ethernet/802.3, the maximum physical frame size is 1500 octets. The default value is 1500. Note that the protocol overhead of LLC1 and RPL is 32 octets, resulting in a maximum data length of 1468 octets.

Signals The RPL server accepts two signals to change run-time parameters and display status information, respectively:

- HANGUP** This will cause the RPL server to reread the default configuration file `/etc/rpld.conf` or an alternate configuration file if one is specified when the server is started. New values of certain parameters can be used immediately, such as *DebugLevel*, *DebugDest*, *LogFile*, *DelayGran*, and *FrameSize*. For *MaxClients*, if the server is already serving more than the new value, the server will not accept additional boot requests until the number has fallen below the *MaxClients* parameter. For *StartDelay*, this will only affect new boot requests. All the existing delay counts for the various clients in service will not be affected. Finally, the *BackGround* parameter will have no effect once the server has been running. You cannot change the mode of service without first killing the server and then restarting it.
- USR1** This signal will cause the server to dump all the parameter values and the status of each individual boot client to the destination specified by *DebugDest*.

rquotad(1M)

NAME	rquotad – remote quota server
SYNOPSIS	/usr/lib/nfs/rquotad
DESCRIPTION	rquotad is an rpc(4) server which returns quotas for a user of a local file system which is mounted by a remote machine over the NFS. The results are used by quota(1M) to display user quotas for remote file systems. The rquotad daemon is normally invoked by inetd(1M).
USAGE	See largefile(5) for the description of the behavior of rquotad when encountering files greater than or equal to 2 Gbyte (2^{31} bytes).
FILES	quotas quota file at the file system root
ATTRIBUTES	See attributes(5) for descriptions of the following attributes:

Solaris 9 9/04 Installation Guide

NAME	rsh, restricted_shell – restricted shell command interpreter
SYNOPSIS	/usr/lib/rsh [-acefhiknprstuvx] [<i>argument...</i>]
DESCRIPTION	rsh is a limiting version of the standard command interpreter sh, used to restrict logins to execution environments whose capabilities are more controlled than those of sh (see sh(1) for complete description and usage). When the shell is invoked, it scans the environment for the value of the environmental variable, SHELL. If it is found and rsh is the file name part of its value, the shell becomes a restricted shell. The actions of rsh are identical to those of sh, except that the following are disallowed: ■ changing directory (see cd(1)), ■ setting the value of \$PATH, ■ specifying path or command names containing /, ■ redirecting output (> and >>). The restrictions above are enforced after <i>.profile</i> is interpreted. A restricted shell can be invoked in one of the following ways: 1. rsh is the file name part of the last entry in the /etc/passwd file (see passwd(4)); 2. the environment variable SHELL exists and rsh is the file name part of its value; the environment variable SHELL needs to be set in the <i>.login</i> file; 3. the shell is invoked and rsh is the file name part of argument 0; 4. the shell is invoked with the -r option. When a command to be executed is found to be a shell procedure, rsh invokes sh to execute it. Thus, it is possible to provide to the end-user shell procedures that have access to the full power of the standard shell, while imposing a limited menu of commands; this scheme assumes that the end-user does not have write and execute permissions in the same directory. The net effect of these rules is that the writer of the <i>.profile</i> (see profile(4)) has complete control over user actions by performing guaranteed setup actions and leaving the user in an appropriate directory (probably <i>not</i> the login directory). The system administrator often sets up a directory of commands (that is, /usr/rbin) that can be safely invoked by a restricted shell. Some systems also provide a restricted editor, red.
EXIT STATUS	Errors detected by the shell, such as syntax errors, cause the shell to return a non-zero exit status. If the shell is being used non-interactively execution of the shell file is abandoned. Otherwise, the shell returns the exit status of the last command executed.

NOTES The restricted shell, /usr/lib/rsh, should not be confused with the remote shell, /usr/bin/rsh, which is documented in rsh(1).

NAME	rtc – provide all real-time clock and GMT-lag management							
SYNOPSIS	/usr/sbin/rtc [-c] [-z zone-name]							
DESCRIPTION	On x86 systems, the rtc command reconciles the difference in the way that time is established between UNIX and MS-DOS systems. UNIX systems utilize Greenwich Mean Time (GMT), while MS-DOS systems utilize local time. Without arguments, rtc displays the currently configured time zone string. The currently configured time zone string is based on what was last recorded by rtc-z zone-name. The rtc command is not normally run from a shell prompt; it is generally invoked by the system. Commands such as date(1) and rdate(1M), which are used to set the time on a system, invoke /usr/sbin/rtc -c to ensure that daylight savings time (DST) is corrected for properly.							
OPTIONS	-c	This option checks for DST and makes corrections if necessary. It is normally run once a day by a cron job. If there is no RTC time zone or /etc/rtc_config file, this option will do nothing.						
	-z zone-name	This option, which is normally run by the system at software installation time, is used to specify the time zone in which the RTC is to be maintained. It updates the configuration file /etc/rtc_config with the name of the specified zone and the current GMT lag for that zone. If there is an existing rtc_config file, this command will update it. If not, this command will create it.						
FILES	/etc/rtc_config	The data file used to record the time zone and GMT lag. This file is completely managed by /usr/sbin/rtc, and it is read by the kernel.

rtquery(1M)

NAME	rtquery – query routing daemons for their routing tables
SYNOPSIS	rtquery [-np1] [-w <i>timeout</i>] [-r <i>addr</i>] [-a <i>secret</i>] <i>host</i> ... rtquery [-t <i>operation</i>] <i>host</i> ...
DESCRIPTION	The rtquery command is used to query a RIP network routing daemon, in.routed(1M) or GateD, for its routing table by sending a request or poll command. The routing information in any routing response packets returned is displayed numerically and symbolically. By default, rtquery uses the request command. When the -p option is specified, rtquery uses the poll command, an undocumented extension to the RIP protocol supported by GateD. When querying GateD, the poll command is preferred over the request command because the response is not subject to Split Horizon and/or Poisoned Reverse, and because some versions of GateD do not answer the request command. in.routed does not answer the poll command, but recognizes requests coming from rtquery and so answers completely. The rtquery command is also used to turn tracing on or off in in.routed.
OPTIONS	The following options are supported: -a <i>passwd=XXX</i> -a <i>md5_passwd=XXX KeyID</i> Causes the query to be sent with the indicated cleartext or MD5 password. -n Displays only the numeric network and host addresses instead of both numeric and symbolic names. -p Uses the poll command to request full routing information from GateD. This is an undocumented extension RIP protocol supported only by GateD. -r <i>addr</i> Asks about the route to destination <i>addr</i>. -t <i>operation</i> Changes tracing, where <i>operation</i> is one of the actions listed below. Requests from processes not running with UID 0 or on distant networks are generally ignored by the daemon except for a message in the system log. GateD is likely to ignore these debugging requests. on=<i>tracefile</i> Turns tracing on, directing tracing into the specified file. That file must have been specified when the daemon was started or have the name, <i>/var/log/in.routed.trace</i>. more Increases the debugging level. off Turns off tracing.

rtquery(1M)

dump

Dumps the daemon's routing table to the current trace file.

-w *timeout*

Changes the delay for an answer from each host. By default, each host is given 15 seconds to respond.

-1

Queries using RIP version 1 instead of RIP version 2.

EXIT STATUS The following exit values are returned:

0 Successful completion.

>0 An error occurred.

Routing Information Protocol, RIPv2, RFC 2453, STD 0056

runacct(1M)

NAME	runacct – run daily accounting																						
SYNOPSIS	<code>/usr/lib/acct/runacct [mmdd [state]]</code>																						
DESCRIPTION	runacct is the main daily accounting shell procedure. It is normally initiated using cron. runacct processes connect, fee, disk, and process accounting files. It also prepares summary files for prdaily or billing purposes. runacct is distributed only to source code licensees. runacct takes care not to damage active accounting files or summary files in the event of errors. It records its progress by writing descriptive diagnostic messages into active. When an error is detected, a message is written to /dev/console, mail (see mail(1)) is sent to root and adm, and runacct terminates. runacct uses a series of lock files to protect against re-invocation. The files lock and lock1 are used to prevent simultaneous invocation, and lastdate is used to prevent more than one invocation per day. runacct breaks its processing into separate, restartable <i>states</i> using statefile to remember the last <i>state</i> completed. It accomplishes this by writing the <i>state</i> name into statefile. runacct then looks in statefile to see what it has done and to determine what to process next. <i>states</i> are executed in the following order: <table> <tr> <td>SETUP</td><td>Move active accounting files into working files.</td></tr> <tr> <td>WTMPFIX</td><td>Verify integrity of wtmpx file, correcting date changes if necessary.</td></tr> <tr> <td>CONNECT</td><td>Produce connect session records in tacct.h format.</td></tr> <tr> <td>PROCESS</td><td>Convert process accounting records into tacct.h format.</td></tr> <tr> <td>MERGE</td><td>Merge the connect and process accounting records.</td></tr> <tr> <td>FEES</td><td>Convert output of chargefee into tacct.h format, merge with connect, and process accounting records.</td></tr> <tr> <td>DISK</td><td>Merge disk accounting records with connect, process, and fee accounting records.</td></tr> <tr> <td>MERGETACCT</td><td>Merge the daily total accounting records in daytacct with the summary total accounting records in /var/adm/acct/sum/tacct.</td></tr> <tr> <td>CMS</td><td>Produce command summaries.</td></tr> <tr> <td>USEREXIT</td><td>Any installation dependent accounting programs can be included here.</td></tr> <tr> <td>CLEANUP</td><td>Clean up temporary files and exit. To restart runacct after a failure, first check the active file for diagnostics, then fix any corrupted data files, such as pacct or wtmpx. The lock, lock1, and lastdate files must be removed before runacct can be restarted. The argument <i>mmdd</i> is necessary if runacct is being restarted. <i>mmdd</i> specifies the month and day for which runacct will rerun the accounting. The entry point for processing is based</td></tr> </table>	SETUP	Move active accounting files into working files.	WTMPFIX	Verify integrity of wtmpx file, correcting date changes if necessary.	CONNECT	Produce connect session records in tacct.h format.	PROCESS	Convert process accounting records into tacct.h format.	MERGE	Merge the connect and process accounting records.	FEES	Convert output of chargefee into tacct.h format, merge with connect, and process accounting records.	DISK	Merge disk accounting records with connect, process, and fee accounting records.	MERGETACCT	Merge the daily total accounting records in daytacct with the summary total accounting records in /var/adm/acct/sum/tacct.	CMS	Produce command summaries.	USEREXIT	Any installation dependent accounting programs can be included here.	CLEANUP	Clean up temporary files and exit. To restart runacct after a failure, first check the active file for diagnostics, then fix any corrupted data files, such as pacct or wtmpx. The lock, lock1, and lastdate files must be removed before runacct can be restarted. The argument <i>mmdd</i> is necessary if runacct is being restarted. <i>mmdd</i> specifies the month and day for which runacct will rerun the accounting. The entry point for processing is based
SETUP	Move active accounting files into working files.																						
WTMPFIX	Verify integrity of wtmpx file, correcting date changes if necessary.																						
CONNECT	Produce connect session records in tacct.h format.																						
PROCESS	Convert process accounting records into tacct.h format.																						
MERGE	Merge the connect and process accounting records.																						
FEES	Convert output of chargefee into tacct.h format, merge with connect, and process accounting records.																						
DISK	Merge disk accounting records with connect, process, and fee accounting records.																						
MERGETACCT	Merge the daily total accounting records in daytacct with the summary total accounting records in /var/adm/acct/sum/tacct.

CLEANUP	Clean up temporary files and exit. To restart runacct after a failure, first check the active file for diagnostics, then fix any corrupted data files, such as pacct or wtmpx. The lock, lock1, and lastdate files must be removed before runacct can be restarted. The argument <i>mmdd</i> is necessary if runacct is being restarted. <i>mmdd</i> specifies the month and day for which runacct will rerun the accounting. The entry point for processing is based																						

runacct(1M)

on the contents of *statefile*; to override this, include the desired *state* on the command line to designate where processing should begin.

EXAMPLES

EXAMPLE 1 Starting runacct

The following example starts runacct:

```
example% nohup runacct 2> /var/adm/acct/nite/fd2log &
```

EXAMPLE 2 Restarting runacct

The following example restarts runacct:

```
example% nohup runacct 0601 2>> /var/adm/acct/nite/fd2log &
```

EXAMPLE 3 Restarting runacct at a Specific State

The following example restarts runacct at a specific state:

```
example% nohup runacct 0601 MERGE 2>> /var/adm/acct/nite/fd2log &
```

FILES

History of user access and administration information

/var/adm/pacctincr

/var/adm/acct/nite/active

/var/adm/acct/nite/daytacct

/var/adm/acct/nite/lock

/var/adm/acct/nite/lock1

/var/adm/acct/nite/lastdate

/var/adm/acct/nite/statefile

ATTRIBUTES

See *attributes(5)* for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWaccu

SEE ALSO

acctcom(1), *mail(1)*, *acct(1M)*, *acctcms(1M)*, *acctcon(1M)*, *acctmerg(1M)*, *acctprc(1M)*, *acctsh(1M)*, *cron(1M)*, *fwtmp(1M)*, *acct(2)*, *acct(3HEAD)*, *utmpx(4)*, *attributes(5)*

NOTES

It is not recommended to restart runacct in the *SETUP* *state*. Run *SETUP* manually and restart using:

runacct(1M)

`runacct mddd WTMPFIX`

If `runacct` failed in the *PROCESS state*, remove the last `ptacct` file because it will not be complete.

The `runacct` command can process a maximum of

- 6000 distinct sessions
- 1000 distinct terminal lines
- 2000 distinct login names

during a single invocation of the command. If at some point the actual number of any one of these items exceeds the maximum, the command will not succeed.

Do not invoke `runacct` at the same time as `ckpacct`, as there may be a conflict if both scripts attempt to execute `turnacct switch` simultaneously.

NAME	rwall – write to all users over a network				
SYNOPSIS	<pre>/usr/sbin/rwall hostname... /usr/sbin/rwall -n netgroup... /usr/sbin/rwall -h hostname -n netgroup</pre>				
DESCRIPTION	rwall reads a message from standard input until EOF. It then sends this message, preceded by the line: <pre>Broadcast Message . . .</pre> to all users logged in on the specified host machines. With the <code>-n</code> option, it sends to the specified network groups.				
OPTIONS	<code>-n netgroup</code> Send the broadcast message to the specified network groups. <code>-h hostname</code> Specify the hostname, the name of the host machine.				
ATTRIBUTES	See <code>attributes(5)</code> for descriptions of the following attributes: <table border="1"> <thead> <tr> <th>ATTRIBUTE TYPE</th><th>ATTRIBUTE VALUE</th></tr> </thead> <tbody> <tr> <td>Availability</td><td>SUNWrcmdc</td></tr> </tbody> </table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	Availability	SUNWrcmdc
ATTRIBUTE TYPE	ATTRIBUTE VALUE				
Availability	SUNWrcmdc				
SEE ALSO	<code>inetd(1M)</code> , <code>listen(1M)</code> , <code>pmadm(1M)</code> , <code>sacadm(1M)</code> , <code>wall(1M)</code> , <code>attributes(5)</code>				
NOTES	The timeout is fairly short to allow transmission to a large group of machines (some of which may be down) in a reasonable amount of time. Thus the message may not get through to a heavily loaded machine.				

sac(1M)

NAME	sac – service access controller										
SYNOPSIS	sac -t <i>sanity_interval</i> /usr/lib/saf/sac										
DESCRIPTION	The Service Access Controller (SAC) is the overseer of the server machine. It is started when the server machine enters multiuser mode. The SAC performs several important functions as explained below.										
Customizing the SAC Environment	When sac is invoked, it first looks for the per-system configuration script /etc/saf/_sysconfig . sac interprets _sysconfig to customize its own environment. The modifications made to the SAC environment by _sysconfig are inherited by all the children of the SAC. This inherited environment may be modified by the children.										
Starting Port Monitors	After it has interpreted the _sysconfig file, the sac reads its administrative file /etc/saf/_sactab . _sactab specifies which port monitors are to be started. For each port monitor to be started, sac forks a child (see fork(2)) and creates a utmpx entry with the type field set to LOGIN_PROCESS . Each child then interprets its per-port monitor configuration script /etc/saf/pmtag/_config , if the file exists. These modifications to the environment affect the port monitor and will be inherited by all its children. Finally, the child process execs the port monitor, using the command found in the _sactab entry. (See sacadm ; this is the command given with the -c option when the port monitor is added to the system.)										
Polling Port Monitors to Detect Failure	The -t option sets the frequency with which sac polls the port monitors on the system. This time may also be thought of as half of the maximum latency required to detect that a port monitor has failed and that recovery action is necessary.										
Administrative functions	The Service Access Controller represents the administrative point of control for port monitors. Its administrative tasks are explained below. When queried (sacadm with either -l or -L), the Service Access Controller returns the status of the port monitors specified, which sacadm prints on the standard output. A port monitor may be in one of six states: <table><tr><td>ENABLED</td><td>The port monitor is currently running and is accepting connections. See sacadm(1M) with the -e option.</td></tr><tr><td>DISABLED</td><td>The port monitor is currently running and is not accepting connections. See sacadm with the -d option, and see NOTRUNNING, below.</td></tr><tr><td>STARTING</td><td>The port monitor is in the process of starting up. STARTING is an intermediate state on the way to ENABLED or DISABLED.</td></tr><tr><td>FAILED</td><td>The port monitor was unable to start and remain running.</td></tr><tr><td>STOPPING</td><td>The port monitor has been manually terminated but has not completed its shutdown procedure. STOPPING is an intermediate state on the way to NOTRUNNING.</td></tr></table>	ENABLED	The port monitor is currently running and is accepting connections. See sacadm(1M) with the -e option.	DISABLED	The port monitor is currently running and is not accepting connections. See sacadm with the -d option, and see NOTRUNNING , below.	STARTING	The port monitor is in the process of starting up. STARTING is an intermediate state on the way to ENABLED or DISABLED .	FAILED	The port monitor was unable to start and remain running.	STOPPING	The port monitor has been manually terminated but has not completed its shutdown procedure. STOPPING is an intermediate state on the way to NOTRUNNING .
ENABLED	The port monitor is currently running and is accepting connections. See sacadm(1M) with the -e option.										
DISABLED	The port monitor is currently running and is not accepting connections. See sacadm with the -d option, and see NOTRUNNING , below.										
STARTING	The port monitor is in the process of starting up. STARTING is an intermediate state on the way to ENABLED or DISABLED .										
FAILED	The port monitor was unable to start and remain running.										
STOPPING	The port monitor has been manually terminated but has not completed its shutdown procedure. STOPPING is an intermediate state on the way to NOTRUNNING .										

NOTRUNNING The port monitor is not currently running. (See `sacadm` with `-k`.) This is the normal “not running” state. When a port monitor is killed, all ports it was monitoring are inaccessible. It is not possible for an external user to tell whether a port is not being monitored or the system is down. If the port monitor is not killed but is in the `DISABLED` state, it may be possible (depending on the port monitor being used) to write a message on the inaccessible port telling the user who is trying to access the port that it is disabled. This is the advantage of having a `DISABLED` state as well as the `NOTRUNNING` state.

When a port monitor terminates, the SAC removes the `utmpx` entry for that port monitor.

The SAC receives all requests to enable, disable, start, or stop port monitors and takes the appropriate action.

The SAC is responsible for restarting port monitors that terminate. Whether or not the SAC will restart a given port monitor depends on two things:

- The restart count specified for the port monitor when the port monitor was added by `sacadm`; this information is included in `/etc/saf/pmtag/_sactab`.
- The number of times the port monitor has already been restarted.

SECURITY `sac` uses `pam(3PAM)` for session management. The PAM configuration policy, listed through `/etc/pam.conf`, specifies the session management module to be used for `sac`. Here is a partial `pam.conf` file with entries for `sac` using the UNIX session management module.

```
sac session required pam_unix_session.so.1
```

If there are no entries for the `sac` service, then the entries for the “other” service will be used.

OPTIONS `-t sanity_interval` Sets the frequency (*sanity_interval*) with which `sac` polls the port monitors on the system.

FILES `/etc/saf/_sactab`
`/etc/saf/_sysconfig`
`/var/adm/utmpx`
`/var/saf/_log`

NAME	sacadm – service access controller administration
SYNOPSIS	<pre> sacadm -a -p <i>pmtag</i> -t <i>type</i> -c <i>cmd</i> -v <i>ver</i> [-f <i>dx</i>] [-n <i>count</i>] [-y <i>comment</i>] [-z <i>script</i>] sacadm -r -p <i>pmtag</i> sacadm -s -p <i>pmtag</i> sacadm -k -p <i>pmtag</i> sacadm -e -p <i>pmtag</i> sacadm -d -p <i>pmtag</i> sacadm -l [-p <i>pmtag</i> -t <i>type</i>] sacadm -L [-p <i>pmtag</i> -t <i>type</i>] sacadm -g -p <i>pmtag</i> [-z <i>script</i>] sacadm -G [-z <i>script</i>] sacadm -x [-p <i>pmtag</i>] </pre>
DESCRIPTION	sacadm is the administrative command for the upper level of the Service Access Facility hierarchy (port monitor administration). sacadm performs the following functions: ■ adds or removes a port monitor ■ starts or stops a port monitor ■ enables or disables a port monitor ■ installs or replaces a per-system configuration script ■ installs or replaces a per-port monitor configuration script ■ prints requested port monitor information Requests about the status of port monitors (-l and -L) and requests to print per-port monitor and per-system configuration scripts (-g and -G without the -z option) may be executed by any user on the system. Other sacadm commands may be executed only by the super-user.
OPTIONS	-a Add a port monitor. When adding a port monitor, sacadm creates the supporting directory structure in /etc/saf and /var/saf and adds an entry for the new port monitor to /etc/saf/_sactab. The file _sactab already exists on the delivered system. Initially, it is empty except for a single line, which contains the version number of the Service Access Controller. Unless the command line that adds the new port monitor includes the -f option with the -x argument, the new port monitor will be started. Because of the complexity of the options and arguments that follow the -a option, it may be convenient to use a command script or the menu system to add port monitors.

sacadm(1M)

-c <i>cmd</i>	Execute the command string <i>cmd</i> to start a port monitor. The -c option may be used only with a -a. A -a option requires a -c.
-d	Disable the port monitor <i>pmtag</i> .
-e	Enable the port monitor <i>pmtag</i> .
-f <i>dx</i>	The -f option specifies one or both of the following two flags which are then included in the flags field of the <i>_sactab</i> entry for the new port monitor. If the -f option is not included on the command line, no flags are set and the default conditions prevail. By default, a port monitor is started. A -f option with no following argument is illegal. d Do not enable the new port monitor. x Do not start the new port monitor.
-g	The -g option is used to request output or to install or replace the per-port monitor configuration script <i>/etc/saf/pmtag/_config</i> . -g requires a -p option. The -g option with only a -p option prints the per-port monitor configuration script for port monitor <i>pmtag</i> . The -g option with a -p option and a -z option installs the file <i>script</i> as the per-port monitor configuration script for port monitor <i>pmtag</i> . Other combinations of options with -g are invalid.
-G	The -G option is used to request output or to install or replace the per-system configuration script <i>/etc/saf/_sysconfig</i> . The -G option by itself prints the per-system configuration script. The -G option in combination with a -z option installs the file <i>script</i> as the per-system configuration script. Other combinations of options with a -G option are invalid.
-k	Stop port monitor <i>pmtag</i> .
-l	The -l option is used to request port monitor information. The -l by itself lists all port monitors on the system. The -l option in combination with the -p option lists only the port monitor specified by <i>pmtag</i> . A -l in combination with the -t option lists all port monitors of type <i>type</i> . Any other combination of options with the -l option is invalid.
-L	The -L option is identical to the -l option except that the output appears in a condensed format.
-n <i>count</i>	Set the restart count to <i>count</i> . If a restart count is not specified, count is set to 0. A count of 0 indicates that the port monitor is not to be restarted if it fails.
-p <i>pmtag</i>	Specifies the tag associated with a port monitor.
-r	Remove port monitor <i>pmtag</i> . <i>sacadm</i> removes the port monitor entry from <i>/etc/saf/_sactab</i> . If the removed port monitor is

not running, then no further action is taken. If the removed port monitor is running, the Service Access Controller (SAC) sends it SIGTERM to indicate that it should shut down. Note that the port monitor's directory structure remains intact.

- s Start a port monitor. The SAC starts the port monitor *pmtag*.
- t type Specifies the port monitor type.
- v ver Specifies the version number of the port monitor. This version number may be given as
 -v '*pmspec* -V'
 where *pmspec* is the special administrative command for port monitor *pmtag*. This special command is *tttadm* for *tttmon* and *nlsadmin* for *listen*. The version stamp of the port monitor is known by the command and is returned when *pmspec* is invoked with a -V option.
- x The -x option by itself tells the SAC to read its database file (*_sactab*). The -x option with the -p option tells port monitor *pmtag* to read its administrative file.
- y comment Include *comment* in the *_sactab* entry for port monitor *pmtag*.
- z script Used with the -g and -G options to specify the name of a file that contains a configuration script. With the -g option, *script* is a per-port monitor configuration script; with -G it is a per-system configuration script. Modifying a configuration script is a three-step procedure. First a copy of the existing script is made (-g or -G). Then the copy is edited. Finally, the copy is put in place over the existing script (-g or -G with -z).

OUTPUT If successful, *sacadm* will exit with a status of 0. If *sacadm* fails for any reason, it will exit with a nonzero status. Options that request information will write the information on the standard output. In the condensed format (-L), port monitor information is printed as a sequence of colon-separated fields; empty fields are indicated by two successive colons. The standard format (-l) prints a header identifying the columns, and port monitor information is aligned under the appropriate headings. In this format, an empty field is indicated by a hyphen. The comment character is #.

EXAMPLES **EXAMPLE 1** A sample output of the *sacadm* command.

The following command line adds a port monitor. The port monitor tag is *npack*; its type is *listen*; if necessary, it will restart three times before failing; its administrative command is *nlsadmin*; and the configuration script to be read is in the file *script*:

```
sacadm -a -p npack -t listen -c /usr/lib/saf/listen npack
-v 'nlsadmin -V' -n 3 -z script
```

Remove a port monitor whose tag is *pmtag*:

```
sacadm -r -p pmtag
```

sacadm(1M)

EXAMPLE 1 A sample output of the `sacadm` command. (Continued)

Start the port monitor whose tag is `pmtag`:

```
sacadm -s -p pmtag
```

Stop the port monitor whose tag is `pmtag`:

```
sacadm -k -p pmtag
```

Enable the port monitor whose tag is `pmtag`:

```
sacadm -e -p pmtag
```

Disable the port monitor whose tag is `pmtag`:

```
sacadm -d -p pmtag
```

List status information for all port monitors:

```
sacadm -l
```

List status information for the port monitor whose tag is `pmtag`:

```
sacadm -l -p pmtag
```

List the same information in condensed format:

```
sacadm -L -p pmtag
```

List status information for all port monitors whose type is `listen`:

```
sacadm -l -t listen
```

Replace the per-port monitor configuration script associated with the port monitor whose tag is `pmtag` with the contents of the file `file.config`:

```
sacadm -g -p pmtag -z file.config
```

NAME	sadmind – distributed system administration daemon								
SYNOPSIS	sadmind [-c <i>keywords</i>] [-i <i>secs</i>] [-l [<i>logfile</i>]] [-O <i>OW_path_name</i>] [-S <i>security_level</i>] [-v]								
DESCRIPTION	sadmind is the daemon used by Solstice AdminSuite applications to perform distributed system administration operations. The sadmind daemon is started automatically by the inetd daemon whenever a request to invoke an operation is received. The sadmind daemon process continues to run for 15 minutes after the last request is completed, unless a different idle-time is specified with the -i command line option. The sadmind daemon may be started independently from the command line, for example, at system boot time. In this case, the -i option has no effect; sadmind continues to run, even if there are no active requests. The sadmind daemon process can be configured to write tracing information into a log file by specifying the -c and -l command line options. The -c option specifies a comma-separated list of keywords indicating the types of information to be logged. The following keywords may be useful to administrators: <table> <tr> <td>Errors</td><td>Includes messages about errors that occurred during the daemon execution.</td></tr> <tr> <td>Requests</td><td>Includes messages about which operations sadmind invoked and when.</td></tr> <tr> <td>System-Info</td><td>Includes messages about when the sadmind daemon was started and stopped.</td></tr> <tr> <td>*</td><td>Includes all possible log messages.</td></tr> </table> The -l option enables logging and optionally specifies the path and file name of the log file. If no log file is specified, the default log file <code>/var/adm/admin.log</code> is used.	Errors	Includes messages about errors that occurred during the daemon execution.	Requests	Includes messages about which operations sadmind invoked and when.	System-Info	Includes messages about when the sadmind daemon was started and stopped.	*	Includes all possible log messages.
Errors	Includes messages about errors that occurred during the daemon execution.								
Requests	Includes messages about which operations sadmind invoked and when.								
System-Info	Includes messages about when the sadmind daemon was started and stopped.								
*	Includes all possible log messages.								
OPTIONS	The following options are supported: <table> <tr> <td>-c <i>keywords</i></td><td>Specify the types of information to be logged as a comma-separated list of keywords. The default is to log all types of messages.</td></tr> <tr> <td>-i <i>secs</i></td><td>Specify the number of seconds for sadmind to stay up after the last request is completed. The default is 15 minutes (900 seconds). If <i>secs</i> is 0 or over 10,000,000, sadmind stays up forever. -i only applies when sadmind is started by the inetd daemon. You may want sadmind to run permanently (or for extended durations) on systems that are frequently administered by applications using sadmind (for example, a server managed through Host Manager) to improve application performance.</td></tr> </table>	-c <i>keywords</i>	Specify the types of information to be logged as a comma-separated list of keywords. The default is to log all types of messages.	-i <i>secs</i>	Specify the number of seconds for sadmind to stay up after the last request is completed. The default is 15 minutes (900 seconds). If <i>secs</i> is 0 or over 10,000,000, sadmind stays up forever. -i only applies when sadmind is started by the inetd daemon. You may want sadmind to run permanently (or for extended durations) on systems that are frequently administered by applications using sadmind (for example, a server managed through Host Manager) to improve application performance.				
-c <i>keywords</i>	Specify the types of information to be logged as a comma-separated list of keywords. The default is to log all types of messages.								
-i <i>secs</i>	Specify the number of seconds for sadmind to stay up after the last request is completed. The default is 15 minutes (900 seconds). If <i>secs</i> is 0 or over 10,000,000, sadmind stays up forever. -i only applies when sadmind is started by the inetd daemon. You may want sadmind to run permanently (or for extended durations) on systems that are frequently administered by applications using sadmind (for example, a server managed through Host Manager) to improve application performance.								

sadmind(1M)

-l [<i>logfile</i>]	Enable logging and optionally define the path name to the distributed system administration log file. The default log file is: <code>/var/adm/admin.log</code>				
-O <i>OW_path_name</i>	Define the path name to the OpenWindows home directory. If this option is not specified, the <code>sadmind</code> daemon will use the OpenWindows home directory defined in the <code>OPENWINHOME</code> environment variable, if defined; the home directory specified in the <code>/etc/OPENWINHOME</code> file, if it exists; or the default directory <code>/usr/openwin</code> . When the <code>sadmind</code> daemon is started by the <code>inetd</code> daemon, the environment variable <code>OPENWINHOME</code> is typically not defined. If the OpenWindows home directory is not one of the path names specified (<code>/usr/openwin</code> or in the file <code>/etc/OPENWINHOME</code>), the <code>-O</code> option must be added to the <code>sadmind</code> entry in the <code>inetd.conf(4)</code> configuration file.				
-S <i>security_level</i>	Define the level of security to be used by the <code>sadmind</code> daemon when checking a client's right to perform an operation on the server system. Security level specifies the authentication mechanism used to provide and check the client's identity. The client's identity must be authenticated by the specified mechanism for <code>sadmind</code> to accept his or her request. The system-wide authentication requirements set by the security level may take precedence over any operation-specific requirements. Consequently, the security level can be used system-wide to ensure that all operations meet minimum authentication requirements, regardless of the requirements assigned specifically to an operation. In addition, the security level determines whether <code>sadmind</code> will perform authorization access control checking. Security level may be one of the following: <table><tr><td>0</td><td>Set authentication type to <code>NONE</code>. All clients' user and group identities are set to the <code>nobody</code> identity by <code>sadmind</code> (see <i>Solstice AdminSuite 2.1 User's Guide</i>). If access is granted to <code>nobody</code>, <code>sadmind</code> executes the operation. Use this level only for testing.</td></tr><tr><td>1</td><td>Set authentication type to <code>WEAK</code>. Clients' user and group identities are set by <code>sadmind</code> from their authentication credentials. Client identities are accepted by</td></tr></table>	0	Set authentication type to <code>NONE</code> . All clients' user and group identities are set to the <code>nobody</code> identity by <code>sadmind</code> (see <i>Solstice AdminSuite 2.1 User's Guide</i>). If access is granted to <code>nobody</code> , <code>sadmind</code> executes the operation. Use this level only for testing.	1	Set authentication type to <code>WEAK</code> . Clients' user and group identities are set by <code>sadmind</code> from their authentication credentials. Client identities are accepted by
0	Set authentication type to <code>NONE</code> . All clients' user and group identities are set to the <code>nobody</code> identity by <code>sadmind</code> (see <i>Solstice AdminSuite 2.1 User's Guide</i>). If access is granted to <code>nobody</code> , <code>sadmind</code> executes the operation. Use this level only for testing.				
1	Set authentication type to <code>WEAK</code> . Clients' user and group identities are set by <code>sadmind</code> from their authentication credentials. Client identities are accepted by				

sadmind when they have satisfied either AUTH_SYS or AUTH_DES authentication mechanisms. The authenticated client identity is checked by `sadmind` for authorization to execute the operation. If an operation calls for a stronger security level, `sadmind` demotes the user identity to nobody, and then checks whether nobody is authorized to execute the operation. Since AUTH_SYS client credentials are easily forged, this level should be used only in relatively secure environments. No check is done that the user ID of the client represents the same user on the server system as on the client system. It is assumed that user and group identities are set up consistently on the network.

- 2 Set authentication type to `STRONG`. Clients' user and group identities are set by `sadmind` from their authentication credential mappings (effectively, user and group IDs from `netid.byname` for NIS, or `cred` table for NIS+). Client identities are accepted by `sadmind` only when they have satisfied the AUTH_DES authentication mechanism. The `sadmind` daemon checks whether the client identity is authorized to execute the operation. This level provides the most secure environment for executing distributed administration operations. It overrides any weaker level specific to an operation. A DES credential must exist for the host running the `sadmind` daemon and all administration client user identities. This security level is the default.

`-v` Enable the writing of log messages to the system logger, `syslogd`. Messages logged include fatal errors encountered while attempting to start the `sadmind` daemon process and those specified by the `-c` trace message keywords.

EXAMPLES

EXAMPLE 1 Using the `sadmind` command

By default, the line in `/etc/inetd.conf` that starts `sadmind` appears as follows:

```
100232/10      tli      rpc/udp      wait root
/usr/sbin/sadmind sadmind
```

sadmind(1M)

EXAMPLE 1 Using the `sadmind` command (Continued)

To make a network as secure as possible, change the line to:

```
100232/10      tli      rpc/udp    wait root
/usr/sbin/sadmind sadmind -S 2
```

To minimize delays due to starting up `sadmind`, change the line to include the `-i` option:

```
100232/10      tli      rpc/udp    wait root
/usr/sbin/sadmind sadmind -i 86400
```

In this example, the duration that `sadmind` remains up after the last operation request was completed is extended to 24 hours (86,400 seconds). Extending the timeout period may enhance performance on servers and workstations that frequently run or are administered by applications that use the `sadmind` daemon (for example, Solstice AdminSuite applications such as Host Manager).

FILES	<code>/var/adm/admin.log</code>	Distributed system administration default log file
	<code>/etc/inetd.conf</code>	Internet servers database file

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWadmfw

SEE ALSO `inetd(1M)`, `rpcbind(1M)`, `inetd.conf(4)`, `attributes(5)`

Solstice AdminSuite 2.1 User's Guide

NOTES Whenever `inetd` fails to start `sadmind`, re-register the RPC number for `sadmind`, 100232, with `rpcbind` by sending the `inetd` process a `SIGHUP` signal:

```
example% kill -HUP pid
```

or

```
example% kill -1
```

Sometimes `inetd` does not start `sadmind` in response to system administration requests, even though the `inetd.conf` file has the correct entry for the `sadmind` daemon. This can happen when `sadmind` is started manually from the command line and takes over the previous registration of the `sadmind` RPC number, 100232, by `inetd`. When the manually-started `sadmind` daemon is terminated, the `sadmind` RPC number, 100232, is de-registered with `rpcbind`. Consequently, system administration requests are ignored by `inetd`.

NAME	saf – Service Access Facility
DESCRIPTION	The SAF generalizes the procedures for service access so that login access on the local system and network access to local services are managed in similar ways. Under the SAF, systems may access services using a variety of port monitors, including ttymon, the listener, and port monitors written expressly for a user's application. The manner in which a port monitor observes and manages access ports is specific to the port monitor and not to any component of the SAF. Users may therefore extend their systems by developing and installing their own port monitors. One of the important features of the SAF is that it can be extended in this way by users. Relative to the SAF, a service is a process that is started. There are no restrictions on the functions a service may provide. The SAF consists of a controlling process, the service access controller (SAC), and two administrative levels corresponding to two levels in the supporting directory structure. The top administrative level is concerned with port monitor administration, the lower level with service administration. The SAC is documented in the <code>sac(1M)</code> man page. The administrative levels and associated utilities are documented in the <i>System Administration Guide - Volume II</i>. The requirements for writing port monitors and the functions a port monitor must perform to run under the SAF and the SAC are documented here.
Port Monitors	A port monitor is a process that is responsible for monitoring a set of homogeneous, incoming ports on a machine. A port monitor's major purpose is to detect incoming service requests and to dispatch them appropriately. A port is an externally seen access point on a system. A port may be an address on a network (TSAP or PSAP), a hardwired terminal line, an incoming phone line, etc. The definition of what constitutes a port is strictly a function of the port monitor itself. A port monitor performs certain basic functions. Some of these are required to conform to the SAF; others may be specified by the requirements and design of the port monitor itself. Port monitors have two main functions: managing ports and monitoring ports for indications of activity. Port Management The first function of a port monitor is to manage a port. The actual details of how a port is managed are defined by the person who defines the port monitor. A port monitor is not restricted to handling a single port; it may handle multiple ports simultaneously. Some examples of port management are setting the line speed on incoming phone connections, binding an appropriate network address, reinitializing the port when the service terminates, outputting a prompt, etc. Activity Monitoring The second function of a port monitor is to monitor the port or ports for which it is responsible for indications of activity. Two types of activity may be detected.

saf(1M)

Other Port Monitor Functions

The first is an indication to the port monitor to take some port monitor-specific action. Pressing the break key to indicate that the line speed should be cycled is an example of a port monitor activity. Not all port monitors need to recognize and respond to the same indications. The indication used to attract the attention of the port monitor is defined by the person who defines the port monitor.

The second is an incoming service request. When a service request is received, a port monitor must be able to determine which service is being requested from the port on which the request is received. The same service may be available on more than one port.

This section briefly describes other port monitor functions.

Restricting Access to the System

A port monitor must be able to restrict access to the system without disturbing services that are still running. In order to do this, a port monitor must maintain two internal states: enabled and disabled. The port monitor starts in the state indicated by the ISTATE environment variable provided by the sac. See sac(1M) for details. Enabling or disabling a port monitor affects all ports for which the port monitor is responsible. If a port monitor is responsible for a single port, only that port will be affected. If a port monitor is responsible for multiple ports, the entire collection of ports will be affected. Enabling or disabling a port monitor is a dynamic operation: it causes the port monitor to change its internal state. The effect does not persist across new invocations of the port monitor. Enabling or disabling an individual port, however, is a static operation: it causes a change to an administrative file. The effect of this change will persist across new invocations of the port monitor.

Creating utmpx Entries

Port monitors are responsible for creating utmpx entries with the type field set to USER_PROCESS for services they start. If this action has been specified, by using the -fu option in the pmadm command line that added the service, these utmpx entries may in turn be modified by the service. When the service terminates, the utmpx entry must be set to DEAD_PROCESS.

Port Monitor Process IDs and Lock Files

When a port monitor starts, it writes its process id into a file named _pid in the current directory and places an advisory lock on the file.

Changing the Service Environment: Running

doconfig(3NSL) Before invoking the service designated in the port monitor administrative file, _pmtab, a port monitor must arrange for the per-service configuration script to be run, if one exists, by calling the library function doconfig(3NSL). Because the per-service configuration script may specify the execution of restricted commands, as well as for other security reasons, port monitors are invoked with root permissions. The details of how services are invoked are specified by the person who defines the port monitor.

Terminating a Port Monitor

A port monitor must terminate itself gracefully on receipt of the signal SIGTERM. The termination sequence is the following:

	1. The port monitor enters the stopping state; no further service requests are accepted. 2. Any attempt to re-enable the port monitor will be ignored. 3. The port monitor yields control of all ports for which it is responsible. It must be possible for a new instantiation of the port monitor to start correctly while a previous instantiation is stopping. 4. The advisory lock on the process id file is released. Once this lock is released, the contents of the process id file are undefined and a new invocation of the port monitor may be started.
SAF Files	This section briefly covers the files used by the SAF. The Port Monitor Administrative File A port monitor's current directory contains an administrative file named <code>_pmtab</code>; <code>_pmtab</code> is maintained by the <code>pmadm</code> command in conjunction with a port monitor-specific administrative command. The port monitor administrative command for a listen port monitor is <code>nlsadmin(1M)</code>; the port monitor administrative command for <code>ttymon</code> is <code>ttyadm(1M)</code>. Any port monitor written by a user must be provided with an administrative command specific to that port monitor to perform similar functions. Per-Service Configuration Files A port monitor's current directory also contains the per-service configuration scripts, if they exist. The names of the per-service configuration scripts correspond to the service tags in the <code>_pmtab</code> file. Private Port Monitor Files A port monitor may create private files in the directory <code>/var/saf/tag</code>, where <i>tag</i> is the name of the port monitor. Examples of private files are log files or temporary files.
The SAC/Port Monitor Interface	The SAC creates two environment variables for each port monitor it starts: <code>PMTAG</code> and <code>ISTATE</code>. This variable is set to a unique port monitor tag by the SAC. The port monitor uses this tag to identify itself in response to <code>sac</code> messages. <code>ISTATE</code> is used to indicate to the port monitor what its initial internal state should be. <code>ISTATE</code> is set to "enabled" or "disabled" to indicate that the port monitor is to start in the enabled or disabled state respectively. The SAC performs a periodic sanity poll of the port monitors. The SAC communicates with port monitors through FIFOs. A port monitor should open <code>_pmpipe</code>, in the current directory, to receive messages from the SAC and <code>./_sacpipe</code> to send return messages to the SAC.
Message Formats	This section describes the messages that may be sent from the SAC to a port monitor (<code>sac</code> messages), and from a port monitor to the SAC (port monitor messages). These messages are sent through FIFOs and are in the form of C structures.

saf(1M)

Port Monitor Messages

sac Messages

The format of messages from the SAC is defined by the structure `sacmsg`:

```
struct sacmsg
{
    int sc_size; /* size of optional data portion */
    char sc_type; /* type of message */
};
```

The SAC may send four types of messages to port monitors. The type of message is indicated by setting the `sc_type` field of the `sacmsg` structure to one of the following:

SC_STATUS	status request
SC_ENABLE	enable message
SC_DISABLE	disable message
SC_READDB	message indicating that the port monitor's <code>_pmtab</code> file should be read

The `sc_size` field indicates the size of the optional data part of the message. See "Message Classes." For Solaris, `sc_size` should always be set to 0. A port monitor must respond to every message sent by the sac.

The format of messages from a port monitor to the SAC is defined by the structure `pmmsg`:

```
struct pmmsg {
    char pm_type; /* type of message */
    uchar_t pm_state; /* current state of port monitor */
    char pm_maxclass; /* maximum message class this port
                      monitor understands */
    char pm_tag[PMTAGSIZE + 1]; /* port monitor's tag */
    int pm_size; /* size of optional data portion */
};
```

Port monitors may send two types of messages to the SAC. The type of message is indicated by setting the `pm_type` field of the `pmmsg` structure to one of the following:

PM_STATUS	state information
PM_UNKNOWN	negative acknowledgment

For both types of messages, the `pm_tag` field is set to the port monitor's tag and the `pm_state` field is set to the port monitor's current state. Valid states are:

PM_STARTING	starting
PM_ENABLED	enabled
PM_DISABLED	disabled

	PM_STOPPING	stopping	The current state reflects any changes caused by the last message from the SAC. The status message is the normal return message. The negative acknowledgment should be sent only when the message received is not understood. <code>pm_size</code> indicates the size of the optional data part of the message. <code>pm_maxclass</code> is used to specify a message class. Both are discussed under "Message Classes." In Solaris, always set <code>pm_maxclass</code> to 1 and <code>sc_size</code> to 0. Port monitors may never initiate messages; they may only respond to messages that they receive.
Message Classes			The concept of message class has been included to accommodate possible SAF extensions. The messages described above are all class 1 messages. None of these messages contains a variable data portion; all pertinent information is contained in the message header. If new messages are added to the protocol, they will be defined as new message classes (for example, class 2). The first message the SAC sends to a port monitor will always be a class 1 message. Since all port monitors, by definition, understand class 1 messages, the first message the SAC sends is guaranteed to be understood. In its response to the SAC, the port monitor sets the <code>pm_maxclass</code> field to the maximum message class number for that port monitor. The SAC will not send messages to a port monitor from a class with a larger number than the value of <code>pm_maxclass</code>. Requests that require messages of a higher class than the port monitor can understand will fail. For Solaris, always set <code>pm_maxclass</code> to 1. For any given port monitor, messages of class <code>pm_maxclass</code> and messages of all classes with values lower than <code>pm_maxclass</code> are valid. Thus, if the <code>pm_maxclass</code> field is set to 3, the port monitor understands messages of classes 1, 2, and 3. Port monitors may not generate messages; they may only respond to messages. A port monitor's response must be of the same class as the originating message. Since only the SAC can generate messages, this protocol will function even if the port monitor is capable of dealing with messages of a higher class than the SAC can generate. <code>pm_size</code> (an element of the <code>pmmsg</code> structure) and <code>sc_size</code> (an element of the <code>sacmsg</code> structure) indicate the size of the optional data part of the message. The format of this part of the message is undefined. Its definition is inherent in the type of message. For Solaris, always set both <code>sc_size</code> and <code>pm_size</code> to 0.
Administrative Interface The SAC Administrative File <code>_sactab</code>			This section discusses the port monitor administrative files available under the SAC. The service access controller's administrative file contains information about all the port monitors for which the SAC is responsible. This file exists on the delivered system. Initially, it is empty except for a single comment line that contains the version number of the SAC. Port monitors are added to the system by making entries in the SAC's administrative file. These entries should be made using the administrative command <code>sacadm(1M)</code> with a <code>-a</code> option. <code>sacadm(1M)</code> is also used to remove entries from the SAC's administrative file. Each entry in the SAC's administrative file contains the following information.

saf(1M)

**The Port Monitor
Administrative
File `_pmtab`**

PMTAG

A unique tag that identifies a particular port monitor. The system administrator is responsible for naming a port monitor. This tag is then used by the SAC to identify the port monitor for all administrative purposes. PMTAG may consist of up to 14 alphanumeric characters.

PMTYPE

The type of the port monitor. In addition to its unique tag, each port monitor has a type designator. The type designator identifies a group of port monitors that are different invocations of the same entity. `ttymon` and `listen` are examples of valid port monitor types. The type designator is used to facilitate the administration of groups of related port monitors. Without a type designator, the system administrator has no way of knowing which port monitor tags correspond to port monitors of the same type. PMTYPE may consist of up to 14 alphanumeric characters.

FLGS

The flags that are currently defined are:

- `d` When started, do not enable the port monitor.
- `x` Do not start the port monitor.

If no flag is specified, the default action is taken. By default a port monitor is started and enabled.

RCNT

The number of times a port monitor may fail before being placed in a failed state. Once a port monitor enters the failed state, the SAC will not try to restart it. If a count is not specified when the entry is created, this field is set to 0. A restart count of 0 indicates that the port monitor is not to be restarted when it fails.

COMMAND

A string representing the command that will start the port monitor. The first component of the string, the command itself, must be a full path name.

Each port monitor will have two directories for its exclusive use. The current directory will contain files defined by the SAF (`_pmtab`, `_pid`) and the per-service configuration scripts, if they exist. The directory `/var/saf/pmtag`, where *pmtag* is the tag of the port monitor, is available for the port monitor's private files. Each port monitor has its own administrative file. The `pmadm(1M)` command should be used to add, remove, or modify service entries in this file. Each time a change is made using `pmadm(1M)`, the corresponding port monitor rereads its administrative file. Each entry in a port monitor's administrative file defines how the port monitor treats a specific port and what service is to be invoked on that port. Some fields must be present for all types of port monitors. Each entry must include a service tag to identify the service uniquely and an identity to be assigned to the service when it is started (for example, `root`).

The combination of a service tag and a port monitor tag uniquely define an instance of a service. The same service tag may be used to identify a service under a different port monitor. The record must also contain port monitor specific data (for example, for a

ttymon port monitor, this will include the prompt string which is meaningful to ttymon). Each type of port monitor must provide a command that takes the necessary port monitor-specific data as arguments and outputs these data in a form suitable for storage in the file. The `ttynam(1M)` command does this for ttymon and `nlsadmin(1M)` does it for listen. For a user-defined port monitor, a similar administrative command must also be supplied. Each service entry in the port monitor administrative file must have the following format and contain the information listed below:

```
svctag:flgs:id:reserved:reserved:reserved:pmspecific# comment
```

SVCTAG is a unique tag that identifies a service. This tag is unique only for the port monitor through which the service is available. Other port monitors may offer the same or other services with the same tag. A service requires both a port monitor tag and a service tag to identify it uniquely. SVCTAG may consist of up to 14 alphanumeric characters. The service entries are defined as:

FLGS

Flags with the following meanings may currently be included in this field:

- `x` Do not enable this port. By default the port is enabled.
- `u` Create a utmpx entry for this service. By default no utmpx entry is created for the service.

ID

The identity under which the service is to be started. The identity has the form of a login name as it appears in `/etc/passwd`.

PMSPECIFIC

Examples of port monitor information are addresses, the name of a process to execute, or the name of a STREAMS pipe to pass a connection through. This information will vary to meet the needs of each different type of port monitor.

COMMENT

A comment associated with the service entry. Port monitors may ignore the `u` flag if creating a utmpx entry for the service is not appropriate to the manner in which the service is to be invoked. Some services may not start properly unless utmpx entries have been created for them (for example, login). Each port monitor administrative file must contain one special comment of the form:

```
# VERSION=value
```

where *value* is an integer that represents the port monitor's version number. The version number defines the format of the port monitor administrative file. This comment line is created automatically when a port monitor is added to the system. It appears on a line by itself, before the service entries.

Monitor-Specific Administrative Command

Previously, two pieces of information included in the `_pmtab` file were described: the port monitor's version number and the port monitor part of the service entries in the port monitor's `_pmtab` file. When a new port monitor is added, the version number

saf(1M)

The Port Monitor/Service Interface

must be known so that the `_pmtab` file can be correctly initialized. When a new service is added, the port monitor part of the `_pmtab` entry must be formatted correctly. Each port monitor must have an administrative command to perform these two tasks. The person who defines the port monitor must also define such an administrative command and its input options. When the command is invoked with these options, the information required for the port monitor part of the service entry must be correctly formatted for inclusion in the port monitor's `_pmtab` file and must be written to the standard output. To request the version number the command must be invoked with a `-V` option; when it is invoked in this way, the port monitor's current version number must be written to the standard output. If the command fails for any reason during the execution of either of these tasks, no data should be written to standard output.

The interface between a port monitor and a service is determined solely by the service. Two mechanisms for invoking a service are presented here as examples.

New Service Invocations

The first interface is for services that are started anew with each request. This interface requires the port monitor to first `fork(2)` a child process. The child will eventually become the designated service by performing an `exec(1)`. Before the `exec(1)` happens, the port monitor may take some port monitor-specific action; however, one action that must occur is the interpretation of the per-service configuration script, if one is present. This is done by calling the library routine `doconfig(3NSL)`.

Standing Service Invocations

The second interface is for invocations of services that are actively running. To use this interface, a service must have one end of a stream pipe open and be prepared to receive connections through it.

Port Monitor Requirements

To implement a port monitor, several generic requirements must be met. This section summarizes these requirements. In addition to the port monitor itself, an administrative command must be supplied.

Initial Environment

When a port monitor is started, it expects an initial execution environment in which:

- It has no file descriptors open
- It cannot be a process group leader
- It has an entry in `/etc/utmpx` of type `LOGIN_PROCESS`
- An environment variable, `ISTATE`, is set to "enabled" or "disabled" to indicate the port monitor's correct initial state
- An environment variable, `PMTAG`, is set to the port monitor's assigned tag
- The directory that contains the port monitor's administrative files is its current directory
- The port monitor is able to create private files in the directory `/var/saf/tag`, where `tag` is the port monitor's tag
- The port monitor is running with user id 0 (root)

Important Files

Relative to its current directory, the following key files exist for a port monitor.

_config

The port monitor's configuration script. The port monitor configuration script is run by the SAC. The SAC is started by `init(1M)` as a result of an entry in `/etc/inittab` that calls `sac(1M)`.

_pid

The file into which the port monitor writes its process id.

_pmtab

The port monitor's administrative file. This file contains information about the ports and services for which the port monitor is responsible.

_pmpipe

The FIFO through which the port monitor will receive messages from the SAC.

svctag

The per-service configuration script for the service with the tag *svctag*.

../_sacpipe

The FIFO through which the port monitor will send messages to `sac(1M)`.

Port Monitor Responsibilities

A port monitor is responsible for performing the following tasks in addition to its port monitor function:

- Write its process id into the file `_pid` and place an advisory lock on the file
- Terminate gracefully on receipt of the signal `SIGTERM`
- Follow the protocol for message exchange with the SAC

A port monitor must perform the following tasks during service invocation:

- Create a `utmpx` entry if the requested service has the `u` flag set in `_pmtab`
- Port monitors may ignore this flag if creating a `utmpx` entry for the service does not make sense because of the manner in which the service is to be invoked. On the other hand, some services may not start properly unless `utmpx` entries have been created for them.
- Interpret the per-service configuration script for the requested service, if it exists, by calling the `doconfig(3NSL)` library routine

Configuration Files and Scripts

The library routine `doconfig(3NSL)`, defined in `libnsl.so`, interprets the configuration scripts contained in the files `/etc/saf/_sysconfig` (the per-system configuration file), and `/etc/saf/pmtag/_config` (per-port monitor configuration files); and in `/etc/saf/pmtag/svctag` (per-service configuration files). Its syntax is:

```
#include <sac.h>
int doconfig(int fd, char *script, long rflag);
```

script is the name of the configuration script; *fd* is a file descriptor that designates the stream to which stream manipulation operations are to be applied; *rflag* is a bitmask that indicates the mode in which *script* is to be interpreted. *rflag* may take two values, `NORUN` and `NOASSIGN`, which may be or'd. If *rflag* is zero, all commands in

saf(1M)

the configuration script are eligible to be interpreted. If *rflag* has the NOASSIGN bit set, the assign command is considered illegal and will generate an error return. If *rflag* has the NORUN bit set, the run and runwait commands are considered illegal and will generate error returns. If a command in the script fails, the interpretation of the script ceases at that point and a positive integer is returned; this number indicates which line in the script failed. If a system error occurs, a value of -1 is returned. If a script fails, the process whose environment was being established should not be started. In the example, doconfig(3NSL) is used to interpret a per-service configuration script.

```
. . .
    if ((i = doconfig (fd, svctag, 0)) != 0){
        error ("doconfig failed on line %d of script %s",i,svctag);
    }
}
```

The Per-System Configuration File

The per-system configuration file, `/etc/saf/_sysconfig`, is delivered empty. It may be used to customize the environment for all services on the system by writing a command script in the interpreted language described in this chapter and on the `doconfig(3NSL)` manpage. When the SAC is started, it calls the `doconfig(3NSL)` function to interpret the per-system configuration script. The SAC is started when the system enters multiuser mode.

Per-Port Monitor Configuration Files

Per-port monitor configuration scripts (`/etc/saf/pmtag/_config`) are optional. They allow the user to customize the environment for any given port monitor and for the services that are available through the ports for which that port monitor is responsible. Per-port monitor configuration scripts are written in the same language used for per-system configuration scripts. The per-port monitor configuration script is interpreted when the port monitor is started. The port monitor is started by the SAC after the SAC has itself been started and after it has run its own configuration script, `/etc/saf/_sysconfig`. The per-port monitor configuration script may override defaults provided by the per-system configuration script.

Per-Service Configuration Files

Per-service configuration files allow the user to customize the environment for a specific service. For example, a service may require special privileges that are not available to the general user. Using the language described in the `doconfig(3NSL)` manpage, you can write a script that will grant or limit such special privileges to a particular service offered through a particular port monitor. The per-service configuration may override defaults provided by higher-level configuration scripts. For example, the per-service configuration script may specify a set of STREAMS modules other than the default set.

The Configuration Language

The language in which configuration scripts are written consists of a sequence of commands, each of which is interpreted separately. The following reserved keywords are defined: `assign`, `push`, `pop`, `runwait`, and `run`. The comment character is `#`. Blank lines are not significant. No line in a command script may exceed 1024 characters.

`assign variable=value`

Used to define environment variables; *variable* is the name of the environment variable and *value* is the value to be assigned to it. The value assigned must be a string constant; no form of parameter substitution is available. *value* may be quoted. The quoting rules are those used by the shell for defining environment variables. `assign` will fail if space cannot be allocated for the new variable or if any part of the specification is invalid.

`push module1 [, module2, module3, ...]`

Used to push STREAMS modules onto the stream designated by `fd`; *module1* is the name of the first module to be pushed, *module2* is the name of the second module to be pushed, and so on. The command will fail if any of the named modules cannot be pushed. If a module cannot be pushed, the subsequent modules on the same command line will be ignored and modules that have already been pushed will be popped.

`pop [module]`

Used to pop STREAMS modules off the designated stream. If `pop` is invoked with no arguments, the top module on the stream is popped. If an argument is given, modules will be popped one at a time until the named module is at the top of the stream. If the named module is not on the designated stream, the stream is left as it was and the command fails. If *module* is the special keyword `ALL`, then all modules on the stream will be popped. Only modules above the topmost driver are affected.

`runwait command`

The `runwait` command runs a command and waits for it to complete; `command` is the path name of the command to be run. The command is run with `/bin/sh -c` prepended to it; shell scripts may thus be executed from configuration scripts. The `runwait` command will fail if `command` cannot be found or cannot be executed, or if `command` exits with a nonzero status.

`run command`

The `run` command is identical to `runwait` except that it does not wait for `command` to complete; `command` is the path name of the command to be run. `run` will not fail unless it is unable to create a child process to execute the command. Although they are syntactically indistinguishable, some of the commands available to `run` and `runwait` are interpreter built-in commands. Interpreter built-ins are used when it is necessary to alter the state of a process within the context of that process. The `doconfig` interpreter built-in commands are similar to the shell special commands and, like these, they do not spawn another process for execution. See the `sh(1)` man page. The initial set of built-in commands is: `cd`, `ulimit`, `umask`.

Sample Port Monitor Code

This example shows an example of a "null" port monitor that simply responds to messages from the SAC.

```
# include <stdlib.h>
# include <stdio.h>
# include <unistd.h>
# include <fcntl.h>
# include <signal.h>
```

saf(1M)

```
# include <sac.h>

char Scratch[BUFSIZ]; /* scratch buffer */
char Tag[PMTAGSIZE + 1]; /* port monitor's tag */
FILE *Fp; /* file pointer for log file */
FILE *Tfp; /* file pointer for pid file */
char State; /* portmonitor's current state*/

main(argc, argv)
    int argc;
    char *argv[];
{
    char *istate;
    strcpy(Tag, getenv("PMTAG"));
/*
 * open up a log file in port monitor's private directory
 */
    sprintf(Scratch, "/var/saf/%s/log", Tag);
    Fp = fopen(Scratch, "a+");
    if (Fp == (FILE *)NULL)
        exit(1);
    log(Fp, "starting");
/*
 * retrieve initial state (either "enabled" or "disabled") and set
 * State accordingly
 */
    istate = getenv("ISTATE");
    sprintf(Scratch, "ISTATE is %s", istate);
    log(Fp, Scratch);
    if (!strcmp(istate, "enabled"))
        State = PM_ENABLED;
    else if (!strcmp(istate, "disabled"))
        State = PM_DISABLED;
    else {
        log(Fp, "invalid initial state");
        exit(1);
    }
    sprintf(Scratch, "PMTAG is %s", Tag);
    log(Fp, Scratch);
/*
 * set up pid file and lock it to indicate that we are active
 */
    Tfp = fopen("_pid", "w");
    if (Tfp == (FILE *)NULL) {
        log(Fp, "couldn't open pid file");
        exit(1);
    }
    if (lockf(fileno(Tfp), F_TEST, 0) < 0) {
        log(Fp, "pid file already locked");
        exit(1);
    }

    log(Fp, "locking file");
    if (lockf(fileno(Tfp), F_LOCK, 0) < 0) {
        log(Fp, "lock failed");
        exit(1);
    }
    fprintf(Tfp, "%d", getpid());
}
```

```

        fflush(Tfp);

/*
 * handle poll messages from the sac ... this function never returns
 */
    handlepoll();
    pause();
    fclose(Tfp);
    fclose(Fp);
}

handlepoll()
{
    int pfd; /* file descriptor for incoming pipe */
    int sfd; /* file descriptor for outgoing pipe */
    struct sacmsg sacmsg; /* incoming message */
    struct pmmsg pmmsg; /* outgoing message */

/*
 * open pipe for incoming messages from the sac
 */
    pfd = open("_pmpipe", O_RDONLY|O_NONBLOCK);
    if (pfd < 0) {
        log(Fp, "_pmpipe open failed");

        break;
    case SC_READDB:
        /*
         * if this were a fully functional port
         * monitor it would read _pmtab here
         * and take appropriate action
         */
        log(Fp, "Got SC_READDB message");
        pmmsg.pm_type = PM_STATUS;
        pmmsg.pm_state = State;
        break;
    default:
        sprintf(Scratch, "Got unknown message <%d>",
            sacmsg.sc_type);
        log(Fp, Scratch);
        pmmsg.pm_type = PM_UNKNOWN;
        pmmsg.pm_state = State;
        break;
    }
}
/*
 * send back a response to the poll
 * indicating current state
 */
    if (write(sfd, &pmmsg, sizeof(pmmsg)) != sizeof(pmmsg))
        log(Fp, "sanity response failed");
}
}
/*
 * general logging function
 */
log(fp, msg)
    FILE *fp;
    char *msg;
{
    fprintf(fp, "%d: %s\n", getpid(), msg);
    fflush(fp);
}
```

The sac.h Header File

The following example shows the sac.h header file.

```
/* length in bytes of a utmpx id */
# define IDLEN 4
/* wild character for utmpx ids */
# define SC_WILDC 0xff
/* max len in bytes for port monitor tag */
# define PMTAGSIZE 14
/*
```

```

* values for rflag in doconfig()
*/
/* don't allow assign operations */
# define NOASSIGN 0x1
/* don't allow run or runwait operations */
# define NORUN 0x2
/*
* message to SAC (header only). This header is forever fixed. The
* size field (pm_size) defines the size of the data portion of the
* message, which follows the header. The form of this optional data
* portion is defined strictly by the message type (pm_type).
*/
struct pmmsg {
    char pm_type;           /* type of message */
    uchar_t pm_state;       /* current state of pm */
    char pm_maxclass;       /* max message class this port monitor
                           understands */
    char pm_tag[PMTAGSIZE + 1]; /* pm's tag */
    int pm_size;           /* size of opt data portion */
};
/*
* pm_type values
*/
# define PM_STATUS 1 /* status response */
# define PM_UNKNOWN 2 /* unknown message was received */
/*
* pm_state values
*/
/*
* Class 1 responses
*/
# define PM_STARTING 1 /* monitor in starting state */
# define PM_ENABLED 2 /* monitor in enabled state */
# define PM_DISABLED 3 /* monitor in disabled state */
# define PM_STOPPING 4 /* monitor in stopping state */
/*
* message to port monitor
*/
struct sacmsg {
    int sc_size;           /* size of optional data portion */
    char sc_type;          /* type of message */
};
/*
* sc_type values
* These represent commands that the SAC sends to a port monitor.
* These commands are divided into "classes" for extensibility. Each
* subsequent "class" is a superset of the previous "classes" plus
* the new commands defined within that "class". The header for all
* commands is identical; however, a command may be defined such that
* an optional data portion may be sent in addition to the header.
* The format of this optional data piece is self-defining based on
* the command. The first message sent by the SAC
* will always be a class 1 message. The port monitor response
* indicates the maximum class that it is able to understand. Another
* note is that port monitors should only respond to a message with
* an equivalent class response (i.e. a class 1 command causes a
* class 1 response).
*/

```

saf(1M)

```
/*
 * Class 1 commands (currently, there are only class 1 commands)
 */

```

Directory Structure

This section gives a description of the SAF files and directories.

<code>/etc/saf/_sysconfig</code>	The per-system configuration script.
<code>/etc/saf/_sactab</code>	The SAC's administrative file. Contains information about the port monitors for which the SAC is responsible.
<code>/etc/saf/pmtag</code>	The home directory for port monitor <i>pmtag</i> .
<code>/etc/saf/pmtag/_config</code>	The per-port monitor configuration script for port monitor <i>pmtag</i> .
<code>/etc/saf/pmtag/_pmtab</code>	Port monitor <i>pmtag</i> 's administrative file. Contains information about the services for which <i>pmtag</i> is responsible.
<code>/etc/saf/pmtag/svctag</code>	The file in which the per-service configuration script for service <i>svctag</i> (available through port monitor <i>pmtag</i>) is placed.
<code>/etc/saf/pmtag/_pid</code>	The file in which a port monitor writes its process id in the current directory and places an advisory lock on the file.
<code>/etc/saf/pmtag/_pmpipe</code>	The file in which the port monitor receives messages from the SAC and <code>../_sacpipe</code> and sends return messages to the SAC.
<code>/var/saf/_log</code>	The SAC's log file.
<code>/var/saf/pmtag</code>	The directory for files created by port monitor <i>pmtag</i> , for example its log file.

sar(1M)

NAME	sar, sa1, sa2, sadc – system activity report package
SYNOPSIS	<pre> /usr/lib/sa/sadc [t n] [ofile] /usr/lib/sa/sa1 [t n] /usr/lib/sa/sa2 [-aAbcdgkmpgruvwy] [-e time] [-f filename] [-i sec] [-s time] </pre>
DESCRIPTION	System activity data can be accessed at the special request of a user (see sar(1)) and automatically, on a routine basis, as described here. The operating system contains several counters that are incremented as various system actions occur. These include counters for CPU utilization, buffer usage, disk and tape I/O activity, TTY device activity, switching and system-call activity, file-access, queue activity, inter-process communications, and paging. For more general system statistics, use iostat (1M), sar(1), or vmstat(1M). sadc and two shell procedures, sa1 and sa2, are used to sample, save, and process this data. sadc, the data collector, samples system data <i>n</i> times, with an interval of <i>t</i> seconds between samples, and writes in binary format to <i>ofile</i> or to standard output. The sampling interval <i>t</i> should be greater than 5 seconds; otherwise, the activity of sadc itself may affect the sample. If <i>t</i> and <i>n</i> are omitted, a special record is written. This facility can be used at system boot time, when booting to a multi-user state, to mark the time at which the counters restart from zero. For example, when accounting is enabled, the /etc/init.d/perf file writes the restart mark to the daily data file using the command entry: <pre> su sys -c "/usr/lib/sa/sadc /var/adm/sa/sa`date +%d`" </pre> The shell script sa1, a variant of sadc, is used to collect and store data in the binary file /var/adm/sa/sadd, where dd is the current day. The arguments <i>t</i> and <i>n</i> cause records to be written <i>n</i> times at an interval of <i>t</i> seconds, or once if omitted. The following entries in /var/spool/cron/crontabs/sys will produce records every 20 minutes during working hours and hourly otherwise: <pre> 0 * * * 0-6 /usr/lib/sa/sa1 20,40 8-17 * * 1-5 /usr/lib/sa/sa1 </pre> See crontab(1) for details. The shell script sa2, a variant of sar, writes a daily report in the file /var/adm/sa/sardd. See the OPTIONS section in sar(1) for an explanation of the various options. The following entry in /var/spool/cron/crontabs/sys will report important activities hourly during the working day: <pre> 5 18 * * 1-5 /usr/lib/sa/sa2 -s 8:00 -e 18:01 -i 1200 -A </pre>

sar(1M)

FILES /etc/init.d/perf

System Administration Guide: Basic Administration

savecore(1M)

NAME	savecore – save a crash dump of the operating system
SYNOPSIS	/usr/bin/savecore [-Lvd] [-f <i>dumpfile</i>] [<i>directory</i>]
DESCRIPTION	The savecore utility saves a crash dump of the kernel (assuming that one was made) and writes a reboot message in the shutdown log. It is invoked by the <code>/etc/init.d/savecore</code> file after the system boots, if savecore is enabled by way of <code>dumpadm(1M)</code>. savecore is enabled on reboot by default. The savecore utility checks the crash dump to be certain it corresponds with the version of the operating system currently running. If it does, savecore saves the crash dump data in the file <i>directory/vmcore.n</i> and the kernel's namelist in <i>directory/unix.n</i>. The trailing <i>.n</i> in the pathnames is replaced by a number which grows every time savecore is run in that directory. Before writing out a crash dump, savecore reads a number from the file <i>directory/minfree</i>. This is the minimum number of kilobytes that must remain free on the file system containing <i>directory</i>. If after saving the crash dump the file system containing <i>directory</i> would have less free space the number of kilobytes specified in <i>minfree</i>, the crash dump is not saved. If the <i>minfree</i> file does not exist, savecore assumes a <i>minfree</i> value of 1 megabyte. The savecore utility also logs a reboot message using facility LOG_AUTH (see <code>syslog(3C)</code>). If the system crashed as a result of a panic, savecore logs the panic string too.
OPTIONS	The following options are supported: -d Disregard dump header valid flag. Force savecore to attempt to save a crash dump even if the header information stored on the dump device indicates the dump has already been saved. -f <i>dumpfile</i> Attempt to save a crash dump from the specified file instead of from the system's current dump device. This option may be useful if the information stored on the dump device has been copied to an on-disk file by means of the <code>dd(1M)</code> command. -L Save a crash dump of the live running Solaris system, without actually rebooting or altering the system in any way. This option forces savecore to save a live snapshot of the system to the dump device, and then immediately to retrieve the data and to write it out to a new set of crash dump files in the specified directory. Live system crash dumps can only be performed if you have configured your system to have a dedicated dump device using <code>dumpadm(1M)</code>. - savecore -L does not suspend the system, so the contents of memory continue to change while the dump is saved. This means that live crash dumps are not fully self-consistent. -v Verbose. Enables verbose error messages from savecore.

OPERANDS The following operands are supported:

directory Save the crash dump files to the specified directory. If *directory* is not specified, *savecore* saves the crash dump files to the default *savecore directory*, configured by *dumpadm(1M)*.

FILES *directory/vmcore.n*

directory/unix.n

directory/bounds

directory/minfree

/dev/ksyms the kernel namelist

/etc/init.d/savecore

/var/crash/'uname -n' default crash dump directory

ATTRIBUTES See *attributes(5)* for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu (32-bit)
	SUNWcsxu (64-bit)

SEE ALSO *adb(1)*, *mdb(1)*, *dd(1M)*, *dumpadm(1M)*, *syslog(3C)*, *attributes(5)*

BUGS If the dump device is also being used as a swap device, you must run *savecore* very soon after booting, before the swap space containing the crash dump is overwritten by programs currently running.

scadm(1M)

NAME	scadm – administer System Controller (SC)																												
SYNOPSIS	<code>/usr/platform/platform-name/sbin/scadm subcommand [option] [argument...]</code>																												
DESCRIPTION	The <code>scadm</code> utility administers the System Controller (SC). This utility allows the host server to interact with the SC. The <code>scadm</code> utility <i>must</i> be run as root. The interface, output, and location in the directory hierarchy for <code>scadm</code> are uncommitted and might change. <i>platform-name</i> is the name of the platform implementation. Use the <code>uname -i</code> command to identify the platform implementation. See <code>uname(1)</code>. The <code>scadm</code> utility has fifteen subcommands. Some subcommands have specific options and arguments associated with them. See SUBCOMMANDS, OPTIONS, OPERANDS, and USAGE.																												
SUBCOMMANDS	Subcommands immediately follow the <code>scadm</code> command on the command line, and are separated from the command by a SPACE. The following subcommands are supported <table><tr><td>date</td><td>Display the SC's time and date</td></tr><tr><td></td><td>The format for the date subcommand is:</td></tr><tr><td></td><td><code>scadm date</code></td></tr><tr><td>download</td><td>Program the SC's firmware.</td></tr><tr><td></td><td>There are two parts to the firmware, the boot monitor and the main image.</td></tr><tr><td></td><td>By default, The <code>scadm</code> command's download programs the main firmware image. The <code>boot</code> argument selects programming of the boot monitor.</td></tr><tr><td></td><td>The format for the download subcommand is:</td></tr><tr><td></td><td><code>scadm download [boot] file</code></td></tr><tr><td>help</td><td>Display a list of commands.</td></tr><tr><td></td><td>The format for the help subcommand is:</td></tr><tr><td></td><td><code>scadm help</code></td></tr><tr><td>loghistory</td><td>Display the most recent entries in the SC event log.</td></tr><tr><td></td><td>The format for the loghistory subcommand is:</td></tr><tr><td></td><td><code>scadm loghistory</code></td></tr></table>	date	Display the SC's time and date		The format for the date subcommand is:		<code>scadm date</code>	download	Program the SC's firmware.		There are two parts to the firmware, the boot monitor and the main image.		By default, The <code>scadm</code> command's download programs the main firmware image. The <code>boot</code> argument selects programming of the boot monitor.		The format for the download subcommand is:		<code>scadm download [boot] file</code>	help	Display a list of commands.		The format for the help subcommand is:		<code>scadm help</code>	loghistory	Display the most recent entries in the SC event log.		The format for the loghistory subcommand is:		<code>scadm loghistory</code>
date	Display the SC's time and date																												
	The format for the date subcommand is:																												
	<code>scadm date</code>																												
download	Program the SC's firmware.																												
	There are two parts to the firmware, the boot monitor and the main image.																												
	By default, The <code>scadm</code> command's download programs the main firmware image. The <code>boot</code> argument selects programming of the boot monitor.																												
	The format for the download subcommand is:																												
	<code>scadm download [boot] file</code>																												
help	Display a list of commands.																												
	The format for the help subcommand is:																												
	<code>scadm help</code>																												
loghistory	Display the most recent entries in the SC event log.																												
	The format for the loghistory subcommand is:																												
	<code>scadm loghistory</code>																												

resetrsc	Reset the SC. There are two types of resets allowed, a <code>hard reset</code> and a <code>soft reset</code>. The <code>hard reset</code> is done by default. The <code>soft reset</code> can be selected by using the <code>-s</code> option. The format for the <code>resetrsc</code> subcommand is: <pre>scadm resetrsc [-s]</pre>
send_event	Manually send a text based event. The SC can forward the event to the SC event log. You can configure the <code>-c</code> option to send a critical warning to email, alert to logged in SC users, and <code>syslog</code>. Critical events are logged to <code>syslog(3C)</code>. There is an 80 character limit to the length of the associated text message. The format for the <code>send_event</code> subcommand is: <pre>scadm send_event [-c] "message"</pre>
set	Set SC configuration variables to a value. Examples of SC configuration variables include: SC IP address <code>netsc_ipaddr</code> and SC Customer Information <code>sc_customerinfo</code>. See the output from the <code>scadm help</code> command for a complete list of SC configuration variables. The format for the <code>set</code> subcommand is: <pre>scadm set variable value</pre>
show	Display the current SC configuration variable settings. If no variable is specified, <code>scadm</code> shows all variable settings. The format for the <code>show</code> subcommand is: <pre>scadm show [variable]</pre>
shownetwork	Display the current network configuration parameters for SC. The format for the <code>shownetwork</code> subcommand is: <pre>scadm shownetwork</pre>
useradd	Add user accounts to the SC. The SC supports up to sixteen separate users. The format for the <code>useradd</code> subcommand is: <pre>scadm useradd username</pre>

scadm(1M)

	userdel	Delete a user account from SC. The format for the userdel subcommand is: scadm userdel <i>username</i>
	userpassword	Set a password for the user account specified. This password overrides any existing password currently set. There is no verification of the old password before setting the new password. The format for the userpassword subcommand is: scadm userpassword <i>username</i>
	userperm	Set the permission level for the user. The format for the userperm subcommand is: scadm userperm <i>username</i> [aucr]
	usershow	Display details on the specified user account. If a username is not specified, all user accounts are displayed. The format for the usershow subcommand is: scadm usershow <i>username</i>
	version	Display the version numbers of the SC and its components. The format for the version subcommand is: scadm version [-v]
	OPTIONS	The resetrsc, send_event, and version subcommands have associated options. Options follow subcommands on the command line and are separated from the subcommand by a SPACE. The resetrsc subcommand supports the following options: -s Perform a soft reset instead of a hard reset. A hard reset physically resets the SC hardware. The SC software jumps to the boot firmware, simulating a reset, for a soft reset. The send_event subcommand supports the following options: -c Send a critical event. Without the -c, -send_event sends a warning. The version subcommand supports the following options: -v Display a verbose output of version numbers and associated information.

OPERANDS

The `download`, `send_event`, `set`, `show`, `useradd`, `userdel`, `userperm`, `usershow`, `userpassword`, and `userperm` subcommands have associated arguments (operands).

If the subcommand has an option, the arguments follow the option on the command line and is separated from the option by a SPACE. If the subcommand does not have an option, the arguments follow the subcommand on the command line and are separated from the subcommand by a SPACE. If there are more than one arguments, they are separated from each other by a SPACE.

The `download` subcommand supports the following arguments:

boot Program the boot monitor portion of the flash. The main portion of the flash is programmed without any arguments

file Specify *file* as the path to where the boot or main firmware image resides for download.

Examples of *file* are:

`/usr/platform/platform_type/lib/image/alommainfw`

or

`/usr/platform/platform_type/lib/image/alombootfw`

The `send_event` subcommand supports the following arguments:

"message" Describe event using the text contained in *message*. Enclose *message* in quotation marks.

The `set` subcommand supports the following arguments:

variable Set SC configuration *variable*.

value Set SC configuration variable to *value*.

The `show` subcommand supports the following arguments:

variable Display the value of that particular variable.

The `useradd` subcommand supports the following arguments:

username Add new SC account *username*.

The `userdel` subcommand supports the following arguments:

username Remove SC account *username*.

The `userperm` subcommand supports the following arguments:

-aucr Set permissions for SC user accounts. If no permissions are specified, all four permissions are disabled and read only access is assigned.

The following are the definitions for permissions:

a	Allow user to administer or change the SC configuration variables
u	Allow user to use the user commands to modify SC accounts
c	Allow user to connect to console.
r	Allow user to reset SC and to power on and off the host.

username Change permissions on SC account *username*.

The `-usershow` subcommand supports the following arguments:

username Display information on SC account *username* . If *username* is not specified, all accounts are displayed.

The `userpassword` subcommand supports the following arguments:

username Set SC password for *username*.

The `userperm` subcommand supports the following arguments:

username Change SC permissions for *username*.

EXAMPLES

EXAMPLE 1 Displaying the SC's Date and Time

The following command displays the SC's date and time.

```
scadm date
```

EXAMPLE 2 Setting the SC's Configuration Variables

The following command sets the SC's configuration variable `netsc_ipaddr` to `192.168.1.2`:

```
scadm set netsc_ipaddr 192.168.1.2
```

EXAMPLE 3 Displaying the Current SC's Configuration Settings:

The following command displays the current SC configuration settings:

```
scadm show
```

EXAMPLE 4 Displaying the Current Settings for a Variable

The following command displays the current settings for the `sys_hostname` variable:

```
scadm show sys_hostname
```

EXAMPLE 4 Displaying the Current Settings for a Variable (Continued)**EXAMPLE 5** Sending a Text-Based Critical Event

The following command sends a critical event to the SC logs, alerts the current SC users, and sends an event to syslog(3C):

```
scadm send_event -c "The UPS signaled a loss in power"
```

EXAMPLE 6 Sending an Informational Text-Based Event

The following command sends a non-critical informational text based event to the SC event log:

```
scadm send_event "The disk is close to full capacity"
```

EXAMPLE 7 Adding a User To the SC

The following command adds user `rscroot` to the SC:

```
scadm useradd rscroot
```

EXAMPLE 8 Deleting a User From the SC

The following command deletes user `olduser` from the SC:

```
scadm userdel olduser
```

EXAMPLE 9 Displaying User Details

The following command displays details of all user accounts:

```
scadm usershow
```

EXAMPLE 10 Displaying Details for a Specific User

The following command displays details of user account `rscroot`:

```
scadm usershow rscroot
```

EXAMPLE 11 Setting the User Permission Level

The following command sets the full permission level for user `rscroot` to `aucr`:

```
scadm userperm rscroot aucr
```

scadm(1M)

EXAMPLE 12 Setting the User Permission Level

The following command sets only console access for user `newuser` to `c`:

```
scadm userperm newuser c
```

EXAMPLE 13 Setting the User Permission Level

The following command sets the permission level for user `newuser` to read only access:

```
scadm userperm newuser
```

EXAMPLE 14 Displaying the Current Network Parameters

The following command displays the current network configuration parameters for the SC:

```
scadm shownetwork
```

EXAMPLE 15 Viewing the Loghistory

The following command displays the most recent entries in the SC event log:

```
scadm loghistory
```

EXAMPLE 16 Displaying Verbose Information

The following command displays verbose version information on the SC and its components:

```
scadm version -v
```

EXIT STATUS

The following exit values are returned:

0	Successful completion.
non-zero	An error occurred.

ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWkvm

SEE ALSO

`uname(1)`, `syslog(3C)`, `attributes(5)`

NAME	sckmd – Sun Fire High-End system key management daemon						
SYNOPSIS	<code>/usr/platform/SUNW,Sun-Fire-15000/lib/sckmd</code>						
DESCRIPTION	sckmd is a server process that resides on a Sun Fire high-end system domain. sckmd maintains the Internet Protocol Security (IPsec) Security Associations (SAs) needed to secure the communication between the Sun Fire 15K System Controller (SC) and the cvcd(1M) and dcs(1M) daemons running on a Sun Fire 15K domain. See ipsec(7P) for a description of Security Associations. sckmd receives SAs from the SC and provides these SAs to the Security Association Databases (SADB) using pf_key(7P). sckmd normally starts up at system boot time. Each domain supports only one running sckmd process at a time.						
FILES	<table> <tr> <td><code>/etc/inet/ipsecinit.conf</code></td><td>Configuration file for default system-wide IPsec policies</td></tr> </table>	<code>/etc/inet/ipsecinit.conf</code>	Configuration file for default system-wide IPsec policies				
<code>/etc/inet/ipsecinit.conf</code>	Configuration file for default system-wide IPsec policies						
ATTRIBUTES	See attributes(5) for descriptions of the following attributes: <table> <tr> <th>ATTRIBUTE TYPE</th><th>ATTRIBUTE VALUE</th></tr> <tr> <td>Architecture</td><td>Sun Fire High-End systems</td></tr> <tr> <td>Availability</td><td>SUNWsckmx.u, SUNWsckmu.u, SUNWsckmr</td></tr> </table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	Architecture	Sun Fire High-End systems	Availability	SUNWsckmx.u, SUNWsckmu.u, SUNWsckmr
ATTRIBUTE TYPE	ATTRIBUTE VALUE						
Architecture	Sun Fire High-End systems						
Availability	SUNWsckmx.u, SUNWsckmu.u, SUNWsckmr						
SEE ALSO	cvcd(1M), dcs(1M), ipsecconf(1M), attributes(5), authmd5h(7M), encr3des(7M), ipsec(7P), pf_key(7P) <i>Sun Enterprise 10000 SSP Reference Manual</i> <i>System Management Services (SMS) Reference Manual</i>						
NOTES	IPsec is used by Sun Fire high-end systems such as a Sun Fire 15K, to secure the communication between the SC, and the cvcd(1M) and dcs(1M) daemons running on a domain. System-wide IPsec policies for these daemons are configured on a domain with ipsecconf(1M). Default policies are defined when the SUNWsckmr package is installed on a Sun Fire high-end system domain at OS install time. Package SUNWsckmr configures default system-wide policies for cvcd(1M) and dcs(1M) by adding the following entries in <code>/etc/inet/ipsecinit.conf</code>: <pre>{ dport sun-dr ulp tcp } permit { auth_alg md5 } { sport sun-dr ulp tcp } apply { auth_alg md5 sa unique } { dport cvc_hostd ulp tcp } permit { auth_alg md5 } { sport cvc_hostd ulp tcp } apply { auth_alg md5 sa unique }</pre>						

sckmd(1M)

The `cvc_hostd` service represents `cvcd(1M)` and the `sun-dr` service represents `dcs(1M)` in the preceding entries.

These policies conform to the format defined by `ipsec(7P)` and require HMAC-MD5 authentication. See `authmd5h(7M)`.

System-wide policies for `cvcd(1M)` and `dcs(1M)` configured on a domain using `ipseccnf(1M)` must match the IPsec policies defined for these services on the SC. On an SC, IPsec policies for these services are defined by the SMS key management daemon. Refer to `thekmd(1M)` man page in the *System Management Services (SMS) Reference Manual*.

IPsec encryption or authentication with encryption can be enabled on the domain using the `encr_algs` and `encr_auth_algs` properties, as described in the `ipseccnf(1M)` manual page. For example, the following `ipseccnf(1M)` entries require Triple-DES and HMAC-MD5 authentication for the network console `cvcd(1M)` service:

```
{ dport cvc_hostd ulp tcp } permit
    { encr_algs 3des encr_auth_algs md5 }
{ sport cvc_hostd ulp tcp } apply
    { encr_algs 3des encr_auth_algs md5 sa unique }
```

See `encr3des(7M)` for Triple-DES authentication and `authmd5h(7M)` for HMAC-M5 authentication.

NAME	sendmail – send mail over the internet
SYNOPSIS	<pre> /usr/lib/sendmail [-Ac] [-Am] [-ba] [-bD] [-bd] [-bi] [-bm] [-bp] [-bP] [-bs] [-bt] [-bv] [-B type] [-C file] [-d X] [-F fullname] [-f name] [-G] [-h N] [-L tag] [-M xvalue] [-Nnotifications] [-n] [-Option =value] [-o xvalue] [-p protocol] [-q [time]] [-q Xstring] [-R ret] [-r name] [-t] [-V envuid] [-v] [-X logfile] [address...] </pre>
DESCRIPTION	The sendmail utility sends a message to one or more people, routing the message over whatever networks are necessary. sendmail does internetwork forwarding as necessary to deliver the message to the correct place. sendmail is not intended as a user interface routine. Other programs provide user-friendly front ends. sendmail is used only to deliver pre-formatted messages. With no flags, sendmail reads its standard input up to an EOF, or a line with a single dot, and sends a copy of the letter found there to all of the addresses listed. It determines the network to use based on the syntax and contents of the addresses. Local addresses are looked up in the local <code>aliases(4)</code> file, or in a name service as defined by the <code>nsswitch.conf(4)</code> file, and aliased appropriately. In addition, if there is a <code>.forward</code> file in a recipient's home directory, sendmail forwards a copy of each message to the list of recipients that file contains. Refer to the NOTES section for more information about <code>.forward</code> files. Aliasing can be prevented by preceding the address with a backslash. There are several conditions under which the expected behavior is for the alias database to be either built or rebuilt. This cannot occur under any circumstances unless root owns <i>and</i> has exclusive write permission to the <code>/etc/mail/aliases*</code> files. If a message is found to be undeliverable, it is returned to the sender with diagnostics that indicate the location and nature of the failure; or, the message is placed in a <code>dead.letter</code> file in the sender's home directory.
Startup Options	The <code>/etc/default/sendmail</code> file stores startup options for sendmail so that the options are not removed when a host is upgraded. You can use the following variables in the <code>/etc/default/sendmail</code> startup file: CLIENTOPTIONS="string" Selects additional options to be used with the client daemon, which looks in the client-only queue (<code>/var/spool/clientmqueue</code>) and acts as a client queue runner. No syntax checking is done, so be careful when making changes to this variable. CLIENTQUEUEINTERVAL=# Similar to the <code>QUEUEINTERVAL</code> option, <code>CLIENTQUEUEINTERVAL</code> sets the time interval for mail queue runs. However, the <code>CLIENTQUEUEINTERVAL</code> option controls the functions of the client daemon, instead of the functions of the master daemon. Typically, the master daemon is able to deliver all messages to the SMTP

sendmail(1M)

port. However, if the message load is too high or the master daemon is not running, then messages go into the client-only queue, `/var/spool/clientmqueue`. The client daemon, which checks in the client-only queue, then acts as a client queue processor.

ETRN_HOSTS=*string*

Enables an SMTP client and server to interact immediately without waiting for the queue run intervals, which are periodic. The server can immediately deliver the portion of its queue that goes to the specified hosts. For more information, refer to the `etrn(1M)` man page.

MODE=`bd`

Selects the mode to start `sendmail` with. Use the `-bd` option or leave it undefined.

OPTIONS=*string*

Selects additional options to be used with the master daemon. No syntax checking is done, so be careful when making changes to this variable.

QUEUEINTERVAL=`#`

Sets the interval for mail queue runs on the master daemon. `#` can be a positive integer that is followed by either `s` for seconds, `m` for minutes, `h` for hours, `d` for days, or `w` for weeks. The syntax is checked before `sendmail` is started. If the interval is negative or if the entry does not end with an appropriate letter, the interval is ignored and `sendmail` starts with a queue interval of 15 minutes.

QUEUEOPTIONS=`p`

Enables one persistent queue runner that sleeps between queue run intervals, instead of a new queue runner for each queue run interval. You can set this option to `p`, which is the only setting available. Otherwise, this option is not set.

OPTIONS

The following options are supported:

<code>-Ac</code>	Uses <code>submit.cf</code> even if the operation mode does not indicate an initial mail submission.
<code>-Am</code>	Uses <code>sendmail.cf</code> even if the operation mode indicates an initial mail submission.
<code>-ba</code>	Goes into ARPANET mode. All input lines must end with a RETURN-LINEFEED, and all messages are generated with a RETURN-LINEFEED at the end. Also, the <code>From:</code> and <code>Sender:</code> fields are examined for the name of the sender.
<code>-bd</code>	Runs as a daemon in the background, waiting for incoming SMTP connections.
<code>-bD</code>	Runs as a daemon in the foreground, waiting for incoming SMTP connections.
<code>-bi</code>	Initializes the <code>aliases(4)</code> database. Root must own <i>and</i> have exclusive write permission to the <code>/etc/mail/aliases*</code> files for successful use of this option.

-bm	Delivers mail in the usual way (default).
-bp	Prints a summary of the mail queues.
-bP	Prints the number of entries in the queues. This option is only available with shared memory support.
-bs	Uses the SMTP protocol as described in RFC 821. This flag implies all the operations of the -ba flag that are compatible with SMTP.
-bt	Runs in address test mode. This mode reads addresses and shows the steps in parsing; it is used for debugging configuration tables.
-bv	Verifies names only. Does not try to collect or deliver a message. Verify mode is normally used for validating users or mailing lists.
-B <i>type</i>	Indicates body <i>type</i> (7BIT or 8BITMIME).
-C <i>file</i>	Uses alternate configuration file.
-d <i>X</i>	Sets debugging value to <i>X</i> .
-f <i>name</i>	Sets the name of the "from" person (that is, the sender of the mail).
-F <i>fullname</i>	Sets the full name of the sender.
-G	When accepting messages by way of the command line, indicates that they are for relay (gateway) submission. When this flag is set, sendmail might complain about syntactically invalid messages, for example, unqualified host names, rather than fixing them. sendmail does not do any canonicalization in this mode.
-h <i>N</i>	Sets the hop count to <i>N</i> . The hop count is incremented every time the mail is processed. When it reaches a limit, the mail is returned with an error message, the victim of an aliasing loop.
-L <i>tag</i>	Sets the identifier used in syslog messages to the supplied <i>tag</i> .
-M <i>xvalue</i>	Sets macro <i>x</i> to the specified <i>value</i> .
-n	Does not do aliasing.
-N <i>notifications</i>	Tags all addresses being sent as wanting the indicated <i>notifications</i> , which consists of the word "NEVER" or a comma-separated list of "SUCCESS", "FAILURE", and "DELAY" for successful delivery, failure and a message that is stuck in a queue somewhere. The default is "FAILURE,DELAY".
-o <i>xvalue</i>	Sets option <i>x</i> to the specified <i>value</i> . Processing Options are described below.
-O <i>option=value</i>	Sets <i>option</i> to the specified <i>value</i> (for long from names). Processing Options are described below.
-p <i>protocol</i>	Sets the sending protocol. The <i>protocol</i> field can be in form <i>protocol: host</i> to set both the sending protocol and the sending host.

sendmail(1M)

	For example: <code>-pUUCP:uunet</code> sets the sending <i>protocol</i> to UUCP and the sending host to uunet. Some existing programs use <code>-oM</code> to set the <i>r</i> and <i>s</i> macros; this is equivalent to using <code>-p</code> .
<code>-q[time]</code>	Processes saved messages in the queue at given intervals. If <i>time</i> is omitted, processes the queue once. <i>time</i> is given as a tagged number, where <i>s</i> is seconds, <i>m</i> is minutes, <i>h</i> is hours, <i>d</i> is days, and <i>w</i> is weeks. For example, <code>-q1h30m</code> or <code>-q90m</code> would both set the timeout to one hour thirty minutes.
<code>-qp [time]</code>	By default, sendmail runs in the background. This option can be used safely with <code>-bd</code> . Similar to <code>-q[time]</code> , except that instead of periodically forking a child to process the queue, <code>sendmail</code> forks a single persistent child for each queue that alternates between processing the queue and sleeping. The sleep time (<i>time</i>) is specified as the argument; it defaults to 1 second. The process always sleeps at least 5 seconds if the queue was empty in the previous queue run.
<code>-qf</code>	Processes saved messages in the queue once and does not <code>fork(2)</code> , but runs in the foreground.
<code>-qG name</code>	Processes jobs in queue group called <i>name</i> only.
<code>-q[!]I substr</code>	Limits processed jobs to those containing <i>substr</i> as a substring of the queue ID or not when <code>!</code> is specified.
<code>-q[!]R substr</code>	Limits processed jobs to those containing <i>substr</i> as a substring of one of the recipients or not when <code>!</code> is specified.
<code>-q[!]S substr</code>	Limits processed jobs to those containing <i>substr</i> as a substring of the sender or not when <code>!</code> is specified.
<code>-r name</code>	An alternate and obsolete form of the <code>-f</code> flag.
<code>-R ret</code>	Identifies the information you want returned if the message bounces. <i>ret</i> can be HDRS for headers only or FULL for headers plus body.
<code>-t</code>	Reads message for recipients. <code>To:</code> , <code>Cc:</code> , and <code>Bcc:</code> lines are scanned for people to send to. The <code>Bcc:</code> line is deleted before transmission. Any addresses in the argument list is suppressed. The NoRecipientAction Processing Option can be used to change the behavior when no legal recipients are included in the message.
<code>-v</code>	Goes into verbose mode. Alias expansions are announced, and so forth.
<code>-V envid</code>	The indicated <i>envid</i> is passed with the envelope of the message and returned if the message bounces.

Processing Options

-x logfile Logs all traffic in and out of `sendmail` in the indicated *logfile* for debugging mailer problems. This produces a lot of data very quickly and should be used sparingly.

There are a number of "random" options that can be set from a configuration file. Options are represented by a single character or by multiple character names. The syntax for the single character names of is:

Oxvalue

This sets option *x* to be *value*. Depending on the option, *value* may be a string, an integer, a boolean (with legal values `t`, `T`, `f`, or `F`; the default is `TRUE`), or a time interval.

The multiple character or long names use this syntax:

o Longname=argument

This sets the option *Longname* to be *argument*. The long names are beneficial because they are easier to interpret than the single character names.

Not all processing options have single character names associated with them. In the list below, the multiple character name is presented first followed by the single character syntax enclosed in parentheses.

`AliasFile (Afile)`

Specifies possible alias files.

`AliasWait (a N)`

If set, waits up to *N* minutes for an "@:@" entry to exist in the `aliases(4)` database before starting up. If it does not appear in *N* minutes, issues a warning. Defaults to 10 minutes.

`AllowBogusHELO`

Allows a `HELO` SMTP command that does not include a host name. By default this option is disabled.

`BadRcptThrottle=N`

If set and more than the specified number of recipients in a single SMTP envelope are rejected, sleeps for one second after each rejected `RCPT` command.

`BlankSub (Bc)`

Sets the blank substitution character to *c*. Unquoted spaces in addresses are replaced by this character. Defaults to `SPACE` (that is, no change is made).

`CheckAliases (n)`

Validates the RHS of aliases when rebuilding the `aliases(4)` database.

`CheckpointInterval (CN)`

Checkpoints the queue every *N* (default 10) addresses sent. If your system crashes during delivery to a large list, this prevents retransmission to any but the last *N* recipients.

sendmail(1M)

ClassFactor (*zfact*)

The indicated factor *fact* is multiplied by the message class (determined by the `Precedence:` field in the user header and the `P` lines in the configuration file) and subtracted from the priority. Thus, messages with a higher `Priority:` are favored. Defaults to 1800.

ClientPortOptions

Sets client SMTP options. The options are key=value pairs. Known keys are:

<code>Addr Address Mask</code>	<code>Address Mask</code> defaults to <code>INADDR_ANY</code> . The address mask can be a numeric address in dot notation or a network name.
<code>Family</code>	Address family (defaults to <code>INET</code>).
<code>Listen</code>	Size of listen queue (defaults to 10).
<code>Port</code>	Name/number of listening port (defaults to <code>smtp</code>).
<code>RcvBufSize</code>	The size of the TCP/IP receive buffer.
<code>SndBufSize</code>	The size of the TCP/IP send buffer.
<code>Modifier</code>	Options (flags) for the daemon. Can be: <code>h</code> Uses name of interface for <code>HELO</code> command. If <code>h</code> is set, the name corresponding to the outgoing interface address (whether chosen by means of the <code>Connection</code> parameter or the default) is used for the <code>HELO/EHLO</code> command.

ColonOkInAddr

If set, colons are treated as a regular character in addresses. If not set, they are treated as the introducer to the RFC 822 “group” syntax. This option is on for version 5 and lower configuration files.

ConnectionCacheSize (*kN*)

The maximum number of open connections that are to be cached at a time. The default is 1. This delays closing the current connection until either this invocation of `sendmail` needs to connect to another host or it terminates. Setting it to 0 defaults to the old behavior, that is, connections are closed immediately.

ConnectionCacheTimeout (*Ktimeout*)

The maximum amount of time a cached connection is permitted to idle without activity. If this time is exceeded, the connection is immediately closed. This value should be small (on the order of ten minutes). Before `sendmail` uses a cached connection, it always sends a `NOOP` (no operation) command to check the connection. If the `NOOP` command fails, it reopens the connection. This keeps your end from failing if the other end times out. The point of this option is to be a good network neighbor and avoid using up excessive resources on the other end. The default is five minutes.

ConnectionRateThrottle

The maximum number of connections permitted per second. After this many connections are accepted, further connections are delayed. If not set or ≤ 0 , there is no limit.

ControlSocketName

Name of the control socket for daemon management. A running `sendmail` daemon can be controlled through this Unix domain socket. Available commands are: `help`, `restart`, `shutdown`, and `status`. The `status` command returns the current number of daemon children, the free disk space (in blocks) of the queue directory, and the load average of the machine expressed as an integer. If not set, no control socket is available. For the sake of security, this Unix domain socket must be in a directory which is accessible only by root; `/var/spool/mqueue/.smcontrol` is recommended for the socket name.

DaemonPortOptions (*Options*)

Sets server SMTP options. The options are *key=value* pairs. Known keys are:

Name	User-definable name for the daemon (defaults to "Daemon#"). Used for error messages and logging.																
Addr	Address mask (defaults <code>INADDR_ANY</code>). The address mask may be a numeric address in dot notation or a network name.																
Family	Address family (defaults to <code>INET</code>).																
Listen	Size of listen queue (defaults to 10).																
Modifier	Options (flags) for the daemon; can be a sequence (without any delimiters) of: <table> <tr> <td>a</td><td>Requires authentication.</td></tr> <tr> <td>b</td><td>Binds to interface through which mail has been received.</td></tr> <tr> <td>c</td><td>Performs hostname canonification (<code>.cf</code>).</td></tr> <tr> <td>f</td><td>Requires fully qualified hostname (<code>.cf</code>).</td></tr> <tr> <td>h</td><td>Uses name of interface for HELO command.</td></tr> <tr> <td>u</td><td>Allows unqualified addresses (<code>.cf</code>).</td></tr> <tr> <td>C</td><td>Does not perform hostname canonification.</td></tr> <tr> <td>E</td><td>Disallows ETRN (see RFC 2476).</td></tr> </table>	a	Requires authentication.	b	Binds to interface through which mail has been received.	c	Performs hostname canonification (<code>.cf</code>).	f	Requires fully qualified hostname (<code>.cf</code>).	h	Uses name of interface for HELO command.	u	Allows unqualified addresses (<code>.cf</code>).	C	Does not perform hostname canonification.	E	Disallows ETRN (see RFC 2476).
a	Requires authentication.																
b	Binds to interface through which mail has been received.																
c	Performs hostname canonification (<code>.cf</code>).																
f	Requires fully qualified hostname (<code>.cf</code>).																
h	Uses name of interface for HELO command.																
u	Allows unqualified addresses (<code>.cf</code>).																
C	Does not perform hostname canonification.																
E	Disallows ETRN (see RFC 2476).																
Name	User-definable name for the daemon (defaults to <code>Daemon#</code>). Used for error messages and logging.																
Port	Name/number of listening port (defaults to <code>smtp</code>).																
ReceiveSize	The size of the TCP/IP receive buffer.																

sendmail(1M)

SendSize	The size of the TCP/IP send buffer.
sendmail	listens on a new socket for each occurrence of the DaemonPortOptions option in a configuration file.
DataFileBufferSize	Sets the threshold, in bytes, before a memory-based queue data file becomes disk-based. The default is 4096 bytes.
DeadLetterDrop	Defines the location of the system-wide dead.letter file, formerly hard-coded to /var/tmp/dead.letter. If this option is not set (the default), sendmail does not attempt to save to a system-wide dead.letter file in the event it cannot bounce the mail to the user or postmaster. Instead, it renames the qf file as it has in the past when the dead.letter file could not be opened.
DefaultCharSet	Sets the default character set to use when converting unlabeled 8 bit input to MIME.
DefaultUser (gid) or (uid)	Sets the default group ID for mailers to run in to gid or set the default userid for mailers to uid. Defaults to 1. The value can also be given as a symbolic group or user name.
DelayLA=LA	When the system load average exceeds LA, sendmail sleeps for one second on most SMTP commands and before accepting connections.
DeliverByMin=time	Sets minimum time for Deliver By SMTP Service Extension (RFC 2852). If 0, no time is listed, if less than 0, the extension is not offered, if greater than 0, it is listed as minimum time for the EHLO keyword DELIVERBY.
DeliveryMode (dx)	Delivers in mode x. Legal modes are: - i Delivers interactively (synchronously). - b Delivers in background (asynchronously). - d Deferred mode. Database lookups are deferred until the actual queue run. - q Just queues the message (delivers during queue run). Defaults to b if no option is specified, i if it is specified but given no argument (that is, Od is equivalent to Odi).
DialDelay	If a connection fails, waits this many seconds and tries again. Zero means "do not retry".

DontBlameSendmail

If set, overrides the file safety checks. This compromises system security and should not be used. See <http://www.sendmail.org/tips/DontBlameSendmail.html> for more information.

DontExpandCnames

If set, `$[ ... $]` lookups that do DNS-based lookups do not expand CNAME records.

DontInitGroups

If set, the `initgroups(3C)` routine is never invoked. If you set this, agents run on behalf of users only have their primary (`/etc/passwd`) group permissions.

DontProbeInterfaces

If set, `sendmail` does not insert the names and addresses of any local interfaces into the `$=w` class. If set, you must also include support for these addresses, otherwise mail to addresses in this list bounces with a configuration error.

DontPruneRoutes (R)

If set, does not prune route-addr syntax addresses to the minimum possible.

DoubleBounceAddress

If an error occurs when sending an error message, sends that “double bounce” error message to this address.

EightBitMode (8)

Uses 8-bit data handling. This option requires one of the following keys. The key can be selected by using just the first character, but using the full word is better for clarity.

mimify

Does any necessary conversion of 8BITMIME to 7-bit.

pass

Passes unlabeled 8-bit input through as is.

strict

Rejects unlabeled 8-bit input.

ErrorHeader (Efile/message)

Appends error messages with the indicated message. If it begins with a slash, it is assumed to be the pathname of a file containing a message (this is the recommended setting). Otherwise, it is a literal message. The error file might contain the name, email address, and/or phone number of a local postmaster who could provide assistance to end users. If the option is missing or NULL, or if it names a file which does not exist or which is not readable, no message is printed.

ErrorMode (ex)

Disposes of errors using mode *x*. The values for *x* are:

- e** Mails back errors and gives 0 exit status always.
- m** Mails back errors.
- p** Prints error messages (default).

sendmail(1M)

q	No messages, just gives exit status.
w	Writes back errors (mail if user not logged in).
FallbackMXhost	(<i>Vfallbackhost</i>) If specified, the <i>fallbackhost</i> acts like a very low priority MX on every host. This is intended to be used by sites with poor network connectivity.
FastSplit	 If set to a value greater than zero (the default is one), it suppresses the MX lookups on addresses when they are initially sorted, that is, for the first delivery attempt. This usually results in faster envelope splitting unless the MX records are readily available in a local DNS cache. To enforce initial sorting based on MX records set FastSplit to zero. If the mail is submitted directly from the command line, then the value also limits the number of processes to deliver the envelopes; if more envelopes are created they are only queued up and must be taken care of by a queue run. Since the default submission method is by way of SMTP (either from a MUA or by way of the MSP), the value of FastSplit is seldom used to limit the number of processes to deliver the envelopes.
ForkEachJob	(Y) If set, delivers each job that is run from the queue in a separate process. Use this option if you are short of memory, since the default tends to consume considerable amounts of memory while the queue is being processed.
ForwardPath	(<i>Jpath</i>) Sets the path for searching for users' .forward files. The default is \$z/.forward. Some sites that use the automounter may prefer to change this to /var/forward/\$u to search a file with the same name as the user in a system directory. It can also be set to a sequence of paths separated by colons; sendmail stops at the first file it can successfully and safely open. For example, /var/forward/\$u:\$z/.forward searches first in /var/forward/ <i>username</i> and then in <i>~username/</i> .forward (but only if the first file does not exist). Refer to the NOTES section for more information.
HelpFile	(<i>Hfile</i>) Specifies the help file for SMTP.
HoldExpensive	(c) If an outgoing mailer is marked as being expensive, does not connect immediately.
HostsFile	 Sets the file to use when doing "file" type access of host names.
HostStatusDirectory	 If set, host status is kept on disk between sendmail runs in the named directory tree. If a full path is not used, then the path is interpreted relative to the queue directory.
IgnoreDots	(i) Ignores dots in incoming messages. This is always disabled (that is, dots are always accepted) when reading SMTP mail.

`LogLevel` (*Ln*)

Sets the default log level to *n*. Defaults to 9.

(*Mx value*)

Sets the macro *x* to *value*. This is intended only for use from the command line.

`MailboxDatabase`

Type of lookup to find information about local mail boxes, defaults to `pw` which uses `getpwnam(3C)`. Other types can be introduced by adding them to the source code, see `libsm/mbdb.c` for details.

`MatchGECOS` (*G*)

Tries to match recipient names using the GECOS field. This allows for mail to be delivered using names defined in the GECOS field in `/etc/passwd` as well as the login name.

`MaxDaemonChildren`

The maximum number of children the daemon permits. After this number, connections are rejected. If not set or ≤ 0 , there is no limit.

`MaxHopCount` (*hN*)

The maximum hop count. Messages that have been processed more than *N* times are assumed to be in a loop and are rejected. Defaults to 25.

`MaxMessageSize`

The maximum size of messages that are accepted (in bytes).

`MaxMimeHeaderLength=M[/N]`

Sets the maximum length of certain MIME header field values to *M* characters. For some of these headers which take parameters, the maximum length of each parameter is set to *N* if specified. If */N* is not specified, one half of *M* is used. By default, these values are 0, meaning no checks are done.

`MaxQueueChildren=N`

When set, this limits the number of concurrent queue runner processes to *N*. This helps to control the amount of system resources used when processing the queue. When there are multiple queue groups defined and the total number of queue runners for these queue groups would exceed `MaxQueueChildren` then the queue groups are not all run concurrently. That is, some portion of the queue groups run concurrently such that `MaxQueueChildren` is not exceeded, while the remaining queue groups are run later (in round robin order). See `MaxRunnersPerQueue`.

`MaxQueueRunSize`

If set, limits the maximum size of any given queue run to this number of entries. This stops reading the queue directory after this number of entries is reached; job priority is not used. If not set, there is no limit.

`MaxRunnersPerQueue=N`

This sets the default maximum number of queue runners for queue groups. Up to *N* queue runners work in parallel on a queue group's messages. This is useful where the processing of a message in the queue might delay the processing of subsequent messages. Such a delay can be the result of non-erroneous situations

sendmail(1M)

such as a low bandwidth connection. The can be overridden on a per queue group basis by setting the `Runners` option. The default is 1 when not set.

MeToo (M)

Sends to me too, even if I am in an alias expansion.

MaxRecipientsPerMessage

If set, allows no more than the specified number of recipients in an SMTP envelope. Further recipients receive a 452 error code and are deferred for the next delivery attempt.

MinFreeBlocks (bN/M)

Insists on at least *N* blocks free on the file system that holds the queue files before accepting email by way of SMTP. If there is insufficient space, `sendmail` gives a 452 response to the `MAIL` command. This invites the sender to try again later. The optional *M* is a maximum message size advertised in the `ESMTP EHLO` response. It is currently otherwise unused.

MinQueueAge

Specifies the amount of time a job must sit in the queue between queue runs. This allows you to set the queue run interval low for better responsiveness without trying all jobs in each run. The default value is 0.

MustQuoteChars

Specifies the characters to be quoted in a full name phrase. `&, ; \ ( ) [ ]` are quoted automatically.

NiceQueueRun

Specifies the priority of queue runners. See `nice(1)`.

NoRecipientAction

Sets action if there are no legal recipient files in the message. The legal values are:

<code>add-apparently-to</code>	Adds an <code>Apparently-to:</code> header with all the known recipients (which may expose blind recipients).
<code>add-bcc</code>	Adds an empty <code>Bcc:</code> header.
<code>add-to</code>	Adds a <code>To:</code> header with all the known recipients (which may expose blind recipients).
<code>add-to-undisclosed</code>	Adds a <code>To: undisclosed-recipients:</code> header.
<code>none</code>	Does nothing, that is, leaves the message as it is.

OldStyleHeaders (o)

Assumes that the headers may be in old format, that is, spaces delimit names. This actually turns on an adaptive algorithm: if any recipient address contains a comma, parenthesis, or angle bracket, it is assumed that commas already exist. If this flag is not on, only commas delimit names. Headers are always output with commas between the names.

OperatorChars or **\$o**

Defines the list of characters that can be used to separate the components of an address into tokens.

PidFile

Specifies the filename of the pid file. The default is `/var/run/sendmail.pid`. The filename is macro-expanded before it is opened.

PostmasterCopy (*Ppostmaster*)

If set, copies of error messages are sent to the named *postmaster*. Only the header of the failed message is sent. Since most errors are user problems, this is probably not a good idea on large sites, and arguably contains all sorts of privacy violations, but it seems to be popular with certain operating systems vendors.

PrivacyOptions (*popt,opt,...*)

Sets privacy options. Privacy is really a misnomer; many of these options are just a way of insisting on stricter adherence to the SMTP protocol.

The *goaway* pseudo-flag sets all flags except *noreceipts*, *restrictmailq*, *restrictqrun*, *restrictexpand*, *noetrn*, and *nobodyreturn*. If *mailq* is restricted, only people in the same group as the queue directory can print the queue. If queue runs are restricted, only root and the owner of the queue directory can run the queue. The *restrict-expand* pseudo-flag instructs sendmail to drop privileges when the *-bv* option is given by users who are neither root nor the *TrustedUser* so users cannot read private aliases, forwards, or *:include:* files. It adds the *NonRootSafeAddr* to the "DontBlame-Sendmail" option to prevent misleading unsafe address warnings. It also overrides the *-v* (verbose) command line option to prevent information leakage. Authentication Warnings add warnings about various conditions that may indicate attempts to fool the mail system, such as using an non-standard queue directory.

The options can be selected from:

<i>authwarnings</i>	Puts X-Authentication-Warning: headers in messages.
<i>goaway</i>	Disallows essentially all SMTP status queries.
<i>needexpnhelo</i>	Insists on HELO or EHLO command before EXPN.
<i>needmailhelo</i>	Insists on HELO or EHLO command before MAIL.
<i>needvrfyhelo</i>	Insists on HELO or EHLO command before VRFY.
<i>noetrn</i>	Disallows ETRN entirely.
<i>noexpn</i>	Disallows EXPN entirely.
<i>noreceipts</i>	Prevents return receipts.
<i>nobodyreturn</i>	Does not return the body of a message with DSNs.
<i>novrfy</i>	Disallows VRFY entirely.
<i>public</i>	Allows open access.

sendmail(1M)

<code>restrictexpand</code>	Restricts <code>-bv</code> and <code>-v</code> command line flags.
<code>restrictmailq</code>	Restricts <code>mailq</code> command.
<code>restrictqrun</code>	Restricts <code>-q</code> command line flag.
<code>ProcessTitlePrefix</code> <i>string</i>	Prefixes the process title shown on <code>/usr/ucb/ps auxww</code> listings with <i>string</i> . The string is macro processed.
<code>QueueDirectory</code> (<i>Qdir</i>)	Uses the named <i>dir</i> as the queue directory.
<code>QueueFactor</code> (<i>qfactor</i>)	Uses <i>factor</i> as the multiplier in the map function to decide when to just queue up jobs rather than run them. This value is divided by the difference between the current load average and the load average limit (<code>x</code> flag) to determine the maximum message priority to be sent. Defaults to 600000.
<code>QueueFileMode</code> = <i>mode</i>	Defaults permissions for queue files (octal). If not set, <code>sendmail</code> uses 0600 unless its real and effective uid are different in which case it uses 0644.
<code>QueueLA</code> (<i>xLA</i>)	When the system load average exceeds <i>LA</i> , just queues messages (that is, does not try to send them). Defaults to eight times the number of processors online when <code>sendmail</code> starts.
<code>QueueSortOrder</code> = <i>algorithm</i>	Sets the algorithm used for sorting the queue. Only the first character of the value is used. Legal values are <code>host</code> (to order by the name of the first host name of the first recipient), <code>filename</code> (to order by the name of the queue file name), <code>time</code> (to order by the submission/creation time), <code>random</code> (to order randomly), <code>modification</code> (to order by the modification time of the <code>qf</code> file (older entries first)), and <code>priority</code> (to order by message priority). Host ordering makes better use of the connection cache, but may tend to process low priority messages that go to a single host over high priority messages that go to several hosts; it probably shouldn't be used on slow network links. Filename and modification time ordering saves the overhead of reading all of the queued items before starting the queue run. Creation (submission) time ordering is almost always a bad idea, since it allows large, bulk mail to go out before smaller, personal mail, but may have applicability on some hosts with very fast connections. Random is useful if several queue runners are started by hand which try to drain the same queue since odds are they are working on different parts of the queue at the same time. Priority ordering is the default.
<code>QueueTimeout</code> (<i>Trtime/wtime</i>)	Sets the queue timeout to <i>rtime</i> . After this interval, messages that have not been successfully sent are returned to the sender. Defaults to five days (5d). The optional <i>wtime</i> is the time after which a warning message is sent. If it is missing or 0, then no warning messages are sent.

RecipientFactor (*yfact*)

The indicated factor *fact* is added to the priority (thus *lowering* the priority of the job) for each recipient, that is, this value penalizes jobs with large numbers of recipients. Defaults to 30000.

RefuseLA (*xLA*)

When the system load average exceeds *LA*, refuses incoming SMTP connections. Defaults to 12 times the number of processors online when `sendmail` starts.

ResolverOptions (*I*)

Tunes DNS lookups.

RetryFactor (*Zfact*)

The indicated factor *fact* is added to the priority every time a job is processed. Thus, each time a job is processed, its priority is decreased by the indicated value. In most environments this should be positive, since hosts that are down are all too often down for a long time. Defaults to 90000.

RrtImpliesDsn

If this option is set, a Return-Receipt-To: header causes the request of a DSN, which is sent to the envelope sender as required by RFC 1891, not to the address given in the header.

RunAsUser

If set, becomes this user when reading and delivering mail. Intended for use of firewalls where users do not have accounts.

SafeFileEnvironment

If set, `sendmail` does a `chroot` into this directory before writing files.

SaveFromLine (*f*)

Saves Unix-style From lines at the front of headers. Normally they are assumed redundant and discarded.

SendMimeErrors (*j*)

If set, sends error messages in MIME format (see RFC 2045 and RFC 1344 for details). If disabled, `sendmail` does not return the DSN keyword in response to an EHLO and does not do Delivery Status Notification processing as described in RFC 1891.

ServiceSwitchFile

Defines the path to the service-switch file. Since the service-switch file is defined in the Solaris operating environment this option is ignored.

SevenBitInput (*7*)

Strips input to seven bits for compatibility with old systems. This should not be necessary.

SharedMemoryKey

Specifies key to use for shared memory segment. If not set (or 0), shared memory is not be used. If this option is set, `sendmail` can share some data between different instances. For example, the number of entries in a queue directory or the available

sendmail(1M)

space in a file system. This allows for more efficient program execution, since only one process needs to update the data instead of each individual process gathering the data each time it is required.

SingleLineFromHeader

If set, `From:` lines that have embedded newlines are unwrapped onto one line.

SingleThreadDelivery

If this option and the `HostStatusDirectory` option are both set, uses single thread deliveries to other hosts.

SmtgGreetingMessage or `$e`

Specifies the initial SMTP greeting message.

StatusFile (*\$file*)

Logs statistics in the named *file*. By default, this is `/etc/mail/sendmail.st`. As root, you must `touch(1)` this file to enable `mailstats(1)`.

SuperSafe (*s*)

This option can be set to `True`, `False`, or `Interactive`. If set to `True`, `sendmail` is set to super-safe when running things, that is, always instantiate the queue file, even if you are going to attempt immediate delivery. `sendmail` always instantiates the queue file before returning control to the client under any circumstances. This should really always be set to `True`. The `Interactive` value has been introduced in 8.12 and can be used together with `DeliveryMode=i`. It skips some synchronization calls which are effectively doubled in the code execution path for this mode.

TempFileMode (*Fmode*)

Specifies the file mode for queue files.

Timeout (*rtimeouts*)

`Timeout` reads after time interval. The *timeouts* argument is a list of *keyword=value* pairs. All but *command* apply to client SMTP. For backward compatibility, a timeout with no *keyword=* part is set all of the longer values. The recognized timeouts and their default values, and their minimum values specified in RFC 1123 section 5.3.2 are:

`connect`

all connections for a single delivery attempt [0, unspecified]

`command`

command read [1h, 5m]

`connect`

initial connect [0, unspecified]

`control`

complete control socket transaction [2m, none]

`datablock`

data block read [1h, 3m]

```

datafinal
    reply to final . in data [1h, 10m]
datainit
    reply to DATA command [5m, 2m]
fileopen
    file open [60sec, none]
helo
    reply to HELO or EHLO command [5m, none]
hoststatus
    host retry [30m, unspecified]
iconnect
    first attempt to connect to a host [0, unspecified]
ident
    IDENT protocol timeout [5s, none]
initial
    wait for initial greeting message [5m, 5m]
lhlo
    wait for reply to an LMTP LHLO command [2m, unspecified]
mail
    reply to MAIL command [10m, 5m]
misc
    reply to NOOP and VERB commands [2m, none]
queuereturn
    undeliverable message returned [5d]
queuwarn
    deferred warning [4h]
quit
    reply to QUIT command [2m, none]
rcpt
    reply to RCPT command [1h, 5m]
resolver.retrans
    Resolver's retransmission time interval (in seconds) [varies]. Sets both
    Timeout.resolver.retrans.first and
    Timeout.resolver.retrans.normal.
resolver.retrans.first
    Resolver's retransmission time interval (in seconds) for the first attempt to
    deliver a message [varies].

```

sendmail(1M)

<code>resolver.retrans.normal</code>	Resolver's retransmission time interval (in seconds) for all look-ups except the first delivery attempt [varies].
<code>resolver.retry</code>	Number of times to retransmit a resolver query [varies]. Sets both <code>Timeout.resolver.retry.first</code> and <code>Timeout.resolver.retry.normal</code> .
<code>resolver.retry.first</code>	Number of times to retransmit a resolver query for the first attempt to deliver a message [varies].
<code>resolver.retry.normal</code>	Number of times to retransmit a resolver query for all look-ups except the first delivery attempt [varies].
<code>rset</code>	reply to RSET command [5m, none]
<code>TimeZoneSpec (tzinfo)</code>	Sets the local time zone info to <i>tzinfo</i> , for example, "PST8PDT ". Actually, if this is not set, the TZ environment variable is cleared (so the system default is used); if set but null, the user's TZ variable is used, and if set and non-null, the TZ variable is set to this value.
<code>TrustedUser</code>	The user parameter can be a user name (looked up in the passwd map) or a numeric user id. Trusted user for file ownership and starting the daemon. If set, generated alias databases and the control socket (if configured) are automatically owned by this user.
<code>TryNullMXList (w)</code>	If you are the "best" (that is, lowest preference) MX for a given host, you should normally detect this situation and treat that condition specially, by forwarding the mail to a UUCP feed, treating it as local, or whatever. However, in some cases (such as Internet firewalls) you may want to try to connect directly to that host as though it had no MX records at all. Setting this option causes <code>sendmail</code> to try this. The downside is that errors in your configuration are likely to be diagnosed as "host unknown" or "message timed out" instead of something more meaningful. This option is deprecated.
<code>UnixFromLine</code> or <code>\$1</code>	The "From " line used when sending to files or programs.
<code>UnsafeGroupWrites</code>	If set, group-writable <code>:include:</code> and <code>.forward</code> files are considered "unsafe", that is, programs and files cannot be directly referenced from such files.
<code>UseErrorsTo (l)</code>	If there is an <code>Errors-To:</code> header, sends error messages to the addresses listed there. They normally go to the envelope sender. Use of this option causes <code>sendmail</code> to violate RFC 1123. This option is not recommended and deprecated.

	UseMSP Uses as mail submission program, that is, allows group writable queue files if the group is the same as that of a set-group-id <code>sendmail</code> binary. UserDatabaseSpec (U) Defines the name and location of the file containing User Database information. Verbose (v) Runs in verbose mode. If this is set, <code>sendmail</code> adjusts the <code>HoldExpensive</code> and <code>DeliveryMode</code> options so that all mail is delivered completely in a single job so that you can see the entire delivery process. The <code>Verbose</code> option should <i>never</i> be set in the configuration file; it is intended for command line use only. XscriptFileBufferSize Sets the threshold, in bytes, before a memory-based queue transcript file becomes disk-based. The default is 4096 bytes. If the first character of the user name is a vertical bar, the rest of the user name is used as the name of a program to pipe the mail to. It may be necessary to quote the name of the user to keep <code>sendmail</code> from suppressing the blanks from between arguments. If invoked as <code>newaliases</code>, <code>sendmail</code> rebuilds the alias database, so long as the <code>/etc/mail/aliases*</code> files are owned by root <i>and</i> root has exclusive write permission. If invoked as <code>mailq</code>, <code>sendmail</code> prints the contents of the mail queue.																
OPERANDS	<i>address</i> address of an intended recipient of the message being sent.																
USAGE	See <code>largefile(5)</code> for the description of the behavior of <code>sendmail</code> when encountering files greater than or equal to 2 Gbyte (2^{31} bytes).																
EXIT STATUS	<code>sendmail</code> returns an exit status describing what it did. The codes are defined in <code>/usr/include/sysexits.h</code>. <table> <tr> <td><code>EX_OK</code></td><td>Successful completion on all addresses.</td></tr> <tr> <td><code>EX_NOUSER</code></td><td>User name not recognized.</td></tr> <tr> <td><code>EX_UNAVAILABLE</code></td><td>Catchall. Necessary resources were not available.</td></tr> <tr> <td><code>EX_SYNTAX</code></td><td>Syntax error in address.</td></tr> <tr> <td><code>EX_SOFTWARE</code></td><td>Internal software error, including bad arguments.</td></tr> <tr> <td><code>EX_OSERR</code></td><td>Temporary operating system error, such as “cannot fork”.</td></tr> <tr> <td><code>EX_NOHOST</code></td><td>Host name not recognized.</td></tr> <tr> <td><code>EX_TEMPFAIL</code></td><td>Message could not be sent immediately, but was queued.</td></tr> </table>	<code>EX_OK</code>	Successful completion on all addresses.	<code>EX_NOUSER</code>	User name not recognized.	<code>EX_UNAVAILABLE</code>	Catchall. Necessary resources were not available.	<code>EX_SYNTAX</code>	Syntax error in address.	<code>EX_SOFTWARE</code>	Internal software error, including bad arguments.	<code>EX_OSERR</code>	Temporary operating system error, such as “cannot fork”.	<code>EX_NOHOST</code>	Host name not recognized.	<code>EX_TEMPFAIL</code>	Message could not be sent immediately, but was queued.
<code>EX_OK</code>	Successful completion on all addresses.																
<code>EX_NOUSER</code>	User name not recognized.																
<code>EX_UNAVAILABLE</code>	Catchall. Necessary resources were not available.																
<code>EX_SYNTAX</code>	Syntax error in address.																
<code>EX_SOFTWARE</code>	Internal software error, including bad arguments.																
<code>EX_OSERR</code>	Temporary operating system error, such as “cannot fork”.																
<code>EX_NOHOST</code>	Host name not recognized.																
<code>EX_TEMPFAIL</code>	Message could not be sent immediately, but was queued.																

sendmail(1M)

ENVIRONMENT VARIABLES

No environment variables are used. However, at system start-up, `/etc/init.d/sendmail` reads `/etc/default/sendmail`. In this file, if the variable `ETRN_HOSTS` is set, `/etc/init.d/sendmail` parses this variable and invokes `etrn(1M)` appropriately. `ETRN_HOSTS` should be of the form:

```
"s1:c1.1,c1.2      s2:c2.1 s3:c3.1,c3.2,c3.3"
```

That is, white-space separated groups of *server:client* where *client* can be one or more comma-separated names. The *:client* part is optional. *server* is the name of the server to prod; a mail queue run is requested for each *client* name. This is comparable to running:

```
/usr/lib/sendmail -qR client
```

on the host *server*.

FILES

<code>dead.letter</code>	Unmailable text
<code>/etc/default/sendmail</code>	Contains default settings. You can override some of the settings by command line options.
<code>/etc/mail/aliases</code>	Mail aliases file (ASCII)
<code>/etc/mail/aliases.db</code>	Database of mail aliases (binary)
<code>/etc/mail/aliases.dir</code>	Database of mail aliases (binary)
<code>/etc/mail/aliases.pag</code>	Database of mail aliases (binary)
<code>/etc/mail/sendmail.cf</code>	Defines environment for <code>sendmail</code>
<code>/var/spool/clientmqueue/*</code>	Temporary files and queued mail
<code>/var/spool/mqueue/*</code>	Temporary files and queued mail
<code>~/.forward</code>	List of recipients for forwarding messages

NOTES

The `sendmail` program requires a fully qualified host name when starting. A script has been included to help verify if the host name is defined properly (see `check-hostname(1M)`).

The permissions and the ownership of several directories have been changed in order to increase security. In particular, access to `/etc/mail` and `/var/spool/mqueue` has been restricted.

Security restrictions have been placed users using `.forward` files to pipe mail to a program or redirect mail to a file. The default shell (as listed in `/etc/passwd`) of these users must be listed in `/etc/shells`. This restriction does not affect mail that is being redirected to another alias.

Additional restrictions have been put in place on `.forward` and `:include:` files. These files and the directory structure that they are placed in cannot be group- or world-writable. See `check-permissions(1M)`.

If you have interfaces that map to domains that have MX records that point to non-local destinations, you might need to enable the `DontProbeInterfaces` option to enable delivery to those destinations. In its default startup behavior, `sendmail` probes each interface and adds an interface's IP addresses, as well as any domains that those addresses map to, to its list of domains that are considered local. For domains thus added, being on the list of local domains is equivalent to having a 0-preference MX record, with `localhost` as the MX value. If this is not the result you want, enable `DontProbeInterfaces`.

setuname(1M)

NAME	setuname – change machine information						
SYNOPSIS	setuname [-t] [-n <i>node</i>] [-s <i>name</i>]						
DESCRIPTION	The setuname utility changes the parameter value for the system name and node name. Each parameter can be changed using setuname and the appropriate option. Either or both the -s and -n options must be given when invoking setuname. The system architecture may place requirements on the size of the system and network node name. The command will issue a fatal warning message and an error message if the name entered is incompatible with the system requirements.						
OPTIONS	The following options are supported: <table><tr><td>-n <i>node</i></td><td>Changes the node name. <i>node</i> specifies the new network node name and can consist of alphanumeric characters and the special characters dash, underbar, and dollar sign.</td></tr><tr><td>-s <i>name</i></td><td>Changes the system name. <i>name</i> specifies new system name and can consist of alphanumeric characters and the special characters dash, underbar, and dollar sign.</td></tr><tr><td>-t</td><td>Temporary change. No attempt will be made to create a permanent change.</td></tr></table>	-n <i>node</i>	Changes the node name. <i>node</i> specifies the new network node name and can consist of alphanumeric characters and the special characters dash, underbar, and dollar sign.	-s <i>name</i>	Changes the system name. <i>name</i> specifies new system name and can consist of alphanumeric characters and the special characters dash, underbar, and dollar sign.	-t	Temporary change. No attempt will be made to create a permanent change.
-n <i>node</i>	Changes the node name. <i>node</i> specifies the new network node name and can consist of alphanumeric characters and the special characters dash, underbar, and dollar sign.						
-s <i>name</i>	Changes the system name. <i>name</i> specifies new system name and can consist of alphanumeric characters and the special characters dash, underbar, and dollar sign.						
-t	Temporary change. No attempt will be made to create a permanent change.						
ATTRIBUTES	See attributes(5) for descriptions of the following attributes: <table><thead><tr><th>ATTRIBUTE TYPE</th><th>ATTRIBUTE VALUE</th></tr></thead><tbody><tr><td>Availability</td><td>SUNWcsu (32-bit) SUNWcsxu (64-bit)</td></tr></tbody></table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	Availability	SUNWcsu (32-bit) SUNWcsxu (64-bit)		
ATTRIBUTE TYPE	ATTRIBUTE VALUE						
Availability	SUNWcsu (32-bit) SUNWcsxu (64-bit)						
SEE ALSO	attributes(5)						
NOTES	setuname attempts to change the parameter values in two places: the running kernel and, as necessary per implementation, to cross system reboots. A temporary change changes only the running kernel.						

sf880drd(1M)

NAME	sf880drd – Sun Fire 880 Dynamic Reconfiguration daemon				
SYNOPSIS	sf880drd				
DESCRIPTION	The Sun Fire 880 Dynamic Reconfiguration daemon, <code>sf880drd</code>, is part of the PCI and system bus hotplug framework. <code>sf880drd</code> starts at boot time. It has no configuration options and does not report any system status. <code>sf880drd</code> implements the Sun Fire 880 console-less system administration (per-slot pushbuttons and LED status indicators). It also manages various aspects of CPU/memory hotplug.				
FILES	<code>/usr/platform/SUNW,Sun-Fire-880/lib/sf880drd</code>				
ATTRIBUTES	See <code>attributes(5)</code> for descriptions of the following attributes: <table><tr><th>ATTRIBUTE TYPE</th><th>ATTRIBUTE VALUE</th></tr><tr><td>Availability</td><td>SUNWsfdr.u</td></tr></table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	Availability	SUNWsfdr.u

sftp-server(1M)

NAME	sftp-server – SFTP server subsystem				
SYNOPSIS	/usr/lib/ssh/sftp-server				
DESCRIPTION	sftp-server implements the server side of the SSH File Transfer Protocol as defined in the IETF draft-ietf-secsh-filexfer. sftp-server is a subsystem for sshd(1M) and must not be run directly. There are no options or config settings. To enable the sftp-server subsystem for sshd add the following to /etc/ssh/sshd_config: <pre>Subsystem sftp /usr/lib/ssh/sftp-server</pre> See sshd_config(4) for a description of the format and contents of that file. There is no relationship between the protocol used by sftp-server and the FTP protocol (RFC 959) provided by in.ftpd.				
EXIT STATUS	The following exit values are returned: <table><tr><td>0</td><td>Successful completion.</td></tr><tr><td>>0</td><td>An error occurred.</td></tr></table>	0	Successful completion.	>0	An error occurred.
0	Successful completion.				
>0	An error occurred.				
FILES	/usr/lib/sftp-server				
ATTRIBUTES	See attributes(5) for descriptions of the following attributes: <table><tr><th>ATTRIBUTE TYPE</th><th>ATTRIBUTE VALUE</th></tr><tr><td>Availability</td><td>SUNWsshd</td></tr></table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	Availability	SUNWsshd
ATTRIBUTE TYPE	ATTRIBUTE VALUE				
Availability	SUNWsshd				
SEE ALSO	sftp(1), ssh(1), ssh-add(1), ssh-keygen(1), sshd(1M), sshd_config(4), attributes(5) To view license terms, attribution, and copyright for OpenSSH, the default path is /var/sadm/pkg/SUNWsshdr/install/copyright. If the Solaris operating environment has been installed anywhere other than the default, modify the given path to access the file at the installed location.				
AUTHOR	Markus Friedl				

NAME	share – make local resource available for mounting by remote systems		
SYNOPSIS	share [-F <i>FSType</i>] [-o <i>specific_options</i>] [-d <i>description</i>] [<i>pathname</i>]		
DESCRIPTION	The share command exports, or makes a resource available for mounting, through a remote file system of type <i>FSType</i> . If the option -F <i>FSType</i> is omitted, the first file system type listed in /etc/dfs/fstypes is used as default. For a description of NFS specific options, see share_nfs(1M). <i>pathname</i> is the pathname of the directory to be shared. When invoked with no arguments, share displays all shared file systems.		
OPTIONS	-F <i>FSType</i>	Specify the filesystem type.	
	-o <i>specific_options</i>	The <i>specific_options</i> are used to control access of the shared resource. (See share_nfs(1M) for the NFS specific options.) They may be any of the following:	
		rw	<i>pathname</i> is shared read/write to all clients. This is also the default behavior.
		rw= <i>client[:client]</i> ...	<i>pathname</i> is shared read/write only to the listed clients. No other systems can access <i>pathname</i> .
		ro	<i>pathname</i> is shared read-only to all clients.
		ro= <i>client[:client]</i> ...	<i>pathname</i> is shared read-only only to the listed clients. No other systems can access <i>pathname</i> .
EXAMPLES		Separate multiple options with colons.	
	-d <i>description</i>	The -d flag may be used to provide a description of the resource being shared.	
	EXAMPLE 1 Sharing a read-only filesystem	This line will share the /disk file system read-only at boot time. share -F nfs -o ro /disk	
	EXAMPLE 2 Invoking multiple options	The following command shares the filesystem /export/manuals, with members of the netgroup having read-only access and users on the specified host having read-write access.	

share(1M)

EXAMPLE 2 Invoking multiple options (Continued)

```
share -F nfs -o ro=netgroup_name:rw=hostname /export/manuals
```

FILES

/etc/dfs/dfstab	list of share commands to be executed at boot time
/etc/dfs/fstypes	list of file system types, NFS by default
/etc/dfs/sharetab	system record of shared file systems

ATTRIBUTES See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

SEE ALSO mountd(1M), nfsd(1M), share_nfs(1M), shareall(1M), unshare(1M), attributes(5)

NOTES Export (old terminology): file system sharing used to be called exporting on SunOS 4.x, so the share command used to be invoked as exportfs(1B) or /usr/sbin/exportfs.

If share commands are invoked multiple times on the same filesystem, the last share invocation supersedes the previous—the options set by the last share command replace the old options. For example, if read-write permission was given to usera on /somefs, then to give read-write permission also to userb on /somefs:

```
example% share -F nfs -o rw=usera:userb /somefs
```

This behavior is not limited to sharing the root filesystem, but applies to all filesystems.

NAME	shareall, unshareall – share, unshare multiple resources				
SYNOPSIS	shareall [-F <i>FSType</i> [, <i>FSType</i> ...]] [- <i>file</i>] unshareall [-F <i>FSType</i> [, <i>FSType</i> ...]]				
DESCRIPTION	When used with no arguments, shareall shares all resources from <i>file</i>, which contains a list of share command lines. If the operand is a hyphen (-), then the share command lines are obtained from the standard input. Otherwise, if neither a <i>file</i> nor a hyphen is specified, then the file <i>/etc/dfs/dfstab</i> is used as the default. Resources may be shared by specific file system types by specifying the file systems in a comma-separated list as an argument to -F. unshareall unshares all currently shared resources. Without a -F flag, it unshares resources for all distributed file system types.				
OPTIONS	-F <i>FSType</i> Specify file system type. Defaults to the first entry in <i>/etc/dfs/fstypes</i> .				
FILES	<i>/etc/dfs/dfstab</i>				
ATTRIBUTES	See attributes(5) for descriptions of the following attributes:				
	<table border="1"> <thead> <tr> <th>ATTRIBUTE TYPE</th><th>ATTRIBUTE VALUE</th></tr> </thead> <tbody> <tr> <td>Availability</td><td>SUNWcsu</td></tr> </tbody> </table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	Availability	SUNWcsu

share_nfs(1M)

NAME	share_nfs – make local NFS file systems available for mounting by remote systems						
SYNOPSIS	share [-d <i>description</i>] [-F nfs] [-o <i>specific_options</i>] <i>pathname</i>						
DESCRIPTION	The share utility makes local file systems available for mounting by remote systems. If no argument is specified, then share displays all file systems currently shared, including NFS file systems and file systems shared through other distributed file system packages.						
OPTIONS	The following options are supported: <table><tr><td>-d <i>description</i></td><td>Provide a comment that describes the file system to be shared.</td></tr><tr><td>-F nfs</td><td>Share NFS file system type.</td></tr><tr><td>-o <i>specific_options</i></td><td>Specify <i>specific_options</i> in a comma-separated list of keywords and attribute-value-assertions for interpretation by the file-system-type-specific command. If <i>specific_options</i> is not specified, then by default sharing will be read-write to all clients. <i>specific_options</i> can be any combination of the following:</td></tr></table> aclok Allows the NFS server to do access control for NFS Version 2 clients (running SunOS 2.4 or earlier). When aclok is set on the server, maximal access is given to all clients. For example, with aclok set, if anyone has read permissions, then everyone does. If aclok is not set, minimal access is given to all clients. anon=<i>uid</i> Set <i>uid</i> to be the effective user ID of unknown users. By default, unknown users are given the effective user ID <code>UID_NOBODY</code>. If <i>uid</i> is set to <code>-1</code>, access is denied. index=<i>file</i> Load <i>file</i> rather than a listing of the directory containing this file when the directory is referenced by an NFS URL. log=<i>tag</i> Enables NFS server logging for the specified file system. The optional tag determines the location of the related log files. The tag is defined in <code>etc/nfs/nfslog.conf</code>. If no tag is specified, the default values associated with the “global” tag in <code>etc/nfs/nfslog.conf</code> will be used.	-d <i>description</i>	Provide a comment that describes the file system to be shared.	-F nfs	Share NFS file system type.	-o <i>specific_options</i>	Specify <i>specific_options</i> in a comma-separated list of keywords and attribute-value-assertions for interpretation by the file-system-type-specific command. If <i>specific_options</i> is not specified, then by default sharing will be read-write to all clients. <i>specific_options</i> can be any combination of the following:
-d <i>description</i>	Provide a comment that describes the file system to be shared.						
-F nfs	Share NFS file system type.						
-o <i>specific_options</i>	Specify <i>specific_options</i> in a comma-separated list of keywords and attribute-value-assertions for interpretation by the file-system-type-specific command. If <i>specific_options</i> is not specified, then by default sharing will be read-write to all clients. <i>specific_options</i> can be any combination of the following:						

share_nfs(1M)

nosub

Prevents clients from mounting subdirectories of shared directories. For example, if `/export` is shared with the `nosub` option on server *fooey* then a NFS client will not be able to do:

```
mount -F nfs fooey:/export/home/mnt
```

nosuid

By default, clients are allowed to create files on the shared file system with the `setuid` or `setgid` mode enabled. Specifying `nosuid` causes the server file system to silently ignore any attempt to enable the `setuid` or `setgid` mode bits.

public

Moves the location of the public file handle from root (`/`) to the exported directory for WebNFS-enabled browsers and clients. This option does not enable WebNFS service; WebNFS is always on. Only one file system per server may use this option. Any other option, including the `-ro=list` and `-rw=list` options can be included with the `public` option.

ro

Sharing will be read-only to all clients.

ro=access_list

Sharing will be read-only to the clients listed in *access_list*; overrides the `rw` suboption for the clients specified. See *access_list* below.

root=access_list

Only root users from the hosts specified in *access_list* will have root access. See *access_list* below. By default, no host has root access, so root users are mapped to an anonymous user ID (see the `anon=uid` option described above). Netgroups can be used if the file system shared is using UNIX authentication (`AUTH_SYS`).

rw

Sharing will be read-write to all clients.

rw=access_list

Sharing will be read-write to the clients listed in *access_list*; overrides the `ro` suboption for the clients specified. See *access_list* below.

share_nfs(1M)

	<code>sec=mode[:mode]. . .</code> Sharing will use one or more of the specified security modes. The <i>mode</i> in the <code>sec=mode</code> option must be a node name supported on the client. If the <code>sec=</code> option is not specified, the default security mode used is <code>AUTH_SYS</code>. Multiple <code>sec=</code> options can be specified on the command line, although each mode can appear only once. The security modes are defined in <code>nfssec(5)</code>. Each <code>sec=</code> option specifies modes that apply to any subsequent <code>window=</code>, <code>rw</code>, <code>ro</code>, <code>rw=</code>, <code>ro=</code> and <code>root=</code> options that are provided before another <code>sec=</code> option. Each additional <code>sec=</code> resets the security mode context, so that more <code>window=</code>, <code>rw</code>, <code>ro</code>, <code>rw=</code>, <code>ro=</code> and <code>root=</code> options can be supplied for additional modes. <code>sec=none</code> If the option <code>sec=none</code> is specified when the client uses <code>AUTH_NONE</code>, or if the client uses a security mode that is not one that the file system is shared with, then the credential of each NFS request is treated as unauthenticated. See the <code>anon=uid</code> option for a description of how unauthenticated requests are handled. <code>secure</code> This option has been deprecated in favor of the <code>sec=dh</code> option. <code>window=value</code> When sharing with <code>sec=dh</code>, set the maximum life time (in seconds) of the RPC request's credential (in the authentication header) that the NFS server will allow. If a credential arrives with a life time larger than what is allowed, the NFS server will reject the request. The default value is 30000 seconds (8.3 hours).				
<i>access_list</i>	The <i>access_list</i> argument is a colon-separated list whose components may be any number of the following: <table><tr><td>hostname</td><td>The name of a host. With a server configured for DNS or LDAP naming in the <code>nsswitch "hosts"</code> entry, any hostname must be represented as a fully qualified DNS or LDAP name.</td></tr><tr><td>netgroup</td><td>A netgroup contains a number of hostnames. With a server configured for DNS or LDAP naming in the</td></tr></table>	hostname	The name of a host. With a server configured for DNS or LDAP naming in the <code>nsswitch "hosts"</code> entry, any hostname must be represented as a fully qualified DNS or LDAP name.	netgroup	A netgroup contains a number of hostnames. With a server configured for DNS or LDAP naming in the
hostname	The name of a host. With a server configured for DNS or LDAP naming in the <code>nsswitch "hosts"</code> entry, any hostname must be represented as a fully qualified DNS or LDAP name.				
netgroup	A netgroup contains a number of hostnames. With a server configured for DNS or LDAP naming in the				

	nsswitch "hosts" entry, any hostname in a netgroup must be represented as a fully qualified DNS or LDAP name. To use domain membership the server must use DNS or LDAP to resolve hostnames to IP addresses; that is, the "hosts" entry in the <code>/etc/nsswitch.conf</code> must specify "dns" or "ldap" ahead of "nis" or "nisplus", since only DNS and LDAP return the full domain name of the host. Other name services like NIS or NIS+ cannot be used to resolve hostnames on the server because when mapping an IP address to a hostname they do not return domain information. For example, NIS or NIS+ 129.144.45.9 --> "myhost DNS or LDAP 129.144.45.9 --> "myhost.mydomain.mycompany.com" The domain name suffix is distinguished from hostnames and netgroups by a prefixed dot. For example, <code>rw=.mydomain.mycompany.com</code> A single dot can be used to match a hostname with no suffix. For example, <code>rw=.</code> will match "mydomain" but not "mydomain.mycompany.com". This feature can be used to match hosts resolved through NIS and NIS+ rather than DNS and LDAP.
network	The network or subnet component is preceded by an at-sign (@). It can be either a name or a dotted address. If a name, it will be converted to a dotted address by <code>getnetbyname(3SOCKET)</code>. For example, <code>=@mynet</code> would be equivalent to: <code>=@129.144</code> or <code>=@129.144.0.0</code> The network prefix assumes an octet aligned netmask determined from the zero octets in the low-order part of the address. In the case where network prefixes are not byte-aligned, the

share_nfs(1M)

	syntax will allow a mask length to be specified explicitly following a slash (/) delimiter. For example, <code>=@theothernet/17</code> or <code>=@129.144.132/22</code> where the mask is the number of leftmost contiguous significant bits in the corresponding IP address. A prefixed minus sign (-) denies access to that component of <i>access_list</i>. The list is searched sequentially until a match is found that either grants or denies access, or until the end of the list is reached. For example, if host "terra" is in the "engineering" netgroup, then <code>rw=-terra:engineering</code> will deny access to terra but <code>rw=engineering:-terra</code> will grant access to terra.								
OPERANDS	The following operands are supported: <i>pathname</i> The pathname of the file system to be shared.								
EXAMPLES	EXAMPLE 1 Sharing A File System With Logging Enabled The following example shows the /export file system shared with logging enabled: <pre>example% share -o log /export</pre> The default global logging parameters are used since no tag identifier is specified. The location of the log file, as well as the necessary logging work files, is specified by the global entry in /etc/nfs/nfslog.conf. Note that the nfslogd(1M) daemon will run only if at least one file system entry in /etc/dfs/dfstab is shared with logging enabled upon starting or rebooting the system. Simply sharing a file system with logging enabled from the command line will not start the nfslogd(1M).								
EXIT STATUS	The following exit values are returned: 0 Successful completion. >0 An error occurred.								
FILES	<table><tr><td>/etc/dfs/fstypes</td><td>list of system types, NFS by default</td></tr><tr><td>/etc/dfs/sharetab</td><td>system record of shared file systems</td></tr><tr><td>/etc/nfs/nfslogtab</td><td>system record of logged file systems</td></tr><tr><td>/etc/nfs/nfslog.conf</td><td>logging configuration file</td></tr></table>	/etc/dfs/fstypes	list of system types, NFS by default	/etc/dfs/sharetab	system record of shared file systems	/etc/nfs/nfslogtab	system record of logged file systems	/etc/nfs/nfslog.conf	logging configuration file
/etc/dfs/fstypes	list of system types, NFS by default								
/etc/dfs/sharetab	system record of shared file systems								
/etc/nfs/nfslogtab	system record of logged file systems								
/etc/nfs/nfslog.conf	logging configuration file								

ATTRIBUTES See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWnfsu

SEE ALSO mount(1M), mountd(1M), nfsd(1M), nfslogd(1M), share(1M), unshare(1M), getnetbyname(3SOCKET), nfslog.conf(4), netgroup(4), attributes(5), nfssec(5)

NOTES If the `sec=` option is presented at least once, all uses of the `window=`, `rw`, `ro`, `rw=`, `ro=` and `root=` options must come after the first `sec=` option. If the `sec=` option is not presented, then `sec=sys` is implied.

If one or more explicit `sec=` options are presented, `sys` must appear in one of the options mode lists for accessing using the `AUTH_SYS` security mode to be allowed. For example:

```
share -F nfs /var
share -F nfs -o sec=sys /varwill grant read-write access to any host using
AUTH_SYS, but
share -F nfs -o sec=dh /varwill grant no access to clients that use AUTH_SYS.
```

Unlike previous implementations of `share_nfs(1M)`, access checking for the `window=`, `rw`, `ro`, `rw=`, and `ro=` options is done per NFS request, instead of per mount request.

Combining multiple security modes can be a security hole in situations where the `ro=` and `rw=` options are used to control access to weaker security modes. In this example,

```
share -F nfs -o sec=dh,rw,sec=sys,rw=hosta /varan intruder can forge the IP address
for hosta (albeit on each NFS request) to side-step the stronger controls of
AUTH_DES. Something like:
```

```
share -F nfs -o sec=dh,rw,sec=sys,ro /varis safer, because any client (intruder or
legitimate) that avoids AUTH_DES will only get read-only access. In general, multiple
security modes per share command should only be used in situations where the
clients using more secure modes get stronger access than clients using less secure
modes.
```

If `rw=`, and `ro=` options are specified in the same `sec=` clause, and a client is in both lists, the order of the two options determines the access the client gets. If client `hosta` is in two netgroups - `group1` and `group2` - in this example, the client would get read-only access:

```
share -F nfs -o ro=group1,rw=group2 /var
```

share_nfs(1M)

In this example `hosta` would get read-write access:

```
share -F nfs -o rw=group2,ro=group1 /var
```

If within a `sec=` clause, both the `ro` and `rw=` options are specified, for compatibility, the order of the options rule is not enforced. All hosts would get read-only access, with the exception to those in the read-write list. Likewise, if the `ro=` and `rw` options are specified, all hosts get read-write access with the exceptions of those in the read-only list.

The `ro=` and `rw=` options are guaranteed to work over UDP and TCP but may not work over other transport providers.

The `root=` option with `AUTH_SYS` is guaranteed to work over UDP and TCP but may not work over other transport providers.

The `root=` option with `AUTH_DES` is guaranteed to work over any transport provider.

There are no interactions between the `root=` option and the `rw`, `ro`, `rw=`, and `ro=` options. Putting a host in the `root` list does not override the semantics of the other options. The access the host gets is the same as when the `root=` options is absent. For example, the following `share` command will deny access to `hostb`:

```
share -F nfs -o ro=hosta,root=hostb /var
```

The following will give read-only permissions to `hostb`:

```
share -F nfs -o ro=hostb,root=hostb /var
```

The following will give read-write permissions to `hostb`:

```
share -F nfs -o ro=hosta,rw=hostb,root=hostb /var
```

If the file system being shared is a symbolic link to a valid pathname, the canonical path (the path which the symbolic link follows) will be shared. For example, if `/export/foo` is a symbolic link to `/export/bar` (`/export/foo -> /export/bar`), the following `share` command will result in `/export/bar` as the shared pathname (and not `/export/foo`).

```
example# share -F nfs /export/foo
```

Note that an NFS mount of `server:/export/foo` will result in `server:/export/bar` really being mounted.

This line in the `/etc/dfs/dfstab` file will share the `/disk` file system read-only at boot time:

```
share -F nfs -o ro /disk
```

Note that the same command entered from the command line will not share the `/disk` file system unless there is at least one file system entry in the `/etc/dfs/dfstab` file. The `mountd(1M)` and `nfsd(1M)` daemons only run if there is a file system entry in `/etc/dfs/dfstab` when starting or rebooting the system.

NAME	showmount – show all remote mounts				
SYNOPSIS	/usr/sbin/showmount [-ade] [<i>hostname</i>]				
DESCRIPTION	showmount lists all the clients that have remotely mounted a filesystem from <i>host</i> . This information is maintained by the mountd(1M) server on <i>host</i> , and is saved across crashes in the file <i>/etc/rmtab</i> . The default value for <i>host</i> is the value returned by <i>hostname(1)</i> .				
OPTIONS	-a Print all remote mounts in the format: <i>hostname</i> : <i>directory</i> where <i>hostname</i> is the name of the client, and <i>directory</i> is the root of the file system that has been mounted. -d List directories that have been remotely mounted by clients. -e Print the list of shared file systems.				
FILES	<i>/etc/rmtab</i>				
ATTRIBUTES	See <i>attributes(5)</i> for descriptions of the following attributes:				
	<table border="1"> <thead> <tr> <th>ATTRIBUTE TYPE</th><th>ATTRIBUTE VALUE</th></tr> </thead> <tbody> <tr> <td>Availability</td><td>SUNWnfscu</td></tr> </tbody> </table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	Availability	SUNWnfscu
ATTRIBUTE TYPE	ATTRIBUTE VALUE				
Availability	SUNWnfscu				
SEE ALSO	<i>hostname(1)</i>, <i>mountd(1M)</i>, <i>attributes(5)</i> <i>Solaris 9 9/04 Installation Guide</i>				
BUGS	If a client crashes, its entry will not be removed from the list of remote mounts on the server.				

showrev(1M)

NAME	showrev – show machine, software revision, and patch revision information
SYNOPSIS	<code>/usr/bin/showrev [-a] [-p -p -R <i>root_path</i>] [-w] [-c <i>command</i>] [-s <i>hostname</i>]</code>
DESCRIPTION	showrev displays revision information for the current hardware and software. With no arguments, showrev shows the system revision information including hostname, hostid, release, kernel architecture, application architecture, hardware provider, domain, and kernel version. If a command is supplied with the -c option, showrev shows the PATH and LD_LIBRARY_PATH and finds out all the directories within the PATH that contain it. For each file found, its file type, revision, permissions, library information, and checksum are printed as well.
OPTIONS	The following options are supported: -a Print all system revision information available. Window system and patch information are added. -c <i>command</i> Print the revision information about <i>command</i>. -p Print only the revision information about patches. -R <i>root_path</i> Define the full path name of a directory to use as the <i>root_path</i>. By specifying the root path, showrev retrieves the revision information about the patch from package system information files located under a directory tree starting at <i>root_path</i>. The <i>root_path</i> can be specified when retrieving installed patch information in a client from a server, for example, /export/root/client1. -s <i>hostname</i> Perform this operation on the specified <i>hostname</i>. The -s operation completes correctly only when <i>hostname</i> is running Solaris 2.5 or compatible versions. -w Print only the OpenWindows revision information.
OUTPUT	Varies, based on flags passed. If no flags are passed, output similar to the following appears: <pre> Hostname: system1 Hostid: 7233808e Release: 5.9 Kernel architecture: sun4u Application architecture: sparc Hardware provider: Sun_Microsystems Domain: a.network.COM Kernel version: SunOS 5.9 generic February 2001 </pre>
EXIT STATUS	The following error values are returned: 0 Successful completion. >0 An error occurred.

showrev(1M)

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWadmc

SEE ALSO `arch(1)`, `ldd(1)`, `mcs(1)`, `sum(1)`, `patchadd(1M)`, `attributes(5)`

BUGS For the `-s` option to work when `hostname` is running a version of Solaris prior to 2.5, the Solstice AdminSuite must be installed on `hostname`.

shutdown(1M)

NAME	shutdown – shut down system, change system state										
SYNOPSIS	/usr/sbin/shutdown [-y] [-g <i>grace-period</i>] [-i <i>init-state</i>] [<i>message</i>]										
DESCRIPTION	shutdown is executed by the super user to change the state of the machine. In most cases, it is used to change from the multi-user state (state 2) to another state. By default, shutdown brings the system to a state where only the console has access to the operating system. This state is called single-user. Before starting to shut down daemons and killing processes, shutdown sends a warning message and, by default, a final message asking for confirmation. <i>message</i> is a string that is sent out following the standard warning message "The system will be shut down in . . ." If the string contains more than one word, it should be contained within single (') or double (") quotation marks. The warning message and the user provided <i>message</i> are output when there are 7200, 3600, 1800, 1200, 600, 300, 120, 60, and 30 seconds remaining before shutdown begins. See EXAMPLES. System state definitions are: <table> <tr> <td>state 0</td><td>Stop the operating system.</td></tr> <tr> <td>state 1</td><td>State 1 is referred to as the administrative state. In state 1 file systems required for multi-user operations are mounted, and logins requiring access to multi-user file systems can be used. When the system comes up from firmware mode into state 1, only the console is active and other multi-user (state 2) services are unavailable. Note that not all user processes are stopped when transitioning from multi-user state to state 1.</td></tr> <tr> <td>state s, S</td><td>State s (or S) is referred to as the single-user state. All user processes are stopped on transitions to this state. In the single-user state, file systems required for multi-user logins are unmounted and the system can only be accessed through the console. Logins requiring access to multi-user file systems cannot be used.</td></tr> <tr> <td>state 5</td><td>Shut the machine down so that it is safe to remove the power. Have the machine remove power, if possible. The rc0 procedure is called to perform this task.</td></tr> <tr> <td>state 6</td><td>Stop the operating system and reboot to the state defined by the initdefault entry in /etc/inittab. The rc6 procedure is called to perform this task.</td></tr> </table>	state 0	Stop the operating system.	state 1	State 1 is referred to as the administrative state. In state 1 file systems required for multi-user operations are mounted, and logins requiring access to multi-user file systems can be used. When the system comes up from firmware mode into state 1, only the console is active and other multi-user (state 2) services are unavailable. Note that not all user processes are stopped when transitioning from multi-user state to state 1.	state s, S	State s (or S) is referred to as the single-user state. All user processes are stopped on transitions to this state. In the single-user state, file systems required for multi-user logins are unmounted and the system can only be accessed through the console. Logins requiring access to multi-user file systems cannot be used.	state 5	Shut the machine down so that it is safe to remove the power. Have the machine remove power, if possible. The rc0 procedure is called to perform this task.	state 6	Stop the operating system and reboot to the state defined by the initdefault entry in /etc/inittab. The rc6 procedure is called to perform this task.
state 0	Stop the operating system.										
state 1	State 1 is referred to as the administrative state. In state 1 file systems required for multi-user operations are mounted, and logins requiring access to multi-user file systems can be used. When the system comes up from firmware mode into state 1, only the console is active and other multi-user (state 2) services are unavailable. Note that not all user processes are stopped when transitioning from multi-user state to state 1.										
state s, S	State s (or S) is referred to as the single-user state. All user processes are stopped on transitions to this state. In the single-user state, file systems required for multi-user logins are unmounted and the system can only be accessed through the console. Logins requiring access to multi-user file systems cannot be used.										
state 5	Shut the machine down so that it is safe to remove the power. Have the machine remove power, if possible. The rc0 procedure is called to perform this task.										
state 6	Stop the operating system and reboot to the state defined by the initdefault entry in /etc/inittab. The rc6 procedure is called to perform this task.										
OPTIONS	<table> <tr> <td>-y</td><td>Pre-answer the confirmation question so the command can be run without user intervention.</td></tr> <tr> <td>-g <i>grace-period</i></td><td>Allow the super user to change the number of seconds from the 60-second default.</td></tr> </table>	-y	Pre-answer the confirmation question so the command can be run without user intervention.	-g <i>grace-period</i>	Allow the super user to change the number of seconds from the 60-second default.						
-y	Pre-answer the confirmation question so the command can be run without user intervention.										
-g <i>grace-period</i>	Allow the super user to change the number of seconds from the 60-second default.										

`-i init-state` If there are warnings, *init-state* specifies the state `init` is to be in. By default, system state `'s'` is used.

EXAMPLES

EXAMPLE 1 Using shutdown

In the following example, `shutdown` is being executed on host `foo` and is scheduled in 120 seconds. The warning message is output 2 minutes, 1 minute, and 30 seconds before the final confirmation message.

```
example# shutdown -i S -g 120 "==== disk replacement ====="
Shutdown started.  Tue Jun  7 14:51:40 PDT 1994

Broadcast Message from root (pts/1) on foo Tue Jun  7 14:51:41. . .
The system will be shut down in 2 minutes
==== disk replacement =====
Broadcast Message from root (pts/1) on foo Tue Jun  7 14:52:41. . .
The system will be shut down in 1 minutes
==== disk replacement =====
Broadcast Message from root (pts/1) on foo Tue Jun  7 14:53:41. . .
The system will be shut down in 30 seconds
==== disk replacement =====
Do you want to continue? (y or n):
```

FILES `/etc/inittab` controls process dispatching by `init`

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

SEE ALSO `boot(1M)`, `halt(1M)`, `init(1M)`, `killall(1M)`, `reboot(1M)`, `ufsdump(1M)`, `init.d(4)`, `inittab(4)`, `nologin(4)`, `attributes(5)`

NOTES When a system transitions down to the `S` or `s` state, the `/etc/nologin` file (see `nologin(4)`) is created. Upon subsequent transition to state 2 (multi-user state), this file is removed by a script in the `/etc/rc2.d` directory.

slpd(1M)

NAME	slpd – Service Location Protocol Daemon								
SYNOPSIS	<code>/usr/lib/inet/slpd [-f <i>configuration-file</i>]</code>								
DESCRIPTION	The <code>slpd</code> daemon provides common server functionality for the Service Location Protocol (“SLP”) versions 1 and 2, as defined by IETF in <i>RFC 2165</i> and <i>RFC 2608</i>. SLP provides a scalable framework for the discovery and selection of network services. <code>slpd</code> provides the following framework services: <table><tr><td>Directory Agent</td><td>This service automatically caches service advertisements from service agents to provide them to user agents, and makes directory agent advertisements of its services. This service is optional. <code>slpd</code> does not provide directory agent service by default. Directory agents are not databases, and they do not need to be maintained.</td></tr><tr><td>Service Agent Server</td><td>All service agents on the local host register and deregister with this server. This service responds to all requests for services, and forwards registrations to directory agents. By default, <code>slpd</code> is a service agent server.</td></tr><tr><td>Passive Directory Agent Discovery</td><td>This service listens for directory agent advertisements and maintains a table of active directory agents. When a user agent wishes to discover a directory agent, it can simply query <code>slpd</code>, obviating the need to perform discovery by means of multicast. By default, <code>slpd</code> performs this service.</td></tr><tr><td>Proxy Registration</td><td>This service can act as a proxy service agent for services that cannot register themselves. <code>slpd</code> reads the proxy registration file for information on services it is to proxy. By default, no services are registered by proxy.</td></tr></table> All configuration options are available from the configuration file. <code>slpd</code> reads its configuration file upon startup. Stop and start the <code>slpd</code> daemon by using the startup script: <code>/etc/init.d/slpd</code>. Use the command <code>/etc/init.d/slpd stop</code> to stop the <code>slpd</code> daemon. Use the command <code>/etc/init.d/slpd start</code> to start it. The file <code>/etc/inet/slp.conf</code> must exist before the startup script can start the daemon. Only the example file <code>/etc/inet/slp.conf.example</code> is present by default. To enable SLP, copy <code>/etc/inet/slp.conf.example</code> to <code>/etc/inet/slp.conf</code>.	Directory Agent	This service automatically caches service advertisements from service agents to provide them to user agents, and makes directory agent advertisements of its services. This service is optional. <code>slpd</code> does not provide directory agent service by default. Directory agents are not databases, and they do not need to be maintained.	Service Agent Server	All service agents on the local host register and deregister with this server. This service responds to all requests for services, and forwards registrations to directory agents. By default, <code>slpd</code> is a service agent server.	Passive Directory Agent Discovery	This service listens for directory agent advertisements and maintains a table of active directory agents. When a user agent wishes to discover a directory agent, it can simply query <code>slpd</code> , obviating the need to perform discovery by means of multicast. By default, <code>slpd</code> performs this service.	Proxy Registration	This service can act as a proxy service agent for services that cannot register themselves. <code>slpd</code> reads the proxy registration file for information on services it is to proxy. By default, no services are registered by proxy.
Directory Agent	This service automatically caches service advertisements from service agents to provide them to user agents, and makes directory agent advertisements of its services. This service is optional. <code>slpd</code> does not provide directory agent service by default. Directory agents are not databases, and they do not need to be maintained.								
Service Agent Server	All service agents on the local host register and deregister with this server. This service responds to all requests for services, and forwards registrations to directory agents. By default, <code>slpd</code> is a service agent server.								
Passive Directory Agent Discovery	This service listens for directory agent advertisements and maintains a table of active directory agents. When a user agent wishes to discover a directory agent, it can simply query <code>slpd</code> , obviating the need to perform discovery by means of multicast. By default, <code>slpd</code> performs this service.								
Proxy Registration	This service can act as a proxy service agent for services that cannot register themselves. <code>slpd</code> reads the proxy registration file for information on services it is to proxy. By default, no services are registered by proxy.								

OPTIONS The following options are supported:

-f *configuration-file* Specify an alternate configuration file

EXAMPLES **EXAMPLE 1** Stopping the slpd daemon

The following command stops the slpd daemon:

```
example# /etc/init.d/slpd stop
```

EXAMPLE 2 Restarting the slpd daemon

The following command restarts the slpd daemon:

```
example# /etc/init.d/slpd start
```

FILES /etc/inet/slp.conf The default configuration file

slpd.reg The proxy registration file

smartcard(1M)

NAME	smartcard – configure and administer a smart card
SYNOPSIS	<pre> smartcard -c admin [-a <i>application</i>] [<i>propertyname</i>...] smartcard -c admin [-a <i>application</i>] [-x { add delete modify } <i>propertyname=value</i>...] smartcard -c admin -t service -j <i>classname</i> -x { add delete modify} smartcard -c admin -t terminal { -j <i>classname</i> -H <i>libraryname</i> } -d <i>device</i> -r <i>userfriendlyreadername</i> -n <i>readername</i> -x { add delete modify } [-R] smartcard -c admin -t debug -j <i>classname</i> -l <i>level</i> -x { add delete modify} smartcard -c admin -t override -x { add delete modify} <i>propertyname=value</i> smartcard -c admin -I -k <i>keytype</i> -i <i>filename</i> smartcard -c admin -E -k <i>keytype</i> -o <i>filename</i> smartcard -c load -A <i>aid</i> [-r <i>userfriendlyreadername</i>] -P <i>pin</i> [-s <i>slot</i>] [-i <i>inputfile</i>] [-p <i>propfile</i>] [-v] [<i>propertyname=value</i>...] smartcard -c load -u -P <i>pin</i> [-A <i>aid</i>] [-r <i>userfriendlyreadername</i>] [-s <i>slot</i>] [-v] smartcard -c bin2capx -T <i>cardname</i> [-i <i>inputfile</i>] [-o <i>outputfile</i>] [-p <i>propfile</i>] [-I <i>anothercapxfile</i>] [-v] [<i>propertyname=value</i>...] smartcard -c init -A <i>aid</i> [-r <i>readername</i>] [-s <i>slot</i>] -L smartcard -c init -A <i>aid</i> [-r <i>readername</i>] -P <i>pin</i> [-s <i>slot</i>] [<i>propertyname=value</i>...] smartcard -c enable smartcard -c disable </pre>
DESCRIPTION	The smartcard utility is used for all configurations related to a smart card. It comprises the following subcommands: Administration of OCF properties. (-c admin) This subcommand is used to list and modify any of the OCF properties. With no arguments it will list all the current properties. It can only be executed by root. Some OCF properties are: <pre> defaultcard # default card for an application defaultreader # default reader for an application authmechanism # authentication mechanism </pre>

```
validcards
    # list of cards valid for an application
```

A complete listing can be obtained by using the `smartcard` utility as described in the EXAMPLES section.

2. Loading and Unloading of applets from the smart card (`-c load`) and performing initial configuration of a non-Java card.

This subcommand administers the applets or properties on a smartcard. It can be used to load or unload applets and/or properties to and from a smart card. The applet is a Java class file that has been run through a converter to make the byte code JavaCard-compliant. This command can be used to load both an applet file in the standard format or a file converted to the `capx` format. If no `-r` option is specified, the loader tries to load to any connected reader, provided it has already been inserted using the `smartcard -c admin` command.

3. Converting card applets or properties to the `capx` format (`-c bin2capx`)

This subcommand is used to convert a Java card applet or properties into a new format called `capx` before downloading it onto the smart card. Converting to this format enables the applet developer to add applet-specific information that is useful during the downloading process and identifies the applet.

In the following example,

```
smartcard -c bin2capx -i cyberflex.bin \
-T CyberFlex aidto-000102030405060708090A0B0C0D0E0F fileID=2222 \
instanceID=2223 and more.
```

if no output file is specified, a default file with the name *input_filename.capx* is created in the current directory. The mandatory `-T` option requires the user to specify the card name for which the `capx` file is being generated.

The following example

```
smartcard -c bin2capx -T IButton
```

tells the loader that the `capx` file contains the binary for `IButton`. A single `capx` file can hold binaries for multiple cards (1 per card.) Users can, for example, hold binary files for both `CyberFlex` and `IButton` in the same `capx` file as follows:

```
smartcard -c bin2capx -T IButton -i IButton.jib -o file.capx
```

In the following example,

```
smartcard -c bin2capx -T CyberFlex -i cyberflex.bin \
-l file.capx -o file.capx
```

the `-l` option is used to provide an already-generated `capx` file. The output is directed to the same `capx` file, resulting in `capx` file holding binaries for both cards.

4. Personalizing a smart card (`-c init`)

smartcard(1M)

	This subcommand is used to set user-specific information required by an applet on a smart card. For example, the Sun applet requires a user name to be set on the card. This subcommand is also used to personalize information for non-Java cars. 5. Enabling and disabling the smart card desktop login (-c {enable disable})																																		
OPTIONS	The following options are supported: <table><tr><td>-a <i>application</i></td><td>Specify application name for the configuration parameter. Parameters may differ depending on the application. If no application name is specified, then ocf is the default application.</td></tr><tr><td>-A <i>aid</i></td><td>Specify a unique alphanumeric string that identifies the applet. The <i>aid</i> argument must be a minimum of 5 characters and can be a maximum of 16 characters in length. If an applet with an identical <i>aid</i> already exists on the card, a load will result in an error.</td></tr><tr><td>-c</td><td>Specify subcommand name. Valid options are: admin, load, bin2capx, init, enable, and disable.</td></tr><tr><td>-d <i>device</i></td><td>Specify device on which the reader is connected (for example, /dev/cua/a).</td></tr><tr><td>-D</td><td>Disable a system from using smart cards.</td></tr><tr><td>-E</td><td>Export the keys to a file.</td></tr><tr><td>-H <i>libraryname</i></td><td>Specify the full path of the IFD handler library for the reader.</td></tr><tr><td>-i <i>filename</i></td><td>Specify input file name.</td></tr><tr><td>-I</td><td>Import from a file.</td></tr><tr><td>-j <i>classname</i></td><td>Specify fully-qualified class name.</td></tr><tr><td>-k <i>keytype</i></td><td>Specify type of key (for example, challenge_response, pki.)</td></tr><tr><td>-l</td><td>Specify debug level (0–9), signifying level of debug information displayed.</td></tr><tr><td>-L</td><td>List all properties configurable in an applet.</td></tr><tr><td>-n <i>readername</i></td><td>Specify reader name as required by the driver.</td></tr><tr><td>-o <i>filename</i></td><td>Specify output file name.</td></tr><tr><td>-p <i>propfile</i></td><td>Specify properties file name. This file could contain a list of property names and value pairs, in the format <i>propertyname=value</i>.</td></tr><tr><td>-P <i>pin</i></td><td>Specify pin used to validate to the card.</td></tr></table>	-a <i>application</i>	Specify application name for the configuration parameter. Parameters may differ depending on the application. If no application name is specified, then ocf is the default application.	-A <i>aid</i>	Specify a unique alphanumeric string that identifies the applet. The <i>aid</i> argument must be a minimum of 5 characters and can be a maximum of 16 characters in length. If an applet with an identical <i>aid</i> already exists on the card, a load will result in an error.	-c	Specify subcommand name. Valid options are: admin, load, bin2capx, init, enable, and disable.	-d <i>device</i>	Specify device on which the reader is connected (for example, /dev/cua/a).	-D	Disable a system from using smart cards.	-E	Export the keys to a file.	-H <i>libraryname</i>	Specify the full path of the IFD handler library for the reader.	-i <i>filename</i>	Specify input file name.	-I	Import from a file.	-j <i>classname</i>	Specify fully-qualified class name.	-k <i>keytype</i>	Specify type of key (for example, challenge_response, pki.)	-l	Specify debug level (0–9), signifying level of debug information displayed.	-L	List all properties configurable in an applet.	-n <i>readername</i>	Specify reader name as required by the driver.	-o <i>filename</i>	Specify output file name.	-p <i>propfile</i>	Specify properties file name. This file could contain a list of property names and value pairs, in the format <i>propertyname=value</i> .	-P <i>pin</i>	Specify pin used to validate to the card.
-a <i>application</i>	Specify application name for the configuration parameter. Parameters may differ depending on the application. If no application name is specified, then ocf is the default application.																																		
-A <i>aid</i>	Specify a unique alphanumeric string that identifies the applet. The <i>aid</i> argument must be a minimum of 5 characters and can be a maximum of 16 characters in length. If an applet with an identical <i>aid</i> already exists on the card, a load will result in an error.																																		
-c	Specify subcommand name. Valid options are: admin, load, bin2capx, init, enable, and disable.																																		
-d <i>device</i>	Specify device on which the reader is connected (for example, /dev/cua/a).																																		
-D	Disable a system from using smart cards.																																		
-E	Export the keys to a file.																																		
-H <i>libraryname</i>	Specify the full path of the IFD handler library for the reader.																																		
-i <i>filename</i>	Specify input file name.																																		
-I	Import from a file.																																		
-j <i>classname</i>	Specify fully-qualified class name.																																		
-k <i>keytype</i>	Specify type of key (for example, challenge_response, pki.)																																		
-l	Specify debug level (0–9), signifying level of debug information displayed.																																		
-L	List all properties configurable in an applet.																																		
-n <i>readername</i>	Specify reader name as required by the driver.																																		
-o <i>filename</i>	Specify output file name.																																		
-p <i>propfile</i>	Specify properties file name. This file could contain a list of property names and value pairs, in the format <i>propertyname=value</i> .																																		
-P <i>pin</i>	Specify pin used to validate to the card.																																		

<i>-r userfriendlyreadername</i>	Specify user-defined reader name where the card to be initialized is inserted.								
<i>-R</i>	Restart the ocf server.								
<i>-s slot</i>	Specify slot number. If a reader has multiple slots, this option specifies which slot to use for initialization. If a reader has only one slot, this option is not required. If no slot number is specified, by default the first slot of the reader is used.								
<i>-t</i>	Specify type of property being updated. The valid values are: <table> <tr> <td>service</td><td>Updating a card service provider details.</td></tr> <tr> <td>terminal</td><td>Updating a card reader provider details.</td></tr> <tr> <td>debug</td><td>OCF trace level.</td></tr> <tr> <td>override</td><td>Override a system property of the same name.</td></tr> </table>	service	Updating a card service provider details.	terminal	Updating a card reader provider details.	debug	OCF trace level.	override	Override a system property of the same name.
service	Updating a card service provider details.								
terminal	Updating a card reader provider details.								
debug	OCF trace level.								
override	Override a system property of the same name.								
<i>-T cardname</i>	Specify card name.								
<i>-u</i>	Unload the applet specified by the application ID from the card. If no application ID is specified, all applets are unloaded from the card.								
<i>-v</i>	Verbose mode (displays helpful messages).								
<i>-x</i>	Specify action to be taken. Valid values are: add, delete, or modify.								

EXAMPLES**EXAMPLE 1** Viewing the Values of All Properties

Enter the following command to view the values of all the properties that are set:

```
% smartcard -c admin
```

EXAMPLE 2 Viewing the Values of Specific Properties

Enter the following command to view the values of specific properties:

```
% smartcard -c admin language country
```

EXAMPLE 3 Adding a Card Service

Enter the following command to add a card service factory for a CyberFlex card, available in the package `com.sun.services.cyberflex`, to the properties:

EXAMPLE 3 Adding a Card Service *(Continued)*

```
% smartcard -c admin -t service \
-j com.sun.services.cyberflex.CyberFlexCardServiceFactory -x add
```

EXAMPLE 4 Adding a Reader

Enter the following command to add an SCM reader, available in the package `com.sun.services.scm`, to the properties on device `/dev/cua/a` and assign it a name of SCM:

```
% smartcard -c admin -t terminal \
-j com.sun.opencard.terminal.scm.SCMStc.SCMstcCardTerminalFactory \
-x add -d /dev/cua/a -r SCM -n SunSCRI
```

Enter the following command to add a reader for which an IFD handler is available:

```
% smartcard -c admin -t terminal \
-H /usr/lib/smartcard/libifdmyserial.so \
-x add -d /dev/cua/a -r MySerialReader -n MySerial
```

EXAMPLE 5 Deleting a Reader

Enter the following command to delete the SCM reader, added in the previous example, from the properties:

```
% smartcard -c admin -t terminal -r SCM -x delete
```

EXAMPLE 6 Changing the Debug Level

Enter the following command to change the debug level for all of the `com.sun` package to 9:

```
% smartcard -c admin -t debug -j com.sun -l 9 -x modify
```

EXAMPLE 7 Setting the Default Card for an Application

Enter one of the following commands to set the default card for an application (`dtlogin`) to be CyberFlex.

If the property default card does not exist, enter the following command:

```
% smartcard -c admin -a dtlogin -x add defaultcard=CyberFlex
```

If the property default card exists, enter the following command:

```
% smartcard -c admin -a dtlogin -x modify defaultcard=CyberFlex
```

EXAMPLE 8 Exporting Keys for a User into a File

Enter the following command to export the challenge-response keys for a user into a file:

```
% smartcard -c admin -k challenge_response -E -o /tmp/mykeys
```

EXAMPLE 9 Importing Keys from a File

Enter the following command to import the challenge-response keys for a user from a file:

```
% smartcard -c admin -k challenge_response -I -i /tmp/mykeys
```

EXAMPLE 10 Downloading an Applet into a Java Card

Enter the following command to download an applet into a Java card or to configure a PayFlex (non-Java) card inserted into an SCM reader for the capx file supplied in the /usr/share/lib/smartcard directory:

```
% smartcard -c load -r SCM \
-i /usr/share/lib/smartcard/SolarisAuthApplet.capx
```

EXAMPLE 11 Downloading an Applet Binary

Enter the following command to download an applet binary from some place other than the capx file supplied with Solaris 8 into an IButton (the aid and input file are mandatory, the remaining parameters are optional):

```
% smartcard -c load -A A000000062030400 -i newapplet.jib
```

EXAMPLE 12 Downloading an Applet on a CyberFlex Access Card

On a CyberFlex Access Card, enter the following command to download an applet newapplet.bin at fileID 2222, instanceID 3333 using the specified verifyKey and a heap size of 2000 bytes:

```
% smartcard -c load -A newaid -i newapplet.bin \
fileID=2222 instanceID=3333 verifyKey=newKey \
MAC=newMAC heapsize=2000
```

EXAMPLE 13 Configuring a PayFlex Card

Enter the following command to configure a PayFlex (non-Java) card with specific aid, transport key, and initial pin:

```
% smartcard -c load aid=A00000006203400 \
pin=242424246A617661 transportKey=4746584932567840
```

smartcard(1M)

EXAMPLE 14 Unloading an Applet from a Card

Enter the following command to unload an applet from iButton:

```
% smartcard -c load -u
```

EXAMPLE 15 Displaying Usage of smartcard -c load

Enter the following command to display the usage of the smartcard -c load command:

```
% smartcard -c load
```

EXAMPLE 16 Displaying All Configurable Parameters for an Applet

Enter the following command to display all the configurable parameters for an applet with aid 123456 residing on a card inserted into an SCM reader:

```
% smartcard -c init -r SM -A 123456 -L
```

EXAMPLE 17 Changing the PIN

Enter the following command to change the pin for the SolarisAuthApplet residing on a card or to change the PIN for a PayFlex (non-Java) card inserted into an SCM reader:

```
% smartcard -c init -A A000000062030400 -P oldpin pin=newpin
```

EXAMPLE 18 Displaying All Configurable Parameters for the SolarisAuthApplet.

Enter the following command to display all the configurable parameters for the SolarisAuthApplet residing on a card inserted into an SCM reader:

```
% smartcard -c init -A A000000062030400 -L
```

EXAMPLE 19 Setting a Property to a Value on a smart card

Enter the following command to set properties called "user" to the value "james" and "application" to the value "login" on a card inserted into an SCM reader that has a pin "testpin":

```
% smartcard -c init -A A000000062030400 -r CyberFlex -P testpin \  
application=login user=james
```

EXAMPLE 20 Converting an Applet for the CyberFlex Card into capx Format.

Enter the following command to convert an applet for the CyberFlex card into the capx format required for downloading the applet into the card:

```
% smartcard -c bin2capx \  
-i /usr/share/lib/smartcard/SolarisAuthApplet.bin \  

```

EXAMPLE 20 Converting an Applet for the CyberFlex Card into capx Format. (Continued)

```
-T CyberFlex -o /home/CorporateCard.capx -v memory=128 heapsize=12
```

EXAMPLE 21 Converting an Applet for the IButton Card into capx Format

Enter the following command to convert an applet for the IButton card into the capx format required for downloading the applet into the button:

```
% smartcard -c bin2capx \
-i /usr/share/lib/smartcard/SolarisAuthApplet.jib \
-T IButton -o /home/CorporateCard.capx -v
```

EXIT STATUS The following exit values are returned:

```
0          Successful completion.
1          An error occurred.
```

ATTRIBUTES See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWocf
Interface Stability	Stable

SEE ALSO ocfserv(1M), attributes(5), smartcard(5)

NOTES The command line options contain only alphanumeric input.

smattrpop(1M)

NAME	smattrpop – populate security attribute databases in a name service
SYNOPSIS	smattrpop [-c] [-f] [-m] [-p <i>policy</i>] [-r] -s <i>scope</i> -t <i>scope</i> [-v] <i>database</i>
DESCRIPTION	The smattrpop command updates the <code>auth_attr(4)</code>, <code>exec_attr(4)</code>, <code>prof_attr(4)</code>, and <code>user_attr(4)</code> role-based access control databases in a target NIS, NIS+, LDAP, or local <code>/etc</code> files name service from the corresponding databases in a source name service or files. This command processes the table entries from the source database and merges each source entry field into the same field in the corresponding table entry in the target database. If a source entry does not exist in the target database, the entry is created. If the source entry exists in the target database, the fields are merged or replaced according to the command options. Any errors encountered while updating the target entry are reported to <code>stdout</code>, and the command continues with the next source database entry.
OPTIONS	The following options are supported: -c Performs cross-table checking. If you specify this option and a check error occurs, a message identifying the check error is written to <code>stdout</code>. The target entry values are checked against entries in related databases: ■ <code>auths</code> values — Each value must exist as the name of an authorization in the <code>auth_attr(4)</code> database. ■ <code>profiles</code> values — Each value must exist as a name of a profile in the <code>prof_attr(4)</code> database. ■ <code>roles</code> values — Each value must exist as the name of a role identity in the <code>user_attr(4)</code> database. ■ For each <code>exec_attr(4)</code> entry in the source database, the name must exist as the name of a profile in the <code>prof_attr(4)</code> database. -f Specifies that the value in each field in the source entry replaces the value in the corresponding field in the target entry, if the source entry field has a non-empty value. -m For the <code>auths</code>, <code>profiles</code>, and <code>roles</code> attributes, specifies that the values in each field in the source entry are merged with the values in the corresponding target entry field. If a source value does not exist in the target field, the value is appended to the set of target values. If the target field is empty, the source values replace the target field. The attribute values that merge depend on the database being updated: ■ <code>prof_attr(4)</code> — the <code>auths</code> and <code>profiles</code> attribute values are merged.

	■ <code>user_attr(4)</code> — the <code>auths</code>, <code>profiles</code>, and <code>roles</code> attribute values are merged. ■ <code>exec_attr(4)</code> — the <code>uid</code>, <code>gid</code>, <code>euid</code>, and <code>egid</code> values are merged.
<code>-p policy</code>	Specifies the value of the <code>policy</code> field in the <code>exec_attr(4)</code> database. Valid values are <code>suser</code> (standard Solaris superuser) and <code>tsol</code> (Trusted Solaris). If you specify this option, only the entries in the source <code>exec_attr</code> database with the specified policy are processed. If you omit this option, all entries in the source <code>exec_attr</code> database are processed.
<code>-r</code>	Specifies that role identities in the <code>user_attr(4)</code> database in the source name service are processed. If you omit this option, only the normal user entries in the <code>user_attr</code> source database are processed.
<code>-s scope</code>	Specifies the source name service or local file directory for database updates, using the following syntax: <i>type</i> : <i>/server/domain</i> where <i>type</i> indicates the type of name service. Valid values for <i>type</i> are: ■ <code>file</code> — local files ■ <code>nis</code> — NIS name service ■ <code>nisplus</code> — NIS+ name service ■ <code>ldap</code> — LDAP name service <i>server</i> indicates the local host name of the Solaris system on which the <code>smattrpop</code> command is executed, and on which both the source and target databases exist. <i>domain</i> specifies the management domain name for the name service. You can use two special cases of <i>scope</i> values: ■ To indicate the databases in the <code>/etc/security</code> local system directory, use the scope <code>file:/server</code>, where <i>server</i> is the name of the local system. ■ To load from databases in an arbitrary directory on the Solaris server, use the scope <code>file:/server/pathname</code>, where <i>server</i> is the name of the local system and <i>pathname</i> is the fully-qualified directory path name to the database files.
<code>-t scope</code>	Specifies the target name service or local file directory for database updates, using the following syntax: <i>type</i> : <i>/server/domain</i>

smattrpop(1M)

where *type* indicates the type of name service. Valid values for *type* are:

- *file* — local files
- *nis* — NIS name service
- *nisplus* — NIS+ name service
- *ldap* — LDAP name service

server indicates the local host name of the Solaris system on which the `smattrpop` command is executed, and on which both the source and target databases exist.

domain specifies the management domain name for the name service.

You can use two special cases of *scope* values:

- To indicate the databases in the `/etc/security` local system directory, use the scope `file:/server`, where *server* is the name of the local system.
- To update to databases in an arbitrary directory on the Solaris server, use the scope `file:/server/pathname`, where *server* is the name of the local system and *pathname* is the fully-qualified directory path name to the database files.

`-v` Specifies that verbose messages are written. A message is written to `stdout` for each entry processed.

OPERANDS The following operands are supported:

database Populates one or all databases. You can specify either the name of the database you want to process (for example, `auth_attr`), or `all` to process all databases. If you specify `all`, the databases are processed in the following order:

1. `auth_attr(4)`
2. `prof_attr(4)`
3. `exec_attr(4)`
4. `user_attr(4)`

EXAMPLES **EXAMPLE 1** Populating all tables in the NIS name service

The following example merges the values from all four attribute databases in the `/etc/security` directory of the local system into the corresponding tables in the NIS domain, `east.sun.com`. The command is executed on the master server, `hoosier`, for the NIS domain and the source files are in the `/etc` and `/etc/security` directories on the NIS master server. No cross-table checking is performed. A summary message indicating the number of entries processed and updated for each table is written to `stdout`.

EXAMPLE 1 Populating all tables in the NIS name service (Continued)

```
/usr/sadm/bin/smattrpop -s file:/hoosier \
-t nis:/hoosier/east.sun.com all
```

EXAMPLE 2 Updating the authorization table in the NIS+ name service

This example merges new authorization data from a local system file in the `auth_attr` text format into the existing `auth_attr` database in the NIS+ domain, `east.sun.com`. The command is executed on the NIS+ master server, `foobar`. Values from the source `auth_attr` file replace the corresponding field values in the NIS+ tables for each entry. A message is written to `stdout` for each entry processed. Database cross-checking is performed and any check error is written to `stdout`. A summary message indicating the number of entries processed and updated for the `auth_attr` database is written to `stdout`.

```
/usr/sadm/bin/smattrpop -c -f -v -s file:/foobar/var/temp \
-t nisplus:/foobar/East.Sun.COM auth_attr
```

ENVIRONMENT VARIABLES

See `environ(5)` for a description of the `JAVA_HOME` environment variable, which affects the execution of the `smattrpop` command. If this environment variable is not specified, the `/usr/java` location is used. See `smc(1M)`.

EXIT STATUS

Any errors encountered while updating the target entry are reported to `stdout`. The following exit values are returned:

- 0 The specified tables were updated. Individual entries may have encountered checking errors.
- 1 A syntax error occurred in the command line.
- 2 A fatal error occurred and the tables were not completely processed. Some entries may have been updated before the failure.

FILES

<code>/etc/security/auth_attr</code>	Authorization description database. See <code>auth_attr(4)</code> .
<code>/etc/security/exec_attr</code>	Execution profiles database. See <code>exec_attr(4)</code> .
<code>/etc/security/prof_attr</code>	Profile description database. See <code>prof_attr(4)</code> .
<code>/etc/user_attr</code>	Extended user attribute database. See <code>user_attr(4)</code> .

NAME	smc – start the Solaris Management Console
SYNOPSIS	smc [<i>subcommand</i>] [<i>args</i>] smc [<i>subcommand</i>] [<i>args</i>] -T <i>tool_name</i> [- - <i>tool_args</i>]
DESCRIPTION	The smc command starts the Solaris Management Console. The Solaris Management Console is a graphical user interface that provides access to Solaris system administration tools. It relies on Solaris Management Console servers running on one or more computers to perform modifications and report data. Each of these servers is a repository for code which the console can retrieve after the user of the console has authenticated himself or herself to the server. The console can also retrieve toolboxes from the server. These toolboxes are descriptions of organized collections of tools available on that and possibly other servers. Once one of these toolboxes is loaded, the console will display it and the tools referenced in it. The console can also run in a terminal (non-graphically), for use over remote connections or non-interactively from a script. For information on the use of the graphical console, and for more detailed explanations of authentication, tools, and toolboxes, please refer to the Solaris Management Console online help available under the "Help" menu in the Solaris Management Console. To enable an NIS/NIS+ map to be managed from the Solaris Management Console, you must use the smc edit command to create a new toolbox for that map and enter the information about your NIS/NIS+ server where necessary. For instructions on creating a new toolbox, in the Solaris Management Console Help menu, select "Contents," then "About the Solaris Management Console Editor," then "To Create a Toolbox."
<i>subcommands</i>	smc subcommands are: open The default subcommand for the Solaris Management Console is open. This will launch the console and allow you to run tools from the toolboxes you load. It does not need to be specified explicitly on the command line. edit The edit subcommand will also launch the console, like the open subcommand. However, after loading a toolbox, you will not be able to run the referenced tools. Instead, you will be able to edit that toolbox, that is, add, remove, or modify any tools or folders in that toolbox.
OPTIONS	The following options are supported. These letter options can also be specified by their equivalent option words preceded by a double dash. For example, you can use either -D or --domain with the <i>domain</i> argument. If <i>tool_args</i> are specified, they must be preceded by the -- option and separated from the double dashes by a space.

smc(1M)

-auth-data *file*

Specifies a file which the console can read to collect authentication data. When running the Solaris Management Console non-interactively, the console will still need to authenticate itself with the server to retrieve tools. This data can either be passed on the command line using the `-u`, `-p`, `-r`, and `-l` options (which is insecure, because any user can see this data), or it can be placed in a file for the console to read. For security reasons, this file should be readable only by the user running the console, although the console does not enforce this restriction.

The format of *file* is:

```
hostname=host name
username=user name
password=password for user name
rolename=role name
rolepassword=password for role name
```

Only one set of `hostname-username-password-rolename-rolepassword` may be specified in any one file. If the `rolename` is not specified, no role will be assumed.

-B | - -toolbox *toolbox*

Loads the specified toolbox. *toolbox* can be either a fully-qualified URL or a filename. If you specify an HTTP URL as, for example,

```
http://host_name:port/. . .
```

it must point to a *host_name* and *port* on which an Solaris Management Console server is running. If you omit *port*, the default port, 898, is used. This option overrides the `-H` option.

-D | - -domain *domain*

Specifies the default domain that you want to manage. The syntax of *domain* is *type:/host_name/domain_name*, where *type* is `nis`, `nisplus`, `dns`, `ldap`, or `file`; *host_name* is the name of the machine that serves the domain; and *domain_name* is the name of the domain you want to manage. (Note: Do not use `nis+` for `nisplus`.) This option applies only to a single tool run in the terminal console.

If you do not specify this option, the Solaris Management Console assumes the `file` default domain on whatever server you choose to manage, meaning that changes are local to the server. Toolboxes can change the domain on a tool-by-tool basis; this option specifies the domain for all other tools.

-h | - -help

Prints a usage statement about the `smc` command and its subcommands to the terminal window. To print a usage statement for one of the subcommands, enter `-h` after the subcommand.

-H | - -hostname *host_name:port*

Specifies the *host_name* and *port* to which you want to connect. If you do not specify a *port*, the system connects to the default port, 898. If you do not specify *host_name:port*, the Solaris Management Console connects to the local host on port

898. You may still have to choose a toolbox to load into the console. To override this behavior, use the `-B` option (see above), or set your console preferences to load a “home toolbox” by default.

`-Jjava_option`

Specifies an option that can be passed directly to the Java runtime (see `java(1)`). Do not enter a space between `-J` and the argument. This option is most useful for developers.

`-l | - --rolepassword role_password`

Specifies the password for the *role_name*. If you specify a *role_name* but do not specify a *role_password*, the system prompts you to supply a *role_password*. Passwords specified on the command line can be seen by any user on the system, hence this option is considered insecure.

`-p | - --password password`

Specifies the password for the *user_name*. If you do not specify a password, the system prompts you for one. Passwords specified on the command line can be seen by any user on the system, hence this option is considered insecure.

`-r | - --rolename role_name`

Specifies a role name for authentication. If you are running the Solaris Management Console in a terminal and you do not specify this option, no role is assumed. The GUI console may prompt you for a role name, although you may not need to assume a role.

`-s | - --silent`

Disables informational messages printed to the terminal.

`-t`

Runs the Solaris Management Console in terminal mode. If this option is not given, the Solaris Management Console will automatically run in terminal mode if it cannot find a graphical display.

`- --trust`

Trusts all downloaded code implicitly. Use this option when running the terminal console non-interactively and you cannot let the console wait for user input.

`-T | - --tool tool_name`

Runs the tool with the Java class name that corresponds to *tool_name*. If you do not specify this option and the Solaris Management Console is running in terminal mode, the system prompts you. If the Solaris Management Console is running in graphical mode, the system either loads a toolbox or prompts you for one (see options `-H` and `-B`).

`-u | - --username user_name`

Specifies the user name for authentication. If you do not specify this option, the user identity running the console process is assumed.

`-v | - --version`

Prints the version of the Solaris Management Console to the terminal. In the graphical console, this information can be found in the About box, available from the Help menu.

smc(1M)

`-y` | `-` `-yes`

Answers yes to all yes/no questions. Use this option when running the terminal console non-interactively and you cannot let the console wait for user input.

EXAMPLES

EXAMPLE 1 Printing a Usage Statement

The following prints a usage statement about the `smc` command to the terminal window:

```
smc --help
```

EXAMPLE 2 Passing an Option to Java

The following passes an option through to the Java VM, which sets the `com.example.boolean` system property to `true`. This system property is only an example; the Solaris Management Console does not use it.

```
smc -J-Dcom.example.boolean=true
```

ENVIRONMENT VARIABLES

See `environ(5)` for a description of the following environment variable that affects the execution of the `smc` command:

JAVA_HOME If you do not specify this environment variable, your `PATH` is searched for a suitable java. Otherwise, the `/usr/j2se` location is used.

EXIT STATUS

The following exit values are returned. Other error codes may be returned if you specify a tool (using `-T tool_name`) that has its own error codes. See the documentation for the appropriate tool.

0 Successful completion.
1 An error occurred.

ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

NAME	smccompile – build class list and compile Solaris Management Console service beans for remote use												
SYNOPSIS	<pre> /usr/sadm/bin/smccompile -c beanname /usr/sadm/bin/smccompile -j tool service [-n altjarname] jarfile /usr/sadm/bin/smccompile -j library [-n altjarname] ALLTOOL ALLSERVICE ALL attachedBeanname jarfile </pre>												
DESCRIPTION	The <code>smccompile</code> command is used by developers of tools, services, and libraries for the Solaris Management Console. For information regarding the Solaris Management Console, see <code>smc(1M)</code>. <code>smccompile</code> compiles service class files given by the bean name for use with the Solaris Management Console. This step builds the extra proxy and stub classes for services to be used with Solaris Management Console tools. Solaris Management Console requires running <code>smccompile -c</code> before creating service jar files, and <code>smccompile -j</code> after creating tool, service, and library jars. <code>smccompile</code>, in conjunction with <code>smcregister(1M)</code>, is intended to replace the <code>smccconf</code> command as the preferred interface for managing the Solaris Management Console repository as well as toolboxes from within scripts, due to significant performance enhancements over <code>smccconf</code>.												
OPTIONS	The following options are supported: <table> <tr> <td>ALL</td><td>Specify that the library being registered to or unregistered from the repository is for use by all tools and services.</td></tr> <tr> <td>ALLSERVICE</td><td>Specify that the library being registered to or unregistered from the repository is for use by all services.</td></tr> <tr> <td>ALLTOOL</td><td>Specify that the library being registered to or unregistered from the repository is for use by all tools.</td></tr> <tr> <td><i>attachedBeanname</i></td><td>Specify the name of a registered jar to which the library jarfile should be attached to (or detached from). This is typically the same as <i>altjarname</i> (if provided) or <i>jarfile</i> used to register the jar to which this library is being attached or detached. An attached library means the library is only available for use by the tool or service to which it is being attached.</td></tr> <tr> <td><i>beanname</i></td><td>The full package path of the bean name to be compiled. An example bean name is: <code>com.mycompany.myproduct.MyService.</code></td></tr> <tr> <td>-c</td><td>Compile and build service class files for the specified bean name. This step builds the extra proxy and stub classes for services to be used with Solaris Management Console tools. You must run <code>smccompile</code> with this option before creating service type jar files.</td></tr> </table>	ALL	Specify that the library being registered to or unregistered from the repository is for use by all tools and services.	ALLSERVICE	Specify that the library being registered to or unregistered from the repository is for use by all services.	ALLTOOL	Specify that the library being registered to or unregistered from the repository is for use by all tools.	<i>attachedBeanname</i>	Specify the name of a registered jar to which the library jarfile should be attached to (or detached from). This is typically the same as <i>altjarname</i> (if provided) or <i>jarfile</i> used to register the jar to which this library is being attached or detached. An attached library means the library is only available for use by the tool or service to which it is being attached.	<i>beanname</i>	The full package path of the bean name to be compiled. An example bean name is: <code>com.mycompany.myproduct.MyService.</code>	-c	Compile and build service class files for the specified bean name. This step builds the extra proxy and stub classes for services to be used with Solaris Management Console tools. You must run <code>smccompile</code> with this option before creating service type jar files.
ALL	Specify that the library being registered to or unregistered from the repository is for use by all tools and services.												
ALLSERVICE	Specify that the library being registered to or unregistered from the repository is for use by all services.												
ALLTOOL	Specify that the library being registered to or unregistered from the repository is for use by all tools.												
<i>attachedBeanname</i>	Specify the name of a registered jar to which the library jarfile should be attached to (or detached from). This is typically the same as <i>altjarname</i> (if provided) or <i>jarfile</i> used to register the jar to which this library is being attached or detached. An attached library means the library is only available for use by the tool or service to which it is being attached.												
<i>beanname</i>	The full package path of the bean name to be compiled. An example bean name is: <code>com.mycompany.myproduct.MyService.</code>												
-c	Compile and build service class files for the specified bean name. This step builds the extra proxy and stub classes for services to be used with Solaris Management Console tools. You must run <code>smccompile</code> with this option before creating service type jar files.												

smccompile(1M)

<code>-j</code>	Build a list of classes in text format, suitable as input to <code>smcregister</code> for registration with the Solaris Management Console repository. The output is written to standard out and should be redirected to a file. You must run <code>smccompile</code> with this option after creating any tool, service, or library jar.
<code>jarfile</code>	Specify the full path to the jar file to be registered. The name must be in the form <code>beanname.jar</code> , where <code>beanname</code> is the package path to the bean. If it is not, an alternate name must be given in that form using the <code>-n</code> option.
<code>-n altjarname</code>	Rename the jarfile in the repository to <code>altjarname</code> . Typically, this is the full bean name. For example, if the jarfile was <code>MyTool.jar</code> , then <code>altjarname</code> might be <code>com.mycompany.myproject.MyTool.jar</code> . It is recommended that an <code>altjarname</code> containing the full package path be used. You must use this same name when registering the jar with <code>smcregister</code> .

EXAMPLES

EXAMPLE 1 Compiling a Service

The following command takes a Solaris Management Console service and builds its proxy and stub classes to make the service usable by Solaris Management Console tools:

```
/usr/sadm/bin/smccompile -c com.mycompany.myproject.MyServiceImpl
```

EXAMPLE 2 Building a Class List for a Service

The following command builds the class list file (`classlist.txt`) for a service suitable for use with the `smcregister(1M)` command:

```
/usr/sadm/bin/smccompile -j service \  
-n com.mycompany.myproject.MyServiceImpl.jar \  
{HOME}/workarea/MyServiceImpl.jar > classlist.txt
```

The following command does the same thing without specifying an alternate name:

```
/usr/sadm/bin/smccompile -j service \  
{HOME}/workarea/com.mycompany.myproject.MyServiceImpl.jar > classlist.txt
```

EXAMPLE 3 Building a Class List for a Tool

The following command builds the class list file (`classlist.txt`) for a tool suitable for use with the `smcregister(1M)` command:

```
/usr/sadm/bin/smccompile -j tool \  
-n com.mycompany.myproject.MyTool.jar \  
{HOME}/workarea/MyTool.jar > classlist.txt
```

The following command does the same thing without specifying an alternate name:

EXAMPLE 3 Building a Class List for a Tool *(Continued)*

```
/usr/sadm/bin/smccompile -j tool \
    ${HOME}/workarea/com.mycompany.myproject.MyTool.jar > classlist.txt
```

EXAMPLE 4 Building a Class List for a Library Attached to All Tools

The following command builds the class list file (`classlist.txt`) for a library suitable for use with the `smcregister(1M)` command, and is attached to all tools:

```
/usr/sadm/bin/smccompile -j library \
    -n com.mycompany.myproject.MyLibrary.jar \
    ALLTOOL ${HOME}/workarea/MyLibrary.jar > classlist.txt
```

The following command does the same thing without specifying an alternate name:

```
/usr/sadm/bin/smccompile -j library \
    ALLTOOL \
    ${HOME}/workarea/com.mycompany.myproject.MyLibrary.jar > classlist.txt
```

EXAMPLE 5 Building a Class List for a Library Attached to a Specific Tool

The following command builds the class list file (`classlist.txt`) for a library suitable for use with the `smcregister(1M)` command, and is attached to a specific tool:

```
/usr/sadm/bin/smccompile -j library \
    -n com.mycompany.myproject.MyLibrary.jar \
    com.mycompany.myproject.MyTool.jar \
    ${HOME}/workarea/MyLibrary.jar > classlist.txt
```

The following command does the same thing without specifying an alternate name:

```
/usr/sadm/bin/smccompile -j library \
    com.mycompany.myproject.MyTool.jar \
    ${HOME}/workarea/com.mycompany.myproject.MyLibrary.jar > classlist.txt
```

**ENVIRONMENT
VARIABLES**

See `environ(5)` for descriptions of the following environment variables that affect the execution of `smccompile`:

JAVA_HOME

If you do not specify this environment variable, your `PATH` is searched for a suitable `java`. Otherwise, the `/usr/j2se` location is used.

EXIT STATUS

The following exit values are returned:

0	Successful completion.
1	An error occurred.

smccompile(1M)

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWMc

SEE ALSO `smc(1M)`, `smccconf(1M)`, `smcregister(1M)`, `attributes(5)`, `environ(5)`

NOTES All standard shell quoting rules apply.

NAME	smcconf – configure the Solaris Management Console
SYNOPSIS	<pre>/usr/sadm/bin/smcconf [-h] [-v] toolbox [action] [target] [parameters] [options] /usr/sadm/bin/smcconf [-h] [-v] repository [action] [target] [parameters] [options]</pre>
DESCRIPTION	The <code>smcconf</code> command configures the Solaris Management Console. See <code>smc(1M)</code>. This command enables you to add to, remove from, and list the contents of the toolboxes and bean repository. Using <code>smcconf</code> to edit toolboxes is not as feature-rich as using the graphical editor in Solaris Management Console. The command line interface is intended for use in packaging scripts that do not require user interaction. To edit all the properties of a toolbox or to modify the hierarchy of folders in a toolbox, you must use the specialized graphical editor, that is, <code>smc edit</code>. See <code>smc(1M)</code>. <code>smcregister</code> is intended to replace the <code>smcconf</code> command as the preferred interface for managing the Solaris Management Console repository as well as toolboxes from within scripts, due to significant performance enhancements over <code>smcconf</code>. See <code>smcregister(1M)</code>, <code>smccompile(1M)</code>, and the Solaris Management Console SDK Guide at /usr/sadm/lib/smc/docs/sdkguide/index.html for details.
OPTIONS	The following options are supported: -h Prints out a usage summary for the command. -v Verbose option. Displays the debugging output at any time.
toolbox configuration	<i>action</i> Legal values are: - add - Adds a <i>target</i> to the toolbox. Specify the path to the toolbox using the <code>-B toolboxpath</code> option and, optionally, provide locale information with the <code>-L locale</code> option. - remove - Removes a <i>target</i> from the toolbox. Specify the path to the toolbox using the <code>-B toolboxpath</code> option and, as an alternative, provide locale information with the <code>-L locale</code> option. - create - Creates a new toolbox with no tools in it. The only <i>target</i> recognized is <code>toolbox</code>. - list - Lists the contents of the toolbox. No <i>target</i> is recognized. If you specify a <i>parameter</i>, it is taken as the path to a toolbox and the contents of that toolbox are listed. If you do not specify a <i>parameter</i>, the contents of the default toolbox are listed.

target

Legal values are:

tool

If the *action* is specified as *add*, this target adds a native Solaris Management Console tool from the toolbox. The required *parameter* is the full Java classname of the tool you are adding. If you specify a folder name with the *-F* option, the tool is placed inside that folder (the folder will not be created if it does not already exist). Otherwise, the tool is appended to the end of the toolbox and not placed inside any folder.

If the *action* is specified as *remove*, this target removes a native Solaris Management Console tool from the toolbox. The required *parameter* is the full Java classname of the tool you want to remove. If you specify a folder name with the *-F* option, any tool with the given name in that folder will be removed. If no folder name is specified, all tools with the given name in the toolbox are removed.

For the tool to appear in the console, the tool must also be registered in the repository. See the *repository configuration* section below for more information. If a tool is referenced in a toolbox but is not registered, it will not appear in the console when the toolbox is loaded.

Removing a tool from a toolbox does not remove the tool from the server repository.

tbxURL

If the *action* is specified as *add* or *remove*, this target adds to or removes from the toolbox a link to another toolbox. The required *parameter* is the URL to the other toolbox.

The properties of addition and removal are the same as for the *tool target*.

toolbox

If the *action* is specified as *create*, this target creates a skeleton toolbox with no tools. The required *parameters* are: the toolbox name, description, and small and large icon paths. These must be followed by the *-B toolboxpath* and *-D scope* options.

legacy

If the *action* is specified as *add* or *remove*, this target adds or removes legacy applications (command-line, X-windows, and web-based) to or from the toolbox. The *-N*, *-T*, *-E*, and *-B* options are required. The *-A* option is optional. Placement in the toolbox with the *-F* option follows the same rules as for the *tool* and *tbxURL* targets. See *NOTES* for more information about legacy applications.

	folder If the <i>action</i> is specified as <code>add</code>, this target adds a folder to the toolbox. The required <i>parameters</i> are: the folder name, description, and small and large icon paths. If the <i>action</i> is specified as <code>remove</code>, this target removes a folder from the toolbox. If the folder to be removed is itself inside a folder, the containing folder must be specified with the <code>-F</code> option.
<i>parameters</i>	Specifies values that might be required, depending on the combination of <i>action</i> and <i>target</i> .
<i>options</i>	Supported options for various <i>action</i> and <i>target</i> combinations for the toolbox configuration are: -A <i>parameters</i> Specifies the parameters to pass to the legacy application. This option is available only for the <code>legacy</code> target. -B <i>toolboxpath</i> Specifies the path of the toolbox that is being modified. If this option is not given, the modifications will be performed on the default toolbox, "This Computer". -D <i>scope</i> Specifies the scope (domain) in which the tool should be run. The legal values for <i>scope</i> are <code>file</code>, <code>nis</code>, <code>nisplus</code>, <code>dns</code>, and <code>ldap</code>. This can also be specified for a folder or a toolbox. In the former case, all tools in that folder and its subfolders are run in that scope; in the latter, all tools in the toolbox are run in that scope. -E <i>appPath</i> Specifies the absolute executable path of the legacy application. This option is available only for the <code>legacy</code> target. -F <i>folder</i> Specifies the full path of the container folder. If this option is not given, the default folder is the 'root' folder of the toolbox. -H [<i>host_name</i>][:<i>port</i>] Specifies the host and port from which a tool should be loaded. If <i>host_name</i> is not given, the default host is used. The default host is <code>localhost</code>, if the toolbox is loaded from the local file system, or the host from which the toolbox is loaded if loaded from a remote Solaris Management Console server. If <code>:port</code> is not given, the default port will be used. If this option is not given at all, both the default host and the default port are used.

smcconf(1M)

repository configuration

- L *locale*
Specifies the locale of the toolbox that is being modified. The default is the C *locale*.
- N *appName*
Specifies the name of the legacy application being registered. This is the name that appears in the console. This option is available only for the *legacy* target.
- P *key:value*
Specifies the key/value pairs that define parameters to a tool. Multiple key/value pairs can be specified at a time.
- T *appType*
Specifies the legacy application type. Legal values are CLI, XAPP, or HTML. This option is available only for the *legacy* target.

The Solaris Management Console repository stores information about the registered tools and services, as well as libraries (for instance, resource jars) and properties attached to tools or services.

action

Legal values are:

add

Adds information to the repository. If the -f option is given to *add*, the information overwrites any information of the same name already in the repository. If the -f option is not given, an error might be returned if the information is already in the repository.

remove

Removes information from the repository.

list

Lists the contents of the repository:

- All registered tools
- All registered services
- All libraries attached to all tools
- All libraries attached to all services
- All libraries attached to all tools and services

target

Legal values are:

bean

If the *action* is specified as *add*, this target will add a tool or service bean (which kind is determined by the contents of the bean) to the repository. The required *parameter* is the path to the jar file that contains the bean to be added.

If the *action* is specified as `remove`, this target will remove a tool or service bean from the repository. The required *parameter* is the full Java classname of the desired bean.

library

If the *action* is specified as `add`, this target adds a “library” jar file to a tool or service bean. The two required *parameters* are the full Java classname of the desired bean and the path to the jar file to be attached. The bean name can also be one of the “pseudo-beans,” `ALL`, `ALLTOOL`, or `ALLSERVICE`, in which case the library is attached, respectively, to all beans, all tools, or all services in the repository.

If the *action* is specified as `remove`, this target detaches a “library” jar file from a tool or service bean. The two required *parameters* are the full Java classname of the desired bean and the name of the jar file that is attached. As with the `add` action, the three “pseudo-beans” `ALL`, `ALLTOOL`, or `ALLSERVICE` can be used.

property

If the *action* is specified as `add`, this target defines a property on a tool or service. One or more key/value pairs must be specified in the form,

`-P key=value` Following this property list is a “pseudo-bean name,” *pseudoBeanName*, as defined for the `library` target, on which the properties are defined. Optionally, a library name can follow the “pseudo-bean” name, in which case the properties are defined on the library that is attached to the named bean.

If the *action* is specified as `remove`, this target undefines a property on a tool or service. The key/value pairs, “pseudo-bean” name, and optional library are specified for the `add` action.

EXAMPLES

EXAMPLE 1 Adding Legacy Applications to a Toolbox

The following command adds to the default toolbox the command line interface (CLI) application, `/usr/bin/ls`, with arguments `-al -R`, giving it the name, `Directory Listing`:

```
/usr/sadm/bin/smcconf toolbox add legacy -N "Directory Listing" \
-T CLI -E /usr/bin/ls -A "-al -R"
```

EXAMPLE 2 Adding a Folder to a Toolbox

The following command adds to the standard Management Tools toolbox a folder with the name, `New Folder`, the description, `This is a new folder`, and the small and large icons, `folder_s.gif` and `folder_l.gif`:

EXAMPLE 2 Adding a Folder to a Toolbox (Continued)

```
/usr/sadm/bin/smcconf toolbox add folder "New Folder" \
    "This is a new folder" folder_s.gif folder_l.gif \
    -B /var/sadm/smc/toolboxes/smc/smc.tbx
```

EXAMPLE 3 Adding a Native Solaris Management Console Tool to a Toolbox

The following command adds a native Solaris Management Console tool to the default toolbox. The Java classname of the tool is `HelloWorld.client>HelloTool` (the name, description, and icons visible in the console are provided by the tool itself). When loaded, it is run in the NIS domain, `syrinx`, which is hosted by the machine, `temple`, and is retrieved from port 2112 on the machine from which the toolbox was loaded:

```
/usr/sadm/bin/smcconf toolbox add tool HelloWorld.client>HelloTool \
    -D nis:/temple/syrinx -H :2112
```

EXAMPLE 4 Adding an Solaris Management Console Tool to the Repository

The following command adds the Java bean found in `HelloWorld.jar` to the repository. The jar file contains information that the bean is a tool:

```
/usr/sadm/bin/smcconf repository add bean HelloWorld.jar
```

EXAMPLE 5 Removing an Solaris Management Console Service from the repository

The following command removes a Java bean from the repository. Although the name of the bean implies that it is a service, that is merely a convention; the repository knows whether a particular registered bean is a tool or a service:

```
/usr/sadm/bin/smcconf repository remove bean \
    HelloWorld.server>HelloService
```

EXAMPLE 6 Attaching a Library to a Tool

The following command adds the library jar file, `HelloWorld_fr.jar` (probably a French localized version of the `HelloTool`'s resources) to the bean, `HelloWorld.client>HelloTool`:

```
/usr/sadm/bin/smcconf repository add library \
    HelloWorld.client>HelloTool HelloWorld_fr.jar
```

EXAMPLE 7 Attaching a Library to all Tools

The following command adds the library jar file, `widgets.jar`, to all tools in the repository. The library probably contains a widget set that might be useful to any registered tools:

```
/usr/sadm/bin/smcconf repository add library ALLTOOL widgets.jar
```

**ENVIRONMENT
VARIABLES**

See `environ(5)` for descriptions of the following environment variables that affect the execution of the `smcconf` command:

JAVA_HOME	If you do not specify this environment variable, your PATH is searched for a suitable java. Otherwise, the /usr/j2se location is used.
DISPLAY	If you do not set this environment variable, set it to null, or set it to an X(7) display to which you are not authorized to connect, the Solaris Management Console starts in terminal mode instead of graphical mode.

EXIT STATUS The following exit values are returned:

0	Successful completion.
1	An error occurred.

ATTRIBUTES See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWmc

SEE ALSO jar(1), java(1), javac(1), smc(1M), smccompile(1M), smcregister(1M), attributes(5), environ(5)

NOTES All standard shell quoting rules apply.

Legacy applications (X-windows, command-line, and web-based applications) are handled differently from “native” Solaris Management Console tools. Legacy tools are handled by an instantiation of a native Solaris Management Console tool, LegacyAppLauncher, which, through the toolbox, is given the necessary information to run the legacy application: path, options, and so forth. Thus, you do not register a legacy application into the repository as you would a native Solaris Management Console tool. Instead, legacy applications appear only in toolboxes.

smcregister(1M)

NAME	smcregister – configure the Solaris Management Console
SYNOPSIS	<pre> /usr/sadm/bin/smcregister [-h] tool [-n altjarname] jarfile classlistfile xmlfile /usr/sadm/bin/smcregister [-h] service [-n altjarname] jarfile classlistfile xmlfile [native_lib_list] /usr/sadm/bin/smcregister [-h] library [-n altjarname] jarfile classlistfile none ALLTOOL ALLSERVICE ALL Attachedbeanname /usr/sadm/bin/smcregister [-h] tool service -u jarfile /usr/sadm/bin/smcregister [-h] library -u jarfile ALL ALLTOOL ALLSERVICE Attachedbeanname /usr/sadm/bin/smcregister [-h] toolbox [-D] [action] [-f] [target] [parameters] [options] /usr/sadm/bin/smcregister [-h] property key value ALL ALLTOOL ALLSERVICE Attachedbeanname /usr/sadm/bin/smcregister [-h] property -u key ALL ALLTOOL ALLSERVICE Attachedbeanname /usr/sadm/bin/smcregister [-h] repository list /usr/sadm/bin/smcregister [-h] scripts regscript unregscript </pre>
DESCRIPTION	The <code>smcregister</code> command configures the Solaris Management Console. For information regarding the Solaris Management Console, see <code>smc(1M)</code>. This command enables you to add to, remove from, and list the contents of toolboxes and the Solaris Management Console repository. <code>smcregister</code> also allows you to register scripts to perform registrations and unregistrations. Typically, a package containing one or more tools or services posts tool and service registrations immediately after installation. On Solaris, this is by way of invocations of <code>smcregister</code> from within a package post-install script. Similarly, unregistrations would be posted from within a package pre-remove script. These are per-machine registrations - that is, registration requests must be posted on each machine on which the Solaris Management Console server will be running. However, due to the way that diskless clients are installed, registration requests cannot be made at install time. Therefore, packages should include and install registration and unregistration scripts, and then register these scripts during installation by way of the <code>scripts</code> subcommand. These scripts should contain tool, toolbox, service, library or property configurations in any of its forms as listed in this man page. While these scripts function very much like package post-install and pre-remove scripts, do not assume the normal package environment is available. However, <code>PATH</code> can assumed to be <code>/usr/sbin:/usr/bin</code>

Using `smcregister` to edit toolboxes is not as feature-rich as using the Solaris Management Console's graphical editor. The command line interface is intended for use in packaging scripts that do not require user interaction. To edit all the properties of a toolbox or to modify the hierarchy of folders in a toolbox, you must use the specialized graphical editor, that is, `smc edit`. See `smc(1M)`.

`smcregister` is intended to replace the `smcconf` command as the preferred interface for managing the Solaris Management Console repository as well as toolboxes from within scripts, due to significant performance enhancements over `smcconf`.

OPTIONS The following options are supported:

`-h`

Prints out a usage summary for the command.

**Scripts
Configuration**

`regscript`

The full path of a script containing registration commands. The script is executed upon the next restart of the Solaris Management Console server after the package containing the script is installed.

`unregscript`

The full path of a script containing unregistration commands. The script is executed upon the next restart of the Solaris Management Console server after the package containing the script is removed.

**Toolbox
Configuration**

`action`

Legal values are:

`add`

Adds a target to the toolbox. Specify the path to the toolbox using the `-B toolboxpath` option and, optionally, provide locale information with the `-L locale` option.

`create`

Creates a new toolbox with no tools in it. The only target recognized is `toolbox`.

`list`

Lists the contents of the toolbox. No target is recognized. If you specify a parameter, it is taken as the path to a toolbox and the contents of that toolbox are listed. If you do not specify a parameter, the contents of the default toolbox are listed.

`remove`

Removes a target from the toolbox. Specify the path to the toolbox using the `-B toolboxpath` option and, optionally, provide locale information with the `-L locale` option.

smcregister(1M)

-D

Defers execution of the `toolbox` command until the Solaris Management Console server is restarted. This is a convenient option for use in packaging scripts during install and un-install. Additionally, the command runs much faster than if run interactively (without `-D`).

target

Legal values are:

folder

If the action is specified as `add`, this target adds a folder to the toolbox. There are four required parameters: the folder name, description, and small and large icon paths. If the action is specified as `remove`, this target removes a folder from the toolbox. If the folder to be removed is itself inside a folder, the containing folder must be specified with the `-F` option.

legacy

If the action is specified as `add` or `remove`, this target adds or removes legacy applications (command line, X-windows, and web-based) to or from the toolbox. The `-N`, `-T`, `-E`, and `-B` options are required, and the `-A` option is optional. Placement in the toolbox with the `-F` option follows the same rules as for the `tool` and `tbxURL` targets. See NOTES for more information about legacy applications.

tbxURL

If the action is specified as `add` or `remove`, this target adds to or removes from the toolbox a link to another toolbox. The required parameter is the URL to the other toolbox. The properties of addition and removal are the same as for the `tool` target.

tool

If the action is specified as `add`, this target adds a native Solaris Management Console tool from the toolbox. The required parameter is the full Java classname of the tool you are adding. If you specify a folder name with the `-F` option, the tool is placed inside that folder (the folder will not be created if it does not already exist). Otherwise, the tool is appended to the end of the toolbox and not placed inside any folder. If the action is specified as `remove`, this target removes a native Solaris Management Console tool from the toolbox. The required parameter is the full Java classname of the tool you wish to remove. If you specify a folder name with the `-F` option, any tool with the given name in that folder will be removed. If no folder name is specified, all tools with the given name in the toolbox will be removed. For the tool to show up in the console, the tool must also be registered in the repository. See the repository configuration section below for more information. If a tool is referenced in a toolbox but is not registered, it will not appear in the console when the toolbox is loaded. Removing a tool from a toolbox does not remove the tool from the server repository.

toolbox

If the action is specified as `create`, this target creates a skeleton toolbox with no tools. There are four required parameters: the toolbox name, description, and

small and large icon paths. These must be followed by the `-B toolboxpath` and `-D scope` options.

parameters

Specifies values that may be required depending on the combination of action and target.

options

Supported options for various action and target combinations for the toolbox configuration are:

-A

Specifies the parameters to pass to the legacy application. This option is available only for the legacy target.

-B

Specifies the path of the toolbox that is being modified. If this option is not given, the modifications will be performed on the default toolbox, `This Computer`.

-D

Specifies the scope (domain) in which the tool should be run. The legal values for scope are `file`, `nis`, `nisplus`, `dns`, and `ldap`. This may also be specified for a folder or a toolbox. In the former case, all tools in that folder and its subfolders will be run in that scope; in the latter, all tools in the toolbox will be run in that scope.

-E

Specifies the absolute executable path of the legacy application. This option is available only for the legacy target.

-f

If the `-f` option is given to add, the information will overwrite any information of the same name already in the toolbox. If the `-f` option is not given, an error may be returned if the information is already in the toolbox.

-F *folder*

Specifies the full path of the container folder. If this option is not given, the default folder is the `root` folder of the toolbox.

-H [*host_name*][:*port*]

Specifies the host and port from which a tool should be loaded. If `host_name` is not given, the default host (`localhost`, if the toolbox is loaded from the local filesystem, or the host from which the toolbox is loaded if loaded from a remote Solaris Management Console server) will be used. If `:port` is not given, the default port will be used. If this option is not given at all, both the default host and the default port will be used.

-L *locale*

Specifies the locale of the toolbox which is being modified. The default is the `C` locale.

smcregister(1M)

Tool, Service, and Library Configuration

-N *appName*

Specifies the name of the legacy application being registered. This is the name that will appear in the console. This option is available only for the legacy target.

-P *key:value*

Specifies the key/value pairs that define parameters to a tool. Multiple key/value pairs can be specified at a time.

-T *appType*

Specifies the legacy application type. Legal values are CLI, XAPP, or HTML. This option is available only for the legacy target.

See NOTES for more information about registration and unregistration of tools, services, and libraries.

ALL

Specify that the library being registered to or unregistered from the repository is for use by all tools and services.

ALLSERVICE

Specify that the library being registered to or unregistered from the repository is for use by all services.

ALLTOOL

Specify that the library being registered to or unregistered from the repository is for use by all tools.

attachedBeanname

The name of a registered jar to which the library jarfile should be attached to (or detached from). This is typically the same as *altjarname* (if provided) or *jarfile* used to register the jar to which this library is being attached or detached. An attached library means the library is only available for use by the tool or service to which it is being attached.

classlistfile

The classlist text file generated from the smccompile(1M) command.

Library registration does not require that a classlist file be specified. Instead, you can substitute the keyword *none* in place of the classlist path argument to *smcregister*, in which case one will be generated automatically. Generating the classlist automatically during server startup will cause the next server restart to take longer, so it is strongly suggested that developers always provide a classlist file with their libraries. Auto-generation is more appropriately used to register 3rd-party library jars.

jarfile

The full path to the jar file to be registered/unregistered. The name must be in the form *beanname.jar*, where *beanname* is the package path to the bean. If it is not, an alternate name must be given in that form using the -n option.

**Repository
Configuration**

-n altjarname

Rename the jarfile in the repository to *altjarname*. This would typically be the full bean name. For example, if the jarfile was `MyTool.jar`, then *altjarname* might be `com.mycompany.myproduct.MyTool.jar`. It is recommended that an *altjarname* containing the full package path be used.

native_lib_list

List of up to 4 native libraries that can be associated with a service bean.

-u

The operation will be to un-register the jar with the Solaris Management Console repository. The jarfile argument must be identical to the *altjarname* used to register the jar (if provided), or jarfile.

xmlfile

The xml descriptor file that describes this jarfile. Every tool or services must have one. See the Solaris Management Console SDK Guide located at `/usr/sadm/lib/smc/docs/sdkguide/index.html`.

The Solaris Management Console repository stores information about the registered tools and services, as well as libraries (for instance, resource jars) and properties attached to tools or services.

list

Lists the contents of the repository:

- All registered tools
- All registered services
- All libraries attached to all tools
- All libraries attached to all services
- All libraries attached to all tools and services

**Property
Configuration**

See NOTES for more information about registration and unregistration of properties. If registering a property, this defines a property on a tool or service. Only one key value pair at a time can be registered.

beanname

The name of a registered jar on which the properties will be defined. Optionally, a library name may follow the bean name, in which case the properties are defined on the library that is attached to the named bean.

If unregistering a property, this undefines a property from a tool or service. Only one key value pair at a time can be registered. The key, *beanname*, and optional library are specified as for registering a property.

EXAMPLES**EXAMPLE 1** Adding Legacy Applications to a Toolbox

The following command adds to the default toolbox the Command Line Interface (CLI) application, `/usr/bin/ls` with arguments `-al -R`, giving it the name, Directory Listing:

```
/usr/sadm/bin/smcregister toolbox add legacy -N "Directory Listing" \
-T CLI -E /usr/bin/ls -A "-al -R"
```

EXAMPLE 1 Adding Legacy Applications to a Toolbox *(Continued)*

Use this variation to defer execution of this command until the Solaris Management Console server is restarted:

```
/usr/sadm/bin/smcregister toolbox -D add legacy -N "Directory Listing" \
-T CLI -E /usr/bin/ls -A "-al -R"
```

EXAMPLE 2 Adding a Folder to a Toolbox

The following command adds to the standard Management Tools toolbox a folder with the name, New Folder, the description, This is a new folder, and the small and large icons, folder_s.gif and folder_l.gif:

```
/usr/sadm/bin/smcregister toolbox add folder "New Folder" \
"This is a new folder" folder_s.gif folder_l.gif \
-B /var/sadm/smc/toolboxes/smc/smc.tbx
```

EXAMPLE 3 Adding a Native Solaris Management Console Tool to a Toolbox

The following command adds a native Solaris Management Console tool to the default toolbox. The Java classname of the tool is `com.mycompany.myproject.client.MyTool` (the name, description, and icons visible in the console are provided by the tool itself). When loaded, it will be run in the NIS domain, `syrix`, which is hosted by the machine, `temple`, and will be retrieved from port 2112 on the machine from which the toolbox was loaded.

```
/usr/sadm/bin/smcregister toolbox add tool \
com.mycompany.myproject.client.MyTool \
-D nis:/temple/syrix -H :2112
```

EXAMPLE 4 Adding an Solaris Management Console Tool to the Repository

The following command adds the Java bean found in `MyTool.jar` to the repository. The xml file contains information about the tool. The classlist file would have been generated by `smccompile -j`:

```
/usr/sadm/bin/smcregister tool -n com.mycompany.myproject.client.MyTool.jar \
${HOME}/workarea/MyTool.jar \
${HOME}/workarea/MyTool_classlist.txt \
${HOME}/workarea/MyTool.xml
```

Use this variation to add an Solaris Management Console tool to the repository without specifying an alternate name:

```
/usr/sadm/bin/smcregister tool \
${HOME}/workarea/com.mycompany.myproject.client.MyTool.jar \
${HOME}/workarea/MyTool_classlist.txt \
${HOME}/workarea/MyTool.xml
```

EXAMPLE 5 Adding an Solaris Management Console Service to the Repository

The following command adds the Java bean found in `MyServiceImpl.jar` to the repository. The xml file contains information about the service. The classlist file would have been generated by `smccompile -j`. The extra proxy and stub classes included in the jar would have been generated by `smccompile -c`:

EXAMPLE 5 Adding an Solaris Management Console Service to the Repository
(Continued)

```
/usr/sadm/bin/smcregister service \
-n com.mycompany.myproject.server.MyServiceImpl.jar \
${HOME}/workarea/MyServiceImpl.jar \
${HOME}/workarea/MyServiceImpl_classlist.txt \
${HOME}/workarea/MyServiceImpl.xml
```

Use this variation to add a Solaris Management Console service to the repository without specifying an alternate name:

```
/usr/sadm/bin/smcregister service \
${HOME}/workarea/com.mycompany.myproject.server.MyServiceImpl.jar \
${HOME}/workarea/MyServiceImpl_classlist.txt \
${HOME}/workarea/MyServiceImpl.xml
```

EXAMPLE 6 Removing an Solaris Management Console Tool From the Repository

The following command removes a Java tool bean from the repository:

```
/usr/sadm/bin/smcregister tool \
-u com.mycompany.myproject.client.MyTool.jar
```

EXAMPLE 7 Removing an Solaris Management Console Service From the Repository

The following command removes a Java service bean from the repository:

```
/usr/sadm/bin/smcregister service \
-u com.mycompany.myproject.server.MyServiceImpl.jar
```

EXAMPLE 8 Attaching a Library to a Specific Tool

The following command adds the library jar file, MyTool_fr.jar (probably a French localized version of the MyTool's resources) to the bean, com.mycompany.myproject.client.MyTool:

```
/usr/sadm/bin/smcregister library \
-n MyTool_fr.jar \
${HOME}/workarea/MyTool_fr.jar \
${HOME}/workarea/MyTool_fr_classlist.txt \
com.mycompany.myproject.client.MyTool
```

EXAMPLE 9 Attaching a Library to All Tools

The following command adds the library jar file, widgets.jar, to all tools in the repository. The library probably contains a widget set which might be useful to any registered tools. The classlist file would have been generated by smccompile -j.

```
/usr/sadm/bin/smcregister library \
${HOME}/workarea/lib/widgets.jar\
${HOME}/workarea/lib/widgets_classlist.txt \
ALLTOOL
```

smcregister(1M)

EXAMPLE 9 Attaching a Library to All Tools *(Continued)*

Alternatively, to add a 3rd-party library jar to all tools, replace the classlist file with none:

```
/usr/sadm/bin/smcregister library \  
    /opt/lib/XYZwidgets.jar none ALLTOOL
```

EXAMPLE 10 Detaching a Library from All Tools

The following command removes the Java library bean from the repository:

```
/usr/sadm/bin/smcregister library -u MyTool_fr.jar ALLTOOL
```

EXAMPLE 11 Detaching a Library from a Specific Tool

The following command detaches the library jar file, MyTool_fr.jar (probably a French localized version of the MyTool's resources) from the bean com.mycompany.myproject.client.MyTool, and removes it from the repository:

```
/usr/sadm/bin/smcregister library -u MyTool_fr.jar \  
    com.mycompany.myproject.client.MyTool
```

EXAMPLE 12 Registering Scripts

The following command registers the following scripts containing registration and unregistration commands. MyProduct_reg.sh will be executed upon the next server restart after the file is installed by the owning package. MyProduct_unreg.sh will be executed upon the next server restart after the file is removed by the owning package:

```
/usr/sadm/bin/smcregister scripts \  
    /usr/sadm/lib/myProduct/MyProduct_reg.sh \  
    /usr/sadm/lib/myProduct/MyProduct_unreg.sh
```

ENVIRONMENT VARIABLES

See environ(5) for descriptions of the following environment variables that affect the execution of smcregister:

JAVA_HOME

If you do not specify this environment variable, your PATH is searched for a suitable java. Otherwise, the /usr/j2se location is used.

EXIT STATUS

The following exit values are returned:

0	Successful completion.
1	An error occurred.

smcregister(1M)

ATTRIBUTES See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWmc

SEE ALSO smc(1M), smcconf(1M), smccompile(1M), attributes(5), environ(5)

NOTES All standard shell quoting rules apply.

Legacy applications (X-windows, command-line, and web-based applications) are handled differently from native Solaris Management Console tools. Legacy tools are handled by an instantiation of a native Solaris Management Console tool, LegacyAppLauncher, which, through the toolbox, is given the necessary information to run the legacy application: path, options, and so forth. Thus, you do not register a legacy application into the repository as you would a native Solaris Management Console tool. Instead, legacy applications appear only in toolboxes.

Registration and unregistration of tools, services, libraries, and properties do not take effect until the Solaris Management Console server is restarted. Run `/etc/init.d/init.wbem stop` followed by `/etc/init.d/init.wbem start`

smcron(1M)

NAME	smcron – manage jobs in the crontab database								
SYNOPSIS	<code>/usr/sadm/bin/smcron subcommand [auth_args] - - [subcommand_args]</code>								
DESCRIPTION	The smcron command manages jobs in the crontab(1) database.								
<i>subcommands</i>	smcron <i>subcommands</i> are: <table> <tr> <td>add</td><td>Adds a job to the crontab(1) database. To add a job, the administrator must have the solaris.jobs.user authorization. To add a job to another user's crontab file, the administrator must have the solaris.jobs.admin authorization.</td></tr> <tr> <td>delete</td><td>Deletes a job from the crontab(1) database. To delete a job, the administrator must have the solaris.jobs.user authorization. To delete a job from another user's crontab file, the administrator must have the solaris.jobs.admin authorization.</td></tr> <tr> <td>list</td><td>Lists one or more jobs in the crontab(1) database. To list all jobs, the administrator must have the solaris.jobs.user authorization. To list a job in another user's crontab file, the administrator must have the solaris.jobs.admin authorization. No authorization is needed to list a user's own jobs.</td></tr> <tr> <td>modify</td><td>Modifies a job in the crontab(1) database. To modify a job, the administrator must have the solaris.jobs.user authorization. To modify a job in another user's crontab file, the administrator must have the solaris.jobs.admin authorization.</td></tr> </table>	add	Adds a job to the crontab(1) database. To add a job, the administrator must have the solaris.jobs.user authorization. To add a job to another user's crontab file, the administrator must have the solaris.jobs.admin authorization.	delete	Deletes a job from the crontab(1) database. To delete a job, the administrator must have the solaris.jobs.user authorization. To delete a job from another user's crontab file, the administrator must have the solaris.jobs.admin authorization.	list	Lists one or more jobs in the crontab(1) database. To list all jobs, the administrator must have the solaris.jobs.user authorization. To list a job in another user's crontab file, the administrator must have the solaris.jobs.admin authorization. No authorization is needed to list a user's own jobs.	modify	Modifies a job in the crontab(1) database. To modify a job, the administrator must have the solaris.jobs.user authorization. To modify a job in another user's crontab file, the administrator must have the solaris.jobs.admin authorization.
add	Adds a job to the crontab(1) database. To add a job, the administrator must have the solaris.jobs.user authorization. To add a job to another user's crontab file, the administrator must have the solaris.jobs.admin authorization.								
delete	Deletes a job from the crontab(1) database. To delete a job, the administrator must have the solaris.jobs.user authorization. To delete a job from another user's crontab file, the administrator must have the solaris.jobs.admin authorization.								
list	Lists one or more jobs in the crontab(1) database. To list all jobs, the administrator must have the solaris.jobs.user authorization. To list a job in another user's crontab file, the administrator must have the solaris.jobs.admin authorization. No authorization is needed to list a user's own jobs.								
modify	Modifies a job in the crontab(1) database. To modify a job, the administrator must have the solaris.jobs.user authorization. To modify a job in another user's crontab file, the administrator must have the solaris.jobs.admin authorization.								
OPTIONS	The smcron authentication arguments, <i>auth_args</i>, are derived from the smc(1M) arg set and are the same regardless of which subcommand you use. The smcron command requires the Solaris Management Console to be initialized for the command to succeed (see smc(1M)). After rebooting the Solaris Management Console server, the first Solaris Management Console connection might time out, so you might need to retry the command. The subcommand-specific options, <i>subcommand_args</i>, must come after the <i>auth_args</i> and must be separated from them by the - - option.								
<i>auth_args</i>	The valid <i>auth_args</i> are -D, -H, -l, -p, -r, and -u; they are all optional. If no <i>auth_args</i> are specified, certain defaults will be assumed and the user may be prompted for additional information, such as a password for authentication purposes. These letter options can also be specified by their equivalent option words preceded by a double dash. For example, you can use either -D or - --domain with the <i>domain</i> argument. -D - --domain <i>domain</i> Specifies the default domain that you want to manage. smcron accepts only file for this option. file is also the default value.								

The `file` default domain means that changes are local to the server. Toolboxes can change the domain on a tool-by-tool basis; this option specifies the domain for all other tools.

-H | - `-hostname host_name:port`

Specifies the *host_name* and *port* to which you want to connect. If you do not specify a *port*, the system connects to the default port, 898. If you do not specify *host_name:port*, the Solaris Management Console connects to the local host on port 898. You may still have to choose a toolbox to load into the console. To override this behavior, use the `smcron(1M) -B` option, or set your console preferences to load a "home toolbox" by default.

-l | - `-rolepassword role_password`

Specifies the password for the *role_name*. If you specify a *role_name* but do not specify a *role_password*, the system prompts you to supply a *role_password*. Passwords specified on the command line can be seen by any user on the system, hence this option is considered insecure.

-p | - `-password password`

Specifies the password for the *user_name*. If you do not specify a password, the system prompts you for one. Passwords specified on the command line can be seen by any user on the system, hence this option is considered insecure.

-r | - `-rolename role_name`

Specifies a role name for authentication. If you do not specify this option, no role is assumed.

-u | - `-username user_name`

Specifies the user name for authentication. If you do not specify this option, the user identity running the console process is assumed.

- -

This option is required and must always follow the preceding options. If you do not enter the preceding options, you must still enter the `- -` option.

subcommand_args

For the time-related subcommands described below, `-m`, `-M`, `-t`, and `-w`, you can enter multiple arguments, separated only by commas. `smcron` will construct `crontab` entries appropriate for your arguments. See **EXAMPLES**.

Note: Descriptions and other `arg` options that contain white spaces must be enclosed in double quotes.

■ For subcommand `add`:

-c `command`

Specifies the command that you want to run.

-h

(Optional) Displays the command's usage statement.

smcron(1M)

-m *day_of_month*

(Optional) Specifies the day of the month you want to run the job. Valid values are 1–31. If you specify both **-t** and **-m** options, the job executes one day per month at the time specified by **-t**.

-M *month*

(Optional) Specifies the month that you want to run the job. Valid values are 1–12. If you specify both **-t** and **-M** options, the job executes during the specified month at the time specified by **-t**.

-n *name*

Specifies the unique name of the job.

-o *owner*

(Optional) Specifies the user name that is the owner of the job. If you do not specify this option, the user name specified by the **-U** option is assumed.

-t *time_of_day*

Specifies the time (in *hh:mm*) that you want to execute the command. If no other time-related options are specified (**-m**, **-M**, or **-w**), the job executes every day at the time specified by **-t**. If you specify both **-t** and **-w** options, the job executes one day per week at the time specified by **-t**. If you specify both **-t** and **-m** options, the job executes one day per month at the time specified by **-t**. If you specify both **-t** and **-M** options, the job executes each day during the specified month at the time specified by **-t**.

-w *day_of_week*

(Optional) Specifies the day of the week you want to execute the command. Valid values are as follows:

- 0=Sunday
- 1=Monday
- 2=Tuesday
- 3=Wednesday
- 4=Thursday
- 5=Friday
- 6=Saturday

If you specify both **-t** and **-w** options, the job executes one day per week at the time specified by **-t**.

■ For subcommand **delete**:

-h

(Optional) Displays the command's usage statement.

-n *name*

Specifies the unique name of the job.

-o *owner*

(Optional) Specifies the user name that is the owner of the job. If you do not specify this option, the user name specified by the **-U** option is assumed.

■ For subcommand **list**:

- f *n|s|v*
(Optional) Specifies the format of the output. See EXAMPLES for examples of each output type.
 - *n* — Displays the data in native format, as it appears in the `crontab(1)` database.
 - *s* — Default format. Displays the data in summary format.
 - *v* — Displays the data in verbose format.
- h
(Optional) Displays the command's usage statement.
- o *owner*
(Optional) Lists all jobs for the specified owner (user name). If you do not specify this option, all jobs in the `crontab(1)` database are listed.
- For subcommand `modify`:
 - c *command*
(Optional) Specifies the command that you want to run.
 - h
(Optional) Displays the command's usage statement.
 - m *day_of_month*
(Optional) Specifies the day of the month you want to run the job. Valid values are 1–31. If you specify both `-t` and `-m` options, the job executes one day per month at the time specified by `-t`.
 - M *month*
(Optional) Specifies the month that you want to run the job. Valid values are 1–12. If you specify both `-t` and `-M` options, the job executes during the specified month at the time specified by `-t`.
 - n *name*
Specifies the current unique name of the job.
 - N *new_name*
(Optional) Specifies the new unique name of the job.
 - o *owner*
(Optional) Specifies the user name that is the owner of the job. If you do not specify this option, the user name specified by the `-U` option is assumed.
 - O *new_owner*
(Optional) Specifies the new owner of the job.
 - t *time_of_day*
(Optional) Specifies the time (in *hh:mm*) that you want to execute the command. If no other time-related options are specified (`-m`, `-M`, or `-w`), then the job executes every day at the time specified by `-t`. If you specify both `-t` and `-w` options, the job executes one day per week at the time specified by `-t`. If you specify both `-t` and `-m` options, the job executes one day per month at the time specified by `-t`. If you specify both `-t` and `-M`, then the job executes each day during the specified month at the time specified by `-t`.

smcron(1M)

-w day_of_week

(Optional) Specifies the day of the week you want to execute the command.
Valid values are as follows:

- 0=Sunday
- 1=Monday
- 2=Tuesday
- 3=Wednesday
- 4=Thursday
- 5=Friday
- 6=Saturday

If you specify both *-t* and *-w* options, the job executes one day per week at the time specified by *-t*.

EXAMPLES

EXAMPLE 1 Adding a Job

The following adds a new job, owned by `root`, that removes the old log files from `/tmp` daily at 1:30 AM.

```
./smcron add -H myhost -u root -p mypassword -- -n "Remove old logs" \  
            -t 1:30 -c "rm /tmp/*.log" -o root
```

EXAMPLE 2 Deleting a Job

The following deletes the job `Remove old logs` owned by `root`:

```
./smcron delete -H myhost -u root -p mypassword -- \  
              -n "Remove old logs" -o root
```

EXAMPLE 3 Listing Jobs in Native Format

The following lists all jobs in native, or `crontab(1)`, format:

```
./smcron list -H myhost -u root -p mypassword -- -f n  
MINUTE HOUR DATE MONTH DAY COMMAND  
  
10 3 * * * /usr/sbin/logadm  
15 3 * * 0 /usr/lib/fs/nfs/nfsfind  
1 2 * * * [ -x /usr/sbin/rtc ] && /usr/sbin/rtc -c > /dev/null 2>&1  
30 3 * * * [ -x /usr/lib/gss/gsscred_clean ] && /usr/lib/gss/gsscred_clean
```

EXAMPLE 4 Listing Jobs in Standard Format

The following lists all jobs owned by `lp` in standard format:

```
./smcron list -H myhost -u root -p mypassword -- -f s -o lp  
NAME::OWNER::SCHEDULE::COMMAND  
  
NoName_1765663371::lp::Weekly on Sundays at 3:13 AM::cd /var/lp/logs;  
    if [ -f requests ]; then if [ -f requests.1 ]; then /bin/mv requests.1  
        requests.2; fi; /usr/bin/cp requests requests.1; > requests; fi  
NoName_512822673::lp::Weekly on Sundays at 4:15 AM::cd /var/lp/logs;
```

EXAMPLE 4 Listing Jobs in Standard Format *(Continued)*

```
if [ -f lpsched ]; then if [ -f lpsched.1 ]; then /bin/mv lpsched.1
lpsched.2; fi; /usr/bin/cp lpsched lpsched.1; >lpsched; fi
```

EXAMPLE 5 Listing jobs in verbose format

The following lists all jobs in verbose format:

```
./smcron list -H myhost -u root -p mypassword -- -f v
NAME::OWNER::SCHEDULE::NEXT_RUN::STATUS::COMMAND

NoName_1075488942::root::Advanced:::Finished on Feb 10 3:10 with code 1
::/etc/cron.d/logchecker
databackup::root::Weekly on Sundays at 3:10 AM::3/19/00 3:10 AM
::Finished on Sep 19 3:10::/usr/lib/newsyslog
runlog::root::Daily at 2:01 AM::3/14/00 2:01 AM::Finished on Feb 11
2:01 AM::/usr/sbin/rtc
```

EXAMPLE 6 Changing a Job

The following modifies the job Remove old logs owned by root to execute daily at 2:00 AM:

```
./smcron modify -H myhost -u root -p mypassword -- -n "Remove old logs" \
-o root -t 2:00
```

EXAMPLE 7 Specifying Multiple Time Arguments

smcron allows you to specify a range of times for all of its time-related subcommands, -m, -M, -t, and -w. For example, the following command:

```
# smcron add -u root -p xxxx -- -n cronjob1 -w 1-4,5 \
-t 12:00,13:15,14:30 -c ls
```

...creates the following entry in crontab:

```
0,15,30 12,13,14 * * 1,2,3,4,6 ls #cronjob1
```

This job would run on Monday through Thursday and Saturday at the following times:

```
12:00 12:15 12:30
13:00 13:15 13:30
14:00 14:15 14:30
```

**ENVIRONMENT
VARIABLES**

See environ(5) for a description of the JAVA_HOME environment variable, which affects the execution of the smcron command. If this environment variable is not specified, the /usr/java location is used. See smc(1M).

EXIT STATUS

The following exit values are returned:

```
0            Successful completion.
```

smcron(1M)

- 1 Invalid command syntax. A usage message displays.
- 2 An error occurred while executing the command. An error message displays.

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWmga

SEE ALSO `crontab(1)`, `cron(1M)`, `smc(1M)`, `attributes(5)`, `environ(5)`

NOTES The timezone of the `cron` daemon sets the system-wide timezone for `cron` entries. This, in turn, is by set by default system-wide using `/etc/default/init`.

If some form of *daylight savings* or *summer/winter time* is in effect, then jobs scheduled during the switchover period could be executed once, twice, or not at all.

NAME	smcwebserver – start the Sun Management Center console web server														
SYNOPSIS	<code>/usr/sadm/bin/smcwebserver</code> <i>subcommand</i>														
DESCRIPTION	The <code>smcwebserver</code> utility starts the Sun Management Center web console server. Sun Management Center Web Console is a browser-based interface that performs systems management. System administrators can manage systems, devices and services from the console. When the console webserver is running, you can view the console by opening a browser and pointing to: <code>https://host:6789</code> <i>host</i> is the machine where the console has been installed and the console server is running.														
SUBCOMMANDS	The following subcommands are supported: <table> <tr> <td><code>disable</code></td><td>Disable automatic start or stop. Until the administrator reruns the script with the <code>smcwebserver enable</code> subcommand the webserver can be started/stopped only when the administrator executes the script manually using the following command:</td></tr> <tr> <td></td><td><code>/usr/sadm/bin/smcwebserver [start stop]</code></td></tr> <tr> <td><code>enable</code></td><td>Enable the webserver to startup automatically during subsequent system boot and gracefully stop during system shutdown.</td></tr> <tr> <td><code>help</code></td><td>Display the usage statement.</td></tr> <tr> <td><code>restart</code></td><td>Stop and subsequently start the console webserver.</td></tr> <tr> <td><code>start</code></td><td>Start the console webserver.</td></tr> <tr> <td><code>stop</code></td><td>Stop the console webserver.</td></tr> </table>	<code>disable</code>	Disable automatic start or stop. Until the administrator reruns the script with the <code>smcwebserver enable</code> subcommand the webserver can be started/stopped only when the administrator executes the script manually using the following command:		<code>/usr/sadm/bin/smcwebserver [start stop]</code>	<code>enable</code>	Enable the webserver to startup automatically during subsequent system boot and gracefully stop during system shutdown.	<code>help</code>	Display the usage statement.	<code>restart</code>	Stop and subsequently start the console webserver.	<code>start</code>	Start the console webserver.	<code>stop</code>	Stop the console webserver.
<code>disable</code>	Disable automatic start or stop. Until the administrator reruns the script with the <code>smcwebserver enable</code> subcommand the webserver can be started/stopped only when the administrator executes the script manually using the following command:														
	<code>/usr/sadm/bin/smcwebserver [start stop]</code>														
<code>enable</code>	Enable the webserver to startup automatically during subsequent system boot and gracefully stop during system shutdown.														
<code>help</code>	Display the usage statement.														
<code>restart</code>	Stop and subsequently start the console webserver.														
<code>start</code>	Start the console webserver.														
<code>stop</code>	Stop the console webserver.														
EXAMPLES	EXAMPLE 1 Displaying the Usage Statement The following command displays the <code>smcwebserver</code> usage statement: <pre>smcwebserver help</pre>														
ENVIRONMENT VARIABLES	See <code>environ(5)</code> for descriptions of the following environment variables that affect the execution of <code>smcwebserver</code>: JAVA_HOME If you do not specify this environment variable, your <code>PATH</code> is searched for a suitable <code>java</code>. Otherwise, the <code>/usr/j2se</code> location is used. CATALINA_HOME If you do not specify this environment variable, your <code>PATH</code> is searched for a suitable Tomcat 4.X version. Otherwise, the command returns with an error status.														

smcwebserver(1M)

EXIT STATUS The following exit values are returned:

- 0 Successful completion.
- 1 An error occurred.

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWmcon

SEE ALSO `attributes(5)`, `environ(5)`

NAME	smdiskless – manage diskless client support for a server								
SYNOPSIS	<code>/usr/sadm/bin/smdiskless subcommand [auth_args] - - [subcommand_args]</code>								
DESCRIPTION	The <code>smdiskless</code> command manages diskless client support for a server. <code>smdiskless</code> subcommands are: <table> <tr> <td>add</td><td>Adds a new diskless client to a server. There are two usages for this command. The user can either specify all the optional arguments directly on the command line, or provide a <code>sysidcfg(4)</code> formatted file as input. A future enhancement will allow specifying both a <code>sysidcfg(4)</code> formatted file and optional arguments, which will override the values in the <code>sysidcfg(4)</code> file.</td></tr> <tr> <td>delete</td><td>Deletes an existing diskless client from the system databases and removes any server support associated with the host, depending on the <code>os_server</code> type.</td></tr> <tr> <td>list</td><td>Lists existing diskless clients served by <code>os_server</code>.</td></tr> <tr> <td>modify</td><td>Modifies the specified attributes of the diskless client <code>os_server</code>.</td></tr> </table>	add	Adds a new diskless client to a server. There are two usages for this command. The user can either specify all the optional arguments directly on the command line, or provide a <code>sysidcfg(4)</code> formatted file as input. A future enhancement will allow specifying both a <code>sysidcfg(4)</code> formatted file and optional arguments, which will override the values in the <code>sysidcfg(4)</code> file.	delete	Deletes an existing diskless client from the system databases and removes any server support associated with the host, depending on the <code>os_server</code> type.	list	Lists existing diskless clients served by <code>os_server</code> .	modify	Modifies the specified attributes of the diskless client <code>os_server</code> .
add	Adds a new diskless client to a server. There are two usages for this command. The user can either specify all the optional arguments directly on the command line, or provide a <code>sysidcfg(4)</code> formatted file as input. A future enhancement will allow specifying both a <code>sysidcfg(4)</code> formatted file and optional arguments, which will override the values in the <code>sysidcfg(4)</code> file.								
delete	Deletes an existing diskless client from the system databases and removes any server support associated with the host, depending on the <code>os_server</code> type.								
list	Lists existing diskless clients served by <code>os_server</code> .								
modify	Modifies the specified attributes of the diskless client <code>os_server</code> .								
OPTIONS	The <code>smdiskless</code> authentication arguments, <code>auth_args</code>, are derived from the <code>smc(1M)</code> arg set and are the same regardless of which subcommand you use. The <code>smdiskless</code> command requires the Solaris Management Console to be initialized for the command to succeed (see <code>smc(1M)</code>). After rebooting the Solaris Management Console server, the first Solaris Management Console connection might time out, so you might need to retry the command. The subcommand-specific options, <code>subcommand_args</code>, must come after the <code>auth_args</code> and must be separated from them by the <code>- -</code> option.								
auth_args	The valid <code>auth_args</code> are <code>-D</code>, <code>-H</code>, <code>-l</code>, <code>-p</code>, <code>-r</code>, and <code>-u</code>; they are all optional. If no <code>auth_args</code> are specified, certain defaults will be assumed and the user may be prompted for additional information, such as a password for authentication purposes. These letter options can also be specified by their equivalent option words preceded by a double dash. For example, you can use either <code>-D</code> or <code>--domain</code>. Note – <code>smdiskless</code> supports the <code>--auth-data file</code> option, which enables you to specify a file the console can read to collect authentication data. See <code>smc(1M)</code> for a description of this option. <code>-D - --domain domain</code> Specifies the default domain that you want to manage. The syntax of <code>domain</code> is <code>type:/host_name/domain_name</code>, where <code>type</code> is <code>nis</code>, <code>nis+</code>, <code>dns</code>, <code>ldap</code>, or <code>file</code>; <code>host_name</code> is the name of the machine that serves the domain; and <code>domain_name</code> is the name of the domain you want to manage. (Note: Do <i>not</i> use <code>nis+</code> for <code>nisplus</code>.)								

smdiskless(1M)

If you do not specify this option, the Solaris Management Console assumes the `file` default domain on whatever server you choose to manage, meaning that changes are local to the server. Toolboxes can change the domain on a tool-by-tool basis; this option specifies the domain for all other tools.

-H | - `-hostname host_name:port`

Specifies the *host_name* and *port* to which you want to connect. If you do not specify a *port*, the system connects to the default port, 898. If you do not specify *host_name:port*, the Solaris Management Console connects to the local host on port 898. You may still have to choose a toolbox to load into the console. To override this behavior, use the `smc(1M) -B` option, or set your console preferences to load a "home toolbox" by default.

-l | - `-rolepassword role_password`

Specifies the password for the *role_name*. If you specify a *role_name* but do not specify a *role_password*, the system prompts you to supply a *role_password*. Passwords specified on the command line can be seen by any user on the system, hence this option is considered insecure.

-p | - `-password password`

Specifies the password for the *user_name*. If you do not specify a password, the system prompts you for one. Passwords specified on the command line can be seen by any user on the system, hence this option is considered insecure.

-r | - `-rolename role_name`

Specifies a role name for authentication. If you do not specify this option, no role is assumed.

-u | - `-username user_name`

Specifies the user name for authentication. If you do not specify this option, the user identity running the console process is assumed.

- -

This option is required and must always follow the preceding options. If you do not enter the preceding options, you must still enter the `- -` option.

subcommand_args

Note: Descriptions and other arg options that contain white spaces must be enclosed in double quotes.

■ For subcommand add:

- h** (Optional) Displays the command's usage statement.
- i *IP_address*** Specifies the IP address for the host in the form of `129.9.200.1`.
- e *ethernet_addr*** Specifies the Ethernet address.
- n *host*** Specifies the client name.
- o *os_server*** (optional) Specifies the name of the host where the OS service filesystems reside. If this option is not specified, the host will be the same as that specified

in the `smc(1M) -D` option. This option is useful in the event that the name service server and the OS server are not the same machine.

`-x os=platform`

Specifies the operating system. The syntax for *platform* is as follows:

instruction_set.implementation.Solaris_version

where

- *instruction_set* is one of `sparc` or `i386`
- *implementation* is the implementation architecture, that is, `i86pc` and `sun4u`.
- *version* is the Solaris version number. The supported *version* numbers are 2.6, 2.7 (for Solaris 7), 8, and 9. Examples are:

`sparc.sun4u.Solaris_8`

`-x root=pathname`

(Optional) Specifies the absolute path of the directory in which to create the root directory for diskless clients. The default (and recommended) *pathname* is `/export/root/client_name`.

`-x swap=pathname`

(Optional) Specifies the absolute path of the directory in which to create the swap file for diskless clients. The default (and recommended) *pathname* is `/export/swap/client_name`.

`-x swapsize=size`

(Optional) Specifies the size, in megabytes, of the swap file for diskless clients. The default swap size is 24M.

`-x dump=pathname`

(Optional) Specifies the absolute path of the dump directory for diskless clients. The default (and recommended) *pathname* is `/export/dump/client_name`.

`-x dumpsize=size`

(Optional) Specifies the size, in megabytes, of the dump file for diskless clients. The default swap size is 24M.

`-x pw=Y`

(Optional) Prompts for the system's root password. The default is not to prompt. The following options

are used to configure workstations on first boot by `sysidtool(1M)`. They can either be specified on the command line, or in a `sysidcfg(4)` formatted file. *Note:* Use the `sysidcfg(4)` file to:

- Add a DNS client.

smdiskless(1M)

- Specify use of the LDAP name service.
- Specify a security policy.

The keywords and functions supported by `sysidtool` and `sysidcfg` vary among Solaris releases. Consult the man pages for your operating system release (`uname -r`) to determine the level of support available.

- x *tz=timezone*
(Optional) Specifies the path of a timezone file, relative to `/usr/share/lib/zoneinfo`. The default is the server's timezone.
- x *ns=NIS | NIS+ | NONE*
(Optional) Specifies the client's nameservice. This is one of NIS, NIS+, or NONE. Use a `sysidcfg(4)` file to specify DNS or LDAP. The default *ns* value is NONE, which results in the use of the `files` source in `nsswitch.conf`. See `nsswitch.conf(4)` for a description of the `files` source.
- x *nameserver=hostname*
(Optional) Specifies the nameserver's hostname. The default is the server's nameserver.
- x *domain=domain*
(Optional) Specifies the client's domain. The default is the server's domain.
- x *nameserver_ipaddress=ip_address*
(Optional) Specifies the nameserver's IP address.
- x *netmask=ip_address*
(Optional) Specifies the client's IP address netmask. The default is the server's netmask.
- x *locale=locale*
(Optional) Specifies the client's system locale. The default is the C locale.
- x *terminal=term*
(Optional) Specifies the workstation's terminal type, typically, `sun` or `xterms`.
- x *passwd=root_password*
(Optional) Specifies the system's root password. The default is no password.
- x *sysidcfg=path_to_sysidcfg_file*
(Optional) Specifies the file to be placed in the `/etc` directory of the diskless client. On first boot, `/etc/.UNCONFIGURED` exists and `sysidtool(1M)` will run. If a file called `/etc/sysidcfg` exists, `sysidtool(1M)` reads this file and uses the information for system configuration.
- For subcommand `delete`:
 - h
(Optional) Displays the command's usage statement.
 - n *host*
Specifies the hostname of the diskless client to delete. This host is deleted from relevant tables and OS Services for this client are deleted.

-o *os_server*
 (Optional) Specifies the name of the host where the OS service filesystems reside. If this option is not specified, the host will be the same as that specified in the `smc(1M)` -D option. This option is useful in the event that the name service server and the OS server are not the same machine.

■ For subcommand `list`:

-h
 (Optional) Displays the command's usage statement.

-o *os_server*
 (Optional) Specifies the name of the host where the OS service filesystems reside. If this option is not specified, the host will be the same as that specified in the `smc(1M)` -D option. This option is useful in the event that the name service server and the OS server are not the same machine.

■ For subcommand `modify`:

-e *ethernet_addr*
 Changes the specified diskless client's ethernet address to *ethernet_addr*.

-h
 (Optional) Displays the command's usage statement.

-n *host*
 Specifies the host name of the diskless client to modify.

-o *os_server*
 (Optional) Specifies the name of the host where the OS service filesystems reside. If this option is not specified, the host will be the same as that specified in the `smc(1M)` -D option. This option is useful in the event that the name service server and the OS server are not the same machine.

-x *tz=timezone*
 (Optional) Changes the specified diskless client's timezone.

EXAMPLES

EXAMPLE 1 Creating a new diskless client

The following command adds a new diskless client named `client1` which will run Solaris 9 on a sun4u machine:

```
example% /usr/sadm/bin/smdiskless add -- -i 129.9.200.1 \
-e 8:0:11:12:13:14 -n client1 -x os=sparc.sun4u.Solaris_9 \
-x root=/export/root/client1 -x swap=/export/swap/client1 \
-x swapsize=32 -x tz=US/Eastern -x locale=en_US
```

EXAMPLE 2 Deleting an existing diskless client

The following command deletes the diskless client named `client1` from the OS server named `osserver`, where the OS server is using NIS+ and the NIS+ server is `nisplusservice`:

```
example% /usr/sadm/bin/smdiskless delete \
-D nisplus:/nisplusservice/my.domain.com -- \
-o osserver -n client1
```

smdiskless(1M)

EXAMPLE 3 Listing the diskless clients served by a host

The following command lists the diskless clients running on the OS server, `osserver`:

```
example% /usr/sadm/bin/smdiskless list -D file:/osserver/osserver -- \
-o oserver
```

EXAMPLE 4 Modifying the attributes of the diskless client host

The following command modifies the ethernet address for the client named `client1` on the OS server, `osserver`, to be `8:0:11:12:13:15`:

```
example% /usr/sadm/bin/smdiskless modify -D file:/osserver/osserver -- \
-o oserver -n client1 -e 8:0:11:12:13:15
```

ENVIRONMENT VARIABLES

See `environ(5)` for a description of the `JAVA_HOME` environment variable, which affects the execution of the `smdiskless` command. If this environment variable is not specified, the `/usr/java1.2` location is used. See `smc(1M)`.

EXIT STATUS

The following exit values are returned:

0	Successful completion.
1	Invalid command syntax. A usage message displays.
2	An error occurred while executing the command. An error message displays.

ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWdcInt

NAME	smexec – manage entries in the exec_attr database						
SYNOPSIS	<code>/usr/sadm/bin/smexec subcommand [auth_args] - - [subcommand_args]</code>						
DESCRIPTION	The smexec command manages an entry in the exec_attr(4) database in the local /etc files name service or a NIS or NIS+ name service.						
<i>subcommands</i>	smexec <i>subcommands</i> are: <table> <tr> <td>add</td><td>Adds a new entry to the exec_attr(4) database. To add an entry to the exec_attr database, the administrator must have the solaris.profmgr.execattr.write authorization.</td></tr> <tr> <td>delete</td><td>Deletes an entry from the exec_attr(4) database. To delete an entry from the exec_attr database, the administrator must have the solaris.profmgr.execattr.write authorization.</td></tr> <tr> <td>modify</td><td>Modifies an entry in the exec_attr(4) database. To modify an entry in the exec_attr database, the administrator must have the solaris.profmgr.execattr.write authorization.</td></tr> </table>	add	Adds a new entry to the exec_attr(4) database. To add an entry to the exec_attr database, the administrator must have the solaris.profmgr.execattr.write authorization.	delete	Deletes an entry from the exec_attr(4) database. To delete an entry from the exec_attr database, the administrator must have the solaris.profmgr.execattr.write authorization.	modify	Modifies an entry in the exec_attr(4) database. To modify an entry in the exec_attr database, the administrator must have the solaris.profmgr.execattr.write authorization.
add	Adds a new entry to the exec_attr(4) database. To add an entry to the exec_attr database, the administrator must have the solaris.profmgr.execattr.write authorization.						
delete	Deletes an entry from the exec_attr(4) database. To delete an entry from the exec_attr database, the administrator must have the solaris.profmgr.execattr.write authorization.						
modify	Modifies an entry in the exec_attr(4) database. To modify an entry in the exec_attr database, the administrator must have the solaris.profmgr.execattr.write authorization.						
OPTIONS	The smexec authentication arguments, <i>auth_args</i>, are derived from the smc(1M) arg set and are the same regardless of which subcommand you use. The smexec command requires the Solaris Management Console to be initialized for the command to succeed (see smc(1M)). After rebooting the Solaris Management Console server, the first Solaris Management Console connection might time out, so you might need to retry the command. The subcommand-specific options, <i>subcommand_args</i>, must come after the <i>auth_args</i> and must be separated from them by the - - option.						
<i>auth_args</i>	The valid <i>auth_args</i> are -D, -H, -l, -p, -r, and -u; they are all optional. If no <i>auth_args</i> are specified, certain defaults will be assumed and the user may be prompted for additional information, such as a password for authentication purposes. These letter options can also be specified by their equivalent option words preceded by a double dash. For example, you can use either -D or - -domain with the <i>domain</i> argument. -D - -domain <i>domain</i> Specifies the default domain that you want to manage. The syntax of <i>domain</i> is <i>type: /host_name /domain_name</i>, where <i>type</i> is nis, nisplus, dns, ldap, or file; <i>host_name</i> is the name of the machine that serves the domain; and <i>domain_name</i> is the name of the domain you want to manage. (Note: Do not use nis+ for nisplus.) If you do not specify this option, the Solaris Management Console assumes the file default domain on whatever server you choose to manage, meaning that changes are local to the server. Toolboxes can change the domain on a tool-by-tool basis; this option specifies the domain for all other tools. -H - -hostname <i>host_name:port</i> Specifies the <i>host_name</i> and <i>port</i> to which you want to connect. If you do not specify a <i>port</i>, the system connects to the default port, 898. If you do not specify						

smexec(1M)

host_name:port, the Solaris Management Console connects to the local host on port 898. You may still have to choose a toolbox to load into the console. To override this behavior, use the `smc(1M) -B` option, or set your console preferences to load a “home toolbox” by default.

`-l | -rolepassword role_password`

Specifies the password for the *role_name*. If you specify a *role_name* but do not specify a *role_password*, the system prompts you to supply a *role_password*. Passwords specified on the command line can be seen by any user on the system, hence this option is considered insecure.

`-p | -password password`

Specifies the password for the *user_name*. If you do not specify a password, the system prompts you for one. Passwords specified on the command line can be seen by any user on the system, hence this option is considered insecure.

`-r | -rolename role_name`

Specifies a role name for authentication. If you do not specify this option, no role is assumed.

`-u | -username user_name`

Specifies the user name for authentication. If you do not specify this option, the user identity running the console process is assumed.

`- -`

This option is required and must always follow the preceding options. If you do not enter the preceding options, you must still enter the `- -` option.

subcommand_args

Note: Descriptions and other arg options that contain white spaces must be enclosed in double quotes.

■ For subcommand `add`:

`-c command_path`

Specifies the full path to the command associated with the new `exec_attr` entry.

`-g egid`

(Optional) Specifies the effective group ID that executes with the command.

`-G gid`

(Optional) Specifies the real group ID that executes with the command.

`-h`

(Optional) Displays the command’s usage statement.

`-n profile_name`

Specifies the name of the profile associated with the new `exec_attr` entry.

`-t type`

Specifies the type for the command. Currently, the only acceptable value for *type* is `cmd`.

- u *euid*
(Optional) Specifies the effective user ID that executes with the command.
- U *uid*
(Optional) Specifies the real user ID that executes with the command.
- For subcommand `delete`:
 - c *command_path*
Specifies the full path to the command associated with the `exec_attr` entry.
 - h
(Optional) Displays the command's usage statement.
 - n *profile_name*
Specifies the name of the profile associated with the `exec_attr` entry.
 - t *type*
Specifies the type `cmd` for command. Currently, the only acceptable value for *type* is `cmd`.
- For subcommand `modify`:
 - c *command_path*
Specifies the full path to the command associated with the `exec_attr` entry that you want to modify.
 - g *egid*
(Optional) Specifies the new effective group ID that executes with the command.
 - G *gid*
(Optional) Specifies the new real group ID that executes with the command.
 - h
(Optional) Displays the command's usage statement.
 - n *profile_name*
Specifies the name of the profile associated with the `exec_attr` entry.
 - t *type*
Specifies the type `cmd` for command. Currently, the only acceptable value for *type* is `cmd`.
 - u *euid*
(Optional) Specifies the new effective user ID that executes with the command.
 - U *uid*
(Optional) Specifies the new real user ID that executes with the command.

EXAMPLES**EXAMPLE 1** Creating an `exec_attr` database entry

The following creates a new `exec_attr` entry for the User Manager profile on the local file system. The entry type is `cmd` for the command `/usr/bin/cp`. The command has an effective user ID of 0 and an effective group ID of 0.

```
./smexec add -H myhost -p mypasswd -u root -- -n "User Manager" \
-t cmd -c /usr/bin/cp -u 0 -g 0
```

smexec(1M)

EXAMPLE 2 Deleting an exec_attr database entry

The following example deletes an `exec_attr` database entry for the User Manager profile from the local file system. The entry designated for the command `/usr/bin/cp` is deleted.

```
./smexec delete -H myhost -p mypasswd -u root -- -n "User Manager" \  
-t cmd -c /usr/bin/cp
```

EXAMPLE 3 Modifying an exec_attr database Entry

The following modifies the attributes of the `exec_attr` database entry for the User Manager profile on the local file system. The `/usr/bin/cp` entry is modified to execute with the real user ID of 0 and the real group ID of 0.

```
./smexec modify -H myhost -p mypasswd -u root -- -n "User Manager" \  
-t cmd -c /usr/bin/cp -U 0 -G 0
```

ENVIRONMENT VARIABLES

See `environ(5)` for a description of the `JAVA_HOME` environment variable, which affects the execution of the `smexec` command. If this environment variable is not specified, the `/usr/java` location is used. See `smc(1M)`.

EXIT STATUS

The following exit values are returned:

0	Successful completion.
1	Invalid command syntax. A usage message displays.
2	An error occurred while executing the command. An error message displays.

FILES

The following file is used by the `smexec` command:

<code>/etc/security/exec_attr</code>	Execution profiles database. See <code>exec_attr(4)</code> .

ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWmga

SEE ALSO

`smc(1M)`, `exec_attr(4)`, `attributes(5)`, `environ(5)`

NAME	smgroup – manage group entries								
SYNOPSIS	<code>/usr/sadm/bin/smgroup subcommand [auth_args] - - [subcommand_args]</code>								
DESCRIPTION	The smgroup command manages one or more group definitions in the group database for the appropriate files in the local /etc files name service or a NIS or NIS+ name service. The following smgroup subcommands are supported <table> <tr> <td>add</td><td>Adds a new group entry. To add an entry, the administrator must have the <code>solaris.admin.usermgr.write</code> authorization.</td></tr> <tr> <td>delete</td><td>Deletes a group entry. You can delete only one entry at a time. To delete an entry, the administrator must have the <code>solaris.admin.usermgr.write</code> authorization. <i>Note:</i> You cannot delete the system groups with IDs less than 100, or the groups 60001, 60002, or 65534.</td></tr> <tr> <td>list</td><td>Lists one or more group entries in the form of a three-column list, containing the group name, group ID, and group members, separated by colons (:). To list entries, the administrator must have the <code>solaris.admin.usermgr.read</code> authorization.</td></tr> <tr> <td>modify</td><td>Modifies a group entry. To modify an entry, the administrator must have the <code>solaris.admin.usermgr.write</code> authorization.</td></tr> </table>	add	Adds a new group entry. To add an entry, the administrator must have the <code>solaris.admin.usermgr.write</code> authorization.	delete	Deletes a group entry. You can delete only one entry at a time. To delete an entry, the administrator must have the <code>solaris.admin.usermgr.write</code> authorization. <i>Note:</i> You cannot delete the system groups with IDs less than 100, or the groups 60001, 60002, or 65534.	list	Lists one or more group entries in the form of a three-column list, containing the group name, group ID, and group members, separated by colons (:). To list entries, the administrator must have the <code>solaris.admin.usermgr.read</code> authorization.	modify	Modifies a group entry. To modify an entry, the administrator must have the <code>solaris.admin.usermgr.write</code> authorization.
add	Adds a new group entry. To add an entry, the administrator must have the <code>solaris.admin.usermgr.write</code> authorization.								
delete	Deletes a group entry. You can delete only one entry at a time. To delete an entry, the administrator must have the <code>solaris.admin.usermgr.write</code> authorization. <i>Note:</i> You cannot delete the system groups with IDs less than 100, or the groups 60001, 60002, or 65534.								
list	Lists one or more group entries in the form of a three-column list, containing the group name, group ID, and group members, separated by colons (:). To list entries, the administrator must have the <code>solaris.admin.usermgr.read</code> authorization.								
modify	Modifies a group entry. To modify an entry, the administrator must have the <code>solaris.admin.usermgr.write</code> authorization.								
OPTIONS	The smgroup authentication arguments, <i>auth_args</i>, are derived from the smc(1M) arg set and are the same regardless of which subcommand you use. The smgroup command requires the Solaris Management Console to be initialized for the command to succeed (see smc(1M)). After rebooting the Solaris Management Console server, the first Solaris Management Console connection might time out, so you might need to retry the command. The subcommand-specific options, <i>subcommand_args</i>, must come after the <i>auth_args</i> and must be separated from them by the - - option.								
<i>auth_args</i>	The valid <i>auth_args</i> are -D, -H, -l, -p, -r, and -u; they are all optional. If no <i>auth_args</i> are specified, certain defaults will be assumed and the user may be prompted for additional information, such as a password for authentication purposes. These letter options can also be specified by their equivalent option words preceded by a double dash. For example, you can use either -D or - -domain. The following <i>auth_args</i> are supported: <table> <tr> <td>-D - -domain <i>domain</i></td><td>Specifies the default domain that you want to manage. The syntax of <i>domain</i> is <i>type</i>:<i>/host_name/domain_name</i>, where <i>type</i> is nis, nisplus, dns, ldap or file; <i>host_name</i> is the name of the machine that serves the domain; and <i>domain_name</i> is the name of the domain you want to manage. (<i>Note:</i> Do not use nis+ for nisplus.)</td></tr> </table>	-D - -domain <i>domain</i>	Specifies the default domain that you want to manage. The syntax of <i>domain</i> is <i>type</i> : <i>/host_name/domain_name</i> , where <i>type</i> is nis, nisplus, dns, ldap or file; <i>host_name</i> is the name of the machine that serves the domain; and <i>domain_name</i> is the name of the domain you want to manage. (<i>Note:</i> Do not use nis+ for nisplus.)						
-D - -domain <i>domain</i>	Specifies the default domain that you want to manage. The syntax of <i>domain</i> is <i>type</i> : <i>/host_name/domain_name</i> , where <i>type</i> is nis, nisplus, dns, ldap or file; <i>host_name</i> is the name of the machine that serves the domain; and <i>domain_name</i> is the name of the domain you want to manage. (<i>Note:</i> Do not use nis+ for nisplus.)								

smgroup(1M)

If you do not specify this option, the Solaris Management Console assumes the file default domain on whatever server you choose to manage, meaning that changes are local to the server. Toolboxes can change the domain on a tool-by-tool basis; this option specifies the domain for all other tools.

-H | - -hostname *host_name:port*

Specifies the *host_name* and *port* to which you want to connect. If you do not specify a *port*, the system connects to the default port, 898. If you do not specify *host_name:port*, the Solaris Management Console connects to the local host on port 898. You may still have to choose a toolbox to load into the console. To override this behavior, use the smc(1M) -B option, or set your console preferences to load a "home toolbox" by default.

-l | - -rolepassword *role_password*

Specifies the password for the *role_name*. If you specify a *role_name* but do not specify a *role_password*, the system prompts you to supply a *role_password*. Passwords specified on the command line can be seen by any user on the system, hence this option is considered insecure.

-p | - -password *password*

Specifies the password for the *user_name*. If you do not specify a password, the system prompts you for one. Passwords specified on the command line can be seen by any user on the system, hence this option is considered insecure.

-r | - -rolename *role_name*

Specifies a role name for authentication. If you do not specify this option, no role is assumed.

-u | - -username *user_name*

Specifies the user name for authentication. If you do not specify this option, the user identity running the console process is assumed.

- -

This option is required and must always follow the preceding options. If you do not enter the preceding options, you must still enter the - - option.

subcommand_args

Descriptions and other argument options that contain white spaces must be enclosed in double quotes.

The add subcommand supports the following *subcommand_args*:

-g *gid*

(Optional) Specifies the group ID for the new group. The group ID must be a non-negative decimal integer with a maximum value of 2MB (2,147,483,647). Group IDs 0–99 are reserved for the system and should be used with care. If you do not specify a *gid*, the system automatically assigns the next available *gid*. To maximize interoperability and compatibility, administrators are recommended to assign groups using the range of GIDs below 60000 where possible.

-h

(Optional) Displays the command's usage statement.

`-m group_member1 -m group_member2 . . .`

(Optional) Specifies the new members to add to the group.

`-n group_name`

Specifies the name of the new group. The group name must be unique within a domain, contain 2–32 alphanumeric characters, begin with a letter, and contain at least one lowercase letter.

The `delete` subcommand supports the following *subcommand_args*:

`-h`

(Optional) Displays the command's usage statement.

`-n group_name`

Specifies the name of the group you want to delete.

The `list` subcommand supports the following *subcommand_args*:

`-h`

(Optional) Displays the command's usage statement.

`-n group_name`

(Optional) Specifies the name of the group you want to list. If you do not specify a group name, all groups are listed.

The `modify` subcommand supports the following *subcommand_args*:

`-h`

(Optional) Displays the command's usage statement.

`-m group_member1 -m group_member2 . . .`

(Optional) Specifies the new members to add to the group. Note that *group_member* overwrites the existing member list in the group file.

`-n group_name`

Specifies the name of the group you want to modify.

`-N new_group`

(Optional) Specifies the new group name. The group name must be unique within a domain, contain 2–32 alphanumeric characters, begin with a letter, and contain at least one lowercase letter.

EXAMPLES

EXAMPLE 1 Creating a Test Group

The following creates the `test_group` group entry with a group ID of 123 and adds `test_member1` and `test_member2` to the group:

```
./smgroup add -H myhost -p mypasswd -u root -- -n test_group \
    -m test_member1 -m test_member2 -g 123
```

EXAMPLE 2 Deleting a Group

The following deletes `test_group`:

```
./smgroup delete -H myhost -p mypasswd -u root -- -n test_group
```

smgroup(1M)

EXAMPLE 3 Displaying All Groups

The following displays all groups in a three-column list showing the group name, group ID, and group members:

```
./smgroup list -H myhost -p mypasswd -u root --
```

EXAMPLE 4 Displaying a Group

The following displays the `group_1` data in a three-column list showing the group name, group ID, and group members:

```
./smgroup list -H myhost -p mypasswd -u root -- -n group_1
```

EXAMPLE 5 Renaming a Group

The following renames a group from `finance` to `accounting`:

```
./smgroup modify -H myhost -p mypasswd -u root -- \
-n finance -N accounting
```

ENVIRONMENT VARIABLES

See `environ(5)` for a description of the `JAVA_HOME` environment variable, which affects the execution of the `smgroup` command. If this environment variable is not specified, the `/usr/java` location is used. See `smc(1M)`.

EXIT STATUS

The following exit values are returned:

0	Successful completion.
1	Invalid command syntax. A usage message displays.
2	An error occurred while executing the command. An error message displays.

FILES

The following files are used by the `smgroup` command:

`/etc/group` Group file. See `group(4)`.

ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWmga

SEE ALSO

`smc(1M)`, `group(4)`, `attributes(5)`, `environ(5)`

NAME	smlog – manage and view WBEM log files
SYNOPSIS	<code>/usr/sadm/bin/smlog subcommand [auth_args] -- [subcommand_args]</code>
DESCRIPTION	The smlog command manages WBEM log files and allows a user to view WBEM log file records.
Subcommands	The smlog command supports the following subcommands: backup Backs up the entries in the current WBEM log file. The backup command then creates a new log file and makes this log file the current log file. delete Deletes an existing (backed up) WBEM log file. list Lists the names of all the WBEM log files available for viewing. view Allows the user to view the contents of the specified WBEM log file.
OPTIONS	The smlog authentication arguments, <i>auth_args</i>, are derived from the smc(1M) arg set and are the same regardless of which subcommand you use. The smlog command requires the Solaris Management Console to be initialized for the command to succeed (see smc(1M)). After rebooting the Solaris Management Console server, the first Solaris Management Console connection might time out, so you might need to retry the command. The subcommand-specific options, <i>subcommand_args</i>, must come after the <i>auth_args</i> and must be separated from them by the <code>--</code> option.
<i>auth_args</i>	The valid <i>auth_args</i> are <code>-D</code>, <code>-H</code>, <code>-l</code>, <code>-p</code>, <code>-r</code>, and <code>-u</code>; they are all optional. If no <i>auth_args</i> are specified, certain defaults will be assumed and the user may be prompted for additional information, such as a password for authentication purposes. These letter options can also be specified by their equivalent option words preceded by a double dash. For example, you can use either <code>-D</code> or <code>--domain</code> with the <i>domain</i> argument. -D --domain <i>domain</i> Specifies the default domain that you want to manage. smlog accepts only <i>file</i> for this option. <i>file</i> is also the default value. The <i>file</i> default domain means that changes are local to the server. Toolboxes can change the domain on a tool-by-tool basis; this option specifies the domain for all other tools. -H --hostname <i>host_name:port</i> Specifies the <i>host_name</i> and <i>port</i> to which you want to connect. If you do not specify a <i>port</i>, the system connects to the default port, 898. If you do not specify <i>host_name:port</i>, the Solaris Management Console connects to the local host on port

smlog(1M)

898. You may still have to choose a toolbox to load into the console. To override this behavior, use the `smc -B` option (see `smc(1M)`), or set your console preferences to load a “home toolbox” by default.

`-l | - --rolepassword role_password`

Specifies the password for the *role_name*. If you specify a *role_name* but do not specify a *role_password*, the system prompts you to supply a *role_password*. Passwords specified on the command line can be seen by any user on the system, hence this option is considered insecure.

`-p | - --password password`

Specifies the password for the *user_name*. If you do not specify a password, the system prompts you for one. Passwords specified on the command line can be seen by any user on the system, hence this option is considered insecure.

`-r | - --rolename role_name`

Specifies a role name for authentication. If you do not specify this option, no role is assumed.

`-u | - --username user_name`

Specifies the user name for authentication. If you do not specify this option, the user identity running the console process is assumed.

`- -`

This option is required and must always follow the preceding options. If you do not enter the preceding options, you must still enter the `- -` option.

subcommand_args

Descriptions and other `arg` options that contain white spaces must be enclosed in double quotes.

The `backup` subcommand supports the following *subcommand_args*:

`-h`

Displays the command’s usage statement.

This *subcommand_arg* is optional.

The `delete` subcommand supports the following *subcommand_args*:

`-h`

Displays the command’s usage statement.

This *subcommand_arg* is optional.

`-n name`

Specifies the name of the log file you want to delete.

The `list` subcommand supports the following *subcommand_args*:

`-h`

Displays the command’s usage statement.

This *subcommand_arg* is optional.

The view subcommand supports the following *subcommand_args*:

-h

Displays the command's usage statement.

This *subcommand_arg* is optional.

-n *name*

Specifies the name of the log file you want to view.

-v

Displays the data in verbose format.

This *subcommand_arg* is optional.

EXAMPLES

EXAMPLE 1 Listing WBEM Log Files

The following command lists all available WBEM log files:

```
./smlog list -H myhost -p mypasswd -u root --
```

```
Log.01/03/2001.14:38:29
```

```
Log.01/04/2001.16:34:59
```

```
Log.01/08/2001.14:13:33
```

```
Log.01/11/2001.18:39:53
```

```
Log.01/12/2001.10:31:31
```

```
Log.12/21/2000.17:41:11
```

EXAMPLE 2 Displaying a WBEM Log File

The following command displays the contents of a log file:

```
./smlog view -H myhost -p mypasswd -u root -- -n Log.01/04/2001.16:34:59
```

Date and Time	Client	User	Source	Severity	Cate gory
1/5/01 5:22:47 PM	hostname1	root	Solaris_OsService	Informational	Appl ication log No services found.
1/5/01 5:21:46 PM	hostname1	root	Solaris_OsService	Informational	Appl ication log No services found.

The smlog output wraps when it exceeds 80 characters.

ENVIRONMENT VARIABLES

See environ(5) for a description of the JAVA_HOME environment variable, which affects the execution of the smlog command. If this environment variable is not specified, the /usr/java1.2 location is used. See smc(1M).

EXIT STATUS

The following exit values are returned:

- 0 Successful completion.
- 1 Invalid command syntax. A usage message displays.
- 2 An error occurred while executing the command. An error message displays.

smlog(1M)

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWmga

NAME	smmaillist – manage email alias entries								
SYNOPSIS	/usr/sadm/bin/smmaillist <i>subcommand</i> [<i>auth_args</i>] - - [<i>subcommand_args</i>]								
DESCRIPTION	The smmaillist command manages one or more email alias entries for the appropriate files in the local /etc files name service or a NIS or NIS+ name service.								
<i>subcommands</i>	smmaillist <i>subcommands</i> are: <table> <tr> <td>add</td><td>Creates a new email alias definition and adds it to the appropriate files. To add an entry, the administrator must have the <code>solaris.admin.usermgr.write</code> authorization.</td></tr> <tr> <td>delete</td><td>Deletes an email alias entry. You can delete only one entry at a time. To delete an entry, the administrator must have the <code>solaris.admin.usermgr.write</code> authorization. <i>Note:</i> You cannot delete Postmaster or Mailer-Daemon aliases.</td></tr> <tr> <td>list</td><td>Lists one or more email alias entries. To list an entry, the administrator must have the <code>solaris.admin.usermgr.read</code> authorization.</td></tr> <tr> <td>modify</td><td>Modifies an email alias entry. To modify an entry, the administrator must have the <code>solaris.admin.usermgr.write</code> authorization.</td></tr> </table>	add	Creates a new email alias definition and adds it to the appropriate files. To add an entry, the administrator must have the <code>solaris.admin.usermgr.write</code> authorization.	delete	Deletes an email alias entry. You can delete only one entry at a time. To delete an entry, the administrator must have the <code>solaris.admin.usermgr.write</code> authorization. <i>Note:</i> You cannot delete Postmaster or Mailer-Daemon aliases.	list	Lists one or more email alias entries. To list an entry, the administrator must have the <code>solaris.admin.usermgr.read</code> authorization.	modify	Modifies an email alias entry. To modify an entry, the administrator must have the <code>solaris.admin.usermgr.write</code> authorization.
add	Creates a new email alias definition and adds it to the appropriate files. To add an entry, the administrator must have the <code>solaris.admin.usermgr.write</code> authorization.								
delete	Deletes an email alias entry. You can delete only one entry at a time. To delete an entry, the administrator must have the <code>solaris.admin.usermgr.write</code> authorization. <i>Note:</i> You cannot delete Postmaster or Mailer-Daemon aliases.								
list	Lists one or more email alias entries. To list an entry, the administrator must have the <code>solaris.admin.usermgr.read</code> authorization.								
modify	Modifies an email alias entry. To modify an entry, the administrator must have the <code>solaris.admin.usermgr.write</code> authorization.								
OPTIONS	The smmaillist authentication arguments, <i>auth_args</i>, are derived from the smc(1M) arg set and are the same regardless of which subcommand you use. The smmaillist command requires the Solaris Management Console to be initialized for the command to succeed (see smc(1M)). After rebooting the Solaris Management Console server, the first Solaris Management Console connection might time out, so you might need to retry the command. The subcommand-specific options, <i>subcommand_args</i>, must come after the <i>auth_args</i> and must be separated from them by the - - option.								
<i>auth_args</i>	The valid <i>auth_args</i> are -D, -H, -l, -p, -r, and -u; they are all optional. If no <i>auth_args</i> are specified, certain defaults will be assumed and the user may be prompted for additional information, such as a password for authentication purposes. These letter options can also be specified by their equivalent option words preceded by a double dash. For example, you can use either -D or - -domain with the <i>domain</i> argument. -D - -domain <i>domain</i> Specifies the default domain that you want to manage. The syntax of <i>domain</i> is <i>type</i>:/<i>host_name</i>/<i>domain_name</i>, where <i>type</i> is nis, nisplus, dns, ldap, or file; <i>host_name</i> is the name of the machine that serves the domain; and <i>domain_name</i> is the name of the domain you want to manage. (<i>Note:</i> Do not use nis+ for nisplus.)								

smmaillist(1M)

If you do not specify this option, the Solaris Management Console assumes the file default domain on whatever server you choose to manage, meaning that changes are local to the server. Toolboxes can change the domain on a tool-by-tool basis; this option specifies the domain for all other tools.

-H | - *-hostname host_name:port*

Specifies the *host_name* and *port* to which you want to connect. If you do not specify a *port*, the system connects to the default port, 898. If you do not specify *host_name:port*, the Solaris Management Console connects to the local host on port 898. You may still have to choose a toolbox to load into the console. To override this behavior, use the `smc(1M)` **-B** option, or set your console preferences to load a "home toolbox" by default.

-l | - *-rolepassword role_password*

Specifies the password for the *role_name*. If you specify a *role_name* but do not specify a *role_password*, the system prompts you to supply a *role_password*. Passwords specified on the command line can be seen by any user on the system, hence this option is considered insecure.

-p | - *-password password*

Specifies the password for the *user_name*. If you do not specify a password, the system prompts you for one. Passwords specified on the command line can be seen by any user on the system, hence this option is considered insecure.

-r | - *-rolename role_name*

Specifies a role name for authentication. If you do not specify this option, no role is assumed.

-u | - *-username user_name*

Specifies the user name for authentication. If you do not specify this option, the user identity running the console process is assumed.

- -

This option is required and must always follow the preceding options. If you do not enter the preceding options, you must still enter the **- -** option.

subcommand_args

Note: Descriptions and other arg options that contain white spaces must be enclosed in double quotes.

■ For subcommand add:

-a *address1 -a address2 . . .*

(Optional) Specifies the new email address. See `sendmail(1M)`.

-h

(Optional) Displays the command's usage statement.

-n *alias_name*

Specifies the name of the alias you want to add. See `sendmail(1M)`.

■ For subcommand delete:

-h

(Optional) Displays the command's usage statement.

- n *alias_name*
Specifies the alias you want to delete.
- For subcommand **list**:
 - h
(Optional) Displays the command's usage statement.
 - n *alias_name*
(Optional) Specifies the name of the alias you want to display. If you do not specify an alias, all aliases are listed.
- For subcommand **modify**:
 - a *address1* -a *address2* . . .
(Optional) Specifies new email address(es) to replace the existing one(s). See [sendmail\(1M\)](#).
 - h
(Optional) Displays the command's usage statement.
 - n *alias_name*
(Optional) Specifies the name of the alias you want to modify.
 - N *new_alias_name*
Specifies the new alias name. Use only when renaming an alias. See [sendmail\(1M\)](#).

EXAMPLES

EXAMPLE 1 Creating an alias

The following creates the `coworkers` alias and adds the following member list: `bill@machine1`, `sue@machine2`, and `me@machine3` to the alias.

```
./smmailist add -H myhost -p mypasswd -u root -- -n coworkers \  
-a bill@machine1 -a sue@machine2 -a me@machine3
```

EXAMPLE 2 Deleting a mail alias

The following deletes the `my_alias` alias:

```
./smmailist delete -H myhost -p mypasswd -u root -- -n my_alias
```

EXAMPLE 3 Displaying members of a mail alias

The following displays the list of members belonging to the `my_alias` alias:

```
./smmailist list -H myhost -p mypasswd -u root -- -n my_alias
```

EXAMPLE 4 Displaying members of all mail aliases

The following displays the list of members belonging to all mail aliases:

```
./smmailist list -H myhost -p mypasswd -u root --
```

EXAMPLE 5 Renaming a mail alias

The following renames the `current_name` mail alias to `new_name`:

smmaillist(1M)

EXAMPLE 5 Renaming a mail alias (Continued)

```
./smmaillist modify -H myhost -p mypasswd -u root -- \  
-n current_name -N new_name
```

EXAMPLE 6 Redefining an address list

The following changes the recipients of the alias `my_alias` to `bill@machine1`. Any previous recipients are deleted from the alias.

```
./smmaillist modify -H myhost -p mypasswd -u root -- \  
-n my_alias -a bill@machine1
```

ENVIRONMENT VARIABLES

See `environ(5)` for a description of the `JAVA_HOME` environment variable, which affects the execution of the `smmaillist` command. If this environment variable is not specified, the `/usr/java` location is used. See `smc(1M)`.

EXIT STATUS

The following exit values are returned:

- 0 Successful completion.
- 1 Invalid command syntax. A usage message displays.
- 2 An error occurred while executing the command. An error message displays.

FILES

The following files are used by the `smmaillist` command:

`/var/mail/aliases` Aliases for `sendmail(1M)`. See `aliases(4)`.

ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWmga

SEE ALSO

NAME	smmultiuser – manage bulk operations on user accounts						
SYNOPSIS	<code>/usr/sadm/bin/smmultiuser subcommand [auth_args] - - [subcommand_args]</code>						
DESCRIPTION	The <code>smmultiuser</code> command allows bulk operations on user entries in the local <code>/etc</code> filesystem or a NIS or NIS+ name service, using either an input file or piped input. <i>Note:</i> Both input files and piped input contain a cleartext (non-encrypted) password for each new user entry.						
subcommands	<code>smmultiuser</code> subcommands are: <table> <tr> <td>add</td><td>Adds multiple user entries to the appropriate files. To add an entry, the administrator must have the <code>solaris.admin.usermgr.write</code> authorization.</td></tr> <tr> <td>delete</td><td>Deletes one or more user entries from the appropriate files. To delete an entry, the administrator must have the <code>solaris.admin.usermgr.write</code> authorization.</td></tr> <tr> <td>modify</td><td> Modifies existing user entries in the user account database. To modify an entry, the administrator must have the <code>solaris.admin.usermgr.write</code> authorization. Here is the list of what can be modified using the <code>modify</code> subcommand: 1. UserName (only under certain conditions; see Note 2 in NOTES). 2. Password (only under certain conditions; see Note 3 in NOTES). To modify a password, the administrator must have the <code>solaris.admin.usermgr.pswd</code> authorization. 3. Description. 4. Primary Group ID. 5. Shell type. 6. FullName. </td></tr> </table>	add	Adds multiple user entries to the appropriate files. To add an entry, the administrator must have the <code>solaris.admin.usermgr.write</code> authorization.	delete	Deletes one or more user entries from the appropriate files. To delete an entry, the administrator must have the <code>solaris.admin.usermgr.write</code> authorization.	modify	Modifies existing user entries in the user account database. To modify an entry, the administrator must have the <code>solaris.admin.usermgr.write</code> authorization. Here is the list of what can be modified using the <code>modify</code> subcommand: 1. UserName (only under certain conditions; see Note 2 in NOTES). 2. Password (only under certain conditions; see Note 3 in NOTES). To modify a password, the administrator must have the <code>solaris.admin.usermgr.pswd</code> authorization. 3. Description. 4. Primary Group ID. 5. Shell type. 6. FullName.
add	Adds multiple user entries to the appropriate files. To add an entry, the administrator must have the <code>solaris.admin.usermgr.write</code> authorization.						
delete	Deletes one or more user entries from the appropriate files. To delete an entry, the administrator must have the <code>solaris.admin.usermgr.write</code> authorization.						
modify	Modifies existing user entries in the user account database. To modify an entry, the administrator must have the <code>solaris.admin.usermgr.write</code> authorization. Here is the list of what can be modified using the <code>modify</code> subcommand: 1. UserName (only under certain conditions; see Note 2 in NOTES). 2. Password (only under certain conditions; see Note 3 in NOTES). To modify a password, the administrator must have the <code>solaris.admin.usermgr.pswd</code> authorization. 3. Description. 4. Primary Group ID. 5. Shell type. 6. FullName.						
OPTIONS	The <code>smmultiuser</code> authentication arguments, <i>auth_args</i>, are derived from the <code>smc(1M)</code> arg set and are the same regardless of which subcommand you use. The <code>smmultiuser</code> command requires the Solaris Management Console to be initialized for the command to succeed (see <code>smc(1M)</code>). After rebooting the Solaris Management Console server, the first Solaris Management Console connection might time out, so you might need to retry the command. The subcommand-specific options, <i>subcommand_args</i>, must come after the <i>auth_args</i> and must be separated from them by the <code>- -</code> option.						
auth_args	The valid <i>auth_args</i> are <code>-D</code>, <code>-H</code>, <code>-l</code>, <code>-p</code>, <code>-r</code>, <code>- -trust</code>, and <code>-u</code>; they are all optional. If no <i>auth_args</i> are specified, certain defaults will be assumed and the user may be prompted for additional information, such as a password for authentication purposes. These letter options can also be specified by their equivalent option words preceded by a double dash. For example, you can use either <code>-D</code> or <code>- -domain</code>.						

smmultiuser(1M)

-D | - -domain *domain*

Specifies the default domain that you want to manage. The syntax of *domain* is *type:/host_name/domain_name*, where *type* is *nis*, *nisplus*, *dns*, *ldap*, or *file*; *host_name* is the name of the machine that serves the domain; and *domain_name* is the name of the domain you want to manage. (Note: Do not use *nis+* for *nisplus*.)

If you do not specify this option, the Solaris Management Console assumes the *file* default domain on whatever server you choose to manage, meaning that changes are local to the server. Toolboxes can change the domain on a tool-by-tool basis; this option specifies the domain for all other tools.

-H | - -hostname *host_name:port*

Specifies the *host_name* and *port* to which you want to connect. If you do not specify a *port*, the system connects to the default port, 898. If you do not specify *host_name:port*, the Solaris Management Console connects to the local host on port 898. You may still have to choose a toolbox to load into the console. To override this behavior, use the *smc(1M)* -B option, or set your console preferences to load a "home toolbox" by default.

-l | - -rolepassword *role_password*

Specifies the password for the *role_name*. If you specify a *role_name* but do not specify a *role_password*, the system prompts you to supply a *role_password*. Passwords specified on the command line can be seen by any user on the system, hence this option is considered insecure.

-p | - -password *password*

Specifies the password for the *user_name*. If you do not specify a password, the system prompts you for one. Passwords specified on the command line can be seen by any user on the system, hence this option is considered insecure.

-r | - -rolename *role_name*

Specifies a role name for authentication. If you do not specify this option, no role is assumed.

- -trust

Trusts all downloaded code implicitly. Use this option when running the terminal console non-interactively and you cannot let the console wait for user input.

If using piped input into any of the *smmultiuser* subcommands, it will now be necessary to use the - -trust option with the -L *logfile* option. See EXAMPLES.

-u | - -username *user_name*

Specifies the user name for authentication. If you do not specify this option, the user identity running the console process is assumed.

- -

This option is required and must always follow the preceding options. If you do not enter the preceding options, you must still enter the - - option.

subcommand_args

Note: Descriptions and other arg options that contain white spaces must be enclosed in double quotes.

- For subcommand **add**:
 - h
(Optional) Displays the command's usage statement.
 - i *input_file*
Specifies the input file containing the user account information. After the command is executed, the input file is removed. The input file must follow the `/etc/passwd` file format. If you do not specify the -i *input_file* option, you must include a *pipedReader* operand immediately before the command. See EXAMPLES.
 - L *logfile*
(Optional) Specifies the full pathname to the text file that stores the command's success/failure data. *Note*: This text file is an ASCII—formatted log file; it is different from and unrelated to the output of the normal logging mechanism that also occurs within the Log Viewer tool. The -L *logfile* option is used to dump additional logging information to a text file.
- For subcommand **delete**:
 - h
(Optional) Displays the command's usage statement.
 - i *input_file*
Specifies the input file containing the user account information. After the command is executed, the input file is removed. The input file must follow the `/etc/passwd` file format. If you do not specify the -i *input_file* option, you must include a *pipedReader* operand immediately before the command. See EXAMPLES.
 - L *logfile*
(Optional) Specifies the full pathname to the text file that stores the command's success/failure data.
- For subcommand **modify**:
 - h
(Optional) Displays the command's usage statement.
 - i *input_file*
Specifies the input file containing the user account information. After the command is executed, the input file is removed. The input file must follow the `/etc/passwd` file format. If you do not specify the -i *input_file* option, you must include a *pipedReader* operand immediately before the command. See EXAMPLES. *Note*: When modifying passwords, use the pipedReader input, since it is more secure than keeping passwords in a file. See Note 1 in NOTES.
 - L *logfile*
(Optional) Specifies the full pathname to the text file that stores the command's success/failure data.

OPERANDS The following operands are supported:

smmultiuser(1M)

	<i>pipedReader</i> You must include <i>pipedReader</i> if you do not specify an <i>input_file</i>. Include the pipedReader immediately before the command. The pipedReader must follow the <code>/etc/passwd</code> file format. See EXAMPLES. <i>Note:</i> Use the <code>-t trust</code> option when using pipedReader with the <code>-L logfile</code> option to avoid the user prompt from the Security Alert Manager, which normally asks the user whether the log file should be created. Without the <code>-t trust</code> option, the pipedReader is improperly taken as the answer to the prompt before the user can answer “Y” or “N”, and the logging operation will probably fail.						
EXAMPLES	EXAMPLE 1 Creating multiple user accounts The following reads in user account data from the <code>/tmp/foo</code> file and creates new user accounts on the local file system. The input file is formatted in the <code>/etc/passwd</code> format. <pre>./smmultiuser add -H myhost -p mypasswd -u root -- -i /tmp/foo</pre> EXAMPLE 2 Deleting multiple user accounts The following reads in user account data from the <code>/tmp/foo</code> file and deletes the named user accounts from the local file system: <pre>./smmultiuser delete -H myhost -p mypasswd -u root -- -i /tmp/foo</pre> EXAMPLE 3 Creating a log file with pipedReader input The following example shows the use of the <code>smc(1M) -t trust</code> option that is required when creating a log file. It is applicable to the <code>delete</code> and <code>modify</code> subcommands also. <pre>cat /tmp/users.txt smmultiuser add --trust -- -L /tmp/mylog.txt</pre>						
ENVIRONMENT VARIABLES	See <code>environ(5)</code> for a description of the <code>JAVA_HOME</code> environment variable, which affects the execution of the <code>smprofile</code> command. If this environment variable is not specified, the <code>/usr/java</code> location is used. See <code>smc(1M)</code>.						
EXIT STATUS	The following exit values are returned: <table> <tr> <td>0</td><td>Successful completion.</td></tr> <tr> <td>1</td><td>Invalid command syntax. A usage message displays.</td></tr> <tr> <td>2</td><td>An error occurred while executing the command. An error message displays.</td></tr> </table>	0	Successful completion.	1	Invalid command syntax. A usage message displays.	2	An error occurred while executing the command. An error message displays.
0	Successful completion.						
1	Invalid command syntax. A usage message displays.						
2	An error occurred while executing the command. An error message displays.						
FILES	The following files are used by the <code>smprofile</code> command:						

/etc/passwd Contains the file format to use for the *input_file* and *pipedReader*. See passwd(4).

ATTRIBUTES See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWmga

SEE ALSO smc(1M), passwd(4), attributes(5), environ(5)

- NOTES**
1. The file format used by both the `add` and `modify` subcommands is the `/etc/passwd` format. But there is an allowance for a mutated version of this file format that contains an extra field at the end of each line to be used for the Full Name. If the extra field is appended to the end of each line, it will be used for the Full Name value, but if it is omitted, it will be assumed that no FullName modification is being done. The extra field is separated with a colon (:), just like all the other fields.

Example of regulation `/etc/passwd` entry:

`rick2:x:101:10:description1:/home/rick2:/bin/sh`Example of `/etc/passwd` variant entry:

`rick2:x:101:10:description1:/home/rick2:/bin/sh:Ricks_fullname`
 2. The modifies are all done based on lookups of the user name in the user tables. If a user name can not be found in this lookup, a secondary check will be made to see if the uid *and* FullName can be found in the user tables. If they are both found, assume that a user rename has occurred. If neither can be found, assume that the user account does not exist and cannot be modified.
 3. If no password is supplied, assume that there is no change to the password information. If a password is being changed, it should be supplied in cleartext as piped input, although this is not required. The password can be supplied in the input file also. Once read in, the password will be changed accordingly.

smoservice(1M)

NAME	smoservice – manage OS services								
SYNOPSIS	/usr/sadm/bin/smoservice <i>subcommand</i> [<i>auth_args</i>] - - [<i>subcommand_args</i>]								
DESCRIPTION	The smoservice command manages OS services. smoservice <i>subcommands</i> are: <table> <tr> <td>add</td><td>Adds the specified OS services.</td></tr> <tr> <td>delete</td><td>Deletes the specified OS services.</td></tr> <tr> <td>list</td><td>Either lists all the installed OS services for the server if you do not specify a hostname, or lists the OS services for the specified diskless client if you do specify a hostname.</td></tr> <tr> <td>patch</td><td>Manages patches on all existing diskless clients. For example, you can use this subcommand to initially establish a patch spool directory on an OS server. Then, you can apply the patch to the spool area, verifying the patch as needed. Once the patch exists in the spool area, you can apply the patch to the clone area. In addition, you can migrate the patched clone area to clients.</td></tr> </table>	add	Adds the specified OS services.	delete	Deletes the specified OS services.	list	Either lists all the installed OS services for the server if you do not specify a hostname, or lists the OS services for the specified diskless client if you do specify a hostname.	patch	Manages patches on all existing diskless clients. For example, you can use this subcommand to initially establish a patch spool directory on an OS server. Then, you can apply the patch to the spool area, verifying the patch as needed. Once the patch exists in the spool area, you can apply the patch to the clone area. In addition, you can migrate the patched clone area to clients.
add	Adds the specified OS services.								
delete	Deletes the specified OS services.								
list	Either lists all the installed OS services for the server if you do not specify a hostname, or lists the OS services for the specified diskless client if you do specify a hostname.								
patch	Manages patches on all existing diskless clients. For example, you can use this subcommand to initially establish a patch spool directory on an OS server. Then, you can apply the patch to the spool area, verifying the patch as needed. Once the patch exists in the spool area, you can apply the patch to the clone area. In addition, you can migrate the patched clone area to clients.								
OPTIONS	The smoservice authentication arguments, <i>auth_args</i>, are derived from the smc(1M) arg set and are the same regardless of which subcommand you use. The smoservice command requires the Solaris Management Console to be initialized for the command to succeed (see smc(1M)). After rebooting the Solaris Management Console server, the first Solaris Management Console connection might time out, so you might need to retry the command. The subcommand-specific options, <i>subcommand_args</i>, must come after the <i>auth_args</i> and must be separated from them by the - - option.								
<i>auth_args</i>	The valid <i>auth_args</i> are -D, -H, -l, -p, -r, and -u; they are all optional. If no <i>auth_args</i> are specified, certain defaults will be assumed and the user may be prompted for additional information, such as a password for authentication purposes. These letter options can also be specified by their equivalent option words preceded by a double dash. For example, you can use either -D or - -domain. -D - -domain <i>domain</i> Specifies the default domain that you want to manage. The syntax of <i>domain</i> is <i>type</i>:/<i>host_name</i>/<i>domain_name</i>, where <i>type</i> is nis, nis+, dns, ldap, or file; <i>host_name</i> is the name of the machine that serves the domain; and <i>domain_name</i> is the name of the domain you want to manage. (Note: Do not use nis+ for nisplus.) If you do not specify this option, the Solaris Management Console assumes the file default domain on whatever server you choose to manage, meaning that changes are local to the server. Toolboxes can change the domain on a tool-by-tool basis; this option specifies the domain for all other tools.								

- H | - -hostname *host_name:port*
Specifies the *host_name* and *port* to which you want to connect. If you do not specify a *port*, the system connects to the default port, 898. If you do not specify *host_name:port*, the Solaris Management Console connects to the local host on port 898. You may still have to choose a toolbox to load into the console. To override this behavior, use the smc(1M) -B option, or set your console preferences to load a "home toolbox" by default.
- l | - -rolepassword *role_password*
Specifies the password for the *role_name*. If you specify a *role_name* but do not specify a *role_password*, the system prompts you to supply a *role_password*. Passwords specified on the command line can be seen by any user on the system, hence this option is considered insecure.
- p | - -password *password*
Specifies the password for the *user_name*. If you do not specify a password, the system prompts you for one. Passwords specified on the command line can be seen by any user on the system, hence this option is considered insecure.
- r | - -rolename *role_name*
Specifies a role name for authentication. If you do not specify this option, no role is assumed.
- u | - -username *user_name*
Specifies the user name for authentication. If you do not specify this option, the user identity running the console process is assumed.
- -
This option is required and must always follow the preceding options. If you do not enter the preceding options, you must still enter the - - option.

subcommand_args

Note: Descriptions and other arg options that contain white spaces must be enclosed in double quotes.

- For subcommand add:

- h
(Optional) Displays the command's usage statement.
- o *os_server*
(Optional) Specifies the name of the host where the OS service filesystems reside. If this option is not specified, the host will be the same as that specified in the smc(1M) -D option. This option is useful in the event that the name service server and the OS server are not the same machine.
- x *mediapath=path*
Specifies the full path to the Solaris CD image.
- x *platform=platform*
Specifies the OS service to add. The instruction architecture, machine class, OS, and version are given in the form:

smoservice(1M)

instruction_set.machine_class.Solaris_os_version for example,
`sparc.sun4m.Solaris_9`

`-x cluster=cluster`

Specifies the Solaris cluster to install. For example, `SUNWCa11`.

`-x locale=locale[locale, . . .]`

(Optional) Specifies the locales to install from the specified cluster. A comma-delimited list of locales can be specified.

■ For subcommand `delete`:

`-h`

(Optional) Displays the command's usage statement.

`-o os_server`

(Optional) Specifies the name of the host where the OS service filesystems reside. If this option is not specified, the host will be the same as that specified in the `smc(1M) -D` option. This option is useful in the event that the name service server and the OS server are not the same machine.

`-x rmplatform=platform`

Specifies the OS service to remove. The instruction architecture, machine class, OS, and version are given in the form:

instruction_set.machine_class.Solaris_os_version for example,
`sparc.all.Solaris_9`. *Note:* Only a machine class of `all` is supported.

■ For subcommand `list`:

`-h`

(Optional) Displays the command's usage statement.

`-o os_server`

(Optional) Specifies the name of the host where the OS service filesystems reside. If this option is not specified, the host will be the same as that specified in the `smc(1M) -D` option. This option is useful in the event that the name service server and the OS server are not the same machine.

■ For subcommand `patch`:

`-a patch_directory/patch_ID`

Adds the specified patch, *patch_ID*, to the spool directory. *patch_directory* specifies the source path of the patch to be spooled which includes the patchid directory name. Patches are spooled to `/export/diskless/Patches/`. If the patch being added obsoletes an existing patch in the spool, the obsolete patch is moved to the archive area, `/export/diskless/Patches/Archive` (to be restored if this new patch is ever removed).

`-h`

(Optional) Displays the command's usage statement.

-m

(Optional) Synchronizes spooled patches with offline copies of each diskless client OS service on the server. Spooled patches and applied patches are compared so that newly spooled patches can be installed and patches recently removed from the spool can be backed out. This option does not apply to patches directly to diskless client OS services or diskless clients; the -u option must be used to update the services and clients with the changes. Clients are not required to be down at this time, as all patching is done off line. *Note:* The server is fully available during this operation.

-P

Lists all currently spooled patches with an associated synopsis. The list is split up into sections detailing the patches for each OS and architecture in this format:

```
Solaris os_rell architecture1:
patchid Synopsis
patchid Synopsis
.....
Solaris os_rell architecture2:
patchid Synopsis
.....
```

-r *patchid*

Removes the specified patchid from the spool if it is not a requirement for any of the other patches in the spool. All archived patches that were obsoleted by the removed patch are restored to the spool.

-U

(Optional) Updates all diskless client OS services and diskless clients with any changes after synchronizing patches with the -m option. Clients must be brought down during this operation. Once execution has completed, each client should be booted again.

EXAMPLES

EXAMPLE 1 Creating a new OS service

The following command adds an OS service for Solaris 9 for the sun4u machine class where the OS server is *not* using a name service:

```
example% /usr/sadm/bin/smoservice add -- \
-x mediapath=/net/imageserver/5.8/sparc \
-x platform=sparc.sun4u.Solaris_9 \
-x cluster=SUNWCXall -x locale=en_US
```

The following command adds an OS service for Solaris 9 for the sun4u machine class where the OS server is using NIS, the NIS server is nisserver, the OS server is osserver, and the port to which you connect on osserver is 898:

```
example% /usr/sadm/bin/smoservice add -D nis:/nisserver/my.domain.com -- \
-H osserver:898 -- \
-x mediapath=/net/imageserver/5.8/sparc \
-x platform=sparc.sun4u.Solaris_9 \
```

smoservice(1M)

```
-x cluster=SUNWCXall -x locale=en_US \  
-o osserver
```

In the preceding example, the OS service is placed in `/export` on `osserver`, while the `hosts.byaddr`, `ethers`, and `bootparams` maps are updated on the NIS server.

EXAMPLE 2 Deleting an OS service

The following command deletes the OS service for Solaris 9 for the `sun4u` machine class where the OS server is using NIS, the NIS server is `nissERVER`, and the OS server is `osserver`:

```
example% /usr/sadm/bin/smoservice delete\  
-D nis:/nissERVER/my.domain.com -- \  
-x rmpatform=sparc.all.Solaris_9 \  
-o osserver
```

EXAMPLE 3 Listing installed OS services

The following command lists the OS services installed on the machine, `osserver`:

```
example% /usr/sadm/bin/smoservice list \  
-D file:/osserver/osserver -- -o osserver
```

ENVIRONMENT VARIABLES

See `environ(5)` for a description of the `JAVA_HOME` environment variable, which affects the execution of the `smoservice` command. If this environment variable is not specified, the `/usr/java1.2` location is used. See `smc(1M)`.

EXIT STATUS

The following exit values are returned:

0	Successful completion.
1	Invalid command syntax. A usage message displays.
2	An error occurred while executing the command. An error message displays.

ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWdclnt

NAME	smpatch – manage patches
SYNOPSIS	<code>/usr/sadm/bin/smpatch subcommand [auth_args] -- [subcommand_args]</code>
DESCRIPTION	The <code>smpatch</code> command manages patch installation on single or multiple machines, analyzes patch requirements, and downloads required patches. To run this command on multiple machines, you must first create a role on each machine that contains the necessary rights to perform patch management. In addition, all of the machines on which you want to install patches must run the same version of the Solaris operating environment, have the same hardware architecture, and have the same patches installed.
Subcommands	The following subcommands are supported: add Installs patches on single or multiple machines. You can either specify the patch IDs and the machine names directly on the command line, or you can specify a <i>patchlist_file</i> and a <i>machinelist_file</i> that contains the list of patches and the machines on which you want to install the patches, respectively. analyze Analyzes and lists the patches required for a specified machine. You must first install the PatchPro application on the host machine before you run the <code>analyze</code> command. To install PatchPro, download the packages from the Sun Microsystems web site and follow the instructions to install the software on your machine. download Downloads patches from the SunSolve Online database to the patch directory. You can either specify the patches that you want to download, or you can specify a machine name to download the recommended patches for that machine. You must first install the PatchPro application on the host machine before you run the <code>download</code> command. To install PatchPro, download the packages from the Sun Microsystems web site and follow the instructions to install the software on your machine. remove Removes a single patch from a system. update Analyzes the single local or remote system, downloads the recommended patches, and installs the recommended patches on the system. The default installation policy installs the standard patches and sequesters the non-standard patches. Standard patches can be safely installed in a multi-user mode. Non-standard patches require special installation instructions. You can find these instructions in the README file for each patch. To change the installation policy, refer to PatchPro documentation (<code>pprosetup</code>). You must install the PatchPro application on the host machine before running the <code>update</code> command. To

smpatch(1M)

	install PatchPro, download the packages from http://www.sun.com and follow the instructions to install the software on your machine.
OPTIONS	There are two kinds of options: authentication arguments (<i>auth_args</i>) and subcommand arguments (<i>subcommand_args</i>).
Authentication Arguments	The <code>smpatch</code> authentication arguments, <i>auth_args</i>, are derived from the <code>smc(1M)</code> argument set and are the same regardless of which subcommand you use. Valid <i>auth_args</i> are <code>-D</code>, <code>-H</code>, <code>-l</code>, <code>-p</code>, <code>-r</code>, and <code>-u</code>; they are all optional. If no <i>auth_args</i> are specified, certain defaults will be assumed and the user may be prompted for additional information, such as a password for authentication purposes. The single letter options can also be specified by their equivalent option words preceded by a double dash. For example, you can use either <code>-D</code> or <code>--domain</code>. Descriptions and other arg options that contain white spaces must be enclosed in double quotes. The following authentication arguments (<i>auth_args</i>) are supported: <code>-D</code> <code>--domain</code> <i>domain</i> Specifies the default domain that you want to manage. <code>smpatch</code> only accepts files for this option. If you do not specify this option, the Solaris Management Console assumes the file default domain on whatever server you choose to manage, meaning that changes are local to the server. Toolboxes can change the domain on a tool-by-tool basis; this option specifies the domain for all other tools. <code>-H</code> <code>--hostname</code> <i>host_name:port</i> Specifies the host and port to which you want to connect. If you do not specify a port, the system connects to the default port, 898. If you do not specify a host (<i>host_name:port</i>, the Solaris Management Console connects to the local host on port 898. You may still have to choose a toolbox to load into the console. To override this behavior, use the <code>smc -B</code> option, or set your console preferences to load a home toolbox by default. <code>-l</code> <code>--rolepassword</code> <i>role_password</i> Specifies the password for the <i>role_name</i>. If you specify a <i>role_name</i> but do not specify a <i>role_password</i>, the system prompts you to supply a <i>role_password</i>. Passwords specified on the command line can be seen by any user on the system, hence this option is considered insecure. <code>-p</code> <code>--password</code> <i>password</i> Specifies the password for the <i>user_name</i>. If you do not specify a password, the system prompts you for one. Because passwords specified on the command line can be seen by any user on the system, this option is considered insecure. <code>-r</code> <code>--rolename</code> <i>role_name</i> Specifies a role name for authentication. If you do not specify this option, no role is assumed.

Subcommand Arguments

`-u | --username user_name`

Specifies the user name for authentication. If you do not specify this option, the user identity running the console process is assumed.

`--`

This option is required and must always follow the preceding options. If you do not enter the preceding options, you must still enter the `--` option.

The subcommand-specific options, `subcommand_args`, must come after the `auth_args` and must be separated from them by the `--` option. Enclose descriptions and `arg` options that contain white space in double quotes.

add

The add subcommand requires one of the following subcommand arguments:

`-i patch_id1 -i patch_id2 . . .`

Specifies the patch or patches that you want to install. You can specify the `-x idlist=patch_id_file` operand instead of specifying this option.

`-x idlist=patchlist_file`

Specifies a file that contains the list of patches that you want to install. You can specify the `-i patch_id1` option instead of specifying this operand.

The following subcommand arguments are optional for the add subcommand:

`-d patchdir`

Specifies the directory where the patches are located. If you do not specify this option, the default patch spool directory (`/var/sadm/spool`), located on the host specified with the `-H` authentication argument, is assumed. The patch directory has the following syntax: *machine_name* : *directory_path*, where *directory_path* is a fully-qualified, shared directory. You can specify just the *directory_path* if the directory is an NFS-mounted network directory or is located on the machine on which you want to install the patches.

`-h`

Displays the command's usage statement.

`-n machine_name1 -n machine_name2 . . .`

Specifies the machine(s) on which you want to install the patches. If you do not specify this option, the machine is assumed to be that specified with the `-H` authentication argument. You can specify the `-x mlist=machine_name_file` operand instead of specifying this option.

`-x mlist=machinelist_file`

Specifies a file that contains the list of machines to which you want to install patches. You can specify the `-n machine_name1` option instead of specifying this operand.

analyze

The following subcommand arguments are optional for the analyze subcommand:

`-h`

Displays the command's usage statement.

smpatch(1M)

-n machine_name

Specifies the machine for which you want to display a list of patches recommended by SunSolve. If you do not specify this option, the machine is assumed to be that specified by the *-H* authentication argument.

download

The `download` subcommand requires one of the following subcommand arguments:

-i patch_id1 -i patch_id2 . . .

Specifies the patch or patches that you want to download. You can specify the *-x idlist=patch_id_file* operand instead of this option or you can omit this argument in favor of *-n download_machine* option.

-x idlist=patchlist_file

Specifies the file containing the list of patches that you want to download. You can specify this operand instead of specifying the *-i patch_id1* option.

The following subcommand arguments are optional for the `download` subcommand:

-n download_machine

Specifies the machine on which you want to download the recommended patches. If you do not specify this option, the machine is assumed to be that specified by the *-H* authentication argument.

-d download_dir

Specifies the directory where the patches are downloaded. This directory must have write permission and be accessible to the `download_machine`. If you do not specify this option, the default patch spool directory (`/var/sadm/spool`) located on the download machine is assumed.

remove

The `remove` subcommand requires the following arguments:

-i patch_id

Specifies the patch that you want to remove.

The following subcommand arguments are optional for the `remove` subcommand:

-n machine

Specifies the machine on which you want to remove the recommended patches. If you do not specify this option, the machine is assumed to be that specified by the *-H* authentication argument.

update

The following subcommand arguments are optional for the `update` subcommand:

-n machine_name

Specifies the machine for which you want to display a list of patches recommended by SunSolve. If you do not specify this option, the machine is assumed to be that specified by the *-H* authentication argument.

-d *patchdir*

Specifies the directory where the patches are downloaded. This directory must have write permission and must be accessible to the machine that is being analyzed. If you do not specify this option, the default patch spool directory (`/var/sadm/spool`) located on the machine that is being analyzed is assumed. After the required patches are downloaded, they are installed from the effective patch directory.

Patches that could not be installed are sequestered to the `patchdir/patchproSequester` directory, where *patchdir* is the effective patch directory. See `update -d`.

OPERANDS The following operands are supported:

<i>machinelist_file</i>	Specifies the fully-qualified path and file name of the file containing the list of machine names on which you want to install the patches. The <i>machinelist_file</i> file contains one machine name per line.
<i>patchlist_file</i>	Specifies the fully-qualified path and file name of the file containing the list of patches that you want to install. The <i>patchlist_file</i> contains one patch ID per line.

EXAMPLES **EXAMPLE 1** Installing Patches on Multiple Machines

The following example installs patches 102893-01, 106895-09, and 106527-05 on the machines lab1 and lab2. The patches are located in the `/files/patches/s9` shared directory on the machine fileserver:

```
/usr/sadm/bin/smpatch add -H myhost -p mypasswd -u root -- \
-i 102893-01 -i 106895-09 -i 106527-05 \
-d fileserver:/files/patches/s9 \
-n lab1 -n lab2
```

EXAMPLE 2 Installing Patches Using a `patch_list` File

The following example specifies the `/tmp/patch/patch_file` to install patches on the machines lab1 and lab2. The patches are located in the NFS network-mounted directory `/net/fileserver/export/patchspool/Solaris9`:

```
/usr/sadm/bin/smpatch add -H myhost -p mypasswd -u root -- \
-x mlist=/tmp/patch/patch_file \
-d /net/fileserver/export/patchspool/Solaris9 \
-n lab1 -n lab2
```

EXAMPLE 3 Installing Patches Using a `patch_list` File and a `machine_list` File

The following example installs the patches listed in `/tmp/patch/patch_file` on the machines listed in `/tmp/patch/machine_file`. The patches are located in the default `/var/sadm/spool` directory on the default machine myhost.

smpatch(1M)

EXAMPLE 3 Installing Patches Using a patch_list File and a machine_list File *(Continued)*

```
/usr/sadm/bin/smpatch add -H myhost -p mypasswd -u root -- \
-x mlist=/tmp/patch/patch_file \
-x mlist=/tmp/patch/machine_file
```

EXAMPLE 4 Analyzing and Downloading Patches from Sunsolve Online

The following example analyzes the lab1 machine and downloads the assessed patches from the Sunsolve Online database to the default patch pool directory.

```
/usr/sadm/bin/smpatch download -p mypasswd -u root -- -n lab1
```

EXAMPLE 5 Downloading Patches From the Sunsolve Database

The following example downloads the 102893-01 and 106895-09 patches from the Sunsolve Online database to the /files/patches/s8 directory located on the default machine.

```
/usr/sadm/bin/smpatch download -p mypasswd -u root -- \
-i 102893-01 -i 106895-09 -d /files/patches/s8
```

EXAMPLE 6 Removing Patches

The following example removes patch 102893-01:

```
/usr/sadm/bin/smpatch remove -p mypasswd -u root -- \
-i 10283-01
```

EXAMPLE 7 Updating Your System

The following example analyzes your local or remote system and lists the recommended patches. It downloads them in a specified directory and installs the standard patches:

```
/usr/sadm/bin/smpatch update -u root --
```

ENVIRONMENT VARIABLES

See environ(5) for descriptions of the following environment variables that affect the execution of smpatch: JAVA_HOME. If this environment variable is not specified, the /usr/java location is used. See smc(1M).

EXIT STATUS

The following exit values are returned:

0	Successful completion.
1	Invalid command syntax. A usage message displays.
2	An error occurred while executing the command. An error message displays.

smpatch(1M)

ATTRIBUTES See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWmga

smprofile(1M)

NAME	smprofile – manage profiles in the prof_attr and exec_attr databases								
SYNOPSIS	<code>/usr/sadm/bin/smprofile subcommand [auth_args] - - [subcommand_args]</code>								
DESCRIPTION	The smprofile command manages one or more profiles in the prof_attr(4) or exec_attr(4) databases in the local /etc files name service or a NIS or NIS+ name service.								
<i>subcommands</i>	smprofile subcommands are: <table> <tr> <td>add</td><td>Adds a new profile (right) to the prof_attr(4) database. To add a profile, the administrator must have the solaris.profmgr.write authorization.</td></tr> <tr> <td>delete</td><td>Deletes a profile from the prof_attr(4) database, deletes all associated entries from the exec_attr(4) database, and deletes the assigned profile from the user_attr(4) database. To delete a profile, the administrator must have the solaris.profmgr.execattr.write and solaris.profmgr.write authorization.</td></tr> <tr> <td>list</td><td>Lists one or more profiles from the prof_attr(4) or exec_attr(4) databases. To list a profile, the administrator must have the solaris.profmgr.read authorization.</td></tr> <tr> <td>modify</td><td>Modifies a profile in the prof_attr(4) database. To modify a profile, the administrator must have the solaris.profmgr.write authorization.</td></tr> </table>	add	Adds a new profile (right) to the prof_attr(4) database. To add a profile, the administrator must have the solaris.profmgr.write authorization.	delete	Deletes a profile from the prof_attr(4) database, deletes all associated entries from the exec_attr(4) database, and deletes the assigned profile from the user_attr(4) database. To delete a profile, the administrator must have the solaris.profmgr.execattr.write and solaris.profmgr.write authorization.	list	Lists one or more profiles from the prof_attr(4) or exec_attr(4) databases. To list a profile, the administrator must have the solaris.profmgr.read authorization.	modify	Modifies a profile in the prof_attr(4) database. To modify a profile, the administrator must have the solaris.profmgr.write authorization.
add	Adds a new profile (right) to the prof_attr(4) database. To add a profile, the administrator must have the solaris.profmgr.write authorization.								
delete	Deletes a profile from the prof_attr(4) database, deletes all associated entries from the exec_attr(4) database, and deletes the assigned profile from the user_attr(4) database. To delete a profile, the administrator must have the solaris.profmgr.execattr.write and solaris.profmgr.write authorization.								
list	Lists one or more profiles from the prof_attr(4) or exec_attr(4) databases. To list a profile, the administrator must have the solaris.profmgr.read authorization.								
modify	Modifies a profile in the prof_attr(4) database. To modify a profile, the administrator must have the solaris.profmgr.write authorization.								
OPTIONS	The smprofile authentication arguments, <i>auth_args</i>, are derived from the smc(1M) arg set and are the same regardless of which subcommand you use. The smprofile command requires the Solaris Management Console to be initialized for the command to succeed (see smc(1M)). After rebooting the Solaris Management Console server, the first Solaris Management Console connection might time out, so you might need to retry the command. The subcommand-specific options, <i>subcommand_args</i>, must come after the <i>auth_args</i> and must be separated from them by the - - option.								
<i>auth_args</i>	The valid <i>auth_args</i> are -D, -H, -l, -p, -r, and -u; they are all optional. If no <i>auth_args</i> are specified, certain defaults will be assumed and the user may be prompted for additional information, such as a password for authentication purposes. These letter options can also be specified by their equivalent option words preceded by a double dash. For example, you can use either -D or - -domain with the <i>domain</i> argument. -D - -domain <i>domain</i> Specifies the default domain that you want to manage. The syntax of <i>domain</i> is <i>type:/host_name/domain_name</i>, where <i>type</i> is nis, nisplus, dns, ldap, or file; <i>host_name</i> is the name of the machine that serves the domain; and <i>domain_name</i> is the name of the domain you want to manage. (Note: Do not use nis+ for nisplus.)								

If you do not specify this option, the Solaris Management Console assumes the file default domain on whatever server you choose to manage, meaning that changes are local to the server. Toolboxes can change the domain on a tool-by-tool basis; this option specifies the domain for all other tools.

-H | - *-hostname host_name:port*

Specifies the *host_name* and *port* to which you want to connect. If you do not specify a *port*, the system connects to the default port, 898. If you do not specify *host_name:port*, the Solaris Management Console connects to the local host on port 898. You may still have to choose a toolbox to load into the console. To override this behavior, use the `smc(1M) -B` option, or set your console preferences to load a "home toolbox" by default.

-l | - *-rolepassword role_password*

Specifies the password for the *role_name*. If you specify a *role_name* but do not specify a *role_password*, the system prompts you to supply a *role_password*. Passwords specified on the command line can be seen by any user on the system, hence this option is considered insecure.

-p | - *-password password*

Specifies the password for the *user_name*. If you do not specify a password, the system prompts you for one. Passwords specified on the command line can be seen by any user on the system, hence this option is considered insecure.

-r | - *-rolename role_name*

Specifies a role name for authentication. If you do not specify this option, no role is assumed.

-u | - *-username user_name*

Specifies the user name for authentication. If you do not specify this option, the user identity running the console process is assumed.

- -

This option is required and must always follow the preceding options. If you do not enter the preceding options, you must still enter the **- -** option.

subcommand_args

Note: Descriptions and other arg options that contain white spaces must be enclosed in double quotes.

■ For subcommand **add**:

-a *addauth1* **-a** *addauth2* . . .

(Optional) Specifies the authorization name(s) to add to the new profile. The administrator must have the `solaris.profmgr.write` authorization and must have the corresponding "grant" authorization. A "grant" authorization is one in which the lowest component of the authorization name is replaced by the word `grant`. For example, to grant some profile the `solaris.role.write` authorization, the administrator needs that authorization and also the `solaris.role.grant` authorization. For more information on granting authorizations, see `auth_attr(4)`.

smprofile(1M)

- d *description*
Specifies the description of the new profile.
- h
(Optional) Displays the command's usage statement.
- m *html_help*
Specifies the HTML help file name for the new profile. The help file name must be put in the `/usr/lib/help/profiles/locale/C` directory.
- n *name*
Specifies the name of the new profile.
- p *addprof1* -p *addprof2* . . .
(Optional) Specifies the supplementary profile name(s) to add to the new profile.
- For subcommand `delete`:
 - h
(Optional) Displays the command's usage statement.
 - n *name*
Specifies the name of the profile you want to delete.
- For subcommand `list`:
 - h
(Optional) Displays the command's usage statement.
 - l
(Optional) Displays the detailed output for each profile in a block of *key:value* pairs, followed by a blank line that delimits each profile block. Each *key:value* pair is displayed on a separate line. All the attributes associated with a profile from the `prof_attr` and `exec_attr` databases are displayed. If you do not specify this option, only the specified profile name(s) and associated profile description(s) are displayed.
 - n *name1* -n *name2* . . .
(Optional) Specifies the profile(s) that you want to display. If you do not specify a profile name, all profiles are displayed.
- For subcommand `modify`:
 - a *addauth1* -a *addauth2* . . .
(Optional) Specifies the authorization name(s) to add to the profile. The administrator must currently have been granted each of the specified authorizations and must have the ability to grant each of those authorizations to other users or roles. For more information on granting authorizations, see `auth_attr(4)`.
 - d *description*
(Optional) Specifies the new description of the profile.
 - h
(Optional) Displays the command's usage statement.

- m *html_help*
(Optional) Specifies the new HTML help file name of the profile. If you change this name, you must accordingly rename the help file name entered in the `/usr/lib/help/profiles/locale/C` directory.
- n *name*
Specifies the name of the profile you want to modify.
- p *addprof1* -p *addprof2* ...
(Optional) Specifies the supplementary profile name(s) to add to the profile. The administrator must have the `solaris.profmgr.assign` authorization to add any profile and the `solaris.profmgr.delegate` authorization to add any profile that has been assigned to the authenticated user.
- q *delprof1* -q *delprof2* ...
(Optional) Specifies the supplementary profile name(s) to delete from the profile. The administrator must have the `solaris.profmgr.assign` authorization to delete any profile and the `solaris.profmgr.delegate` authorization to delete any profile that has been assigned to the authenticated user.
- r *delauth1* -r *delauth2* ...
(Optional) Specifies the authorization name(s) to delete from the profile. The administrator must have the `solaris.profmgr.write` authorization and must have the corresponding "grant" authorization. For more information about "grant" authorizations, see the `-a` option description for the `add` subcommand above.

EXAMPLES**EXAMPLE 1** Creating a new profile

The following creates a new User Manager profile on the local file system. The new profile description is Manage users and groups, and the authorizations assigned are `solaris.admin.usermgr.write` and `solaris.admin.usermgr.read`. The supplementary profile assigned is Operator. The help file name is `RtUserMgmt.html`.

```
./smprofile add -H myhost -p mypasswd -u root -- -n "User Manager" \
-d "Manage users and groups" -a solaris.admin.usermgr.write \
-a solaris.admin.usermgr.read -p Operator -m RtUserMgmt.html
```

EXAMPLE 2 Deleting a profile

The following deletes the User Manager profile from the local file system:

```
./smprofile delete -H myhost -p mypasswd -u root -- -n "User Manager"
```

EXAMPLE 3 Listing all profiles

The following lists all profiles and their associated profile descriptions on the local file system.

```
./smprofile list -H myhost -p mypasswd -u root --
```

smprofile(1M)

EXAMPLE 4 Modifying a profile

The following modifies the User Manager profile on the local file system. The new profile description is Manage world, the new authorization assignment is solaris.admin.usermgr.* authorizations, and the new supplementary profile assignment is All. (The -a option argument must be enclosed in double quotes when the wildcard character (*) is used.)

```
./smprofile modify -H myhost -p mypasswd -u root -- -n "User Manager" \  
-d "Manage world" -a "solaris.admin.usermgr.*" -p All
```

ENVIRONMENT VARIABLES

See environ(5) for a description of the JAVA_HOME environment variable, which affects the execution of the smprofile command. If this environment variable is not specified, the /usr/java location is used. See smc(1M).

EXIT STATUS

The following exit values are returned:

0	Successful completion.
1	Invalid command syntax. A usage message displays.
2	An error occurred while executing the command. An error message displays.

FILES

The following files are used by the smprofile command:

/etc/security/exec_attr	Execution profiles database. See exec_attr(4).
/etc/security/prof_attr	Profile description database. See prof_attr(4).
/etc/user_attr	Extended user attribute database. See user_attr(4).

ATTRIBUTES

See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWmga

NAME	smrole – manage roles and users in role accounts								
SYNOPSIS	<code>/usr/sadm/bin/smrole subcommand [auth_args] - - [subcommand_args]</code>								
DESCRIPTION	The smrole command manages roles and adds or deletes users in role accounts.								
subcommands	smrole subcommands are: <table> <tr> <td>add</td><td>Adds a new role entry. To add an entry, the administrator must have the <code>solaris.role.write</code> authorization.</td></tr> <tr> <td>delete</td><td>Deletes one or more roles. To delete an entry, the administrator must have the <code>solaris.role.write</code> authorization.</td></tr> <tr> <td>list</td><td>Lists one or more roles. If you do not specify a role name, all roles are listed. To list an entry, the administrator must have the <code>solaris.admin.usermgr.read</code> authorization.</td></tr> <tr> <td>modify</td><td>Adds or deletes users from a role account. To modify an entry, the administrator must have the <code>solaris.role.write</code> authorization.</td></tr> </table>	add	Adds a new role entry. To add an entry, the administrator must have the <code>solaris.role.write</code> authorization.	delete	Deletes one or more roles. To delete an entry, the administrator must have the <code>solaris.role.write</code> authorization.	list	Lists one or more roles. If you do not specify a role name, all roles are listed. To list an entry, the administrator must have the <code>solaris.admin.usermgr.read</code> authorization.	modify	Adds or deletes users from a role account. To modify an entry, the administrator must have the <code>solaris.role.write</code> authorization.
add	Adds a new role entry. To add an entry, the administrator must have the <code>solaris.role.write</code> authorization.								
delete	Deletes one or more roles. To delete an entry, the administrator must have the <code>solaris.role.write</code> authorization.								
list	Lists one or more roles. If you do not specify a role name, all roles are listed. To list an entry, the administrator must have the <code>solaris.admin.usermgr.read</code> authorization.								
modify	Adds or deletes users from a role account. To modify an entry, the administrator must have the <code>solaris.role.write</code> authorization.								
OPTIONS	The smrole authentication arguments, <i>auth_args</i>, are derived from the smc(1M) arg set and are the same regardless of which subcommand you use. The smrole command requires the Solaris Management Console to be initialized for the command to succeed (see smc(1M)). After rebooting the Solaris Management Console server, the first Solaris Management Console connection might time out, so you might need to retry the command. The subcommand-specific options, <i>subcommand_args</i>, must come after the <i>auth_args</i> and must be separated from them by the - - option.								
auth_args	The valid <i>auth_args</i> are -D, -H, -l, -p, -r, and -u; they are all optional. If no <i>auth_args</i> are specified, certain defaults will be assumed and the user may be prompted for additional information, such as a password for authentication purposes. These letter options can also be specified by their equivalent option words preceded by a double dash. For example, you can use either -D or - --domain with the <i>domain</i> argument. -D - --domain <i>domain</i> Specifies the default domain that you want to manage. The syntax of <i>domain</i> is <i>type: /host_name /domain_name</i>, where <i>type</i> is nis, nisplus, dns, ldap, or file; <i>host_name</i> is the name of the machine that serves the domain; and <i>domain_name</i> is the name of the domain you want to manage. (Note: Do not use nis+ for nisplus.) If you do not specify this option, the Solaris Management Console assumes the file default domain on whatever server you choose to manage, meaning that changes are local to the server. Toolboxes can change the domain on a tool-by-tool basis; this option specifies the domain for all other tools. -H - --hostname <i>host_name:port</i> Specifies the <i>host_name</i> and <i>port</i> to which you want to connect. If you do not specify a <i>port</i>, the system connects to the default port, 898. If you do not specify								

smrole(1M)

host_name:port, the Solaris Management Console connects to the local host on port 898. You may still have to choose a toolbox to load into the console. To override this behavior, use the `smc(1M) -B` option, or set your console preferences to load a “home toolbox” by default.

`-l | - -rolepassword role_password`

Specifies the password for the *role_name*. If you specify a *role_name* but do not specify a *role_password*, the system prompts you to supply a *role_password*. Passwords specified on the command line can be seen by any user on the system, hence this option is considered insecure.

`-p | - -password password`

Specifies the password for the *user_name*. If you do not specify a password, the system prompts you for one. Passwords specified on the command line can be seen by any user on the system, hence this option is considered insecure.

`-r | - -rolename role_name`

Specifies a role name for authentication. If you do not specify this option, no role is assumed.

`-u | - -username user_name`

Specifies the user name for authentication. If you do not specify this option, the user identity running the console process is assumed.

`- -`

This option is required and must always follow the preceding options. If you do not enter the preceding options, you must still enter the `- -` option.

subcommand_args

Note: Descriptions and other arg options that contain white spaces must be enclosed in double quotes.

■ For subcommand `add`:

`-a adduser1 -a adduser2 . . .`

(Optional) Specifies the user name(s) to add to the new role. The administrator must have the `solaris.role.assign` authorization.

`-c comment`

(Optional) Includes a short description of the role. Consists of a string of up to 256 printable characters, excluding the colon (:).

`-d dir`

(Optional) Specifies the home directory of the new role, limited to 1024 characters.

`-F full_name`

(Optional) Specifies the full, descriptive name of the role. The *full_name* must be unique within a domain, and can contain alphanumeric characters and spaces. If you use spaces, you must enclose the *full_name* in double quotes.

-G *group1* -G *group2* . . .

(Optional) Specifies the new role's supplementary group membership in the system group database with the character string names of one or more existing groups. *Note:* You cannot assign a primary group to a role. A role's primary group is always sysadmin (group 14).

-h

(Optional) Displays the command's usage statement.

-n *rolename*

Specifies the name of the role you want to create.

-p *addprof1* -p *addprof2* . . .

(Optional) Specifies the profile(s) to add to the role. To assign a profile to a role, the administrator must have the `solaris.profmgr.assign` or `solaris.profmgr.delegate` authorization.

-P *password*

(Optional) Specifies the role's password. The *password* can contain up to eight characters. If you do not specify a password, the system prompts you for one. To set the password, the administrator must have the `solaris.admin.usermgr.pswd` authorization. *Note:* When you specify a password using the **-P** option, you type the password in plain text. Specifying a password using this method introduces a security gap while the command is running. However, if you do not specify a password (and the system prompts you for one), the echo is turned off when you type in the password.

-s *shell*

(Optional) Specifies the full pathname of the program used as the role's shell on login. Valid entries are `/bin/pfcs` (C shell), `/bin/pfksh` (Korn shell), and `/bin/pfsh` (Bourne shell), the default.

-u *uid*

(Optional) Specifies the ID of the role you want to add. If you do not specify this option, the system assigns the next available unique ID greater than 100.

-x *autohome*=Y|N

(Optional) Sets the role's home directory. The home directory path in the password entry is set to `/home/login name`.

-x *perm*=*home_perm*

(Optional) Sets the permissions on the role's home directory. *perm* is interpreted as an octal number, and the default is 0775.

-x *serv*=*homedir_server*

(Optional) If **-D** is `nis`, `nisplus`, or `ldap`, use this option to specify the name of the server where the user's home directory resides. Users created in a local scope must have their home directory server created on their local machines.

■ For subcommand **delete**:

-h

(Optional) Displays the command's usage statement.

smrole(1M)

- n *rolename1* -n *rolename2* ...
Specifies the name of the role(s) you want to delete.
- For subcommand **list**:
 - h
(Optional) Displays the command's usage statement.
 - l
(Optional) Displays the output for each user in a block of *key:value* pairs (for example, *user name:root*), followed by a blank line that delimits each user block. Each *key:value* pair is displayed on a separate line. The keys are:
autohome setup, *comment*, *home directory*, *login shell*, *primary group*, *secondary groups*, *server*, *user ID (UID)*, and *user name*.
 - n *role1* -n *role2* ...
(Optional) Specifies the role(s) that you want to list. If you do not specify a role name, all roles are listed.
- For subcommand **modify**:
 - a *adduser1* -a *adduser2* ...
(Optional) Specifies the user name(s) to add to the new role. The administrator must have the *solaris.role.assign* authorization, or must have the *solaris.role.delegate* authorization and be a member of the role being modified.
 - c *comment*
(Optional) Includes a short description of the role. Consists of a string of up to 256 printable characters, excluding the colon (:).
 - d *dir*
(Optional) Specifies the home directory of the new role, limited to 1024 characters.
 - F *full_name*
(Optional) Specifies the full, descriptive name of the role. The *full_name* must be unique within a domain, and can contain alphanumeric characters and spaces. If you use spaces, you must enclose the *full_name* in double quotes.
 - G *group1* -G *group2* ...
(Optional) Specifies the new role's secondary group membership in the system group database with the character string names of one or more existing groups.
Note: You cannot assign a primary group to a role. A role's primary group is always *sysadmin* (group 14).
 - h
(Optional) Displays the command's usage statement.
 - n *rolename*
Specifies the name of the role you want to modify.
 - N *new_rolename*
(Optional) Specifies the new name of the role.

- p *addprof1* -p *addprof2* . . .
(Optional) Specifies the profile(s) to add to the role. To assign a profile to a role, the administrator must have the `solaris.profmgr.assign` or `solaris.profmgr.delegate` authorization.
- P *password*
(Optional) Specifies the role's password. The *password* can contain up to eight characters. To set the password, the administrator must have the `solaris.admin.usermgr.pswd` authorization. *Note:* When you specify a password, you type the password in plain text. Specifying a password using this method introduces a security gap while the command is running.
- q *delprof1* -q *delprof2* . . .
(Optional) Specifies the profile(s) to delete from the role.
- r *deluser1* -r *deluser2* . . .
(Optional) Specifies the user name(s) to delete from the role.
- s *shell*
(Optional) Specifies the full pathname of the program used as the role's shell on login. Valid entries are `/bin/pfcs`h (C shell), `/bin/pfksh` (Korn shell), and `/bin/pfsh` (Bourne shell), the default.
- x *autohome=Y|N*
(Optional) Sets the role's home directory. The home directory path in the password entry is set to `/home/login_name`.
- x *perm=home_perm*
(Optional) Sets the permissions on the role's home directory. *perm* is interpreted as an octal number, and the default is 0775.

EXAMPLES**EXAMPLE 1** Creating a role account

The following creates the `role1` account with a full name of Engineering Admin and a password of `abc123` on the local file system, and assigns `user1` and `user2` to the role. This role has Name Service Security and Audit Review rights. The system assigns the next available unique UID greater than 100.

```
./smrole add -H myhost -p mypasswd -u root -- -n role1 \
-F "Engineering Admin" -P abc123 -a user1 -a user2 \
-p "Name Service Security" -p "Audit Review"
```

EXAMPLE 2 Deleting role accounts

The following deletes the `role1` and `role2` accounts from the local file system.

```
./smrole delete -H myhost -p mypasswd -u root -- -n role1 -n role2
```

EXAMPLE 3 Listing role accounts

The following lists all role accounts on the local file system in summary form.

```
./smrole list -H myhost -p mypasswd -u root --
```

smrole(1M)

EXAMPLE 4 Modifying a role account

The following modifies the `role1` account so the role defaults to the Korn shell, includes the `user3` account, and does not include the `user2` account.

```
./smrole modify -H myhost -p mypasswd -u root -- -n role1 \  
-s /bin/pfksh -a user3 -r user2
```

ENVIRONMENT VARIABLES

See `environ(5)` for a description of the `JAVA_HOME` environment variable, which affects the execution of the `smrole` command. If this environment variable is not specified, the `/usr/java` location is used. See `smc(1M)`.

EXIT STATUS

The following exit values are returned:

0	Successful completion.
1	Invalid command syntax. A usage message displays.
2	An error occurred while executing the command. An error message displays.

FILES

The following files are used by the `smrole` command:

<code>/etc/aliases</code>	Mail aliases. See <code>aliases(4)</code> .
<code>/etc/auto_home</code>	Automatic mount points. See <code>automount(1M)</code> .
<code>/etc/group</code>	Group file. See <code>group(4)</code> .
<code>/etc/passwd</code>	Password file. See <code>passwd(4)</code> .
<code>/etc/security/policy.conf</code>	Configuration file for security policy. See <code>policy.conf(4)</code> .
<code>/etc/shadow</code>	Shadow password file. See <code>shadow(4)</code> .
<code>/etc/user_attr</code>	Extended user attribute database. See <code>user_attr(4)</code> .

ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWmga

NAME	smrsh – restricted shell for sendmail				
SYNOPSIS	smrsh -c <i>command</i>				
DESCRIPTION	The smrsh program is intended as a replacement for the sh command in the program mailer in sendmail(1M) configuration files. The smrsh program sharply limits commands that can be run using the program syntax of sendmail. This improves overall system security. smrsh limits the set of programs that a programmer can execute, even if sendmail runs a program without going through an alias or forward file. Briefly, smrsh limits programs to be in the directory /var/adm/sm.bin, allowing system administrators to choose the set of acceptable commands. It also rejects any commands with the characters: , , < , > , , ; , & , \$, \r (RETURN), or \n (NEWLINE) on the command line to prevent end run attacks. Initial pathnames on programs are stripped, so forwarding to /usr/ucb/vacation, /usr/bin/vacation, /home/server/mydir/bin/vacation, and vacation all actually forward to /var/adm/sm.bin/vacation. System administrators should be conservative about populating /var/adm/sm.bin. Reasonable additions are utilities such as vacation(1) and procmail. Never include any shell or shell-like program (for example, perl) in the sm.bin directory. This does not restrict the use of shell or perl scripts in the sm.bin directory (using the #! syntax); it simply disallows the execution of arbitrary programs.				
OPTIONS	The following options are supported: -c <i>command</i> Where <i>command</i> is a valid command, executes <i>command</i>.				
FILES	/var/adm/sm.bin directory for restricted programs				
ATTRIBUTES	See attributes(5) for descriptions of the following attributes:				
	<table> <tr> <th>ATTRIBUTE TYPE</th><th>ATTRIBUTE VALUE</th></tr> <tr> <td>Availability</td><td>SUNWcsr, SUNWcsu</td></tr> </table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	Availability	SUNWcsr, SUNWcsu
ATTRIBUTE TYPE	ATTRIBUTE VALUE				
Availability	SUNWcsr, SUNWcsu				
SEE ALSO	sendmail(1M), attributes(5)				

smserialport(1M)

NAME	smserialport – manage serial port								
SYNOPSIS	<code>/usr/sadm/bin/smserialport subcommand [auth_args] -- [subcommand_args]</code>								
DESCRIPTION	The smserialport command manages serial ports.								
Sub-commands	The following smserialport sub-commands (<i>subcommand</i>) are supported: <table><tr><td>configure</td><td>Configures a serial port's basic settings for a device such as a terminal, modem or no connection.</td></tr><tr><td>delete</td><td>Deletes a given port. You can disable a port and prevent new services from being spawned for incoming connections, without interfering with existing services.</td></tr><tr><td>list</td><td>Lists all serial ports.</td></tr><tr><td>modify</td><td>Modifies a serial port's parameters.</td></tr></table>	configure	Configures a serial port's basic settings for a device such as a terminal, modem or no connection.	delete	Deletes a given port. You can disable a port and prevent new services from being spawned for incoming connections, without interfering with existing services.	list	Lists all serial ports.	modify	Modifies a serial port's parameters.
configure	Configures a serial port's basic settings for a device such as a terminal, modem or no connection.								
delete	Deletes a given port. You can disable a port and prevent new services from being spawned for incoming connections, without interfering with existing services.								
list	Lists all serial ports.								
modify	Modifies a serial port's parameters.								
OPTIONS	There are two kinds of options: authentication arguments (<i>args</i>) and sub-command arguments (<i>subcommand_args</i>).								
Authentication Arguments	The smserialport authentication arguments, <i>args</i>, are derived from the smc(1M) argument set and are the same regardless of which sub-command you use. Valid <i>args</i> are -D, -H, -l, -p, -r, and -u; they are all optional. If no <i>args</i> are specified, certain defaults will be assumed and the user may be prompted for additional information, such as a password for authentication purposes. The single letter options can also be specified by their equivalent option words preceded by a double dash. For example, you can use either -D or --domain. Descriptions and other arg options that contain white spaces must be enclosed in double quotes. The following authentication arguments (<i>args</i>) are supported: -D --domain <i>domain</i> Specifies the default domain that you want to manage. smserialport accepts only the <i>file</i> value for this option. <i>file</i> is also the default value. The <i>file</i> default domain means that changes are local to the server. Toolboxes can change the domain on a tool-by-tool basis; this option specifies the <i>domain</i> for all other tools. -H --hostname <i>host_name:port</i> Specifies the host and port to which you want to connect. If you do not specify a port, the system connects to the default port, 898. If you do not specify a host (<i>host_name:port</i>, the Solaris Management Console connects to the local host on port 898. You may still have to choose a toolbox to load into the console. To override this behavior, use the smc -B option, or set your console preferences to load a home toolbox by default.								

	-l --rolepassword <i>role_password</i> Specifies the password for the <i>role_name</i>. If you specify a <i>role_name</i> but do not specify a <i>role_password</i>, the system prompts you to supply a <i>role_password</i>. Passwords specified on the command line can be seen by any user on the system, hence this option is considered insecure. -p --password <i>password</i> Specifies the password for the <i>user_name</i>. If you do not specify a password, the system prompts you for one. Because passwords specified on the command line can be seen by any user on the system, this option is considered insecure. -r --rolename <i>role_name</i> Specifies a role name for authentication. If you do not specify this option, no role is assumed. -u --username <i>user_name</i> Specifies the user name for authentication. If you do not specify this option, the user identity running the console process is assumed. -- This option is required and must always follow the preceding options. If you do not enter the preceding options, you must still enter the -- option.
Sub-command Arguments	The sub-command specific options, <i>subcommand_args</i>, must come after the <i>args</i> and must be separated from them by the -- option. Enclose descriptions and <i>arg</i> options that contain white space in double quotes. configure The configure sub-command requires the following sub-command argument: -n <i>port_name</i> Specifies the name of the serial port to reconfigure. The following sub-command arguments are optional for the configure sub-command: -b <i>baudrate</i> Specifies the port baud rate. The supported baud rate are 38400, 19200, 9600, 4800, 2400, 1200, 300 and auto. The default is 9600. -c <i>comment</i> Specifies a short comment description of the service. The default is a description of the requested device type. -h Displays the command's usage statement. -l <i>login_prompt</i> Specifies the login prompt. The default is <i>tty 'port_name' login:.</i>

smserialport(1M)

	<code>-t <i>terminal_type</i></code> Specifies the terminal type. The default is <code>tvi925</code>. <code>-x device=<i>device_name</i></code> Specifies the device to be configured. Valid <code>device_names</code> are: <code>terminal</code>, <code>modemdialin</code>, <code>modemdialout</code>, <code>modemdialinout</code> or <code>initializeonly</code> for no connection. The default is <code>terminal</code>. <code>-x service=y n</code> Specifies the status of service, that is <code>y</code> for enabled or <code>n</code> for disabled. The default is <code>y</code>.
delete	The <code>delete</code> sub-command requires the following sub-command arguments: <code>-n <i>port_name</i></code> Specifies the name of the serial port to be disabled. The following sub-command arguments are optional for the <code>delete</code> sub-command: <code>-h</code> Displays the command's usage statement.
list	The <code>list</code> sub-command does not require any sub-command arguments. The following sub-command arguments are optional for the <code>list</code> sub-command: <code>-h</code> Displays the command's usage statement. <code>-v</code> Displays the data in verbose format.
modify	The <code>modify</code> sub-command requires the following sub-command arguments: <code>-n <i>port_name</i></code> Specifies the name of the serial port to modify. The following sub-command arguments are optional for the <code>modify</code> sub-command: <code>-b <i>baudrate</i></code> Specifies the port baud rate. The supported baud rate are 38400, 19200, 9600, 4800, 2400, 1200, 300 and <code>auto</code>. <code>-c <i>comment</i></code> A short comment description of the service.

- h
Displays the command usage statement.
- l *login_prompt*
Specifies the login prompt.
- t *terminal_type*
Specifies the terminal type.
- x *bidirectional=y | n*
Specifies the bi-directional port flag, *y* for set or *n* for not set.
When this flag is set, the line can be used in both directions.
- x *connect_on_carrier=y | n*
Specifies if to connect on carrier, that is *y* or *n*.
- x *initialize_only=y | n*
Specifies if the service invocation. If *y* the service is invoked only once. This can be used to configure a particular device without actually monitoring it, as with software carrier.
- x *service_program=command*
Specifies the full pathname of the service command to invoke when a connection request is received.
- x *service_status=y | n*
Specifies the status of service, that is *y* for enabled or *n* for disabled.
- x *software_carrier=y | n*
Specifies the carrier detection. *y* for software or *n* for hardware.
- x *timeout=timeout*
Specifies the time to close a port if the open on the port succeeds, and no input data is received in *timeout* seconds. The supported *timeout* are never, 30, 60 and 90.

EXAMPLES

EXAMPLE 1 Listing Serial Ports

The following example lists the serial ports:

```
example% ./smserialport list -H myhost -u root -p mypassword --
```

Port	Service	Baud-Rate	Terminal-Type	Prompt	Comment
a	enabled	9600	xterm	as	welcome
b	enabled	9600	tvi925	ttyb login:	

EXAMPLE 2 Modifying Serial Ports

The following example contains two commands. The first command modifies serial port *b* for a baud rate of 4800, an *xterm* as terminal type, a *b:* for login prompt and a comment. The second command lists the ports.

```
example% ./smserialport modify -H myhost -u root -p mypassword -- \
-n b -b 4800 -t xterm -l b: -c "modified port b"
```

smserialport(1M)

EXAMPLE 2 Modifying Serial Ports (Continued)

```
example% ./smserialport list -H myhost -u root -p mypassword --
```

Port	Service	Baud-Rate	Terminal-Type	Prompt	Comment
a	enabled	9600	xterm	as	welcome
b	enabled	4800	xterm	b:	modified port b

EXAMPLE 3 Deleting a Serial Port

The following example contains two commands. The first command deletes serial port b. The second command lists the ports.

```
example% ./smserialport delete -H myhost -u root \
        -p mypassword -- -n b
```

```
example% ./smserialport list -H myhost -u root -p mypassword --
```

Port	Service	Baud-Rate	Terminal-Type	Prompt	Comment
a	enabled	9600	xterm	as	welcome
b	disabled	9600	tvi925	ttyb login:	

EXAMPLE 4 Configuring a Serial Port

The following example contains two commands. The first command configures serial port b for a bi-directional modem. The second command lists the ports.

```
example% ./smserialport configure -H myhost -u root \
        -p mypassword -- -n b -x device=modemdialinout
```

```
example% ./smserialport list -H myhost -u root -p mypassword --
```

Port	Service	Baud-Rate	Terminal-Type	Prompt	Comment
a	enabled	9600	xterm	as	welcome
b	enabled	9600	tvi925	ttyb login:	Modem - Dial In and Out

ENVIRONMENT VARIABLES

See environ(5) for descriptions of the following environment variables that affect the execution of smserialport: JAVA_HOME. If this environment variable is not specified, the /usr/java location is used. See smc(1M).

EXIT STATUS

The following exit values are returned:

0	Successful completion.
1	Invalid command syntax. A usage message displays.
2	An error occurred while executing the command. An error message displays.

ATTRIBUTES

See attributes(5) for descriptions of the following attributes:

smserialport(1M)

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWmga

smuser(1M)

NAME	smuser – manage user entries								
SYNOPSIS	<code>/usr/sadm/bin/smuser subcommand [auth_args] - - [subcommand_args]</code>								
DESCRIPTION	The <code>smuser</code> command manages one or more user entries in the local <code>/etc</code> filesystem or a NIS or NIS+ target name service.								
<i>subcommands</i>	<code>smuser subcommands</code> are: <table> <tr> <td><code>add</code></td><td>Adds a new user entry to the appropriate files. You can use a template and input file instead of supplying the additional command line options. If you use a template and command line options, the command line options take precedence and override any conflicting template values. To add an entry, the administrator must have the <code>solaris.admin.usermgr.write</code> authorization.</td></tr> <tr> <td><code>delete</code></td><td>Deletes one or more user entries from the appropriate files. To delete an entry, the administrator must have the <code>solaris.admin.usermgr.write</code> authorization. <i>Note:</i> You cannot delete the system accounts with IDs less than 100, or 60001, 60002, or 65534.</td></tr> <tr> <td><code>list</code></td><td>Lists one more user entries from the appropriate files. To list entries, the administrator must have the <code>solaris.admin.usermgr.read</code> authorization.</td></tr> <tr> <td><code>modify</code></td><td>Modifies a user entry in the appropriate files. To modify an entry, the administrator must have the <code>solaris.admin.usermgr.write</code> authorization.</td></tr> </table>	<code>add</code>	Adds a new user entry to the appropriate files. You can use a template and input file instead of supplying the additional command line options. If you use a template and command line options, the command line options take precedence and override any conflicting template values. To add an entry, the administrator must have the <code>solaris.admin.usermgr.write</code> authorization.	<code>delete</code>	Deletes one or more user entries from the appropriate files. To delete an entry, the administrator must have the <code>solaris.admin.usermgr.write</code> authorization. <i>Note:</i> You cannot delete the system accounts with IDs less than 100, or 60001, 60002, or 65534.	<code>list</code>	Lists one more user entries from the appropriate files. To list entries, the administrator must have the <code>solaris.admin.usermgr.read</code> authorization.	<code>modify</code>	Modifies a user entry in the appropriate files. To modify an entry, the administrator must have the <code>solaris.admin.usermgr.write</code> authorization.
<code>add</code>	Adds a new user entry to the appropriate files. You can use a template and input file instead of supplying the additional command line options. If you use a template and command line options, the command line options take precedence and override any conflicting template values. To add an entry, the administrator must have the <code>solaris.admin.usermgr.write</code> authorization.								
<code>delete</code>	Deletes one or more user entries from the appropriate files. To delete an entry, the administrator must have the <code>solaris.admin.usermgr.write</code> authorization. <i>Note:</i> You cannot delete the system accounts with IDs less than 100, or 60001, 60002, or 65534.								
<code>list</code>	Lists one more user entries from the appropriate files. To list entries, the administrator must have the <code>solaris.admin.usermgr.read</code> authorization.								
<code>modify</code>	Modifies a user entry in the appropriate files. To modify an entry, the administrator must have the <code>solaris.admin.usermgr.write</code> authorization.								
OPTIONS	The <code>smuser</code> authentication arguments, <i>auth_args</i>, are derived from the <code>smc(1M)</code> arg set and are the same regardless of which subcommand you use. The <code>smuser</code> command requires the Solaris Management Console to be initialized for the command to succeed (see <code>smc(1M)</code>). After rebooting the Solaris Management Console server, the first Solaris Management Console connection might time out, so you might need to retry the command. The subcommand-specific options, <i>subcommand_args</i>, must come after the <i>auth_args</i> and must be separated from them by the <code>- -</code> option.								
<i>auth_args</i>	The valid <i>auth_args</i> are <code>-D</code>, <code>-H</code>, <code>-l</code>, <code>-p</code>, <code>-r</code>, and <code>-u</code>; they are all optional. If no <i>auth_args</i> are specified, certain defaults will be assumed and the user may be prompted for additional information, such as a password for authentication purposes. These letter options can also be specified by their equivalent option words preceded by a double dash. For example, you can use either <code>-D</code> or <code>- -domain</code> with the <i>domain</i> argument. <code>-D - -domain domain</code> Specifies the default domain that you want to manage. The syntax of <i>domain</i> is <i>type:/host_name/domain_name</i>, where <i>type</i> is <code>nis</code>, <code>nisplus</code>, <code>dns</code>, <code>ldap</code>, or <code>file</code>; <i>host_name</i> is the name of the machine that serves the domain; and <i>domain_name</i> is the name of the domain you want to manage. (<i>Note:</i> Do not use <code>nis+</code> for <code>nisplus</code>.)								

If you do not specify this option, the Solaris Management Console assumes the file default domain on whatever server you choose to manage, meaning that changes are local to the server. Toolboxes can change the domain on a tool-by-tool basis; this option specifies the domain for all other tools.

-H | **-** **-hostname** *host_name:port*

Specifies the *host_name* and *port* to which you want to connect. If you do not specify a *port*, the system connects to the default port, 898. If you do not specify *host_name:port*, the Solaris Management Console connects to the local host on port 898. You may still have to choose a toolbox to load into the console. To override this behavior, use the smc(1M) **-B** option, or set your console preferences to load a "home toolbox" by default.

-l | **-** **-rolepassword** *role_password*

Specifies the password for the *role_name*. If you specify a *role_name* but do not specify a *role_password*, the system prompts you to supply a *role_password*. Passwords specified on the command line can be seen by any user on the system, hence this option is considered insecure.

-p | **-** **-password** *password*

Specifies the password for the *user_name*. If you do not specify a password, the system prompts you for one. Passwords specified on the command line can be seen by any user on the system, hence this option is considered insecure.

-r | **-** **-rolename** *role_name*

Specifies a role name for authentication. If you do not specify this option, no role is assumed.

-u | **-** **-username** *user_name*

Specifies the user name for authentication. If you do not specify this option, the user identity running the console process is assumed.

- **-**

This option is required and must always follow the preceding options. If you do not enter the preceding options, you must still enter the **- -** option.

subcommand_args

Note: Descriptions and other arg options that contain white spaces must be enclosed in double quotes.

■ For subcommand **add**:

-c *comment*

(Optional) Includes a short description of the login, which is typically the user's name. Consists of a string of up to 256 printable characters, excluding the colon (:).

-d *dir*

(Optional) Specifies the home directory of the new user, limited to 1024 characters.

-e *ddmmyyyy*

(Optional) Specifies the expiration date for a login. After this date, no user can access this login. This option is useful for creating temporary logins. Specify a

smuser(1M)

null value (" ") to indicate that the login is always valid. The administrator must have the `solaris.admin.usermgr.pswd` authorization.

-f *inactive*

(Optional) Specifies the maximum number of days allowed between uses of a login ID before that ID is declared invalid. Normal values are positive integers. Enter zero to indicate that the login account is always active.

-F *full_name*

(Optional) Specifies the full, descriptive name of the user. The *full_name* must be unique within a domain and can contain alphanumeric characters and spaces. If you use spaces, you must enclose the *full_name* in double quotes.

-g *group*

(Optional) Specifies the new user's primary group membership in the system group database with an existing group's integer ID.

-G *group1 -G group2 . . .*

(Optional) Specifies the new user's supplementary group membership in the system group database with the character string names of one or more existing groups. Duplicates of groups specified with the `-g` and `-G` options are ignored.

-h

(Optional) Displays the command's usage statement.

-n *login*

Specifies the new user's login name. The login name must be unique within a domain, contain 2–32 alphanumeric characters, begin with a letter, and contain at least one lowercase letter.

-P *password*

(Optional) Specifies up to an eight-character password assigned to the user account. *Note:* When you specify a password, you type the password in plain text. Specifying a password using this method introduces a security gap while the command is running. To set the password, the administrator must have the `solaris.admin.usermgr.pswd` authorization.

-s *shell*

(Optional) Specifies the full pathname (limited to 1024 characters) of the program used as the user's shell on login. Valid entries are a user-defined shell, `/bin/csh` (C shell), `bin/ksh` (Korn shell), and the default, `/bin/sh` (Bourne shell).

-t *template*

(Optional) Specifies a template, created using the User Manager tool, that contains a set of pre-defined user attributes. You may have entered a name service server in the template. However, when a user is actually added with this template, if a name service is unavailable, the user's local server will be used for both the Home Directory Server and Mail Server.

- u *uid*
(Optional) Specifies the user ID of the user you want to add. If you do not specify this option, the system assigns the next available unique user ID greater than 100.
- x *autohome=Y|N*
(Optional) Sets the home directory to automount if set to Y. The user's home directory path in the password entry is set to */home/login name*.
- x *mail=mail_server*
(Optional) Specifies the host name of the user's mail server, and creates a mail file on the server. Users created in a local scope must have a mail server created on their local machines.
- x *perm=home_perm*
(Optional) Sets the permissions on the user's home directory. *perm* is interpreted as an octal number, and the default is 0775.
- x *pwmax=days*
(Optional) Specifies the maximum number of days that the user's password is valid. The administrator must have the `solaris.admin.usermgr.pswd` authorization.
- x *pwmin=days*
(Optional) Specifies the minimum number of days between user password changes. The administrator must have the `solaris.admin.usermgr.pswd` authorization.
- x *pwwarn=days*
(Optional) Specifies the number of days relative to *pwmax* that the user is warned about password expiration prior to the password expiring. The administrator must have the `solaris.admin.usermgr.pswd` authorization.
- x *serv=homedir_server*
(Optional) Specifies the name of the server where the user's home directory resides. Users created in a local scope must have their home directory server created on their local machines.
- For subcommand `delete`:
 - h
(Optional) Displays the command's usage statement.
 - n *login1*
Specifies the login name of the user you want to delete.
 - n *login2 . . .*
(Optional) Specifies the additional login name(s) of the user(s) you want to delete.
- For subcommand `list`:
 - h
(Optional) Displays the command's usage statement.

-l

Displays the output for each user in a block of *key:value* pairs (for example, *user name:root*) followed by a blank line to delimit each user block. Each *key:value* pair is displayed on a separate line. The keys are: *autohome setup*, *comment*, *days to warn*, *full name*, *home directory*, *home directory permissions*, *login shell*, *mail server*, *max days change*, *max days inactive*, *min days change*, *password expires*, *password type*, *primary group*, *rights*, *roles*, *secondary groups*, *server*, *user ID (UID)*, and *user name*.

-n *login1*

Specifies the login name of the user you want to list.

-n *login2* . . .

(Optional) Specifies the additional login name(s) of the user(s) you want to list.

■ For subcommand *modify*:

-a *addrole1* -a *addrole2* . . .

(Optional) Specifies the role(s) to add to the user account. To assign a role to a user, the administrator must have the *solaris.role.assign* authorization or must have the *solaris.role.delegate* authorization and be a member of each of the roles specified.

-c *comment*

(Optional) Describes the changes you made to the user account. Consists of a string of up to 256 printable characters, excluding the colon (:).

-d *description*

(Optional) Specifies the user's home directory, limited to 1024 characters.

-e *ddmmyyyy*

(Optional) Specifies the expiration date for a login in a format appropriate to the locale. After this date, no user can access this login. This option is useful for creating temporary logins. Specify a null value (" ") to indicate that the login is always valid.

-f *inactive*

(Optional) Specifies the maximum number of days allowed between uses of a login ID before the ID is declared invalid. Normal values are positive integers. Specify zero to indicate that the login account is always active.

-F *full_name*

(Optional) Specifies the full, descriptive name of the user. The *full_name* must be unique within a domain and can contain alphanumeric characters and spaces. If you use spaces, you must enclose the *full_name* in double quotes.

-g *group*

(Optional) Specifies the new user's primary group membership in the system group database with an existing group's integer ID.

- G *group1* -G *group2* . . .
(Optional) Specifies the new user's supplementary group membership in the system group database with the character string names of one or more existing groups. Duplicates of groups specified with the -g and -G options are ignored.
- h
(Optional) Displays the command's usage statement.
- n *name*
Specifies the user's current login name.
- N *new_name*
(Optional) Specifies the user's new login name. The login name must be unique within a domain, contain 2–32 alphanumeric characters, begin with a letter, and contain at least one lowercase letter.
- p *addprof1* -p *addprof2* . . .
(Optional) Specifies the profile(s) to add to the user account. To assign a profile to a user, the administrator must have the `solaris.profmgr.assign` or `solaris.profmgr.delegate` authorization.
- P *password*
(Optional) Specifies up to an eight-character password assigned to the user account.

When you specify a password, you type the password in plain text. Specifying a password using this method introduces a security gap while the command is running.
- q *delprof1* -q *delprof2* . . .
(Optional) Specifies the profile(s) to delete from the user account.
- r *delrole1* -r *delrole2* . . .
(Optional) Specifies the role(s) to delete from the user account.
- s *shell*
(Optional) Specifies the full pathname (limited to 1024 characters) of the program used as the user's shell on login. Valid entries are a user-defined shell, `/bin/csh` (C shell), `bin/ksh` (Korn shell), and the default, `/bin/sh` (Bourne shell).l)
- x *autohome=Y|N*
(Optional) Sets up the home directory to automount if set to Y. The user's home directory path in the password entry is set to `/home/login name`.
- x *pwmax=days*
(Optional) Specifies the maximum number of days that the user's password is valid.
- x *pwmin=days*
(Optional) Specifies the minimum number of days between password changes.

smuser(1M)

`-x pwwarn=days`

(Optional) Specifies the number of days relative to *pwmax* that the user is warned about password expiration before the password expires.

EXAMPLES

EXAMPLE 1 Creating a new user account

The following creates a new user account on the local file system. The account name is `user1`, and the full name is Joe Smith. The comment field verifies that the account is for Joe Smith. The system will assign the next available user ID greater than 100 to this account. There is no password set for this account, so when Joe Smith logs in for the first time, he will be prompted to enter a password.

```
./smuser add -H myhost -p mypasswd -u root -- -F "Joe Smith" \
-n user1 -c "Joe's account"
```

EXAMPLE 2 Deleting a user account

The following deletes the `user1` account from the local file system:

```
./smuser delete -H myhost -p mypasswd -u root -- -n user1
```

EXAMPLE 3 Listing all user accounts

The following lists all user accounts on the local file system in summary form:

```
./smuser list -H myhost -p mypasswd -u root --
```

EXAMPLE 4 Modifying a user account

The following modifies the `user1` account to default to a Korn shell, and assigns the account to the `qa_group` secondary group.

```
./smuser modify -H myhost -p mypasswd -u root -- -n user1 \
-s /bin/ksh -G qa_group
```

ENVIRONMENT VARIABLES

See `environ(5)` for a description of the `JAVA_HOME` environment variable, which affects the execution of the `smuser` command. If this environment variable is not specified, the `/usr/java` location is used. See `smc(1M)`.

EXIT STATUS

The following exit values are returned:

- 0 Successful completion.
- 1 Invalid command syntax. A usage message displays.
- 2 An error occurred while executing the command. An error message displays.

FILES

The following files are used by the `smuser` command:

<code>/etc/aliases</code>	Mail aliases. See <code>aliases(4)</code> .
<code>/etc/auto_home</code>	Automatic mount points. See <code>automount(1M)</code> .

smuser(1M)

/etc/group	Group file. See group(4).
/etc/passwd	Password file. See passwd(4).
/etc/security/policy.conf	Configuration file for security policy. See policy.conf(4).
/etc/shadow	Shadow password file. See shadow(4).
/etc/user_attr	Extended user attribute database. See user_attr(4).

ATTRIBUTES See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWmga

SEE ALSO automount(1M), smc(1M), aliases(4), group(4), passwd(4), policy.conf(4), shadow(4), user_attr(4), attributes(5), environ(5)

snmpdx(1M)

NAME	snmpdx – Sun Solstice Enterprise Master Agent														
SYNOPSIS	<pre>/usr/lib/snmpp/snmppdx [-hy] [-a filename] [-c config-dir] [-d debug-level] [-i filename] [-m GROUP -m SPLIT] [-o filename] [-p port] [-r filename]</pre>														
DESCRIPTION	The Master Agent, <i>snmpdx</i>, is the main component of Solstice Enterprise Agent technology. It runs as a daemon process and listens to User Datagram Protocol (UDP) port 161 for SNMP requests. The Master Agent also opens another port to receive SNMP trap notifications from various subagents. These traps are forwarded to various managers, as determined by the configuration file. Upon invocation, <i>snmpdx</i> reads its various configuration files and takes appropriate actions by activating subagents, determining the subtree Object Identifier (OID) for various subagents, populating its own Management Information Bases (MIBs), and so forth. The Master Agent invokes subagents, registers subagents, sends requests to subagents, receives responses from subagents, and traps notifications from subagents. The Master Agent is invoked from a start-up script at boot time only if contents of the resource configuration file <i>/etc/snmpp/conf/snmppdx.rsrc</i> are non-trivial.														
OPTIONS	The following options are supported: <table> <tr> <td><i>-a filename</i></td><td>Specify the full path of the access control file used by the Master Agent. The default access control file is <i>/etc/snmpp/conf/snmppdx.acl</i>.</td></tr> <tr> <td><i>-c config-dir</i></td><td>Specify the full path of the directory containing the Master Agent configuration files. The default directory is <i>/etc/snmpp/conf</i>.</td></tr> <tr> <td><i>-d debug-level</i></td><td>Debug. Levels from 0 to 4 are supported, giving various levels of debug information. The default is 0 which means no debug information is given.</td></tr> <tr> <td><i>-h</i></td><td>Help. Print the command line usage.</td></tr> <tr> <td><i>-i filename</i></td><td>Specify the full path of the enterprise-name OID map. This file contains the PID used by the Master Agent for recovery after a crash. It contains tuples of the UNIX process ID, port number, resource name, and agent name. The default file is <i>/var/snmpp/snmppdx.st</i>.</td></tr> <tr> <td><i>-m GROUP -m SPLIT</i></td><td>Specify the mode to use for forwarding of SNMP requests.</td></tr> <tr> <td>GROUP</td><td>Multiple variables can be included in each request from the Master Agent to the subagents. This results in, at most, one send-request per agent.</td></tr> </table>	<i>-a filename</i>	Specify the full path of the access control file used by the Master Agent. The default access control file is <i>/etc/snmpp/conf/snmppdx.acl</i> .	<i>-c config-dir</i>	Specify the full path of the directory containing the Master Agent configuration files. The default directory is <i>/etc/snmpp/conf</i> .	<i>-d debug-level</i>	Debug. Levels from 0 to 4 are supported, giving various levels of debug information. The default is 0 which means no debug information is given.	<i>-h</i>	Help. Print the command line usage.	<i>-i filename</i>	Specify the full path of the enterprise-name OID map. This file contains the PID used by the Master Agent for recovery after a crash. It contains tuples of the UNIX process ID, port number, resource name, and agent name. The default file is <i>/var/snmpp/snmppdx.st</i> .	<i>-m GROUP -m SPLIT</i>	Specify the mode to use for forwarding of SNMP requests.	GROUP	Multiple variables can be included in each request from the Master Agent to the subagents. This results in, at most, one send-request per agent.
<i>-a filename</i>	Specify the full path of the access control file used by the Master Agent. The default access control file is <i>/etc/snmpp/conf/snmppdx.acl</i> .														
<i>-c config-dir</i>	Specify the full path of the directory containing the Master Agent configuration files. The default directory is <i>/etc/snmpp/conf</i> .														
<i>-d debug-level</i>	Debug. Levels from 0 to 4 are supported, giving various levels of debug information. The default is 0 which means no debug information is given.														
<i>-h</i>	Help. Print the command line usage.														
<i>-i filename</i>	Specify the full path of the enterprise-name OID map. This file contains the PID used by the Master Agent for recovery after a crash. It contains tuples of the UNIX process ID, port number, resource name, and agent name. The default file is <i>/var/snmpp/snmppdx.st</i> .														
<i>-m GROUP -m SPLIT</i>	Specify the mode to use for forwarding of SNMP requests.														
GROUP	Multiple variables can be included in each request from the Master Agent to the subagents. This results in, at most, one send-request per agent.														

	SPLIT Each variable in the incoming request results in one send-request to each subagent. The default is GROUP. -o <i>filename</i> Specify the full path of the file containing the tuple (enterprise-name, OID). For example, (Sun Microsystems, 1.3.1.6.1.4.32). The Master Agent uses this file as a base for look-up in the trap-filtering and forwarding process. The default file is <code>/etc/snmp/conf/enterprises.oid</code>. -p <i>port</i> Specify the port number. The default port number is 161. -r <i>filename</i> Specify the full path of the resource file to be used by the Master Agent. This file stores information about the subagents that the Master Agent invokes and manages. The default resource file is <code>/etc/snmp/conf/snmpdx.rsrc</code>. -y Set a recovery indicator to invoke the recovery module. The recovery process discovers which subagents in the previous session are still active; those subagents not active are re-spawned by the Master Agent.
FILES	<code>/etc/snmp/conf/enterprises.oid</code> Enterprise-name OID map <code>/etc/snmp/conf/snmpdx.acl</code> Access control file <code>/etc/snmp/conf/snmpdx.rsrc</code> Resource configuration file <code>/var/snmp/snmpdx.st</code> Master Agent status file <code>/var/snmp/mib/snmpdx.mib</code> Master Agent MIB file

NAME	snmpXdmid – Sun Solstice Enterprise SNMP-DMI mapper subagent												
SYNOPSIS	<code>/usr/lib/dmi/snmpXdmid -s hostname [-h] [-c config-dir] [-d debug-level]</code>												
DESCRIPTION	The <code>snmpXdmid</code> utility is a subagent in the Solstice Enterprise Agent Desktop Management Interface package. It maps the SNMP requests forwarded by the Master Agent (<code>snmpdx(1M)</code>) into one or more equivalent DMI requests. Further, it remaps the DMI response into SNMP response back to <code>snmpdx</code>. By default, <code>snmpXdmid</code> also forwards the DMI indications as SNMP traps to <code>snmpdx</code>. The feature is configurable and can be disabled by setting <code>TRAP_FORWARD_TO_MAGENT=0</code> in the <code>snmpXdmid</code> configuration file, <code>snmpXdmid.conf</code>. This subagent runs as a daemon in the system. The subagent uses a set of <code>.MAP</code> files located in <code>/var/dmi/map</code> to map the SNMP Object Identifier (OID) into a corresponding DMI component. The map files are generated using the MIF-to-MIB utility, <code>miftomib</code>. They are read by <code>snmpXdmid</code> when a corresponding MIF file gets registered with the DMI Service Provider (<code>dmispd(1M)</code>). The <code>snmpXdmid.conf</code> file is used for configuration information. Each entry in the file consists of a keyword followed by an equal sign (=), followed by a parameter string. The keyword must begin in the first position. A line beginning with a pound sign (#) is treated as a comment and the subsequent characters on that line are ignored. The keywords currently supported are: <table><tr><td>WARNING_TIMESTAMP</td><td>Indication subscription expiration, warning time.</td></tr><tr><td>EXPIRATION_TIMESTAMP</td><td>Indication subscription expiration timestamp.</td></tr><tr><td>FAILURE_THRESHOLD</td><td>DMISP retries before dropping indication due to comm errors.</td></tr><tr><td>TRAP_FORWARD_TO_MAGENT</td><td></td></tr><tr><td></td><td>0 Drop indication at the subagent level.</td></tr><tr><td></td><td>non-zero Forward indications as SNMP traps to <code>snmpdx</code>.</td></tr></table> By default, the configuration file <code>snmpXdmid.conf</code> is located in the <code>/etc/dmi/conf</code> directory. You can specify an alternative directory with the <code>-c</code> option.	WARNING_TIMESTAMP	Indication subscription expiration, warning time.	EXPIRATION_TIMESTAMP	Indication subscription expiration timestamp.	FAILURE_THRESHOLD	DMISP retries before dropping indication due to comm errors.	TRAP_FORWARD_TO_MAGENT			0 Drop indication at the subagent level.		non-zero Forward indications as SNMP traps to <code>snmpdx</code> .
WARNING_TIMESTAMP	Indication subscription expiration, warning time.												
EXPIRATION_TIMESTAMP	Indication subscription expiration timestamp.												
FAILURE_THRESHOLD	DMISP retries before dropping indication due to comm errors.												
TRAP_FORWARD_TO_MAGENT													
	0 Drop indication at the subagent level.												
	non-zero Forward indications as SNMP traps to <code>snmpdx</code> .												
OPTIONS	The following options are supported: <table><tr><td><code>-c config-dir</code></td><td>Specify the directory where <code>snmpXdmid.conf</code> file is located.</td></tr><tr><td><code>-d debug-level</code></td><td>Debug. Levels from 1 to 5 are supported, giving various levels of debug information.</td></tr><tr><td><code>-h</code></td><td>Help. Print the command line usage.</td></tr><tr><td><code>-s hostname</code></td><td>Specify the host on which <code>dmispd</code> is running.</td></tr></table>	<code>-c config-dir</code>	Specify the directory where <code>snmpXdmid.conf</code> file is located.	<code>-d debug-level</code>	Debug. Levels from 1 to 5 are supported, giving various levels of debug information.	<code>-h</code>	Help. Print the command line usage.	<code>-s hostname</code>	Specify the host on which <code>dmispd</code> is running.				
<code>-c config-dir</code>	Specify the directory where <code>snmpXdmid.conf</code> file is located.												
<code>-d debug-level</code>	Debug. Levels from 1 to 5 are supported, giving various levels of debug information.												
<code>-h</code>	Help. Print the command line usage.												
<code>-s hostname</code>	Specify the host on which <code>dmispd</code> is running.

NAME	snmpXwbemd – SNMP Adapter Subagent for WBEM
SYNOPSIS	<code>/usr/sadm/lib/wbem/snmpXwbemd [-d] [-h] [-p port]</code>
DESCRIPTION	The <code>snmpXwbemd</code> daemon is a subagent in the Web-Based Enterprise Management (WBEM) services package. This daemon maps the Simple Network Management Protocol (SNMP) requests forwarded by the Solstice Enterprise Agents (SEA) Master Agent <code>snmpdx(1M)</code> into one or more equivalent WBEM Common Information Model (CIM) properties and instances. Further, it remaps the response from the CIM Object Manager into a SNMP response, which it passes back to <code>snmpdx(1M)</code>. A mapping file contains the corresponding Object Identifier (OID), class name, property name, and Abstract Syntax Notation 1 (ASN.1) type for each object. You can also create your own mapping file.
OPTIONS	The following options are supported: <code>-d</code> Displays all debug information. <code>-h</code> Displays help by printing the correct command line usage. <code>-p</code> Specifies the port number to use.
OPERANDS	The following operand is supported: <code>port</code> Specifies the port number you want to use.
EXAMPLES	EXAMPLE 1 An Example of a <code>050SUNWwbcou.map</code> File This mapping file that Sun Microsystems provides contains definitions of objects, in this format: <pre># #pragma ident "@(#)050SUNWwbcou.map 1.0 01/04/03 SMI" # # Copyright (c) 2001 by Sun Microsystems, Inc. # All rights reserved. # # *** Description of contents *** # # First non-commented non-blank line contains required Version label. # Remaining non-commented non-blank lines are considered map entries # used as described below: # # Column 1 - SNMP OID - Uniquely describes an SNMP variable # Column 2 - CIM Class Name - CIM class associated with this variable # Column 3 - CIM Property Name - CIM property that maps to SNMP OID variable # Column 4 - ASN.1 type - SNMP datatype that dictates how data is mapped # to/from SNMP requests. Supported types are: SnmpString, SnmpOid, # SnmpTimeticks, SnmpCounter, SnmpInt, SnmpGauge, SnmpIpAddress, # SnmpOpaque) # Column 5 and greater are ignored #</pre>

NAME	snoop – capture and inspect network packets
SYNOPSIS	snoop [-aqrCDNPSvV] [-t [r a d]] [-c <i>maxcount</i>] [-d <i>device</i>] [-i <i>filename</i>] [-n <i>filename</i>] [-o <i>filename</i>] [-p <i>first</i> [, <i>last</i>]] [-s <i>snaplen</i>] [-x <i>offset</i> [, <i>length</i>]] [<i>expression</i>]
DESCRIPTION	snoop captures packets from the network and displays their contents. snoop uses both the network packet filter and streams buffer modules to provide efficient capture of packets from the network. Captured packets can be displayed as they are received, or saved to a file (which is <i>RFC 1761</i>-compliant) for later inspection. snoop can display packets in a single-line summary form or in verbose multi-line forms. In summary form, only the data pertaining to the highest level protocol is displayed. For example, an NFS packet will have only NFS information displayed. The underlying RPC, UDP, IP, and ethernet frame information is suppressed but can be displayed if either of the verbose options are chosen. In the absence of a name service, such as LDAP or NIS, snoop displays host names as numeric IP addresses. snoop requires an interactive interface.
OPTIONS	-C List the code generated from the filter expression for either the kernel packet filter, or snoop's own filter. -D Display number of packets dropped during capture on the summary line. -N Create an IP address-to-name file from a capture file. This must be set together with the -i option that names a capture file. The address-to-name file has the same name as the capture file with .names appended. This file records the IP address to hostname mapping at the capture site and increases the portability of the capture file. Generate a .names file if the capture file is to be analyzed elsewhere. Packets are not displayed when this flag is used. -P Capture packets in non-promiscuous mode. Only broadcast, multicast, or packets addressed to the host machine will be seen. -S Display size of the entire ethernet frame in bytes on the summary line. -V Verbose summary mode. This is halfway between summary mode and verbose mode in degree of verbosity. Instead of displaying just the summary line for the highest level protocol in a packet, it displays a summary line for each protocol layer in the packet. For instance, for an NFS packet it will display a line each

snoop(1M)

	for the ETHER, IP, UDP, RPC and NFS layers. Verbose summary mode output may be easily piped through <code>grep</code> to extract packets of interest. For example, to view only RPC summary lines, enter the following: example# snoop -i rpc.cap -v grep RPC
-a	Listen to packets on <code>/dev/audio</code> (warning: can be noisy).
-c <i>maxcount</i>	Quit after capturing <i>maxcount</i> packets. Otherwise keep capturing until there is no disk left or until interrupted with Control-C.
-d <i>device</i>	Receive packets from the network using the interface specified by <i>device</i> , for example, <code>le0</code> or <code>hme0</code> . The program <code>netstat(1M)</code> , when invoked with the <code>-i</code> flag, lists all the interfaces that a machine has. Normally, <code>snoop</code> will automatically choose the first non-loopback interface it finds.
-i <i>filename</i>	Display packets previously captured in <i>filename</i> . Without this option, <code>snoop</code> reads packets from the network interface. If a <i>filename.names</i> file is present, it is automatically loaded into the <code>snoop</code> IP address-to-name mapping table (See <code>-N</code> flag).
-n <i>filename</i>	Use <i>filename</i> as an IP address-to-name mapping table. This file must have the same format as the <code>/etc/hosts</code> file (IP address followed by the hostname).
-o <i>filename</i>	Save captured packets in <i>filename</i> as they are captured. (This <i>filename</i> is referred to as the "capture file".) The format of the capture file is RFC 1761-compliant. During packet capture, a count of the number of packets saved in the file is displayed. If you wish just to count packets without saving to a file, name the file <code>/dev/null</code> .
-p <i>first</i> [, <i>last</i>]	Select one or more packets to be displayed from a capture file. The <i>first</i> packet in the file is packet number 1.
-q	When capturing network packets into a file, do not display the packet count. This can improve packet capturing performance.
-r	Do not resolve the IP address to the symbolic name. This prevents <code>snoop</code> from generating network traffic while capturing and displaying packets. However, if

	the <code>-n</code> option is used, and an address is found in the mapping file, its corresponding name will be used.
<code>-s snaplen</code>	Truncate each packet after <i>snaplen</i> bytes. Usually the whole packet is captured. This option is useful if only certain packet header information is required. The packet truncation is done within the kernel giving better utilization of the streams packet buffer. This means less chance of dropped packets due to buffer overflow during periods of high traffic. It also saves disk space when capturing large traces to a capture file. To capture only IP headers (no options) use a <i>snaplen</i> of 34. For UDP use 42, and for TCP use 54. You can capture RPC headers with a <i>snaplen</i> of 80 bytes. NFS headers can be captured in 120 bytes.
<code>-t [r a d]</code>	Time-stamp presentation. Time-stamps are accurate to within 4 microseconds. The default is for times to be presented in <i>d</i> (delta) format (the time since receiving the previous packet). Option <i>a</i> (absolute) gives wall-clock time. Option <i>r</i> (relative) gives time relative to the first packet displayed. This can be used with the <code>-p</code> option to display time relative to any selected packet.
<code>-v</code>	Verbose mode. Print packet headers in lots of detail. This display consumes many lines per packet and should be used only on selected packets.
<code>-x offset [, length]</code>	Display packet data in hexadecimal and ASCII format. The <i>offset</i> and <i>length</i> values select a portion of the packet to be displayed. To display the whole packet, use an <i>offset</i> of 0. If a <i>length</i> value is not provided, the rest of the packet is displayed.
OPERANDS	<i>expression</i> Select packets either from the network or from a capture file. Only packets for which the expression is true will be selected. If no expression is provided it is assumed to be true. Given a filter expression, <code>snoop</code> generates code for either the kernel packet filter or for its own internal filter. If capturing packets with the network interface, code for the kernel packet filter is generated. This filter is implemented as a streams module, upstream of the buffer module. The buffer module accumulates packets until it becomes full and passes the packets on to <code>snoop</code>. The kernel packet filter is very efficient, since it rejects unwanted packets in the kernel before they reach the packet buffer or <code>snoop</code>. The kernel packet filter has some limitations in its implementation; it is possible to construct filter expressions that it cannot handle. In this event, <code>snoop</code> tries to split the filter and do as much filtering in the kernel as

possible. The remaining filtering is done by the packet filter for `snoop`. The `-C` flag can be used to view generated code for either the packet filter for the kernel or the packet filter for `snoop`. If packets are read from a capture file using the `-i` option, only the packet filter for `snoop` is used.

A filter *expression* consists of a series of one or more boolean primitives that may be combined with boolean operators (AND, OR, and NOT). Normal precedence rules for boolean operators apply. Order of evaluation of these operators may be controlled with parentheses. Since parentheses and other filter expression characters are known to the shell, it is often necessary to enclose the filter expression in quotes. Refer to [Example 2](#) for information about setting up more efficient filters.

The primitives are:

`host hostname`

True if the source or destination address is that of `hostname`. The `hostname` argument may be a literal address. The keyword `host` may be omitted if the name does not conflict with the name of another expression primitive. For example, "pink" selects packets transmitted to or received from the host pink, whereas "pink and dink" selects packets exchanged between hosts pink AND dink.

The type of address used depends on the primitive which precedes the `host` primitive. The possible qualifiers are "inet", "inet6", "ether", or none. These three primitives are discussed below. Having none of the primitives present is equivalent to "inet host hostname or inet6 host hostname". In other words, `snoop` tries to filter on all IP addresses associated with `hostname`.

`inet` or `inet6`

A qualifier that modifies the `host` primitive that follows. If it is `inet`, then `snoop` tries to filter on all IPv4 addresses returned from a name lookup. If it is `inet6`, `snoop` tries to filter on all IPv6 addresses returned from a name lookup.

`ipaddr`, `atalkaddr`, or `etheraddr`

Literal addresses, IP dotted, AppleTalk dotted, and ethernet colon are recognized. For example,

- "129.144.40.13" matches all packets with that IP ;
- "2::9255:a00:20ff:fe73:6e35" matches all packets with that IPv6 address as source or destination;
- "65281.13" matches all packets with that AppleTalk address;
- "8:0:20:f:b1:51" matches all packets with the ethernet address as source or destination.

An ethernet address beginning with a letter is interpreted as a hostname. To avoid this, prepend a zero when specifying the address. For example, if the ethernet address is "aa:0:45:23:52:44", then specify it by add a leading zero to make it "0aa:0:45:23:52:44".

from or src

A qualifier that modifies the following *host*, *net*, *ipaddr*, *atalkaddr*, *etheraddr*, *port* or *rpc* primitive to match just the source address, port, or RPC reply.

to or dst

A qualifier that modifies the following *host*, *net*, *ipaddr*, *atalkaddr*, *etheraddr*, *port* or *rpc* primitive to match just the destination address, port, or RPC call.

ether

A qualifier that modifies the following *host* primitive to resolve a name to an ethernet address. Normally, IP address matching is performed.

ethertype *number*

True if the ethernet type field has value *number*. Equivalent to "*ether* [12:2] = *number*".

ip, ip6, arp, rarp, pppoe, pppoes

True if the packet is of the appropriate ethertype.

pppoe

True if the ethertype of the packet is either pppoe or pppoes.

broadcast

True if the packet is a broadcast packet. Equivalent to "*ether* [2:4] = 0xffffffff".

multicast

True if the packet is a multicast packet. Equivalent to "*ether*[0] & 1 = 1".

bootp, dhcp

True if the packet is an unfragmented UDP packet with either a source port of BOOTPS (67) and a destination port of BOOTPC (68), or a source port of BOOTPC (68) and a destination of BOOTPS (67).

apple

True if the packet is an Apple Ethertalk packet. Equivalent to "*ethertype* 0x809b or *ethertype* 0x80f3".

decnet

True if the packet is a DECNET packet.

greater *length*

True if the packet is longer than *length*.

less *length*

True if the packet is shorter than *length*.

udp, tcp, icmp, icmp6, ah, esp

True if the IP or IPv6 protocol is of the appropriate type.

net *net*

True if either the IP source or destination address has a network number of *net*. The *from* or *to* qualifier may be used to select packets for which the network number occurs only in the source or destination address.

snoop(1M)

port *port*

True if either the source or destination port is *port*. The *port* may be either a port number or name from `/etc/services`. The `tcp` or `udp` primitives may be used to select TCP or UDP ports only. The `from` or `to` qualifier may be used to select packets for which the *port* occurs only as the source or destination.

rpc *prog* [, *vers* [, *proc*]]

True if the packet is an RPC call or reply packet for the protocol identified by *prog*. The *prog* may be either the name of an RPC protocol from `/etc/rpc` or a program number. The *vers* and *proc* may be used to further qualify the program *version* and *procedure* number, for example, "rpc nfs, 2, 0" selects all calls and replies for the NFS null procedure. The `to` or `from` qualifier may be used to select either call or reply packets only.

ldap

True if the packet is an LDAP packet on port 389.

gateway *host*

True if the packet used *host* as a gateway, that is, the ethernet source or destination address was for *host* but not the IP address. Equivalent to "ether host *host* and not host *host*".

nofrag

True if the packet is unfragmented or is the first in a series of IP fragments. Equivalent to "ip[6:2] & 0x1fff = 0".

expr relop expr

True if the relation holds, where *relop* is one of `>`, `<`, `>=`, `<=`, `=`, `!=`, and *expr* is an arithmetic expression composed of numbers, packet field selectors, the `length` primitive, and arithmetic operators `+`, `-`, `*`, `&`, `|`, `^`, and `%`. The arithmetic operators within *expr* are evaluated before the relational operator and normal precedence rules apply between the arithmetic operators, such as multiplication before addition. Parentheses may be used to control the order of evaluation. To use the value of a field in the packet use the following syntax:

`base[expr [: size ] ]`

where *expr* evaluates the value of an offset into the packet from a *base* offset which may be `ether`, `ip`, `ip6`, `udp`, `tcp`, or `icmp`. The *size* value specifies the size of the field. If not given, 1 is assumed. Other legal values are 2 and 4. For example,

`ether[0] & 1 = 1`

is equivalent to `multicast`

`ether[2:4] = 0xffffffff`

is equivalent to `broadcast`.

`ip[ip[0] & 0xf * 4 : 2] = 2049`

is equivalent to `udp[0:2] = 2049`

```
ip[0] & 0xf > 5
```

selects IP packets with options.

```
ip[6:2] & 0x1fff = 0
```

eliminates IP fragments.

```
udp and ip[6:2]&0x1fff = 0 and udp[6:2] != 0
```

finds all packets with UDP checksums.

The length primitive may be used to obtain the length of the packet. For instance "length > 60" is equivalent to "greater 60", and "ether[length - 1]" obtains the value of the last byte in a packet.

and

Perform a logical AND operation between two boolean values. The AND operation is implied by the juxtaposition of two boolean expressions, for example "dinky pinky" is the same as "dinky AND pinky".

or or ,

Perform a logical OR operation between two boolean values. A comma may be used instead, for example, "dinky, pinky" is the same as "dinky OR pinky".

not or !

Perform a logical NOT operation on the following boolean value. This operator is evaluated before AND or OR.

slp

True if the packet is an SLP packet.

sctp

True if the packet is a SCTP packet.

EXAMPLES

EXAMPLE 1 Using the snoop Command

Capture all packets and display them as they are received:

```
example# snoop
```

Capture packets with host funky as either the source or destination and display them as they are received:

```
example# snoop funky
```

Capture packets between funky and pinky and save them to a file. Then inspect the packets using times (in seconds) relative to the first captured packet:

```
example# snoop -o cap funky pinky
```

```
example# snoop -i cap -t r | more
```

To look at selected packets in another capture file:

```
example# snoop -i pkts -p 99,108
```

```
99 0.0027 boutique -> sunroof NFS C GETATTR FH=8E6
```

snoop(1M)

EXAMPLE 1 Using the snoop Command (Continued)

```
100  0.0046  sunroof -> boutique      NFS R GETATTR OK
101  0.0080  boutique -> sunroof NFS C RENAME FH=8E6C MTra00192 to .nfs08
102  0.0102  marmot -> viper      NFS C LOOKUP FH=561E screen.r.13.i386
103  0.0072  viper -> marmot     NFS R LOOKUP No such file or directory
104  0.0085  bugbomb -> sunroof  RLOGIN C PORT=1023 h
105  0.0005  kandinsky -> sparky  RSTAT C Get Statistics
106  0.0004  beebledbrox -> sunroof NFS C GETATTR FH=0307
107  0.0021  sparky -> kandinsky  RSTAT R
108  0.0073  office -> jeremiah  NFS C READ FH=2584 at 40960 for 8192
```

To look at packet 101 in more detail:

```
example# snoop -i pkts -v -p101
ETHER: ----- Ether Header -----
ETHER:
ETHER: Packet 101 arrived at 16:09:53.59
ETHER: Packet size = 210 bytes

IP: Destination address = 129.144.40.200, sunroof
IP:
UDP: ----- UDP Header -----
UDP:
UDP: Source port = 1023
UDP: Destination port = 2049 (Sun RPC)
UDP: Length = 176
UDP: Checksum = 0
UDP:
RPC: ----- SUN RPC Header -----
RPC:
RPC: Transaction id = 665905
RPC: Type = 0 (Call)
RPC: RPC version = 2
RPC: Program = 100003 (NFS), version = 2, procedure = 1
RPC: Credentials: Flavor = 1 (Unix), len = 32 bytes
```

EXAMPLE 1 Using the snoop Command (Continued)

```

RPC:      Time = 06-Mar-90 07:26:58
RPC:      Hostname = boutique
RPC:      Uid = 0, Gid = 1
RPC:      Groups = 1
RPC: Verifier : Flavor = 0 (None), len = 0 bytes
RPC:
NFS: ----- SUN NFS -----
NFS:
NFS: Proc = 11 (Rename)
NFS: File handle = 0000164300000000100080000305A1C47
NFS:           597A00000008000002046314AFC450000
NFS: File name = MTra00192
NFS: File handle = 0000164300000000100080000305A1C47
NFS:           597A00000008000002046314AFC450000
NFS: File name = .nfs08
NFS:

```

To view just the NFS packets between sunroof and boutique:

```

example# snoop -i pkts rpc nfs and sunroof and boutique
1  0.0000  boutique -> sunroof    NFS C GETATTR FH=8E6C
2  0.0046  sunroof -> boutique    NFS R GETATTR OK
3  0.0080  boutique -> sunroof    NFS C RENAME FH=8E6C MTra00192 to .nfs08

```

To save these packets to a new capture file:

```

example# snoop -i pkts -o pkts.nfs rpc nfs sunroof boutique

```

To view encapsulated packets, there will be an indicator of encapsulation:

```

example# snoop ip-in-ip
sunroof -> boutique ICMP Echo request      (1 encap)

```

If -V is used on an encapsulated packet:

```

example# snoop -V ip-in-ip
sunroof -> boutique ETHER Type=0800 (IP), size = 118 bytes
sunroof -> boutique IP D=129.144.40.222 S=129.144.40.200 LEN=104, ID=27497
sunroof -> boutique IP D=10.1.1.2 S=10.1.1.1 LEN=84, ID=27497
sunroof -> boutique ICMP Echo request

```

EXAMPLE 2 Setting Up A More Efficient Filter

To set up a more efficient filter, the following filters should be used toward the end of the expression, so that the first part of the expression can be set up in the kernel: greater, less, port, rpc, nofrag, and relop. The presence of OR makes it difficult to split the filtering when using these primitives that cannot be set in the kernel. Instead, use parentheses to enforce the primitives that should be OR'd.

To capture packets between funky and pinky of type tcp or udp on port 80:

```

example# snoop funky and pinky and port 80 and tcp or udp

```

snoop(1M)

EXAMPLE 2 Setting Up A More Efficient Filter *(Continued)*

Since the primitive `port` cannot be handled by the kernel filter, and there is also an `OR` in the expression, a more efficient way to filter is to move the `OR` to the end of the expression and to use parentheses to enforce the `OR` between `tcp` and `udp`:

```
example# snoop funky and pinky and (tcp or udp) and port 80
```

EXIT STATUS 0 Successful completion.

1 An error occurred.

FILES `/dev/audio` Symbolic link to the system's primary audio device.
`/dev/null` The null file.
`/etc/hosts` Host name database.
`/etc/rpc` RPC program number data base.
`/etc/services` Internet services and aliases.

Callaghan, B. and Gilligan, R. *RFC 1761, Snoop Version 2 Packet Capture File Format*. Network Working Group. February 1995.

WARNINGS The processing overhead is much higher for realtime packet interpretation. Consequently, the packet drop count may be higher. For more reliable capture, output raw packets to a file using the `-o` option and analyze the packets off-line.

Unfiltered packet capture imposes a heavy processing load on the host computer, particularly if the captured packets are interpreted realtime. This processing load further increases if verbose options are used. Since heavy use of `snoop` may deny computing resources to other processes, it should not be used on production servers. Heavy use of `snoop` should be restricted to a dedicated computer.

`snoop` does not reassemble IP fragments. Interpretation of higher level protocol halts at the end of the first IP fragment.

snoop may generate extra packets as a side-effect of its use. For example it may use a network name service (NIS or NIS+) to convert IP addresses to host names for display. Capturing into a file for later display can be used to postpone the address-to-name mapping until after the capture session is complete. Capturing into an NFS-mounted file may also generate extra packets.

Setting the snaplen (-s option) to small values may remove header information that is needed to interpret higher level protocols. The exact cutoff value depends on the network and protocols being used. For NFS Version 2 traffic using UDP on 10 Mb/s ethernet, do not set snaplen less than 150 bytes. For NFS Version 3 traffic using TCP on 100 Mb/s ethernet, snaplen should be 250 bytes or more.

snoop requires information from an RPC request to fully interpret an RPC reply. If an RPC reply in a capture file or packet range does not have a request preceding it, then only the RPC reply header will be displayed.

soconfig(1M)

NAME	soconfig – configure transport providers for use by sockets								
SYNOPSIS	<pre>/sbin/soconfig -f file</pre> <pre>/sbin/soconfig family type protocol [path]</pre>								
DESCRIPTION	The <code>soconfig</code> utility configures the transport provider driver for use with sockets. It specifies how the family, type, and protocol parameters in the <code>socket(3SOCKET)</code> call are mapped to the name of a transport provider such as <code>/dev/tcp</code>. This utility can be used to add an additional mapping or remove a previous mapping. The <code>init(1M)</code> utility uses <code>soconfig</code> with the <code>sock2path(4)</code> file during the booting sequence.								
OPTIONS	The following options are supported: <code>-f file</code> Set up the <code>soconfig</code> configuration for each driver according to the information stored in <code>file</code>. A <code>soconfig</code> file consists of lines of at least the first three fields listed below, separated by spaces: <i>family type protocol path</i> These fields are described in the OPERANDS section below. An example of <code>file</code> can be found in the EXAMPLES section below.								
OPERANDS	The following operands are supported: <table><tr><td><i>family</i></td><td>The protocol family as listed in the <code>/usr/include/sys/socket.h</code> file, expressed as an integer.</td></tr><tr><td><i>type</i></td><td>The socket type as listed in the <code>/usr/include/sys/socket.h</code> file, expressed as an integer.</td></tr><tr><td><i>protocol</i></td><td>The protocol number as specified in the family-specific <code>include</code> file, expressed as an integer. For example, for <code>AF_INET</code> this number is specified in <code>/usr/include/netinet/in.h</code>. An unspecified protocol number is denoted with the value zero.</td></tr><tr><td><i>path</i></td><td>The string that specifies the path name of the device that corresponds to the transport provider. If this parameter is specified, the configuration will be added for the specified family, type, and protocol. If this parameter is not specified, the configuration will be removed.</td></tr></table>	<i>family</i>	The protocol family as listed in the <code>/usr/include/sys/socket.h</code> file, expressed as an integer.	<i>type</i>	The socket type as listed in the <code>/usr/include/sys/socket.h</code> file, expressed as an integer.	<i>protocol</i>	The protocol number as specified in the family-specific <code>include</code> file, expressed as an integer. For example, for <code>AF_INET</code> this number is specified in <code>/usr/include/netinet/in.h</code> . An unspecified protocol number is denoted with the value zero.	<i>path</i>	The string that specifies the path name of the device that corresponds to the transport provider. If this parameter is specified, the configuration will be added for the specified family, type, and protocol. If this parameter is not specified, the configuration will be removed.
<i>family</i>	The protocol family as listed in the <code>/usr/include/sys/socket.h</code> file, expressed as an integer.								
<i>type</i>	The socket type as listed in the <code>/usr/include/sys/socket.h</code> file, expressed as an integer.								
<i>protocol</i>	The protocol number as specified in the family-specific <code>include</code> file, expressed as an integer. For example, for <code>AF_INET</code> this number is specified in <code>/usr/include/netinet/in.h</code> . An unspecified protocol number is denoted with the value zero.								
<i>path</i>	The string that specifies the path name of the device that corresponds to the transport provider. If this parameter is specified, the configuration will be added for the specified family, type, and protocol. If this parameter is not specified, the configuration will be removed.								
EXAMPLES	EXAMPLE 1 Using <code>soconfig</code> The following example sets up <code>/dev/tcp</code> for family <code>AF_INET</code> and type <code>SOCK_STREAM</code>: <pre>example# soconfig 2 2 0 /dev/tcp</pre>								

EXAMPLE 1 Using soconfig (Continued)

The following is a sample file used with the -f option. Comment lines begin with a number sign (#):

```
#      Family   Type  Protocol   Path
      2         2      0      /dev/tcp
      2         2      6      /dev/tcp

      2         1      0      /dev/udp
      2         1     17      /dev/udp

      1         2      0      /dev/ticotsord
      1         1      0      /dev/ticlts

      2         4      0      /dev/rawip
```

ATTRIBUTE TYPE	ATTRIBUTE VALUE										
Availability	SUNWsadml										
SEE ALSO	soldelapp(1M) , solstice(1M) , attributes(5)										
NOTES	Globally registered applications are used by local and remote users sharing the software in a particular /opt directory. They can be added only using soladdapp.										

NAME	soldelapp – remove an application from the Solstice application registry				
SYNOPSIS	<code>/usr/snadm/bin/soldelapp [-r <i>registry</i>] -n <i>name</i></code>				
DESCRIPTION	soldelapp removes an application from the Solstice application registry. After removal, the application is no longer displayed in the Solstice Launcher main window (see <code>solstice(1M)</code>).				
OPTIONS	<code>-r <i>registry</i></code> Define the full path name of the Solstice registry file. <code>-n <i>name</i></code> Define the name of the tool to be removed. When executed without options, soldelapp uses <code>/opt/SUNWadm/etc/.solstice_registry</code> (the default registry path).				
RETURN VALUES	0 on success 1 on failure 2 if the registry is locked 3 if <i>name</i> is not found in the registry 4 if the named registry or default registry is not found				
EXAMPLES	EXAMPLE 1 A sample display of the soldelapp command. The following removes an application called Disk Manager from the Solstice application registry and the Solstice Launcher main window. <pre># soldelapp -r /opt/SUNWadm/etc/.solstice_registry -n "Disk Manager"</pre>				
FILES	<code>/opt/SUNWadm/etc/.solstice_registry</code> The default registry file.				
ATTRIBUTES	See <code>attributes(5)</code> for descriptions of the following attributes:				
	<table> <tr> <th>ATTRIBUTE TYPE</th><th>ATTRIBUTE VALUE</th></tr> <tr> <td>Availability</td><td>SUNWsadml</td></tr> </table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	Availability	SUNWsadml
ATTRIBUTE TYPE	ATTRIBUTE VALUE				
Availability	SUNWsadml				
SEE ALSO	<code>soladdapp(1M)</code> , <code>solstice(1M)</code> , <code>attributes(5)</code>				
NOTES	Globally registered applications are used by local and remote users sharing the software in a particular <code>/opt</code> directory. They can be removed only using <code>soldelapp</code> .				

solstice(1M)

NAME	solstice – access system administration tools with a graphical user interface				
SYNOPSIS	/bin/solstice				
DESCRIPTION	solstice used on a system presents the Solstice Launcher, a graphical user interface that provides access to the Solstice AdminSuite product family of system administration tools. The tools that appear in the launcher depend on what Solstice products you installed on your system. Help is available by using the Help button.				
USAGE	The Solstice Launcher allows you to do the following tasks: Launch applications Use the Solstice Launcher to launch system administration tools. Register applications Use the Solstice Launcher to add and register applications locally with the launcher. Remove applications Use the Solstice Launcher to remove locally registered applications. Customize application properties Use the Solstice Launcher to show, hide, or remove applications in the launcher, reorder the icons, change the launcher window width, modify applications properties, and add applications.				
FILES	/\$HOME/.solstice_registry Local registry information.				
ATTRIBUTES	See attributes(5) for descriptions of the following attributes: <table><tr><th>ATTRIBUTE TYPE</th><th>ATTRIBUTE VALUE</th></tr><tr><td>Availability</td><td>SUNWsadml</td></tr></table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	Availability	SUNWsadml
ATTRIBUTE TYPE	ATTRIBUTE VALUE				
Availability	SUNWsadml				
SEE ALSO	soladdapp(1M), soldelapp(1M), attributes(5)				
NOTES	The Solstice Launcher adds or removes local applications that are private to the user (not local to the system) only. The properties of globally registered applications that are used by local and remote users sharing the software from a particular /opt directory cannot be modified from the Solstice Launcher. To register global applications for use by local and remote users, use the soladdapp(1M) command. To remove globally registered applications, use the soldelapp(1M) command.				

NAME	sppptun – PPP tunneling driver utility
SYNOPSIS	sppptun plumb sppptun plumb <i>protocol device</i> sppptun unplumb <i>interface</i> sppptun query
DESCRIPTION	The sppptun utility is used to configure and query the Solaris PPP tunneling device driver, /dev/sppptun. Currently, only PPP over Ethernet (PPPoE) is supported, so the plumb and unplumb arguments are used to specify Ethernet interfaces that are to be used for PPPoE, and the query option lists the plumbed interfaces. The use of sppptun to add interfaces is similar to the use of ifconfig(1M) to add interfaces to IP. The plumbing is done once for each interface, preferably at system start-up time, and is not normally manipulated on a running system. If multiple instances of PPP are run over a single interface, they share the plumbing to that interface. Plumbing for each session is not required (and not possible for PPPoE). The proper way to plumb interfaces for PPPoE is to list the interfaces, one per line, in the /etc/ppp/pppoe.if file.
USAGE	sppptun plumb When specified with no additional arguments, the plumb argument lists the protocols that are supported by the utility. These are the strings that are used as the <i>protocol</i> argument below. sppptun plumb <i>protocol device</i> This plumbs a new interface into the driver. The <i>protocol</i> parameter is <i>pppoe</i> for the PPP-carrying "Session Stage" connection or <i>pppoed</i> for the PPPoE "Discovery Stage" connection. Both connections must be present for each Ethernet interface that is to be used for PPPoE. The <i>device</i> parameter is the path name of the Ethernet interface to use (use ifconfig(1M) to list available devices). If the path begins with /dev/, then this portion may be omitted. sppptun unplumb <i>interface</i> This removes an existing interface from the driver and terminates any PPP sessions that were using the interface. The <i>interface</i> parameter is the name of the interface as reported when the interface was plumbed. sppptun query Displays the canonical names of all interfaces plumbed into the /dev/sppptun device driver.
EXAMPLES	EXAMPLE 1 Setting up to Use PPPoE on hme0 Plumb the hme0 interface.

sppptun(1M)

EXAMPLE 1 Setting up to Use PPPoE on hme0 (Continued)

```
# sppptun plumb pppoe hme0
hme0:pppoe
# sppptun plumb pppoe hme0
hme0:pppoe
```

Remove the hme0 interface.

```
# sppptun unplumb hme0:pppoe
# sppptun unplumb hme0:pppoe
```

EXAMPLE 2 Script to Remove All Plumbed Interfaces

```
#!/bin/sh
for intf in `sppptun query`
do
    sppptun unplumb $intf
done
```

EXIT STATUS The following exit values are returned:

0 Successful completion.
1 One or more errors occurred.

FILES

/etc/ppp/pppoe.if	list of Ethernet interfaces to be plumbed at boot time
/usr/sbin/sppptun	executable command
/dev/sppptun	Solaris PPP tunneling device driver

RFC 2516, Method for Transmitting PPP Over Ethernet (PPPoE), Mamakos et al, February 1999

NAME	spray – spray packets				
SYNOPSIS	/usr/sbin/spray [-c <i>count</i>] [-d <i>delay</i>] [-l <i>length</i>] [-t <i>nettype</i>] <i>host</i>				
DESCRIPTION	spray sends a one-way stream of packets to <i>host</i> using RPC, and reports how many were received, as well as the transfer rate. The <i>host</i> argument can be either a name or an Internet address. spray is not useful as a networking benchmark, as it uses unreliable connectionless transports, UDP for example. spray can report a large number of packets dropped when the drops were caused by spray sending packets faster than they can be buffered locally, that is, before the packets get to the network medium.				
OPTIONS	-c <i>count</i> Specify how many packets to send. The default value of <i>count</i> is the number of packets required to make the total stream size 100000 bytes. -d <i>delay</i> Specify how many microseconds to pause between sending each packet. The default is 0. -l <i>length</i> The <i>length</i> parameter is the numbers of bytes in the Ethernet packet that holds the RPC call message. Since the data is encoded using XDR, and XDR only deals with 32 bit quantities, not all values of <i>length</i> are possible, and spray rounds up to the nearest possible value. When <i>length</i> is greater than 1514, then the RPC call can no longer be encapsulated in one Ethernet packet, so the <i>length</i> field no longer has a simple correspondence to Ethernet packet size. The default value of <i>length</i> is 86 bytes, the size of the RPC and UDP headers. -t <i>nettype</i> Specify class of transports. Defaults to netpath. See rpc(3NSL) for a description of supported classes.				
ATTRIBUTES	See attributes(5) for descriptions of the following attributes: <table border="1"> <thead> <tr> <th>ATTRIBUTE TYPE</th><th>ATTRIBUTE VALUE</th></tr> </thead> <tbody> <tr> <td>Availability</td><td>SUNWrcmdc</td></tr> </tbody> </table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	Availability	SUNWrcmdc
ATTRIBUTE TYPE	ATTRIBUTE VALUE				
Availability	SUNWrcmdc				
SEE ALSO	rpc(3NSL), attributes(5)				

h1>ssaadm(1M)

NAME	ssaadm – administration program for SPARCstorage Array and SPARCstorage RSM disk systems
SYNOPSIS	ssaadm [-v] [-e] <i>subcommand</i> [<i>subcommand_option...</i>] <i>pathname...</i>
DESCRIPTION	The ssaadm program is an administrative command that manages the SPARCstorage Array and SPARCstorage RSM disk systems (henceforth called SPARCstorage systems). ssaadm performs a variety of control and query tasks depending on the command line arguments and options used. The luxadm(1M) utility replaces ssaadm and should be used instead. The command line must contain a <i>subcommand</i> (listed under USAGE) and at least one <i>pathname</i>. Commands specific to either a SPARCstorage Array or a SPARCstorage RSM state that fact. It may also contain options and other parameters depending on the subcommand. The subcommand is applied to each of the pathnames on the command line. <i>pathname</i> specifies the SPARCstorage system controller or a disk in the SPARCstorage system. The controller name is specified by its physical name, for example, <pre>/devices/. . . /. . . /SUNW,soc@3,0/SUNW, pln@xxxxxxx,xxxxxxx:ctlr</pre> or by a name of the form <pre>cN</pre> where <i>N</i> is the logical controller number. ssaadm uses the <i>cN</i> name to find an entry in the <code>/dev/rdisk</code> directory of a disk that is attached to the SPARCstorage system controller. The <code>/dev/rdisk</code> entry is then used to determine the physical name of the SPARCstorage system controller. A disk in the SPARCstorage system is specified by its logical or physical device name, for example, <pre>/dev/rdisk/clt0d0s2</pre> or <pre>/devices/. . . /. . . /SUNW,soc@3,0/SUNW, pln@xxxxxxx,xxxxxxx/ssd@0,0:c,raw</pre> See disks(1M) for more information on logical names for disks and controllers. The SPARCstorage Array is obsolete. Support for this device will be removed in a future version of Solaris.
OPTIONS	The following options are supported: -e Expert mode. This is required for the expert mode subcommands listed below.

	-v	Verbose mode.
	Subcommands and their options are described below. Expert mode subcommands are listed separately.	
OPERANDS	The following operands are supported:	
	<i>pathname</i>	The SPARCstorage system controller or a disk in the SPARCstorage system.
USAGE		
Subcommands	<code>display [-p] <i>pathname</i> . . .</code> Display configuration information for the specified units or display performance information for the specified SPARCstorage Array controller. If <i>pathname</i> specifies the controller, the configuration information is displayed for all disks in the SPARCstorage Array. For each drive that has fast write enabled, (FW) are displayed after the drive identification. <code>-p</code> Display performance information for the specified SPARCstorage Array controller. The accumulation of the performance statistics must be enabled using the <code>perf_statistics</code> subcommand before displaying the performance information. If not enabled, all of the I/Os per second are displayed as zeros. The performance display reports the following information: BUSY How busy the controller in the SPARCstorage Array is, expressed as a percentage. IOPS The total I/Os per second for the SPARCstorage Array. entries for each disk The total number of I/Os per second. <code>download -f <i>filename</i> <i>pathname</i></code> <code>download -w <i>wwn</i> <i>pathname</i></code> Download an image to the SPARCstorage Array controller. <code>-f</code> Download the prom image specified by <i>filename</i> to the SPARCstorage Array controller FEPROMs. When the download is complete, the SPARCstorage Array must be reset in order to use the downloaded code. Note that the <code>download</code> subcommand modifies the FEPROM on the SPARCstorage Array and should be used <i>with caution</i>. <code>-w</code> Change the SPARCstorage Array controller's World Wide Name. <i>wwn</i> is a 12 digit hex number, leading zeros required. The new SPARCstorage Array controller's image have the least significant 6 bytes of the 8-byte World Wide Name modified to <i>wwn</i>.	

`fast_write [-s] -c pathname`

`fast_write [-s] -d pathname`

`fast_write [-s] -e pathname`

Enable or disable the use of the NVRAM to enhance the performance of writes in the SPARCstorage Array. *pathname* may refer to the SPARCstorage Array controller or to an individual disk.

-c

Enable fast writes for synchronous writes only.

-d

Disable fast writes.

-e

Enable fast writes.

-s

Save the state that is currently being requested so it persists across power-cycles.

`fc_s_download [-f fcode-file]`

Download the fcode contained in the file *fcode-file* into *all* the FC/S Sbus Cards. This subcommand is interactive and expects user confirmation before downloading the fcode. When invoked without the [-f *fcode-file*] option, the current version of the fcode in each FC/S Sbus card is printed. Note that the `fc_s_download` subcommand should be used *only in single-user mode*; otherwise the FC/S card could be reset.

`insert_device pathname`

Guide user through hot insertion of a disk device.

This subcommand only applies to the RSM. See NOTES for hot plugging limitations.

`perf_statistics -d pathname`

`perf_statistics -e pathname`

Enable or disable the accumulation of performance statistics for the specified SPARCstorage Array controller. The accumulation of performance statistics must be enabled before using the `display -p` subcommand. This subcommand can be issued only to the SPARCstorage Array controller.

-d

Disable the accumulation of performance statistics.

-e

Enable the accumulation of performance statistics.

`purge pathname`

Purge any fast write data from NVRAM for one disk, or all disks if the controller is specified. This option should be used with caution, usually only when a drive has failed.

release *pathname*

Release a reservation held on the specified controllers or disks. When HA (High_Availability) Software is running on a system, do not use this subcommand to release a disk on an SSA. Doing so could cause problems for the HA software.

remove_device *pathname*

Guide user through hot removal of a disk device.

This subcommand only applies to the RSM. See NOTES for hot plugging limitations.

replace_device *pathname*

Guide user through hot replacement of a disk device.

This subcommand only applies to the RSM. See NOTES for hot plugging limitations.

reserve *pathname*

Reserve the specified controllers or disks for exclusive use by the issuing host. When HA (High_Availability) Software is running on a system, do not use this subcommand to reserve a disk on an SSA. Doing so could cause problems for the HA software.

set_boot_dev [-y] *pathname*

Set the boot-device variable in the PROM to the physical device name specified by *pathname* which can be a block special device or the pathname of the directory on which the boot file system is mounted. This subcommand normally runs interactively and requests confirmation for setting the default boot device in the PROM. The -y option can be used to run it in non-interactive mode, in which case no confirmation is requested or required.

start [-t *tray-number*] *pathname*

Spin up the specified disks. If *pathname* specifies the controller, this action applies to all disks in the SPARCstorage Array.

-t

Spin up all disks in the tray specified by *tray-number*. *pathname* must specify the controller.

stop [-t *tray-number*] *pathname*

Spin down the specified disks. If *pathname* specifies the controller, this action applies to all disks in the SPARCstorage Array.

-t

Spin down all disks in the tray specified by *tray-number*. *pathname* must specify the controller.

sync_cache *pathname*

Flush all outstanding writes for the specified disk from NVRAM to the media. If *pathname* specifies the controller, this action applies to all disks in the SPARCstorage Array.

ssaadm(1M)

**SCSI Enclosure
Services (SES)
Subcommands**

The SPARCstorage RSM tray is addressed by the using the logical or physical path of the SES device or specifying the controller followed by the tray number if that controller has multiple trays. The controller is addressed by *cN* or the physical path to the SPARCstorage Array's controller.

See *ses(7D)* for more information about environmental sensor cards and associated devices.

These subcommands also work with RSM trays directly attached to wide differential SCSI controllers.

alarm pathname | controller tray-number

Display the current state of the audible alarm.

alarm_on pathname | controller tray-number

alarm_off pathname | controller tray-number

Enable or disable the audible alarm for this enclosure.

alarm_set pathname | controller tray-number [seconds]

Set the audible alarm setting to seconds.

env_display pathname | controller tray-number

Display the environmental information for the specified unit.

led pathname

Display the current state of the led for the specified disk.

led_on pathname

led_off pathname

Turn on or off the led for this disk.

power_off pathname | controller tray-number

Power down this RSM. The RSM will need to be powered back on manually.

This subcommand does not work with RSMs directly attached to wide differential SCSI controllers.

**Expert Mode
Subcommands**

See NOTES for limitations of these subcommands. Only users that are knowledgeable about the systems they are managing should use the expert mode subcommands.

For the following subcommands that work on a bus if a disk is specified then the bus that disk attached to is used.

bus_getstate pathname

Get and display the state of the specified bus.

bus_quiesce pathname

Quiesce the specified bus.

bus_reset pathname

Reset the specified bus.

bus_resetall pathname

Reset the specified bus and all devices on that bus.

bus_unquiesce pathname

Unquiesce the specified bus.

dev_getstate pathname	Get the state (online or offline) of the specified device.
dev_reset pathname	Reset the specified device.
offline pathname	Turn the specified disk offline.
online pathname	Turn the specified disk online.

EXAMPLES

EXAMPLE 1 Using ssaadm to remove a disk on an SSA

An example of using the expert mode hot plugging subcommands to hot remove a disk on a SSA follows. See NOTES for hot plugging limitations.

The first step reserves the SCSI device so that it can't be accessed via its second SCSI bus:

```
example# ssaadm reserve /dev/dsk/c1t8d0s2
```

The next two steps take the disk to be removed offline then quiesce the bus:

```
example# ssaadm -e offline /dev/dsk/c1t8d0s2
example# ssaadm -e bus_quiesce /dev/dsk/c1t8d0s2
```

The user then removes the disk and continues by unquiescing the bus, putting the disk back online, then releasing it:

```
example# ssaadm -e bus_unquiesce /dev/dsk/c1t8d0s2
example# ssaadm -e online /dev/dsk/c1t8d0s2
example# ssaadm release /dev/dsk/c1t8d0s2
```

EXIT STATUS

The following exit values are returned:

0	Successful completion.
non-zero	An error occurred.

ATTRIBUTES

See attributes(5) for descriptions of the following attributes:

SPARCstorage Array User's Guide

NOTES

Currently, only some device drivers support hot plugging. If hot plugging is attempted on a disk or bus where it is not supported, an error message of the form:

```
ssaadm: can't acquire "PATHNAME": No such file or directory
```

ssaadm(1M)

is displayed.

Do not quiesce any bus containing a disk with the `root`, `usr`, or `swap` partitions to avoid possible system deadlock.

NAME	<code>sshd</code> – secure shell daemon
SYNOPSIS	sshd [-diQ46] [-b <i>bits</i>] [-f <i>config_file</i>] [-g <i>login_grace_time</i>] [-h <i>host_key_file</i>] [-k <i>key_gen_time</i>] [-p <i>port</i>] [-V <i>client_protocol_id</i>]
DESCRIPTION	The <code>sshd</code> (Secure Shell daemon) is the daemon program for <code>ssh(1)</code>. Together these programs replace <code>rlogin</code> and <code>rsh</code>, and provide secure encrypted communications between two untrusted hosts over an insecure network. The programs are intended to be as easy to install and use as possible. <code>sshd</code> is the daemon that listens for connections from clients. It forks a new daemon for each incoming connection. The forked daemons handle key exchange, encryption, authentication, command execution, and data exchange. This implementation of <code>sshd</code> supports both SSH protocol versions 1 and 2 simultaneously. Because of security weaknesses in the v1 protocol, sites should run only v2, if possible. In the default configuration, only protocol v2 is enabled for the server. To enable v1 and v2 simultaneously, see the instructions in <code>sshd_config(4)</code>. Support for v1 is provided to help sites with existing <code>ssh</code> v1 clients and servers to transition to v2. v1 might not be supported in a future release.
SSH Protocol Version 1	Each host has a host-specific RSA key (normally 1024 bits) used to identify the host. Additionally, when the daemon starts, it generates a server RSA key (normally 768 bits). This key is normally regenerated every hour if it has been used, and is never stored on disk. Whenever a client connects the daemon responds with its public host and server keys. The client compares the RSA host key against its own database to verify that it has not changed. The client then generates a 256-bit random number. It encrypts this random number using both the host key and the server key, and sends the encrypted number to the server. Both sides then use this random number as a session key which is used to encrypt all further communications in the session. The rest of the session is encrypted using a conventional cipher, currently Blowfish or 3DES, with 3DES being used by default. The client selects the encryption algorithm to use from those offered by the server. Next, the server and the client enter an authentication dialog. The client tries to authenticate itself using <code>.rhosts</code> authentication, <code>.rhosts</code> authentication combined with RSA host authentication, RSA challenge-response authentication, or password-based authentication. Rhosts authentication is normally disabled because it is fundamentally insecure, but can be enabled in the server configuration file if desired. System security is not improved unless <code>rshd(1M)</code>, <code>rlogind(1M)</code>, <code>rexecd(1M)</code>, and <code>rexed(1M)</code> are disabled (thus completely disabling <code>rlogin(1)</code> and <code>rsh(1)</code> into the machine).
SSH Protocol Version 2	Version 2 works similarly to version 1: Each host has a host-specific DSA/RSA key. However, when the daemon starts, it does not generate a server key. Forward security is provided through a Diffie-Hellman key agreement. This key agreement results in a

sshd(1M)

**Command
Execution and
Data Forwarding**

shared session key. The rest of the session is encrypted using a symmetric cipher, currently Blowfish, 3DES, or AES. The client selects the encryption algorithm to use from those offered by the server. Additionally, session integrity is provided through a cryptographic message authentication code (`hmac-sha1` or `hmac-md5`).

Protocol version 2 provides a public key based user authentication method (`PubKeyAuthentication`) and conventional password authentication.

If the client successfully authenticates itself, a dialog for preparing the session is entered. At this time the client can request things like allocating a pseudo-tty, forwarding X11 connections, forwarding TCP/IP connections, or forwarding the authentication agent connection over the secure channel.

Finally, the client either requests a shell or execution of a command. The sides then enter session mode. In this mode, either side may send data at any time, and such data is forwarded to/from the shell or command on the server side, and the user terminal on the client side.

When the user program terminates and all forwarded X11 and other connections have been closed, the server sends command exit status to the client, and both sides exit.

`sshd` can be configured using command-line options or the configuration files `/etc/ssh/ssh_config` and `~/.ssh/config`, both described in `ssh_config(4)`. Command-line options override values specified in the configuration file.

`sshd` rereads its configuration file when it receives a hangup signal, `SIGHUP`.

**Host Access
Control**

The `sshd` daemon uses TCP Wrappers to restrict access to hosts. It uses the service name of `sshd` for `hosts_access()`. For more information on TCP Wrappers see `tcpd(1M)` and `hosts_access(3)` man pages, which are part of the `SUNWsfman` package (they are not SunOS man pages). TCP wrappers binaries, including `libwrap`, are in `SUNWtcpd`, a required package for `SUNWsshdu`, the package containing `sshd`.

OPTIONS

The options for `sshd` are as follows:

`-b bits`

Specifies the number of bits in the server key (the default is 768).

`-d`

Debug mode. The server sends verbose debug output to the system log, and does not put itself in the background. The server also will not fork and will only process one connection. This option is only intended for debugging for the server. Multiple `-d` options increase the debugging level. Maximum is 3.

`-f configuration_file`

Specifies the name of the configuration file. The default is `/etc/ssh/sshd_config`. `sshd` refuses to start if there is no configuration file.

- g *login_grace_time*
Gives the grace time for clients to authenticate themselves (the default is 300 seconds). If the client fails to authenticate the user within this number of seconds, the server disconnects and exits. A value of zero indicates no limit.
- h *host_key_file*
Specifies the file from which the host key is read (the default is `/etc/ssh/ssh_host_key`). This option must be given if `sshd` is not run as root (as the normal host file is normally not readable by anyone but root).
- i
Specifies that `sshd` is being run from `inetd`. `sshd` is normally not run from `inetd` because it needs to generate the server key before it can respond to the client, and this may take tens of seconds. Clients would have to wait too long if the key was regenerated every time. However, with small key sizes (for example, 512) using `sshd` from `inetd` may be reasonable.
- k *key_gen_time*
Specifies how often the server key is regenerated (the default is 3600 seconds, or one hour). The motivation for regenerating the key fairly often is that the key is not stored anywhere, and after about an hour, it becomes impossible to recover the key for decrypting intercepted communications even if the machine is cracked into or physically seized. A value of zero indicates that the key will never be regenerated.
- p *port*
Specifies the port on which the server listens for connections (the default is 22).
- q
Quiet mode. Nothing is sent to the system log. Normally the beginning, authentication, and termination of each connection is logged.
- 4
Forces `sshd` to use IPv4 addresses only.
- 6
Forces `sshd` to use IPv6 addresses only.

**EXTENDED
DESCRIPTION**
**authorized_keys
File Format**

The `$HOME/.ssh/authorized_keys` file lists the public keys that are permitted for RSA authentication. Each line of the file contains one key (empty lines and lines starting with a hash mark [#] are ignored as comments). Each line consists of the following fields, separated by spaces: options, bits, exponent, modulus, comment. The options field is optional; its presence is determined by whether the line starts with a number or not (the option field never starts with a number). The bits, exponent, modulus and comment fields give the RSA key; the comment field is not used for anything (but may be convenient for the user to identify the key).

Lines in this file are usually several hundred bytes long (because of the size of the RSA key modulus). You will find it very inconvenient to type them in; instead, copy the `identity.pub` file and edit it.

Permissions of this file must be set so that it is not world or group writable. See the `StrickModes` option of `ssh_config(4)`.

The options (if present) consist of comma-separated option specifications. No spaces are permitted, except within double quotes. The following option specifications are supported:

`from="pattern-list"`

Specifies that in addition to RSA authentication, the canonical name of the remote host must be present in the comma-separated list of patterns (* and ? serve as wildcards). The list can also contain patterns negated by prefixing them with !; if the canonical host name matches a negated pattern, the key is not accepted. The purpose of this option is to optionally increase security: RSA authentication by itself does not trust the network or name servers or anything (but the key); however, if somebody somehow steals the key, the key permits an intruder to log in from anywhere in the world. This additional option makes using a stolen key more difficult (name servers and/or routers would have to be compromised in addition to just the key).

`command="command"`

Specifies that the *command* is executed whenever this key is used for authentication. The command supplied by the user (if any) is ignored. The command is run on a pty if the connection requests a pty; otherwise it is run without a tty. A quote can be included in the command by quoting it with a backslash. This option might be useful to restrict certain RSA keys to perform only a specific operation. An example might be a key that permits remote backups but nothing else. The client might specify TCP/IP and/or X11 forwarding unless they are explicitly prohibited.

`environment="NAME=value"`

Specifies that the string *NAME=value* is to be added to the environment when logging in using this key. Environment variables set this way override other default environment values. Multiple options of this type are permitted.

`no-port-forwarding`

Forbids TCP/IP forwarding when this key is used for authentication. Any port forward requests by the client will return an error. This might be used, for example, in connection with the `command` option.

`no-X11-forwarding`

Forbids X11 forwarding when this key is used for authentication. Any X11 forward requests by the client will return an error.

`no-agent-forwarding`

Forbids authentication agent forwarding when this key is used for authentication.

`no-pty`

Prevents tty allocation (a request to allocate a pty will fail).

ssh_known_hosts File Format

The `/etc/ssh/ssh_known_hosts` and `$HOME/.ssh/known_hosts` files contain host public keys for all known hosts. The global file should be prepared by the administrator (optional), and the per-user file is maintained automatically: whenever the user connects from an unknown host its key is added to the per-user file.

Each line in these files contains the following fields: hostnames, bits, exponent, modulus, comment. The fields are separated by spaces.

Hostnames is a comma-separated list of patterns (* and ? act as wildcards); each pattern in turn is matched against the canonical host name (when authenticating a client) or against the user-supplied name (when authenticating a server). A pattern can also be preceded by ! to indicate negation: if the host name matches a negated pattern, it is not accepted (by that line) even if it matched another pattern on the line.

Bits, exponent, and modulus are taken directly from the RSA host key; they can be obtained, for example, from /etc/ssh/ssh_host_rsa_key.pub. The optional comment field continues to the end of the line, and is not used.

Lines starting with a hash mark (#) and empty lines are ignored as comments.

When performing host authentication, authentication is accepted if any matching line has the proper key. It is thus permissible (but not recommended) to have several lines or different host keys for the same names. This will inevitably happen when short forms of host names from different domains are put in the file. It is possible that the files contain conflicting information; authentication is accepted if valid information can be found from either file.

The lines in these files are typically hundreds of characters long. You should definitely not type in the host keys by hand. Rather, generate them by a script or by taking /etc/ssh/ssh_host_rsa_key.pub and adding the host names at the front.

EXAMPLES

EXAMPLE 1 authorized_key File Entries

The following are examples of authorized_key file entries.

```
1024 33 12121...312314325 ylo@foo.bar

from="*.niksula.hut.fi,!pc.niksula.hut.fi" 1024 35 23...2334 ylo@niksula

command="dump /home",no-pty,no-port-forwarding 1024 33 23...2323
backup.hut.fi
```

EXAMPLE 2 ssh_known_hosts File Entries

The following are examples of ssh_known_hosts file entries.

```
closenet,closenet.hut.fi,...,130.233.208.41 1024 37 159...93
closenet.hut.fi
```

EXIT STATUS

The following exit values are returned:

```
0          Successful completion.
>0        An error occurred.
```

FILES

```
/etc/ssh/sshd_config
Contains configuration data for sshd. This file should be writable by root only, but
it is recommended (though not necessary) that it be world-readable.
```

sshd(1M)

`/etc/ssh/ssh_host_key`

Contains the private part of the host key. This file should only be owned by root, readable only by root, and not accessible to others. `sshd` does not start if this file is group/world-accessible.

`/etc/ssh/ssh_host_key.pub`

Contains the public part of the host key. This file should be world-readable but writable only by root. Its contents should match the private part. This file is not used for encryption; it is provided only for the convenience of the user so its contents can be copied to known hosts files. These two files are created using `ssh-keygen(1)`.

`/var/run/sshd.pid`

Contains the process ID of the `sshd` listening for connections. If there are several daemons running concurrently for different ports, this contains the pid of the one started last. The content of this file is not sensitive; it can be world-readable. You can use the `PidFile` keyword in `sshd_config` to specify a file other than `/var/run/sshd.pid`. See `sshd_config(4)`.

`/etc/ssh/ssh_known_hosts` and `$HOME/.ssh/known_hosts`

These files are consulted when using `rhosts` with RSA host authentication to check the public key of the host. The key must be listed in one of these files to be accepted. The client uses the same files to verify that the remote host is the one it intended to connect. These files should be writable only by root or the owner.

`/etc/ssh/ssh_known_hosts` should be world-readable, and `$HOME/.ssh/known_hosts` can but need not be world-readable.

`/etc/nologin`

If this file exists, `sshd` refuses to let anyone except root log in. The contents of the file are displayed to anyone trying to log in, and non-root connections are refused. The file should be world-readable.

`$HOME/.rhosts`

This file contains host-username pairs, separated by a space, one per line. The given user on the corresponding host is permitted to log in without password. The same file is used by `rlogin` and `rshd`. The file must be writable only by the user; it is recommended that it not be accessible by others. It is also possible to use `netgroups` in the file. Either host or user name may be of the form `+%groupname` to specify all hosts or all users in the group.

`$HOME/.shosts`

For `ssh`, this file is exactly the same as for `.rhosts`. However, this file is not used by `rlogin` and `rshd`, so using this permits access using `SSH` only.

`/etc/hosts.equiv`

This file is used during `.rhosts` authentication. In its simplest form, this file contains host names, one per line. Users on these hosts are permitted to log in without a password, provided they have the same user name on both machines. The host name can also be followed by a user name; such users are permitted to log in as any user on this machine (except root). Additionally, the syntax `+%group` can be used to specify `netgroups`. Negated entries start with a hyphen (-).

If the client host/user is successfully matched in this file, login is automatically permitted, provided the client and server user names are the same. Additionally, successful RSA host authentication is normally required. This file must be writable only by root; it is recommended that it be world-readable.

Warning: It is almost never a good idea to use user names in `hosts.equiv`. Beware that it really means that the named user(s) can log in as anybody, which includes `bin`, `daemon`, `adm`, and other accounts that own critical binaries and directories. For practical purposes, using a user name grants the user root access. Probably the only valid use for user names is in negative entries. This warning also applies to `rsh/rlogin`.

`/etc/ssh/shosts.equiv`

This file is processed exactly as `/etc/hosts.equiv`. However, this file might be useful in environments that want to run both `rsh/rlogin` and `ssh`.

`$HOME/.ssh/environment`

This file is read into the environment at login (if it exists). It can contain only empty lines, comment lines (that start with `#`), and assignment lines of the form `name=value`. The file should be writable only by the user; it need not be readable by anyone else.

`$HOME/.ssh/rc`

If this file exists, it is run with `/bin/sh` after reading the environment files but before starting the user's shell or command. If X11 spoofing is in use, this will receive the "proto cookie" pair in standard input (and `DISPLAY` in environment). This must call `xauth(1)` in that case.

The primary purpose of `$HOME/.ssh/rc` is to run any initialization routines that might be needed before the user's home directory becomes accessible; AFS is a particular example of such an environment.

This file will probably contain some initialization code followed by something similar to:

```
if read proto cookie;
then echo add $DISPLAY $proto $cookie | xauth -q -;
fi
```

If this file does not exist, `/etc/ssh/sshrd` is run, and if that does not exist, `xauth` is used to store the cookie. `$HOME/.ssh/rc` should be writable only by the user, and need not be readable by anyone else.

`/etc/ssh/sshrd`

Similar to `$HOME/.ssh/rc`. This can be used to specify machine-specific login-time initializations globally. This file should be writable only by root, and should be world-readable.

To view license terms, attribution, and copyright for OpenSSH, the default path is `/var/sadm/pkg/SUNWsshdr/install/copyright`. If the Solaris operating environment has been installed anywhere other than the default, modify the given path to access the file at the installed location.

AUTHORS OpenSSH is a derivative of the original and free `ssh 1.2.12` release by Tatu Ylonen. Aaron Campbell, Bob Beck, Markus Friedl, Niels Provos, Theo de Raadt and Dug Song removed many bugs, added newer features and created Open SSH. Markus Friedl contributed the support for SSH protocol versions 1.4 and 2.0.

NAME	statd – network status monitor				
SYNOPSIS	<code>/usr/lib/nfs/statd</code>				
DESCRIPTION	statd is an intermediate version of the status monitor. It interacts with lockd(1M) to provide the crash and recovery functions for the locking services on NFS. statd keeps track of the clients with processes which hold locks on a server. When the server reboots after a crash, statd sends a message to the statd on each client indicating that the server has rebooted. The client statd processes then inform the lockd on the client that the server has rebooted. The client lockd then attempts to reclaim the lock(s) from the server. statd on the client host also informs the statd on the server(s) holding locks for the client when the client has rebooted. In this case, the statd on the server informs its lockd that all locks held by the rebooting client should be released, allowing other processes to lock those files.				
FILES	<code>/var/statmon/sm</code> lists hosts and network addresses to be contacted after a reboot <code>/var/statmon/sm.bak</code> lists hosts and network addresses that could not be contacted after last reboot <code>/var/statmon/state</code> includes a number which changes during a reboot <code>/usr/include/rpcsvc/sm_inter.x</code> contains the rpcgen source code for the interface services provided by the statd daemon.				
ATTRIBUTES	See attributes(5) for descriptions of the following attributes: <table border="1"> <thead> <tr> <th>ATTRIBUTE TYPE</th><th>ATTRIBUTE VALUE</th></tr> </thead> <tbody> <tr> <td>Availability</td><td>SUNWnfscu</td></tr> </tbody> </table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	Availability	SUNWnfscu
ATTRIBUTE TYPE	ATTRIBUTE VALUE				
Availability	SUNWnfscu				
SEE ALSO	lockd(1M), attributes(5) <i>System Administration Guide: IP Services</i>				
NOTES	The crash of a server is only detected upon its recovery.				

strace(1M)

NAME	strace – print STREAMS trace messages																
SYNOPSIS	strace [<i>mid sid level...</i>]																
DESCRIPTION	strace without arguments writes all STREAMS event trace messages from all drivers and modules to its standard output. These messages are obtained from the STREAMS log driver (see <code>log(7D)</code>). If arguments are provided, they must be in triplets of the form <i>mid, sid, level</i>, where <i>mid</i> is a STREAMS module ID number, <i>sid</i> is a sub-ID number, and <i>level</i> is a tracing priority level. Each triplet indicates that tracing messages are to be received from the given module/driver, sub-ID (usually indicating minor device), and priority level equal to, or less than the given level. The token <code>all</code> may be used for any member to indicate no restriction for that attribute. The format of each trace message output is: <pre><seq> <time> <ticks> <level> <flags> <mid> <sid> <text></pre> <table><tr><td><seq></td><td>trace sequence number</td></tr><tr><td><time></td><td>time of message in <i>hh:mm:ss</i></td></tr><tr><td><ticks></td><td>time of message in machine ticks since boot</td></tr><tr><td><level></td><td>tracing priority level</td></tr><tr><td><flags></td><td>E : message is also in the error log F : indicates a fatal error N : mail was sent to the system administrator (hardcoded as root)</td></tr><tr><td><mid></td><td>module ID number of source</td></tr><tr><td><sid></td><td>sub-ID number of source</td></tr><tr><td><text></td><td>formatted text of the trace message</td></tr></table> Once initiated, <code>strace</code> will continue to execute until terminated by the user.	<seq>	trace sequence number	<time>	time of message in <i>hh:mm:ss</i>	<ticks>	time of message in machine ticks since boot	<level>	tracing priority level	<flags>	E : message is also in the error log F : indicates a fatal error N : mail was sent to the system administrator (hardcoded as root)	<mid>	module ID number of source	<sid>	sub-ID number of source	<text>	formatted text of the trace message
<seq>	trace sequence number																
<time>	time of message in <i>hh:mm:ss</i>																
<ticks>	time of message in machine ticks since boot																
<level>	tracing priority level																
<flags>	E : message is also in the error log F : indicates a fatal error N : mail was sent to the system administrator (hardcoded as root)																
<mid>	module ID number of source																
<sid>	sub-ID number of source																
<text>	formatted text of the trace message																
EXAMPLES	EXAMPLE 1 A sample output of the <code>strace</code> command: The following example outputs all trace messages from the module or driver whose module ID is 41: <pre>strace 41 all all</pre> The following example outputs those trace messages from driver or module ID 41 with sub-IDs 0, 1, or 2: <pre>strace 41 0 1 41 1 1 41 2 0</pre> Messages from sub-IDs 0 and 1 must have a tracing level less than or equal to 1. Those from sub-ID 2 must have a tracing level of 0.																

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

SEE ALSO `attributes(5)`, `log(7D)`

STREAMS Programming Guide

- NOTES**
- There is no restriction to the number of `strace` processes opening the STREAMS log driver at a time.
 - The log-driver records the list of the triplets specified in the command invocation, and compares each potential trace message against this list to decide if it should be formatted and sent up to the `strace` process. Hence, long lists of triplets will have a greater impact on overall STREAMS performance. Running `strace` will have the most impact on the timing of the modules and drivers generating the trace messages that are sent to the `strace` process. If trace messages are generated faster than the `strace` process can handle them, some of the messages will be lost. This last case can be determined by examining the sequence numbers on the trace messages output.

strclean(1M)

NAME	strclean – STREAMS error logger cleanup program				
SYNOPSIS	strclean [-a <i>age</i>] [-d <i>logdir</i>]				
DESCRIPTION	<i>strclean</i> is used to clean up the STREAMS error logger directory on a regular basis (for example, by using <i>cron</i>). By default, all files with names matching <i>error.*</i> in <i>/var/adm/streams</i> that have not been modified in the last three days are removed.				
OPTIONS	The following options are supported: -<i>age</i> The maximum age in days for a log file can be changed using the -a option. -<i>dlogdir</i> A directory other than <i>/var/adm/streams</i> can be specified using the -d option.				
EXAMPLES	EXAMPLE 1 A sample of using the <i>strclean</i> command. This example has the same result as running <i>strclean</i> with no arguments: <pre>example% strclean -d /var/adm/streams -a 3</pre>				
FILES	<i>/var/adm/streams/error.*</i>				
ATTRIBUTES	See <i>attributes(5)</i> for descriptions of the following attributes: <table><thead><tr><th>ATTRIBUTE TYPE</th><th>ATTRIBUTE VALUE</th></tr></thead><tbody><tr><td>Availability</td><td>SUNWcsu</td></tr></tbody></table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	Availability	SUNWcsu
ATTRIBUTE TYPE	ATTRIBUTE VALUE				
Availability	SUNWcsu				
SEE ALSO	<i>cron(1M)</i> , <i>strerr(1M)</i> , <i>attributes(5)</i> <i>STREAMS Programming Guide</i>				
NOTES	<i>strclean</i> is typically run from <i>cron</i> on a daily or weekly basis.				

NAME	strerr – STREAMS error logger daemon				
SYNOPSIS	strerr				
DESCRIPTION	strerr receives error log messages from the STREAMS log driver (see log(7D)) and appends them to a log file. The resultant error log files reside in the directory <code>/var/adm/streams</code>, and are named <code>error.mm-dd</code>, where <i>mm</i> is the month and <i>dd</i> is the day of the messages contained in each log file. The format of an error log message is: <pre><seq> <time> <ticks> <flags> <mid> <sid> <text></pre> <seq> error sequence number <time> time of message in hh:mm:ss <ticks> time of message in machine ticks since boot priority level <flags> T : the message was also sent to a tracing process F : indicates a fatal error N : send mail to the system administrator (hardcoded as root) <mid> module ID number of source <sid> sub-ID number of source <text> formatted text of the error message Messages that appear in the error log are intended to report exceptional conditions that require the attention of the system administrator. Those messages which indicate the total failure of a STREAMS driver or module should have the F flag set. Those messages requiring the immediate attention of the administrator will have the N flag set, which causes the error logger to send the message to the system administrator using mail. The priority level usually has no meaning in the error log but will have meaning if the message is also sent to a tracer process. Once initiated, strerr continues to execute until terminated by the user. It is commonly executed asynchronously.				
FILES	<code>/var/adm/streams/error.mm-dd</code> error log file.				
ATTRIBUTES	See attributes(5) for descriptions of the following attributes:				
	<table> <tr> <th>ATTRIBUTE TYPE</th><th>ATTRIBUTE VALUE</th></tr> <tr> <td>Availability</td><td>SUNWcsu</td></tr> </table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	Availability	SUNWcsu
ATTRIBUTE TYPE	ATTRIBUTE VALUE				
Availability	SUNWcsu				
SEE ALSO	attributes(5), log(7D) <i>STREAMS Programming Guide</i>				

strerr(1M)

NOTES | There is no restriction to the number of `strerr` processes opening the STREAMS log driver at a time.

If a module or driver is generating a large number of error messages, running the error logger will cause a degradation in STREAMS performance. If a large burst of messages are generated in a short time, the log driver may not be able to deliver some of the messages. This situation is indicated by gaps in the sequence numbering of the messages in the log files.

NAME	sttydefs – maintain line settings and hunt sequences for TTY ports
SYNOPSIS	<pre> /usr/sbin/sttydefs -a ttylabel [-b] [-f final-flags] [-i initial-flags] [-n nextlabel] /usr/sbin/sttydefs -l [ttylabel] /usr/sbin/sttydefs -r ttylabel </pre>
DESCRIPTION	sttydefs is an administrative command that maintains the line settings and hunt sequences for the system's TTY ports by making entries in, and deleting entries from the <code>/etc/ttydefs</code> file. sttydefs with a <code>-a</code> or <code>-r</code> option may be invoked only by the super-user. sttydefs with <code>-l</code> may be invoked by any user on the system.
OPTIONS	The following options are supported: <code>-a ttylabel</code> Add a record to the <code>ttydefs</code> file, using <i>ttylabel</i> as its label. The following describes the effect of the <code>-b</code>, <code>-n</code>, <code>-i</code>, or <code>-f</code> options when used in conjunction with the <code>-a</code> option: <code>-b</code> Enable autobaud. Autobaud allows the system to set the line speed of a given TTY port to the line speed of the device connected to the port without the user's intervention. <code>-f final-flags</code> Specify the value to be used in the <i>final-flags</i> field in <code>/etc/ttydefs</code>. <i>final-flags</i> must be in a format recognized by the <code>stty</code> command. <i>final-flags</i> are the <code>termio(7I)</code> settings used by <code>ttymon</code> after receiving a successful connection request and immediately before invoking the service on the port. If this option is not specified, sttydefs will set <i>final-flags</i> equal to the <code>termio(7I)</code> flags <code>9600</code> and <code>sane</code>. <code>-i initial-flags</code> Specify the value to be used in the <i>initial-flags</i> field in <code>/etc/ttydefs</code>. <i>initial-flags</i> must be in a format recognized by the <code>stty</code> command. These flags are used by <code>ttymon</code> when searching for the correct baud rate. They are set prior to writing the prompt. If this option is not specified, sttydefs will set <i>initial-flags</i> equal to the <code>termio(7I)</code> flag <code>9600</code>. <code>-n nextlabel</code> Specify the value to be used in the <i>nextlabel</i> field in <code>/etc/ttydefs</code>. If this option is not specified, sttydefs will set <i>nextlabel</i> equal to <i>ttylabel</i>. <code>-l[ttylabel]</code> If a <i>ttylabel</i> is specified, sttydefs displays the record from <code>/etc/ttydefs</code> whose TTY label matches the specified <i>ttylabel</i>. If no <i>ttylabel</i> is specified, sttydefs

sttydefs(1M)

	displays the entire contents of <code>/etc/ttydefs</code>. <code>sttydefs</code> verifies that each entry it displays is correct and that the entry's <i>nextlabel</i> field references an existing <code>-r <i>ttlabel</i></code> Remove any record in the <code>tttydefs</code> file that has <i>ttlabel</i> as its label.				
OUTPUT	If successful, <code>sttydefs</code> will exit with a status of 0. <code>sttydefs -l</code> will generate the requested information and send it to standard output.				
EXAMPLES	EXAMPLE 1 A sample of <code>sttydefs</code> command. The following command lists all the entries in the <code>tttydefs</code> file and prints an error message for each invalid entry that is detected. <pre>example# sttydefs -l</pre> The following shows a command that requests information for a single label and its output: <pre>example# sttydefs -l 9600 ----- 9600:9600 hupcl erase ^h:9600 sane ixany tab3 hupcl erase ^h::4800 ----- ttylabel: 9600 initial flags: 9600 hupcl erase ^h final flags: 9600 sane ixany tab3 hupcl erase ^h autobaud: no nextlabel: 4800</pre> The following sequence of commands will add the labels 1200, 2400, 4800, and 9600 and put them in a circular list: <pre>sttydefs -a 1200 -n 2400 -i 1200 -f "1200 sane" sttydefs -a 2400 -n 4800 -i 2400 -f "2400 sane" sttydefs -a 4800 -n 9600 -i 4800 -f "4800 sane" sttydefs -a 9600 -n 1200 -i 9600 -f "9600 sane"</pre>

NAME	su – become superuser or another user
SYNOPSIS	su [-] [<i>username</i> [<i>arg...</i>]]
DESCRIPTION	The su command allows one to become another user without logging off or to assume a role. The default user <i>name</i> is <i>root</i> (superuser). To use su, the appropriate password must be supplied (unless the invoker is already <i>root</i>). If the password is correct, su creates a new shell process that has the real and effective user ID, group IDs, and supplementary group list set to those of the specified <i>username</i>. Additionally, the new shell's project ID is set to the default project ID of the specified user. See <code>getdefaultproj(3PROJECT)</code>, <code>setproject(3PROJECT)</code>. The new shell will be the shell specified in the shell field of <i>username</i>'s password file entry (see <code>passwd(4)</code>). If no shell is specified, <code>/usr/bin/sh</code> is used (see <code>sh(1)</code>). If superuser privilege is requested and the shell for the superuser cannot be invoked using <code>exec(2)</code>, <code>/sbin/sh</code> is used as a fallback. To return to normal user ID privileges, type an EOF character (CTRL-D) to exit the new shell. Any additional arguments given on the command line are passed to the new shell. When using programs such as <code>sh</code>, an <i>arg</i> of the form <code>-c string</code> executes <i>string</i> using the shell and an <i>arg</i> of <code>-r</code> gives the user a restricted shell. The following statements are true if the login shell is <code>/usr/bin/sh</code> or an empty string (which defaults to <code>/usr/bin/sh</code>) in the specific user's password file entry. If the first argument to su is a dash (-), the environment will be changed to what would be expected if the user actually logged in as the specified user. Otherwise, the environment is passed along, with the exception of <code>\$PATH</code>, which is controlled by <code>PATH</code> and <code>SUPATH</code> in <code>/etc/default/su</code>. All attempts to become another user using su are logged in the log file <code>/var/adm/sulog</code> (see <code>sulog(4)</code>).
SECURITY	su uses <code>pam(3PAM)</code> with the service name su for authentication, account management, and credential establishment.
EXAMPLES	EXAMPLE 1 Becoming User <code>bin</code> While Retaining Your Previously Exported Environment To become user <code>bin</code> while retaining your previously exported environment, execute: <pre>example% su bin</pre> EXAMPLE 2 Becoming User <code>bin</code> and Changing to <code>bin</code>'s Login Environment To become user <code>bin</code> but change the environment to what would be expected if <code>bin</code> had originally logged in, execute: <pre>example% su - bin</pre> EXAMPLE 3 Executing command with user <code>bin</code>'s Environment and Permissions To execute command with the temporary environment and permissions of user <code>bin</code>, type:

**ENVIRONMENT
VARIABLES**

EXAMPLE 3 Executing command with user bin's Environment and Permissions
(Continued)

```
example% su - bin -c "command args"
```

Variables with LD_ prefix are removed for security reasons. Thus, su bin will not retain previously exported variables with LD_ prefix while becoming user bin.

If any of the LC_* variables (LC_CTYPE, LC_MESSAGES, LC_TIME, LC_COLLATE, LC_NUMERIC, and LC_MONETARY) (see environ(5)) are not set in the environment, the operational behavior of su for each corresponding locale category is determined by the value of the LANG environment variable. If LC_ALL is set, its contents are used to override both the LANG and the other LC_* variables. If none of the above variables are set in the environment, the "C" (U.S. style) locale determines how su behaves.

LC_CTYPE Determines how su handles characters. When LC_CTYPE is set to a valid value, su can display and handle text and filenames containing valid characters for that locale. su can display and handle Extended Unix Code (EUC) characters where any individual character can be 1, 2, or 3 bytes wide. su can also handle EUC characters of 1, 2, or more column widths. In the "C" locale, only characters from ISO 8859-1 are valid.

LC_MESSAGES Determines how diagnostic and informative messages are presented. This includes the language and style of the messages, and the correct form of affirmative and negative responses. In the "C" locale, the messages are presented in the default form found in the program itself (in most cases, U.S. English).

FILES

\$HOME/.profile user's login commands for sh and ksh

/etc/passwd system's password file

/etc/profile system-wide sh and ksh login commands

/var/adm/sulog log file

/etc/default/su the default parameters in this file are:

SULOG If defined, all attempts to su to another user are logged in the indicated file.

CONSOLE If defined, all attempts to su to root are logged on the console.

PATH Default path. (/usr/bin:)

SUPATH Default path for a user invoking su to root. (/usr/sbin:/usr/bin)

SYSLOG Determines whether the syslog(3C) LOG_AUTH facility

su(1M)

should be used to log all su attempts. LOG_NOTICE messages are generated for su's to root, LOG_INFO messages are generated for su's to other users, and LOG_CRIT messages are generated for failed su attempts.

SLEEPTIME

If present, sets the number of seconds to wait before login failure is printed to the screen and another login attempt is allowed. Default is 4 seconds. Minimum is 0 seconds. Maximum is 5 seconds.

sulogin(1M)

NAME	sulogin – access single-user mode						
SYNOPSIS	sulogin						
DESCRIPTION	The sulogin utility is automatically invoked by <code>init</code> when the system is first started. It prompts the user to type the root password to enter system maintenance mode (single-user mode) or to type EOF (typically CTRL-D) for normal startup (multi-user mode). The user should never directly invoke <code>sulogin</code>. The <code>sulogin</code> utility can prompt the user to enter the root password on a variable number of serial console devices, in addition to the traditional console device. See <code>consadm(1M)</code> and <code>msglog(7D)</code> for a description of how to configure a serial device to display the single-user login prompt.						
FILES	/etc/default/sulogin	Default value can be set for the following flag:					
		PASSREQ	Determines if login requires a password. Default is PASSREQ=YES.				
	/etc/default/login	Default value can be set for the following flag:					
		SLEEPTIME	If present, sets the number of seconds to wait before login failure is printed to the screen and another login attempt is allowed. Default is 4 seconds. Minimum is 0 seconds. Maximum is 5 seconds.

NAME	suninstall – install the Solaris environment				
SYNOPSIS	suninstall				
DESCRIPTION	suninstall is a forms-based subsystem for installing the operating system. suninstall only exists on the Solaris CD-ROM and should only be invoked from there. Refer to the installation manual for more details. suninstall allows installation of the operating system onto any stand-alone system. suninstall loads the software available on the CD-ROM. Refer to the installation manual for disk space requirements. To abort the installation procedure, use the interrupt character (typically, CTRL-C).				
USAGE	Refer to the installation manual for more information on the various menus and selections.				
ATTRIBUTES	See attributes(5) for descriptions of the following attributes: <table border="1"> <thead> <tr> <th>ATTRIBUTE TYPE</th><th>ATTRIBUTE VALUE</th></tr> </thead> <tbody> <tr> <td>Availability</td><td>SUNWcdrom (Solaris CD)</td></tr> </tbody> </table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	Availability	SUNWcdrom (Solaris CD)
ATTRIBUTE TYPE	ATTRIBUTE VALUE				
Availability	SUNWcdrom (Solaris CD)				
SEE ALSO	pkginfo(1), install(1M), pkgadd(1M), attributes(5) <i>Solaris 9 9/04 Installation Guide</i>				
NOTES	It is advisable to exit suninstall through the exit options from the suninstall menus.				

SUNWgfb_config(1M)

NAME	SUNWgfb_config – fbconfig module for configuring Sun XVR-1000 Graphics Accelerator
SYNOPSIS	<pre> fbconfig [-dev <i>device-filename</i>] [-active a b both auto] [-res <i>video-mode</i> [now try] [noconfirm]] [-file machine system] [-doublewide enable disable reverse] [-doublehigh enable disable reverse] [-multisample enable disable auto [static dynamic]] [-samples <i>samples-per-pixel</i>] [-g <i>gamma-correction-value</i>] [-master a b input] [-buffer-size [width height] auto] [-clearpixel0 255] fbconfig [-dev <i>device-filename</i>] -stream a b [-port hd15 dvid svideo auto] [-res <i>video-mode</i> [now try] [noconfirm]] [-file machine system] [-offset <i>xoff-value</i> [<i>yoff-value</i>]] [-slave [enable disable] [internal external]] fbconfig [-dev <i>device-filename</i>] -defaults fbconfig [-dev <i>device-filename</i>] [-propt -prconf -res \?] fbconfig [-help -list] </pre>
DESCRIPTION	SUNWgfb_config is the Sun XVR-1000 Graphics Accelerator device dependent layer for fbconfig(1M). It configures the Sun XVR-1000 Graphics Accelerator and some of the X11 window system defaults. The device can drive two monitors, each with a unique video stream (called stream a and stream b). The first form of SUNWgfb_config shown in the synopsis above sets card options, which are options common to both stream a and stream b, and apply to the entire card. The second form is used to set stream options, which are options specific to either stream a or stream b. The second form usage requires the -stream option to define which stream is affected. Both the first form and the second form store the specified options in the OWconfig file. These options will be used to initialize the device the next time the window system is run on that device. Updating options in the OWconfig file provides persistence of these options across window system sessions and system reboots. For -res now, -try, -slave, -master, -port, and -g, the device will be immediately programmed. The third form, which invokes the -defaults option, sets all card options and all stream options to their default values. The fourth form, which invokes the -prconf, -propt, and -res \? options, queries the device for status that is card-specific. The fifth form, which invokes the -help, and -list options, provides instruction on using SUNWgfb_config and a list of available devices. Additionally for the fifth form, all other options are ignored.

**GENERAL
OPTIONS**

You can specify options for only one device at a time. Specifying options for multiple devices requires multiple invocations of `SUNWgfb_config`.

Only Sun XVR-1000 Graphics Accelerator-specific options can be specified through `SUNWgfb_config`. The normal window system options for specifying default depth, default visual class, and so forth are still specified as device modifiers on the command line when the X server is started.

You can also specify the `OWconfig` file that is to be updated. By default, the machine-specific file in the `/etc/openwin` directory tree is updated. You can use the `-file` option to specify an alternate file. For example, the system-global `OWconfig` file in the `/usr/openwin` directory tree can be updated instead.

`-dev device-filename`

Specifies the device's special file. The default is `/dev/fb`.

`-file machine | system`

Specifies which `OWconfig` file to update. If `machine`, the machine-specific `OWconfig` file in the `/etc/openwin` directory tree is used. If `system`, the global `OWconfig` file in the `/usr/openwin` directory tree is used. If the file does not exist, it is created.

`-res video-mode [ now | try [ noconfirm ] ]`

Specifies the video mode used to drive the monitor connected to the specified device. If `-res` is invoked with `now` or `try`, you must specify a `-stream` option or a device, such as `/dev/fbs/gfb0a`. If `-active` is set to `both` or `auto`, then both stream `video-mode` values will be modified.

The `video-mode` argument specifies resolution and timing information for the display (for example, `SUNW_STD_1280x1024x76`). The naming convention for the `video-mode` specifier is:

origin_type_widthheightxrate

The elements of the specifier are described as follows:

origin

This can be one of:

- SUNW, Sun derived resolution
- VESA, Video Electronics Standards Association-derived resolution
- other, other source

type

This can be one of:

- STD, normal resolution, usable by most display devices
- DIG, resolution tuned only for LCD flat panels
- INT, interlaced
- STEREO, stereo

width

screen width in pixels

SUNWgfb_config(1M)

height
screen height in pixels

rate
vertical frequency of the screen refresh

Note that some video-modes supported by the device, might not be supported by the monitor. The list of video-modes supported by the device and the monitor can be obtained by running `SUNWgfb_config` with the `-res \?` option (the fourth form shown in the command synopsis above).

The `-res` option also accepts additional, optional arguments, listed below, immediately following the video mode specification. Either `now` or `try` (`try` subsumes `now`) and `noconfirm` can be present.

now
If present, not only is the video mode updated in the `OWconfig` file, but the device is immediately programmed to display this video mode. This is useful for changing the video mode before starting the window system.

Note – It is recommended that you not use this suboption with `SUNWgfb_config` while the configured device is being used (for example, while running the window system). Unpredictable results can occur. To run `SUNWgfb_config` with the `now` suboption, first bring the window system down. If the `now` suboption is used within a window system session, the video mode is changed immediately, but the width and height of the affected screen do not change until the window system is exited and reentered. In addition, the system might not recognize changes in stereo mode.

noconfirm
Using the `-res` option, the user can put the system into an unusable state, with no video output. To reduce the chance of this, the default behavior of `SUNWgfb_config` is to display a warning message and to ask the user whether to continue. The `noconfirm` bypasses this confirmation. This option is useful when `SUNWgfb_config` is being run from a shell script.

try
If present, the specified video mode will be programmed on a trial basis. The user is asked to confirm the video mode by typing **y** within 10 seconds. Alternatively, the user can terminate the trial before 10 seconds elapse by typing any character other than **y** or carriage return. Such input is considered a no and the previous video mode is restored. With a negative response, `SUNWgfb_config` does not change the video mode in the `OWconfig` file; other options specified still take effect. If a carriage return is typed, the user is asked (**y** or **n**) whether to keep the new video mode. The `try` suboption implies the `now` suboption. See the warning note in the description of the `now` suboption, above.

-defaults
Resets all option values to their default values. Writes these values to the `OWconfig` file.

-propt

Displays the current values of all options in the OWconfig file specified by the -file option for the device specified by the -dev option. Displays the values of options as they will be in the OWconfig file after the call to SUNWgfb_config completes. The following is an example display:

```
--- OpenWindows Configuration for /dev/fbs/gfb0 ---
OWconfig: machine
Active Streams: both
Samples Per Pixel: 2
Multisample Allocation Model: static
Multisample Mode: auto
Doublewide: disable
Gamma Correction Value: 2.22

--- OpenWindows Configuration for Stream a ---
Video Mode: SUNW_STD_1280x1024x76

--- OpenWindows Configuration for Stream b ---
Video Mode: VESA_STD_640x480x60
```

-prconf

Displays the XVR-1000 hardware configuration. The following is an example display:

```
--- Hardware Configuration for /dev/fb (SUNWgfb0) ---
Type:   Sun Graphics Accelerator
Part:   501-5865
Memory:
        MAJC:           32MB
        Texture:        256MB total
        3DRAM64:        5.0M pixels

Versions:  FCode 1.14  MCode 0.19  MAJC 2.1  FBC3 3.0  XChip 2.0

Video Streams:
  Stream a
    Current resolution Setting: SUNW_STD_1280x1024x76
    Monitor/EDID data (13W3)
      Monitor Manufacturer: SUN
      Monitor Name:   GDM-5410
      EDID:   Version 1, Revision 2
  Stream b
    Current resolution Setting: VESA_STD_640x480x60
    Port: svideo
```

-help

Displays a list of the SUNWgfb_config command line options, along with a brief explanation of each.

-res \?

Displays list of defined *video-mode* names.

CARD OPTIONS**-active a | b | both | auto**

Specifies which streams are enabled. both select both streams. The default is auto, which means whichever stream is chosen by the console.

SUNWgfb_config(1M)

`-multisample enable | disable | auto`
[`static | dynamic`]

The suboptions for `-multisample` are described as follows:

`disable`
No multisample is possible.

`enable`
Multisample is possible but is selected on a per-application basis.

`auto`
All Sun OpenGL applications are rendered using multisampling.

`static`
Multisample allocation occurs at X startup/config load time. The config *samples-per-pixel* or *max* parameter specifies the depth that is pre-allocated.

`dynamic`
OpenGL tasks allocate buffers themselves.

`-samples samples-per-pixel`
Specifies the number of samples/pixel to pre-allocate in static mode. Provides a hint to OpenGL in dynamic mode. The allowable choices for *samples-per-pixel* are 2, 3, 4, 5, 6, 8, 10, 16, and max. The default is max, which means to use the maximum number of samples that can be supported with the amount of memory available.

`-doublewide enable | disable | reverse`
This option makes it easy for you to combine both streams into one side-by-side virtual display. If you specify `enable`, stream a is to the left of stream b. If `reverse` is specified, stream b is to the left of stream a. Both will be the same resolution defined with the `-res` option. If you specify `disable`, only one stream will be enabled. `-doublewide` precludes `-doublehigh`.

`-doublehigh enable | disable | reverse`
This option makes it easy for you to combine both streams into one virtual display, with one monitor on a shelf above the other. If you specify `enable`, stream a is above stream b. If `reverse` is specified, stream b is above stream a. Both will be the same resolution defined with the `-res` option. If you specify `disable`, only one stream will be enabled. `-doublehigh` precludes `-doublewide`.

`-g gamma-correction value`
This option changes the gamma correction value. By default the gamma correction value is 2.22. Any value less than zero is illegal. This option can be used while the window system is running. Changing the gamma correction value will affect all the windows being displayed using gamma-corrected visuals. The gamma correction value is also saved in the `OWconfig` file for the next time the window system starts.

`-master a | b | input`
This option controls the setting frame pins on the stereo/sync connector on the device. It also controls which stream drives stereo glasses, which attach to the same connector.

**STREAM
OPTIONS**

If a (the default) or b is selected, the card is setup to be a sync master, and the frame sync signal from the corresponding stream will be sent out this connector.

If you select input, the card is setup to take its frame sync from another card through this connector. This sync can then be used to sync either or both streams by setting the stream-specific `-slave` option(s) to `external`.

If stereo glasses are used, the a or b options select which stream is used for the sync signal to the glasses.

`-buffer size [ width height ] | auto`

Explicitly allows you to specify size of managed area, which occupies all or a portion of the device's 3D RAM. The default is `auto`, that is, to automatically size the buffer based on the current stream resolutions. This should be sufficient for most users.

`-clear pixel 0 | 255`

Selects the overlay transparent color. This is the pixel value (color index) used by the transparent overlay visual to display the underlay (RGB) pixel contents. The default is 255 (all bits 1), but some applications require 0. All other color indices display a colormap color.

`-stream a | b`

Specifies for which stream options will be set. It is a required option for each of the other options in this section. It is optional for `-res`. Only one `-stream` option can be specified.

`-port hd15 | dvid | svideo | auto`

Directs stream b to the appropriate output connector: `hd-15`, `dvid`, or `svideo`. If `auto`, then the output connector for stream b is selected by the console. Stream a is always output through the 13W3 connector.

`-offset xoff-value [yoff-value]`

Offsets display of child stream (specified by `-stream`) relative to parent and child alignment edges.

xoff-value

Number of pixels offset in horizontal direction. Positive direction is right; negative is left. Default is 0, which means the two edges touch.

yoff-value

Number of pixels offset in vertical direction. Positive direction is down; negative is up. Default is 0, which means the two edges touch.

`-slave [ enable | disable ] [ internal | external ]`

This option allows you to specify the sync source for the specified stream.

`internal` indicates that the sync source is the other stream of this device.

`external` indicates the sync is taken from a source outside the device. If you use `external`, you also need to use the card option `-master input`.

SUNWgfb_config(1M)

DEFAULTS

For a given invocation of `SUNWgfb_config`, if an option does not appear on the command line, the corresponding `OWconfig` option is not updated. It retains its previous value.

When the window system is run, if an option has never been specified through `SUNWgfb_config`, a default value is used. The option defaults are as follows:

Option	Default
-dev	/dev/fb
-file	machine
-res	none
-samples	max
-multisample	enable/dynamic
-clearpixel	255
-master	a
-slave	disable/external
-doublewide	not set
-g	2.22
-active	auto
-port	auto
-offset	0/0

The default for the `-res` option of `none` means that, when the window system is run, the screen resolution will be the video mode that is currently programmed in the device. This provides compatibility for users who are used to specifying the device resolution through the PROM.

EXAMPLES

EXAMPLE 1 Switching Resolution of a Monitor

The following example switches to the resolution of 1280 by 1024 at 76 Hz:

```
example% fbconfig -stream a -res -SUNW_STD_1280x1024x76
```

SUNWifb_config(1M)

NAME	SUNWifb_config – configure the Sun Expert3D Graphics Accelerator
SYNOPSIS	<pre> /usr/lib/fbconfig/SUNWifb_config [-dev <i>device-filename</i>] [-res <i>video-mode</i> [now try] [noconfirm nocheck]] [-file machine system] [-deflinear true false] [-defoverlay true false] [-linearorder first last] [-overlayorder first last] [-expvis enable disable] [-slave enable disable] [-accum enable disable] [-g <i>gamma-correction-value</i>] [-gfile <i>gamma-correction-file</i>] [-propt] [-prconf] [-defaults] [-slave] [] [-samples 1 2 4 8 16] [-multisample enable disable auto] /usr/lib/fbconfig/SUNWifb_config [-propt] [prconf] /usr/lib/fbconfig/SUNWifb_config [-help] [-res \?] </pre>
DESCRIPTION	SUNWifb_config configures the Sun Expert3D Graphics Accelerator, Sun Expert3D-Lite, and Sun XVR-500 Graphics Accelerators, and some of the X11 window system defaults for the graphics accelerator. The first form of SUNWifb_config shown in the synopsis above stores the specified options in the OWconfig file. These options will be used to initialize the Sun Expert3D device the next time the window system is run on that device. Updating options in the OWconfig file provides persistence of these options across window system sessions and system reboots. The second and third forms of SUNWifb_config, which invoke only the -prconf, -propt, -help, and -res \? options, do not update the OWconfig file. Additionally, for the third form of the command, all other options are ignored. Options may be specified for only one Sun Expert3D device at a time. Specifying options for multiple Sun Expert3D devices requires multiple invocations of SUNWifb_config. Only options specific to the Sun Expert3D device can be specified through SUNWifb_config. The normal window system options for specifying default depth, default visual class and so forth are still specified as device modifiers on the openwin command line (see the Xsun(1) manual page in the OpenWindows Desktop Reference Manual).
OPTIONS	The following options are supported: -dev <i>device-filename</i> Specifies the Sun Expert3D special file. The default is /dev/fbs/ifb0. -file machine system Specifies which OWconfig file to update. If machine, the machine-specific OWconfig file in the /etc/openwin directory tree is used. If system, the global OWconfig file in the /usr/openwin directory tree is used. If the file does not exist, it is created.

-res *video-mode*

Specifies the video mode used to drive the monitor connected to the specified Sun Expert3D device.

The format of these built-in video modes is:

widthxheightxrate

where *width* is the screen width in pixels, *height* is the screen height in pixels, and *rate* is the vertical frequency of the screen refresh. The *s* suffix of 960x680x112s and 960x680x108s means that these are stereo video modes. The *i* suffix of 640x480x60i and 768x575x50i designates interlaced video timing. If absent, non-interlaced timing will be used. As a convenience, -res also accepts formats with @ (at sign) in front of the refresh rate instead of x. For example: 1280x1024@76. Note that some video-modes supported by the Sun Expert3D device might not be supported by the monitor. The list of video-modes supported by the Sun Expert3D device and the monitor can be obtained by running SUNWifb_config with the -res \? option (shown in the command synopsis above). The following is a list of all possible video-modes supported on the Sun Expert3D device:

```
1024x768x60
1024x768x70
1024x768x75
1024x768x75
1024x768x77
1024x800x84
1152x900x66
1152x900x76
1280x800x76
1280x1024x60
1280x1024x67
1280x1024x76
1280x1024x85
1280x1024x112s (Stereo)
960x680x112s (Stereo)
960x680x108s (Stereo)
640x480x60
640x480x60i (Interlaced)
768x575x50i (Interlaced)
1440x900x76
1600x1000x66
1600x1000x76
```

SUNWifb_config(1M)

Symbolic names

1600x1280x76
1792x1344x75
1920x1080x72
1920x1200x70
1920x1200x75

For convenience, some of the above video modes have symbolic names defined for them. Instead of the form *width x height x rate*, one of these names may be supplied as the argument to *-res*. The meaning of the symbolic name *none* is that when the window system is run the screen resolution will be the video mode that is currently programmed in the device.

Name	Corresponding Video Mode
svga	1024x768x60
1152	1152x900x76
1280	1280x1024x76
stereo	960x680x112s
ntsc	640x480x60i
pal	768x575x50i
none	(see text above)

The *res* option also accepts additional, optional arguments immediately following the video mode specification. Any or all of the following might be present.

now

If present, not only will the video mode be updated in the *OWconfig* file, but the Sun Expert3D device will be immediately programmed to display this video mode. (This is useful for changing the video mode before starting the window system).

Note that it is inadvisable to use this suboption with *SUNWifb_config* while the configured device is being used (for example, while running the window system); unpredictable results might occur. To run *SUNWifb_config* with the *now* suboption, first bring the window system down. If the *now* suboption is used within a window system session, the video mode will be changed immediately, but the width and height of the affected screen will not change until the window system is exited and reentered again. In addition, the system may not recognize changes in stereo mode. Consequently, this usage is strongly discouraged.

noconfirm	Using the <code>-res</code> option, the user could potentially put the system into an unusable state, a state where there is no video output. This can happen if there is ambiguity in the monitor sense codes for the particular code read. To reduce the chance of this, the default behavior of <code>SUNWifb_config</code> is to print a warning message to this effect and to prompt the user to find out if it is okay to continue. The <code>noconfirm</code> option instructs <code>SUNWifb_config</code> to bypass this confirmation and to program the requested video mode anyway. This option is useful when <code>SUNWifb_config</code> is being run from a shell script.
nocheck	If present, the normal error checking based on the monitor sense code (described above) will be suspended. The video mode specified by the user will be accepted regardless of whether it is appropriate for the currently attached monitor. (This option is useful if a different monitor is to be connected to the Sun Expert3D device). Use of this option implies <code>noconfirm</code> as well.
try	If present, the specified video mode will be programmed on a trial basis. The user will be asked to confirm the video mode by typing <code>y</code> within 10 seconds. Or the user may terminate the trial before 10 seconds are up by typing any character. Any character other than <code>y</code> or carriage return is considered a "no" and the previous video mode will be restored and <code>SUNWifb_config</code> will not change the video mode in the <code>OWconfig</code> file (other options specified will still take effect). If a carriage return is typed, the user is prompted for a yes or no answer on whether to keep the new video mode. This option implies the <code>now</code> suboption (see the warning paragraph under the <code>now</code> suboption).
-deflinear true false	
The Sun Expert3D device possesses two types of visuals: linear and nonlinear. Linear visuals are gamma corrected and nonlinear visuals are not. There are two visuals that have both linear and nonlinear versions: 24-bit TrueColor and 8-bit StaticGray. If <code>true</code> , the default visual is set to the linear visual that satisfies other specified default visual selection options (specifically, the <code>Xsun(1) -defdepth</code> and <code>-defclass</code> options described in the OpenWindows Desktop Reference Manual). If <code>false</code> , or if there is no linear visual that satisfies the other default visual selection options, the non-linear visual specified by these other options will be chosen to be the default. This option cannot be used when the <code>-defoverlay</code> option is present, because the Sun Expert3D does not possess a linear overlay visual.	

SUNWifb_config(1M)

`-defoverlay true | false`

The Sun Expert3D device provides an 8-bit PseudoColor visual whose pixels are disjoint from the rest of the Sun Expert3D visuals. This is called the overlay visual. Windows created in this visual will not damage windows created in other visuals. The converse, however, is not true. Windows created in other visuals will damage overlay windows. If the value of this option is `true`, the overlay visual will be made the default visual. If `false`, the nonoverlay visual that satisfies the other default visual selection options, such as `-defdepth` and `-defclass`, will be chosen as the default visual. See the `Xsun(1)` manual page in the OpenWindows Desktop Reference Manual. Whenever `-defoverlay true` is used, the default depth and class chosen on the `openwin` command line must be 8-bit PseudoColor. If not, a warning message will be printed and the `-defoverlay` option will be treated as `false`. This option cannot be used when the `-deflinear` option is present, because the Sun Expert3D device does not possess a linear overlay visual.

`-linearorder first | last`

If `first`, linear visuals will come before their non-linear counterparts on the X11 screen visual list for the Sun Expert3D screen. If `last`, the nonlinear visuals will come before the linear ones.

`-overlayorder first | last`

If `-first`, the depth 8 PseudoColor Overlay visual will come before the non-overlay visual on the X11 screen visual list for the Sun Expert3D screen. If `last`, the non-overlay visual will come before the overlay one.

`-expvis enable | disable`

If enabled, OpenGL Visual Expansion will be activated. Multiple instances of selected visual groups (8-bit PseudoColor, 24-bit TrueColor, and so forth) can be found in the screen visual list.

`-slave enable | disable`

If enabled, the video for this frame buffer will be synced with the video of the display which is connected to it. For applications which support it buffers will also be swapped synchronously.

`-accum enable | disable`

If enabled, frame buffer memory is allocated for accelerated accumulation buffer for windows. If disabled, software accumulation buffering will be done for windows. Accelerated accumulation buffers for pBuffers are always available as memory allows.

`-g gamma-correction_value`

This option allows changing the gamma correction value. All linear visuals provide gamma correction. By default the gamma correction value is 2.22. Any value less than zero is illegal. The gamma correction value is applied to the linear visual, which then has an effective gamma value of 1.0, which is the value returned by `XSolarisGetVisualGamma()`. See `XSolarisGetVisualGamma(3)` for a description of that function. This option can be used while the window system is running. Changing the gamma correction value will affect all the windows being displayed using the linear visuals.

-gfile *gamma-correction_file*

This option loads gamma correction table from the specified file. This file should be formatted to provide the gamma correction values for R, G and B channels on each line. Each of these values should be in hexadecimal format and separated from each other by at least one space. Also, this file should provide 1024 such triplets. An example of this file is as follows.

```
0x00 0x00 0x000
0x01 0x01 0x001
0x02 0x02 0x002
...
...
0x3ff 0x3ff 0x3ff
```

Using this option, the gamma correction table can be loaded while the window system is running. The new gamma correction will affect all the windows being displayed using the linear visuals. Note that, when gamma correction is being done using a user-specified table, the gamma correction value is undefined. By default, the window system assumes a gamma correction value of 2.22 and loads the gamma table it creates corresponding to this value.

-defaults

Resets all option values to their default values.

-propt

Prints the current values of all Sun Expert3D options in the OWconfig file specified by the -file option for the device specified by the -dev option. Prints the values of options as they will be in the OWconfig file after the call to SUNWifb_config completes. This is a typical display:

```
--- OpenWindows Configuration for /dev/fbs/ifb0 ---
OWconfig: machine
Video Mode: 1280x1024x76
Accum: Disabled (do not allocate an accumulation buffer)
Default Visual: Non-Linear Normal Visual
Visual Ordering: Linear Visuals are last
                  Overlay Visuals are last
OpenGL Visual Expansion: enabled
Gamma Correction Value: 2.22
Gamma Correction Table: Available
```

-prconf

Prints the Sun Expert3D hardware configuration. This is a typical display:

```
--- Hardware Configuration for /dev/fbs/ifb0 ---
PROM Information: @(#)ifb.fth 1.25 99/10/12 SMI
EDID Data: Available - EDID version 1 revision 1
Monitor possible resolutions: 1024x768x60, 1024x768x70, 1024x768x75,
1152x900x66, 1152x900x76, 1280x1024x67, 1280x1024x76, 960x680x112s,
640x480x60
Current resolution setting: 1280x1024x76
```

SUNWifb_config(1M)

-help

Prints a list of the `SUNWifb_config` command-line options, along with a brief explanation of each.

-samples 1 | 2 | 4 | 8 | 16

Requested number of samples to compute per display pixel. The requested number of samples per pixel will be used if `-multisample` is not disabled and resources exist for the request.

Query the number of samples used with `-propt` (see above) or the `xglnfo` utility. The `xglnfo` utility can return the number of multisamples after you specify the option `-multisample enable`.

The default is 16.

-multisample enable | disable | auto

If set to `disable`, no multisample is possible. If set to `enable`, multisample is possible but is selected on a per-window basis using a library interface. If set to `auto`, all Sun OpenGL windows are rendered using multisampling.

Query the number of samples used with `-propt` (see above) or the `xglnfo` utility. The `xglnfo` utility can return the number of multisamples if `-multisample` is set to `enable`.

The default is `disable`.

The `xglnfo` utility is shipped with the Sun OpenGL package, `SUNWglrt`. The man page for `xglnfo` is part of another Sun OpenGL package, `SUNWgldoc`.

DEFAULTS

For a given invocation of `SUNWifb_config` command line if an option does not appear on the command line, the corresponding `OWconfig` option is not updated; it retains its previous value. When the window system is run, if an Sun Expert3D option has never been specified via `SUNWifb_config`, a default value is used. The option defaults are as follows:

Option	Default
<code>-dev</code>	<code>/dev/fbs/ifb0</code>
<code>-file</code>	<code>machine</code>
<code>-res</code>	<code>none</code>
<code>-deflinear</code>	<code>false</code>
<code>-defoverlay</code>	<code>false</code>
<code>-linearorder</code>	<code>last</code>
<code>-overlayorder</code>	<code>last</code>
<code>-expvis</code>	<code>enable</code>
<code>-slave</code>	<code>disable</code>
<code>-accum</code>	<code>enable</code>
<code>-g</code>	<code>2.22</code>
<code>-samples</code>	<code>16</code>
<code>-multisample</code>	<code>disable</code>

SUNWifb_config(1M)

The default for the `-res` option of none means that, when the window system is run, the screen resolution will be the video mode that is currently programmed in the device. This design choice provides compatibility for users who are used to specifying the device resolution through the PROM. On some devices (for example, GX), this is the only way of specifying the video mode. This means that the PROM ultimately determines the default Sun Expert3D video mode.

EXAMPLES **EXAMPLE 1** Changing Monitor Resolution

The following example switches the monitor type to the resolution of 1280 x 1024 at 76 Hz:

```
example% /usr/lib/fbconfig/SUNWifb_config -res 1280x1024x76
```

SUNWpfb_config(1M)

NAME	SUNWpfb_config – fbconfig module for configuring Sun XVR-100 Graphics Accelerator
SYNOPSIS	<pre>/usr/lib/fbconfig/SUNWpfb_config [-dev <i>device-filename</i>] [-res <i>video-mode</i> [now try] [noconfirm nocheck]] [-file machine system] [-fake8 enable disable] [-doublewide enable disable] [-doublehigh enable disable] [-outputs swapped direct] [-depth 8 24] [-offset <i>xval yval</i>] [-defaults] /usr/lib/fbconfig/SUNWpfb_config [-propt] [-prconf] /usr/lib/fbconfig/SUNWpfb_config [-help] [-res \?]</pre>
DESCRIPTION	SUNWpfb_config is the Sun XVR-100 device dependent layer for fbconfig(1M). It configures the Sun XVR-100 Graphics Accelerator and some of the X11 window system defaults for Sun XVR-100. The Sun XVR-100 provides the capability to drive two monitors, each with a unique video stream (Stream #1 and Stream #2). The first form of SUNWpfb_config shown in the SYNOPSIS section sets options for the Sun XVR-100. It stores the specified options in the OWconfig file. These options initialize the Sun XVR-100 device the next time the window system is run on that device. Updating options in the OWconfig file provides persistence of these options across window system sessions and system reboots. The Sun XVR-100 device is immediately programmed if you specify the -res now. The second form, which invokes the only the -prconf and -propt options, queries the Sun XVR-100 for status. The third form, which invokes the -help, and -res and \? options, provides instruction on using SUNWpfb_config. Additionally, for the third form all other options are ignored. You can only specify options for only one Sun XVR-100 device at a time. If you want to specify options for multiple Sun XVR-100 devices, you must requires multiple invocations of SUNWpfb_config. You can only use SUNWpfb_config to specify Sun XVR-100-specific options. You can use the normal window system options to specify the default depth, default visual class and so forth as device modifiers on the command line when the X Server is started. See dtlogin(1) for information regarding the Xservers File. You can also specify the OWconfig file to update. The machine-specific file in the /etc/openwin directory tree is updated by default. You can used the -file option to specify an alternate file. For example, you can update the system-global OWconfig file in the /usr/openwin directory tree instead.
OPTIONS	The following options are supported: -defaults Reset all option values to their default values.

```

-depth 8 | 24
    Set the depth (bits per pixel) for the window system. Possible values for the
    -depth option are 8 or 24. You must log out of the current window system session
    and log back in again for the change to take effect. Any depth setting in the Xserver
    command line takes precedence over what is set using fbconfig. The default is 8.

-dev device-filename
    Specify the Sun XVR-100 special file. The default is /dev/fb.

-doublehigh enable | disable
    Configure the two outputs of the Sun XVR-100 into one vertical virtual display. The
    default is disable.

-doublewide enable | disable
    Configure the two outputs of the Sun XVR-100 into one horizontal virtual display.
    The default is disable.

-fake8 enable | disable
    Enable or disable simple 8 bit X windows to be rendered without a hardware
    colormap to reduce colormap flashing. You might notice performance reductions.
    The default is disable.

-file machine | system
    Specify which OWconfig file to update. If you specify machine, SUNWpfb_config
    updates the machine-specific OWconfig file in the /etc/openwin directory tree. If
    you specify system, SUNWpfb_config updates the global OWconfig file in the
    /usr/openwin directory tree. If either file does not exist, it is created.

-help
    Print a list of the SUNWpfb_config command line options, along with a brief
    explanation of each.

-offset xval yval
    Adjust the position of the specified stream by the value specified. This option is
    only implemented in -doublewide and -doublehigh modes. For
    -doublewide, use the xval to position the rightmost stream. Negative is left
    (overlaps with the left stream). For -doublehigh, use the yval to position the
    bottom stream. Negative is up (overlaps with top stream). The default is [0, 0].

-outputs swapped | direct
    Reverse or not reverse the positions of the -doublewide or -doublehigh outputs
    relative to each other. The default is direct.

-propt
    Print the current values of all Sun XVR-100 options in the OWconfig file specified
    by the -file option for the device specified by the -dev option. Print the values of
    options as they will be in the OWconfig file after the call to SUNWpfb_config
    completes.

    This is a typical display:

    --- OpenWindows Configuration for /dev/fbs/pfb0 ---

```

SUNWpfb_config(1M)

```
OWconfig: machine
Video Mode: NONE
Depth: not set

Screen Information:
    Doublewide: Disable
    Doublehigh: Disable
    Output Configuration: Direct
```

-prconf

Print the Sun XVR-100 hardware configuration.

This is a typical display:

```
--- Hardware Configuration for /dev/fbs/pfb0 ---
```

```
Type: XVR-100
ASIC: version 0x5159
REV : version 0x3000000
PROM: version 0
```

```
Monitor/Resolution Information:
    EDID Data: Not Available
    Current resolution setting: 1280x1024x75
```

```
Depth Information:
    Possible depths:  8, 24
    Current depth: 8
```

-res *video-mode* [now | try [noconfirm | nocheck]]

Specify the video mode that drives the monitor connected to the specified Sun XVR-100 device.

Video modes are built-in. The `-res` option requires you to specify the video-mode. You can specify *video-mode* in the format of *widthxheightxrate* or as a symbolic name.

widthxheightxrate

Specify *video-mode* in the format of *widthxheightxrate*, where *width* is the screen width in pixels, *height* is the screen height in pixels, and *rate* is the the vertical frequency of the screen refresh. An example video mode specified in this format is 1280x1024x76.

The `-res` option also accepts formats with @ preceding the refresh rate instead of x, (1280x1024@76).

Symbolic Names

Some video modes have symbolic names defined for them. Instead of the form *widthxheightxrate* format, you can specify one of the symbolic names as the argument to the `-res`. The meaning of the symbolic name none is that when the window system is run the screen resolution is the video mode that is currently programmed in the device.

The following symbolic names and their corresponding video modes are supported:

svga	1024x768x60
1152	1152x900x76
1280	1280x1024x75
none	Programmed video mode

Some video-modes, supported by Sun XVR-100, might not be supported by the monitor. Use the `-res \?` option to obtain the list of video-modes supported by the Sun XVR-100 device and the monitor.

The `-res` option also accepts additional, optional arguments immediately following the video mode specification. The following additional, optional arguments are supported:

<code>nocheck</code>	If present, the normal error checking based on the monitor sense code is suspended. The video mode specified by the user is accepted regardless of whether it is appropriate for the currently attached monitor. This option is useful if a different monitor is to be connected to the Sun XVR-100 device. Use of this option implies <code>noconfirm</code> as well.
<code>noconfirm</code>	You could put the system into an unusable state using the <code>-res</code> option, which has no video output. To reduce the chance of this, the default behavior of <code>SUNWpfb_config</code> is to print a warning message and to ask the user whether to continue. The <code>noconfirm</code> option bypasses this confirmation. This option is useful when you are running <code>SUNWpfb_config</code> from a shell script.
<code>now</code>	If present, updates the video mode in the <code>OWconfig</code> file and immediately programs the Sun XVR-100 device to display this video mode. This is useful for changing the video mode before starting the window system. Do not use this suboption with <code>SUNWpfb_config</code> while the configured device is being used, for example, while running the window system. Unpredictable results can occur. If you want to run <code>SUNWpfb_config</code> with the <code>now</code> suboption, first bring the window system down. If you use the <code>now</code> within a window system session, the video mode is changed immediately. The width and height of the affected screen will not change until the window system is exited and re-entered again. Additionally, the system might not recognize changes in stereo mode. This usage is discouraged.
<code>try</code>	If present, programs the specified video mode on a trial basis. You are asked to confirm the video mode by entering a <code>y</code> within 10 seconds. You can terminate the trial before 10 seconds by entering any character but <code>y</code> or RETURN. If you want to run <code>SUNWpfb_config</code> with the <code>now</code> suboption, first bring the

SUNWpfb_config(1M)

window system down. If you use the `now` suboption within a window system session, the video mode is changed immediately. The width and height of the affected screen won't change until the window system is exited and re-entered again. Additionally, the system might not recognize changes in stereo mode. This usage is strongly discouraged.

`-res \?`

Print a list of defined *video-mode* names.

DEFAULTS

For a given invocation of `SUNWpfb_config` command line if an option does not appear on the command line, the corresponding `OWconfig` option is not updated; it retains its previous value.

When the window system is run, if an Sun XVR-100 option has never been specified by `SUNWpfb_config`, a default value is used. The options and their corresponding defaults are as follows:

Option	Default
<code>-dev</code>	<code>/dev/fb</code>
<code>-file</code>	<code>machine</code>
<code>-res</code>	<code>none</code>
<code>-fake8</code>	<code>disable</code>
<code>-depth</code>	<code>8</code>
<code>-doublewide</code>	<code>disable</code>
<code>-doublehigh</code>	<code>disable</code>
<code>-outputs</code>	<code>direct</code>
<code>-offset</code>	<code>[0,0]</code>

The default for the `-res` option `none` means that when the window system is run the screen resolution will be the video mode that is currently programmed in the Sun XVR-100 PROM.

This provides compatibility for users who are used to specifying the device resolution through the Sun XVR-100 PROM. On some devices (e.g. GX) this is the only way of specifying the video mode. This means that the PROM ultimately determines the default Sun XVR-100 video mode.

EXAMPLES

EXAMPLE 1 Switching the Monitor Type

The following example switches the monitor type to the resolution of 1280 × 1024 at 76 Hz:

```
example% fbconfig -res 1280x1024x76
```

FILES `/dev/fbs/pfbn`
 Device special file for Sun XVR-100 single screen

`/dev/fbs/pfbna`
 Device special file for the Sun XVR-100 first video out

`/dev/fbs/pfbnb`
 Device special file for the Sun XVR-100 second video out

`/usr/lib/fbconfig/SUNWpfb_config`
 Device special file

SUNWzulu_config(1M)

NAME	SUNWzulu_config – fbconfig module for configuring SunXVR-4000 Graphics Accelerator
SYNOPSIS	<pre> fbconfig [-dev <i>device-filename</i>] [-file machine system] [<i>options...</i> -defaults] fbconfig [-dev <i>device-filename</i>] [-propt] [-prconf] fbconfig [-dev <i>device-filename</i>] [-list -help -res \?] fbconfig [-dev <i>device-filename</i>] [-doublewide enable disable] [-doublehigh enable disable] [-outputs direct swapped streamA streamB] [-master a b] [-clearpixel 0 255] fbconfig [-dev <i>device-filename</i>] [-res <i>video_mode</i> [now try] [noconfirm]] [-multisample available disable forceon] [-samples <i>samples-per-pixel</i>] [-jitter regular random permuted auto] fbconfig [-dev <i>device-filename</i>] [-stream a b] [-filter cylinder gaussian mitchell catmull] [-filter_file <i>filter_filename</i> [-offset <i>xoff-value</i> <i>yoff-value</i>] [-g <i>gamma-correction-value</i>] [-slave [enable disable] [framelock [internal external] genlock bothlock]] [-genlock [defaults] [hphase <i>±hphs</i>] [vphase <i>±vphs</i>] [sync [auto tip tri slice]] [pol [auto pos neg]]] </pre>
DESCRIPTION	SUNWzulu_config is the Sun XVR-4000 Graphics Accelerator device-dependent layer for fbconfig(1M). It configures the Sun XVR-4000 Graphics Accelerator and some of the X11 window system defaults and some interactions with 3D-accelerated graphics (through OpenGL). The first through third synopses, above, show the general form of a SUNWzulu_config command. The fourth synopsis (with -res as the first option) shows card options. The fifth synopsis is for managed-area options. The sixth and last synopsis shows stream options. These option categories—card, managed-area, and streams—are used mainly to explain the SUNWzulu_config functions. Where appropriate, you can use options of different types on the same command line. The Sun XVR-4000 device can support one or two unique video streams (called stream a and stream b), each of which can drive a display device.
Option Classes	The many options that fbconfig can select on the Sun XVR-4000 Graphics Accelerator are divided into the following categories: general options Shared among different invocation forms or used for query without selecting device settings.

Device Usage and Invocation Forms**card options**

Of the entire XVR-4000 Graphics Accelerator, shared between up to two video streams.

managed area options

Pertain to an area of the frame buffer managed by X and possibly shared between two video streams.

stream options

Specific to a video stream.

To use the device to provide a single X managed area with one video stream, use a stream-independent device argument (for example, `-dev zulu0`) without a trailing `a` or `b`. The device name (for example, `/dev/fb` or `/dev/fbs/zulu0`), without any trailing stream indicator should appear on the `Xsun` command line. Stream options will control `stream a` (the only stream used).

To enable two streams from a single X managed area (without needing X's `+xinerama` option), use the device name (for example, `-dev zulu0`) without any trailing `a` or `b`. Enable card option `-doublewide` or `-doublehigh`. Without using the `-stream` option, any stream options you specify are applied to both streams. Stream options can differ between the video streams if `fbconfig` is be run separately for each stream, using the `-stream a | b` option, as shown in EXAMPLES (second example), below.

To use the device's two streams as independent X screens, run `fbconfig` separately for each stream (`-dev zulu0a` and `-dev zulu0b`), as shown in EXAMPLES (third example). Card options `-doublehigh` and `-doublewide` are not available. The device names with trailing stream indicators (for example, `/dev/fbs/zulu0a` and `/dev/fbs/zulu0b`) must be added to the `Xsun` command line to use these independent X screens. The `-stream` option is not needed; the stream is implied by the stream-specific device name.

The `fbconfig` utility checks settings for the two stream devices to assure X can use them simultaneously. Therefore, you might need to use `fbconfig` to reduce resource consumption (for example, `-samples`) used by one stream's device (for example, `zulu0a`) before you can use `fbconfig` to increase consumption by the other stream's device (for example, `zulu0b`).

The first form of `SUNWzulu_config` shown in SYNOPSIS, above, stores the specified options in the `OWconfig` file associated with the device and (for stream options) the stream. These options are used to initialize the device the next time the window system is started on that device-filename. Updating options in the `OWconfig` file provides persistence of these options across window system sessions and system reboots. You can select the `OWconfig` file that is to be updated using the `-file` option. For `-jitter`, `-res now`, `-res try`, and all stream options, the device will also be immediately programmed.

The second form, which invokes any of the `-prconf` and `-propt` options, queries the device for status that is card-specific.

SUNWzulu_config(1M)

The third form, which invokes the `-help`, `-list`, or `-res \?` options, provides instruction on using `SUNWzulu_config`, a list of available devices, or a list of available resolutions. When using this form, all other options are ignored.

You can specify options for only one device at a time. Specifying options for multiple devices (or multiple independent X managed areas or streams) requires multiple invocations of `fbconfig`.

Only Sun XVR-4000 Graphics Accelerator-specific options can be specified through `SUNWzulu_config`. Window system options for specifying default depth, default visual class, `-nobanner`, and so forth are still specified as device modifiers on the `Xsun` command line when the X server is started, probably in CDE's `Xservers` file. See the `Xsun(1)` man page in the OpenWindows man page collection and `/usr/dt/config/Xservers`.

OPTIONS

This section is subdivided into general, card, managed area, and stream options.

General Options

`-dev device-filename`

Specifies the device's special file, such as `/dev/fbs/zulu0` or the basename such as `zulu0` as a shorthand. The default is `/dev/fb`. See "Device Usage and Invocation Forms," above.

`-file machine | system`

Selects which `OWconfig` file to update. If `machine`, the machine-specific `OWconfig` file in the `/etc/openwin` directory tree is used. (This is the default.) If `system`, the global `OWconfig` file in the `/usr/openwin` directory tree is used. If the file does not exist, it is created.

`-defaults`

Resets all option values to their default values, listed in the DEFAULTS section, below. For example, invoking `-defaults` on `zulu0`, `zulu0a`, or `zulu0b` will reset all card, managed area, and stream options for all these `zulu0` subdevices.

`-propt`

Displays the current values of all options in the `OWconfig` file specified by the `-file` option for the device specified by the `-dev` option. Displays the values of options as they will be in the `OWconfig` file after the call to `SUNWzulu_config` completes. The following is an example display:

```
--- OpenWindows Configuration for /dev/fbs/zulu0 ---
```

```
OWconfig File: machine
```

```
Card:
```

```
Double(wide/high):      disable
Stream to Port Mapping:  direct (Stream A to Port A; B to B)
Clearpixel Value:        255
```

```
Managed Area:
```

```
Resolution:              SUNW_STD_1280x1024x76
Samples Per Pixel:        max
Multisample Mode:         forceon
Jitter Table:             auto
```

```

Video Streams:
  Stream A:
    Offset (x,y):      (0, 0)
    Gamma Correction Value: 2.22
    Filter Type:       mitchell

  Stream B:
    Offset (x,y):      (0, 0)
    Gamma Correction Value: 2.22
    Filter Type:       mitchell

Framelock:
  Framelock/Stereo Port: Output from Stream A
  Stream A Sync:         Free Run (no frame sync)
  Stream B Sync:         Free Run (no frame sync)

```

-prconf

Displays the current XVR-4000 hardware configuration, including version numbers of each class of chip. The following is an example display:

```

--- Hardware Configuration for /dev/fbs/zulu0 ---
Type:  XVR-4000 Graphics Accelerator
Part:   501-5588

Memory:
  MAJC:      128MB
  Texture:   1GB total
  3DRAM64:   10.0M samples

Versions:
  Fcode 1.19   MCode 1.4   MAJC 2.1
  FBC3 3.0     Master 1.0   Convolve 0.0
  Sched 1.0    I/O 1.0     FPGA 0.0

Power Level:
  Monitor Power: On
  Board Power:   On

Video Streams:
  Stream A:
    Current resolution setting: SUNW_STD_1280x1024x76
    Flags: Allocated Default Primary
    Samples per pixel: 6
    Port: 13W3a
    Monitor/EDID data (13W3)
      Monitor Manufacturer: SUN
      Monitor Name: GDM-5410
      EDID: Version 1, Revision 2

  Stream B:
    Current resolution setting: SUNW_STD_1280x1024x76
    Flags: Allocated
    Samples per pixel: 2
    Port: 13W3b
    Monitor/EDID data (13W3)
      Monitor Manufacturer: SUN
      EDID: Version 1, Revision 3

```

SUNWzulu_config(1M)

Card Options

- help
Displays a list of the `SUNWzulu_config` command line options, along with a brief explanation of each.
 - res \?
Displays list of defined video mode names supported by the XVR-4000 Graphics Accelerator and the display device.
 - doublewide enable | disable
This option makes it easy for you to combine both streams into one side-by-side virtual display. When enabled with `-outputs direct`, stream a is to the left of stream b. Both streams will use the same video mode defined with the `-res` option. If you specify `disable`, only stream a will be enabled. Enabling `-doublewide` disables `-doublehigh`.
 - doublehigh enable | disable
This option makes it easy for you to combine both streams into one virtual display with one display device above the other. When enabled with `-outputs direct`, stream a is above stream b. Both streams will use the same video mode defined with the `-res` option. If you specify `disable`, only stream a will be enabled. Enabling `-doublehigh` disables `-doublewide`.
 - outputs direct | swapped | streamA | streamB
Controls the internal routing of video streams to output ports (that is, backplane 13W3 connectors). The choices are:
 - direct
Stream a to output port a, stream b to output port b
 - swapped
Stream a to output port b, stream b to output port a
 - streamA
Stream a to both output ports
 - streamB
Stream b to both output ports

The default is `direct`. `swapped` can be used to reverse the connectors when `-doublewide` or `-doublehigh` is enabled. The `streamA` and `streamB` arguments are incompatible with stream-specific device names (for example, `zulu0a` or `zulu0b`). When the `-res` option selects an S-video (NTSC or PAL composite) video mode, the svideo output port is automatically selected, sometimes overriding `-outputs` selection.
 - master a | b
This option controls which stream drives the `FIELD` and `FRAME_OUT` pins on the device's stereo/sync connector. This pin can drive stereo shutter glasses, and allow another device to framelock to this device's output. The default is `a`.
- Independent of this option, the `-slave external` option allows a stream to sync to another card by means of this connector's `FIELD_IN` pin.

**Managed Area
Options**

`-clearpixel 0 | 255`

Selects the overlay transparent color. This is the pixel value (color index) used by the transparent overlay visual to display the underlay (RGB) pixel contents. The default is 255 (all bits 1), but some applications require 0. All other color indices display a colormap color.

`-res video_mode [ now | try [ noconfirm ] ]`

The *video_mode* argument specifies resolution and timing information for the display (for example, SUNW_STD_1280x1024x76). The naming convention for the video mode specifier is:

origin_type_widthxheightxrate

The elements of the specifier are described as follows:

origin

This can be one of:

SUNW

Sun-derived resolution

VESA

Video Electronics Standards Association-derived resolution

other

other source

type

This can be one or more of:

STD

normal resolution, usable by most display devices

DIG

resolution tuned only for LCD flat panels

INT

interlaced

STEREO

stereo

width

screen width in pixels

height

screen height in pixels

rate

vertical frequency of the screen refresh (in hertz, that is, video frames per second)

Note that some video modes supported by the XVR-4000 might not be supported by the display device. The list of video modes supported by the device and the display device can be obtained by running `SUNWzulu_config` with the `-res \?` option.

SUNWzulu_config(1M)

The `-res` option also implicitly specifies the resolution of the X screen's managed area. It is the same as the video mode resolution, or twice the width or height in the case of `-doublewide` or `-doublehigh`, respectively.

The `-res` option also accepts additional, optional arguments, listed below, immediately following the video mode specification. Either `now` or `try` (`try` subsumes `now`) and `noconfirm` can be present.

`now`

If present, not only is the video mode updated in the `OWconfig` file, but the device is immediately programmed to display this video mode. This is useful for testing the video mode before starting the window system.

It is recommended that you not use the `try` or `now` suboptions while the configured device is being used (for example, while running the window system). The best practice is to exit the window system beforehand. If these suboptions are used within a window system session, the video mode is changed immediately, but the width and height of the affected X window system's screen do not change until the window system restarts. (The buffer may be scaled or cropped if the resolution is lowered; a black border may surround the buffer if it is increased. In addition, the system might not recognize changes in stereo mode.)

`noconfirm`

Using the `-res` option, the user can put the system into an unusable state, with no video output. To reduce the chance of this, the default behavior of `SUNWzulu_config` is to display a warning message and ask the user whether to continue. The `noconfirm` argument bypasses this confirmation. This option is useful when `SUNWzulu_config` is being run from a shell script.

`try`

If present, the specified video mode will be programmed on a trial basis. The user is asked to confirm the video mode by typing `y` within 10 seconds. Alternatively, the user can terminate the trial before 10 seconds elapse by typing any character other than `y` or return. Such input is considered a `no` and the previous video mode is restored. With a negative response, `SUNWzulu_config` does not change the video mode in the `OWconfig` file; other options specified still take effect. If a carriage return is typed, the user is asked (`y` or `n`) whether to keep the new video mode.

The `try` suboption implies the `now` suboption. See the warning note in the description of the `now` suboption, above. The `try` option can be used to test a video mode. Best practice is to then restart the window system or to reject the video mode and then set it again without the `try` or `now` suboptions (for the next time the window system starts).

`-multisample available | disable | forceon`

The `-multisample` option controls whether a multisample buffer is allocated by the window system and used by OpenGL applications. The suboptions are:

disable

No multisample rendering is possible. Only one sample per pixel is allocated, despite the `-samples` option value. Furthermore, display filtering is disabled.

available

Multisample is possible but is selected on a per-application basis. (Each process may choose whether to multisample at the density allocated when the window system started, or not to multisample at all. Intermediate densities are not possible.)

forceon

Sun OpenGL will use multisample rendering for all applications. There may be a minor performance penalty for rendering at higher sample densities.

Multisample allocation occurs when the window system starts up. This is the only allocation mode supported on the Sun XVR-4000 Graphics Accelerator.

-samples samples-per-pixel

Specifies the number of samples per pixel to allocate when multisample is not **disable**. Allowable choices are 1 to 16 or **max**, but a very high sample density can be allocated only at low resolution. Setting sample density to 1 is not equivalent to disabling multisampling; samples will still be subject to filtering and jitter. Sample resolutions (without frame rates) and their maximum sample densities follow.

Resolution	Maximum Density	Maximum Balanced Density
width by height	(single stream)	(one stream + another)
1920 by 1200	4 samples	2 + 2 samples
1600 by 1200	5 samples	3 + 2 samples
1600 by 1024	6 samples	3 + 3 samples
1280 by 1024	8 samples	4 + 4 samples
1152 by 900	9 samples	5 + 4 samples
1024 by 800	11 samples	5 + 5 samples
800 by 600	15 samples	7 + 7 samples
768 by 575	15 samples	7 + 7 samples
640 by 480	16 samples	9 + 9 samples

The default is **max**, which means to use the maximum number of samples that can be supported with the amount of memory available, possibly dependent on the video timing (horizontal frequency).

SUNWzulu_config(1M)

For dual independent streams, if the first stream used by the window system (typically, the first in the `Xservers` file) chooses `max`, it takes most of the memory and video resources. The second stream can then use only a low sample density. If it also chooses `max`, X automatically finds the highest sample density remaining, such as 1 or 2 samples per pixel. To assign sample density more evenly, set each stream's density explicitly. `SUNWzulu_config` allows a combination of resolutions and sample densities only if they will coexist successfully. You might have to reduce one stream's sample density (or choose `max`) before you can increase the other stream's.

`-jitter regular | random | permuted | auto`

Indirectly determines the subpixel (X,Y) locations of the samples stored in the sample buffer. (The sample density also affects the sample locations.) Choices are:

`regular`

Samples are regularly-spaced both vertically and horizontally. The sample locations repeat every pixel or two in X and Y.

`random`

Samples are pseudo-randomly (irregularly) spaced within the pixel. The sample locations repeat every 2 pixels in X and Y.

`permuted`

Samples are pseudo-randomly spaced within the pixel, and also permuted (stirred) in hardware so that the sample locations repeat every 128 pixels in X and Y. At moderate to high sample density, this choice can improve visual quality. At low sample density, straight lines or edges can appear jagged.

`auto`

Automatically selects the best jitter option for the current sample density. This is the default.

The same jitter selection must be used by OpenGL when rendering and by the display subsystem when refreshing the display from the sample buffer. The jitter value is changed immediately in hardware, but any multisamples already in the sample buffer were rendered using the prior jitter selection; that will look incorrect (for example, unstraight lines or edges) if the jitter selection is changed.

When a new OpenGL application starts up, it will render using the new jitter selection. (The window system need not be restarted.) The jitter value is also saved in the `OWconfig` file for the next time the window system starts.

Stream Options

`-stream a | b`

Determines whether stream options will be set for stream a or stream b. The "Device Usage and Invocation Forms" section, above, describes the usage and the default. The `-stream` option is required only to set different stream options for the two video streams enabled using card option `-doublewide` or `-doublehigh`.

`-filter cylinder | gaussian | mitchell | catmull`

`-filter_file filter_filename`

There are two ways to configure filtering. The `-filter` option is the simpler. It selects from these predefined filters:

cylinder

Poorest visual quality, most like a box filter.

gaussian

Blurriest; suitable for users who want to forgo detail to avoid all visible sampling artifacts.

mitchell

The best photo-realistic compromise between sharp detail and noticeable blurriness. This filter is the default.

catmull

The Catmull-Rom filter produces images a little sharper than Mitchell, but are more likely to have visible sampling artifacts, widely known as "jaggies".

The `-filter_file` option allows a user to provide his own filter by producing a filter file and copying or linking it into the directory

`/etc/openwin/server/etc/filters` or

`/usr/openwin/server/etc/filters`. (Both directories are writable by super-user by default.) The *filter_filename* must not start with `/` or `./` nor contain the substring `./`, but can contain subdirectory components.

`fbconfig` and `X` search the directories above in the order listed. If the *filter_filename* is present and valid, the file takes precedence over a predefined filter.

The format of the file is a sequence of floating-point radius and weight values, each value separated by whitespace. Radius values must be monotonically increasing from 0. Weight values must be between -1.0 and +1.0, inclusive. Though more values can be present in the file, only values through radius 2.0 are used. Whitespace and comment lines prefixed with a hash mark (#) are ignored.

Example files contain the (irregular) radius values for which the device uses weight values. The file reader interpolates between existing values if the required radius is not present.

A valid filter option is changed immediately in hardware and saved in the `OWconfig` file for the next time the window system starts. However, when `multisample` is disabled, no filtering occurs.

-offset *xoff-value* *yoff-value*

Offsets the display of the stream (specified by `-stream`) relative to the adjoining edge of the other stream when `doublewide` or `doublehigh` is enabled. This can be used to cause an overlap.

xoff-value

Number of pixels offset in horizontal direction for the righthand stream when `doublewide` is enabled. Positive direction is to the right (create a gap); negative is to the left (overlap the streams). Default is 0, which means the two edges abut.

yoff-value

Number of pixels offset in vertical direction for the bottom stream when `doublehigh` is enabled. Positive direction is down (create a gap); negative is up

SUNWzulu_config(1M)

(overlap the streams). Default is 0, which means the two edges touch.

`-g gamma-correction-value`

This option changes the gamma correction value. By default the gamma correction value is 2.22. Any value less than zero is illegal. This option can be used while the window system is running. Changing the gamma correction value will affect all the windows being displayed using gamma-corrected visuals. The gamma correction value is also saved in the `OWconfig` file for the next time the window system starts.

`-slave [enable | disable]`

`[framelock [internal | external] | genlock | bothlock]`

This option allows you to enable a synchronization technique for the specified stream. Available techniques:

`framelock [internal | external]`

This provides "asynchronous frame reset": multiple streams all start a frame at roughly the same time. This allows stereo shutters to view the same eye's image from all the synchronized display devices. Using `framelock` requires the incoming synchronization signal have the same frame rate as the stream's video format.

When using `framelock` (or `bothlock`), you can also specify the synchronization source:

`internal`

Indicates that the sync source is the other stream of this device.

`external`

Indicates the sync is taken from a source outside the device. Using `external` requires a Frame Lock Cable (part number 530-2754) to be connected. If `-slave enable` is used without specifying a technique, `framelock external` is used.

`genlock`

This provides pixel-accurate horizontal synchronization, which is important in some video mixing situations. Use of `genlock` requires a genlock cable. Use of `bothlock` is recommended, when possible. Certain video formats are incompatible with `genlock`.

`bothlock`

This enables both `framelock` and `genlock` techniques, and requires both `framelock` (if `external`) and `genlock` cables.

`-genlock [defaults] [hphase $\pm$ hphs][vphase $\pm$ vphs]`

`[sync [auto|tip|tri|slice]] [pol [auto|pos|neg]]`

When `-slave` is enabled and the `genlock` technique is selected, the selections chosen with the `-genlock` option determine `genlock` details. These details are used immediately by the hardware, and saved in the `OWconfig` file for future use. Note that they may no longer be desired after changing to a different video format.

defaults

Reset all genlock details to their defaults.

hphase $\pm hphs$

The horizontal phase allows a pixel offset between the external video format and the stream's output. It may be specified as an absolute integer ranging from 0 to the total number of pixel clocks in a horizontal period (active video plus blanked pixels). Or, if the *hphs* starts with a + or -, the value will be added to the current horizontal phase and saved, modulo the valid range. Small deltas can be used repeatedly until the desired effect is observed.

vphase $\pm vphs$

The vertical phase allows a scanline offset between the the external video format and the stream's output. It can be specified as an absolute integer ranging from 0 to the total number of scanlines in a frame (active video plus blanked scanlines). Or, if the *vphs* starts with a + or -, the value will be added to the current vertical phase and saved, modulo the valid range. Small deltas can be used repeatedly until the desired effect is observed.

sync [auto | tip | slice | tri]

This option controls the details of input sync signal sampling, if necessary:

auto

Sample the genlock input pulses as most appropriate for the (Sun) video format. This is the default, and should be used whenever the sync master is also a Sun video format.

tip

Consider the sync to have occurred at the minimum signal value. This can be used with RS-170 (NTSC or PAL) or with TTL signals.

slice

Consider the frame sync to have occurred halfway between the minimum and maximum value (sync tip and back porch "blank" levels). This can be used with RS-170 (NTSC or PAL) or with TTL signals.

tri

Synchronize to a tri-level signal, used by HDTV analog formats.

pol [auto | pos | neg]

When the sync master is not a Sun video format, it might be necessary to choose which edge of the genlock input sync pulse should be used for genlock.

auto

Choose rising or falling edge for sync pulse, whichever is most appropriate for the video format. This is the default, and should be used whenever the sync master is also a Sun video format.

pos

Synchronize with a rising edge of a sync pulse.

neg

Synchronize with a falling edge of a sync pulse.

SUNWzulu_config(1M)

DEFAULTS For a given invocation of `SUNWzulu_config`, if an option does not appear on the command line, the corresponding `OWconfig` option is not updated. It retains its previous value.

When the window system starts, if an option has never been specified through `SUNWzulu_config`, a default value is used. The option defaults are as follows:

<i>Option Class</i>	<i>Option</i>	<i>Default</i>
General	-dev	/dev/fb
General	-file	machine (/etc/openwin/server/etc/OWconfig)
Card	-doublewide	disable
Card	-doublehigh	disable
Card	-master	a
Card	-outputs	direct
Card	-clearpixel	255
Managed Area	-res	SUNW_STD_1280x1024x76
Managed Area	-multisample	forceon
Managed Area	-samples	max
Managed Area	-jitter	auto
Stream	-offset	0,0
Stream	-filter	mitchell
Stream	-slave	disable/external/framelock
Stream	-genlock	hphase 0/vphase 0/auto/auto
Stream	-g	2.22

EXAMPLES **EXAMPLE 1** Switching Resolution of a Monitor

The following example switches to the resolution of 1280 by 1024 at 76 hertz:

```
% fbconfig -dev zulu0 -res SUNW_STD_1280x1024x76
```

EXAMPLE 2 Using Two Side-by-side Monitors with One Large X Screen

The following example enables use of two side-by-side monitors to display together a single large shared X window system "screen" (frame buffer managed area):

```
% fbconfig -dev zulu0 -doublewide enable
```

If the wrong monitor is on the left, they can be swapped in software:

```
% fbconfig -dev zulu0 -outputs swapped
```

A stream option selects a Gaussian (blurry) filter for video stream b:

```
% fbconfig -dev zulu0 -stream b -filter gaussian
```

For the two examples above, the factory-installed `/usr/dt/config/Xservers` file is sufficient (if `/dev/fb` is a link to the Sun XVR-4000 Graphics Accelerator device). If an `/etc/dt/config/Xservers` file exists, for Example 1 or 2, the file would refer to device `zulu0` (not `zulu0a` or `zulu0b`):

```
:0 Local local_uid@console root /usr/openwin/bin/Xsun -dev /dev/fbs/zulu0
```

EXAMPLE 2 Using Two Side-by-side Monitors with One Large X Screen (Continued)

EXAMPLE 3 Using Two Displays as Independent X Screens

The following example enables use of two displays, each with their own X window system managed frame buffer area and resolution. The larger resolution is not multisampled or filtered, so the smaller resolution will have more samples available to it.

```
% fbconfig -dev zulu0a -res SUNW_STD_1920x1200x75 -multisample disable
% fbconfig -dev zulu0b -res SUNW_STD_1280x1024x76 -samples max
```

In this example, and assuming the display device for stream b is to the right of that for stream a, the `/etc/dt/config/Xservers` file might contain (as one long line):

```
:0 Local local_uid@console root /usr/openwin/bin/Xsun -nobanner
    -dev /dev/fbs/zulu0a -dev /dev/fbs/zulu0b right
```

FILES

`/dev/fb`
default device file

`/usr/lib/fbconfig/SUNWzulu_config`
device configuration program

`/etc/openwin/server/etc/filters/`
root file system directory for filter files

`/usr/openwin/server/etc/filters/`
`/usr` file system directory for filter files

An administrator might also have to edit `/etc/dt/config/Xservers`.

swap(1M)

NAME	swap – swap administrative interface
SYNOPSIS	<pre>/usr/sbin/swap -a swapname [swaplow] [swaplen] /usr/sbin/swap -d swapname [swaplow] /usr/sbin/swap -l /usr/sbin/swap -s</pre>
DESCRIPTION	The swap utility provides a method of adding, deleting, and monitoring the system swap areas used by the memory manager.
OPTIONS	The following options are supported: <i>-a swapname</i> Add the specified swap area. This option can only be used by the super-user. <i>swapname</i> is the name of the swap file: for example, <i>/dev/dsk/c0t0d0s1</i> or a regular file. <i>swaplow</i> is the offset in 512-byte blocks into the file where the swap area should begin. <i>swaplen</i> is the desired length of the swap area in 512-byte blocks. The value of <i>swaplen</i> can not be less than 16. For example, if <i>n</i> blocks are specified, then <i>(n-1)</i> blocks would be the actual swap length. <i>swaplen</i> must be at least one page in length. The size of a page of memory can be determined by using the <i>pagesize</i> command. See <i>pagesize(1)</i>. Since the first page of a swap file is automatically skipped, and a swap file needs to be at least one page in length, the minimum size should be a multiple of 2 <i>pagesize</i> bytes. The size of a page of memory is machine dependent. <i>swaplow + swaplen</i> must be less than or equal to the size of the swap file. If <i>swaplen</i> is not specified, an area will be added starting at <i>swaplow</i> and extending to the end of the designated file. If neither <i>swaplow</i> nor <i>swaplen</i> are specified, the whole file will be used except for the first page. Swap areas are normally added automatically during system startup by the <i>/sbin/swapadd</i> script. This script adds all swap areas which have been specified in the <i>/etc/vfstab</i> file; for the syntax of these specifications, see <i>vfstab(4)</i>. To use an NFS or local file-system <i>swapname</i>, you should first create a file using <i>mkfile(1M)</i>. A local file-system swap file can now be added to the running system by just running the <i>swap -a</i> command. For NFS mounted swap files, the server needs to export the file. Do this by performing the following steps: 1. Add the following line to <i>/etc/dfs/dfstab</i>: <pre>share -F nfs -o rw=clientname , root=clientname path-to-swap-file</pre>

2. Run `shareall(1M)`.
3. Have the client add the following lines to `/etc/vfstab`:

```
server:path-to-swap-file - local-path-to-swap-file fs - - -
local-path-to-swap-file - - swap - - -
```

4. Have the client run `mount`:

```
# mount local-path-to-swap-file
```

5. The client can then run `swap -a` to add the swap space:

```
# swap -a local-path-to-swap-file
```

`-d swapname`

Delete the specified swap area. This option can only be used by the super-user. *swapname* is the name of the swap file: for example, `/dev/dsk/c0t0d0s1` or a regular file. *swaplow* is the offset in 512-byte blocks into the swap area to be deleted. If *swaplow* is not specified, the area will be deleted starting at the second page. When the command completes, swap blocks can no longer be allocated from this area and all swap blocks previously in use in this swap area have been moved to other swap areas.

`-l`

List the status of all the swap areas. The output has five columns:

<code>path</code>	The path name for the swap area.
<code>dev</code>	The major/minor device number in decimal if it is a block special device; zeroes otherwise.
<code>swaplo</code>	The <i>swaplow</i> value for the area in 512-byte blocks.
<code>blocks</code>	The <i>swapplen</i> value for the area in 512-byte blocks.
<code>free</code>	The number of 512-byte blocks in this area that are not currently allocated.

The list does not include swap space in the form of physical memory because this space is not associated with a particular swap area.

If `swap -l` is run while *swapname* is in the process of being deleted (by `swap -d`), the string `INDEL` will appear in a sixth column of the swap stats.

`-s`

Print summary information about total swap space usage and availability:

<code>allocated</code>	The total amount of swap space in bytes currently allocated for use as backing store.

swap(1M)

	reserved used available These numbers include swap space from all configured swap areas as listed by the -l option, as well swap space in the form of physical memory.	The total amount of swap space in bytes not currently allocated, but claimed by memory mappings for possible future use. The total amount of swap space in bytes that is either allocated or reserved. The total swap space in bytes that is currently available for future reservation and allocation.				
USAGE	Only the first 2 Gbyte of a block device larger than 2 Gbyte in size can be used for swap in swapfs on a 32-bit operating system. With a 64-bit operating system, a block device larger than 2 Gbyte can be fully utilized for swap up to 2 ⁶³ −1 bytes.					
ENVIRONMENT VARIABLES	See environ(5) for descriptions of the following environment variables that affect the execution of swap: LC_CTYPE and LC_MESSAGE.

NAME	swmtool – install, upgrade, and remove software packages				
SYNOPSIS	swmtool [-d <i>directory</i>]				
DESCRIPTION	The swmtool command invokes the admintool(1M) application, which is preselected to add or remove software. Using the swmtool command, you can add software from a product CD or hard disk to an installed system, or you can remove software from an installed system. Once logged in, you may run swmtool to examine the packages on your local system. Membership in the sysadmin group (gid 14) is used to restrict access to administrative tasks. Members of the sysadmin group can use swmtool to add or remove software packages. Non-members have read-only permissions (where applicable). Help is available by using the Help button.				
OPTIONS	-d <i>directory</i> Specify the directory containing the software to be installed.				
EXAMPLES	EXAMPLE 1 A sample display of using swmtool command. The following example starts the admintool() application and tells it to look for software packages in the local directory /cdrom/cdrom0/s0 (the default directory for a CD when running Volume Manager). <pre>example% /usr/sbin/swmtool -d /cdrom/cdrom0/s0</pre>				
ATTRIBUTES	See attributes(5) for descriptions of the following attributes: <table border="1"> <thead> <tr> <th>ATTRIBUTE TYPE</th><th>ATTRIBUTE VALUE</th></tr> </thead> <tbody> <tr> <td>Availability</td><td>SUNWadmap</td></tr> </tbody> </table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	Availability	SUNWadmap

sxconfig(1M)

NAME	<code>sxconfig</code> – configure contiguous memory for the SX video subsystem
SYNOPSIS	<pre> /usr/platform/platform-name/sbin/sxconfig -c /usr/platform/platform-name/sbin/sxconfig -d /usr/platform/ platform-name /sbin/sxconfig [-f -n] [-l limit] [-s size] </pre>
DESCRIPTION	The <code>sxconfig</code> command configures contiguous memory parameters for exclusive use by the SX video system on the Desktop SPARCsystems with graphics option. <i>platform-name</i> can be found using the <code>-i</code> option of <code>uname(1)</code>. After configuring the physically contiguous memory, using the various options described below, the system must be rebooted for the changes to take effect. If this command is being used to configure physically contiguous memory for the first time after the system software has been installed, then the system must be rebooted using the reconfiguration option (<code>-r</code>) of <code>boot(1M)</code>. The amount of memory to be reserved depends upon the type of application. Applications that benefit from the availability of contiguous memory are those that are written to the XGL and XIL graphics and imaging foundation library APIs. The <i>Platform Notes: SPARCstation 10SX System Configuration Guide</i> provides more detailed information regarding how much memory to reserve for various types of graphics and imaging applications. <code>sxconfig</code> is supported only on Desktop SPARCsystems with SX graphics option. The interface, output, and command location are uncommitted and subject to change in future releases.
OPTIONS	The following options are supported: -c Display the current configuration parameters in the driver configuration file. If the system was not rebooted after previously changing the configuration parameters, then the displayed values do not reflect the actual system setup. -d Restore all configuration parameters to the default values. By default, 0 megabytes of physically contiguous memory are reserved, fragmentation is not allowed, and 32 megabytes of memory are reserved for system use. -f Allow fragmentation. If no single chunk of memory of at least the requested size is found, allow the request to span multiple chunks. This flag also specifies that less than <i>size</i> megabytes of data may be reserved if there are not enough contiguous chunks available. If this flag is not specified, then the memory reserved must be exactly one chunk of the requested size for the request to succeed. -n Specify that fragmentation is not allowed.

-l <i>limit</i>	Specify that at least <i>limit</i> megabytes of total memory must remain for system use after the contiguous memory has been reserved.
-s <i>size</i>	Reserve <i>size</i> megabytes of contiguous memory for exclusive use by the SX video subsystem.

EXAMPLES

EXAMPLE 1 Using sxconfig

The following example reserves 16 megabytes of contiguous memory without fragmentation and indicates 32 megabytes of memory should remain for system use after reserving the contiguous memory:

```

example# sxconfig -s 16 -l 32

```

EXAMPLE 2 Using sxconfig with Fragmentation

The following example reserves 16 megabytes of contiguous memory with fragmentation allowed and indicates 32 megabytes of memory should remain for system use after reserving the contiguous memory:

```

example# sxconfig -s 16 -f -l 32

```

EXAMPLE 3 Reporting Current Configuration Parameters

The following example reports current configuration parameters in the driver configuration file:

```

example# sxconfig -c

```

EXAMPLE 4 Restoring Configuration Parameters to Default Values

The following example restores all configuration parameters to the default values:

```

example# sxconfig -d

```

EXAMPLE 5 Disabling Fragmentation

The following example disables fragmentation:

```

example# sxconfig -n

```

EXIT STATUS

sxconfig returns 0 on success, and a positive integer on failure.

1	Permission denied. Only root can run this command.
2	Configuration file <code>sx_cmem.conf</code> does not exist.
3	Illegal option.
4	Illegal combination of options.

sxconfig(1M)

5 Illegal argument for -s option. Should be an integer.

6 Illegal argument for -l option. Should be an integer.

syncinit(1M)

NAME	syncinit – set serial line interface operating parameters																							
SYNOPSIS	<code>/usr/sbin/syncinit device [[baud_rate] [keyword=value,...] [single-word option]]</code>																							
DESCRIPTION	The syncinit utility allows the user to modify some of the hardware operating modes common to synchronous serial lines. This can be useful in troubleshooting a link, or necessary to the operation of a communications package. If run without options, syncinit reports the options as presently set on the port. If options are specified, the new settings are reported after they have been made.																							
OPTIONS	Options to syncinit normally take the form of a keyword, followed by an equal sign and a value. The exception is that a baud rate may be specified as a decimal integer by itself. Keywords must begin with the value shown in the options table, but may contain additional letters up to the equal sign. For example, loop= and loopback= are equivalent. The following options are supported: <table><tr><th>Keyword</th><th>Value</th><th>Effect</th></tr><tr><td rowspan="2">loop</td><td>yes</td><td>Set the port to operate in internal loopback mode. The receiver is electrically disconnected from the DCE receive data input and tied to the outgoing transmit data line. Transmit data is available to the DCE. The Digital Phase-Locked Loop (DPLL) may not be used as a clock source in this mode. If no other clocking options have been specified, perform the equivalent of txc=baud and rxc=baud.</td></tr><tr><td>no</td><td>Disable internal loopback mode. If no other clocking options have been specified, perform the equivalent of txc=txc and rxc=rxc.</td></tr><tr><td rowspan="2">echo</td><td>yes</td><td>Set the port to operate in auto-echo mode. The transmit data output is electrically disconnected from the transmitter and tied to the receive data input. Incoming receive data is still visible. Use of this mode in combination with local loopback mode has no value, and should be rejected by the device driver. The auto-echo mode is useful to make a system become the endpoint of a remote loopback test.</td></tr><tr><td>no</td><td>Disable auto-echo mode.</td></tr><tr><td rowspan="2">nrzi</td><td>yes</td><td>Set the port to operate with NRZI data encoding.</td></tr><tr><td>no</td><td>Set the port to operate with NRZ data encoding.</td></tr><tr><td rowspan="2">txc</td><td>txc</td><td>Transmit clock source will be the TxC signal (pin 15).</td></tr><tr><td>rxc</td><td>Transmit clock source will be the RxC signal (pin 17).</td></tr></table>	Keyword	Value	Effect	loop	yes	Set the port to operate in internal loopback mode. The receiver is electrically disconnected from the DCE receive data input and tied to the outgoing transmit data line. Transmit data is available to the DCE. The Digital Phase-Locked Loop (DPLL) may not be used as a clock source in this mode. If no other clocking options have been specified, perform the equivalent of txc=baud and rxc=baud.	no	Disable internal loopback mode. If no other clocking options have been specified, perform the equivalent of txc=txc and rxc=rxc.	echo	yes	Set the port to operate in auto-echo mode. The transmit data output is electrically disconnected from the transmitter and tied to the receive data input. Incoming receive data is still visible. Use of this mode in combination with local loopback mode has no value, and should be rejected by the device driver. The auto-echo mode is useful to make a system become the endpoint of a remote loopback test.	no	Disable auto-echo mode.	nrzi	yes	Set the port to operate with NRZI data encoding.	no	Set the port to operate with NRZ data encoding.	txc	txc	Transmit clock source will be the TxC signal (pin 15).	rxc	Transmit clock source will be the RxC signal (pin 17).
Keyword	Value	Effect																						
loop	yes	Set the port to operate in internal loopback mode. The receiver is electrically disconnected from the DCE receive data input and tied to the outgoing transmit data line. Transmit data is available to the DCE. The Digital Phase-Locked Loop (DPLL) may not be used as a clock source in this mode. If no other clocking options have been specified, perform the equivalent of txc=baud and rxc=baud.																						
	no	Disable internal loopback mode. If no other clocking options have been specified, perform the equivalent of txc=txc and rxc=rxc.																						
echo	yes	Set the port to operate in auto-echo mode. The transmit data output is electrically disconnected from the transmitter and tied to the receive data input. Incoming receive data is still visible. Use of this mode in combination with local loopback mode has no value, and should be rejected by the device driver. The auto-echo mode is useful to make a system become the endpoint of a remote loopback test.																						
	no	Disable auto-echo mode.																						
nrzi	yes	Set the port to operate with NRZI data encoding.																						
	no	Set the port to operate with NRZ data encoding.																						
txc	txc	Transmit clock source will be the TxC signal (pin 15).																						
	rxc	Transmit clock source will be the RxC signal (pin 17).																						

	baud	Transmit clock source will be the internal baud rate generator.
	pll	Transmit clock source will be the output of the DPLL circuit.
rx	rx	Receive clock source will be the Rx signal (pin 17).
	tx	Receive clock source will be the Tx signal (pin 15).
	baud	Receive clock source will be the internal baud rate generator.
	pll	Receive clock source will be the output of the DPLL circuit.
speed	<i>integer</i>	Set the baud rate to <i>integer</i> bits per second.

There are also several single-word options that set one or more parameters at a time:

Keyword	Equivalent to Options:
external	txc=txc rxc=rxc loop=no
sender	txc=baud rxc=rxc loop=no
internal	txc=pll rxc=pll loop=no
stop	speed=0

EXAMPLES

EXAMPLE 1 Using syncinit

The following command sets the first CPU port to loop internally, using internal clocking and operating at 38400 baud:

```
example# syncinit zsh0 38400 loop=yes
device: /dev/zsh ppa: 0
speed=38400, loopback=yes, echo=no, nrzi=no, txc=baud, rxc=baud
```

The following command sets the same port's clocking, local loopback and baud rate settings to their default values:

```
example# syncinit zsh0 stop loop=no
device: /dev/zsh ppa: 0
speed=0, loopback=no, echo=no, nrzi=no, txc=txc, rxc=rxc
```

syncinit(1M)

DIAGNOSTICS

device missing minor device number

The name *device* does not end in a decimal number that can be used as a minor device number.

bad speed: *arg*

The string *arg* that accompanied the speed= option could not be interpreted as a decimal integer.

Bad arg: *arg*

The string *arg* did not make sense as an option.

ioctl failure code = *errno*

An ioctl(2) system call failed. The meaning of the value of *errno* may be found in intro(2).

WARNINGS

Do not use syncinit on an active serial link, unless needed to resolve an error condition. Do not use this command casually or without being aware of the consequences.

NAME	syncloop – synchronous serial loopback test program
SYNOPSIS	/usr/sbin/syncloop [-cdlstv] <i>device</i>
DESCRIPTION	The <code>syncloop</code> command performs several loopback tests that are useful in exercising the various components of a serial communications link. Before running a test, <code>syncloop</code> opens the designated port and configures it according to command line options and the specified test type. It announces the names of the devices being used to control the hardware channel, the channel number (ppa) corresponding to the <i>device</i> argument, and the parameters it has set for that channel. It then runs the loopback test in three phases. The first phase is to listen on the port for any activity. If no activity is seen for at least four seconds, <code>syncloop</code> proceeds to the next phase. Otherwise, the user is informed that the line is active and that the test cannot proceed, and the program exits. In the second phase, called the "first-packet" phase, <code>syncloop</code> attempts to send and receive one packet. The program will wait for up to four seconds for the returned packet. If no packets are seen after five attempts, the test fails with an excoriating message. If a packet is returned, the result is compared with the original. If the length and content do not match exactly, the test fails. The final phase, known as the "multiple-packet" phase, attempts to send many packets through the loop. Because the program has verified the integrity of the link in the first-packet phase, the test will not fail after a particular number of timeouts. If a packet is not seen after four seconds, a message is displayed. Otherwise, a count of the number of packets received is updated on the display once per second. If it becomes obvious that the test is not receiving packets during this phase, the user may wish to stop the program manually. The number and size of the packets sent during this phase is determined by default values, or by command line options. Each returned packet is compared with its original for length and content. If a mismatch is detected, the test fails. The test completes when the required number of packets have been sent, regardless of errors. After the multiple-packet phase has completed, the program displays a summary of the hardware event statistics for the channel that was tested. The display takes the following form: <pre> CRC errors Aborts Overruns Underruns In<-Drops-> Out 0 0 0 0 0 </pre> This is followed by an estimated line speed, which is an approximation of the bit rate of the line, based on the number of bytes sent and the actual time that it took to send them.
OPTIONS	The options for <code>syncloop</code> are described in the following table:

syncloop(1M)

Option	Parameter	Default	Description
-c	<i>packet_count</i>	100	Specifies the number of packets to be sent in the multiple-packet phase.
-d	<i>hex_data_byte</i>	<i>random</i>	Specifies that each packet will be filled with bytes with the value of <i>hex_data_byte</i> .
-l	<i>packet_length</i>	100	Specifies the length of each packet in bytes.
-s	<i>line_speed</i>	9600	Bit rate in bits per second.
-v			Sets verbose mode. If data errors occur, the expected and received data is displayed.
-t	<i>test_type</i>	<i>none</i>	A number, from 1 to 4, that specifies which test to perform. The values for <i>test_type</i> are as follows: 1: Internal loopback test. Port loopback is on. Transmit and receive clock sources are internal (baud rate generator). 2: External loopback test. Port loopback is off. Transmit and receive clock sources are internal. Requires a loopback plug suitable to the port under test. 3: External loopback test. Port loopback is off. Transmit and receive clock sources are external (modem). Requires that one of the local modem, the remote modem, or the remote system be set in a loopback configuration. 4: Test using predefined parameters. User defines hardware configuration and may select port parameters using the <code>syncinit(1M)</code> command.

All numeric options except -d are entered as decimal numbers (for example, -s 19200). If you do not provide the -t *test_type* option, syncloop prompts for it.

EXAMPLES

EXAMPLE 1 A sample display of using the syncloop command.

In the following command syncloop uses a packet length of 512 bytes over the first CPU port:

```
example# syncloop -l 512 zsh0
```

In response to the above command, syncloop prompts you for the test option you want.

The following command performs an internal loopback test on the first CPU port, using 5000 packets and a bit rate of 56Kbps:

```
example# syncloop -t 1 -s 56000 -c 5000 zsh0
```

SEE ALSO syncinit(1M), syncstat(1M), attributes(5), zsh(7D)

DIAGNOSTICS *device* missing minor device number
 The name *device* does not end in a decimal number that can be used as a minor device number.

invalid packet length: *nnn*
 The packet length was specified to be less than zero or greater than 4096.

poll: nothing to read

poll: nothing to read or write.
 The poll(2) system call indicates that there is no input pending and/or that output would be blocked if attempted.

len *xxx* should be *yyy*
 The packet that was sent had a length of *yyy*, but was received with a length of *xxx*.

nnn packets lost in outbound queueing

nnn packets lost in inbound queueing
 A discrepancy has been found between the number of packets sent by syncloop and the number of packets the driver counted as transmitted, or between the number counted as received and the number read by the program.

WARNINGS To allow its tests to run properly, as well as prevent disturbance of normal operations, syncloop should only be run on a port that is not being used for any other purpose at that time.

syncstat(1M)

NAME	syncstat – report driver statistics from a synchronous serial link																		
SYNOPSIS	<code>/usr/sbin/syncstat [-c] device [interval]</code>																		
DESCRIPTION	The <code>syncstat</code> command reports the event statistics maintained by a synchronous serial device driver. The report may be a single snapshot of the accumulated totals, or a series of samples showing incremental changes. Prior to these it prints the device name being used to query a particular device driver, along with a number indicating the channel number (ppa) under control of that driver. Event statistics are maintained by a driver for each physical channel that it supports. They are initialized to zero at the time the driver module is loaded into the system, which may be either at boot time or when one of the driver's entry points is first called. The <i>device</i> argument is the name of the serial device as it appears in the <code>/dev</code> directory. For example, <code>zsh0</code> specifies the first on-board serial device. The following is a breakdown of <code>syncstat</code> output: <table> <tr> <td>speed</td><td>The line speed the device has been set to operate at. It is the user's responsibility to make this value correspond to the modem clocking speed when clocking is provided by the modem.</td></tr> <tr> <td>ipkts</td><td>The total number of input packets.</td></tr> <tr> <td>opkts</td><td>The total number of output packets.</td></tr> <tr> <td>undrun</td><td>The number of transmitter underrun errors.</td></tr> <tr> <td>ovrrun</td><td>The number of receiver overrun errors.</td></tr> <tr> <td>abort</td><td>The number of aborted received frames.</td></tr> <tr> <td>crc</td><td>The number of received frames with CRC errors.</td></tr> <tr> <td>isize</td><td>The average size (in bytes) of input packets.</td></tr> <tr> <td>osize</td><td>The average size (in bytes) of output packets.</td></tr> </table>	speed	The line speed the device has been set to operate at. It is the user's responsibility to make this value correspond to the modem clocking speed when clocking is provided by the modem.	ipkts	The total number of input packets.	opkts	The total number of output packets.	undrun	The number of transmitter underrun errors.	ovrrun	The number of receiver overrun errors.	abort	The number of aborted received frames.	crc	The number of received frames with CRC errors.	isize	The average size (in bytes) of input packets.	osize	The average size (in bytes) of output packets.
speed	The line speed the device has been set to operate at. It is the user's responsibility to make this value correspond to the modem clocking speed when clocking is provided by the modem.																		
ipkts	The total number of input packets.																		
opkts	The total number of output packets.																		
undrun	The number of transmitter underrun errors.																		
ovrrun	The number of receiver overrun errors.																		
abort	The number of aborted received frames.																		
crc	The number of received frames with CRC errors.																		
isize	The average size (in bytes) of input packets.																		
osize	The average size (in bytes) of output packets.																		
OPTIONS	<code>-c</code> Clear the accumulated statistics for the device specified. This may be useful when it is not desirable to unload a particular driver, or when the driver is not capable of being unloaded. <i>interval</i> <code>syncstat</code> samples the statistics every <i>interval</i> seconds and reports incremental changes. The output reports line utilization for input and output in place of average packet sizes. These are the relationships between bytes transferred and the baud rate, expressed as percentages. The loop repeats indefinitely, with a column heading printed every twenty lines for convenience.																		

EXAMPLES**EXAMPLE 1** Sample output from the syncstat command:

```
example# syncstat zsh0
speed ipkts opkts undrun ovrrun abort crc isize osize
9600 15716 17121 0 0 1 3 98 89

example# syncstat -c zsh0 speed ipkts opkts undrun ovrrun abort crc isize osize
9600 0 0 0 0 0 0 0 0
```

In the following sample output a new line of output is generated every five seconds:

```
example# syncstat zsh0 5 ipkts opkts undrun ovrrun abort crc iutil outil
12 10 0 0 0 0 5% 4%
22 60 0 0 0 0 3% 90%
36 14 0 0 0 1 51% 2%
```

ATTRIBUTES

See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

SEE ALSO
DIAGNOSTICS

syncinit(1M), syncloop(1M), attributes(5), zsh(7D)

bad interval: *arg*

The argument *arg* is expected to be an interval and could not be understood.

device missing minor device number

The name *device* does not end in a decimal number that can be used as a minor device number.

baud rate not set

The *interval* option is being used and the baud rate on the device is zero. This would cause a divide-by-zero error when computing the line utilization statistics.

WARNINGS

Underrun, overrun, frame-abort, and CRC errors have a variety of causes.

Communication protocols are typically able to handle such errors and initiate recovery of the transmission in which the error occurred. Small numbers of such errors are not a significant problem for most protocols. However, because the overhead involved in recovering from a link error can be much greater than that of normal operation, high error rates can greatly degrade overall link throughput. High error rates are often caused by problems in the link hardware, such as cables, connectors, interface electronics or telephone lines. They may also be related to excessive load on the link or the supporting system.

The percentages for input and output line utilization reported when using the *interval* option may occasionally be reported as slightly greater than 100% because of inexact sampling times and differences in the accuracy between the system clock and the modem clock. If the percentage of use greatly exceeds 100%, or never exceeds 50%, then the baud rate set for the device probably does not reflect the speed of the modem.

sysdef(1M)

NAME	sysdef – output system definition
SYNOPSIS	<pre>/usr/sbin/sysdef [-n <i>namelist</i>]</pre> <pre>/usr/sbin/sysdef [-h] [-d] [-D]</pre>
DESCRIPTION	The <i>sysdef</i> utility outputs the current system definition in tabular form. It lists all hardware devices, as well as pseudo devices, system devices, loadable modules, and the values of selected kernel tunable parameters. It generates the output by analyzing the named bootable operating system file (<i>namelist</i>) and extracting the configuration information from it. The default system <i>namelist</i> is <i>/dev/kmem</i>.
OPTIONS	-n <i>namelist</i> Specifies a <i>namelist</i> other than the default (<i>/dev/kmem</i>). The <i>namelist</i> specified must be a valid bootable operating system. -h Prints the identifier of the current host in hexadecimal. This numeric value is unique across all Sun hosts. -d The output includes the configuration of system peripherals formatted as a device tree. -D For each system peripheral in the device tree, display the name of the device driver used to manage the peripheral.
EXAMPLES	EXAMPLE 1 Sample output format The following example displays the format of the <i>sysdef -d</i> output: <pre>example% sysdef -d Node 'Sun 4/60', unit #0 (no driver) Node 'options', unit #0 (no driver) Node 'zs', unit #0 Node 'zs', unit #1 Node 'fd', unit #0 Node 'audio', unit #0 Node 'sbus', unit #0 Node 'dma', unit #0 Node 'esp', unit #0 Node 'st', unit #1 (no driver) Node 'st', unit #0 Node 'sd', unit #2 Node 'sd', unit #1 Node 'sd', unit #0 Node 'le', unit #0 Node 'bwtwo', unit #0 Node 'auxiliary-io', unit #0 Node 'interrupt-enable', unit #0 Node 'memory-error', unit #0 Node 'counter-timer', unit #0 Node 'eeprom', unit #0</pre>

syseventadm(1M)

NAME	syseventadm – sysevent event specification administration
SYNOPSIS	syseventadm add [-R <i>rootdir</i>] [-v <i>vendor</i>] [-p <i>publisher</i>] [-c <i>class</i>] [-s <i>subclass</i>] [-u <i>username</i>] <i>path</i> [<i>args</i>] syseventadm remove [-R <i>rootdir</i>] [-v <i>vendor</i>] [-p <i>publisher</i>] [-c <i>class</i>] [-s <i>subclass</i>] [-u <i>username</i>] [<i>path</i> [<i>args</i>]] syseventadm list [-R <i>rootdir</i>] [-v <i>vendor</i>] [-p <i>publisher</i>] [-c <i>class</i>] [-s <i>subclass</i>] [-u <i>username</i>] [<i>path</i> [<i>args</i>]] syseventadm restart
DESCRIPTION	The syseventadm command is an administrative front-end to add, remove and list sysevent event handlers. syseventadm can only be run by root. The syseventadm add command adds a handler for a sysevent event specified by at least one of vendor, publisher or class. If <i>class</i> is specified, it may be qualified with a <i>sub-class</i>. Only the values specified for <i>vendor</i>, <i>publisher</i>, <i>class</i> and <i>sub-class</i> when adding the handler are matched against sysevent events to determine if the specification matches the event and the handler should be run. <i>path</i> is the full pathname of the command to be run in response to matching events, with optional arguments (<i>args</i>). If <i>username</i> is specified, the command is invoked as user <i>username</i>, otherwise as root. The syseventadm remove command removes handlers for matching sysevent event specifications. Event specifications may be matched by specifying at least one of <i>vendor</i>, <i>publisher</i>, <i>class</i>, <i>username</i> or <i>path</i>. If <i>class</i> is specified, it may be qualified with a <i>sub-class</i>. Any of <i>vendor</i>, <i>publisher</i>, <i>class</i>, <i>sub-class</i>, <i>username</i>, <i>path</i> or <i>args</i> not specified match the corresponding fields of all events. Handlers for all matching specifications are removed. The syseventadm list command lists the handlers for matching sysevent event specifications using the same match criteria as the remove command but without the requirement that at least one of <i>vendor</i>, <i>publisher</i>, <i>class</i>, <i>username</i> or <i>path</i> be specified. With no match criteria, all specifications are listed. The list command output format is: [<i>vendor=vendor</i>] [<i>publisher=publisher</i>] [<i>class=class</i>] [<i>subclass=subclass</i>] [<i>username=username</i>] <i>path</i> [<i>args</i>] where each of <i>class</i>, <i>sub-class</i>, <i>vendor</i>, <i>publisher</i> and <i>username</i> is listed only if part of the match criteria for the listed specification. The syseventadm restart command informs the syseventd daemon to reread the sysevent registry after a change has been made by adding or removing one or more sysevent handler specifications.
Argument Macro Substitution	The sysevent handling facility provides extensive macro capability for constructing the command line arguments to be executed in response to an event. Macro expansion applies only to the command line <i>args</i> specified for an event handler, with macros expanded with data from the event itself. Pre-defined macros are provided for the

event *class*, *subclass*, *publisher* and *vendor* information. Macros not matching one of the pre-defined macro names cause the attribute list attached to the event to be searched for an attribute of that name, with the value of the matching attribute substituted on the command line.

Macros are introduced by the \$ character, with the macro name being the following token separated by a SPACE or TAB character. If the macro name is embedded in text, it may be delineated by \${ and }. A \ before the \$ causes macro expansion not to occur.

\$class

The class string defining the event

\$publisher

The publisher string defining the event

\$sequence

The sequence number of the event.

\$subclass

The subclass string defining the event

\$timestamp

The timestamp of the event.

\$vendor

The vendor string defining the event

Macro names other than those pre-defined are compared against the attribute list provided with the event. An attribute with name matching the macro name causes the value of the attribute to be substituted as ASCII text on the generated command line.

Use of a macro for which no attribute with that name is defined, or for which multiple attributes with that name are provided, cause an error and the command is not invoked.

Attributes with signed data types (DATA_TYPE_INT16, DATA_TYPE_INT32 and DATA_TYPE_INT64) are expanded as decimal digits.

Attributes with unsigned data types (DATA_TYPE_BYTE, DATA_TYPE_UINT16, DATA_TYPE_UINT32, DATA_TYPE_UINT64 and DATA_TYPE_HTTIME) are expanded as hexadecimal digits with a 0x prefix.

Attributes with string data type (DATA_TYPE_STRING) are expanded with the string data. The data is not quoted. If it is desired that the quoted strings be generated on the command line, put quotes around the macro call in the arguments.

Array types are expanded with each element expanded as defined for that scalar type, with a space separating each element substitution.

OPTIONS The following options are supported:

-c *class* The string specifying the event class.

syseventadm(1M)

	-p <i>publisher</i> The string specifying the event publisher. -R <i>rootdir</i> Cause syseventadm to use an alternate root path <i>rootdir</i>. -s <i>subclass</i> The string specifying the event subclass. -u <i>username</i> The user under which the command is to be invoked. -v <i>vendor</i> The string specifying the vendor defining the event. Events defined by third-party software should use the company's stock symbol. Sun-defined events use SUNW.
OPERANDS	The following operands are supported: <i>args</i> Command arguments <i>path</i> Full path of command to be run in response to event
EXAMPLES	EXAMPLE 1 Adding an Event Handler The following example adds an event handler for an event defined by vendor SUNW, class EC_ENV and sub-class ESC_ENV_TEMP. The command to be run is /opt/SUNWenv/bin/ec_env_temp, with arguments being the class name, sub-class name and pathname derived from the event attributes. The \$ characters are preceded by a backslash to circumvent shell interpretation. There is no need to restart the service after the change since the registry is maintained on \$ALTROOT. <pre># syseventadm add -R \\${ALTROOT} -v SUNW -c EC_ENV -s ESC_ENV_TEMP /opt/SUNWenv/bin/ec_env_temp \\${class} \\${subclass} \\${pathname}</pre> EXAMPLE 2 Removing an Event Handler The following example removes the event handler added in Example 1. <pre># syseventadm remove -R \\${ALTROOT} -v SUNW -c EC_ENV -s ESC_ENV_TEMP /opt/SUNWenv/bin/ec_env_temp \\${class} \\${subclass} \\${pathname}</pre> EXAMPLE 3 Listing Event Handlers The following example lists all event handlers for events of class EC_ENV, subclass ESC_ENV_TEMP, as defined by vendor SUNW: <pre># syseventadm list -v SUNW -c EC_ENV -s ESC_ENV_TEMP vendor=SUNW class=EC_ENV subclass=ESC_ENV_TEMP /opt/SUNWenv/bin/ec_env_temp \\${class} \\${subclass} \\${pathname}</pre> EXAMPLE 4 Listing Event Handlers The following example lists all event handlers defined by vendor VRTS. <pre># syseventadm list -v VRTS</pre>

EXAMPLE 5 Removing Event Handlers

The following example removes all event handlers defined by vendor VRTS, and restarts service.

```
# syseventadm remove -v VRTS
# syseventadm restart
```

EXAMPLE 6 Listing All Event Handlers Specified to Run a Command

The following example lists all event handlers specified to run the command `/opt/SUNWenv/bin/ec_env_temp`:

```
# syseventadm list /opt/SUNWenv/bin/ec_env_temp
```

EXAMPLE 7 Removing Event Handlers and Restarting Service

The following example removes all event handlers specified to run the command `/opt/SUNWenv/bin/ec_env_temp`, and restarts service:

```
# syseventadm remove /opt/SUNWenv/bin/ec_env_temp
# syseventadm restart
```

EXIT STATUS

The following exit values are returned:

0	Successful completion.
1	No matching event specification found (remove or list commands only)
2	Incorrect command usage.
3	Permission denied.
4	Command failed.
5	Out of memory

NOTES

To avoid upgrade problems, packages delivering a sysevent event handler should install the event handler by running `syseventadm` from the package's `postinstall` script. The event handler can then be removed by running `syseventadm` from the package's `preremove` script using the same arguments as when added.

syseventconfd(1M)

NAME	syseventconfd – kernel system event command invocation daemon				
SYNOPSIS	/usr/lib/sysevent/syseventconfd [-r <i>rootdir</i>]				
DESCRIPTION	<i>syseventconfd</i> is the user-level daemon that invokes user-level commands in response to kernel system events received from <i>syseventd</i> (1M).				
OPTIONS	The following options are supported: -r <i>rootdir</i> Cause <i>syseventconfd</i> to use an alternate root path when creating its door. The root path must match the root path used to invoke <i>syseventd</i>.				
FILES	/etc/init.d/devfsadm daemon start and stop script /etc/rcS.d/S50devfsadm link to <i>init.d</i> script /etc/rc0.d/K83devfsadm link to <i>init.d</i> script /etc/sysevent/syseventconfd_event_service <i>syseventconfd</i> event service door file /usr/lib/sysevent/modules/sysevent_conf_mod.so <i>syseventd</i> loadable module (SLM) managing <i>sysevent.conf</i> files

NAME	syseventd – kernel system event notification daemon
SYNOPSIS	<code>/usr/lib/sysevent/syseventd [-d <i>debug_level</i>] [-r <i>rootdir</i>]</code>
DESCRIPTION	syseventd is a user-level daemon that accepts delivery of system event buffers from the kernel. Once an event buffer has been delivered to syseventd, it, in turn, attempts to propagate the event to all interested end event subscribers. Event subscribers take the form of a syseventd loadable module (SLM). syseventd passes the event buffer to each of its subscribers and in return expects a notification as to the successful or unsuccessful delivery attempt. Upon successful delivery of the event buffer to all interested event subscribers, syseventd frees the event buffer from the kernel event queue.
OPTIONS	The following options are supported: <code>-d <i>debug_level</i></code> Enable debug mode. Messages are printed to the invoking user's terminal. <code>-r <i>rootdir</i></code> Cause syseventd to use an alternate root path when creating its door and lock files. Modules continue to be loaded from the standard module directories.
EXIT STATUS	The following exit values are returned: 0 Successful completion. non-zero An error occurred.
FILES	<code>/etc/init.d/devfsadm</code> daemon start and stop script <code>/etc/rcS.d/S50devfsadm</code> link to <code>init.d</code> script <code>/etc/rc0.d/K83devfsadm</code> link to <code>init.d</code> script <code>/etc/sysevent/syseventd_daemon.lock</code> daemon lock file <code>/etc/sysevent/sysevent_door</code> kernel to syseventd door file <code>/usr/lib/sysevent/modules</code> SLM directory repository <code>/usr/platform/`uname -i`/lib/sysevent/modules</code> SLM directory repository <code>/usr/platform/`uname -m`/lib/sysevent/modules</code> SLM directory repository

NAME	sysidconfig – execute system configuration applications, or define set of system configuration applications
SYNOPSIS	sysidconfig [-lv] [-a <i>application</i>] [-b <i>basedir</i>] [-r <i>application</i>]
DESCRIPTION	Invoked without any options, the <code>sysidconfig</code> program executes a list of applications. An application on this list is referred to as a "system configuration application." Every application on this list will be passed one command-line argument, <code>-c</code>. This flag will cause the system configuration application to perform its configuration function. Without options, <code>sysidconfig</code> should only be invoked by startup scripts, which occurs during the initial installation and during a reconfigure reboot. All applications on the list will be executed, if possible. All activity taken by the <code>sysidconfig</code> program is logged in the <code>sysidconfig</code> log file, <code>/var/log/sysidconfig.log</code>. If one or more of the applications on the list are either not present at execution time, are not executable, or execute but return a failure code upon completion, then that information will be logged as well. Successful completion of the program can be assumed if no error message is present in the log file. Programs are executed sequentially, with only one configuration application active at a time. Executed with the <code>-l</code>, <code>-a</code>, or <code>-r</code> options, the <code>sysidconfig</code> program allows the super-user to list the defined configuration applications, and to add items to or remove items from that list. Running <code>sysidconfig</code> with options is the only way to view or manipulate the list. Only the super-user can execute the <code>sysidconfig</code> program with options. The <code>-b</code> and <code>-v</code> options change the behavior of <code>sysidconfig</code>, and can be used with or without the list manipulation options discussed above. The <code>-b basedir</code> option is used to specify a reference root directory other than the default, <code>/</code>. The <code>-v</code> option duplicates the log file output on <code>stdout</code>. By default, no SPARC based applications exist on this list. However, the x86 based systems are delivered with one application, <code>kdmconfig(1M)</code>, on the list. <code>kdmconfig</code> is not delivered on SPARC based systems. This application is an extension of the <code>sysidtool(1M)</code> suite of programs. It is executed during initial installation and during a reconfigure reboot, before the window system has been started. Graphical User Interface (GUI) applications will not execute successfully if they are added to the list of configuration applications via <code>sysidconfig -a</code>. This program is referenced, but not fully described, in the <code>sysidtool(1M)</code> manual page.
OPTIONS	The valid options are: <code>-a application</code> Add the named application to the list of defined applications. When next invoked without arguments, <code>sysidconfig</code> will run

sysidconfig(1M)

	this newly added application after all previously defined applications. <i>application</i> must be a fully qualified path name that is not currently on the list of applications to execute.
-b <i>basedir</i>	Specify an alternate base directory (/ is defined as the default base directory if no other is specified). The specified directory is used as the root directory when adding, listing, removing, or executing configuration applications. The log file where information is recorded is in /var/log, relative to the specified <i>basedir</i> . In the log file, the <i>basedir</i> is not noted. This means, for example, that if the super-user on a diskless client's server executes: <pre>sysidconfig -b /export/root/client -a /sbin/someapp</pre> then the diskless client <i>client</i> would have /sbin/someapp executed upon reconfigure reboot. The diskless client's log file would note that /sbin/someapp was added, not /export/root/client/sbin/someapp.
-l	List defined configuration applications. Applications will be executed one at a time, in the order shown in the list.
-r <i>application</i>	Remove the named application from the list of defined applications. <i>application</i> must be a fully qualified path name and it must be on the existing list of applications to execute.
-v	Verbose mode. This option echoes all information sent to the log file to stdout. Such information includes timestamp information about when the program was executed, the names of applications being executed, and results of those executions.

RETURN VALUES The sysidconfig program will return 0 if it completes successfully.

When executed with the -r or -a options, error conditions or warnings will be reported on stderr. If the requested action completes successfully, an exit code of 0 will be returned.

ERRORS	EPERM	The program was executed by a user other than the super-user.
	EINVAL	Option -l, -a, or -r was passed and the action could not be completed successfully.

FILES /var/log/sysidconfig.log sysidconfig log file

ATTRIBUTES See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWadmap

SEE ALSO sys-unconfig(1M), sysidtool(1M), attributes(5)

x86 Only | kdmconfig(1M)

DIAGNOSTICS When run without options, a log of the `sysidconfig` program's activity can be found in `/var/log/sysidconfig.log`. This file contains a timestamp log of each program executed, its resulting `stderr` output, and its exit code. If an application in the list was not found or is not executable, that will also be noted.

sysidtool(1M)

NAME	sysidtool, sysidnet, sysidns, sysidsys, sysidroot, sysidpm – system configuration													
SYNOPSIS	<pre>/usr/sbin/sysidnet /usr/sbin/sysidns /usr/sbin/sysidsys /usr/sbin/sysidroot /usr/sbin/sysidpm</pre>													
DESCRIPTION	sysidtool is a suite of five programs that configure a new system, or one that has been unconfigured with sys-unconfig(1M). The sysidtool programs run automatically at system installation, or during the first boot after a machine has been successfully unconfigured. These programs have no effect except at such times, and should never be run manually. The sysidtool programs set up the appropriate information in the machine's configuration files, in the kernel, and on the machine's network interface. The following list shows the available commands and the information for which each of the commands lists. <table><tr><td>sysidnet: network configuration</td><td>Machine's default locale. Machine's console type. Machine's host name. Machine's IP address.</td></tr><tr><td>sysidns: Name Service configuration</td><td>Name service choice: NIS, NIS+, DNS, LDAP, or none. Machine's IP subnet mask (if no NIS/NIS+ server can automatically be located on the machine's sub-network. Domain name for chosen name service. Hostname and IP address of name server(s). DNS search list (DNS name service only)</td></tr><tr><td>sysidsys: miscellaneous system configuration</td><td>Machine's IP subnet mask (if an NIS/NIS+ server was automatically located on the machine's sub-network). Machine's time zone. Date and time.</td></tr><tr><td>sysidroot: control superuser information</td><td>Machine's root password.</td></tr><tr><td>sysidpm: Power Management configuration</td><td>Auto-shutdown confirmation if the system is Energystar-V2 compliant, that is, a new system model shipped after October 1, 1995.</td></tr><tr><td>sysidconfig: host or platform-specific configuration</td><td>This command controls specification and execution of custom configuration applications that may be specified for a particular host or a particular platform. See sysidconfig(1M).</td></tr></table>		sysidnet: network configuration	Machine's default locale. Machine's console type. Machine's host name. Machine's IP address.	sysidns: Name Service configuration	Name service choice: NIS, NIS+, DNS, LDAP, or none. Machine's IP subnet mask (if no NIS/NIS+ server can automatically be located on the machine's sub-network. Domain name for chosen name service. Hostname and IP address of name server(s). DNS search list (DNS name service only)	sysidsys: miscellaneous system configuration	Machine's IP subnet mask (if an NIS/NIS+ server was automatically located on the machine's sub-network). Machine's time zone. Date and time.	sysidroot: control superuser information	Machine's root password.	sysidpm: Power Management configuration	Auto-shutdown confirmation if the system is Energystar-V2 compliant, that is, a new system model shipped after October 1, 1995.	sysidconfig: host or platform-specific configuration	This command controls specification and execution of custom configuration applications that may be specified for a particular host or a particular platform. See sysidconfig(1M).
sysidnet: network configuration	Machine's default locale. Machine's console type. Machine's host name. Machine's IP address.													
sysidns: Name Service configuration	Name service choice: NIS, NIS+, DNS, LDAP, or none. Machine's IP subnet mask (if no NIS/NIS+ server can automatically be located on the machine's sub-network. Domain name for chosen name service. Hostname and IP address of name server(s). DNS search list (DNS name service only)													
sysidsys: miscellaneous system configuration	Machine's IP subnet mask (if an NIS/NIS+ server was automatically located on the machine's sub-network). Machine's time zone. Date and time.													
sysidroot: control superuser information	Machine's root password.													
sysidpm: Power Management configuration	Auto-shutdown confirmation if the system is Energystar-V2 compliant, that is, a new system model shipped after October 1, 1995.													
sysidconfig: host or platform-specific configuration	This command controls specification and execution of custom configuration applications that may be specified for a particular host or a particular platform. See sysidconfig(1M).													

The `sysidtool` programs attempt to obtain system configuration information from various name service databases, for example, NIS, or from the `sysidcfg(4)` file, and you are prompted to provide the information if it cannot be found. However, you can avoid one or more of the prompts by preconfiguring the appropriate configuration information in the name service databases or in the `sysidcfg(4)` file.

To preconfigure the information in the name service databases, you must use the name service commands or the Solstice AdminSuite tools. See *Solaris 9 9/04 Installation Guide* for more details about how to preconfigure the system configuration information.

The machine's configuration information is set up in its `/etc` and `/var` files.

If a system has more than one network interface, you can use `sysidtool` to configure only the primary interface on the system. All other interfaces on the system must be configured manually.

You cannot use the name service databases or the `sysidcfg(4)` file to suppress the Power Management configuration prompt. However, you can suppress it by creating either the `/autosshutdown` or `/noautosshutdown` file before installation reboot. Accordingly, the auto-shutdown feature is silently configured. The `/autosshutdown` or `/noautosshutdown` files are removed by `sysidpm` before it exits.

NAME	syslogd – log system messages
SYNOPSIS	/usr/sbin/syslogd [-d] [-f <i>configfile</i>] [-m <i>markinterval</i>] [-p <i>path</i>] [-t -T]
DESCRIPTION	syslogd reads and forwards system messages to the appropriate log files or users, depending upon the priority of a message and the system facility from which it originates. The configuration file <code>/etc/syslog.conf</code> (see <code>syslog.conf(4)</code>) controls where messages are forwarded. syslogd logs a mark (timestamp) message every <i>markinterval</i> minutes (default 20) at priority LOG_INFO to the facility whose name is given as mark in the <code>syslog.conf</code> file. A system message consists of a single line of text, which may be prefixed with a priority code number enclosed in angle-brackets (< >); priorities are defined in <code><sys/syslog.h></code>. syslogd reads from the STREAMS log driver, <code>/dev/log</code>, and from any transport provider specified in <code>/etc/netconfig</code>, <code>/etc/net/transport/hosts</code>, and <code>/etc/net/transport/services</code>. syslogd reads the configuration file when it starts up, and again whenever it receives a HUP signal (see <code>signal(3HEAD)</code>), at which time it also closes all files it has open, re-reads its configuration file, and then opens only the log files that are listed in that file. syslogd exits when it receives a TERM signal. As it starts up, syslogd creates the file <code>/etc/syslog.pid</code>, if possible, containing its process identifier (PID). If message ID generation is enabled (see <code>log(7D)</code>), each message will be preceded by an identifier in the following format: <code>[ID msgid facility . priority]</code>. <i>msgid</i> is the message's numeric identifier described in <code>msgid(1M)</code>. <i>facility</i> and <i>priority</i> are described in <code>syslog.conf(4)</code>. <code>[ID 123456 kern.notice]</code> is an example of an identifier when message ID generation is enabled. If the message originated in a loadable kernel module or driver, the kernel module's name (for example, <code>ufs</code>) will be displayed instead of <code>unix</code>. See EXAMPLES for sample output from syslogd with and without message ID generation enabled. In an effort to reduce visual clutter, message IDs are not displayed when writing to the console; message IDs are only written to the log file. See EXAMPLES. The <code>/etc/default/syslogd</code> file contains the following default parameter settings. See FILES. LOG_FROM_REMOTE Specifies whether remote messages are logged. LOG_FROM_REMOTE=NO is equivalent to the <code>-t</code> command-line option. The default value for LOG_FROM_REMOTE is YES.
OPTIONS	The following options are supported:

syslogd(1M)

-d	Turn on debugging. This option should only be used interactively in a root shell once the system is in multi-user mode. It should <i>not</i> be used in the system start-up scripts, as this will cause the system to hang at the point where <code>syslogd</code> is started.
-f <i>configfile</i>	Specify an alternate configuration file.
-m <i>markinterval</i>	Specify an interval, in minutes, between mark messages.
-p <i>path</i>	Specify an alternative log device name. The default is <code>/dev/log</code> .
-T	Enable the <code>syslogd</code> UDP port to turn on logging of remote messages. This is the default behavior. See FILES .
-t	Disable the <code>syslogd</code> UDP port to turn off logging of remote messages. See FILES .

EXAMPLES

EXAMPLE 1 syslogd Output Without Message ID Generation Enabled

The following example shows the output from `syslogd` when message ID generation *is not* enabled:

```
Sep 29 21:41:18 cathy unix: alloc /: file system full
```

EXAMPLE 2 syslogd Output with ID generation Enabled

The following example shows the output from `syslogd` when message ID generation *is* enabled. The message ID is displayed when writing to log file `/var/adm/messages`.

```
Sep 29 21:41:18 cathy ufs: [ID 845546 kern.notice]
                                alloc /: file system full
```

EXAMPLE 3 syslogd Output with ID Generation Enabled

The following example shows the output from `syslogd` when message ID generation *is* enabled when writing to the console. Even though message ID is enabled, the message ID is not displayed at the console.

```
Sep 29 21:41:18 cathy ufs: alloc /: file system full
```

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

SEE ALSO logger(1), msgid(1M), syslog(3C), syslog.conf(4), attributes(5), signal(3HEAD), log(7D)

NOTES The mark message is a system time stamp, and so it is only defined for the system on which syslogd is running. It can not be forwarded to other systems.

When syslogd receives a HUP signal, it attempts to complete outputting pending messages, and close all log files to which it is currently logging messages. If, for some reason, one (or more) of these files does not close within a generous grace period, syslogd discards the pending messages, forcibly closes these files, and starts reconfiguration. If this shutdown procedure is disturbed by an unexpected error and syslogd cannot complete reconfiguration, syslogd sends a mail message to the superuser on the current system stating that it has shut down, and exits.

Care should be taken to ensure that each window displaying messages forwarded by syslogd (especially console windows) is run in the system default locale (which is syslogd's locale). If this advice is not followed, it is possible for a syslog message to alter the terminal settings for that window, possibly even allowing remote execution of arbitrary commands from that window.

sys-unconfig(1M)

NAME	sys-unconfig – undo a system’s configuration
SYNOPSIS	<code>/usr/sbin/sys-unconfig</code>
DESCRIPTION	The <code>sys-unconfig</code> command is used to restore a system’s configuration to an “as-manufactured” state, ready to be reconfigured again. The system’s configuration consists of hostname, Network Information Service (NIS) domain name, timezone, IP address, IP subnet mask, and root password. This operation is the inverse of those performed by the <code>sysidnet(1M)</code>, <code>sysidns(1M)</code>, and <code>sysidsys(1M)</code> programs run at boot. See <code>sysidtool(1M)</code>. <code>sys-unconfig</code> does the following: ■ Saves current <code>/etc/inet/hosts</code> file information in <code>/etc/inet/hosts.saved</code>. ■ If the current <code>/etc/vfstab</code> file contains NFS mount entries, saves the <code>/etc/vfstab</code> file to <code>/etc/vfstab.orig</code>. ■ Restores the default <code>/etc/inet/hosts</code> file. ■ Removes the default hostname in <code>/etc/hostname.interface</code> files for all interfaces configured when this command is run. To determine which interfaces are configured, run the command <code>'ifconfig-a'</code>. The <code>/etc/hostname.interface</code> files corresponding to all of the interfaces listed in the resulting output, with the exception of the loopback interface (lo0), will be removed. ■ Removes the default domainname in <code>/etc/defaultdomain</code>. ■ Restores the timezone to PST8PDT in <code>/etc/TIMEZONE</code>. ■ Disables the Network Information Service (NIS) and Network Information Service Plus (NIS+) if either NIS or NIS+ was configured. ■ Removes the entries for this host in <code>/etc/net/*/hosts</code>. ■ Removes the file <code>/etc/inet/netmasks</code>. ■ Removes the file <code>/etc/defaultrouter</code>. ■ Removes the password set for root in <code>/etc/shadow</code>. ■ Removes the file <code>/etc/.rootkey</code>. ■ Executes all system configuration applications. These applications are defined by prior executions of a <code>sysidconfig -a application</code>. (See <code>sysidconfig(1M)</code>). When <code>sys-unconfig</code> is run, all system configuration applications are passed one argument, <code>-u</code>. ■ Removes the file <code>/etc/resolv.conf</code>. ■ Disables LDAP by removing <code>/var/ldap/ldap_client_cache</code>, <code>/var/ldap/ldap_client_file</code>, <code>/var/ldap/ldap_client_cred</code>, and <code>/var/ldap/cachemgr.log</code>. ■ Regenerates keys for <code>sshd(1M)</code>. When <code>sys-unconfig</code> is finished, it performs a system shutdown. <code>sys-unconfig</code> is a potentially dangerous utility and can only be run by the super user.
FILES	<code>/etc/default/init</code> process control initialization

tapes(1M)

NAME	tapes – creates /dev entries for tape drives attached to the system
SYNOPSIS	/usr/sbin/tapes [-r <i>root_dir</i>]
DESCRIPTION	devfsadm(1M) is now the preferred command for /dev and /devices and should be used instead of tapes. tapes creates symbolic links in the /dev/rmt directory to the actual tape device special files under the /devices directory tree. tapes searches the kernel device tree to see what tape devices are attached to the system. For each equipped tape drive, the following steps are performed: 1. The /dev/rmt directory is searched for a /dev/rmt/<i>n</i> entry that is a symbolic link to the /devices special node of the current tape drive. If one is found, this determines the logical controller number of the tape drive. 2. The rest of the special devices associated with the drive are checked, and incorrect symbolic links are removed and necessary ones added. 3. If none are found, a new logical controller number is assigned (the lowest-unused number), and new symbolic links are created for all the special devices associated with the drive. tapes does not remove links to non-existent devices; these must be removed by hand. tapes is run each time a reconfiguration-boot is performed, or when add_drv(1M) is executed.
Notice to Driver Writers	tapes(1M) considers all devices with the node type DDI_NT_TAPE to be tape devices; these devices must have their minor name created with a specific format. The minor name encodes operational modes for the tape device and consists of an ASCII string of the form [<i>l,m,h,c,u</i>][<i>b</i>][<i>n</i>]. The first character set is used to specify the tape density of the device, and are named low (<i>l</i>), medium (<i>m</i>), high (<i>h</i>), compressed (<i>c</i>), and ultra (<i>u</i>). These specifiers only express a relative density; it is up to the driver to assign specific meanings as needed. For example, 9 track tape devices interpret these as actual bits-per-inch densities, where <i>l</i> means 800 BPI, <i>m</i> means 1600 BPI, and <i>h</i> means 6250 BPI, whereas 4mm DAT tapes defines <i>l</i> as standard format, and <i>m</i>, <i>h</i>, <i>c</i> and <i>u</i> as compressed format. Drivers may choose to implement any or all of these format types. During normal tape operation (non-BSD behavior), once an EOF mark has been reached, subsequent reads from the tape device return an error. An explicit IOCTL must be issued to space over the EOF mark before the next file can be read. <i>b</i> instructs the device to observe BSD behavior, where reading at EOF will cause the tape device to automatically space over the EOF mark and begin reading from the next file. <i>n</i> or no-rewind-on-close instructs the driver to not rewind to the beginning of tape when the device is closed. Normal behavior for tape devices is to reposition to BOT when closing. See mtio(7I).

The minor number for tape devices should be created by encoding the device's instance number using the tape macro `MTMINOR` and `ORing` in the proper combination of density, BSD behavior, and no-rewind flags. See `mtio(7I)`.

To prevent tapes from attempting to automatically generate links for a device, drivers must specify a private node type and refrain from using the node type string `DDI_NT_TAPE` when calling `ddi_create_minor_node(9F)`.

OPTIONS The following options are supported:

`-r root_dir` Causes tapes to presume that the `/dev/rmt` directory tree is found under `root_dir`, not directly under `/`.

ERRORS If tapes finds entries of a particular logical controller linked to different physical controllers, it prints an error message and exits without making any changes to the `/dev` directory, since it cannot determine which of the two alternative logical to physical mappings is correct. The links should be manually corrected or removed before another reconfiguration boot is performed.

EXAMPLES **EXAMPLE 1** Creating Tape Device Nodes From Within the Driver's `attach()` Function

This example demonstrates creating tape device nodes from within the `xktape` driver's `attach(9E)` function.

```
#include <sys/mtio.h>
struct tape_minor_info {
    char *minor_name;
    int  minor_mode;
};
/*
 * create all combinations of logical tapes
 */
static struct tape_minor_info example_tape[] = {
    {"", 0}, /* default tape */
    {"1", MT_DENSITY1},
    {"1b", MT_DENSITY1 | MT_BSD},
    {"1bn", MT_DENSITY1 | MT_BSD | MT_NOREWIND},
    {"m", MT_DENSITY2},
    {"mb", MT_DENSITY2 | MT_BSD},
    {"mbn", MT_DENSITY2 | MT_BSD | MT_NOREWIND},
    {"h", MT_DENSITY3},
    {"hb", MT_DENSITY3 | MT_BSD},
    {"hbn", MT_DENSITY3 | MT_BSD | MT_NOREWIND},
    {"c", MT_DENSITY4},
    {"cb", MT_DENSITY4 | MT_BSD},
    {"cbn", MT_DENSITY4 | MT_BSD | MT_NOREWIND},
    {NULL, 0},
};

int
xktapeattach(dev_info_t *dip, ddi_attach_cmd_t cmd)
{
    int instance;
    struct tape_minor_info *mdp;
```

EXAMPLE 1 Creating Tape Device Nodes From Within the Driver's `attach()` Function
(Continued)

```

/* other stuff in attach... */
instance = ddi_get_instance(dip);

for (mdp = example_tape; mdp->minor_name != NULL; mdp++) {
    ddi_create_minor_node(dip, mdp->minor_name, S_IFCHR,
        (MTMINOR(instance) | mdp->minor_mode), DDI_NT_TAPE, 0);
}

```

Installing the `xktape` driver on a Sun Fire 4800, with the driver controlling a SCSI tape (target 4 attached to an `isp(7D)` SCSI HBA) and performing a reconfiguration-boot creates the following special files in `/devices`.

```

# ls -l /devices/ssm@0,0/pci@18,700000/pci@1/SUNW,isp@0,0
crw-rw-rw-  1 root sys  33,136 Aug 29 00:02  xktape@4,0:

taskstat(1M)

NAME	taskstat – prints ASET tasks status				
SYNOPSIS	/usr/aset/util/taskstat [-d <i>aset_dir</i>]				
DESCRIPTION	taskstat is located in the <code>/usr/aset/util</code> directory. <code>/usr/aset</code> is the default operating directory of the Automated Security Enhancement Tool (ASET). An alternative working directory can be specified by the administrators through the <code>aset -d</code> command or the <code>ASETDIR</code> environment variable. See <code>aset(1M)</code>. Because <code>aset</code> dispatches its tasks to run in the background, when it returns, these tasks may or may not have completed. <code>taskstat</code> prints the status of the tasks, listing those that are completed and those that are still executing. The ASET reports, which are located in the <code>/usr/aset/reports</code> directory (see the <code>-d</code> option), are not complete until all the tasks finish executing.				
OPTIONS	<table><tr><td><code>-d <i>aset_dir</i></code></td><td>Specify the working directory for ASET. By default, this directory is <code>/usr/aset</code>. With this option, the <code>reports</code> directory will be located under <i>aset_dir</i>.</td></tr></table>	<code>-d <i>aset_dir</i></code>	Specify the working directory for ASET. By default, this directory is <code>/usr/aset</code> . With this option, the <code>reports</code> directory will be located under <i>aset_dir</i> .

NAME	tcxconfig – configure the default linearity of the 24-bit TrueColor Visual for OpenWindows on a system with an S24 frame buffer (TCX)				
SYNOPSIS	/usr/sbin/tcxconfig [linear nonlinear]				
DESCRIPTION	The <code>tcxconfig</code> script changes the default linearity of a 24-bit TrueColor Visual for OpenWindows on a system with an S24 frame buffer. When the S24 graphics driver for OpenWindows is installed, the default 24-bit TrueColor Visual is nonlinear. You can run <code>tcxconfig</code> with an argument that specifies the setting you want. OpenWindows should not be running when you execute the <code>tcxconfig</code> script with an option. Start OpenWindows after <code>tcxconfig</code> has set the linearity you desire.				
OPTIONS	If you specify no option, <code>tcxconfig</code> displays the current default setting. You must become superuser before you can execute <code>tcxconfig</code> with one of the following options. <table> <tr> <td><code>linear</code></td><td>Set linear visual to be the default 24-bit TrueColor Visual. This means colors will be gamma-corrected.</td></tr> <tr> <td><code>nonlinear</code></td><td>Set nonlinear visual to be the default 24-bit TrueColor Visual.</td></tr> </table>	<code>linear</code>	Set linear visual to be the default 24-bit TrueColor Visual. This means colors will be gamma-corrected.	<code>nonlinear</code>	Set nonlinear visual to be the default 24-bit TrueColor Visual.
<code>linear</code>	Set linear visual to be the default 24-bit TrueColor Visual. This means colors will be gamma-corrected.				
<code>nonlinear</code>	Set nonlinear visual to be the default 24-bit TrueColor Visual.				
EXIT STATUS	The following exit values are returned: <table> <tr> <td>0</td><td>success</td></tr> <tr> <td>1</td><td>an error has occurred.</td></tr> </table>	0	success	1	an error has occurred.

th_define(1M)

NAME	th_define – create fault injection test harness error specifications
SYNOPSIS	<pre>th_define [-n name -i instance -P path] [-a acc_types] [-r reg_number] [-l offset [length]] [-c count [failcount]] [-o operator [operand]] [-f acc_chk] [-w max_wait_period [report_interval]] or th_define [-n name -i instance -P path] [-a log [acc_types] [-r reg_number] [-l offset [length]]] [-c count [failcount]] [-s collect_time] [-p policy] [-x flags] [-C comment_string] [-e fixup_script [args]] or th_define [-h]</pre>
DESCRIPTION	The <code>th_define</code> utility provides an interface to the <code>bus_ops</code> fault injection <code>bofi</code> device driver for defining error injection specifications (referred to as <code>errdefs</code>). An <code>errdef</code> corresponds to a specification of how to corrupt a device driver's accesses to its hardware. The command line arguments determine the precise nature of the fault to be injected. If the supplied arguments define a consistent <code>errdef</code>, the <code>th_define</code> process will store the <code>errdef</code> with the <code>bofi</code> driver and suspend itself until the criteria given by the <code>errdef</code> become satisfied (in practice, this will occur when the access counts go to zero). You use the <code>th_manage(1M)</code> command with the <code>start</code> option to activate the resulting <code>errdef</code>. The effect of <code>th_manage</code> with the <code>start</code> option is that the <code>bofi</code> driver acts upon the <code>errdef</code> by matching the number of hardware accesses—specified in <i>count</i>, that are of the type specified in <i>acc_types</i>, made by instance number <i>instance</i>—of the driver whose name is <i>name</i>, (or by the driver instance specified by <i>path</i>) to the register set (or DMA handle) specified by <i>reg_number</i>, that lie within the range <i>offset</i> to <i>offset</i> + <i>length</i> from the beginning of the register set or DMA handle. It then applies <i>operator</i> and <i>operand</i> to the next <i>failcount</i> matching accesses. If <i>acc_types</i> includes <code>log</code>, <code>th_define</code> runs in automatic test script generation mode, and a set of test scripts (written in the Korn shell) is created and placed in a sub-directory of the current directory with the name <code><driver>.test.<id></code> (for example, <code>glm.test.978177106</code>). A separate, executable script is generated for each access handle that matches the logging criteria. The log of accesses is placed at the top of each script as a record of the session. If the current directory is not writable, file output is written to standard output. The base name of each test file is the driver name, and the extension is a number that discriminates between different access handles. A control script (with the same name as the created test directory) is generated that will run all the test scripts sequentially. Executing the scripts will install, and then activate, the resulting error definitions. Error definitions are activated sequentially and the driver instance under test is taken offline and brought back online before each test (refer to the <code>-e</code> option for more information). By default, logging applies to all PIO accesses, all interrupts, and all

th_define(1M)

DMA accesses to and from areas mapped for both reading and writing. You can constrain logging by specifying additional *acc_types*, *reg_number*, *offset* and *length*. Logging will continue for *count* matching accesses, with an optional time limit of *collect_time* seconds.

Either the *-n* or *-P* option must be provided. The other options are optional. If an option (other than *-a*) is specified multiple times, only the final value for the option is used. If an option is not specified, its associated value is set to an appropriate default, which will provide maximal error coverage as described below.

OPTIONS

The following options are available:

-n name

Specify the name of the driver to test. (String)

-i instance

Test only the specified driver instance (-1 matches all instances of driver). (Numeric)

-P path

Specify the full device path of the driver to test. (String)

-r reg_number

Test only the given register set or DMA handle (-1 matches all register sets and DMA handles). (Numeric)

-a acc_types

Only the specified access types will be matched. Valid values for the *acc_types* argument are *log*, *pio*, *pio_r*, *pio_w*, *dma*, *dma_r*, *dma_w* and *intr*. Multiple access types, separated by spaces, can be specified. The default is to match all hardware accesses.

If *acc_types* is set to *log*, logging will match all *PIO* accesses, interrupts and *DMA* accesses to and from areas mapped for both reading and writing. *log* can be combined with other *acc_types*, in which case the matching condition for logging will be restricted to the specified additional *acc_types*. Note that *dma_r* will match only *DMA* handles mapped for reading only; *dma_w* will match only *DMA* handles mapped for writing only; *dma* will match only *DMA* handles mapped for both reading and writing.

-l offset [length]

Constrain the range of qualifying accesses. The *offset* and *length* arguments indicate that any access of the type specified with the *-a* option, to the register set or *DMA* handle specified with the *-r* option, lie at least *offset* bytes into the register set or *DMA* handle and at most *offset + length* bytes into it. The default for *offset* is 0. The default for *length* is the maximum value that can be placed in an *offset_t* C data type (see *types.h*). Negative values are converted into unsigned quantities. Thus, *th_define -l 0 -1* is maximal.

-c count [failcount]

Wait for *count* number of matching accesses, then apply an operator and operand (see the *-o* option) to the next *failcount* number of matching accesses. If the access

th_define(1M)

type (see the `-a` option) includes logging, the number of logged accesses is given by $count + failcount - 1$. The `-1` is required because the last access coincides with the first faulting access.

Note that access logging may be combined with error injection if *failcount* and *operator* are nonzero and if the access type includes logging and any of the other access types (`pio`, `dma` and `intr`) See the description of access types in the definition of the `-a` option, above.

When the *count* and *failcount* fields reach zero, the status of the `errdef` is reported to standard output. When all active `errdefs` created by the `th_define` process complete, the process exits. If *acc_types* includes `log`, *count* determines how many accesses to log. If *count* is not specified, a default value is used. If *failcount* is set in this mode, it will simply increase the number of accesses logged by a further $failcount - 1$.

-o *operator* [*operand*]

For qualifying PIO read and write accesses, the value read from or written to the hardware is corrupted according to the value of *operator*:

- `EQ` *operand* is returned to the driver.
- `OR` *operand* is bitwise ORed with the real value.
- `AND` *operand* is bitwise ANDed with the real value.
- `XOR` *operand* is bitwise XORed with the real value.

For PIO write accesses, the following operator is allowed:

- `NO` Simply ignore the driver's attempt to write to the hardware.

Note that a driver performs PIO via the `ddi_getX()`, `ddi_putX()`, `ddi_rep_getX()` and `ddi_rep_putX()` routines (where *X* is 8, 16, 32 or 64). Accesses made using `ddi_getX()` and `ddi_putX()` are treated as a single access, whereas an access made using the `ddi_rep_*(9F)` routines are broken down into their respective number of accesses, as given by the *repcount* parameter to these DDI calls. If the access is performed via a DMA handle, *operator* and *value* are applied to every access that comprises the DMA request. If interference with interrupts has been requested then the operator may take any of the following values:

- `DELAY` After *count* accesses (see the `-c` option), delay delivery of the next *failcount* number of interrupts for *operand* number of microseconds.
- `LOSE` After *count* number of interrupts, fail to deliver the next *failcount* number of real interrupts to the driver.
- `EXTRA` After *count* number of interrupts, start delivering *operand* number of extra interrupts for the next *failcount* number of real interrupts.

The default value for *operand* and *operator* is to corrupt the data access by flipping each bit (XOR with `-1`).

-f *acc_chk*

If the *acc_chk* parameter is set to 1 or *pio*, then the driver's calls to `ddi_check_acc_handle(9F)` return `DDI_FAILURE` when the access count goes to 1. If the *acc_chk* parameter is set to 2 or *dma*, then the driver's calls to `ddi_check_dma_handle(9F)` return `DDI_FAILURE` when the access count goes to 1.

-w *max_wait_period* [*report_interval*]

Constrain the period for which an error definition will remain active. The option applies only to non-logging errdefs. If an error definition remains active for *max_wait_period* seconds, the test will be aborted. If *report_interval* is set to a nonzero value, the current status of the error definition is reported to standard output every *report_interval* seconds. The default value is zero. The status of the errdef is reported in parsable format (eight fields, each separated by a colon (:) character, the last of which is a string enclosed by double quotes and the remaining seven fields are integers):

ft:mt:ac:fc:chk:ec:s:"message" which are defined as follows:

<i>ft</i>	The UTC time when the fault was injected.
<i>mt</i>	The UTC time when the driver reported the fault.
<i>ac</i>	The number of remaining non-faulting accesses.
<i>fc</i>	The number of remaining faulting accesses.
<i>chk</i>	The value of the <i>acc_chk</i> field of the errdef.
<i>ec</i>	The number of fault reports issued by the driver against this errdef (<i>mt</i> holds the time of the initial report).
<i>s</i>	The severity level reported by the driver.
<i>"message"</i>	Textual reason why the driver has reported a fault.

-h

Display the command usage string.

-s *collect_time*

If *acc_types* is given with the *-a* option and includes *log*, the errdef will log accesses for *collect_time* seconds (the default is to log until the log becomes full). Note that, if the errdef specification matches multiple driver handles, multiple logging errdefs are registered with the *bofi* driver and logging terminates when all logs become full or when *collect_time* expires or when the associated errdefs are cleared. The current state of the log can be checked with the `th_manage(1M)` command, using the *broadcast* parameter. A log can be terminated by running `th_manage(1M)` with the *clear_errdefs* option or by sending a *SIGALRM* signal to the `th_define` process. See *alarm(2)* for the semantics of *SIGALRM*.

-p *policy*

Applicable when the *acc_types* option includes *log*. The parameter modifies the policy used for converting from logged accesses to errdefs. All policies are inclusive:

th_define(1M)

- Use `rare` to bias error definitions toward rare accesses (default).
- Use `operator` to produce a separate error definition for each operator type (default).
- Use `common` to bias error definitions toward common accesses.
- Use `median` to bias error definitions toward median accesses.
- Use `maximal` to produce multiple error definitions for duplicate accesses.
- Use `unbiased` to create unbiased error definitions.
- Use `onebyte`, `twobyte`, `fourbyte`, or `eightbyte` to select `errdefs` corresponding to 1, 2, 4 or 8 byte accesses (if chosen, the `-xr` option is enforced in order to ensure that `ddi_rep_*()` calls are decomposed into *multiple single accesses*).
- Use `multibyte` to create error definitions for multibyte accesses performed using `ddi_rep_get*()` and `ddi_rep_put*()`.

Policies can be combined by adding together these options. See the NOTES section for further information.

`-x flags`

Applicable when the `acc_types` option includes `log`. The `flags` parameter modifies the way in which the `bofi` driver logs accesses. It is specified as a string containing any combination of the following letters:

<code>w</code>	Continuous logging (that is, the log will wrap when full).
<code>t</code>	Timestamp each log entry (access times are in seconds).
<code>r</code>	Log repeated I/O as individual accesses (for example, a <code>ddi_rep_get16(9F)</code> call which has a <code>repcount</code> of <code>N</code> is logged <code>N</code> times with each transaction logged as size 2 bytes. Without this option, the default logging behavior is to log this access once only, with a transaction size of twice the <code>repcount</code>).

`-C comment_string`

Applicable when the `acc_types` option includes `log`. It provides a comment string to be placed in any generated test scripts. The string must be enclosed in double quotes.

`-e fixup_script [args]`

Applicable when the `acc_types` option includes `log`. The output of a logging `errdefs` is to generate a test script for each driver access handle. Use this option to embed a command in the resulting script before the errors are injected. The generated test scripts will take an instance offline and bring it back online before injecting errors in order to bring the instance into a known fault-free state. The executable `fixup_script` will be called twice with the set of optional `args`— once just before the instance is taken offline and again after the instance has been brought online. The following variables are passed into the environment of the called executable:

`DRIVER_PATH`

Identifies the device path of the instance.

`DRIVER_INSTANCE`

Identifies the instance number of the device.

DRIVER_UNCONFIGURE

Has the value 1 when the instance is about to be taken offline.

DRIVER_CONFIGURE

Has the value 1 when the instance has just been brought online.

Typically, the executable ensures that the device under test is in a suitable state to be taken offline (unconfigured) or in a suitable state for error injection (for example configured, error free and servicing a workload). A minimal script for a network driver could be:

```
#!/bin/ksh

driver=xyznetdriver
ifnum=$driver$DRIVER_INSTANCE

if [[ $DRIVER_CONFIGURE = 1 ]]; then
    ifconfig $ifnum plumb
    ifconfig $ifnum ...
    ifworkload start $ifnum
elif [[ $DRIVER_UNCONFIGURE = 1 ]]; then
    ifworkload stop $ifnum
    ifconfig $ifnum down
    ifconfig $ifnum unplumb
fi
exit $?
```

The `-e` option must be the last option on the command line.

If the `-a log` option is selected but the `-e` option is not given, a default script is used. This script repeatedly attempts to detach and then re-attach the device instance under test.

EXAMPLES**Examples of Error Definitions**

```
th_define -n foo -i 1 -a log
```

Logs all accesses to all handles used by instance 1 of the `foo` driver while running the default workload (attaching and detaching the instance). Then generates a set of test scripts to inject appropriate errdefs while running that default workload.

```
th_define -n foo -i 1 -a log pio
```

Logs PIO accesses to each PIO handle used by instance 1 of the `foo` driver while running the default workload (attaching and detaching the instance). Then generates a set of test scripts to inject appropriate errdefs while running that default workload.

```
th_define -n foo -i 1 -p onebyte median -e fixup arg -now
```

th_define(1M)

Logs all accesses to all handles used by instance 1 of the `foo` driver while running the workload defined in the fixup script `fixup` with arguments `arg` and `-now`. Then generates a set of test scripts to inject appropriate `errdefs` while running that workload. The resulting error definitions are requested to focus upon single byte accesses to locations that are accessed a *median* number of times with respect to frequency of access to I/O addresses.

```
th_define -n se -l 0x20 1 -a pio_r -o OR 0x4 -c 10 1000
```

Simulates a stuck serial chip command by forcing 1000 consecutive read accesses made by any instance of the `se` driver to its command status register, thereby returning status busy.

```
th_define -n foo -i 3 -r 1 -a pio_r -c 0 1 -f 1 -o OR 0x100
```

Causes 0x100 to be ORed into the next physical I/O read access from any register in register set 1 of instance 3 of the `foo` driver. Subsequent calls in the driver to `ddi_check_acc_handle()` return `DDI_FAILURE`.

```
th_define -n foo -i 3 -r 1 -a pio_r -c 0 1 -o OR 0x0
```

Causes 0x0 to be ORed into the next physical I/O read access from any register in register set 1 of instance 3 of the `foo` driver. This is of course a no-op.

```
th_define -n foo -i 3 -r 1 -l 0x8100 1 -a pio_r -c 0 10 -o EQ 0x70003
```

Causes the next ten next physical I/O reads from the register at offset 0x8100 in register set 1 of instance 3 of the `foo` driver to return 0x70003.

```
th_define -n foo -i 3 -r 1 -l 0x8100 1 -a pio_w -c 100 3 -o AND 0xffffffffffffefff
```

The next 100 physical I/O writes to the register at offset 0x8100 in register set 1 of instance 3 of the `foo` driver take place as normal. However, on each of the three subsequent accesses, the 0x1000 bit will be cleared.

```
th_define -n foo -i 3 -r 1 -l 0x8100 0x10 -a pio_r -c 0 1 -f 1 -o XOR 7
```

Causes the bottom three bits to have their values toggled for the next physical I/O read access to registers with offsets in the range 0x8100 to 0x8110 in register set 1 of instance 3 of the `foo` driver. Subsequent calls in the driver to `ddi_check_acc_handle()` return `DDI_FAILURE`.

```
th_define -n foo -i 3 -a pio_w -c 0 1 -o NO 0
```

Prevents the next physical I/O write access to any register in any register set of instance 3 of the `foo` driver from going out on the bus.

```
th_define -n foo -i 3 -l 0 8192 -a dma_r -c 0 1 -o OR 7
```

th_define(1M)

Causes 0x7 to be ORed into each long long in the first 8192 bytes of the next DMA read, using any DMA handle for instance 3 of the foo driver.

```
th_define -n foo -i 3 -r 2 -l 0 8 -a dma_r -c 0 1 -o OR
0x7070707070707070
```

Causes 0x70 to be ORed into each byte of the first long long of the next DMA read, using the DMA handle with sequential allocation number 2 for instance 3 of the foo driver.

```
th_define -n foo -i 3 -l 256 256 -a dma_w -c 0 1 -f 2 -o OR 7
```

Causes 0x7 to be ORed into each long long in the range from offset 256 to offset 512 of the next DMA write, using any DMA handle for instance 3 of the foo driver. Subsequent calls in the driver to ddi_check_dma_handle() return DDI_FAILURE.

```
th_define -n foo -i 3 -r 0 -l 0 8 -a dma_w -c 100 3 -o AND
0xffffffffffffffffffff
```

The next 100 DMA writes using the DMA handle with sequential allocation number 0 for instance 3 of the foo driver take place as normal. However, on each of the three subsequent accesses, the 0x1000 bit will be cleared in the first long long of the transfer.

```
th_define -n foo -i 3 -a intr -c 0 6 -o LOSE 0
```

Causes the next six interrupts for instance 3 of the foo driver to be lost.

```
th_define -n foo -i 3 -a intr -c 30 1 -o EXTRA 10
```

When the thirty-first subsequent interrupt for instance 3 of the foo driver occurs, a further ten interrupts are also generated.

```
th_define -n foo -i 3 -a intr -c 0 1 -o DELAY 1024
```

Causes the next interrupt for instance 3 of the foo driver to be delayed by 1024 microseconds.

NOTES

The policy option in the th_define -p syntax determines how a set of logged accesses will be converted into the set of error definitions. Each logged access will be matched against the chosen policies to determine whether an error definition should be created based on the access.

Any number of policy options can be combined to modify the generated error definitions.

Bytewise Policies

These select particular I/O transfer sizes. Specifying a byte policy will exclude other byte policies that have not been chosen. If none of the byte type policies is selected, all transfer sizes are treated equally. Otherwise, only those specified transfer sizes will be selected.

th_define(1M)

Frequency of Access Policies

onebyte	Create errdefs for one byte accesses (ddi_get8())
twobyte	Create errdefs for two byte accesses (ddi_get16())
fourbyte	Create errdefs for four byte accesses (ddi_get32())
eightbyte	Create errdefs for eight byte accesses (ddi_get64())
multibyte	Create errdefs for repeated byte accesses (ddi_rep_get*())

The frequency of access to a location is determined according to the access type, location and transfer size (for example, a two-byte read access to address A is considered distinct from a four-byte read access to address A). The algorithm is to count the number of accesses (of a given type and size) to a given location, and find the locations that were most and least accessed (let *maxa* and *mina* be the number of times these locations were accessed, and *mean* the total number of accesses divided by total number of locations that were accessed). Then a rare access is a location that was accessed less than

$(mean - mina) / 3 + mina$

times. Similarly for the definition of common accesses:

$maxa - (maxa - mean) / 3$

A location whose access patterns lies within these cutoffs is regarded as a location that is accessed with median frequency.

rare	Create errdefs for locations that are rarely accessed.
common	Create errdefs for locations that are commonly accessed.
median	Create errdefs for locations that are accessed a median frequency.

Policies for Minimizing errdefs

If a transaction is duplicated, either a single or multiple errdefs will be written to the test scripts, depending upon the following two policies:

maximal	Create multiple errdefs for locations that are repeatedly accessed.
unbiased	Create a single errdef for locations that are repeatedly accessed.
operators	For each location, a default operator and operand is typically applied. For maximal test coverage, this default may be modified using the operators policy so that a separate errdef is created for each of the possible corruption operators.

NAME	th_manage – manage the fault injection test harness														
SYNOPSIS	th_manage <i>name instance command</i> th_manage <i>path command</i>														
DESCRIPTION	th_manage applies the action specified by <i>command</i> to the instance specified by <i>instance</i> of the driver specified by <i>name</i> (or the driver instance specified by <i>path</i>). The driver instance must be running fault injection specifications (errdefs) defined by th_define(1M). th_manage supports several commands that operate on the driver instance specified by <i>name</i> and <i>instance</i> (or <i>path</i>). The commands are: <table> <tr> <td>broadcast</td><td>Awaken all th_define processes, causing them to display their current status and exit if the errdef is now defunct (that is, if <i>count</i>, <i>failcount</i>, and <i>acc_chk</i> are all zero).</td></tr> <tr> <td>clear_acc_chk</td><td>Awaken all th_define processes. If <i>count</i> and <i>failcount</i> are already zero, then set <i>acc_chk</i> to zero, so that th_define exits once it has displayed its status.</td></tr> <tr> <td>clear_errdefs</td><td>Awaken all th_define processes. <i>count</i>, <i>failcount</i> and <i>acc_chk</i> are all set to zero so that all th_define commands exit once they have displayed their status.</td></tr> <tr> <td>clear_errors</td><td>Awaken all th_define processes. If <i>count</i> is already zero, set <i>failcount</i> and <i>acc_chk</i> to zero, so that th_define exits once it has displayed its status.</td></tr> <tr> <td>get_handles</td><td>List all the access handles.</td></tr> <tr> <td>start</td><td>Begin or resume execution of all errdefs.</td></tr> <tr> <td>stop</td><td>Suspend all errdefs for this <i>name</i> and <i>instance</i> (or <i>path</i>).</td></tr> </table>	broadcast	Awaken all th_define processes, causing them to display their current status and exit if the errdef is now defunct (that is, if <i>count</i> , <i>failcount</i> , and <i>acc_chk</i> are all zero).	clear_acc_chk	Awaken all th_define processes. If <i>count</i> and <i>failcount</i> are already zero, then set <i>acc_chk</i> to zero, so that th_define exits once it has displayed its status.	clear_errdefs	Awaken all th_define processes. <i>count</i> , <i>failcount</i> and <i>acc_chk</i> are all set to zero so that all th_define commands exit once they have displayed their status.	clear_errors	Awaken all th_define processes. If <i>count</i> is already zero, set <i>failcount</i> and <i>acc_chk</i> to zero, so that th_define exits once it has displayed its status.	get_handles	List all the access handles.	start	Begin or resume execution of all errdefs.	stop	Suspend all errdefs for this <i>name</i> and <i>instance</i> (or <i>path</i>).
broadcast	Awaken all th_define processes, causing them to display their current status and exit if the errdef is now defunct (that is, if <i>count</i> , <i>failcount</i> , and <i>acc_chk</i> are all zero).														
clear_acc_chk	Awaken all th_define processes. If <i>count</i> and <i>failcount</i> are already zero, then set <i>acc_chk</i> to zero, so that th_define exits once it has displayed its status.														
clear_errdefs	Awaken all th_define processes. <i>count</i> , <i>failcount</i> and <i>acc_chk</i> are all set to zero so that all th_define commands exit once they have displayed their status.														
clear_errors	Awaken all th_define processes. If <i>count</i> is already zero, set <i>failcount</i> and <i>acc_chk</i> to zero, so that th_define exits once it has displayed its status.														
get_handles	List all the access handles.														
start	Begin or resume execution of all errdefs.														
stop	Suspend all errdefs for this <i>name</i> and <i>instance</i> (or <i>path</i>).														
EXAMPLES	EXAMPLE 1 Useful Commands To begin the tests, enter: <pre># th_manage foo 0 start</pre> To check the status of the errdefs, enter: <pre># th_manage foo 0 broadcast</pre> This causes each th_define process to print out its current status. If the driver has reported a fatal error, you can take the driver offline using libdevice, clear the error condition by entering: <pre># th_manage foo 0 clear_acc_chk</pre> or														

th_manage(1M)

EXAMPLE 1 Useful Commands *(Continued)*

```
# th_manage foo 0 clear_errors
```

and bring the driver online again using libdevice.

To terminate testing, enter:

```
# th_manage foo 0 clear_errdefs
```

SEE ALSO th_define(1M)

NAME	tic – terminfo compiler				
SYNOPSIS	tic [-v [<i>n</i>]] [-c] <i>file</i>				
DESCRIPTION	The command tic translates a terminfo file from the source format into the compiled format. The results are placed in the directory <code>/usr/share/lib/terminfo</code>. The compiled format is necessary for use with the library routines in curses(3CURSES). If the environment variable TERMINFO is set, the compiled results are placed there instead of <code>/usr/share/lib/terminfo</code>. Total compiled entries cannot exceed 4096 bytes. The name field cannot exceed 128 bytes. Terminal names exceeding 14 characters will be truncated to 14 characters and a warning message will be printed.				
OPTIONS	The following options are supported: -c Specifies to check only <i>file</i> for errors. Errors in <code>use=</code> links are not detected. -v[<i>n</i>] Specify that (verbose) output be written to standard error trace information showing tic's progress. The optional integer <i>n</i> is a number from 1 to 10, indicating the desired level of detail of information. If <i>n</i> is omitted, the default level is 1. If <i>n</i> is specified and greater than 1, the level of detail is increased.				
OPERANDS	<i>file</i> Contains one or more terminfo terminal descriptions in source format [see terminfo(4)]. Each description in the file describes the capabilities of a particular terminal. When a <code>use=entry-name</code> field is discovered in a terminal entry currently being compiled, tic reads in the binary from <code>/usr/share/lib/terminfo</code> to complete the entry. (Entries created from <i>file</i> will be used first. If the environment variable TERMINFO is set, that directory is searched instead of <code>/usr/share/lib/terminfo</code>.) tic duplicates the capabilities in <i>entry-name</i> for the current entry, with the exception of those capabilities that are explicitly defined in the current entry.				
FILES	<code>/usr/share/lib/terminfo/?/*</code> Compiled terminal description database				
ATTRIBUTES	See attributes(5) for descriptions of the following attributes:				
	<table> <tr> <th>ATTRIBUTE TYPE</th><th>ATTRIBUTE VALUE</th></tr> <tr> <td>Availability</td><td>SUNWcsu</td></tr> </table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	Availability	SUNWcsu
ATTRIBUTE TYPE	ATTRIBUTE VALUE				
Availability	SUNWcsu				
SEE ALSO	captainfo(1M) , infocmp(1M) , curses(3CURSES) , terminfo(4) , attributes(5)				

tic(1M)

NOTES	When an entry, for example, <code>entry_name_1</code> , contains a <code>use=entry_name_2</code> field, any canceled capabilities in <code>entry_name_2</code> must also appear in <code>entry_name_1</code> before <code>use=</code> for these capabilities to be canceled in <code>entry_name_1</code> .

NAME	tracert – print the route packets take to network host
SYNOPSIS	<pre> tracert [-adFIlnSvx] [-A <i>addr_family</i>] [-c <i>traffic_class</i>] [-f <i>first_hop</i>] [-g <i>gateway</i> [-g <i>gateway...</i>] -r] [-i <i>iface</i>] [-L <i>flow_label</i>] [-m <i>max_hop</i>] [-P <i>pause_sec</i>] [-p <i>port</i>] [-Q <i>max_timeout</i>] [-q <i>nqueries</i>] [-s <i>src_addr</i>] [-t <i>tos</i>] [-w <i>wait_time</i>] host [<i>packetlen</i>] </pre>
DESCRIPTION	The Internet is a large and complex aggregation of network hardware, connected by gateways. Tracking the route a packet follows can be difficult. The utility <code>tracert</code> traces the route that an IP packet follows to another internet host. The <code>tracert</code> utility utilizes the both the IPv4 and IPv6 protocols. Use the <code>-A</code> option to override the default behavior. <code>tracert</code> uses the IPv4 protocol <i>tll</i> (time to live) field or the IPv6 field <i>hop limit</i>. It attempts to elicit an ICMP or ICMP6 <code>TIME_EXCEEDED</code> response from each <i>gateway</i> along the path, and a <code>PORT_UNREACHABLE</code>(or <code>ECHO_REPLY</code> if <code>-I</code> is used) response from the destination host. It starts by sending probes with a <i>tll</i> or <i>hop limit</i> of 1 and increases by 1 until it either gets to the host, or it hits the maximum <i>max_hop</i>. The default maximum <i>max_hop</i> is 30 hops, but this can be set by the <code>-m</code> option. Three probes are sent at each <i>tll</i> (<i>hop limit</i>) setting, and a line is printed showing the <i>tll</i> (<i>hop limit</i>), the hostname and the address of the gateway, and the <i>rtt</i> (round trip time) of each probe. The number of probes may be specifically set using the <code>-q</code> option. If the probe answers come from different gateways, the hostname and the address of each responding system will be printed. If there is no response within a 5 second timeout interval, a "*" is printed for that probe. The <code>-w</code> option may be used to set the timeout interval. Other possible annotations that may appear after the time are: <pre> ! the <i>tll</i> (<i>hop limit</i>) value in the received packet is <= 1. !H host unreachable. !X communication administratively prohibited. < !N> ICMP (ICMP6) unreachable code N. </pre> The following annotations appear only for IPv4: <pre> !F fragmentation needed. This should never occur. If this is seen, the associated gateway is broken. !N network unreachable. !P protocol unreachable. !S source route failed. It is likely that the gateway does not support source routing. !T unreachable for the specified <i>tos</i> (type-of-service). !U source host isolated or precedence problem. </pre> The following annotations appear only for IPv6:

traceroute(1M)

- !A host unreachable for a reason other than lack of an entry in the routing table.
- !B packet too big.
- !E destination is not a neighbor.
- !R unrecognized next header.

If almost all the probes result in some kind of unreachable code, then `traceroute` gives up and exits.

The destination *host* is not supposed to process the UDP probe packets, so the destination *port* default is set to an unlikely value. However, if some application on the destination is using that value, the value of *port* can be changed with the `-p` option.

The only mandatory parameter is the destination *host* name or IP number. The default probe datagram length is 40 bytes (60 bytes for IPv6), but this may be increased by specifying a packet length (in bytes) after the destination *host* name.

All integer arguments to `traceroute` can be specified in either decimal or hexadecimal notation. For example, *packetlen* can be specified either as 256 or 0x100.

OPTIONS

- A *addr_family* Specify the address family of the target host. *addr_family* can be either `inet` or `inet6`. Address family determines which protocol to use. For an argument of `inet`, IPv4 is used. For `inet6`, IPv6 is used.

By default, if the name of a host is provided, not the literal IP address, and a valid IPv6 address exists in the name service database, `traceroute` will use this address. Otherwise, if the name service database contains an IPv4 address, it will try the IPv4 address.

Specify the address family `inet` or `inet6` to override the default behavior. If the argument specified is `inet`, `traceroute` will use the IPv4 address associated with the hostname. If none exists, `traceroute` will state that the host is unknown and exit. It will not try to determine if an IPv6 address exists in the name service database.

If the specified argument is `inet6`, `traceroute` will use the IPv6 address that is associated with the hostname. If none exists, `traceroute` will state that the host is unknown and exit.
- a Probe all of the addresses of a multi-homed destination. The output looks like `traceroute` has been run once for each IP address of the destination. If

	this option is used together with <code>-A</code>, <code>tracert</code> probes only the addresses that are of the specified address family. While probing one of the addresses of the destination, user can skip to the next address by sending a <code>SIGINT</code>, or exit <code>tracert</code> by sending a <code>SIGQUIT</code> signal. See <code>signal(3C)</code>
<code>-c traffic_class</code>	Specify the traffic class of probe packets. The value must be an integer in the range from 0 to 255. Gateways along the path may route the probe packet differently depending upon the value of <code>traffic_class</code> set in the probe packet. This option is valid only on IPv6.
<code>-d</code>	Set the <code>SO_DEBUG</code> socket option.
<code>-F</code>	Set the "don't fragment" bit. This option is valid only on IPv4.
<code>-f first_hop</code>	Set the starting <code>tll (hop limit)</code> value to <code>first_hop</code> , to override the default value 1. <code>tracert</code> skips processing for those intermediate gateways which are less than <code>first_hop</code> hops away.
<code>-g gateway</code>	Specify a loose source route <i>gateway</i> . The user can specify more than one <i>gateway</i> by using <code>-g</code> for each gateway. The maximum number of gateways is 8 for IPv4 and 127 for IPv6. Note that some factors such as the link MTU can further limit the number of gateways for IPv6. This option cannot be used with the <code>-r</code> option.
<code>-I</code>	Use ICMP (ICMP6) ECHO instead of UDP datagrams.
<code>-i iface</code>	For IPv4, this option specifies a network interface to obtain the source IP address. This is normally only useful on a multi-homed host. The <code>-s</code> option is also another way to do this. For IPv6, it specifies the network interface on which probe packets are transmitted. The argument can be either an interface index, for example, 1, 2, or an interface name, for example, <code>le0</code> , <code>hme0</code> .
<code>-L flow_label</code>	Specify the flow label of probe packets. The value must be an integer in the range from 0 to 1048575. This option is valid only on IPv6.
<code>-l</code>	Print the value of the <code>tll (hop limit)</code> field in each packet received.
<code>-m max_hop</code>	Set the maximum <code>tll (hop limit)</code> used in outgoing probe packets. The default is 30 hops, which is the same default used for TCP connections.

traceroute(1M)

-n	Print hop addresses numerically rather than symbolically and numerically. This saves a nameserver address-to-name lookup for each gateway found on the path.
-P <i>pause_sec</i>	Specify a delay, in seconds, to pause between probe packets. This may be necessary if the final destination does not accept undeliverable packets in bursts. By default, <code>traceroute</code> sends the next probe as soon as it has received a reply. Note that <i>pause_sec</i> is a real number.
-p <i>port</i>	Set the base UDP <i>port</i> number used in probes. The default is 33434. <code>traceroute</code> hopes that nothing is listening on UDP <i>ports</i> $(base + (nhops - 1) * nqueries)$ to $(base + (nhops * nqueries) - 1)$ at the destination host, so that an ICMP (ICMP6) <code>PORT_UNREACHABLE</code> message will be returned to terminate the route tracing. If something is listening on a <i>port</i> in the default range, this option can be used to select an unused <i>port</i> range. <i>nhops</i> is defined as the number of hops between the source and the destination.
-Q <i>max_timeout</i>	Stop probing this hop after <i>max_timeout</i> consecutive timeouts are detected. The default value is 5. Useful in combination with the -q option if you have specified a large <i>nqueries</i> probe count.
-q <i>nqueries</i>	Set the desired number of probe queries. The default is 3.
-r	Bypass the normal routing tables and send directly to a host on an attached network. If the host is not on a directly-attached network, an error is returned. This option can be used to send probes to a local host through an interface that has been dropped by the router daemon. See <code>in.routed(1M)</code> . You cannot use this option if the -g option is used.
-s <i>src_addr</i>	Use the following address, which usually is given as a literal IP address, not a hostname, as the source address in outgoing probe packets. On multi-homed hosts, those with more than one IP address, this option can be used to force the source address to be something other than the IP address <code>traceroute</code> picks by default. If the IP address is not one of this machine's interface addresses, an error is returned and nothing is sent. For IPv4, when used together with the -i option, the given IP address should be configured on the specified

	interface. Otherwise, an error will be returned. In the case of IPv6, the interface name and the source address do not have to match.
	-t <i>tos</i> Set the <i>tos</i>(type-of-service) in probe packets to the specified value. The default is zero. The value must be an integer in the range from 0 to 255. Gateways along the path may route the probe packet differently depending upon the <i>tos</i> value set in the probe packet. This option is valid only on IPv4.
	-v Verbose output. For each hop, the size and the destination of the response packets is displayed. Also ICMP (ICMP6) packets received other than <code>TIME_EXCEEDED</code> and <code>UNREACHABLE</code> are listed as well.
	-w <i>waittime</i> Set the time, in seconds, to wait for a response to a probe. The default is 5 seconds.
	-x Prevent <code>tracert</code> from calculating checksums. Note that checksums are usually required for the last hop when using ICMP ECHO probes. This option is valid only on IPv4. See the <code>-I</code> option.
OPERANDS	The following operands are supported: <i>host</i> The network host.
EXAMPLES	EXAMPLE 1 Sample Output From the <code>tracert</code> Utility Some sample output from the <code>tracert</code> utility might be: <pre>istanbul% tracert london tracert: Warning: london has multiple addresses; \ using 4::114:a00:20ff:ab3d:83ed tracert: Warning: Multiple interfaces found; \ using 4::56:a00:20ff:fe93:8dde @ 1e0:2 tracert to london (4::114:a00:20ff:ab3d:83ed), 30 hops max, \ 60 byte packets 1 frbldg7c-86 (4::56:a00:20ff:felf:65a1) 1.786 ms 1.544 ms 1.719 ms 2 frbldg7b-77 (4::255:0:0:c0a8:517) 2.587 ms 3.001 ms 2.988 ms 3 london (4::114:a00:20ff:ab3d:83ed) 3.122 ms 2.744 ms 3.356 ms</pre> The target host, london, has both IPv4 and IPv6 addresses in the name service database. According to the default behavior, <code>tracert</code> uses IPv6 address of the destination host. EXAMPLE 2 Using the <code>tracert</code> Utility For a Host Which has Only IPv4 Addresses In the following examples, <code>tracert</code> is tracking the route to host sanfrancisco, which has only IPv4 addresses in the name service database. Therefore <code>tracert</code> uses only IPv4 addresses. The following shows the 7-hop path that a packet would follow from the host istanbul to the host sanfrancisco.

traceroute(1M)

EXAMPLE 2 Using the traceroute Utility For a Host Which has Only IPv4 Addresses (Continued)

```
istanbul% traceroute sanfrancisco
traceroute: Warning: Multiple interfaces found; using 172.31.86.247 @ le0
traceroute to sanfrancisco (172.29.64.39), 30 hops max, 40 byte packets
 1  frbldg7c-86 (172.31.86.1)  1.516 ms  1.283 ms  1.362 ms
 2  bldg1a-001 (172.31.1.211)  2.277 ms  1.773 ms  2.186 ms

 4  bldg6-bldg4 (172.30.4.49)  2.655 ms  3.042 ms  2.344 ms
 5  ferbldg11a-001 (172.29.1.236)  2.636 ms  3.432 ms  3.830 ms
 6  frbldg12b-153 (172.29.153.72)  3.452 ms  3.146 ms  2.962 ms
 7  sanfrancisco (172.29.64.39)  3.430 ms  3.312 ms  3.451 ms
```

EXAMPLE 3 Using the traceroute Utility With Source Routing

The following example shows the path of a packet that goes from istanbul to sanfrancisco through the hosts cairo and paris, as specified by the `-g` option. The `-I` option makes `traceroute` send ICMP ECHO probes to the host sanfrancisco. The `-i` options sets the source address to the IP address configured on the interface `qe0`.

```
istanbul% traceroute -g cairo -g paris -i qe0 -q 1 -I sanfrancisco
traceroute to sanfrancisco (172.29.64.39), 30 hops max, 56 byte packets
 1  frbldg7c-86 (172.31.86.1)  2.012 ms
 2  flrbldg7u (172.31.17.131)  4.960 ms
 3  cairo (192.168.163.175)  4.894 ms
 4  flrbldg7u (172.31.17.131)  3.475 ms
 5  frbldg7c-017 (172.31.17.83)  4.126 ms
 6  paris (172.31.86.31)  4.086 ms
 7  frbldg7b-82 (172.31.82.1)  6.454 ms
 8  bldg1a-001 (172.31.1.211)  6.541 ms
 9  bldg6-bldg4 (172.30.4.49)  6.518 ms
10  ferbldg11a-001 (172.29.1.236)  9.108 ms
11  frbldg12b-153 (172.29.153.72)  9.634 ms
12  sanfrancisco (172.29.64.39)  14.631 ms
```

EXIT STATUS The following exit values are returned:

0	Successful operation.
>0	An error occurred.

ATTRIBUTES See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

SEE ALSO netstat(1M), signal(3C), ping(1M), attributes(5)

`traceroute(1M)`

WARNINGS This utility is intended for use in network testing, measurement and management. It should be used primarily for manual fault isolation. Because of the load it could impose on the network, it is unwise to use `traceroute(1M)` during normal operations or from automated scripts.

trapstat(1M)

NAME	trapstat – report trap statistics
SYNOPSIS	<pre> /usr/platform/ platform-name /sbin/trapstat [-t -T -e entry] [-C processor_set_id -c cpulist] [-P] [-a] [-r rate] [[interval [count]] command [args]] /usr/platform/ platform-name /sbin/trapstat -l </pre>
DESCRIPTION	The trapstat utility gathers and displays run-time trap statistics on UltraSPARC-based systems. The default output is a table of trap types and CPU IDs, with each row of the table denoting a trap type and each column of the table denoting a CPU. If standard output is a terminal, the table contains as many columns of data as can fit within the terminal width; if standard output is not a terminal, the table contains at most six columns of data. By default, data is gathered and displayed for all CPUs; if the data cannot fit in a single table, it is printed across multiple tables. The set of CPUs for which data is gathered and displayed can be optionally specified with the <code>-c</code> or <code>-C</code> option. Unless the <code>-r</code> option or the <code>-a</code> option is specified, the value displayed in each entry of the table corresponds to the number of traps per second. If the <code>-r</code> option is specified, the value corresponds to the number of traps over the interval implied by the specified sampling rate; if the <code>-a</code> option is specified, the value corresponds to the accumulated number of traps since the invocation of trapstat. By default, trapstat displays data once per second, and runs indefinitely; both of these behaviors can be optionally controlled with the <i>interval</i> and <i>count</i> parameters, respectively. The <i>interval</i> is specified in seconds; the <i>count</i> indicates the number of intervals to be executed before exiting. Alternatively, <i>command</i> can be specified, in which case trapstat executes the provided command and continues to run until the command exits. A positive integer is assumed to be an <i>interval</i>; if the desired <i>command</i> cannot be distinguished from an integer, the full path of <i>command</i> must be specified. UltraSPARC I, II and III handle translation lookaside buffer (TLB) misses by trapping to the operating system. TLB miss traps can be a significant component of overall system performance for some workloads; the <code>-t</code> option provides in-depth information on these traps. When run with this option, trapstat displays both the rate of TLB miss traps and the percentage of time spent processing those traps. Additionally, TLB misses that hit in the translation storage buffer (TSB) are differentiated from TLB misses that further miss in the TSB. (The TSB is a software structure used as a translation entry cache to allow the TLB to be quickly filled; it is discussed in detail in the <i>UltraSPARC I&II User's Manual</i>.) The TLB and TSB miss information is further broken down into user- and kernel-mode misses. Workloads with working sets that exceed the TLB reach may spend a significant amount of time missing in the TLB. To accommodate such workloads, the operating system supports multiple page sizes: larger page sizes increase the effective TLB reach and thereby reduce the number of TLB misses. To provide insight into the relationship

between page size and TLB miss rate, `trapstat` optionally provides in-depth TLB miss information broken down by page size using the `-T` option. The information provided by the `-T` option is a superset of that provided by the `-t` option; only one of `-t` and `-T` can be specified.

OPTIONS

The following options are supported:

- `-a` Displays the number of traps as accumulating, monotonically increasing values instead of per-second or per-interval rates.
- `-c cpulist` Enables `trapstat` only on the CPUs specified by *cpulist*.

cpulist can be a single processor ID (for example, 4), a range of processor IDs (for example, 4-6), or a comma separated list of processor IDs or processor ID ranges (for example, 4, 5, 6 or 4, 6-8).
- `-C processor_set_id` Enables `trapstat` only on the CPUs in the processor set specified by *processor_set_id*.

`trapstat` modifies its output to always reflect the CPUs in the specified processor set. If a CPU is added to the set, `trapstat` modifies its output to include the added CPU; if a CPU is removed from the set, `trapstat` modifies its output to exclude the removed CPU. At most one processor set can be specified.
- `-e entrylist` Enables `trapstat` only for the trap table entry or entries specified by *entrylist*. A trap table entry can be specified by trap number or by trap name (for example, the level-10 trap can be specified as 74, 0x4A, 0x4a, or level-10).

entrylist can be a single trap table entry or a comma separated list of trap table entries. If the specified trap table entry is not valid, `trapstat` prints a table of all valid trap table entries and values. A list of valid trap table entries is also found in *The SPARC Architecture Manual, Version 9* and the *Sun Microelectronics UltraSPARC I&II User's Manual*. If the parsable option (`-P`) is specified in addition to the `-e` option, the format of the data is as follows:

Field	Contents
1	Timestamp (nanoseconds since start)

trapstat(1M)

	<table> <tr> <th>Field</th><th>Contents</th></tr> <tr> <td>2</td><td>CPU ID</td></tr> <tr> <td>3</td><td>Trap number (in hexadecimal)</td></tr> <tr> <td>4</td><td>Trap name</td></tr> <tr> <td>5</td><td>Trap rate per interval</td></tr> </table>	Field	Contents	2	CPU ID	3	Trap number (in hexadecimal)	4	Trap name	5	Trap rate per interval
Field	Contents										
2	CPU ID										
3	Trap number (in hexadecimal)										
4	Trap name										
5	Trap rate per interval										
	Each field is separated with whitespace. If the format is modified, it will be modified by adding potentially new fields beginning with field 6; exant fields will remain unchanged.										
-l	Lists trap table entries. By default, a table is displayed containing all valid trap numbers, their names and a brief description. The trap name is used in both the default output and in the <i>entrylist</i> parameter for the <i>-e</i> argument. If the parsable option (<i>-P</i>) is specified in addition to the <i>-l</i> option, the format of the data is as follows: <table> <tr> <th>Field</th><th>Contents</th></tr> <tr> <td>1</td><td>Trap number in hexadecimal</td></tr> <tr> <td>2</td><td>Trap number in decimal</td></tr> <tr> <td>3</td><td>Trap name</td></tr> <tr> <td>Remaining</td><td>Trap description</td></tr> </table>	Field	Contents	1	Trap number in hexadecimal	2	Trap number in decimal	3	Trap name	Remaining	Trap description
Field	Contents										
1	Trap number in hexadecimal										
2	Trap number in decimal										
3	Trap name										
Remaining	Trap description										
-P	Generates parsable output. When run without other data gathering modifying options (that is, <i>-e</i>, <i>-t</i> or <i>-T</i>), <i>trapstat</i>'s the parsable output has the following format: <table> <tr> <th>Field</th><th>Contents</th></tr> <tr> <td>1</td><td>Timestamp (nanoseconds since start)</td></tr> <tr> <td>2</td><td>CPU ID</td></tr> <tr> <td>3</td><td>Trap number (in hexadecimal)</td></tr> <tr> <td>4</td><td>Trap name</td></tr> </table>	Field	Contents	1	Timestamp (nanoseconds since start)	2	CPU ID	3	Trap number (in hexadecimal)	4	Trap name
Field	Contents										
1	Timestamp (nanoseconds since start)										
2	CPU ID										
3	Trap number (in hexadecimal)										
4	Trap name										

Field	Contents
5	Trap rate per interval

Each field is separated with whitespace. If the format is modified, it will be modified by adding potentially new fields beginning with field 6; extant fields will remain unchanged.

-r *rate*

Explicitly sets the sampling rate to be *rate* samples per second. If this option is specified, *trapstat*'s output changes from a traps-per-second to traps-per-sampling-interval.

-t

Enables TLB statistics.

A table is displayed with four principal columns of data: *itlb-miss*, *itsb-miss*, *dtlb-miss*, and *dtsb-miss*. The columns contain both the rate of the corresponding event and the percentage of CPU time spent processing the event. The percentage of CPU time is given only in terms of a single CPU. The rows of the table correspond to CPUs, with each CPU consuming two rows: one row for user-mode events (denoted with *u*) and one row for kernel-mode events (denoted with *k*). For each row, the percentage of CPU time is totalled and displayed in the rightmost column. The CPUs are delineated with a solid line. If the parsable option (**-P**) is specified in addition to the **-t** option, the format of the data is as follows:

Field	Contents
1	Timestamp (nanoseconds since start)
2	CPU ID
3	Mode (<i>k</i> denotes kernel, <i>u</i> denotes user)
4	I-TLB misses
5	Percentage of time in I-TLB miss handler
6	I-TSB misses
7	Percentage of time in I-TSB miss handler

trapstat(1M)

-T

Field	Contents
8	D-TLB misses
9	Percentage of time in D-TLB miss handler
10	D-TSB misses
11	Percentage of time in D-TSB miss handler

Each field is separated with whitespace. If the format is modified, it will be modified by adding potentially new fields beginning with field 12; extant fields will remain unchanged.

Enables TLB statistics, with page size information. As with the `-t` option, a table is displayed with four principal columns of data: *itlb-miss*, *itsb-miss*, *dtlb-miss*, and *dtsb-miss*. The columns contain both the absolute number of the corresponding event, and the percentage of CPU time spent processing the event. The percentage of CPU time is given only in terms of a single CPU. The rows of the table correspond to CPUs, with each CPU consuming two sets of rows: one set for user-level events (denoted with *u*) and one set for kernel-level events (denoted with *k*). Each set, in turn, contains as many rows as there are page sizes supported (see `getpagesizes(3C)`). For each row, the percentage of CPU time is totalled and displayed in the right-most column. The two sets are delineated with a dashed line; CPUs are delineated with a solid line. If the parsable option (`-P`) is specified in addition to the `-T` option, the format of the data is as follows:

Field	Contents
1	Timestamp (nanoseconds since start)
2	CPU ID
3	Mode <i>k</i> denotes kernel, <i>u</i> denotes user)
4	Page size, in decimal
5	I-TLB misses

Field	Contents
6	Percentage of time in I-TLB miss handler
7	I-TSB misses
8	Percentage of time in I-TSB miss handler
9	D-TLB misses
10	Percentage of time in D-TLB miss handler
11	D-TSB misses
12	Percentage of time in D-TSB miss handler

Each field is separated with whitespace. If the format is modified, it will be modified by adding potentially new fields beginning with field 13; extant fields will remain unchanged.

EXAMPLES**EXAMPLE 1** Using trapstat Without Options

When run without options, trapstat displays a table of trap types and CPUs. At most six columns can fit in the default terminal width; if (as in this example) there are more than six CPUs, multiple tables are displayed:

```
example# trapstat
vct name | cpu0  cpu1  cpu4  cpu5  cpu8  cpu9
-----+-----
24 cleanwin | 6446  4837  6368  2153  2623  1321
41 level-1  | 100    0      0      0      1      0
44 level-4  | 0      1      1      1      0      0
45 level-5  | 0      0      0      0      0      0
47 level-7  | 0      0      0      0      9      0

EXAMPLE 2 Using trapset with CPU Filtering

The `-c` option can be used to limit the CPUs on which `trapstat` is enabled. This example limits CPU 1 and CPUs 12 through 15.

```
example# trapstat -c 1,12-15
```

vct	name		cpu1	cpu12	cpu13	cpu14	cpu15
24	cleanwin		6923	3072	2500	3518	2261

EXAMPLE 3 Using trapstat with TLB Statistics

The `-t` option displays in-depth TLB statistics, including the amount of time spent performing TLB miss processing. The following example shows that the machine is spending 14.1 percent of its time just handling D-TLB misses:

```
example# trapstat -t
cpu m| itlb-miss %tim itsb-miss %tim | dtlb-miss %tim dtsb-miss %tim |%tim
-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+
0 u|      2571  0.3          0  0.0 |    10802  1.3          0  0.0 |  1.6
0 k|         0  0.0          0  0.0 |   106420 13.4         184  0.1 |13.6

EXAMPLE 4 Using trapstat with TLB Statistics and Page Size Information

By specifying the `-T` option, `trapstat` shows TLB misses broken down by page size. In this example, CPU 0 is spending 7.9 percent of its time handling user-mode TLB misses on 8K pages, and another 2.3 percent of its time handling user-mode TLB misses on 64K pages.

```
example# trapstat -T -c 0
cpu m size| itlb-miss %tim itsb-miss %tim | dtlb-miss %tim dtsb-miss %tim |%tim
-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+
-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+
-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+
```

EXAMPLE 4 Using trapstat with TLB Statistics and Page Size Information (Continued)

0 u 8k	1300	0.1	15	0.0	104897	7.9	90	0.0	8.0
0 u 64k	0	0.0	0	0.0	29935	2.3	7	0.0	2.3

EXAMPLE 5 Using trapstat with Entry Filtering

By specifying the `-e` option, `trapstat` displays statistics for only specific trap types. Using this option minimizes the probe effect when seeking specific data. This example yields statistics for only the `dtlb-prot` and `syscall-32` traps on CPUs 12 through 15:

```
example# trapstat -e dtlb-prot,syscall-32 -c 12-15
vct name | cpu12 cpu13 cpu14 cpu15
-----+-----
6c dtlb-prot | 817 754 1018 560
108 syscall-32 | 1426 1647 2186 1142

vct name | cpu12 cpu13 cpu14 cpu15
-----+-----
6c dtlb-prot | 1085 996 800 707
108 syscall-32 | 2578 2167 1638 1452
```

EXAMPLE 6 Using trapstat with a Higher Sampling Rate

The following example uses the `-r` option to specify a sampling rate of 1000 samples per second, and filter only for the level-10 trap. Additionally, specifying the `-P` option yields parsable output.

Notice the timestamp difference between the level-10 events: 9,998,000 nanoseconds and 10,007,000 nanoseconds. These level-10 events correspond to the system clock, which by default ticks at 100 hertz (that is, every 10,000,000 nanoseconds).

```
example# trapstat -e level-10 -P -r 1000
1070400 0 4a level-10 0
2048600 0 4a level-10 0
3030400 0 4a level-10 1
4035800 0 4a level-10 0
5027200 0 4a level-10 0
6027200 0 4a level-10 0
7027400 0 4a level-10 0
8028200 0 4a level-10 0
9026400 0 4a level-10 0
10029600 0 4a level-10 0
11028600 0 4a level-10 0
12024000 0 4a level-10 0
```

EXAMPLE 6 Using trapstat with a Higher Sampling Rate (Continued)

```

13028400 0 4a level-10 1
14031200 0 4a level-10 0
15027200 0 4a level-10 0
16027600 0 4a level-10 0
17025000 0 4a level-10 0
18026000 0 4a level-10 0
19027800 0 4a level-10 0
20025600 0 4a level-10 0
21025200 0 4a level-10 0
22025000 0 4a level-10 0
23035400 0 4a level-10 1
24027400 0 4a level-10 0
25026000 0 4a level-10 0
26027000 0 4a level-10 0

```

Sun Microelectronics UltraSPARC I&II User's Manual, January 1997, STP1031,

The SPARC Architecture Manual, Version 9, 1994, Prentice-Hall.

NOTES When enabled, trapstat induces a varying probe effect, depending on the type of information collected. While the precise probe effect depends upon the specifics of the hardware, the following table can be used as a rough guide:

Option	Approximate probe effect
default	3-5% per trap
-e	3-5% per specified trap
-t, -T	40-45% per TLB miss trap hitting in the TSB, 25-30% per TLB miss trap missing in the TSB

trapstat(1M)

These probe effects are *per trap* not for the system as a whole. For example, running `trapstat` with the default options on a system that spends 7% of total time handling traps induces a performance degradation of less than one half of one percent; running `trapstat` with the `-t` or `-T` option on a system spending 5% of total time processing TLB misses induce a performance degradation of no more than 2.5%.

When run with the `-t` or `-T` option, `trapstat` accounts for its probe effect when calculating the `%tim` fields. This assures that the `%tim` fields are a reasonably accurate indicator of the time a given workload is spending handling TLB misses — regardless of the perturbing presence of `trapstat`.

While the `%tim` fields include the explicit cost of executing the TLB miss handler, they do *not* include the implicit costs of TLB miss traps (for example, pipeline effects, cache pollution, etc). These implicit costs become more significant as the trap rate grows; if high `%tim` values are reported (greater than 50%), you can accurately infer that much of the balance of time is being spent on the implicit costs of the TLB miss traps.

Due to the potential system wide degradation induced, only the super-user can run `trapstat`.

Due to the limitation of the underlying statistics gathering methodology, only one instance of `trapstat` can run at a time.

NAME	ttyadm – format and output port monitor-specific information
SYNOPSIS	<pre> /usr/sbin/ttyadm [-b] [-c] [-h] [-I] [-r count] [-i msg] [-m modules] [-p prompt] [-t timeout] [-S y n] [-T termtype] -d device -l ttylabel -s service /usr/sbin/ttyadm -V </pre>
DESCRIPTION	The <code>ttyadm</code> command is an administrative command that formats <code>ttymon</code>(1M)-specific information and writes it to standard output. The Service Access Facility (SAF) requires each port monitor to provide such a command. Note that the port monitor administrative file is updated by the Service Access Controller's administrative commands, <code>sacadm</code>(1M) and <code>pmadm</code>(1M). <code>ttyadm</code> provides a means of presenting formatted port monitor-specific (<code>ttymon</code>-specific) data to these commands.
OPTIONS	The following options are supported: -b Set the “bi-directional port” flag. When this flag is set, the line can be used in both directions. <code>ttymon</code> will allow users to connect to the service associated with the port, but if the port is free, <code>uucico</code>(1M), <code>cu</code>(1C), or <code>ct</code>(1C) can use it for dialing out. -c Set the connect-on-carrier flag for the port. If the <code>-c</code> flag is set, <code>ttymon</code> will invoke the port's associated service immediately when a connect indication is received (that is, no prompt is printed and no baud-rate searching is done). -d <i>device</i> <i>device</i> is the full pathname of the device file for the TTY port. -h Set the hangup flag for the port. If the <code>-h</code> flag is not set, <code>ttymon</code> will force a hangup on the line by setting the speed to 0 before setting the speed to the default or specified value. -i <i>message</i> Specify the inactive (disabled) response message. This message will be sent to the TTY port if the port is disabled or the <code>ttymon</code> monitoring the port is disabled. -I Initialize only. If the <code>-I</code> option is used, <code>ttymon</code> will invoke the service only once. This can be used to configure a particular device without actually monitoring it, as with software carrier. -l <i>ttylabel</i> Specify which <i>ttylabel</i> in the <code>/etc/ttydefs</code> file to use as the starting point when searching for the proper baud rate. -m <i>modules</i> Specify a list of pushable STREAMS modules. The modules will be pushed in the order in which they are specified before the service is invoked. <i>modules</i> must be a comma-separated list of modules, with no white space included. Any modules currently on the stream will be popped before these modules are pushed. -p <i>prompt</i> Specify the prompt message, for example, “login:”.

ttyadm(1M)

-r <i>count</i>	When the -r option is invoked, <code>ttymon</code> will wait until it receives data from the port before it displays a prompt. If <i>count</i> is 0, <code>ttymon</code> will wait until it receives any character. If <i>count</i> is greater than 0, <code>ttymon</code> will wait until <i>count</i> newlines have been received.
-s <i>service</i>	<i>service</i> is the full pathname of the service to be invoked when a connection request is received. If arguments are required, the command and its arguments must be enclosed in double quotes ("").
-S <i>y n</i>	Set the software carrier value. <i>y</i> will turn software carrier on. <i>n</i> will turn software carrier off.
-t <i>timeout</i>	Specify that <code>ttymon</code> should close a port if the open on the port succeeds, and no input data is received in <i>timeout</i> seconds.
-T <i>termtype</i>	Set the terminal type. The <code>TERM</code> environment variable will be set to <i>termtype</i> .
-V	Display the version number of the current <code>/usr/lib/saf/ttymon</code> command.

OUTPUT If successful, `ttyadm` will generate the requested information, write it to standard output, and exit with a status of 0. If `ttyadm` is invoked with an invalid number of arguments or invalid arguments, or if an incomplete option is specified, an error message will be written to standard error and `ttymon` will exit with a non-zero status.

System Administration Guide: Basic Administration

NAME	ttypmon – port monitor for terminal ports
SYNOPSIS	<pre> /usr/lib/saf/ttypmon /usr/lib/saf/ttypmon -g [-d device] [-h] [-t timeout] [-l ttylabel] [-p prompt] [-m modules] [-T termtype] </pre>
DESCRIPTION	ttypmon is a STREAMS-based TTY port monitor. Its function is to monitor ports, to set terminal modes, baud rates, and line disciplines for the ports, and to connect users or applications to services associated with the ports. Normally, ttypmon is configured to run under the Service Access Controller, sac(1M), as part of the Service Access Facility (SAF). It is configured using the sacadm(1M) command. Each instance of ttypmon can monitor multiple ports. The ports monitored by an instance of ttypmon are specified in the port monitor's administrative file. The administrative file is configured using the pmadm(1M) and ttyadm(1M) commands. When an instance of ttypmon is invoked by the sac command, it starts to monitor its ports. For each port, ttypmon first initializes the line disciplines, if they are specified, and the speed and terminal settings. For ports with entries in /etc/logindevperm, device owner, group and permissions are set. (See logindevperm(4).) The values used for initialization are taken from the appropriate entry in the TTY settings file. This file is maintained by the sttydefs(1M) command. Default line disciplines on ports are usually set up by the autopush(1M) command of the Autopush Facility. ttypmon then writes the prompt and waits for user input. If the user indicates that the speed is inappropriate by pressing the BREAK key, ttypmon tries the next speed and writes the prompt again. When valid input is received, ttypmon interprets the per-service configuration file for the port, if one exists, creates a utmpx entry if required (see utmpx(4)), establishes the service environment, and then invokes the service associated with the port. Valid input consists of a string of at least one non-newline character, terminated by a carriage return. After the service terminates, ttypmon cleans up the utmpx entry, if one exists, and returns the port to its initial state. If <i>autobaud</i> is enabled for a port, ttypmon will try to determine the baud rate on the port automatically. Users must enter a carriage return before ttypmon can recognize the baud rate and print the prompt. Currently, the baud rates that can be determined by <i>autobaud</i> are 110, 1200, 2400, 4800, and 9600. If a port is configured as a bidirectional port, ttypmon will allow users to connect to a service, and, if the port is free, will allow uucico(1M), cu(1C), or ct(1C) to use it for dialing out. If a port is bidirectional, ttypmon will wait to read a character before it prints a prompt. If the <i>connect-on-carrier</i> flag is set for a port, ttypmon will immediately invoke the port's associated service when a connection request is received. The prompt message will not be sent. If a port is disabled, ttypmon will not start any service on that port. If a disabled message is specified, ttypmon will send out the disabled message when a connection request is received. If ttypmon is disabled, all ports under that instance of ttypmon will also be disabled.

ttymon(1M)

SERVICE INVOCATION

The service `ttymon` invokes for a port is specified in the `ttymon` administrative file. `ttymon` will scan the character string giving the service to be invoked for this port, looking for a `%d` or a `%%` two-character sequence. If `%d` is found, `ttymon` will modify the service command to be executed by replacing those two characters by the full path name of this port (the device name). If `%%` is found, they will be replaced by a single `%`. When the service is invoked, file descriptor 0, 1, and 2 are opened to the port device for reading and writing. The service is invoked with the user ID, group ID and current home directory set to that of the user name under which the service was registered with `ttymon`. Two environment variables, `HOME` and `TTYPROMPT`, are added to the service's environment by `ttymon`. `HOME` is set to the home directory of the user name under which the service is invoked. `TTYPROMPT` is set to the prompt string configured for the service on the port. This is provided so that a service invoked by `ttymon` has a means of determining if a prompt was actually issued by `ttymon` and, if so, what that prompt actually was.

See `ttyadm(1M)` for options that can be set for ports monitored by `ttymon` under the Service Access Controller.

SECURITY

`ttymon` uses `pam(3PAM)` for session management. The PAM configuration policy, listed through `/etc/pam.conf`, specifies the modules to be used for `ttymon`. Here is a partial `pam.conf` file with entries for `ttymon` using the UNIX session management module.

```
ttymon session required /usr/lib/security/pam_unix.so.1
```

If there are no entries for the `ttymon` service, then the entries for the "other" service will be used.

OPTIONS

- `-g` A special invocation of `ttymon` is provided with the `-g` option. This form of the command should only be called by applications that need to set the correct baud rate and terminal settings on a port and then connect to login service, but that cannot be pre-configured under the SAC. The following combinations of options can be used with `-g`:
- `-d device` *device* is the full path name of the port to which `ttymon` is to attach. If this option is not specified, file descriptor 0 must be set up by the invoking process to a TTY port.
- `-h` If the `-h` flag is not set, `ttymon` will force a hangup on the line by setting the speed to zero before setting the speed to the default or specified speed.
- `-l ttylabel` *ttylabel* is a link to a speed and TTY definition in the `ttydefs` file. This definition tells `ttymon` at what speed to run initially, what the initial TTY settings are, and what speed to try next if the user indicates that the speed is inappropriate by pressing the BREAK key. The default speed is 9600 baud.
- `-m modules` When initializing the port, `ttymon` will pop all modules on the port, and then push *modules* in the order specified. *modules* is a

ENVIRONMENT VARIABLES

- comma-separated list of pushable modules. Default modules on the ports are usually set up by the Autopush Facility.
- p *prompt*** Allows the user to specify a prompt string. The default prompt is Login: .
- t *timeout*** Specifies that `ttymon` should exit if no one types anything in *timeout* seconds after the prompt is sent.
- T *termtype*** Sets the `TERM` environment variable to *termtype*.

If any of the `LC_*` variables (`LC_CTYPE`, `LC_MESSAGES`, `LC_TIME`, `LC_COLLATE`, `LC_NUMERIC`, and `LC_MONETARY`) (see `environ(5)`) are not set in the environment, the operational behavior of `ttymon` for each corresponding locale category is determined by the value of the `LANG` environment variable. If `LC_ALL` is set, its contents are used to override both the `LANG` and the other `LC_*` variables. If none of the above variables is set in the environment, the "C" (U.S. style) locale determines how `ttymon` behaves.

LC_CTYPE Determines how `ttymon` handles characters. When `LC_CTYPE` is set to a valid value, `ttymon` can display and handle text and filenames containing valid characters for that locale. `ttymon` can display and handle Extended Unix Code (EUC) characters where any individual character can be 1, 2, or 3 bytes wide. `ttymon` can also handle EUC characters of 1, 2, or more column widths. In the "C" locale, only characters from ISO 8859-1 are valid.

System Administration Guide: Basic Administration

NOTES

If a port is monitored by more than one `ttymon`, it is possible for the `ttymons` to send out prompt messages in such a way that they compete for input.

The `pam_unix(5)` module might not be supported in a future release. Similar functionality is provided by `pam_authtok_check(5)`, `pam_authtok_get(5)`, `pam_authtok_store(5)`, `pam_dhkeys(5)`, `pam_passwd_auth(5)`, `pam_unix_account(5)`, `pam_unix_auth(5)`, and `pam_unix_session(5)`.

tunefs(1M)

NAME	tunefs – tune an existing UFS file system
SYNOPSIS	tunefs [-a <i>maxcontig</i>] [-d <i>rotdelay</i>] [-e <i>maxbpg</i>] [-m <i>minfree</i>] [-o <i>space time</i>] <i>special</i> <i>filesystem</i>
DESCRIPTION	tunefs is designed to change the dynamic parameters of a file system that affect the layout policies. When using tunefs with <i>filesystem</i> , <i>filesystem</i> must be in /etc/vfstab. The parameters that can be changed are indicated by the options given below.
OPTIONS	The following options are supported: -a <i>maxcontig</i> The maximum number of logical blocks, belonging to one file, that is allocated contiguously. The default is calculated as follows: $\text{maxcontig} = \text{disk drive maximum transfer size} / \text{disk block size}$ If the disk drive's maximum transfer size cannot be determined, the default value for maxcontig is calculated from kernel parameters as follows: If maxphys is less than ufs_maxmaxphys, which is 1 Mbyte, then maxcontig is set to maxphys. Otherwise, maxcontig is set to ufs_maxmaxphys. You can set maxcontig to any positive integer value. The actual value will be the lesser of what has been specified and what the hardware supports. -d <i>rotdelay</i> This parameter is obsolete. The value is always set to 0, regardless of the input value. -e <i>maxbpg</i> Indicates the maximum number of contiguous logical blocks any single file can allocate from a cylinder group before it is forced to begin allocating blocks from another cylinder group. Typically this value is set to approximately one quarter of the total contiguous logical blocks in a cylinder group. The intent is to prevent any single file from using up all the blocks in a single cylinder group, thus degrading access times for all files subsequently allocated in that cylinder group. The effect of this limit is to cause big files to do long seeks more frequently than if they were allowed to allocate all the blocks in a cylinder group before seeking elsewhere. For file systems with exclusively large files, this parameter should be set higher. -m <i>minfree</i> Specifies the minimum free space threshold, or the percentage of space held back from normal users. This value can be set to 0. However, up to a factor of three in throughput will be lost over the performance obtained at a 10% threshold. <i>Note:</i> If the value is raised above the current usage level, users will be unable to allocate files until enough files have been deleted to get under the higher threshold.

tunefs(1M)

-o *space* | *time*

The file system can either be instructed to try to minimize the *time* spent allocating blocks, or to try to minimize the *space* fragmentation on the disk. The default is *time*.

Generally, you should optimize for time unless the file system is over 90% full.

USAGE See largefile(5) for the description of the behavior of tunefs when encountering files greater than or equal to 2 Gbyte (2^{31} bytes).

NAME	uadmin – administrative control				
SYNOPSIS	<pre>/usr/sbin/uadmin cmd fcn [mdep] /sbin/uadmin cmd fcn [mdep]</pre>				
DESCRIPTION	The uadmin command provides control for basic administrative functions. This command is tightly coupled to the system administration procedures and is not intended for general use. It may be invoked only by the super-user. Both the <i>cmd</i> (command) and <i>fcn</i> (function) arguments are converted to integers and passed to the uadmin system call. The optional <i>mdep</i> (machine dependent) argument is only available for the <i>cmd</i> values of 1 (A_REBOOT), 2 (A_SHUTDOWN), or 5 (A_DUMP). For any other <i>cmd</i> value, no <i>mdep</i> command-line argument is allowed. When passing an <i>mdep</i> value that contains whitespaces, the string must be grouped together as a single argument enclosed within quotes, for example: <pre>uadmin 1 1 "-s kernel/unix"</pre>

ufsdump(1M)

NAME	ufsdump – incremental file system dump						
SYNOPSIS	/usr/sbin/ufsdump [<i>options</i>] [<i>arguments</i>] <i>files_to_dump</i>						
DESCRIPTION	ufsdump backs up all files specified by <i>files_to_dump</i> (normally either a whole file system or files within a file system changed after a certain date) to magnetic tape, diskette, or disk file. When running ufsdump, the file system must be inactive; otherwise, the output of ufsdump may be inconsistent and restoring files correctly may be impossible. A file system is inactive when it is unmounted or the system is in single user mode. A file system is not considered inactive if one tree of the file system is quiescent while another tree has files or directories being modified. <i>options</i> is a single string of one-letter ufsdump options. <i>arguments</i> may be multiple strings whose association with the options is determined by order. That is, the first argument goes with the first option that takes an argument; the second argument goes with the second option that takes an argument, and so on. <i>files_to_dump</i> is required and must be the last argument on the command line. See OPERANDS for more information. With most devices ufsdump can automatically detect the end-of-media. Consequently, the <i>d</i>, <i>s</i>, and <i>t</i> options are not necessary for multi-volume dumps, unless ufsdump does not understand the way the device detects the end-of-media, or the files are to be restored on a system with an older version of the <i>restore</i> command.						
OPTIONS	The following options are supported: <table> <tr> <td>0–9</td><td>The “dump level.” All files specified by <i>files_to_dump</i> that have been modified since the last ufsdump at a lower dump level are copied to the <i>dump_file</i> destination (normally a magnetic tape device). For instance, if a “level 2” dump was done on Monday, followed by a “level 4” dump on Tuesday, a subsequent “level 3” dump on Wednesday would contain all files modified or added since the “level 2” (Monday) backup. A “level 0” dump copies the entire file system to the <i>dump_file</i>.</td></tr> <tr> <td>a <i>archive_file</i></td><td>Archive file. Archive a dump table-of-contents in the specified <i>archive_file</i> to be used by ufsrestore(1M) to determine whether a file is in the dump file that is being restored.</td></tr> <tr> <td>b <i>factor</i></td><td>Blocking factor. Specify the blocking factor for tape writes. The default is 20 blocks per write for tapes of density less than 6250BPI (bytes-per-inch). The default blocking factor for tapes of density 6250BPI and greater is 64. The default blocking factor for cartridge tapes (<i>c</i> option) is 126. The highest blocking factor available</td></tr> </table>	0–9	The “dump level.” All files specified by <i>files_to_dump</i> that have been modified since the last ufsdump at a lower dump level are copied to the <i>dump_file</i> destination (normally a magnetic tape device). For instance, if a “level 2” dump was done on Monday, followed by a “level 4” dump on Tuesday, a subsequent “level 3” dump on Wednesday would contain all files modified or added since the “level 2” (Monday) backup. A “level 0” dump copies the entire file system to the <i>dump_file</i> .	a <i>archive_file</i>	Archive file. Archive a dump table-of-contents in the specified <i>archive_file</i> to be used by ufsrestore(1M) to determine whether a file is in the dump file that is being restored.	b <i>factor</i>	Blocking factor. Specify the blocking factor for tape writes. The default is 20 blocks per write for tapes of density less than 6250BPI (bytes-per-inch). The default blocking factor for tapes of density 6250BPI and greater is 64. The default blocking factor for cartridge tapes (<i>c</i> option) is 126. The highest blocking factor available
0–9	The “dump level.” All files specified by <i>files_to_dump</i> that have been modified since the last ufsdump at a lower dump level are copied to the <i>dump_file</i> destination (normally a magnetic tape device). For instance, if a “level 2” dump was done on Monday, followed by a “level 4” dump on Tuesday, a subsequent “level 3” dump on Wednesday would contain all files modified or added since the “level 2” (Monday) backup. A “level 0” dump copies the entire file system to the <i>dump_file</i> .						
a <i>archive_file</i>	Archive file. Archive a dump table-of-contents in the specified <i>archive_file</i> to be used by ufsrestore(1M) to determine whether a file is in the dump file that is being restored.						
b <i>factor</i>	Blocking factor. Specify the blocking factor for tape writes. The default is 20 blocks per write for tapes of density less than 6250BPI (bytes-per-inch). The default blocking factor for tapes of density 6250BPI and greater is 64. The default blocking factor for cartridge tapes (<i>c</i> option) is 126. The highest blocking factor available						

	with most tape drives is 126. Note: the blocking factor is specified in terms of 512-byte blocks, for compatibility with <code>tar(1)</code> .
<code>c</code>	Cartridge. Set the defaults for cartridge instead of the standard half-inch reel. This sets the density to 1000BPI and the blocking factor to 126. Since <code>ufsdump</code> can automatically detect the end-of-media, only the blocking parameter normally has an effect. When cartridge tapes are used, and this option is <i>not</i> specified, <code>ufsdump</code> will slightly miscompute the size of the tape. If the <code>b</code> , <code>d</code> , <code>s</code> or <code>t</code> options are specified with this option, their values will override the defaults set by this option.
<code>d bpi</code>	Tape density. Not normally required, as <code>ufsdump</code> can detect end-of-media. This parameter can be used to keep a running tab on the amount of tape used per reel. The default density is 6250BPI except when the <code>c</code> option is used for cartridge tape, in which case it is assumed to be 1000BPI per track. Typical values for tape devices are: 1/2 inch tape 6250 BPI 1/4 inch cartridge 1000 BPI The tape densities and other options are documented in the <code>st(7D)</code> man page.
<code>D</code>	Diskette. Dump to diskette.
<code>f dump_file</code>	Dump file. Use <code>dump_file</code> as the file to dump to, instead of <code>/dev/rmt/0</code> . If <code>dump_file</code> is specified as <code>-</code> , dump to standard output. If the name of the file is of the form <code>machine:device</code> , the dump is done from the specified machine over the network using <code>rmt(1M)</code> . Since <code>ufsdump</code> is normally run by root, the name of the local machine must appear in the <code>/etc/hosts</code> file of the remote machine. If the file is specified as <code>user@machine:device</code> , <code>ufsdump</code> will attempt to execute as the specified user on the remote machine. The specified user must have a <code>.hosts</code> file on the remote machine that allows the user invoking the command from the local machine to access the remote machine.
<code>l</code>	Autoload. When the end-of-tape is reached before the dump is complete, take the drive offline and wait up to two minutes for the tape drive to be ready again. This

ufsdump(1M)

	gives autoloading (stackloader) tape drives a chance to load a new tape. If the drive is ready within two minutes, continue. If it is not, prompt for another tape and wait.
L <i>string</i>	Sets the tape label to <i>string</i> , instead of the default none. <i>string</i> may be no more than sixteen characters long. If it is longer, it is truncated and a warning printed; the dump will still be done. The tape label is specific to the ufsdump tape format, and bears no resemblance to IBM or ANSI-standard tape labels.
n	Notify all operators in the sys group that ufsdump requires attention by sending messages to their terminals, in a manner similar to that used by the wall(1M) command. Otherwise, such messages are sent only to the terminals (such as the console) on which the user running ufsdump is logged in.
N <i>device_name</i>	Use <i>device_name</i> when recording information in /etc/dumpdates (see the u option) and when comparing against information in /etc/dumpdates for incremental dumps. The <i>device_name</i> provided can contain no white space as defined in scanf(3C) and is case-sensitive.
o	Offline. Take the drive offline when the dump is complete or the end-of-media is reached and rewind the tape, or eject the diskette. In the case of some autoloading 8mm drives, the tape is removed from the drive automatically. This prevents another process which rushes in to use the drive, from inadvertently overwriting the media.
s <i>size</i>	Specify the <i>size</i> of the volume being dumped to. Not normally required, as ufsdump can detect end-of-media. When the specified size is reached, ufsdump waits for you to change the volume. ufsdump interprets the specified size as the length in feet for tapes and cartridges, and as the number of 1024-byte blocks for diskettes. The values should be a little smaller than the actual physical size of the media (for example, 425 for a 450-foot cartridge). Typical values for tape devices depend on the c option, for cartridge devices, and the D option for diskettes: 1/2 inch tape 2300 feet

	60-Mbyte 1/4 inch cartridge 425 feet
	150-Mbyte 1/4 inch cartridge 700 feet
	diskette 1422 blocks (Corresponds to a 1.44-Mbyte diskette, with one cylinder reserved for bad block information.)
s	Size estimate. Determine the amount of space that is needed to perform the dump without actually doing it, and display the estimated number of bytes it will take. This is useful with incremental dumps to determine how many volumes of media will be needed.
t <i>tracks</i>	Specify the number of tracks for a cartridge tape. Not normally required, as <code>ufsdump</code> can detect end-of-media. The default is 9 tracks. The <code>t</code> option is not compatible with the <code>D</code> option. Values for Sun-supported tape devices are: 60-Mbyte 1/4 inch cartridge 9 tracks 150-Mbyte 1/4 inch cartridge 18 tracks
T <i>time_wait</i> [hms]	Sets the amount of time to wait for an <code>autoload</code> command to complete. This option is ignored unless the <code>l</code> option has also been specified. The default time period to wait is two minutes. Specify time units with a trailing <code>h</code> (for hours), <code>m</code> (for minutes), or <code>s</code> (for seconds). The default unit is minutes.
u	Update the dump record. Add an entry to the file <code>/etc/dumpdates</code> , for each file system successfully dumped that includes the file system name (or <i>device_name</i> as specified with the <code>N</code> option), date, and dump level.
v	Verify. After each tape or diskette is written, verify the contents of the media against the source file system. If any discrepancies occur, prompt for new media, then repeat the dump/verification process. The file system <i>must</i> be unmounted. This option cannot be used to verify a dump to standard output.
w	Warning. List the file systems that have not been backed up within a day. This information is gleaned from the files <code>/etc/dumpdates</code> and <code>/etc/vfstab</code> . When the <code>w</code> option is used, all other options are ignored. After reporting, <code>ufsdump</code> exits immediately.

ufsdump(1M)

	W	Warning with highlight. Similar to the w option, except that the W option includes all file systems that appear in /etc/dumpdates, along with information about their most recent dump dates and levels. File systems that have not been backed up within a day are highlighted.
OPERANDS	The following operand is supported: <i>files_to_dump</i> Specifies the files to dump. Usually it identifies a whole file system by its raw device name (for example, /dev/rdsk/c0t3d0s6). Incremental dumps (levels 1 to 9) of files changed after a certain date only apply to a whole file system. Alternatively, <i>files_to_dump</i> can identify individual files or directories. All named directories that may be examined by the user running ufsdump, as well as any explicitly-named files, are dumped. This dump is equivalent to a level 0 dump of the indicated portions of the filesystem, except that /etc/dumpdates is not updated even if the -u option has been specified. In all cases, the files must be contained in the same file system, and the file system must be local to the system where ufsdump is being run. <i>files_to_dump</i> is required and must be the last argument on the command line. If no <i>options</i> are given, the default is 9uf /dev/rmt/0 <i>files_to_dump</i> .	
USAGE	See largefile(5) for the description of the behavior of ufsdump when encountering files greater than or equal to 2 Gbyte (2 ³¹ bytes).	
EXAMPLES	EXAMPLE 1 A sample display of the ufsdump command. To make a full dump of a root file system on c0t3d0, on a 150-MByte cartridge tape unit 0, use: example# ufsdump 0cfu /dev/rmt/0 /dev/rdsk/c0t3d0s0 To make and verify an incremental dump at level 5 of the usr partition of c0t3d0, on a 1/2 inch reel tape unit 1, use: example# ufsdump 5fuv /dev/rmt/1 /dev/rdsk/c0t3d0s6	
EXIT STATUS	While running, ufsdump emits many verbose messages. ufsdump returns the following exit values: 0 Normal exit. 1 Startup errors encountered. 3 Abort – no checkpoint attempted.	
FILES	/dev/rmt/0	default unit to dump to

/etc/dumpdates	dump date record
/etc/group	to find group sys
/etc/hosts	to gain access to remote system with drive
/etc/vfstab	list of file systems

NOTES

Read Errors Fewer than 32 read errors on the file system are ignored.

Process Per Reel Because each reel requires a new process, parent processes for reels that are already written hang around until the entire tape is written.

Operator Intervention ufsdump requires operator intervention on these conditions: end of volume, end of dump, volume write error, volume open error or disk read error (if there are more than a threshold of 32). In addition to alerting all operators implied by the `n` option, ufsdump interacts with the operator on ufsdump's control terminal at times when ufsdump can no longer proceed, or if something is grossly wrong. All questions ufsdump poses *must* be answered by typing `yes` or `no`, as appropriate.

Since backing up a disk can involve a lot of time and effort, ufsdump checkpoints at the start of each volume. If writing that volume fails for some reason, ufsdump will, with operator permission, restart itself from the checkpoint after a defective volume has been replaced.

Suggested Dump Schedule It is vital to perform full, "level 0", dumps at regular intervals. When performing a full dump, bring the machine down to single-user mode using `shutdown(1M)`. While preparing for a full dump, it is a good idea to clean the tape drive and heads. Incremental dumps should be performed with the system running in single-user mode.

Incremental dumps allow for convenient backup and recovery of active files on a more frequent basis, with a minimum of media and time. However, there are some tradeoffs. First, the interval between backups should be kept to a minimum (once a day at least). To guard against data loss as a result of a media failure (a rare, but possible occurrence), capture active files on (at least) two sets of dump volumes. Another consideration is the desire to keep unnecessary duplication of files to a minimum to

ufsdump(1M)

save both operator time and media storage. A third consideration is the ease with which a particular backed-up version of a file can be located and restored. The following four-week schedule offers a reasonable tradeoff between these goals.

	Sun	Mon	Tue	Wed	Thu	Fri
Week 1:	Full	5	5	5	5	3
Week 2:		5	5	5	5	3
Week 3:		5	5	5	5	3
Week 4:		5	5	5	5	3

Although the Tuesday through Friday incrementals contain “extra copies” of files from Monday, this scheme assures that any file modified during the week can be recovered from the previous day’s incremental dump.

Process Priority of ufsdump

ufsdump uses multiple processes to allow it to read from the disk and write to the media concurrently. Due to the way it synchronizes between these processes, any attempt to run dump with a *nice* (process priority) of ‘-5’ or better will likely make ufsdump run *slower* instead of faster.

Overlapping Partitions

Most disks contain one or more overlapping slices because slice 2 covers the entire disk. The other slices are of various sizes and usually do not overlap. For example, a common configuration places `root` on slice 0, `swap` on slice 1, `/opt` on slice 5 and `/usr` on slice 6.

It should be emphasized that ufsdump dumps one `ufs` file system at a time. Given the above scenario where slice 0 and slice 2 have the same starting offset, executing ufsdump on slice 2 with the intent of dumping the entire disk would instead dump only the `root` file system on slice 0. To dump the entire disk, the user must dump the file systems on each slice separately.

BUGS

The `/etc/vfstab` file does not allow the desired frequency of backup for file systems to be specified (as `/etc/fstab` did). Consequently, the `w` and `W` options assume file systems should be backed up daily, which limits the usefulness of these options.

NAME	ufsrestore – incremental file system restore
SYNOPSIS	/usr/sbin/ufsrestore <i>i r R t x</i> [<i>abcdfhlmostvyLT</i>] [<i>archive_file</i>] [<i>factor</i>] [<i>dumpfile</i>] [<i>n</i>] [<i>label</i>] [<i>timeout</i>] [<i>filename...</i>]
DESCRIPTION	The <code>ufsrestore</code> utility restores files from backup media created with the <code>ufsdump</code> command. <code>ufsrestore</code>'s actions are controlled by the <i>key</i> argument. The <i>key</i> is exactly one function <i>letter</i> (<i>i</i>, <i>r</i>, <i>R</i>, <i>t</i>, or <i>x</i>) and zero or more <i>function modifiers</i> (letters). The <i>key</i> string contains no SPACE characters. Function modifier arguments are listed on the command line in the same order as their corresponding function modifiers appear in the <i>key</i> string. <i>filename</i> arguments which appear on the command line, or as arguments to an interactive command, are treated as shell <code>glob</code> patterns by the <i>x</i> and <i>t</i> functions; any files or directories matching the patterns are selected. The metacharacters <code>*</code>, <code>?</code>, and <code>[</code> must be protected from the shell if they appear on the command line. There is no way to quote these metacharacters to explicitly match them in a filename. The temporary files <code>rstdir*</code> and <code>rstmode*</code> are placed in <code>/tmp</code> by default. If the environment variable <code>TMPDIR</code> is defined with a non-empty value, that location is used instead of <code>/tmp</code>.
OPTIONS	
Function Letters	You must specify one (and only one) of the function letters listed below. Note that <i>i</i>, <i>x</i>, and <i>r</i> are intended to restore files into an empty directory. The <i>R</i> function is intended for restoring into a populated directory. i Interactive. After reading in the directory information from the media, <code>ufsrestore</code> invokes a shell-like interface that allows you to browse through the dump file's directory hierarchy and select individual files to be extracted. Restoration has the same semantics as <i>x</i> (see below). See <i>Interactive Commands</i>, below, for a description of available commands. r Recursive. Starting with an empty directory and a level 0 dump, the <i>r</i> function recreates the filesystem relative to the current working directory, exactly as it appeared when the dump was made. Information used to restore incremental dumps on top of the full dump (for example, <code>restoresymtable</code>) is also included. Several <code>ufsrestore</code> runs are typical, one for each higher level of dump (0, 1, ..., 9). Files that were deleted between the level 0 and a subsequent incremental dump will not exist after the final restore. To completely restore a file system, use the <i>r</i> function restore the level 0 dump, and again for each incremental dump. Although this function letter is intended for a complete restore onto a new file system (one just created with <code>newfs(1M)</code>), if the file system contains files not on the backup media, they are preserved.

ufsrestore(1M)

	R	Resume restoring. If an <i>r</i> -mode <i>ufsrestore</i> was interrupted, this function prompts for the volume from which to resume restoring and continues the restoration from where it was left off. Otherwise identical to <i>r</i> .
	t	Table of contents. List each <i>filename</i> that appears on the media. If no <i>filename</i> argument is given, the root directory is listed. This results in a list of all files on the media, unless the <i>h</i> function modifier is in effect. The table of contents is taken from the media or from the specified archive file, when the <i>a</i> function modifier is used. The <i>a</i> function modifier is mutually exclusive with the <i>x</i> and <i>r</i> function letters.
	x	Extract the named files from the media. Files are restored to the same relative locations that they had in the original file system. If the <i>filename</i> argument matches a directory whose contents were written onto the media, and the <i>h</i> modifier is not in effect, the directory is recursively extracted, relative to the current directory, which is expected to be empty. For each file, the owner, modification time, and mode are restored (if possible). If you omit the <i>filename</i> argument or specify <i>.</i>, the root directory is extracted. This results in the entire tape being extracted, unless the <i>h</i> modifier is in effect. <i>.</i> With the <i>x</i> function, existing files are overwritten and <i>ufsrestore</i> displays the names of the overwritten files. Overwriting a currently-running executable can have unfortunate consequences. Use the <i>x</i> option to restore partial file system dumps, as they are (by definition) not entire file systems.
	Function Modifiers	
	<i>a archive_file</i>	Read the table of contents from <i>archive_file</i> instead of the media. This function modifier can be used in combination with the <i>t</i> , <i>i</i> , or <i>x</i> function letters, making it possible to check whether files are on the media without having to mount the media. When used with the <i>x</i> and interactive (<i>i</i>) function letters, it prompts for the volume containing the file(s) before extracting them.
	<i>b factor</i>	Blocking factor. Specify the blocking factor for tape reads. For variable length SCSI tape devices, unless the data was written with the default blocking factor, a blocking factor at least as great as that used to write the tape must be used; otherwise, an error will be generated. Note that a tape block is 512 bytes. Refer to the man page for your specific tape driver for the maximum blocking factor.
	<i>c</i>	Convert the contents of the media in 4.1BSD format to the new <i>ufs</i> file system format.
	<i>d</i>	Debug. Turn on debugging output.

<i>f dump_file</i>	Use <i>dump_file</i> instead of <code>/dev/rmt/0</code> as the file to restore from. Typically <i>dump_file</i> specifies a tape or diskette drive. If <i>dump_file</i> is specified as <code>'-'</code>, <code>ufsrestore</code> reads from the standard input. This allows <code>ufsdump(1M)</code> and <code>ufsrestore</code> to be used in a pipeline to copy a file system: <pre>example# ufsdump 0f - /dev/rdsk/c0t0d0s7 \ (cd /home;ufsrestore xf -)</pre> If the name of the file is of the form <i>machine:device</i>, the restore is done from the specified machine over the network using <code>rmt(1M)</code>. Since <code>ufsrestore</code> is normally run by root, the name of the local machine must appear in the <code>/ .rhosts</code> file of the remote machine. If the file is specified as <i>user@machine:device</i>, <code>ufsrestore</code> will attempt to execute as the specified user on the remote machine. The specified user must have a <code>.rhosts</code> file on the remote machine that allows the user invoking the command from the local machine to access the remote machine.
<i>h</i>	Extract or list the actual directory, rather than the files that it references. This prevents hierarchical restoration of complete subtrees from the tape.
<i>l</i>	Autoload. When the end-of-tape is reached before the restore is complete, take the drive off-line and wait up to two minutes (the default, see the <code>T</code> function modifier) for the tape drive to be ready again. This gives autoloading (stackloader) tape drives a chance to load a new tape. If the drive is ready within two minutes, continue. If it is not, prompt for another tape and wait.
<i>L label</i>	The label that should appear in the header of the dump file. If the labels do not match, <code>ufsrestore</code> issues a diagnostic and exits. The tape label is specific to the <code>ufsdump</code> tape format, and bears no resemblance to IBM or ANSI-standard tape labels.
<i>m</i>	Extract by inode numbers rather than by filename to avoid regenerating complete pathnames. Regardless of where the files are located in the dump hierarchy, they are restored into the current directory and renamed with their inode number. This is useful if only a few files are being extracted.
<i>o</i>	Offline. Take the drive off-line when the restore is complete or the end-of-media is reached and rewind the tape, or eject the diskette. In the case of some autoloading 8mm drives, the tape is removed from the drive automatically.
<i>s n</i>	Skip to the <i>n</i> 'th file when there are multiple dump files on the same tape. For example, the command: <pre>example# ufsrestore xfs /dev/rmt/0hn 5</pre>

ufsrestore(1M)

Interactive Commands

	would position you to the fifth file on the tape when reading volume 1 of the dump. If a dump extends over more than one volume, all volumes except the first are assumed to start at position 0, no matter what "s <i>n</i>" value is specified. If "s <i>n</i>" is specified, the backup media must be at BOT (beginning of tape). Otherwise, the initial positioning to read the table of contents will fail, as it is performed by skipping the tape forward <i>n</i> - 1 files rather than by using absolute positioning. This is because on some devices absolute positioning is very time consuming.
T timeout [hms]	Sets the amount of time to wait for an autoload command to complete. This function modifier is ignored unless the l function modifier has also been specified. The default timeout period is two minutes. The time units may be specified as a trailing h (hours), m (minutes), or s (seconds). The default unit is minutes.
v	Verbose. ufsrestore displays the name and inode number of each file it restores, preceded by its file type.
y	Do not ask whether to abort the restore in the event of tape errors. ufsrestore tries to skip over the bad tape block(s) and continue as best it can.
ufsrestore enters interactive mode when invoked with the i function letters. Interactive commands are reminiscent of the shell. For those commands that accept an argument, the default is the current directory. The interactive options are:	
add [filename]	Add the named file or directory to the list of files to extract. If a directory is specified, add that directory and its files (recursively) to the extraction list (unless the h modifier is in effect).
cd directory	Change to <i>directory</i> (within the dump file).
delete [filename]	Delete the current directory, or the named file or directory from the list of files to extract. If a directory is specified, delete that directory and all its descendents from the extraction list (unless the h modifier is in effect). The most expedient way to extract a majority of files from a directory is to add that directory to the extraction list, and then delete specific files to omit.
extract	Extract all files on the extraction list from the dump media. ufsrestore asks which volume the user wishes to mount. The fastest way to extract a small number of files is to start with the last volume and work toward the first. If "s <i>n</i> " is given on the command line, volume 1 will automatically be positioned to file <i>n</i> when it is read.

	help	Display a summary of the available commands.
	ls [<i>directory</i>]	List files in <i>directory</i> or the current directory, represented by a '.' (period). Directories are appended with a '/' (slash). Entries marked for extraction are prefixed with a '*' (asterisk). If the verbose option is in effect, inode numbers are also listed.
	marked [<i>directory</i>]	Like <i>ls</i> , except only files marked for extraction are listed.
	pager	Toggle the pagination of the output from the <i>ls</i> and <i>marked</i> commands. The pager used is that defined by the <i>PAGER</i> environment variable, or <i>more(1)</i> if that <i>envvar</i> is not defined. The <i>PAGER</i> <i>envvar</i> may include white-space-separated arguments for the pagination program.
	pwd	Print the full pathname of the current working directory.
	quit	<i>ufsrestore</i> exits immediately, even if the extraction list is not empty.
	setmodes	Prompts: set owner/mode for '.' (period). Type <i>y</i> for yes to set the mode (permissions, owner, times) of the current directory '.' (period) into which files are being restored equal to the mode of the root directory of the file system from which they were dumped. Normally, this is what you want when restoring a whole file system, or restoring individual files into the same locations from which they were dumped. Type <i>n</i> for no, to leave the mode of the current directory unchanged. Normally, this is what you want when restoring part of a dump to a directory other than the one from which the files were dumped.
	setpager <i>command</i>	Sets the command to use for paginating output instead of the default or that inherited from the environment. The <i>command</i> string may include arguments in addition to the command itself.
	verbose	Toggle the status of the <i>v</i> modifier. While <i>v</i> is in effect, the <i>ls</i> command lists the inode numbers of all entries, and <i>ufsrestore</i> displays information about each file as it is extracted.
	what	Display the dump header on the media.
OPERANDS	The following operands are supported.	

ufsrestore(1M)

	<i>filename</i>	Specifies the pathname of files (or directories) to be restored to disk. Unless the <i>h</i> function modifier is also used, a directory name refers to the files it contains, and (recursively) its subdirectories and the files they contain. <i>filename</i> is associated with either the <i>x</i> or <i>t</i> function letters, and must come last.				
USAGE	See <code>largefile(5)</code> for the description of the behavior of <code>ufsrestore</code> when encountering files greater than or equal to 2 Gbyte (2^{31} bytes).					
EXIT STATUS	The following exit values are returned:					
	0	Successful completion.				
	1	An error occurred. Verbose messages are displayed.				
ENVIRONMENT VARIABLES	PAGER	The command to use as a filter for paginating output. This can also be used to specify the options to be used. Default is <code>more(1)</code> .				
	TMPDIR	Selects the directory for temporary files. Defaults to <code>/tmp</code> if not defined in the environment.				
FILES	<code>/dev/rmt/0</code>	the default tape drive				
	<code>\$TMPDIR/rstdir*</code>	file containing directories on the tape				
	<code>\$TMPDIR/rstmode*</code>	owner, mode, and timestamps for directories				
	<code>./restoresymtable</code>	information passed between incremental restores				
ATTRIBUTES	See <code>attributes(5)</code> for descriptions of the following attributes:					
	<table><tr><th>ATTRIBUTE TYPE</th><th>ATTRIBUTE VALUE</th></tr><tr><td>Availability</td><td>SUNWcsu</td></tr></table>		ATTRIBUTE TYPE	ATTRIBUTE VALUE	Availability	SUNWcsu
ATTRIBUTE TYPE	ATTRIBUTE VALUE					
Availability	SUNWcsu					
SEE ALSO	<code>more(1)</code> , <code>mkfs(1M)</code> , <code>mount(1M)</code> , <code>rmt(1M)</code> , <code>ufsdump(1M)</code> , <code>attributes(5)</code> , <code>largefile(5)</code>					
DIAGNOSTICS	<code>ufsrestore</code> complains about bad option characters. Read errors result in complaints. If <i>y</i> has been specified, or the user responds <i>y</i>, <code>ufsrestore</code> will attempt to continue. If the dump extends over more than one tape, <code>ufsrestore</code> asks the user to change tapes. If the <i>x</i> or <i>i</i> function letter has been specified, <code>ufsrestore</code> also asks which volume the user wishes to mount. If the <i>s</i> modifier has been specified, and volume 1 is mounted, it is automatically positioned to the indicated file. There are numerous consistency checks that can be listed by <code>ufsrestore</code>. Most checks are self-explanatory or can “never happen”. Common errors are given below.					

Converting to new file system format

A dump tape created from the old file system has been loaded. It is automatically converted to the new file system format.

filename: not found on tape

The specified file name was listed in the tape directory, but was not found on the tape. This is caused by tape read errors while looking for the file, using a dump tape created on an active file system, or restoring a partial dump with the *r* function.

expected next file *inumber*, got *inumber*

A file that was not listed in the directory showed up. This can occur when using a dump tape created on an active file system.

Incremental tape too low

When doing an incremental restore, a tape that was written before the previous incremental tape, or that has too low an incremental level has been loaded.

Incremental tape too high

When doing incremental restore, a tape that does not begin its coverage where the previous incremental tape left off, or one that has too high an incremental level has been loaded.

media read error: invalid argument

Blocking factor specified for read is smaller than the blocking factor used to write data.

Tape read error while restoring

Tape read error while skipping over inode *inumber*

Tape read error while trying to resynchronize

A tape read error has occurred

If a file name is specified, then its contents are probably partially wrong. If an inode is being skipped or the tape is trying to resynchronize, then no extracted files have been corrupted, though files may not be found on the tape.

resync ufsrestore, skipped *num*

After a tape read error, ufsrestore may have to resynchronize itself. This message lists the number of blocks that were skipped over.

Incorrect tape label. Expected 'foo', got 'bar'.

The *L* option was specified, and its value did not match what was recorded in the header of the dump file.

NOTES

ufsrestore can get confused when doing incremental restores from dump tapes that were made on active file systems.

A level 0 dump must be done after a full restore. Because ufsrestore runs in user mode, it has no control over inode allocation. This means that ufsrestore repositions the files, although it does not change their contents. Thus, a full dump must be done to get a new set of directories reflecting the new file positions, so that later incremental dumps will be correct.

unshare(1M)

NAME	unshare – make local resource unavailable for mounting by remote systems				
SYNOPSIS	unshare [-F <i>FSType</i>] [-o <i>specific_options</i>] [<i>pathname</i> <i>resourcename</i>]				
DESCRIPTION	The unshare command makes a shared local resource unavailable as file system type <i>FSType</i> . If the option -F <i>FSType</i> is omitted, then the first file system type listed in file <i>/etc/dfs/fstypes</i> will be used as the default. <i>Specific_options</i> , as well as the semantics of <i>resourcename</i> , are specific to particular distributed file systems.				
OPTIONS	-F <i>FSType</i> Specify the file system type. -o <i>specific_options</i> Specify options specific to the file system provided by the -F option.				
FILES	<i>/etc/dfs/fstypes</i> <i>/etc/dfs/sharetab</i>				
ATTRIBUTES	See <i>attributes(5)</i> for descriptions of the following attributes: <table><thead><tr><th>ATTRIBUTE TYPE</th><th>ATTRIBUTE VALUE</th></tr></thead><tbody><tr><td>Availability</td><td>SUNWcsu</td></tr></tbody></table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	Availability	SUNWcsu
ATTRIBUTE TYPE	ATTRIBUTE VALUE				
Availability	SUNWcsu				
SEE ALSO	<i>share(1M)</i> , <i>shareall(1M)</i> , <i>attributes(5)</i>				
NOTES	If <i>pathname</i> or <i>resourcename</i> is not found in the shared information, an error message will be sent to standard error. When an unshare command completes successfully, a client mounting a file system specified in that unshare command no longer has access to that file system.				

NAME	unshare_nfs – make local NFS file systems unavailable for mounting by remote systems
SYNOPSIS	unshare [-F nfs] <i>pathname</i>
DESCRIPTION	The unshare command makes local file systems unavailable for mounting by remote systems. The shared file system must correspond to a line with NFS as the <i>FSType</i> in the file /etc/dfs/sharetab.
OPTIONS	The following options are supported: -F This option may be omitted if NFS is the first file system type listed in the file /etc/dfs/fstypes.
FILES	/etc/dfs/fstypes /etc/dfs/sharetab
ATTRIBUTES	See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWnfssu

SEE ALSO share(1M), attributes(5)

NOTES If the file system being unshared is a symbolic link to a valid pathname, the canonical path (the path which the symbolic link follows) will be unshared.

For example, if /export/foo is a symbolic link to /export/bar (/export/foo -> /export/bar), the following unshare command will result in /export/bar as the unshared pathname (and not /export/foo):

```
example# unshare -F nfs /export/foo
```

update_drv(1M)

NAME	update_drv – modify device driver attributes												
SYNOPSIS	<pre>update_drv [-f] [-v] <i>device_driver</i> update_drv [-b <i>basedir</i>] [-f] [-v] -a -i '<i>identify-name</i>' <i>device_driver</i> update_drv [-b <i>basedir</i>] [-f] [-v] -a -m '<i>permission</i>' <i>device_driver</i> update_drv [-b <i>basedir</i>] [-f] [-v] -a -i '<i>identify-name</i>' -m '<i>permission</i>' <i>device_driver</i> update_drv [-b <i>basedir</i>] [-f] [-v] -d -i '<i>identify-name</i>' <i>device_driver</i> update_drv [-b <i>basedir</i>] [-f] [-v] -d -m '<i>permission</i>' <i>device_driver</i> update_drv [-b <i>basedir</i>] [-f] [-v] -d -i '<i>identify-name</i>' -m '<i>permission</i>' <i>device_driver</i></pre>												
DESCRIPTION	The <code>update_drv</code> command informs the system about attribute changes to an installed device driver. It can be used to re-read the <code>driver.conf(4)</code> file, or to add, modify, or delete a driver's minor node permissions or aliases. Without options, <code>update_drv</code> reloads the <code>driver.conf</code> file. Upon successfully updating the aliases, the driver binding takes effect upon reconfig boot or hotplug of the device. Upon successfully updating the permissions, only the new driver minor nodes get created with the modified set of file permissions. Existing driver minor nodes do not get modified.												
OPTIONS	The following options are supported: <table><tr><td>-a</td><td>Add a <i>permission</i> or <i>aliases</i> entry.</td></tr><tr><td></td><td>With the -a option specified, a permission entry (using the -m option) or a driver's aliases entry (using the -i option) can be added or updated. If a matching minor node permissions entry is encountered (having the same driver name and the minor node), it is replaced. If a matching aliases entry is encountered (having a different driver name and the same alias), an error is reported.</td></tr><tr><td></td><td>The -a and -d options are mutually exclusive.</td></tr><tr><td>-b <i>basedir</i></td><td>Installs or modifies the driver on the system with a root directory of <i>basedir</i> rather than installing on the system executing <code>update_drv</code>.</td></tr><tr><td>-d</td><td>Delete a <i>permission</i> or <i>aliases</i> entry.</td></tr><tr><td></td><td>The -m <i>permission</i> or -i <i>identify-name</i> option needs to be specified with the -d option.</td></tr></table>	-a	Add a <i>permission</i> or <i>aliases</i> entry.		With the -a option specified, a permission entry (using the -m option) or a driver's aliases entry (using the -i option) can be added or updated. If a matching minor node permissions entry is encountered (having the same driver name and the minor node), it is replaced. If a matching aliases entry is encountered (having a different driver name and the same alias), an error is reported.		The -a and -d options are mutually exclusive.	-b <i>basedir</i>	Installs or modifies the driver on the system with a root directory of <i>basedir</i> rather than installing on the system executing <code>update_drv</code> .	-d	Delete a <i>permission</i> or <i>aliases</i> entry.		The -m <i>permission</i> or -i <i>identify-name</i> option needs to be specified with the -d option.
-a	Add a <i>permission</i> or <i>aliases</i> entry.												
	With the -a option specified, a permission entry (using the -m option) or a driver's aliases entry (using the -i option) can be added or updated. If a matching minor node permissions entry is encountered (having the same driver name and the minor node), it is replaced. If a matching aliases entry is encountered (having a different driver name and the same alias), an error is reported.												
	The -a and -d options are mutually exclusive.												
-b <i>basedir</i>	Installs or modifies the driver on the system with a root directory of <i>basedir</i> rather than installing on the system executing <code>update_drv</code> .												
-d	Delete a <i>permission</i> or <i>aliases</i> entry.												
	The -m <i>permission</i> or -i <i>identify-name</i> option needs to be specified with the -d option.												

update_drv(1M)

The -d and -a options are mutually exclusive.

If the entry doesn't exist update_drv returns an error.

-f

Force the system to reread the driver.conf file even if the driver module cannot be unloaded. See NOTES.

-i '*identify-name*'

A white-space separated list of aliases for the driver. If -a or -d option is not specified then this option is ignored. The *identify-name* string is mandatory. If all aliases need to be removed, rem_drv(1M) is recommended.

-m '*permission*'

Specify a white-space separated list of file system permissions for the device node of the device driver. If -a or -d option is not specified then, this option is ignored. The permission string is mandatory.

EXAMPLES

EXAMPLE 1 Adding or Modifying an Existing Minor Permissions Entry

The following command adds or modifies the existing minor permissions entry of the clone driver:

```
example# update_drv -a -m 'llcl 777 joe staff' clone
```

EXAMPLE 2 Removing All Minor Permissions Entries

The following command removes all minor permission entries of the usbprn driver, the USB printer driver:

```
example# update_drv -d -m '* 0666 root sys' usbprn
```

EXAMPLE 3 Adding a Driver Aliases Entry

The following command adds a driver aliases entry of the ugen driver with the identity string of usb459, 20:

```
example# update_drv -a -i '"usb459,20"' ugen
```

EXAMPLE 4 Re-reading the driver.conf File For the ohci Driver

The following command re-reads the driver.conf(4) file.

```
example# update_drv ohci
```

EXIT STATUS

The following exit values are returned:

0	Successful completion.
>0	An error occurred.

update_drv(1M)

ATTRIBUTES See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

SEE ALSO add_drv(1M), modunload(1M), rem_drv(1M), driver.conf(4), attributes(5)

NOTES If -a or -d options are specified, update_drv does not re-read the driver.conf file.

A forced update of the driver.conf file reloads the driver.conf file without reloading the driver binary module. In this case, devices which can not be detached reference driver global properties from the old driver.conf file, while the remaining driver instances reference global properties in the new driver.conf file.

It is possible to add an alias , which changes the driver binding of a device already being managed by a different driver. A force update (-f) with the -a option tries to bind the new driver and reports an error if it cannot. If you specify both the -m and -i option, a force update tries to modify the alias even if permissions modification fails and vice-versa. A force update with the -d option tries to delete entries and reports the error if it cannot.

NAME	useradd – administer a new user login on the system						
SYNOPSIS	<pre> useradd [-c <i>comment</i>] [-d <i>dir</i>] [-e <i>expire</i>] [-f <i>inactive</i>] [-g <i>group</i>] [-G <i>group</i> [, <i>group</i>...]] [-m [-k <i>skel_dir</i>]] [-u <i>uid</i> [-o]] [-s <i>shell</i>] [-A <i>authorization</i> [, <i>authorization</i>...]] [-P <i>profile</i> [, <i>profile</i>...]] [-R <i>role</i> [, <i>role</i>...]] [-p <i>projname</i>] <i>login</i> useradd -D [-b <i>base_dir</i>] [-e <i>expire</i>] [-f <i>inactive</i>] [-g <i>group</i>] [-p <i>projname</i>] </pre>						
DESCRIPTION	useradd adds a new user to the <code>/etc/passwd</code> and <code>/etc/shadow</code> and <code>/etc/user_attr</code> files. The <code>-A</code> and <code>-P</code> options respectively assign authorizations and profiles to the user. The <code>-R</code> option assigns roles to a user. The <code>-p</code> option associates a project with a user. useradd also creates supplementary group memberships for the user (<code>-G</code> option) and creates the home directory (<code>-m</code> option) for the user if requested. The new login remains locked until the <code>passwd(1)</code> command is executed. Specifying useradd <code>-D</code> with the <code>-g</code>, <code>-b</code>, <code>-f</code>, <code>-e</code>, <code>-A</code>, <code>-P</code>, <code>-p</code>, or <code>-R</code> option (or any combination of these options) sets the default values for the respective fields. See the <code>-D</code> option, below. Subsequent useradd commands without the <code>-D</code> option use these arguments. The system file entries created with this command have a limit of 512 characters per line. Specifying long arguments to several options can exceed this limit. The login (<code>login</code>) and role (<code>role</code>) fields accept a string of no more than eight bytes consisting of characters from the set of alphabetic characters, numeric characters, period (<code>.</code>), underscore (<code>_</code>), and hyphen (<code>-</code>). The first character should be alphabetic and the field should contain at least one lower case alphabetic character. A warning message will be written if these restrictions are not met. A future Solaris release may refuse to accept login and role fields that do not meet these requirements. The login and role fields must contain at least one character and must not contain a colon (<code>:</code>) or a newline (<code>\n</code>).						
OPTIONS	The following options are supported: <table> <tr> <td><code>-A <i>authorization</i></code></td><td>One or more comma separated authorizations defined in <code>auth_attr(4)</code>. Only a user or role who has grant rights to the authorization can assign it to an account.</td></tr> <tr> <td><code>-b <i>base_dir</i></code></td><td>The default base directory for the system if <code>-d <i>dir</i></code> is not specified. <i>base_dir</i> is concatenated with the account name to define the home directory. If the <code>-m</code> option is not used, <i>base_dir</i> must exist.</td></tr> <tr> <td><code>-c <i>comment</i></code></td><td>Any text string. It is generally a short description of the login, and is currently used as the field for the user's full name. This information is stored in the user's <code>/etc/passwd</code> entry.</td></tr> </table>	<code>-A <i>authorization</i></code>	One or more comma separated authorizations defined in <code>auth_attr(4)</code> . Only a user or role who has grant rights to the authorization can assign it to an account.	<code>-b <i>base_dir</i></code>	The default base directory for the system if <code>-d <i>dir</i></code> is not specified. <i>base_dir</i> is concatenated with the account name to define the home directory. If the <code>-m</code> option is not used, <i>base_dir</i> must exist.	<code>-c <i>comment</i></code>	Any text string. It is generally a short description of the login, and is currently used as the field for the user's full name. This information is stored in the user's <code>/etc/passwd</code> entry.
<code>-A <i>authorization</i></code>	One or more comma separated authorizations defined in <code>auth_attr(4)</code> . Only a user or role who has grant rights to the authorization can assign it to an account.						
<code>-b <i>base_dir</i></code>	The default base directory for the system if <code>-d <i>dir</i></code> is not specified. <i>base_dir</i> is concatenated with the account name to define the home directory. If the <code>-m</code> option is not used, <i>base_dir</i> must exist.						
<code>-c <i>comment</i></code>	Any text string. It is generally a short description of the login, and is currently used as the field for the user's full name. This information is stored in the user's <code>/etc/passwd</code> entry.						

useradd(1M)

<code>-d <i>dir</i></code>	The home directory of the new user. It defaults to <i>base_dir/account_name</i> , where <i>base_dir</i> is the base directory for new login home directories and <i>account_name</i> is the new login name.																						
<code>-D</code>	Display the default values for <code>group</code>, <code>base_dir</code>, <code>skel_dir</code>, <code>shell</code>, <code>inactive</code>, <code>expire</code>, <code>proj</code> and <code>projname</code>. When used with the <code>-g</code>, <code>-b</code>, <code>-f</code>, <code>-e</code>, <code>-A</code>, <code>-P</code>, <code>-p</code>, or <code>-R</code> options, the <code>-D</code> option sets the default values for the specified fields. The default values are: <table> <tr> <td><code>group</code></td><td><code>other</code> (GID of 1)</td></tr> <tr> <td><code>base_dir</code></td><td><code>/home</code></td></tr> <tr> <td><code>skel_dir</code></td><td><code>/etc/skel</code></td></tr> <tr> <td><code>shell</code></td><td><code>/bin/sh</code></td></tr> <tr> <td><code>inactive</code></td><td><code>0</code></td></tr> <tr> <td><code>expire</code></td><td><code>null</code></td></tr> <tr> <td><code>auths</code></td><td><code>null</code></td></tr> <tr> <td><code>profiles</code></td><td><code>null</code></td></tr> <tr> <td><code>proj</code></td><td><code>3</code></td></tr> <tr> <td><code>projname</code></td><td><code>default</code></td></tr> <tr> <td><code>roles</code></td><td><code>null</code></td></tr> </table>	<code>group</code>	<code>other</code> (GID of 1)	<code>base_dir</code>	<code>/home</code>	<code>skel_dir</code>	<code>/etc/skel</code>	<code>shell</code>	<code>/bin/sh</code>	<code>inactive</code>	<code>0</code>	<code>expire</code>	<code>null</code>	<code>auths</code>	<code>null</code>	<code>profiles</code>	<code>null</code>	<code>proj</code>	<code>3</code>	<code>projname</code>	<code>default</code>	<code>roles</code>	<code>null</code>
<code>group</code>	<code>other</code> (GID of 1)																						
<code>base_dir</code>	<code>/home</code>																						
<code>skel_dir</code>	<code>/etc/skel</code>																						
<code>shell</code>	<code>/bin/sh</code>																						
<code>inactive</code>	<code>0</code>																						
<code>expire</code>	<code>null</code>																						
<code>auths</code>	<code>null</code>																						
<code>profiles</code>	<code>null</code>																						
<code>proj</code>	<code>3</code>																						
<code>projname</code>	<code>default</code>																						
<code>roles</code>	<code>null</code>																						
<code>-e <i>expire</i></code>	Specify the expiration date for a login. After this date, no user will be able to access this login. The expire option argument is a date entered using one of the date formats included in the template file <code>/etc/datemsk</code>. See <code>getdate(3C)</code>. If the date format that you choose includes spaces, it must be quoted. For example, you can enter <code>10/6/90</code> or <code>"October 6, 1990"</code>. A null value (<code>" "</code>) defeats the status of the expired date. This option is useful for creating temporary logins.																						
<code>-f <i>inactive</i></code>	The maximum number of days allowed between uses of a login ID before that ID is declared invalid. Normal values are positive integers. A value of 0 defeats the status.																						
<code>-g <i>group</i></code>	An existing group's integer ID or character-string name. Without the <code>-D</code> option, it defines the new user's																						

	primary group membership and defaults to the default group. You can reset this default value by invoking <code>useradd -D -g group</code> .
<code>-G group</code>	An existing group's integer ID or character-string name. It defines the new user's supplementary group membership. Duplicates between <i>group</i> with the <code>-g</code> and <code>-G</code> options are ignored. No more than <code>NGROUPS_MAX</code> groups can be specified.
<code>-k skel_dir</code>	A directory that contains skeleton information (such as <code>.profile</code>) that can be copied into a new user's home directory. This directory must already exist. The system provides the <code>/etc/skel</code> directory that can be used for this purpose.
<code>-m</code>	Create the new user's home directory if it does not already exist. If the directory already exists, it must have read, write, and execute permissions by <i>group</i> , where <i>group</i> is the user's primary group.
<code>-o</code>	This option allows a UID to be duplicated (non-unique).
<code>-P profile</code>	One or more comma-separated execution profiles defined in <code>prof_attr(4)</code> .
<code>-p projname</code>	Name of the project with which the added user is associated. See the <i>projname</i> field as defined in <code>project(4)</code> .
<code>-R role</code>	One or more comma-separated execution profiles defined in <code>user_attr(4)</code> . Roles cannot be assigned to other roles.
<code>-s shell</code>	Full pathname of the program used as the user's shell on login. It defaults to an empty field causing the system to use <code>/bin/sh</code> as the default. The value of <i>shell</i> must be a valid executable file.
<code>-u uid</code>	The UID of the new user. This UID must be a non-negative decimal integer below <code>MAXUID</code> as defined in <code><sys/param.h></code> . The UID defaults to the next available (unique) number above the highest number currently assigned. For example, if UIDs 100, 105, and 200 are assigned, the next default UID number will be 201. (UIDs from 0-99 are reserved for possible use in future applications.)
FILES	/etc/datemsk /etc/passwd

useradd(1M)

/etc/shadow
/etc/group
/etc/skel
/usr/include/limits.h
/etc/user_attr

ATTRIBUTES See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

SEE ALSO passwd(1), profiles(1), roles(1), users(1B), groupadd(1M), groupdel(1M), groupmod(1M), grpck(1M), logins(1M), pwck(1M), userdel(1M), usermod(1M), getdate(3C), auth_attr(4), passwd(4), prof_attr(4), project(4), user_attr(4), attributes(5)

DIAGNOSTICS In case of an error, useradd prints an error message and exits with a non-zero status.

The following indicates that login specified is already in use:

UX: useradd: ERROR: login is already in use. Choose another.

The following indicates that the *uid* specified with the -u option is not unique:

UX: useradd: ERROR: uid *uid* is already in use. Choose another.

The following indicates that the *group* specified with the -g option is already in use:

UX: useradd: ERROR: group *group* does not exist. Choose another.

The following indicates that the *uid* specified with the -u option is in the range of reserved UIDs (from 0-99):

UX: useradd: WARNING: uid *uid* is reserved.

The following indicates that the *uid* specified with the -u option exceeds MAXUID as defined in <sys/param.h>:

UX: useradd: ERROR: uid *uid* is too big. Choose another.

The following indicates that the /etc/passwd or /etc/shadow files do not exist:

UX: useradd: ERROR: Cannot update system files - login cannot be created.

NOTES The useradd utility adds definitions to only the local /etc/group, etc/passwd, /etc/passwd, /etc/shadow, /etc/project, and /etc/user_attr files. If a network name service such as NIS or NIS+ is being used to supplement the local

/etc/passwd file with additional entries, useradd cannot change information supplied by the network name service. However useradd will verify the uniqueness of the user name (or role) and user id and the existence of any group names specified against the external name service.

userdel(1M)

NAME	userdel – delete a user’s login from the system				
SYNOPSIS	userdel [-r] <i>login</i>				
DESCRIPTION	The <i>userdel</i> utility deletes a user account from the system and makes the appropriate account-related changes to the system file and file system.				
OPTIONS	The following options are supported: -r Remove the user’s home directory from the system. This directory must exist. The files and directories under the home directory will no longer be accessible following successful execution of the command.				
OPERANDS	The following operands are supported: <i>login</i> An existing login name to be deleted.				
EXIT STATUS	The following exit values are returned: 0 Successful completion. 2 Invalid command syntax. A usage message for the <i>userdel</i> command is displayed. 6 The account to be removed does not exist. 8 The account to be removed is in use. 10 Cannot update the <i>/etc/group</i> or <i>/etc/user_attr</i> file but the login is removed from the <i>/etc/passwd</i> file. 12 Cannot remove or otherwise modify the home directory.				
FILES	<i>/etc/passwd</i> system password file <i>/etc/shadow</i> system file contain users’ encrypted passwords and related information <i>/etc/group</i> system file containing group definitions <i>/etc/user_attr</i> system file containing additional user attributes				
ATTRIBUTES	See <i>attributes(5)</i> for descriptions of the following attributes: <table border="1"> <thead> <tr> <th>ATTRIBUTE TYPE</th><th>ATTRIBUTE VALUE</th></tr> </thead> <tbody> <tr> <td>Availability</td><td>SUNWcsu</td></tr> </tbody> </table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	Availability	SUNWcsu
ATTRIBUTE TYPE	ATTRIBUTE VALUE				
Availability	SUNWcsu				
SEE ALSO	<i>auths(1)</i> , <i>passwd(1)</i> , <i>profiles(1)</i> , <i>roles(1)</i> , <i>users(1B)</i> , <i>groupadd(1M)</i> , <i>groupdel(1M)</i> , <i>groupmod(1M)</i> , <i>logins(1M)</i> , <i>roleadd(1M)</i> , <i>rolemod(1M)</i> , <i>useradd(1M)</i> , <i>userdel(1M)</i> , <i>usermod(1M)</i> , <i>passwd(4)</i> , <i>prof_attr(4)</i> , <i>user_attr(4)</i> , <i>attributes(5)</i>				

NOTES | The `userdel` utility only deletes an account definition that is in the local `/etc/group`, `/etc/passwd`, `/etc/shadow`, and `/etc/user_attr` file. If a network name service such as NIS or NIS+ is being used to supplement the local `/etc/passwd` file with additional entries, `userdel` cannot change information supplied by the network name service.

usermod(1M)

NAME	usermod – modify a user’s login information on the system														
SYNOPSIS	usermod [-u <i>uid</i> [-o]] [-g <i>group</i>] [-G <i>group</i> [, <i>group</i> ...]] [-d <i>dir</i> [-m]] [-s <i>shell</i>] [-c <i>comment</i>] [-l <i>new_name</i>] [-f <i>inactive</i>] [-e <i>expire</i>] [-A <i>authorization</i> [, <i>authorization</i>]] [-P <i>profile</i> [, <i>profile</i>]] [-R <i>role</i> [, <i>role</i>]] <i>login</i>														
DESCRIPTION	The usermod utility modifies a user’s login definition on the system. It changes the definition of the specified login and makes the appropriate login-related system file and file system changes. The system file entries created with this command have a limit of 512 characters per line. Specifying long arguments to several options may exceed this limit.														
OPTIONS	The following options are supported: <table> <tr> <td>-A <i>authorization</i></td><td>One or more comma separated authorizations as defined in <code>auth_attr(4)</code>. Only a user or role who has grant rights to the <i>authorization</i> can assign it to an account. This replaces any existing authorization setting.</td></tr> <tr> <td>-c <i>comment</i></td><td>Specify a comment string. <i>comment</i> can be any text string. It is generally a short description of the login, and is currently used as the field for the user’s full name. This information is stored in the user’s <code>/etc/passwd</code> entry.</td></tr> <tr> <td>-d <i>dir</i></td><td>Specify the new home directory of the user. It defaults to <code>base_dir/login</code>, where <i>base_dir</i> is the base directory for new login home directories, and <i>login</i> is the new login.</td></tr> <tr> <td>-e <i>expire</i></td><td>Specify the expiration date for a login. After this date, no user will be able to access this login. The expire option argument is a date entered using one of the date formats included in the template file <code>/etc/datemsk</code>. See <code>getdate(3C)</code>.</td></tr> <tr> <td></td><td>For example, you may enter 10/6/90 or October 6, 1990. A value of ' ' ' ' defeats the status of the expired date.</td></tr> <tr> <td>-f <i>inactive</i></td><td>Specify the maximum number of days allowed between uses of a login ID before that login ID is declared invalid. Normal values are positive integers. A value of 0 defeats the status.</td></tr> <tr> <td>-g <i>group</i></td><td>Specify an existing group’s integer ID or character-string name. It redefines the user’s primary group membership.</td></tr> </table>	-A <i>authorization</i>	One or more comma separated authorizations as defined in <code>auth_attr(4)</code> . Only a user or role who has grant rights to the <i>authorization</i> can assign it to an account. This replaces any existing authorization setting.	-c <i>comment</i>	Specify a comment string. <i>comment</i> can be any text string. It is generally a short description of the login, and is currently used as the field for the user’s full name. This information is stored in the user’s <code>/etc/passwd</code> entry.	-d <i>dir</i>	Specify the new home directory of the user. It defaults to <code>base_dir/login</code> , where <i>base_dir</i> is the base directory for new login home directories, and <i>login</i> is the new login.	-e <i>expire</i>	Specify the expiration date for a login. After this date, no user will be able to access this login. The expire option argument is a date entered using one of the date formats included in the template file <code>/etc/datemsk</code> . See <code>getdate(3C)</code> .		For example, you may enter 10/6/90 or October 6, 1990. A value of ' ' ' ' defeats the status of the expired date.	-f <i>inactive</i>	Specify the maximum number of days allowed between uses of a login ID before that login ID is declared invalid. Normal values are positive integers. A value of 0 defeats the status.	-g <i>group</i>	Specify an existing group’s integer ID or character-string name. It redefines the user’s primary group membership.
-A <i>authorization</i>	One or more comma separated authorizations as defined in <code>auth_attr(4)</code> . Only a user or role who has grant rights to the <i>authorization</i> can assign it to an account. This replaces any existing authorization setting.														
-c <i>comment</i>	Specify a comment string. <i>comment</i> can be any text string. It is generally a short description of the login, and is currently used as the field for the user’s full name. This information is stored in the user’s <code>/etc/passwd</code> entry.														
-d <i>dir</i>	Specify the new home directory of the user. It defaults to <code>base_dir/login</code> , where <i>base_dir</i> is the base directory for new login home directories, and <i>login</i> is the new login.														
-e <i>expire</i>	Specify the expiration date for a login. After this date, no user will be able to access this login. The expire option argument is a date entered using one of the date formats included in the template file <code>/etc/datemsk</code> . See <code>getdate(3C)</code> .														
	For example, you may enter 10/6/90 or October 6, 1990. A value of ' ' ' ' defeats the status of the expired date.														
-f <i>inactive</i>	Specify the maximum number of days allowed between uses of a login ID before that login ID is declared invalid. Normal values are positive integers. A value of 0 defeats the status.														
-g <i>group</i>	Specify an existing group’s integer ID or character-string name. It redefines the user’s primary group membership.														

<code>-G group</code>	Specify an existing group's integer "ID" "," or character string name. It redefines the user's supplementary group membership. Duplicates between <i>group</i> with the <code>-g</code> and <code>-G</code> options are ignored. No more than NGROUPS_UMAX groups may be specified as defined in <param.h>.
<code>-l new_logname</code>	Specify the new login name for the user. The <i>new_logname</i> argument is a string no more than eight bytes consisting of characters from the set of alphabetic characters, numeric characters, period (.), underline (_), and hyphen (-). The first character should be alphabetic and the field should contain at least one lower case alphabetic character. A warning message will be written if these restrictions are not met. A future Solaris release may refuse to accept login fields that do not meet these requirements. The <i>new_logname</i> argument must contain at least one character and must not contain a colon (:) or NEWLINE (\n).
<code>-m</code>	Move the user's home directory to the new directory specified with the <code>-d</code> option. If the directory already exists, it must have permissions read/write/execute by <i>group</i> , where <i>group</i> is the user's primary group.
<code>-o</code>	This option allows the specified UID to be duplicated (non-unique).
<code>-P profile</code>	One or more comma-separated execution profiles defined in <code>prof_attr(4)</code> . This replaces any existing profile setting.
<code>-R role</code>	One or more comma-separated execution profiles defined in <code>auth_attr(4)</code> . This replaces any existing role setting.
<code>-s shell</code>	Specify the full pathname of the program that is used as the user's shell on login. The value of <i>shell</i> must be a valid executable file.
<code>-u uid</code>	Specify a new UID for the user. It must be a non-negative decimal integer less than MAXUID as defined in <param.h>. The UID associated with the user's home directory is not modified with this option; a user will not have access to their home directory until the UID is manually reassigned using <code>chown(1M)</code> .

OPERANDS The following operands are supported:

`login` An existing login name to be modified.

usermod(1M)

EXIT STATUS

In case of an error, `usermod` prints an error message and exits with one of the following values:

2	The command syntax was invalid. A usage message for the <code>usermod</code> command is displayed.
3	An invalid argument was provided to an option.
4	The <i>uid</i> given with the <code>-u</code> option is already in use.
5	The password files contain an error. <code>pwconv(1M)</code> can be used to correct possible errors. See <code>passwd(4)</code> .
6	The login to be modified does not exist, the <i>group</i> does not exist, or the login shell does not exist.
8	The login to be modified is in use.
9	The <i>new_logname</i> is already in use.
10	Cannot update the <code>/etc/group</code> or <code>/etc/user_attr</code> file. Other update requests will be implemented.
11	Insufficient space to move the home directory (<code>-m</code> option). Other update requests will be implemented.
12	Unable to complete the move of the home directory to the new home directory.

FILES

<code>/etc/group</code>	system file containing group definitions
<code>/etc/datemsk</code>	system file of date formats
<code>/etc/passwd</code>	system password file
<code>/etc/shadow</code>	system file containing users' encrypted passwords and related information
<code>/etc/usr_attr</code>	system file containing additional user and role attributes

ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

SEE ALSO

`passwd(1)`, `users(1B)`, `chown(1M)`, `groupadd(1M)`, `groupdel(1M)`, `groupmod(1M)`, `logins(1M)`, `pwconv(1M)`, `roleadd(1M)`, `roledel(1M)`, `rolemod(1M)`, `useradd(1M)`, `userdel(1M)`, `getdate(3C)`, `auth_attr(4)`, `passwd(4)`, `attributes(5)`

NOTES | The usermod utility modifies passwd definitions only in the local `/etc/passwd` and `/etc/shadow` files. If a network nameservice such as NIS or NIS+ is being used to supplement the local files with additional entries, usermod cannot change information supplied by the network nameservice. However usermod will verify the uniqueness of user name and user ID against the external nameservice.

The usermod utility uses the `/etc/datemsk` file, available with SUNWaccr, for date formatting.

utmpd(1M)

NAME	utmpd – utmpx monitoring daemon						
SYNOPSIS	utmpd [-debug]						
DESCRIPTION	The utmpd daemon monitors the /var/adm/utmpx file. See utmpx(4) (and utmp(4) for historical information). utmpd receives requests from pututxline(3C) by way of a named pipe. It maintains a table of processes and uses poll(2) on /proc files to detect process termination. When utmpd detects that a process has terminated, it checks that the process has removed its utmpx entry from /var/adm/utmpx. If the process' utmpx entry has not been removed, utmpd removes the entry. By periodically scanning the /var/adm/utmpx file, utmpd also monitors processes that are not in its table.						
OPTIONS	-debug Run in debug mode, leaving the process connected to the controlling terminal. Write debugging information to standard output.						
EXIT STATUS	The following exit values are returned: 0 Successful completion. >0 An error occurred.						
FILES	/etc/default/utmpd	You can set default values for the flags listed below. For example: SCAN_PERIOD=600					
	SCAN_PERIOD	The number of seconds that utmpd sleeps between checks of /proc to see if monitored processes are still alive. The default is 300.					
	MAX_FDS	The maximum number of processes that utmpd attempts to monitor. The default value is 4096.					
	/var/adm/utmpx	File containing user and accounting information for commands such as who(1), write(1), and login(1).					
	/proc	Directory containing files for processes whose utmpx entries are being monitored.

NAME	uucheck – check the uucp directories and permissions file				
SYNOPSIS	/usr/lib/uucp/uucheck [-v] [-x <i>debug-level</i>]				
DESCRIPTION	uucheck checks for the presence of the uucp system required files and directories. uucheck also does error checking of the Permissions file (/etc/uucp/Permissions). uucheck is executed during package installation. uucheck can only be used by the super-user or uucp.				
OPTIONS	The following options are supported: -v Give a detailed (verbose) explanation of how the uucp programs will interpret the Permissions file. -x <i>debug-level</i> Produce debugging output on the standard output. <i>debug-level</i> is a number from 0 to 9. Higher numbers give more detailed debugging information.				
FILES	/etc/uucp/Devices /etc/uucp/Limits /etc/uucp/Permissions /etc/uucp/Systems /var/spool/locks/* /var/spool/uucp/* /var/spool/uucppublic/*				
ATTRIBUTES	See attributes(5) for descriptions of the following attributes: <table border="1"> <thead> <tr> <th>ATTRIBUTE TYPE</th><th>ATTRIBUTE VALUE</th></tr> </thead> <tbody> <tr> <td>Availability</td><td>SUNWbnuu</td></tr> </tbody> </table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	Availability	SUNWbnuu
ATTRIBUTE TYPE	ATTRIBUTE VALUE				
Availability	SUNWbnuu				
SEE ALSO	uucp(1C), uustat(1C), uux(1C), uucico(1M), uusched(1M), attributes (5)				
BUGS	The program does not check file/directory modes or some errors in the Permissions file such as duplicate login or machine name.				

uucico(1M)

NAME	uucico – file transport program for the uucp system														
SYNOPSIS	/usr/lib/uucp/uucico [-f] [-c <i>type</i>] [-d <i>spool-directory</i>] [-i <i>interface</i>] [-r <i>role-number</i>] [-s <i>system-name</i>] [-x <i>debug-level</i>]														
DESCRIPTION	uucico is the file transport program for uucp work file transfers.														
OPTIONS	The following options are supported: <table><tr><td>-f</td><td>This option is used to "force execution" of uucico by ignoring the limit on the maximum number of uucicos defined in the <code>/etc/uucp/Limits</code> file.</td></tr><tr><td>-c <i>type</i></td><td>The first field in the <code>Devices</code> file is the "Type" field. The -c option forces uucico to only use entries in the "Type" field that match the user specified type. The specified type is usually the name of a local area network.</td></tr><tr><td>-d <i>spool-directory</i></td><td>This option specifies the directory <i>spool-directory</i> that contains the uucp work files to be transferred. The default spool directory is <code>/var/spool/uucp</code>.</td></tr><tr><td>-i <i>interface</i></td><td>This option defines the <i>interface</i> used with uucico. The interface only affects slave mode. Known interfaces are UNIX (default), TLI (basic Transport Layer Interface), and TLIS (Transport Layer Interface with Streams modules, read/write).</td></tr><tr><td>-r <i>role-number</i></td><td>The <i>role-number</i> 1 is used for master mode. <i>role-number</i> 0 is used for slave mode (default). When uucico is started by a program or cron, <i>role-number</i> 1 should be used for master mode.</td></tr><tr><td>-s <i>system-name</i></td><td>The -s option defines the remote system (<i>system-name</i>) that uucico will try to contact. It is required when the role is master; <i>system-name</i> must be defined in the <code>Systems</code> file.</td></tr><tr><td>-x <i>debug-level</i></td><td>Both uux and uucp queue jobs that will be transferred by uucico. These jobs are normally started by the uusched scheduler, for debugging purposes, and can be started manually. For example, the shell Uutry starts uucico with debugging turned on. The <i>debug-level</i> is a number between 0 and 9. Higher numbers give more detailed debugging information.</td></tr></table>	-f	This option is used to "force execution" of uucico by ignoring the limit on the maximum number of uucicos defined in the <code>/etc/uucp/Limits</code> file.	-c <i>type</i>	The first field in the <code>Devices</code> file is the "Type" field. The -c option forces uucico to only use entries in the "Type" field that match the user specified type. The specified type is usually the name of a local area network.	-d <i>spool-directory</i>	This option specifies the directory <i>spool-directory</i> that contains the uucp work files to be transferred. The default spool directory is <code>/var/spool/uucp</code> .	-i <i>interface</i>	This option defines the <i>interface</i> used with uucico. The interface only affects slave mode. Known interfaces are UNIX (default), TLI (basic Transport Layer Interface), and TLIS (Transport Layer Interface with Streams modules, read/write).	-r <i>role-number</i>	The <i>role-number</i> 1 is used for master mode. <i>role-number</i> 0 is used for slave mode (default). When uucico is started by a program or cron, <i>role-number</i> 1 should be used for master mode.	-s <i>system-name</i>	The -s option defines the remote system (<i>system-name</i>) that uucico will try to contact. It is required when the role is master; <i>system-name</i> must be defined in the <code>Systems</code> file.	-x <i>debug-level</i>	Both uux and uucp queue jobs that will be transferred by uucico. These jobs are normally started by the uusched scheduler, for debugging purposes, and can be started manually. For example, the shell Uutry starts uucico with debugging turned on. The <i>debug-level</i> is a number between 0 and 9. Higher numbers give more detailed debugging information.
-f	This option is used to "force execution" of uucico by ignoring the limit on the maximum number of uucicos defined in the <code>/etc/uucp/Limits</code> file.														
-c <i>type</i>	The first field in the <code>Devices</code> file is the "Type" field. The -c option forces uucico to only use entries in the "Type" field that match the user specified type. The specified type is usually the name of a local area network.														
-d <i>spool-directory</i>	This option specifies the directory <i>spool-directory</i> that contains the uucp work files to be transferred. The default spool directory is <code>/var/spool/uucp</code> .														
-i <i>interface</i>	This option defines the <i>interface</i> used with uucico. The interface only affects slave mode. Known interfaces are UNIX (default), TLI (basic Transport Layer Interface), and TLIS (Transport Layer Interface with Streams modules, read/write).														
-r <i>role-number</i>	The <i>role-number</i> 1 is used for master mode. <i>role-number</i> 0 is used for slave mode (default). When uucico is started by a program or cron, <i>role-number</i> 1 should be used for master mode.														
-s <i>system-name</i>	The -s option defines the remote system (<i>system-name</i>) that uucico will try to contact. It is required when the role is master; <i>system-name</i> must be defined in the <code>Systems</code> file.														
-x <i>debug-level</i>	Both uux and uucp queue jobs that will be transferred by uucico. These jobs are normally started by the uusched scheduler, for debugging purposes, and can be started manually. For example, the shell Uutry starts uucico with debugging turned on. The <i>debug-level</i> is a number between 0 and 9. Higher numbers give more detailed debugging information.

uucleanup(1M)

NAME	uucleanup – uucp spool directory clean-up																
SYNOPSIS	/usr/lib/uucp/uucleanup [-C <i>time</i>] [-D <i>time</i>] [-m <i>string</i>] [-o <i>time</i>] [-s <i>system</i>] [-W <i>time</i>] [-x <i>debug-level</i>] [-X <i>time</i>]																
DESCRIPTION	uucleanup will scan the spool directories for old files and take appropriate action to remove them in a useful way: ■ Inform the requester of send/receive requests for systems that can not be reached. ■ Return undeliverable mail to the sender. ■ Deliver rnews files addressed to the local system. ■ Remove all other files. In addition, there is a provision to warn users of requests that have been waiting for a given number of days (default 1 day). Note: uucleanup will process as if all option times were specified to the default values unless time is specifically set. This program is typically started by the shell uudemon.cleanup, which should be started by cron(1M).																
OPTIONS	<table><tr><td>-C<i>time</i></td><td>Remove any C. files greater or equal to <i>time</i> days old and send appropriate information to the requester (default 7 days).</td></tr><tr><td>-D<i>time</i></td><td>Remove any D. files greater or equal to <i>time</i> days old, make an attempt to deliver mail messages, and execute rnews when appropriate (default 7 days).</td></tr><tr><td>-m<i>string</i></td><td>Include <i>string</i> in the warning message generated by the -W option. The default line is "See your local administrator to locate the problem".</td></tr><tr><td>-o<i>time</i></td><td>Delete other files whose age is more than <i>time</i> days (default 2 days).</td></tr><tr><td>-s<i>system</i></td><td>Execute for <i>system</i> spool directory only.</td></tr><tr><td>-W<i>time</i></td><td>Any C. files equal to <i>time</i> days old will cause a mail message to be sent to the requester warning about the delay in contacting the remote. The message includes the <i>JOBID</i>, and in the case of mail, the mail message. The administrator may include a message line telling whom to call to check the problem (-m option) (default 1 day).</td></tr><tr><td>-x<i>debug-level</i></td><td>Produce debugging output on standard output. <i>debug-level</i> is a single digit between 0 and 9; higher numbers give more detailed debugging information. (This option may not be available on all systems.)</td></tr><tr><td>-X<i>time</i></td><td>Any X. files greater or equal to <i>time</i> days old will be removed. The D. files are probably not present (if they were, the X. could get executed). But if there are D. files, they will be taken care of by D. processing (default 2 days).</td></tr></table>	-C <i>time</i>	Remove any C. files greater or equal to <i>time</i> days old and send appropriate information to the requester (default 7 days).	-D <i>time</i>	Remove any D. files greater or equal to <i>time</i> days old, make an attempt to deliver mail messages, and execute rnews when appropriate (default 7 days).	-m <i>string</i>	Include <i>string</i> in the warning message generated by the -W option. The default line is "See your local administrator to locate the problem".	-o <i>time</i>	Delete other files whose age is more than <i>time</i> days (default 2 days).	-s <i>system</i>	Execute for <i>system</i> spool directory only.	-W <i>time</i>	Any C. files equal to <i>time</i> days old will cause a mail message to be sent to the requester warning about the delay in contacting the remote. The message includes the <i>JOBID</i> , and in the case of mail, the mail message. The administrator may include a message line telling whom to call to check the problem (-m option) (default 1 day).	-x <i>debug-level</i>	Produce debugging output on standard output. <i>debug-level</i> is a single digit between 0 and 9; higher numbers give more detailed debugging information. (This option may not be available on all systems.)	-X <i>time</i>	Any X. files greater or equal to <i>time</i> days old will be removed. The D. files are probably not present (if they were, the X. could get executed). But if there are D. files, they will be taken care of by D. processing (default 2 days).
-C <i>time</i>	Remove any C. files greater or equal to <i>time</i> days old and send appropriate information to the requester (default 7 days).																
-D <i>time</i>	Remove any D. files greater or equal to <i>time</i> days old, make an attempt to deliver mail messages, and execute rnews when appropriate (default 7 days).																
-m <i>string</i>	Include <i>string</i> in the warning message generated by the -W option. The default line is "See your local administrator to locate the problem".																
-o <i>time</i>	Delete other files whose age is more than <i>time</i> days (default 2 days).																
-s <i>system</i>	Execute for <i>system</i> spool directory only.																
-W <i>time</i>	Any C. files equal to <i>time</i> days old will cause a mail message to be sent to the requester warning about the delay in contacting the remote. The message includes the <i>JOBID</i> , and in the case of mail, the mail message. The administrator may include a message line telling whom to call to check the problem (-m option) (default 1 day).																
-x <i>debug-level</i>	Produce debugging output on standard output. <i>debug-level</i> is a single digit between 0 and 9; higher numbers give more detailed debugging information. (This option may not be available on all systems.)																
-X <i>time</i>	Any X. files greater or equal to <i>time</i> days old will be removed. The D. files are probably not present (if they were, the X. could get executed). But if there are D. files, they will be taken care of by D. processing (default 2 days).

uusched(1M)

NAME	uusched – uucp file transport program scheduler				
SYNOPSIS	/usr/lib/uucp/uusched [-u <i>debug-level</i>] [-x <i>debug-level</i>]				
DESCRIPTION	uusched is the uucp(1C) file transport scheduler. It is usually started by the daemon <i>uudemon.hour</i> that is started by <i>cron(1M)</i> from an entry in user uucp's crontab file: <pre>11,41 * * * * /etc/uucp/uucp/uudemon.hour</pre>				
OPTIONS	The options are for debugging purposes only. <i>debug-level</i> is a number between 0 and 9. Higher numbers give more detailed debugging information: The following options are supported: -u <i>debug-level</i> Passes the -u <i>debug-level</i> option <i>uucico(1M)</i> as -x <i>debug-level</i>. -x <i>debug-level</i> Outputs debugging messages from uusched.

NAME	Uutry, uutry – attempt to contact remote system with debugging on				
SYNOPSIS	/usr/lib/uucp/Uutry [-r] [-c <i>type</i>] [-x <i>debug-level</i>] <i>system-name</i>				
DESCRIPTION	Uutry is a shell script that is used to invoke uucico(1M) to call a remote site. Debugging is initially turned on and is set to the default value of 5. The debugging output is put in file <i>/tmp/system-name</i> .				
OPTIONS	The following options are supported: -r This option overrides the retry time that is set in file <i>/var/uucp/.Status/system-name</i>. -c <i>type</i> The first field in the Devices file is the "Type" field. The -c option forces uucico to use only entries in the "Type" field that match the user-specified type. The specified type is usually the name of a local area network. -x <i>debug-level</i> <i>debug-level</i> is a number from 0 to 9. Higher numbers give more detailed debugging information.

uuxqt(1M)

NAME	uuxqt – execute remote command requests				
SYNOPSIS	/usr/lib/uucp/uuxqt [-s <i>system</i>] [-x <i>debug-level</i>]				
DESCRIPTION	uuxqt is the program that executes remote job requests from remote systems generated by the use of the uux command. (mail uses uux for remote mail requests). uuxqt searches the spool directories looking for execution requests. For each request, uuxqt checks to see if all the required data files are available, accessible, and the requested commands are permitted for the requesting system. The Permissions file is used to validate file accessibility and command execution permission. There are two environment variables that are set before the uuxqt command is executed: ■ UU_MACHINE is the machine that sent the job (the previous one). ■ UU_USER is the user that sent the job. These can be used in writing commands that remote systems can execute to provide information, auditing, or restrictions.				
OPTIONS	The following options are supported: -s <i>system</i> Specifies the remote <i>system</i> name. -x <i>debug-level</i> <i>debug-level</i> is a number from 0 to 9. Higher numbers give more detailed debugging information.				
FILES	/etc/uucp/Limits /etc/uucp/Permissions /var/spool/locks/* /var/spool/uucp/*

NAME	vmstat – report virtual memory statistics
SYNOPSIS	vmstat [-cipsS] [disks] [interval [count]]
DESCRIPTION	vmstat reports virtual memory statistics regarding kernel thread, virtual memory, disk, trap, and CPU activity. On MP (multi-processor) systems, vmstat averages the number of CPUs into the output. For per-processor statistics, see mpstat(1M). vmstat only supports statistics for certain devices. For more general system statistics, use sar(1), iostat(1M), or sar(1M). Without options, vmstat displays a one-line summary of the virtual memory activity since the system was booted. During execution of this kernel status command, the "state" of the kernel can change. An example would be CPUs going online or offline. vmstat will report this as <<State change>>. See <i>System Administration Guide: Advanced Administration</i> for device naming conventions for disks.
OPTIONS	The following options are supported: -c Report cache flushing statistics. By default, report the total number of each kind of cache flushed since boot time. The types are: user, context, region, segment, page, and partial-page. -i Report the number of interrupts per device. <i>count</i> and <i>interval</i> does not apply to the -i option. -p Report paging activity in details. This option will display the following, respectively: - epi Executable page-ins. - epo Executable page-outs. - epf Executable page-frees. - api Anonymous page-ins. - apo Anonymous page-outs. - apf Anonymous page-frees. - fpi File system page-ins. - fpo File system page-outs. - fpf File system page-frees. -s Display the total number of various system events since boot. <i>count</i> and <i>interval</i> does not apply to the -s option.

vmstat(1M)

	-S	Report on swapping rather than paging activity. This option will change two fields in <i>vmstat</i> 's "paging" display: rather than the "re" and "mf" fields, <i>vmstat</i> will report "si" (swap-ins) and "so" (swap-outs).																																																																																																																																																																																																																										
OPERANDS	The following operands are supported:																																																																																																																																																																																																																											
	<i>count</i>	Specifies the number of times that the statistics are repeated. <i>count</i> does not apply to the -i and -s options.																																																																																																																																																																																																																										
	<i>disks</i>	Specifies which disks are to be given priority in the output (only four disks fit on a line). Common disk names are <i>id</i> , <i>sd</i> , <i>xd</i> , or <i>xy</i> , followed by a number (for example, <i>sd2</i> , <i>xd0</i> , and so forth).																																																																																																																																																																																																																										
	<i>interval</i>	Specifies the last number of seconds over which <i>vmstat</i> summarizes activity. This number of seconds repeats forever. <i>interval</i> does not apply to the -i and -s options.																																																																																																																																																																																																																										
EXAMPLES	EXAMPLE 1 Using <i>vmstat</i>																																																																																																																																																																																																																											
	The following command displays a summary of what the system is doing every five seconds.																																																																																																																																																																																																																											
	<pre>example% vmstat 5</pre> <table><thead><tr><th colspan="2">kthr</th><th colspan="2">memory</th><th colspan="4">page</th><th colspan="4">disk</th><th colspan="4">faults</th><th colspan="4">cpu</th></tr><tr><th>r</th><th>b</th><th>w</th><th>swap</th><th>free</th><th>re</th><th>mf</th><th>pi</th><th>p</th><th>fr</th><th>de</th><th>sr</th><th>s0</th><th>s1</th><th>s2</th><th>s3</th><th>in</th><th>sy</th><th>cs</th><th>us</th><th>sy</th><th>id</th></tr></thead><tbody><tr><td>0</td><td>0</td><td>0</td><td>11456</td><td>4120</td><td>1</td><td>41</td><td>19</td><td>1</td><td>3</td><td>0</td><td>2</td><td>0</td><td>4</td><td>0</td><td>0</td><td>48</td><td>112</td><td>130</td><td>4</td><td>14</td><td>82</td></tr><tr><td>0</td><td>0</td><td>1</td><td>10132</td><td>4280</td><td>0</td><td>4</td><td>44</td><td>0</td><td>0</td><td>0</td><td>0</td><td>0</td><td>23</td><td>0</td><td>0</td><td>211</td><td>230</td><td>144</td><td>3</td><td>35</td><td>62</td></tr><tr><td>0</td><td>0</td><td>1</td><td>10132</td><td>4616</td><td>0</td><td>0</td><td>20</td><td>0</td><td>0</td><td>0</td><td>0</td><td>0</td><td>19</td><td>0</td><td>0</td><td>150</td><td>172</td><td>146</td><td>3</td><td>33</td><td>64</td></tr><tr><td>0</td><td>0</td><td>1</td><td>10132</td><td>5292</td><td>0</td><td>0</td><td>9</td><td>0</td><td>0</td><td>0</td><td>0</td><td>0</td><td>21</td><td>0</td><td>0</td><td>165</td><td>105</td><td>130</td><td>1</td><td>21</td><td>78</td></tr><tr><td>1</td><td>1</td><td>1</td><td>10132</td><td>5496</td><td>0</td><td>0</td><td>5</td><td>0</td><td>0</td><td>0</td><td>0</td><td>0</td><td>23</td><td>0</td><td>0</td><td>183</td><td>92</td><td>134</td><td>1</td><td>20</td><td>79</td></tr><tr><td>1</td><td>0</td><td>1</td><td>10132</td><td>5564</td><td>0</td><td>0</td><td>25</td><td>0</td><td>0</td><td>0</td><td>0</td><td>0</td><td>18</td><td>0</td><td>0</td><td>131</td><td>231</td><td>116</td><td>4</td><td>34</td><td>62</td></tr><tr><td>1</td><td>0</td><td>1</td><td>10124</td><td>5412</td><td>0</td><td>0</td><td>37</td><td>0</td><td>0</td><td>0</td><td>0</td><td>0</td><td>22</td><td>0</td><td>0</td><td>166</td><td>179</td><td>118</td><td>1</td><td>33</td><td>67</td></tr><tr><td>1</td><td>0</td><td>1</td><td>10124</td><td>5236</td><td>0</td><td>0</td><td>24</td><td>0</td><td>0</td><td>0</td><td>0</td><td>0</td><td>14</td><td>0</td><td>0</td><td>109</td><td>243</td><td>113</td><td>4</td><td>56</td><td>39</td></tr></tbody></table> <pre>^Cexample%</pre>		kthr		memory		page				disk				faults				cpu				r	b	w	swap	free	re	mf	pi	p	fr	de	sr	s0	s1	s2	s3	in	sy	cs	us	sy	id	0	0	0	11456	4120	1	41	19	1	3	0	2	0	4	0	0	48	112	130	4	14	82	0	0	1	10132	4280	0	4	44	0	0	0	0	0	23	0	0	211	230	144	3	35	62	0	0	1	10132	4616	0	0	20	0	0	0	0	0	19	0	0	150	172	146	3	33	64	0	0	1	10132	5292	0	0	9	0	0	0	0	0	21	0	0	165	105	130	1	21	78	1	1	1	10132	5496	0	0	5	0	0	0	0	0	23	0	0	183	92	134	1	20	79	1	0	1	10132	5564	0	0	25	0	0	0	0	0	18	0	0	131	231	116	4	34	62	1	0	1	10124	5412	0	0	37	0	0	0	0	0	22	0	0	166	179	118	1	33	67	1	0	1	10124	5236	0	0	24	0	0	0	0	0	14	0	0	109	243	113	4	56	39

vmstat(1M)

NOTES	The sum of CPU utilization might vary slightly from 100 because of rounding errors in the production of a percentage figure.

NAME	volcopy – make an image copy of file system	
SYNOPSIS	volcopy [-F <i>FSType</i>] [-V] [<i>generic_options</i>] [-o <i>FSType-specific_options</i>] <i>operands</i>	
DESCRIPTION	volcopy makes a literal copy of the file system. This command may not be supported for all <i>FSTypes</i> .	
OPTIONS	The following options are supported: -F <i>FSType</i> Specify the <i>FSType</i> on which to operate. The <i>FSType</i> should either be specified here or be determinable from <i>/etc/vfstab</i> by matching the <i>operands</i> with an entry in the table. Otherwise, the default file system type specified in <i>/etc/default/fs</i> will be used. -V Echo the complete command line, but do not execute the command. The command line is generated by using the options and arguments provided by the user and adding to them information derived from <i>/etc/vfstab</i>. This option should be used to verify and validate the command line. <i>generic_options</i> Options that are commonly supported by most <i>FSType</i>-specific command modules. The following options are available: -a Require the operator to respond “yes” or “no” instead of simply waiting ten seconds before the copy is made. -s (Default) Invoke the DEL if wrong verification sequence. -o <i>FSType-specific_options</i> Specify <i>FSType</i>-specific options in a comma separated (without spaces) list of suboptions and keyword-attribute pairs for interpretation by the <i>FSType</i>-specific module of the command.	
OPERANDS	The following operands are supported: <i>operands</i> generally include the device and volume names and are file system specific. A detailed description of the <i>operands</i> can be found on the <i>FSType</i>-specific man pages of volcopy.	
EXIT STATUS	The following exit values are returned:	

volcopy(1M)

- 0 Successful file system copy
- 1 An error has occurred.

FILES `/etc/vfstab` list of default parameters for each file system

`/etc/default/fs` default local file system type. Default values can be set for the following flags in `/etc/default/fs`. For example: `LOCAL=ufs`.

LOCAL: The default partition for a command if no *FSType* is specified.

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

SEE ALSO `labelit(1M)`, `vfstab(4)`, `attributes(5)` Manual pages for the *FSType*-specific modules of `volcopy`.

NAME	volcopy_ufs – make an image copy of a ufs file system					
SYNOPSIS	volcopy [-F ufs] [<i>generic_options</i>] <i>fsname</i> <i>srcdevice</i> <i>volname1</i> <i>destdevice</i> <i>volname2</i>					
DESCRIPTION	volcopy makes a literal copy of the ufs file system using a blocksize matched to the device.					
OPTIONS	The following option is supported: <i>generic_options</i> options supported by the generic volcopy command. See volcopy(1M).					
OPERANDS	The following operands are supported: <i>fsname</i> represents the mount point (for example, root, u1, etc.) of the file system being copied. <i>srcdevice</i> or <i>destdevice</i> the disk partition specified using the raw device (for example, /dev/rdsk/cld0s8, /dev/rdsk/cld1s8, etc.). <i>srcdevice</i> and <i>volname1</i> the device and physical volume from which the copy of the file system is being extracted. <i>destdevice</i> and <i>volname2</i> the target device and physical volume. <i>fsname</i> and <i>volname</i> are limited to six or fewer characters and recorded in the superblock. <i>volname</i> may be ‘-’ to use the existing volume name.					
EXIT STATUS	The following exit values are returned: 0 Successful file system copy. non-zero An error has occurred.					
FILES	/var/adm/filesave.log a record of file systems/volumes copied					
ATTRIBUTES	See attributes(5) for descriptions of the following attributes: <table><tr><th>ATTRIBUTE TYPE</th><th>ATTRIBUTE VALUE</th></tr><tr><td>Availability</td><td>SUNWcsu</td></tr></table>		ATTRIBUTE TYPE	ATTRIBUTE VALUE	Availability	SUNWcsu
ATTRIBUTE TYPE	ATTRIBUTE VALUE					
Availability	SUNWcsu					
SEE ALSO	cpio(1), dd(1M), labelit(1M), volcopy(1M), attributes(5), ufs(7FS)					
NOTES	volcopy does not support copying to tape devices. Use dd(1M) for copying to and from tape devices.					

vold(1M)

NAME	vold – Volume Management daemon to manage CD-ROM and floppy, ZIP/JAZ, and DVD-ROM devices
SYNOPSIS	/usr/sbin/vold [-n] [-t] [-v] [-f <i>config-file</i>] [-l <i>log-file</i>] [-d <i>root-dir</i>] [-L <i>debug-level</i>]
DESCRIPTION	The Volume Management daemon, vold, creates and maintains a file system image rooted at <i>root-dir</i> that contains symbolic names for floppies, CD-ROMs and other removable devices. The default <i>root-dir</i> is set to /vol if no directory is specified by the -d option. vold reads the /etc/vold.conf configuration file upon startup. If the configuration file is modified later, vold must be told to reread the /etc/vold.conf file. Do this by entering <pre>example# kill -HUP vold_pid</pre> To tell vold to clean up and exit, the SIGTERM signal is used: <pre>example# kill -TERM vold_pid</pre> where vold_pid is the process ID of vold.
OPTIONS	The following options are supported: -n Never writeback. Volume Management updates media labels with unique information if labels are not unique. This flag keeps Volume Management from changing your media. The default setting is FALSE. -t Dump NFS trace information to the log file. The default setting is FALSE. -v Provide lots of status information to the log file. The default setting is FALSE (do not provide status info to log file). -d <i>root-dir</i> Specify an alternate root directory. The default location is /vol. Setting this will also cause other Volume Management utilities to use this as the default root directory. -f <i>config-file</i> Specify an alternate configuration file. The default file is /etc/vold.conf. -l <i>log-file</i> Specify an alternate log file. The default log file is /var/adm/vold.log. -L <i>debug-level</i> Change the level (verbosity) of debug messages sent to the log file. The range is 0 to 99 where 0 is nothing and 99 is everything. The default level is 0.
ENVIRONMENT VARIABLES	vold sets the following environment variables to aid programs which are called when events such as insert, notify, and eject occur:

FILES	VOLUME_ACTION	Event that caused this program to be executed.
	VOLUME_PATH	Pathname of the matched <i>regex</i> from the <code>vold.conf</code> file.
	VOLUME_DEVICE	Device (in <code>/vol/dev</code>) that applies to the media.
	VOLUME_NAME	Name of the volume in question.
	VOLUME_USER	User ID of the user causing the event to occur.
	VOLUME_SYMNAME	Symbolic name of a device containing the volume.
	VOLUME_MEDIATYPE	Name of the type of media (CD-ROM, floppy or rmdisk)
	<code>/etc/vold.conf</code>	Volume Management daemon configuration file. Directs the Volume Management daemon to control certain devices, and causes events to occur when specific criteria are met.
	<code>/usr/lib/vold/*.so.1</code>	Shared objects called by Volume Management daemon when certain actions occur.
	<code>/var/adm/vold.log</code>	the default log file location (see the <code>-l</code> option for a description).
ATTRIBUTES	<code>/vol</code>	the default Volume Management root directory.
	See <code>attributes(5)</code> for descriptions of the following attributes:

System Administration Guide: Basic Administration

wall(1M)

NAME	wall – write to all users				
SYNOPSIS	/usr/sbin/wall [-a] [-g <i>grpname</i>] [<i>filename</i>]				
DESCRIPTION	wall reads its standard input until an end-of-file. It then sends this message to all currently logged-in users preceded by: <pre>Broadcast Message from . . .</pre> If <i>filename</i> is given, then the message is read in from that file. Normally, pseudo-terminals that do not correspond to rlogin sessions are ignored. Thus, when using a window system, the message appears only on the console window. However, -a will send the message even to such pseudo-terminals. It is used to warn all users, typically prior to shutting down the system. The sender must be superuser to override any protections the users may have invoked See mesg(1). wall runs setgid() to the group ID tty, in order to have write permissions on other user's terminals. See setuid(2). wall will detect non-printable characters before sending them to the user's terminal. Control characters will appear as a " ^ " followed by the appropriate ASCII character; characters with the high-order bit set will appear in "meta" notation. For example, '\003' is displayed as '^C' and '\372' as 'M-z'.				
OPTIONS	The following options are supported: <table><tr><td>-a</td><td>Broadcast message to the console and pseudo-terminals.</td></tr><tr><td>-g <i>grpname</i></td><td>Broadcast to the users in a specified group only, per the group database (see group(4)).</td></tr></table>	-a	Broadcast message to the console and pseudo-terminals.	-g <i>grpname</i>	Broadcast to the users in a specified group only, per the group database (see group(4)).
-a	Broadcast message to the console and pseudo-terminals.				
-g <i>grpname</i>	Broadcast to the users in a specified group only, per the group database (see group(4)).				
ENVIRONMENT VARIABLES	If the LC_* variables (LC_CTYPE, LC_TIME, LC_COLLATE, LC_NUMERIC, and LC_MONETARY) are not set in the environment, the operational behavior of wall for each corresponding locale category is determined by the value of the LANG environment variable. See environ(5). If LC_ALL is set, its contents are used to override both the LANG and the other LC_* variables. If none of the above variables are set in the environment, the "C" (U.S. style) locale determines how wall behaves.				
FILES	/dev/tty*				
ATTRIBUTES	See attributes(5) for descriptions of the following attributes: <table><tr><th>ATTRIBUTE TYPE</th><th>ATTRIBUTE VALUE</th></tr><tr><td>Availability</td><td>SUNWcsu</td></tr></table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	Availability	SUNWcsu
ATTRIBUTE TYPE	ATTRIBUTE VALUE				
Availability	SUNWcsu				
SEE ALSO	mesg(1), write(1), setuid(2), attributes(5), environ(5)				

wall(1M)

NOTES | wall displays "Cannot send to . . ." when the open on a user's `tty` file fails.

wanboot_keygen(1M)

NAME	wanboot_keygen – create and display client and server keys for WAN booting
SYNOPSIS	<pre> /usr/lib/inet/wanboot/keygen -c -o net=a.b.c.d , cid=client_ID , type=3des /usr/lib/inet/wanboot/keygen -c -o net=a.b.c.d , cid=client_ID , type=aes /usr/lib/inet/wanboot/keygen -m /usr/lib/inet/wanboot/keygen -c -o net=a.b.c.d , cid=client_ID , type=sha1 /usr/lib/inet/wanboot/keygen -d -m /usr/lib/inet/wanboot/keygen -c -o net=a.b.c.d , cid=client_ID , type=keytype </pre>
DESCRIPTION	The keygen utility has three purposes: ■ Using the <code>-c</code> flag, to generate and store per-client 3DES/AES encryption keys, avoiding any DES weak keys. ■ Using the <code>-m</code> flag, to generate and store a “master” HMAC SHA-1 key for WAN install, and to derive from the master key per-client HMAC SHA-1 hashing keys, in a manner described in RFC 3118, Appendix A. ■ Using the <code>-d</code> flag along with either the <code>-c</code> or <code>-m</code> flag to indicate the key repository, to display a key of type specified by <i>keytype</i>, which must be one of <code>3des</code>, <code>aes</code>, or <code>sha1</code>. The <code>net</code> and <code>cid</code> arguments are used to identify a specific client. Both arguments are optional. If the <code>cid</code> option is not provided, the key being created or displayed will have a per-network scope. If the <code>net</code> option is not provided, then the key will have a global scope. Default <code>net</code> and <code>code</code> values are used to derive an HMAC SHA-1 key if the values are not provided by the user.
OPTIONS	The following options are supported: <code>-c</code> Generate and store per-client 3DES/AES encryption keys, avoiding any DES weak keys. Also generates and stores per-client HMAC SHA-1 keys. Used in conjunction with <code>-o</code>. <code>-d</code> Display a key of type specified by <i>keytype</i>, which must be one of <code>3des</code>, <code>aes</code>, or <code>sha1</code>. Use <code>-d</code> with <code>-m</code> or with <code>-c</code> and <code>-o</code>. <code>-m</code> Generate and store a “master” HMAC SHA-1 key for WAN install. <code>-o</code> Specifies the WANboot client and/or <i>keytype</i>.
EXAMPLES	EXAMPLE 1 Generate a Master HMAC SHA-1 Key <pre># keygen -m</pre>

EXAMPLE 1 Generate a Master HMAC SHA-1 Key *(Continued)*

EXAMPLE 2 Generate and Then Display a Client-Specific Master HMAC SHA-1 Key

```
# keygen -c -o net=129.148.174.0,cid=010003BA0E6A36,type=sha1
# keygen -d -c -o net=129.148.174.0,cid=010003BA0E6A36,type=sha1
```

EXAMPLE 3 Generate and Display a 3DES Key with a Per-Network Scope

```
# keygen -c -o net=129.148.174.0,type=3des
# keygen -d -o net=129.148.174.0,type=3des
```

EXIT STATUS 0
 Successful operation.

 >0
 An error occurred.

wanboot_keymgmt(1M)

NAME	wanboot_keymgmt – insert and extract keys
SYNOPSIS	<pre>/usr/lib/inet/wanboot/keymgmt -i -k <i>key_file</i> -s <i>keystore</i> -o type=<i>keytype</i> /usr/lib/inet/wanboot/keymgmt -x -f <i>outfile</i> -s <i>keystore</i> -o type=<i>keytype</i></pre>
DESCRIPTION	The keymgmt utility has two purposes: ■ To take a raw key, stored in <i>key_file</i>, and insert it in the repository specified by <i>keystore</i>. ■ To extract a key of a specified type from the repository specified by <i>keystore</i>, depositing it in <i>outfile</i>. <i>outfile</i> will be created if it does not already exist. The type of key being added or extracted is specified by <i>keytype</i> and may have one of four values: 3des, aes, rsa, or sha1 (the last used by HMAC SHA-1). When extracting a key, the first key with an OID matching the supplied type is used.
ARGUMENTS	The following arguments are supported: -i Used in conjunction with -k to insert a raw key in <i>keystore</i>. -f <i>outfile</i> Used to specify a file to receive an extracted key. -k <i>key_file</i> Used in conjunction with -i to specify the file in which a raw key is stored. This key will be inserted in <i>keystore</i>. -o type=<i>keytype</i> Specifies the type of key being inserted or extracted. Must be one of 3des, aes, rsa, or sha1. -s <i>keystore</i> Specifies a repository in which a key will be inserted or from which a key will be extracted. -x Used in conjunction with -f to extract a key of a specified type and deposit it in <i>outfile</i>.
EXIT STATUS	0 Successful operation. >0 An error occurred.

wanboot_p12split(1M)

NAME	wanboot_p12split – split a PKCS #12 file into separate certificate and key files						
SYNOPSIS	<code>/usr/lib/inet/wanboot/p12split -i p12file -c out_cert -k out_key</code> <code>[-t out_trust -l id -v]</code>						
DESCRIPTION	The <code>p12split</code> utility extracts a certificate and private key from the repository specified by <code>p12file</code> , depositing the certificate in <code>out_cert</code> and the key in <code>out_key</code> . If supplied, the <code>-l</code> option specifies the value for the <code>LocalKeyId</code> that will be used in the new certificate and key files. <code>p12split</code> can optionally extract a trust certificate into the <code>out_trust</code> file if the <code>-t</code> option is specified. Use the <code>-v</code> option to get a verbose description of the split displayed to standard output.						
OPTIONS	The following arguments and options are supported: <code>-c out_cert</code> Specifies a repository that receives a extracted certificate. <code>-i p12file</code> Specifies a repository from which a certificate and private key is extracted. <code>-k out_key</code> Specifies a repository that receives a extracted private key. <code>-l id</code> Specifies the value for the <code>LocalKeyId</code> that will be used in the new certificate and key files. <code>-t out_trust</code> Specifies a file for receiving an extracted trust certificate. <code>-v</code> Displays a verbose description of the split to sdtout.						
EXIT STATUS	0 Successful operation. >0 An error occurred.

NAME	wanbootutil – manage keys and certificates for WAN booting
SYNOPSIS	wanbootutil [keygen] [<i>option_specific_arguments</i>] wanbootutil [keymgmt] [<i>option_specific_arguments</i>] wanbootutil [p12split] [<i>option_specific_arguments</i>]
DESCRIPTION	The wanbootutil command creates and manages WANboot encryption and hashing keys and manipulates PKCS #12 files for use by WAN boot. wanbootutil has three subcommands, each covered in a separate man page: wanboot_keygen(1M) Generates encryption and hashing keys. wanboot_keymgmt(1M) Inserts and extracts keys from WAN boot key repositories. wanboot_p12split(1M) Splits a PKCS #12 file into separate certificate and key files for use by WAN boot.
OPTIONS	The options supported for wanbootutil are the use of keygen, keymgmt, or p12split. The options for these subcommands are described in their respective man pages.
EXAMPLES	EXAMPLE 1 Generate a 3DES Client Key <pre># wanbootutil keygen -c -o net=129.148.174.0,cid=010003BA0E6A36,type=3des</pre> EXAMPLE 2 Insert an RSA Private Client Key <pre>wanbootutil keymgmt -i -k keyfile \ -s /etc/netboot/129.148.174.0/010003BA0E6A36/keystore -o type=rsa</pre> EXAMPLE 3 Split a PKCS #12 File into Certificate and Key Components <pre># wanbootutil p12split -i p12file -c out_cert -k out_key</pre>
EXIT STATUS	0 Successful operation. non-zero An error occurred. Writes an appropriate error message to standard error.

NAME	wbemadmin – start Sun WBEM User Manager				
SYNOPSIS	<code>/usr/sadm/bin/wbemadmin</code>				
DESCRIPTION	The <code>wbemadmin</code> utility starts Sun WBEM User Manager, a graphical user interface that enables you to add and delete authorized WBEM users and to set their access privileges. Use this application to manage access to groups of managed resources, such as disks and installed software, in the Solaris operating environment. The <code>wbemadmin</code> utility allows you to perform the following tasks: <table><tr><td>Manage user access rights</td><td>Use the <code>wbemadmin</code> utility to add, delete, or modify an individual user’s access rights to a namespace on a WBEM-enabled system.</td></tr><tr><td>Manage namespace access rights</td><td>Use the <code>wbemadmin</code> utility to add, delete, or modify access rights for all users to a namespace.</td></tr></table> The Sun WBEM User Manager displays a Login dialog box. You must log in as root or a user with write access to the <code>root\security</code> namespace to grant access rights to users. By default, Solaris users have guest privileges, which grants them read access to the default namespaces. Managed resources are described using a standard information model called Common Information Model (CIM). A CIM object is a computer representation, or model, of a managed resource, such as a printer, disk drive, or CPU. CIM objects can be shared by any WBEM-enabled system, device, or application. CIM objects are grouped into meaningful collections called schema. One or more schemas can be stored in directory-like structures called namespaces. All programming operations are performed within a namespace. Two namespaces are created by default during installation: ■ <code>root\cimv2</code> — Contains the default CIM classes that represent objects on your system. ■ <code>root\security</code> — Contains the security classes used by the CIM Object Manager to represent access rights for users and namespaces. When a WBEM client application connects to the CIM Object Manager in a particular namespace, all subsequent operations occur within that namespace. When you connect to a namespace, you can access the classes and instances in that namespace (if they exist) and in any namespaces contained in that namespace. When a WBEM client application accesses CIM data, the WBEM system validates the user’s login information on the current host. By default, a validated WBEM user is granted read access to the Common Information Model (CIM) Schema. The CIM Schema describes managed objects on your system in a standard format that all WBEM-enabled systems and applications can interpret.	Manage user access rights	Use the <code>wbemadmin</code> utility to add, delete, or modify an individual user’s access rights to a namespace on a WBEM-enabled system.	Manage namespace access rights	Use the <code>wbemadmin</code> utility to add, delete, or modify access rights for all users to a namespace.
Manage user access rights	Use the <code>wbemadmin</code> utility to add, delete, or modify an individual user’s access rights to a namespace on a WBEM-enabled system.				
Manage namespace access rights	Use the <code>wbemadmin</code> utility to add, delete, or modify access rights for all users to a namespace.				

wbemadmin(1M)

You can set access privileges on individual namespaces or for a user-namespace combination. When you add a user and select a namespace, by default the user is granted read access to CIM objects in the selected namespace. An effective way to combine user and namespace access rights is to first restrict access to a namespace. Then grant individual users read, read and write, or write access to that namespace.

You cannot set access rights on individual managed objects. However you can set access rights for all managed objects in a namespace as well as on a per-user basis.

If you log in to the root account, you can set the following types of access to CIM objects:

- **Read Only** — Allows read-only access to CIM Schema objects. Users with this privilege can retrieve instances and classes, but cannot create, delete, or modify CIM objects.
- **Read/Write** — Allows full read, write, and delete access to all CIM classes and instances.
- **Write** — Allows write and delete, but not read access to all CIM classes and instances.
- **None** — Allows no access to CIM classes and instances.

Context help is displayed in the left side of the wbemadmin dialog boxes. When you click on a field, the help content changes to describe the selected field. No context help is available on the main User Manager window.

The wbemadmin security administration tool updates the following Java classes in the root\security namespace:

- **Solaris_UserAcl** — Updated when access rights are granted or changed for a user.
- **Solaris_namespaceAcl** — Updated when access rights are granted or changed for a namespace.

USAGE The wbemadmin utility is not the tool for a distributed environment. It is used for local administration on the machine on which the CIM Object Manager is running.

EXIT STATUS The wbemadmin utility terminates with exit status 0.

WARNING The root\security namespace stores access privileges. If you grant other users access to the root\security namespace, those users can grant themselves or other users rights to all other namespaces.

wbemconfig(1M)

NAME	wbemconfig – convert a JavaSpaces datastore to the newer Reliable Log datastore format				
SYNOPSIS	<code>/usr/sadm/lib/wbem/wbemconfig convert</code>				
DESCRIPTION	A Reliable Log directory is created that contains the converted data. This directory is named <code>/var/sadm/wbem/logr</code>. The <code>convert</code> argument is the only supported option of this command. You should only run this command after stopping WBEM (CIM Object Manager) with the <code>init.wbem stop</code> command. Otherwise your data may be corrupted. This command successfully converts any proprietary custom MOFs you have created in the datastore, but not any CIM or Solaris MOFs you have modified. These will be destroyed. To recompile any modified CIM or Solaris MOFs into the new datastore, run the <code>mofcomp</code> command on the MOF files containing the class definitions. Because the <code>wbemconfig convert</code> command invokes the JVM (Java Virtual Machine) to perform conversion of the JavaSpaces datastore, you must be running the same version of the JVM as when the original JavaSpaces storage was created. After the <code>wbemconfig convert</code> command is completed, you can change to any version of the JVM you want. To see what version of the JVM you are running, issue the <code>java -version</code> command.				
OPTIONS	The following options are supported: <table><tr><td><code>convert</code></td><td>Convert a JavaSpaces datastore to the newer Reliable Log datastore format.</td></tr></table>	<code>convert</code>	Convert a JavaSpaces datastore to the newer Reliable Log datastore format.		
<code>convert</code>	Convert a JavaSpaces datastore to the newer Reliable Log datastore format.

NAME	wbemlogviewer – start WBEM Log Viewer
SYNOPSIS	<code>/usr/sadm/bin/wbemlogviewer</code>
DESCRIPTION	The <code>wbemlogviewer</code> utility starts the WBEM Log Viewer graphical user interface, which enables administrators to view and maintain log records created by WBEM clients and providers. The WBEM Log Viewer displays a Login dialog box. You must log in as root or a user with write access to the <code>root\cimv2</code> namespace to view and maintain log files. Namespaces are described in <code>wbemadmin(1M)</code>. Log events can have three severity levels. ■ Errors ■ Warnings ■ Informational The WBEM log file is created in the <code>/var/sadm/wbem/log</code> directory, with the name <code>wbem_log</code>. The first time the log file is backed up, it is renamed <code>wbem_log.1</code>, and a new <code>wbem_log</code> file is created. Each succeeding time the <code>wbem_log</code> file is backed up, the file extension number of each backup log file is increased by 1, and the oldest backup log file is removed <i>if</i> the limit, which in turn is specified in the log service settings, on the number of logfiles is exceeded. Older backup files have higher file extension numbers than more recent backup files. The log file is renamed with a <code>.1</code> file extension and saved when one of the following two conditions occur: ■ The current file reaches the specified file size limit. ■ A WBEM client application uses the <code>clearLog()</code> method in the <code>Solaris_LogService</code> class to clear the current log file. ■ A WBEM client application uses the <code>clearLog()</code> method in the <code>Solaris_LogService</code> class to clear the current log file. ■ A user chooses Action->Back Up Now in the Log Viewer application. Help is displayed in the left panel of each dialog box. Context help is not displayed in the main Log Viewer window.
USAGE	The WBEM Log Viewer is not the tool for a distributed environment. It is used for local administration. The WBEM Log Viewer allows you to perform the following tasks: View the logs Set properties of log files Click Action->Log File Settings to specify log file parameters and the log file directory. Back up a log file Click Action->Back Up Now to back up and close the current log file and start a new log file.

wbemlogviewer(1M)

Open historical log files	Click Action->Open Log File to open a backed-up log file.
Delete an old log file	Open the file and then click Action->Delete Log File. You can only delete backed-up log files.
View log record details	Double-click a log entry or click View->Log Entry Details to display the details of a log record.
Sort the logs	Click View->Sort By to sort displayed entries. You can also click any column heading to sort the list. By default, the log entries are displayed in reverse chronological order (new logs first).

EXIT STATUS The `wbemlogviewer` utility terminates with exit status 0.

FILES `/var/sadm/wbem/log/wbem_log`
WBEM log file

NAME	whodo – who is doing what
SYNOPSIS	/usr/sbin/whodo [-h] [-l] [<i>user</i>]
DESCRIPTION	The whodo command produces formatted and dated output from information in the /var/adm/utmpx and /proc/pid files. The display is headed by the date, time, and machine name. For each user logged in, device name, user-ID and login time is shown, followed by a list of active processes associated with the user-ID. The list includes the device name, process-ID, CPU minutes and seconds used, and process name. If <i>user</i> is specified, output is restricted to all sessions pertaining to that user.
OPTIONS	The following options are supported: -h Suppress the heading. -l Produce a long form of output. The fields displayed are: the user's login name, the name of the tty the user is on, the time of day the user logged in (in <i>hours:minutes</i>), the idle time — that is, the time since the user last typed anything (in <i>hours:minutes</i>), the CPU time used by all processes and their children on that terminal (in <i>minutes:seconds</i>), the CPU time used by the currently active processes (in <i>minutes:seconds</i>), and the name and arguments of the current process.
EXAMPLES	EXAMPLE 1 Using the whodo Command The command: <pre>example% whodo</pre> produces a display like this: <pre>Tue Mar 12 15:48:03 1985 bailey tty09 mcn 8:51 tty09 28158 0:29 sh tty52 bdr 15:23 tty52 21688 0:05 sh tty52 22788 0:01 whodo tty52 22017 0:03 vi tty52 22549 0:01 sh xtl62 lee 10:20 tty08 6748 0:01 layers xtl62 6751 0:01 sh xtl63 6761 0:05 sh tty08 6536 0:05 sh</pre>

whodo(1M)

EXAMPLE 1 Using the whodo Command (Continued)

**ENVIRONMENT
VARIABLES**

If any of the LC_* variables (LC_CTYPE, LC_MESSAGES, LC_TIME, LC_COLLATE, LC_NUMERIC, and LC_MONETARY) (see environ(5)) are not set in the environment, the operational behavior of whodo(1) for each corresponding locale category is determined by the value of the LANG environment variable. If LC_ALL is set, its contents are used to override both the LANG and the other LC_* variables. If none of the above variables is set in the environment, the "C" (U.S. style) locale determines how whodo behaves.

LC_CTYPE	Determines how whodo handles characters. When LC_CTYPE is set to a valid value, whodo can display and handle text and filenames containing valid characters for that locale. The whodo command can display and handle Extended Unix code (EUC) characters where any individual character can be 1, 2, or 3 bytes wide. whodo can also handle EUC characters of 1, 2, or more column widths. In the "C" locale, only characters from ISO 8859-1 are valid.
LC_MESSAGES	Determines how diagnostic and informative messages are presented. This includes the language and style of the messages, and the correct form of affirmative and negative responses. In the "C" locale, the messages are presented in the default form found in the program itself (in most cases, U.S. English).
LC_TIME	Determines how whodo handles date and time formats. In the "C" locale, date and time handling follow the U.S. rules.

EXIT STATUS

The following exit values are returned:

0	Successful completion.
non-zero	An error occurred.

FILES

/etc/passwd	System password file
/var/adm/utmpx	User access and administration information
/proc/pid

NAME	wracct – write extended accounting records for active processes and tasks
SYNOPSIS	<code>/usr/sbin/wracct [-t <i>record_type</i>] <i>i id_list</i> {<i>task</i> <i>process</i>}</code>
DESCRIPTION	The wracct utility allows the administrator to invoke the extended accounting system, if active, to write intermediate records representing the resource usage of a selected set of processes or tasks. For tasks, a <i>record_type</i> option is also supported, allowing the administrator to request the writing of a partial record, which leaves the current task usage unchanged, or an interval record, which resets the task usage to zero for that system task, with respect to the extended accounting subsystem. If interval records are used, the total task usage is the sum of all interval records and the final record written at the task's completion. If partial records are used, the completion record reflects the total resource usage.
OPTIONS	The following options are supported: <code>-i <i>id_list</i></code> Select the IDs of the tasks or processes to write records for. Specify <i>id_list</i> as a comma- or space-separated list of IDs, presented as a single argument. For some shells, this requires appropriate quoting of the argument. <code>-t <i>record_type</i></code> Select type of record to write for the selected task or process. For tasks, <i>record_type</i> can be <i>partial</i> or <i>interval</i>. <i>partial</i> is the the default type, and the only type available for process records.
OPERANDS	The following operands are supported: <i>process</i> Treat the given ID as a process ID for the purposes of constructing and writing an extended accounting record. <i>task</i> Treat the given ID as a task ID for the purposes of constructing and writing an extended accounting record.
EXAMPLES	EXAMPLE 1 Writing a partial record Write a partial record for all active <code>sendmail</code> processes. <pre># /usr/sbin/wracct -i "`pgrep sendmail`" process</pre> EXAMPLE 2 Writing an interval record Write an interval record for the task with ID 182. <pre># /usr/sbin/wracct -t interval -i 182 task</pre>
EXIT STATUS	The following exit values are returned: 0 Successful completion. 1 An error occurred. 2 Invalid command line options were specified.

wracct(1M)

3 Pertinent components of extended accounting facility are not active.

FILES /var/adm/exacct/task

/var/adm/exacct/proc Extended accounting data files.

NAME	wrsmconf – manage WCI RSM controller configurations
SYNOPSIS	<pre> /usr/platform/sun4u/sbin/wrsmconf create -c controller_id -f config_file wrsmconf initial -f config_file [-c controller_id] wrsmconf remove [-c controller_id] wrsmconf topology [-c controller_id] wrsmconf dump -c controller_id -f config_file </pre>
DESCRIPTION	wrsmconf provides a means to create, install, retrieve, and remove configurations for WCI remote shared memory (RSM) controllers.
OPTIONS	The following options are supported: create -c controller_id -f config_file Create a set of per-node configurations for the specified controller and store them to the file <i>config_file</i>. The created file contains a per-node configuration for each node specified in the input for the specified controller. The file has a checksum on it and cannot be modified directly. This file can be used in a <i>wrsmconf initial</i> call on each node to install the node's configuration into the local driver. A list of nodes and WCI devices connected to those nodes is read from standard input. For each connected pair of links, specify the nodename (uname -n), safari port id, and link number on both sides of the connection. The format of the information looks like this: <pre> <nodename>.<wrsm-portid>.<linkno>=<nodename>.<wrsm-portid>.<linkno> <nodename>.<wrsm-portid>.<linkno>=<nodename>.<wrsm-portid>.<linkno> </pre> This interface is intended for installing configurations for testing (such as for SunVTS). Only direct-connect, non-striped configurations for 1 to 3 nodes can be specified. FM node ids and RSM hardware addresses are assigned to the specified nodes contiguously and in order starting from 0. initial -f config_file [-c controller_id] Install the configuration for the local node stored in the file <i>config_file</i> into the driver as the initial configuration for the specified controller. This command fails under the following circumstances: ■ If <i>controller_id</i> is specified and the configuration in the file is not for the specified controller. ■ If the file does not contain a valid configuration for the local node or if the checksum in the file shows it has been modified. ■ If a configuration has already been installed for the controller. If this happens, use <i>wrsmconf remove</i> to remove the existing configuration. remove [-c controller_id] Disable communication through the installed configuration for all controllers or the specified controller and remove the configuration(s) from the driver.

wrsmconf(1M)

`topology -c controller_id`

For each installed controller (or for the specified controller), print to stdout the set of nodes this controller is configured to reach, including the nodename, FM node id, and RSM hardware address for each node. The following is example output:

FM Node ID	Node Name	Controller Instance	Controller HW Addr
0	hpc00	0	101
0	hpc00	1	333
1	hpc01	0	102
1	hpc01	1	54
1	hpc01	2	34
2	hpc03	0	103
2	hpc03	1	103
2	hpc03	2	103

`dump -c controller-id -f config_file`

Fetch the installed configuration for the specified controller from the driver and store it into the file *config_file* along with a checksum to protect the data. This configuration can later be installed with the command `wrsmconf initial`.

EXIT STATUS This command returns 0 on successful completion, and a non-zero value if an error occurred.

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWwrsm

SEE ALSO `kstat(1M)`, `wrsmstat(1M)`, `attributes(5)`

NAME	wrmstat – report WCI RSM driver statistics
SYNOPSIS	<pre> /usr/platform/sun4u/sbin/wrmstat controller [-c controller_id] wrmstat wrsm [-i wrsm_instance_num] [-v] wrmstat route [-c controller_id] [-h node_hostname] wrmstat set [-i wrsm_instance_num] -c cmmu -s start -e end </pre>
DESCRIPTION	The wrmstat command provides statistics on remote shared memory (RSM) controllers, routes to nodes, and WCI interfaces managed by the WCI RSM driver (wrsm). It also provides an interface for setting extended performance counter control registers that constrain the wrsm counters available through busstat(1M).
OPTIONS	The following options are supported: controller [-c controller_id] Displays information describing the state of the specified controller, or of all controllers if none is specified. The following is sample output: <pre> \$ wrmstat controller -c 5 Controller 5 ----- Controller state: up Local RSM Hardware address: 0x4 Exported segments: 0 # published: 0 # connections: 0 total bound memory: 0 Imported segments: 0 Send Queues: 0 Registered Handlers: 0 Assigned WCIs: 4 Available WCIs: 2 </pre> wrsm [-i wrsm_instance_num] [-v] Displays information describing the state of the specified RSM WCI, or of all RSM WCIs if none is specified. The following is sample output: <pre> \$ wrmstat wrsm -i 2 WCI instance 2 ----- Portid: 5 Controller ID: 0 Config Version: 5 Link Error Shutdown Trigger: 40000 Link #0 is not present. Link #1 Link Enabled: yes Link State: up Remote RSM HW addr: 1 Remote wnode ID: 1 Remote link num: 1 Remote WCI port ID: 3 Error takedowns: 0 Bad Config takedowns: 0 Failed bringups: 0 Total link errors: 0 Maximum link errors: 0 Average link errors: 0 Auto shutdown enabled: yes Link #2 is not present. </pre> If you specify the -v option, the following additional information is displayed:

wrsmstat(1M)

```
Cluster Error Count:      0
Uncorrectable SRAM ECC error:  no
Maximum SRAM ECC errors:  0
Average SRAM ECC errors:  0
```

route [*-c controller_id*] [*-h nodename*]

Displays the route to the specified node through the specified controller. If no node is specified, displays the routes to all nodes. If no controller is specified, displays the specified node's route through all controllers. If neither is specified, displays the routes to all nodes through all controllers. The following is sample output:

```
$ wrsmstat -c 3 -h fred
Controller 3 - Route to fred
-----
Config Version: 1
FM node id: 0x345543
RSM hardware address: 0x9
Route Changes: 3
Route Type: Passthrough
Number of WCIs: 2
Stripes: 4
WCI #0
  Port ID: 3
  Instance: 0
  Num of hops: 2
  Num of links: 2
    link# 1, first hop RSM HW addr: 0x4
    link# 2, first hop RSM HW addr: 0x2
WCI #1
  Port ID: 13
  Instance: 1
  Num of hops: 2
  Num of links: 2
    link# 0, first hop RSM HW addr: 0x4
    link# 2, first hop RSM HW addr: 0x2
```

set [*-i wrsm_instance_num*] *-c cmmu -s <start> -e <end>*

For the specified WCI (or for each RSM WCI if none specified), configure the specified range of CMMU entries so that transactions through them are counted by *wrsm* busstat kstats. Each call will cause transactions to be counted through the new ranges of cmmu entries in addition to the previously specified ranges. To count transactions through all CMMUs, specify a start value of 0 and end value of 0. To clear all ranges (and not count transactions through any cmmu entries), specify a start value of 0 and end value of -1.

EXIT STATUS This command returns 0 on successful completion, and a non-zero value if an error occurred.

wrsmstat(1M)

SEE ALSO busstat(1M), kstat(1M), wrsmconf(1M), attributes(5)

xntpd(1M)

NAME	xntpd – Network Time Protocol daemon																
SYNOPSIS	<pre>/usr/lib/inet/xntpd [-aAbdm] [-c <i>conffile</i>] [-e <i>authdelay</i>] [-f <i>driftfile</i>] [-k <i>keyfile</i>] [-l <i>logfile</i>] [-p <i>pidfile</i>] [-r <i>broadcastdelay</i>] [-s <i>statsdir</i>] [-t <i>trustedkey</i>] [-v <i>variable</i>] [-V <i>variable</i>]</pre>																
DESCRIPTION	xntpd is a daemon which sets and maintains a UNIX system time-of-day in agreement with Internet standard time servers. xntpd is a complete implementation of the Network Time Protocol (NTP) version 3 standard, as defined by <i>RFC 1305</i>. It also retains compatibility with version 1 and 2 servers as defined by <i>RFC 1059</i> and <i>RFC 1119</i>, respectively. The computations done in the protocol and clock adjustment code are carried out with high precision and with attention to the details which might introduce systematic bias into the computations. This is done to try to maintain an accuracy suitable for synchronizing with even the most precise external time source. Ordinarily, xntpd reads its configuration from a configuration file at startup time. The default configuration file name is <code>/etc/inet/ntp.conf</code>, although this may be overridden from the command line. It is also possible to specify a working, although limited, xntpd configuration entirely on the command line, obviating the need for a configuration file. This may be particularly appropriate when xntpd is to be configured as a broadcast or multicast client, with all peers being determined by listening to broadcasts at run time. Through the use of the <code>ntpql(1M)</code> program, various internal xntpd variables can be displayed and configuration options altered while the daemon is running. The daemon can operate in any of several modes, including symmetric active/passive, client/server and broadcast/multicast. A broadcast/multicast client can automatically discover remote servers, compute one-way delay correction factors and configure itself automatically. This makes it possible to deploy a fleet of workstations without specifying a configuration file or configuration details specific to its environment.																
OPTIONS	The following command line arguments are understood by xntpd. See <i>Configuration Commands</i> for a more complete functional description: <table><tr><td>-a</td><td>Run in authentication mode.</td></tr><tr><td>-A</td><td>Disable authentication mode.</td></tr><tr><td>-b</td><td>Listen for broadcast NTP and sync to this if available.</td></tr><tr><td>-c <i>conffile</i></td><td>Specify an alternate configuration file.</td></tr><tr><td>-d</td><td>Specify debugging mode. This flag may occur multiple times, with each occurrence indicating greater detail of display.</td></tr><tr><td>-e <i>authdelay</i></td><td>Specify the time (in seconds) it takes to compute the NTP encryption field on this computer.</td></tr><tr><td>-f <i>driftfile</i></td><td>Specify the location of the drift file.</td></tr><tr><td>-k <i>keyfile</i></td><td>Specify the location of the file which contains the NTP authentication keys.</td></tr></table>	-a	Run in authentication mode.	-A	Disable authentication mode.	-b	Listen for broadcast NTP and sync to this if available.	-c <i>conffile</i>	Specify an alternate configuration file.	-d	Specify debugging mode. This flag may occur multiple times, with each occurrence indicating greater detail of display.	-e <i>authdelay</i>	Specify the time (in seconds) it takes to compute the NTP encryption field on this computer.	-f <i>driftfile</i>	Specify the location of the drift file.	-k <i>keyfile</i>	Specify the location of the file which contains the NTP authentication keys.
-a	Run in authentication mode.																
-A	Disable authentication mode.																
-b	Listen for broadcast NTP and sync to this if available.																
-c <i>conffile</i>	Specify an alternate configuration file.																
-d	Specify debugging mode. This flag may occur multiple times, with each occurrence indicating greater detail of display.																
-e <i>authdelay</i>	Specify the time (in seconds) it takes to compute the NTP encryption field on this computer.																
-f <i>driftfile</i>	Specify the location of the drift file.																
-k <i>keyfile</i>	Specify the location of the file which contains the NTP authentication keys.																

<code>-l logfile</code>	Specify a log file instead of logging to syslog.
<code>-m</code>	Listen for multicast messages and synchronize to them if available (requires multicast kernel).
<code>-p pidfile</code>	Specify the name of the file to record the daemon's process id.
<code>-r broadcast</code>	Ordinarily, the daemon automatically compensates for the network delay between the broadcast/multicast server and the client; if the calibration procedure fails, use the specified default delay (in seconds).
<code>-s statsdir</code>	Specify the directory to be used for creating statistics files.
<code>-t trustedkey</code>	Add a key number to the trusted key list.
<code>-v variable</code>	Add a system variable.
<code>-V variable</code>	Add a system variable listed by default.

USAGE xntpd's configuration file format is similar to other Unix configuration files. Comments begin with a '#' character and extend to the end of the line. Blank lines are ignored. Configuration commands consist of an initial keyword followed by a list of arguments, separated by whitespace. Some arguments may be optional. These commands may not be continued over multiple lines. Arguments may be host names, host addresses written in dotted-decimal, integers, floating point numbers (when specifying times in seconds) and text strings.

Configuration Commands In the following descriptions, optional arguments are delimited by '[]', while alternatives are separated by '|'. The first three commands specify various time servers to be used and time services to be provided.

`peer host_address [ key # ] [ version # ] [ prefer ]`

Specifies that the local server is to operate in "symmetric active" mode with the remote server *host_address* named in the command. In this mode, the local server can be synchronized to the remote server. In addition, the remote server can be synchronized by the local server. This is useful in a network of servers where, depending on various failure scenarios, either the local or remote server host may be the better source of time. The `peer` command, and the `server` and `broadcast` commands that follow, can take the following arguments:

<code>key</code>	Indicates that all packets sent to the address are to include authentication fields, encrypted using the specified key number. The range of this number is that of an unsigned 32 bit integer. By default, an encryption field is not included.
<code>version</code>	Specifies the version number to be used for outgoing NTP packets. Versions 1, 2, and 3 are the choices; version 3 is the default.
<code>prefer</code>	Marks the host as a preferred host. This host will be preferred for synchronization over other comparable hosts.

`server host_address [ key # ] [ version fl# ]`

`[ prefer ] [ mode fl# ] server`

Specifies that the local server is to operate in “client” mode with the remote server named in the command. In this mode the local server can be synchronized to the remote server, but the remote server can never be synchronized to the local server.

`broadcast host_address [ key # ] [ version # ] [ ttl # ]`

Specifies that the local server is to operate in “broadcast” mode where the local server sends periodic broadcast messages to a client population at the broadcast/multicast address named in the command. Ordinarily, this specification applies only to the local server operating as a transmitter. For operation as a broadcast client, see `broadcastclient` or `multicastclient` commands elsewhere in this document. In broadcast mode the *host_address* is usually the broadcast address on a local network or a multicast address assigned to NTP. The IANA has assigned the network, 224.0.1.1 to NTP. This is presently the only network that should be used. The following option is used only with the broadcast mode:

`ttl` Specifies the time-to-live (TTL) to use on multicast packets. Selection of the proper value, which defaults to 127, is something of a black art and must be coordinated with the network administrator(s).

`broadcastclient`

Directs the local server to listen for broadcast messages on the local network, in order to discover other servers on the same subnet. Upon hearing a broadcast message for the first time, the local server measures the nominal network delay using a brief client/server exchange with the remote server. Then the server enters the “broadcastclient” mode, in which it listens for and synchronizes to succeeding broadcast messages. In order to avoid accidental or malicious disruption in this mode, both the local and remote servers must operate using authentication, with the same trusted key and key identifier.

`multicastclient`

`[ IP address ... ]` Used in the same way as the `broadcastclient` command, but operates using IP multicasting. Support for this command requires the use of authentication. If one or more IP addresses are given, the server joins the respective multicast group(s). If none are given, the IP address assigned to NTP (224.0.1.1) is assumed.

`driftfile filename`

Specifies the name of the file used to record the frequency offset of the local clock oscillator. If the file exists, it is read at startup in order to set the initial frequency offset. Then the file is updated once per hour with the current offset computed by the daemon. If the file does not exist or this command is not given, the initial frequency offset is assumed to be zero. In this case, it may take some hours for the frequency to stabilize and the residual timing errors to subside. The file contains a single floating point value equal to the offset in parts-per-million (ppm). The file is updated by first writing the current drift value into a temporary file and then using `rename(2)` to replace the old version. This implies that `xntpd` must have write

permission for the directory the drift file is located in, and that file system links, symbolic or otherwise, should probably be avoided.

```
enable auth | bclient | pll | monitor | stats [ ... ]
disable auth | bclient | pll | monitor | stats
[ ... ]
```

Provides a way to enable or disable various server options. To do so, execute a two word command, where the first word is `enable` or `disable` and the second is the flag. Flags not mentioned are unaffected. Flags that can be changed are described below, along with their default values.

Flag	Default	Description
auth	disable	Causes the server to synchronize with unconfigured peers only if the peer has been correctly authenticated using a trusted key and key identifier.
bclient	disable	Causes the server to listen for a message from a broadcast or multicast server. After this occurs, an association is automatically instantiated for that server. default for this flag is disable (off).
pll	enable	Enables the server to adjust its local clock. If not set, the local clock free-runs at its intrinsic time and frequency offset. This flag is useful in case the local clock is controlled by some other device or protocol and NTP is used only to provide synchronization to other clients.
monitor	disable	Enables the monitoring facility (see elsewhere).
stats	enable	Enables statistics facility filegen (see Monitoring Commands below).

```
slewalways [ yes|no ]
```

Force xntpd to always slew the time.

Authentication Commands

`keys filename` Specifies the name of a file which contains the encryption keys and key identifiers used by xntpd when operating in authenticated mode. The format of this file is described later in this document.

`trustedkey` # [# . . .] Specifies the encryption key identifiers which are trusted for the purposes of authenticating peers suitable for synchronization. The authentication procedures require that both the local and remote servers share the same key and key identifier, defined to be used for this purpose. However, different keys can be used with different servers. The arguments are 32 bit unsigned integers. Note, however, that key 0 is

xntpd(1M)

Access Control Commands

	fixed and globally known. If meaningful authentication is to be performed, the 0 key should not be trusted.				
controlkey #	Specifies the key identifier to use with the ntpq(1M) program, which is useful to diagnose and repair problems that affect xntpd operation. The operation of the ntpq program and xntpd conform to those specified in <i>RFC 1305</i> . Requests from a remote ntpq program which affect the state of the local server must be authenticated. This requires that both the remote program and local server share a common key and key identifier. The argument to this command is a 32 bit unsigned integer. If no controlkey command is included in the configuration file, or if the keys don't match. These requests are ignored.				
restrictaddress [mask numeric_mask] [flag] [...]	xntpd implements a general purpose address-and-mask based restriction list. The list is sorted by IP address and mask, and the list is searched in this order for matches, with the last match found defining the restriction flags associated with the incoming packets. The source address of incoming packets is used for the match, with the 32 bit address being logically and'ed with the mask associated with the restriction entry and then compared with the entry's address (which has also been and'ed with the mask) to look for a match. The "mask" argument defaults to 255.255.255.255, meaning that the "address" is treated as the address of an individual host. A default entry (address 0.0.0.0, mask 0.0.0.0) is always included and, given the sort algorithm, is always the first entry in the list. Note that, while "address" is normally given in dotted-quad format, the text string "default", with no mask option, may be used to indicate the default entry. In the current implementation, flags always restrict access, i.e., an entry with no flags indicates that free access to the server is to be given. The flags are not orthogonal, in that more restrictive flags often make less restrictive ones redundant. The flags can generally be classed into two categories, those which restrict time service and those which restrict informational queries and attempts to do run time reconfiguration of the server. One or more of the following flags may be specified: <table><tr><td>ignore</td><td>Ignore all packets from hosts which match this entry. If this flag is specified neither queries nor time server polls will be responded to.</td></tr><tr><td>noquery</td><td>Ignore all NTP mode 7 packets (i.e., information queries and</td></tr></table>	ignore	Ignore all packets from hosts which match this entry. If this flag is specified neither queries nor time server polls will be responded to.	noquery	Ignore all NTP mode 7 packets (i.e., information queries and
ignore	Ignore all packets from hosts which match this entry. If this flag is specified neither queries nor time server polls will be responded to.				
noquery	Ignore all NTP mode 7 packets (i.e., information queries and				

	configuration requests) from the source. Time service is not affected.
nomodify	Ignore all NTP mode 7 packets which attempt to modify the state of the server (i.e., run time reconfiguration). Queries which return information are permitted.
notrap	Decline to provide mode 6 control message trap service to matching hosts. The trap service is a subsystem of the mode 6 control message protocol which is intended for use by remote event logging programs.
lowpriotrap	Declare traps set by matching hosts to be low priority. The number of traps a server can maintain is limited. The current limit is 3. Traps are usually assigned on a first come, first served basis, with later trap requestors being denied service. This flag modifies the assignment algorithm by allowing low priority traps to be overridden by later requests for normal priority traps.
noserve	Ignore NTP packets whose mode is other than 7. In effect, time service is denied, though queries may still be permitted.
nopeer	Provide stateless time service to polling hosts, but do not allocate peer memory resources to these hosts even if they otherwise might be considered useful as future synchronization partners.
notrust	Treat these hosts normally in other respects, but never use them as synchronization sources.
limited	These hosts are subject to a limitation on number of clients from the same net that will be accepted. Net in this context refers

to the IP notion of net (class A, class B, class C, etc.). Only the first *client_limit* hosts that have shown up at the server and that have been active during the last *client_limit_period* seconds are accepted. Requests from other clients from the same net are rejected. Only time request packets are taken into account. "Private", "control", and "broadcast" packets are not subject to client limitation and therefore do not contribute to client count. A history of clients is kept using the monitoring capability of xntpd. Thus, monitoring is active as long as there is a restriction entry with the *limited* flag. The default value for *client_limit* is 3. The default value for *client_limit_period* is 3600 seconds. Currently both variables are not runtime configurable.

ntpport

This is actually a match algorithm modifier, rather than a restriction flag. Its presence causes the restriction entry to be matched only if the source port in the packet is the standard NTP UDP port (123). Both *ntpport* and *non-ntpport* may be specified. The *ntpport* is considered more specific and is sorted later in the list.

Default restriction list entries, with the flags, *ignore*, *ntpport*, for each of the local host's interface addresses are inserted into the table at startup to prevent the server from attempting to synchronize to its own time. A default entry is also always present, though if it is otherwise unconfigured no flags are associated with the default entry (i.e., everything besides your own NTP server is unrestricted).

xntpd(1M)

The restriction facility was added to allow the current access policies of the time servers running on the NSF net backbone to be implemented with xntpd as well. This facility may be useful for keeping unwanted or broken remote time servers from affecting your own. However, it should not be considered an alternative to the standard NTP authentication facility.

`clientlimit limit` Sets *client_limit* to *limit*; allows configuration of client limitation policy. This variable defines the number of clients from the same network that are allowed to use the server.

`clientperiod period` Sets *client_limit_period*; allows configuration of client limitation policy. This variable specifies the number of seconds after which a client is considered inactive and thus no longer is counted for client limit restriction.

Monitoring Commands

`statsdir /directory path/`

Indicates the full path of a directory where statistics files should be created (see below). This keyword allows the (otherwise constant) *filegen* filename prefix to be modified for file generation sets used for handling statistics logs (see *filegen* statement below).

`statistics name...`

Enables writing of statistics records. Currently, three kinds of statistics are supported. Each type is described below by giving its *name*, a sample line of data, and an explanation of each field:

`loopstats`

enables recording of loop filter statistics information. Each update of the local clock outputs a line of the following form to the file generation set named "loopstats":

```
48773 10847.650 0.0001307 17.3478 2
```

Field No.

Description

1

The date (Modified Julian day)

xntpd(1M)

2	The time (seconds and fraction past UTC midnight)
3	Time offset in seconds
4	Frequency offset in parts-per-million
5	Time constant of the clock-discipline algorithm at each update of the clock
peerstats enables recording of peer statistics information. This includes statistics records of all peers of a NTP server and of the 1-pps signal, where present and configured. Each valid update appends a line similar to the one below, to the current element of a file generation set named "peerstats":	
<pre>48773 10847.650 127.127.4.1 9714 -0.001605 \ 0.00000 0.00142</pre>	
Field No. Description	
1	The date (Modified Julian Day)
2	The time (seconds and fraction past UTC midnight)
3	The peer address in dotted-quad notation
4	peer status. The status field is encoded in hex in the format described in Appendix B.2.2 of the NTP specification, <i>RFC 1305</i> .
5	Offset in seconds
6	Delay in seconds
7	Dispersion in seconds
clockstats enables recording of clock driver statistics information. Each update received from a clock driver outputs a line of the following form to the file generation set named "clockstats":	
<pre>49213 525.624 127.127.4.1 93 226 \ 00:08:29.606 D</pre>	
Field No. Description	

- 1 The date (Modified Julian Day)
- 2 The time (seconds and fraction past UTC midnight)
- 3 The clock address in dotted-quad notation
- 4 The last timecode received from the clock in decoded ASCII format, where meaningful

In some clock drivers a good deal of additional information can be gathered and displayed as well.

Statistic files are managed using file generation sets (see `filegen` below). The information obtained by enabling statistics recording allows analysis of temporal properties of a `xntpd` server. It is usually only useful to primary servers or maybe main campus servers.

```
filegen name [ file filename ] [ type typename ] [ flag flagval ]
[ link | noline ] [ enable | disable ]
```

Configures setting of generation file set *name*. Generation file sets provide a means for handling files that are continuously growing during the lifetime of a server. Server statistics are a typical example for such files. Generation file sets provide access to a set of files used to store the actual data. At any time at most one element of the set is being written to. The *type* given specifies when and how data will be directed to a new element of the set. This way, information stored in elements of a file set that are currently unused are available for administrative operations without the risk of disturbing the operation of `xntpd`. (Most important: they can be removed to free space for new data produced.)

Filenames of set members are built from three elements:

prefix

This is a constant filename path. It is not subject to modifications via the `filegen` statement. It is defined by the server, usually specified as a compile time constant. It may, however, be configurable for individual file generation sets via other commands. For example, the prefix used with “loopstats” and “peerstats” filegens can be configured using the `statsdir` statement explained above.

filename

This string is directly concatenated to the *prefix* mentioned above (no intervening ‘/’ (slash)). This can be modified using the `file` argument to the `filegen` statement. No ‘.’ elements are allowed in this component to prevent filenames referring to parts outside the filesystem hierarchy denoted by *prefix*.

suffix

This part reflects individual elements of a file set. It is generated according to the type of a file set as explained below. A file generation set is characterized by

its type. The following types are supported:

none	The file set is actually a single plain file.
pid	One element of file set is used per incarnation of a xntpd server. This type does not perform any changes to file set members during runtime. However it provides an easy way of separating files belonging to different xntpd server incarnations. The set member filename is built by appending a '.' (dot) to concatenated <i>prefix</i> and <i>filename</i> strings, and appending the decimal representation of the process id of the xntpd server process.
day	One file generation set element is created per day. The term <i>day</i> is based on UTC . A day is defined as the period between 00:00 and 24:00 UTC . The file set member suffix consists of a '.' (dot) and a day specification in the form, <i>YYYYMMDD</i> . <i>YYYY</i> is a 4 digit year number (e.g., 1992). <i>MM</i> is a two digit month number. <i>DD</i> is a two digit day number. Thus, all information written at December 10th, 1992 would end up in a file named, <i>PrefixFilename.19921210</i> .
week	Any file set member contains data related to a certain week of a year. The term <i>week</i> is defined by computing "day of year" modulo 7. Elements of such a file generation set are distinguished by appending the following suffix to the file set filename base: a dot, a four digit year number, the letter 'W', and a two digit week number. For example, information from January, 5th 1992 would end up in a file with suffix ".1992W1".
month	One generation file set element is generated per month. The file name suffix consists of a dot, a four digit year number, and a two digit month.
year	One generation file element is generated per year. The filename suffix consists of a dot and a 4 digit year number.
age	This type of file generation sets changes to a new element of the file set every 24 hours of server operation. The filename suffix consists of a dot, the letter 'a', and an eight digit number. This number is taken to be the number of seconds the server is running at the start of the corresponding 24 hour period.

Information is only written to a file generation set when this set is enabled. Output is prevented by specifying, *disabled*.

It is convenient to be able to access the current element of a file generation set by a fixed name. This feature is enabled by specifying *link* and disabled using *nolink*. If *link* is specified, a hard link from the current file set element to a file without suffix is created. When there is already a file with this name and the number of links of this file is one, it is renamed appending a dot, the letter, 'C', and the pid of the xntpd server process. When the number of links is greater than one, the file is unlinked. This allows the current file to be accessed by a constant name.

**Miscellaneous
Commands**

`broadcastdelay` *seconds*

The broadcast and multicast modes require a special calibration to determine the network delay between the local and remote servers. Ordinarily, this is done automatically by the initial protocol exchanges between the local and remote servers. In some cases, the calibration procedure may fail due to, for example, network or server access controls. This command specifies the default delay to be used under these circumstances. Typically (for Ethernet), a number between 0.003 and 0.007 is appropriate for *seconds*. When this command is not used, the default is 0.004 seconds.

`trap` *host_address* [*port* *port_number*]
[*interface* *interface_address*]

Configures a trap receiver at the given *host_address* and *port_number* for sending messages with the specified local *interface_address*. If the port number is unspecified, a value of 18447 is used. If the interface address is not specified, the message is sent with the source address of the local interface the message is sent through. On a multi-homed host, the interface used may change with routing changes.

C information from the server in a log file. While such monitor programs may also request their own trap dynamically, configuring a trap receiver ensures that no messages are lost when the server is started.

`setvar` *variable* [*default*]

This command adds an additional system variable. Variables like this can be used to distribute additional information such as the access policy. If the variable of the form, *variable_name=value* is followed by the *default* keyword, the variable will be listed as one of the default system variables (see the `ntpq(1M)` command). Additional variables serve informational purposes only. They can be listed; but they are not related to the protocol. The known protocol variables always override any variables defined via the `setvar` mechanism.

Three special variables contain the names of all variable of the same group. *sys_var_list* holds the names of all system variables. *peer_var_list* holds the names of all peer variables. And *clock_var_list* hold the names of the reference clock variables.

`monitor` [*yes* | *no*]

`authenticate` [*yes* | *no*]

These commands have been superseded by the `enable` and `disable` commands. They are listed here for historical purposes.

`logconfig` *configkeyword*

Controls the amount of output written to syslog or the logfile. By default all output is turned on. *configkeyword* is formed by concatenating the message class with the event class. It is permissible to use the prefix, *all*, instead of a message class. A message class may also be followed by the keyword, *all*, meaning to enable/disable all of the respective message class. All *configkeywords* can be prefixed with the symbols, '=', '+' and '-'. Here, '=' sets the syslogmask, '+' adds messages, and '-' removes messages. Syslog messages can be controlled in four classes: *sys*, *peer*, *clock*, *sync*. Within these classes four types of messages can be controlled. Each is described below, along with its *configkeyword*:

xntpd(1M)

Authentication Key File Format

Configkeyword
Message type

info
Informational messages control configuration information.

events
Event messages control logging of events (reachability, synchronization, alarm conditions).

statistics
Statistical messages control statistical output.

status
Status messages describe mainly the synchronization status.

A minimal log configuration might look like this:

```
logconfig =syncstatus +sysevents
```

A configuration like this lists, just the synchronization state of xntpd and the major system events. For a simple reference server, the following minimum message configuration could be useful:

```
logconfig =syncall +clockall
```

This configuration lists all clock information and synchronization information. All other events and messages about peers, system events and so on, is suppressed.

The NTP standard specifies an extension to allow verification of the authenticity of received NTP packets, and to provide an indication of authenticity in outgoing packets. This is implemented in xntpd using the DES or MD5 algorithms to compute a digital signature, or message-digest. The specification allows any one of possibly 4 billion keys, numbered with 32 bit key identifiers, to be used to authenticate an association. The servers involved in an association must agree on the key and key identifier used to authenticate their data. However they must each learn the key and key identifier independently. In the case of DES, the keys are 56 bits long with, depending on type, a parity check on each byte. In the case of MD5, the keys are 64 bits (8 bytes). xntpd reads its keys from a file specified using the -k command line option or the keys statement in the configuration file. While key number 0 is fixed by the NTP standard (as 56 zero bits) and may not be changed, one or more of the keys numbered 1 through 15 may be arbitrarily set in the keys file.

The key file uses the same comment conventions as the configuration file. Key entries use a fixed format of the form, *keyno type key*. Here, *keyno* is a positive integer, *type* is a single character which defines the format the key is given in, and *key* is the key itself.

The *key* may be given in one of several different formats, controlled by the *type* character. The different key types, and corresponding formats, are described below:

Key: S

Format: A 64 bit hexadecimal number in DES format

In this format, the high order 7 bits of each octet are used to form the 56 bit key while the low order bit of each octet is given a value such that odd parity is maintained for the octet. Leading zeroes must be specified (i.e., the key must be exactly 16 hex digits long) and odd parity must be maintained. Hence a zero key, in standard format, would be given as: 0101010101010101.

Key: N

Format: A 64 bit hexadecimal number in NTP format

This format is the same as the DES format except the bits in each octet have been rotated one bit right so that the parity bit is now the high order bit of the octet. Leading zeroes must be specified and odd parity must be maintained. A zero key in NTP format would be specified as: 8080808080808080.

Key: A

Format: A 1-to-8 character ASCII string

A key is formed from this by using the lower order 7 bits of the ASCII representation of each character in the string. Zeroes are added on the right when necessary to form a full width 56 bit key.

Key: M

Format: A 1-to-8 character ASCII string, using the MD5 authentication scheme.

Note that both the keys and the authentication schemes (DES or MD5) must be identical between a set of peers sharing the same key number.

Primary Clock Support

xntpd has been built to be compatible with all supported types of reference clocks. A reference clock is generally (though not always) a radio timecode receiver which is synchronized to a source of standard time such as the services offered by the NRC in Canada and NIST in the U.S. The interface between the computer and the timecode receiver is device dependent and will vary, but it is often a serial port.

For the purposes of configuration, xntpd treats reference clocks in a manner analogous to normal NTP peers as much as possible. Reference clocks are referred to by address, much as a normal peer is. However, an invalid IP address is used to distinguish them from normal peers. Reference clock addresses are of the form *127.127.t.u* where *t* is an integer denoting the clock type and *u* indicates the type-specific unit number. Reference clocks are configured using a *server* statement in the configuration file where the *host_address* is the clock address. The *key*, *version* and *ttl* options are not used for reference clock support. Some reference clocks require a *mode* option to further specify their operation. The *prefer* option can be useful to persuade the server to cherish a reference clock with somewhat more

enthusiasm than other reference clocks or peers. Clock addresses may generally be used anywhere in the configuration file that a normal IP address can be used. For example, they can be used in `restrict` statements, although such use would normally be considered strange.

Reference clock support provides the `fudge` command, which can be used to configure reference clocks in special ways. The generic format that applies to this command is,

```
fudge 127.127.t.u [ time1 secs ] [ time2 secs ] \
    [ stratum int ] [ refid int ] \
    [ flag1 0|1 ] [ flag2 0|1 ] [ flag3 0|1 ] [ flag4 0|1 ]
```

with options described as follows:

time1

time2

Are specified in fixed point seconds and used in some clock drivers as calibration constants. By convention, and unless indicated otherwise, *time1* is used as a calibration constant to adjust the nominal time offset of a particular clock to agree with an external standard, such as a precision PPS signal. The specified offset is in addition to the propagation delay provided by other means, such as internal DIP switches.

stratum

Is a number in the range zero to 15 and is used to assign a nonstandard operating stratum to the clock.

refid

Is an ASCII string in the range one to four characters and is used to assign a nonstandard reference identifier to the clock.

flag1

flag2

flag3

flag4

Are binary flags used for customizing the clock driver. The interpretation of these values, and whether they are used at all, is a function of the needs of the particular clock driver. However, by convention, and unless indicated otherwise, *flag3* invokes the `TIOCSPPS` ioctl, while *flag4* is used to enable recording verbose monitoring data to the clockstats file configured with the `filegen` command.

Ordinarily, the stratum of a reference clock is zero, by default. Since the `xntpd` daemon adds one to the stratum of each peer, a primary server ordinarily displays stratum one. In order to provide engineered backups, it is often useful to specify the reference clock stratum as greater than zero. The `stratum` option is used for this purpose. Also, in cases involving both a reference clock and a 1-pps discipline signal, it is useful to specify the reference clock identifier as other than the default, depending on the driver. The `refid` option is used for this purpose. Except where noted, these options apply to all clock drivers.

xntpd on Unix machines currently supports several different types of clock hardware. It also supports a special pseudo-clock used for backup or when no other clock source is available. In the case of most of the clock drivers, support for a 1-pps precision timing signal is available as described in the README file in the `./doc` directory of the xntp3 program distribution. The clock drivers, and the addresses used to configure them, are described in the file, `README.refclocks`, in the `doc` directory of the current program distribution.

Variables Most variables used by the NTP protocol can be examined with `ntpq` (mode 6 messages). Currently very few variables can be modified via mode 6 messages. These variables are either created with the `setvar` directive or the leap warning variables. The leap warning bits that can be set in the `leapwarning` variable (up to one month ahead). Both, the `leapwarning` and in the `leapindication` variable, have a slightly different encoding than the usual `leap` bits interpretation:

00	The daemon passes the leap bits of its synchronization source (usual mode of operation).
01/10	A leap second is added/deleted (operator forced leap second).
11	Leap information from the synchronization source is ignored (thus LEAP_NOWARNING is passed on).

FILES

<code>/etc/inet/ntp.conf</code>	Default name of the configuration file
<code>/etc/ntp/ntp.drift</code>	Conventional name of the drift file
<code>/etc/inet/ntp.keys</code>	Conventional name of the key file
<code>/etc/inet/ntp.server</code>	Sample server configuration file

xntpd(1M)

NAME	xntpd – special NTP query program												
SYNOPSIS	xntpd [-ilnps] [-c <i>command</i>] [<i>host</i>] [...]												
DESCRIPTION	xntpd queries the xntpd daemon about its current state and requests changes in that state. You can run xntpd in interactive mode or in controlled using command line arguments. Extensive state and statistics information is available through the xntpd interface. In addition, nearly all the configuration options which can be specified at start up using xntpd's configuration file may also be specified at run time using xntpd. If one or more request options is included on the command line when xntpd is executed, each of the requests is sent to the NTP servers running on each of the hosts given as command line arguments, or on the local host by default. If no request options are given, xntpd attempts to read commands from the standard input and execute these on the NTP server running on the first host specified on the command line, again defaulting to the local host when no other host is specified. xntpd prompts for commands if the standard input is a terminal device. xntpd uses NTP mode 7 packets to communicate with the NTP server, and can be used to query any compatible server on the network which permits it. As NTP is a UDP protocol, this communication is somewhat unreliable, especially over large distances. xntpd does not attempt to re-transmit requests, and times requests out if the remote host is not heard from within a suitable timeout time. The operation of xntpd is specific to the particular implementation of the xntpd daemon. You can expect xntpd to work only with this and maybe some previous versions of the daemon. Requests from a remote xntpd program that affect the state of the local server must be authenticated. This requires that both the remote program and local server share a common key and key identifier.												
OPTIONS	xntpd reads interactive format commands from the standard input. If you specify the -c, -l, -p or -s option, the specified queries are sent to the hosts immediately. The following command line options are supported: <table><tr><td>-c <i>command</i> . . .</td><td>Add <i>command</i> to the list of commands to execute on the specified hosts. <i>command</i> is interpreted as an interactive format command.</td></tr><tr><td></td><td>Multiple -c options may be specified.</td></tr><tr><td>-i</td><td>Force xntpd to operate in interactive mode.</td></tr><tr><td></td><td>Prompts are written to the standard output. Commands are read from the standard input.</td></tr><tr><td>-l</td><td>Obtain a list of peers which are known to the servers.</td></tr><tr><td></td><td>This option is equivalent to -c listpeers. See listpeers in Control Message Commands.</td></tr></table>	-c <i>command</i> . . .	Add <i>command</i> to the list of commands to execute on the specified hosts. <i>command</i> is interpreted as an interactive format command.		Multiple -c options may be specified.	-i	Force xntpd to operate in interactive mode.		Prompts are written to the standard output. Commands are read from the standard input.	-l	Obtain a list of peers which are known to the servers.		This option is equivalent to -c listpeers. See listpeers in Control Message Commands.
-c <i>command</i> . . .	Add <i>command</i> to the list of commands to execute on the specified hosts. <i>command</i> is interpreted as an interactive format command.												
	Multiple -c options may be specified.												
-i	Force xntpd to operate in interactive mode.												
	Prompts are written to the standard output. Commands are read from the standard input.												
-l	Obtain a list of peers which are known to the servers.												
	This option is equivalent to -c listpeers. See listpeers in Control Message Commands.												

	-n	Output all host addresses in dotted-quad numeric format rather than converting to the canonical host names.
	-p	Print a list of the peers known to the server as well as a summary of their state. This option is equivalent to -c peers. See peers in Control Message Commands.
	-s	Print a list of the peers known to the server as well as a summary of their state, but in a slightly different format than the -p option. This option is equivalent to -c dmpeers. See dmpeers in Control Message Commands.
OPERANDS	The following operands are supported:	
USAGE		
Interactive Commands	The interactive commands consist of a keyword (<i>command_keyword</i>) followed by zero to four arguments. You need to enter only enough characters of the <i>command_keyword</i> to uniquely identify it. The output of an interactive command is sent to the standard output by default. You can send the output of an interactive command to a file by appending a <, followed by a file name, to the command line. A number of interactive format commands are executed entirely within the xntpd program itself and do not result in NTP mode. The following interactive commands are supported:	
	? [<i>command_keyword</i>]	Without an argument, print a list of ntpq command keywords. If <i>command_keyword</i> is specified, print function and usage information about the <i>command_keyword</i> .
	delay <i>milliseconds</i>	Specify a time interval to add to timestamps included in requests which require authentication. This enables (unreliable) server reconfiguration over long delay network paths or between machines whose clocks are unsynchronized. Because the server no longer requires timestamps in authenticated requests, this command may be obsolete.
	help [<i>command_keyword</i>]	Without an argument, print a list of ntpq command keywords. If <i>command_keyword</i> is specified, print function and usage information about the <i>command_keyword</i> .

xntpd(1M)

	host <i>hostname</i>	Set the host (<i>hostname</i>) to which future queries are sent. Specify <i>hostname</i> as a host name or a numeric address.
	hostnames [yes no]	Print hostnames or numeric addresses in information displays. Specify <i>yes</i> to print host names. Specify <i>no</i> to print numeric addresses. The default is <i>yes</i> , unless the <i>-n</i> command line option is specified.
	keyid <i>keyid</i>	Enable specification of a key number (<i>keyid</i>) to authenticate configuration requests. <i>keyid</i> must correspond to a key number the server has been configured to use for this purpose.
	passwd	Prompt user to enter a password to authenticate configuration requests. The password is not displayed , and must correspond to the key configured for use by the NTP server for this purpose. If the password does not correspond to the key configured for use by the NTP server, requests are not successful.
	quit	Exit xntpd.
	timeout <i>milliseconds</i>	Specify a timeout period for responses to server queries. The default is approximately 8000 milliseconds. As xntpd retries each query once after a timeout, the total waiting time for a timeout is twice the timeout value set.
	Control Message Commands	Query commands result in NTP mode 7 packets containing requests for information being sent to the server. These control message commands are read-only commands in that they make no modification of the server configuration state. The following control message commands are supported:
	clkbug	Obtain debugging information for a reference clock driver. This information is provided only by some clock drivers.
	clockinfo <i>clock_peer_address</i> [...]	Obtain and print information concerning a peer clock.

The values obtained provide information on the setting of fudge factors and other clock performance information.

dmpeers

Obtain a list of peers for which the sserver is maintaining state, along with a summary of that state.

The peer summary list is identical to the output of the `peers` command, except for the character in the leftmost column. Characters only appear beside peers which were included in the final stage of the clock selection algorithm. A `.` indicates that this peer was cast off in the falseticker detection, while a `+` indicates that the peer made it through. A `*` denotes the peer with which the server is currently synchronizing.

iostats

Print statistics counters maintained in the input-output module.

kerninfo

Obtain and print kernel phase-lock loop operating parameters.

This information is available only if the kernel has been specially modified for a precision timekeeping function.

listpeers

Obtain and print a brief list of the peers for which the server is maintaining state.

These should include all configured peer associations as well as those peers whose stratum is such that they are considered by the server to be possible future synchronization candidates.

loopinfo [oneline | multiline]

Print the values of selected loop filter variables.

The loop filter is the part of NTP which deals with adjusting the local system clock.

The `oneline` and `multiline` options specify the format in which this information is printed. `multiline` is the default.

The `offset` is the last offset given to the loop filter by the packet processing code. The `frequency` is the frequency error of the local clock in parts-per-million (ppm). The `time_const` controls the stiffness of the phase-lock loop and thus the speed at which it can adapt to oscillator drift. The `watchdog` timer value is the number of seconds which have elapsed since the last sample offset was given to the loop filter.

memstats

Print statistics counters related to memory allocation code.

monlist [version]

Obtain and print traffic counts collected and maintained by the monitor facility. The version number should not normally need to be specified.

xntpd(1M)

peers

Obtain a list of peers for which the server is maintaining state, along with a summary of that state.

The following summary information is included:

- Address of the remote peer.
- Local interface address. If a local address has yet to be determined it is 0.0.0.0.
- Stratum of the remote peer. A stratum of 16 indicates the remote peer is unsynchronized.
- Polling interval, in seconds.
- Reachability register, in octal.
- Current estimated delay, offset and dispersion of the peer, in seconds.
- Mode in which the peer entry is operating.

This is represented by the character in the left margin. A + denotes symmetric active, a - indicates symmetric passive, a = means the remote server is being polled in client mode, a ^ indicates that the server is broadcasting to this address, a ~ denotes that the remote peer is sending broadcasts and a * marks the peer the server is currently synchronizing to.

- Host.

This field may contain a host name, an IP address, a reference clock implementation name with its parameter or REFCLK (implementation number, parameter). On hostnames no only IP-addresses is displayed.

stats *peer_address* [...]

Show the per-peer statistic counters associated with the specified peers.

reslist

Obtain and print the server's restriction list.

Generally, this list is printed in sorted order.

showpeer *peer_address* [...]

Show a detailed display of the current peer variables for one or more peers. Most of these values are described in the NTP Version 2 specification.

sysinfo

Print a variety of system state variables that are related to the local server.

The output from `sysinfo` is described in NTP Version 3 specification, RFC-1305. All except the last four lines are described in the NTP Version 3 specification, RFC-1305.

The `system flags` show various system flags, some of which can be set and cleared by the `enable` and `disable` configuration commands, respectively. These are the `auth`, `bclient`, `monitor`, `pll`, `pps` and `stats` flags. See the `xntpd`

**Runtime
Configuration
Requests**

documentation for the meaning of these flags. There are two additional flags which are read only, the `kernel_pll` and `kernel_pps`. These flags indicate the synchronization status when the precision time kernel modifications are in use. The `kernel_pll` indicates that the local clock is being disciplined by the kernel, while the `kernel_pps` indicates the kernel discipline is provided by the PPS signal. The `stability` is the residual frequency error remaining after the system frequency correction is applied and is intended for maintenance and debugging. In most architectures, this value initially decreases from as high as 500 ppm to a nominal value in the range .01 to 0.1 ppm. If it remains high for some time after starting the daemon, something may be wrong with the local clock, or the value of the `kernel` variable tick may be incorrect. The `broadcastdelay` shows the default broadcast delay, as set by the `broadcastdelay` configuration command. The `authdelay` shows the default authentication delay, as set by the `authdelay` configuration command.

sysstats

Print statistics counters maintained in the protocol module.

timerstats

Print statistics counters maintained in the timer/event queue support code.

The server authenticates all requests that cause state changes in the server. The server uses a configured NTP key to accomplish this. This facility can also be disabled by the server by not configuring a key).

You must make the key number and the corresponding key known to `xntpd`. Use the `keyid` or `passwd` commands to do so.

The `passwd` command prompts users for a password to use as the encryption key. It also prompts automatically for both the key number and password the first time a command which would result in an authenticated request to the server is given. Authentication provides verification that the requester has permission to make such changes. It also gives an extra degree of protection against transmission errors.

Authenticated requests always include a time stamp in the packet data. The time stamp is included in the computation of the authentication code. This timestamp is compared by the server to its receive time stamp. If the time stamps differ by more than a small amount the request is rejected.

Time stamps are rejected for two reasons. First, it makes simple replay attacks on the server, by someone who might be able to overhear traffic on your LAN, much more difficult. Second, it makes it more difficult to request configuration changes to your server from topologically remote hosts.

While the reconfiguration facility works well with a server on the local host, and may work adequately between time-synchronized hosts on the same LAN, it works very poorly for more distant hosts. If reasonable passwords are chosen, care is taken in the distribution and protection of keys and appropriate source address restrictions are applied, the run time reconfiguration facility should provide an adequate level of security.

xntpd(1M)

The following commands make authenticated requests.

addpeer *peer_address* [*keyid*] [*version*] [*prefer*]

Add a configured peer association at the given address and operating in symmetric active mode. An existing association with the same peer may be deleted when this command is executed, or may simply be converted to conform to the new configuration, as appropriate.

If the optional *keyid* is a non-zero integer, all outgoing packets to the remote server will have an authentication field attached encrypted with this key. If the *keyid* is 0 or omitted, no authentication is done.

Specify *version* as 1, 2 or 3. The default is 3.

The *prefer* keyword indicates a preferred peer. This keyword is used primarily for clock synchronisation if possible. The preferred peer also determines the validity of the PPS signal - if the preferred peer is suitable for synchronisation so is the PPS signal.

addserver *peer_address* [*keyid*] [*version*] [*prefer*]

Identical to the **addpeer** command, except that the operating mode is client.

addtrap [*address* [*port*] [*interface*]

Set a trap for asynchronous messages.

authinfo

Return information concerning the authentication module, including known keys and counts of encryptions and decryptions which have been done.

broadcast *peer_address* [*keyid*] [*version*] [*prefer*]

Identical to the **addpeer** command, except that the operating mode is broadcast. In this case a valid key identifier and key are required. The *peer_address* parameter can be the broadcast address of the local network or a multicast group address assigned to NTP. If a multicast address, a multicast-capable kernel is required.

clrtrap [*address* [*port*] [*interface*]

Clear a trap for asynchronous messages.

delrestrict *address mask* [*ntpport*]

Delete the matching entry from the restrict list.

fudge *peer_address* [*time1*] [*time2*] [*stratum*] [*refid*]

Provide a way to set certain data for a reference clock.

readkeys

Cause the current set of authentication keys to be purged and a new set to be obtained by re-reading the keys file. The keys file must have been specified in the **xntpd** configuration file. This enables encryption keys to be changed without restarting the server.

restrict *address mask flag [flag]*

This command operates in the same way as the restrict configuration file commands of xntpd.

reset

Clear the statistics counters in various modules of the server.

traps

Display the traps set in the server.

trustkey *keyid [...]*

untrustkey *keyid [...]*

These commands operate in the same way as the trustedkey and untrustkey configuration file commands of xntpd.

unconfig *peer_address [...]*

Cause the configured bit to be removed from the specified peers. In many cases this causes the peer association to be deleted. When appropriate, however, the association may persist in an unconfigured mode if the remote peer is willing to continue on in this fashion.

unrestrict *address mask flag [flag]*

Unrestrict the matching entry from the restrict list.

ypbind(1M)

NAME	ypbind – NIS binder process		
SYNOPSIS	<code>/usr/lib/netsvc/yp/ypbind</code> [-broadcast -ypset -ypsetme]		
DESCRIPTION	NIS provides a simple network lookup service consisting of databases and processes. The databases are stored at the machine that runs an NIS server process. The programmatic interface to NIS is described in <code>ypclnt(3NSL)</code>. Administrative tools are described in <code>ypinit(1M)</code>, <code>ypwhich(1)</code>, and <code>ypset(1M)</code>. Tools to see the contents of NIS maps are described in <code>ypcat(1)</code>, and <code>ypmatch(1)</code>. <code>ypbind</code> is a daemon process that is activated at system startup time from the startup script <code>/etc/init.d/rpc</code>. By default, it is invoked as <code>ypbind -broadcast</code>. <code>ypbind</code> runs on all client machines that are set up to use NIS. See <code>sysidtool(1M)</code>. The function of <code>ypbind</code> is to remember information that lets all NIS client processes on a node communicate with some NIS server process. <code>ypbind</code> must run on every machine which has NIS client processes. The NIS server may or may not be running on the same node, but must be running somewhere on the network. If the NIS server is a NIS+ server in NIS (YP) compatibility mode, see the NOTES section of the <code>ypfiles(4)</code> man page for more information. The information <code>ypbind</code> remembers is called a <i>binding</i> — the association of a domain name with a NIS server. The process of binding is driven by client requests. As a request for an unbound domain comes in, if started with the <code>-broadcast</code> option, the <code>ypbind</code> process broadcasts on the net trying to find an NIS server, either a <code>ypserv</code> process serving the domain or an <code>rpc.nisd</code> process in "YP-compatibility mode" serving NIS+ directory with name the same as (case sensitive) the domain in the client request. Since the binding is established by broadcasting, there must be at least one NIS server on the net. If started without the <code>-broadcast</code> option, <code>ypbind</code> process steps through the list of NIS servers that was created by <code>ypinit -c</code> for the requested domain. There must be an NIS server process on at least one of the hosts in the NIS servers file. All the hosts in the NIS servers file must be listed in either the <code>/etc/hosts</code> or <code>/etc/inet/ipnodes</code> files along with their IP addresses. Once a domain is bound by <code>ypbind</code>, that same binding is given to every client process on the node. The <code>ypbind</code> process on the local node or a remote node may be queried for the binding of a particular domain by using the <code>ypwhich(1)</code> command. If <code>ypbind</code> is unable to speak to the NIS server process it is bound to, it marks the domain as unbound, tells the client process that the domain is unbound, and tries to bind the domain once again. Requests received for an unbound domain will wait until the requested domain is bound. In general, a bound domain is marked as unbound when the node running the NIS server crashes or gets overloaded. In such a case, <code>ypbind</code> will try to bind to another NIS server using the process described above. <code>ypbind</code> also accepts requests to set its binding for a particular domain. The request is usually generated by the <code>ypset(1M)</code> command. In order for <code>ypset</code> to work, <code>ypbind</code> must have been invoked with flags <code>-ypset</code> or <code>-ypsetme</code>.		
OPTIONS	<table><tr><td><code>-broadcast</code></td><td>Send a broadcast datagram using UDP/IP that requests the information needed to bind to a specific NIS server.</td></tr></table>	<code>-broadcast</code>	Send a broadcast datagram using UDP/IP that requests the information needed to bind to a specific NIS server.
<code>-broadcast</code>	Send a broadcast datagram using UDP/IP that requests the information needed to bind to a specific NIS server.		

ypbind(1M)

This option is analogous to ypbind with no options in earlier Sun releases and is recommended for ease of use.

-ypset

Allow users from any remote machine to change the binding by means of the ypset command. By default, no one can change the binding. This option is insecure.

-ypsetme

Only allow root on the local machine to change the binding to a desired server by means of the ypset command. ypbind can verify the caller is indeed a root user by accepting such requests only on the loopback transport. By default, no external process can change the binding.

FILES /var/yp/binding/*ypdomain*/ypservers
/etc/inet/hosts
/etc/inet/ipnodes

ATTRIBUTES See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWnisu

SEE ALSO ypcat(1), ypmatch(1), ypwhich(1), ifconfig(1M), rpc.nisd(1M), ypinit(1M), ypset(1M), ypclnt(3NSL), hosts(4), ipnodes(4), ypfiles(4), attributes(5)

NOTES ypbind supports multiple domains. The ypbind process can maintain bindings to several domains and their servers, the default domain is the one specified by the domainname(1M) command at startup time.

The -broadcast option works only on the UDP transport. It is insecure since it trusts "any" machine on the net that responds to the broadcast request and poses itself as an NIS server.

ypinit(1M)

NAME	ypinit – set up NIS client						
SYNOPSIS	/usr/sbin/ypinit [-c] [-m] [-s <i>master_server</i>]						
DESCRIPTION	ypinit can be used to set up an NIS client system. You must be the superuser to run this command. This script need not be used at all if ypbind(1M) is started with the -broadcast option (it is invoked with this option from the start up script /etc/init.d/rpc). Normally, ypinit is run only once after installing the system. It may be run whenever a new NIS server is added to the network or an existing one is decommissioned. ypinit prompts for a list of NIS servers to bind the client to; this list should be ordered from the closest to the furthest server. Each of these NIS servers must be listed in either the /etc/hosts or the /etc/inet/ipnodes file along with its IP address. ypinit stores the list in file /var/yp/binding/domain/ypservers. This file is used by ypbind when run without the -broadcast option.						
OPTIONS	<table><tr><td>-c</td><td>Set up a ypclient system.</td></tr><tr><td>-m</td><td>Build a master ypserver data base.</td></tr><tr><td>-s <i>master_server</i></td><td>Slave data base. <i>master_server</i> must be the same master configured in the YP maps and returned by the ypwhich -m command.</td></tr></table>	-c	Set up a ypclient system.	-m	Build a master ypserver data base.	-s <i>master_server</i>	Slave data base. <i>master_server</i> must be the same master configured in the YP maps and returned by the ypwhich -m command.
-c	Set up a ypclient system.						
-m	Build a master ypserver data base.						
-s <i>master_server</i>	Slave data base. <i>master_server</i> must be the same master configured in the YP maps and returned by the ypwhich -m command.						
FILES	/etc/hosts /etc/inet/ipnodes /var/yp/binding/domain/ypservers						
ATTRIBUTES	See attributes(5) for descriptions of the following attributes: <table><thead><tr><th>ATTRIBUTE TYPE</th><th>ATTRIBUTE VALUE</th></tr></thead><tbody><tr><td>Availability</td><td>SUNWnisu</td></tr></tbody></table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	Availability	SUNWnisu		
ATTRIBUTE TYPE	ATTRIBUTE VALUE						
Availability	SUNWnisu						
SEE ALSO	ypbind(1M), sysinfo(2), hosts(4), ipnodes(4), attributes(5)						
BUGS	ypinit sets up the list of NIS servers only for the current domain on the system when it is run, that is, the domain returned by the SI_SRPC_DOMAIN command to sysinfo(2). Care should be taken to ensure that this is the same as the desired domain for NIS client processes.						

NAME	ypmake – rebuild NIS database								
SYNOPSIS	<code>cd /var/yp ; make [map]</code>								
DESCRIPTION	The file called Makefile in /var/yp is used by make(1) to build the Network Information Service (NIS) database. With no arguments, make creates dbm databases for any NIS maps that are out-of-date, and then executes yppush(1M) to notify slave databases that there has been a change. If you supply a <i>map</i> on the command line, make will update that map only. Typing <code>make passwd</code> will create and yppush the password database (assuming it is out of date). Likewise, <code>make ipnodes</code> and <code>make networks</code> will create and yppush the ipnodes and network files, <code>\$(INETDIR)/ipnodes</code> and <code>\$(DIR)/networks</code>. There are four special variables used by make: <code>DIR</code>, which gives the directory of the source files; <code>NOPUSH</code>, which when non-null inhibits doing a yppush of the new database files; <code>INETDIR</code>, which gives the directory of the ipnodes source file; and <code>DOM</code>, which is used to construct a domain other than the master's default domain. The default for <code>DIR</code> is <code>/etc</code>, and the default for <code>INETDIR</code> is <code>/etc/inet</code>. The default for <code>NOPUSH</code> is the null string. Refer to ypfiles(4) and ypserv(1M) for an overview of the NIS service. If a NIS to LDAP (N2L) configuration file, <code>/var/yp/NISLDAPmapping</code>, is present, the NIS server components run in N2L mode. In N2L mode, the server components use a new set of map files with an LDAP-prefix, based on the LDAP DIT. In N2L mode, authoritative NIS information is obtained from the DIT. The NIS source files and ypmake have no role, and they should not be used. If ypmake is accidentally run, then the server components will detect this, and will log a warning message. For additional information, see ypfiles(4).								
FILES	<table> <tr> <td><code>/var/yp</code></td><td>Directory containing NIS configuration files.</td></tr> <tr> <td><code>/etc/inet/hosts</code></td><td>System hosts file.</td></tr> <tr> <td><code>/etc/inet</code></td><td>Default directory for ipnodes source file.</td></tr> <tr> <td><code>/etc</code></td><td>Default directory for source files other than ipnodes.</td></tr> </table>	<code>/var/yp</code>	Directory containing NIS configuration files.	<code>/etc/inet/hosts</code>	System hosts file.	<code>/etc/inet</code>	Default directory for ipnodes source file.	<code>/etc</code>	Default directory for source files other than ipnodes.
<code>/var/yp</code>	Directory containing NIS configuration files.								
<code>/etc/inet/hosts</code>	System hosts file.								
<code>/etc/inet</code>	Default directory for ipnodes source file.								
<code>/etc</code>	Default directory for source files other than ipnodes.

ypmake(1M)

NOTES | The NIS makefile is only used when running the `ypserv(1M)` server to provide NIS services. If these are being provided by the NIS+ server running in NIS compatibility mode, see `rpc.nisd(1M)`; this makefile is not relevant. See `ypfiles(4)` for more details.

The Network Information Service (NIS) was formerly known as Sun Yellow Pages (YP). The functionality of the two remains the same. Only the name has changed. The name Yellow Pages is a registered trademark in the United Kingdom of British Telecommunications plc, and may not be used without permission.

NAME	ypmap2src – convert NIS maps to NIS source files
SYNOPSIS	<code>/usr/lib/netsvc/yp/ypmap2src [-t] [[-c <i>custom-map-name</i>] ...] [-d <i>domain</i>] -o <i>output-directory</i> [[<i>source-file</i>] ...]</code>
DESCRIPTION	Use the <code>ypmap2src</code> utility to convert standard NIS maps to approximations of the equivalent NIS source files. This utility functions like the reverse of <code>ypmake(1M)</code>. The primary use for <code>ypmap2src</code> is to convert from a NIS server that uses the NIS to LDAP(N2L) transition mechanism, which does not use NIS source files, to traditional NIS, where source files are required. The <code>ypmap2src</code> utility is also used by NIS administrators who wish to discover the contents of NIS maps for which the sources are not available. Generally, this operation is not necessary. More often, administrators will switch from traditional NIS to N2L in anticipation of the eventual transition to LDAP naming. When this switch is made, authoritative information is moved into the LDAP DIT, and the NIS sources have no further role. N2L supports NIS clients until such time as they can be converted to LDAP, and the NIS service suspended. The <code>ypmap2src</code> utility does not guarantee that the files that are generated are identical to the original NIS source files. Some information might have been thrown away by <code>ypmake</code> and cannot be recovered. N2L also might have updated the maps to reflect changes made by LDAP clients. It is essential that the sources generated are checked to confirm no problems have occurred. Per entry comment fields, from existing source files, are not merged into source files generated by <code>ypmap2src</code>. If a user wishes N2L to maintain comment information, then the <code>NISLDAPmapping</code> configuration file should be modified so that the comment fields are mapped into LDAP. This will ensure that the comments are visible to native LDAP clients and present in the N2L map files. When <code>ypmap2src</code> is run, it will take up-to-date comments from the map file and insert them into the NIS source file generated.
Handling Custom Maps	<code>ypmap2src</code> only knows about the standard NIS maps and standard source to map conversion. If an advanced user has changed these, that is, the user has modified the NIS makefile, the equivalent changes must also be made to the <code>ypmap2src</code> script.
OPTIONS	<code>ypmap2src</code> supports the following options: <code>-c</code> Specifies that <i>custom-map-name</i> should be converted to a source file by running <code>makedbm -u</code> on it. This is a short cut so that simple custom maps can be handled without editing <code>ypmap2src</code>. <code>-d <i>domain-name</i></code> Specifies the domain to convert. The <i>domain-name</i> can be a fully qualified file path, such as <code>/var/yp/a.b.c</code>, or just a domain name, <code>a.b.c</code>. In the latter case, <code>ypmap2src</code> looks in <code>/var/yp</code> for the domain directory.

ypmap2src(1M)

- o dest** Specifies the destination directory for the converted files. A directory other than `/etc` should be specified. The maps generated are copied to the correct location, `/etc`, `/etc/security` or other source directory, as appropriate.
- t** Specifies that traditional NIS maps, without N2L's `LDAP_` prefix, should be converted. By default, maps with the `LDAP_` prefix are converted.

OPERANDS ypmap2src supports the following operands:

- source-file** Lists the standard source files to convert. If this option is not given, then all the standard source files, plus any custom files pecified by the `-c` option, are converted.

NAME	ypoll – return current version of a NIS map at a NIS server host				
SYNOPSIS	/usr/sbin/ypoll [-d <i>ypdomain</i>] [-h <i>host</i>] <i>mapname</i>				
DESCRIPTION	The ypoll command asks a ypserv () process what the order number is, and which host is the master NIS server for the named map.				
OPTIONS	-d <i>ypdomain</i> Use <i>ypdomain</i> instead of the default domain. -h <i>host</i> Ask the ypserv process at <i>host</i> about the map parameters. If <i>host</i> is not specified, the NIS server for the local host is used. That is, the default host is the one returned by ypwhich(1).

yppush(1M)

NAME	yppush – force propagation of changed NIS map				
SYNOPSIS	<code>/usr/lib/netsvc/yp/yppush [-v] [-h <i>host</i>] [-d <i>domain</i>] [-p #<i>parallel-xfrs</i>] <i>mapname</i></code>				
DESCRIPTION	yppush copies a new version of a Network Information Service (NIS) map from the master NIS server to the slave NIS servers. It is normally run only on the master NIS server by the Makefile in <code>/var/yp</code> after the master databases are changed. It first constructs a list of NIS server hosts by reading the NIS <code>ypservers</code> map within the <i>domain</i>. Keys within the <code>ypservers</code> map are the ASCII names of the machines on which the NIS servers run. A “transfer map” request is sent to the NIS server at each host, along with the information needed by the transfer agent (the program that actually moves the map) to call back the yppush. When the attempt has completed (successfully or not), and the transfer agent has sent yppush a status message, the results can be printed to <code>stdout</code>. Messages are also printed when a transfer is not possible, for instance, when the request message is undeliverable, or when the timeout period on responses has expired. Refer to <code>ypfiles(4)</code> and <code>ypserv(1M)</code> for an overview of the NIS service.				
OPTIONS	The following options are supported: <code>-d <i>domain</i></code> Specifies a <i>domain</i>. <code>-h <i>host</i></code> Propagates only to the named <i>host</i>. <code>-p #<i>parallel-xfrs</i></code> Allows the specified number of map transfers to occur in parallel. <code>-v</code> Verbose. This prints messages when each server is called, and for each response. If this flag is omitted, only error messages are printed.				
FILES	<code>/var/yp</code> Directory where NIS configuration files reside. <code>/var/yp/<i>domain</i>/ypservers. {<i>dir</i>, <i>pag</i>}</code> Map containing list of NIS servers to bind to when running in server mode.				
ATTRIBUTES	See <code>attributes(5)</code> for descriptions of the following attributes: <table border="1"> <thead> <tr> <th>ATTRIBUTE TYPE</th><th>ATTRIBUTE VALUE</th></tr> </thead> <tbody> <tr> <td>Availability</td><td>SUNWypu</td></tr> </tbody> </table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	Availability	SUNWypu

- NOTES** The Network Information Service (NIS) was formerly known as Sun Yellow Pages (YP). The functionality of the two remains the same; only the name has changed. The name Yellow Pages is a registered trademark in the United Kingdom of British Telecommunications PLC, and must not be used without permission.
- BUGS** In the current implementation (version 2 NIS protocol), the transfer agent is `ypxfr(1M)`, which is started by the `ypserv` program. If `yppush` detects that it is speaking to a version 1 NIS protocol server, it uses the older protocol, sending a version 1 `YPPROC_GET` request and issues a message to that effect. Unfortunately, there is no way of knowing if or when the map transfer is performed for version 1 servers. `yppush` prints a message saying that an “old-style” message has been sent. The system administrator should later check to see that the transfer has actually taken place.

ypserv(1M)

NAME	ypserv, ypxfrd – NIS server and binder processes		
SYNOPSIS	/usr/lib/netsvc/yp/ypserv [-dv] [-i -I] [-r -R] /usr/lib/netsvc/yp/ypxfrd		
DESCRIPTION	The Network Information Service (NIS) provides a simple network lookup service consisting of databases and processes. The databases are ndbm files in a directory tree rooted at /var/yp. See ndbm(3C). These files are described in ypfiles(4). The processes are /usr/lib/netsvc/yp/ypserv, the NIS database lookup server, and /usr/lib/netsvc/yp/ypbind, the NIS binder. The programmatic interface to the NIS service is described in ypclnt(3NSL). Administrative tools are described in yppoll(1M), yppush(1M), ypset(1M), ypxfr(1M), and ypwhich(1). Tools to see the contents of NIS maps are described in ypcat(1), and ypmatch(1). Database generation and maintenance tools are described in ypinit(1M), ypmake(1M), and makedbm(1M). The ypserv utility is a daemon process typically activated at system startup from /etc/init.d/rpc. Alternatively, you can, as the root user, start NIS services using ypstart(1M) from the command-line. ypserv runs only on NIS server machines with a complete NIS database. You can halt all NIS services using the yptest(1M) command. The ypxfrd utility transfers entire NIS maps in an efficient manner. For systems that use this daemon, map transfers are 10 to 100 times faster, depending on the map. To use this daemon, be sure ypxfrd is running on the master server. See /usr/lib/netsvc/yp/ypstart. ypxfr attempts to use ypxfrd first. If that fails, it prints a warning, then uses the older transfer method. The ypserv daemon's primary function is to look up information in its local database of NIS maps. The operations performed by ypserv are defined for the implementor by the <i>YP Protocol Specification</i>, and for the programmer by the header file <rpcsvc/yp_prot.h>. Communication to and from ypserv is by means of RPC calls. Lookup functions are described in ypclnt(3NSL), and are supplied as C-callable functions in the libnsl(3LIB) library. There are four lookup functions, all of which are performed on a specified map within some NIS domain: yp_match(3NSL), yp_first(3NSL), yp_next(3NSL), and yp_all(3NSL). The yp_match operation takes a key, and returns the associated value. The yp_first operation returns the first key-value pair from the map, and yp_next can be used to enumerate the remainder. yp_all ships the entire map to the requester as the response to a single RPC request. A number of special keys in the DBM files can alter the way in which ypserv operates. The keys of interest are: <table><tr><td>YP_INTERDOMAIN</td><td>The presence of this key causes ypserv to forward to a DNS server host lookups that cannot be satisfied by the DBM files.</td></tr></table>	YP_INTERDOMAIN	The presence of this key causes ypserv to forward to a DNS server host lookups that cannot be satisfied by the DBM files.
YP_INTERDOMAIN	The presence of this key causes ypserv to forward to a DNS server host lookups that cannot be satisfied by the DBM files.		

YP_SECURE	This key causes ypserv to answer only questions coming from clients on reserved ports.
YP_MULTI_hostname	This is a special key in the form, YP_MULTI_hostname addr1,...,addrN. A client looking for <i>hostname</i> receives the closest address.

Two other functions supply information about the map, rather than map entries: `yp_order(3NSL)`, and `yp_master(3NSL)`. In fact, both order number and master name exist in the map as key-value pairs, but the server will not return either through the normal lookup functions. If you examine the map with `makedbm(1M)`, however, they are visible. Other functions are used within the NIS service subsystem itself, and are not of general interest to NIS clients. These functions include `do_you_serve_this_domain?`, `transfer_map`, and `reinitialize_internal_state`.

On start up, ypserv checks for the existence of the NIS to LDAP (N2L) configuration file `/var/yp/NISLDAPmapping`. If it is present then a master server starts in N2L mode. If the file is not present it starts in "traditional" (non N2L) mode. Slave servers always start in traditional mode.

In N2L mode, a new set of map files, with an `LDAP_` prefix, are generated, based on the contents of the LDAP DIT. The old map files, NIS source files and `ypmake(1M)` are not used.

It is possible that `ypmake(1M)` can be accidentally run in N2L mode. If the occurs, the old style map files are overwritten. That the map files are overwritten is harmless. However, any resulting `yppush(1M)` operation will push information based on the DIT rather than the source files. The user may not expect information based on the DIT. ypserv keeps track of the last modification date of the old style map files. If the map files have been updated, a warning is logged that suggests that the user call `yppush` directly instead of `ypmake`.

If a server attempts to run in N2L mode and a LDAP server cannot be contacted, it behaves as follows:

1. When ypserv is started, a warning will be logged.
2. When a NIS read access is made and the TTL entry has expired, a warning is logged. Information that is returned from the cache has not been updated.
3. When a NIS write access is made, a warning is logged. The cache will not be updated, and a NIS failure will be returned.

If `ypxfrd` is running in N2L mode and is asked to transfer a map, `ypxfrd` first checks whether the map is out of date. If the map is out of date, `ypxfrd` initiates an update from the DIT. `ypxfrd` cannot wait for the update to complete. If `ypxfrd` waited, the client end `ypxfr` operation could time out. To prevent `ypxfrd` from timing out, the existing map is transferred from the cache. The most up to date map will be transferred on subsequent `ypxfrd` operations.

ypserv(1M)

OPTIONS

ypserv	-d	The NIS service should go to the DNS for more host information. This requires the existence of a correct <code>/etc/resolv.conf</code> file pointing at a machine running <code>in.named(1M)</code> . This option turns on DNS forwarding regardless of whether or not the <code>YP_INTERDOMAIN</code> flag is set in the <code>hosts</code> maps. See <code>makedbm(1M)</code> . In the absence of an <code>/etc/resolv.conf</code> file, <code>ypserv</code> complains, but ignores the <code>-d</code> option.
	-i	If in N2L mode, initialize the NIS related parts of the DIT based on the current, non <code>LDAP_</code> prefixed, map files. The <code>LDAP_</code> prefixed maps are not created or updated. If you require that <code>LDAP_</code> prefixed maps be updated or created, then use the <code>-ir</code> option. The <code>-i</code> option does not attempt to create any NIS domain or container objects. If any NIS domain or container objects have not already been created, then errors will occur, as entries are written to nonexistent containers.
	-I	Identical to <code>-i</code> , except that any missing domain and container objects are created.
	-r	If in N2L mode, then refresh the <code>LDAP_</code> prefixed map files based on the contents of the DIT.
	-ir	If both <code>-i</code> and <code>-r</code> are specified in N2L mode, then the DIT will first be initialized from the current non <code>LDAP_</code> prefixed map files. A new set of <code>LDAP_</code> prefixed maps will then be generated from the contents of the DIT. A new set of <code>LDAP_</code> prefixed maps is required when moving from traditional NIS to N2L mode NIS.
	-Ir	Identical to <code>-ir</code> , except that any missing domain and container objects are created.
	-v	Operate in the verbose mode, printing diagnostic messages to <code>stderr</code> .

When run with the `-i`, `-r`, `-I`, `-ir` or `-Ir` options, the `ypserv` command runs in the foreground and exits once map initialization has been completed. Once the `ypserv` command exits, the user knows the maps are ready and can restart `ypserv` and the other `yp` daemons by running `ypstart(1M)`.

If there is a requirement to initialize the DIT from the NIS source files, which may have been modified since the maps were last remade, run `ypmake` before running `ypserv -i` or `ypserv -ir`. `ypmake` regenerated old style NIS maps. Then `ypserv -ir` dumps them into the DIT. When the `-ir` option is used, the `LDAP_` prefixed maps are also generated or updated. Since these maps will be more recent than the old style maps, `ypmake` will not be reported as erroneous when it is run.

FILES	<code>/var/yp/securenets</code>	Defines the hosts and networks that are granted access to information in the served domain. It is read at startup time by both <code>ypserv</code> and <code>ypxfrd</code> .

ypserv(1M)

/etc/init.d/rpc

Startup file that starts up basic RPC services and NIS by calling ypstart(1M). If the /var/yp/ypserv.log file exists when ypserv starts up, log information is written to it when error conditions arise. The file /var/yp/binding/domainname/ypservers is used to list the NIS server hosts that ypbind can bind to.

Network Interfaces Programmer's Guide

System Administration Guide: Naming and Directory Services (DNS, NIS, and LDAP)

NOTES ypserv supports multiple domains. The ypserv process determines the domains it serves by looking for directories of the same name in the directory /var/yp. It replies to all broadcasts requesting yp service for that domain.

The Network Information Service (NIS) was formerly known as Sun Yellow Pages (YP). The functionality of the two remains the same; only the name has changed. The name Yellow Pages is a registered trademark in the United Kingdom of British Telecommunications PLC, and must not be used without permission.

NIS uses ndbm() files to store maps. Therefore, it is subject to the 1024 byte limitations described in the USAGE and NOTES sections of the ndbm(3C) man page.

ypset(1M)

NAME	ypset – point ypbind at a particular server				
SYNOPSIS	/usr/sbin/ypset [-d <i>ypdomain</i>] [-h <i>host</i>] <i>server</i>				
DESCRIPTION	In order to run <i>ypset</i>, <i>ypbind</i> must be initiated with the <i>-ypset</i> or <i>-ypsetme</i> options. See <i>ypbind</i>(1M). <i>ypset</i> tells <i>ypbind</i> to get NIS services for the specified <i>ypdomain</i> from the <i>ypserv</i> process running on <i>server</i>. If <i>server</i> is down, or is not running <i>ypserv</i>, this might not be discovered until an NIS client process tries to obtain a binding for the domain. At this point, the binding set by <i>ypset</i> is tested by <i>ypbind</i>. If the binding is invalid, <i>ypbind</i> attempts to rebind for the same domain. <i>ypset</i> is useful for binding a client node that is not on a broadcast net, or is on a broadcast net that is not running an NIS server host. It is also useful for debugging NIS client applications, for instance, where an NIS map exists only at a single NIS server host. Where several hosts on the local net are supplying NIS services, <i>ypbind</i> can rebind to another host, even while you attempt to find out if the <i>ypset</i> operation succeeded. For example, if you enter the <i>ypset</i> command below, you might get the subsequent response from <i>ypwhich</i>: <pre>example% ypset host1 example% ypwhich host2</pre> The sequence shown above is a function of the NIS subsystem's attempt to load-balance among the available NIS servers, and occurs when <i>host1</i> does not respond to <i>ypbind</i> because it is not running <i>ypserv</i> (or is overloaded), and <i>host2</i>, running <i>ypserv</i>, obtains the binding. <i>server</i> indicates which NIS server to bind to, and must be specified as a name or an IP address. This works only if the node has a current valid binding for the domain in question and <i>ypbind</i> has been set to allow use of <i>ypset</i>. In most cases, <i>server</i> should be specified as an IP address. <i>ypset</i> tries to bind over a connectionless transport. The NIS library call, <i>yp_all()</i>, uses connection-oriented transport and derives the NIS server's address based on the connectionless address supplied by <i>ypset</i>. Refer to <i>ypfiles</i>(4) for an overview of the NIS name service.				
OPTIONS	<table><tr><td>-d <i>ypdomain</i></td><td>Use <i>ypdomain</i>, instead of the default domain.</td></tr><tr><td>-h <i>host</i></td><td>Set <i>ypbind</i>'s binding on <i>host</i>, instead of locally. Specify <i>host</i> as a name.</td></tr></table>	-d <i>ypdomain</i>	Use <i>ypdomain</i> , instead of the default domain.	-h <i>host</i>	Set <i>ypbind</i> 's binding on <i>host</i> , instead of locally. Specify <i>host</i> as a name.
-d <i>ypdomain</i>	Use <i>ypdomain</i> , instead of the default domain.				
-h <i>host</i>	Set <i>ypbind</i> 's binding on <i>host</i> , instead of locally. Specify <i>host</i> as a name.

ypstart(1M)

NAME ypstart, ypstop – Start and stop NIS services

SYNOPSIS `/usr/lib/netsvc/yp/ypstart`
`/usr/lib/netsvc/yp/ypstop`

DESCRIPTION The `ypstart` command is used to start the Network Information Service (NIS). After the host has been configured using the `ypinit(1M)` command, `ypstart` automatically determines the NIS status of the machine and starts the appropriate daemons.

The `ypstop` command is used to stop the Network Information Service (NIS).

NAME	ypxfr, ypxfr_1perday, ypxfr_1perhour, ypxfr_2perday – transfer NIS map from a NIS server to host	
SYNOPSIS	/usr/lib/netsvc/yp/ypxfr [-c] [-f] [-C <i>tid prog server</i>] [-d <i>ypdomain</i>] [-h <i>host</i>] [-s <i>ypdomain</i>] <i>mapname</i>	
DESCRIPTION	The ypxfr command moves an NIS map in the default domain for the local host to the local host by making use of normal NIS services. It creates a temporary map in the directory <code>/var/yp/ypdomain</code> (this directory must already exist; <i>ypdomain</i> is the default domain for the local host), fills it by enumerating the map's entries, fetches the map parameters (master and order number), and loads them. It then deletes any old versions of the map and moves the temporary map to the real <i>name</i>. If run interactively, ypxfr writes its output to the terminal. However, if it is started without a controlling terminal, and if the log file <code>/var/yp/ypxfr.log</code> exists, it appends all its output to that file. Since ypxfr is most often run from the privileged user's <code>crontab</code> file, or by ypserv, the log file can retain a record of what was attempted, and what the results were. For consistency between servers, ypxfr should be run periodically for every map in the NIS data base. Different maps change at different rates: a map might not change for months at a time, for instance, and can therefore be checked only once a day. Some maps might change several times per day. In such a case, you might want to check hourly for updates. A <code>crontab(1)</code> entry can be used to automatically perform periodic updates. Rather than having a separate <code>crontab</code> entry for each map, you can group commands to update several maps in a shell script. Examples (mnemonically named) are in <code>/usr/sbin/yp: ypxfr_1perday, ypxfr_2perday, and ypxfr_1perhour</code>. Refer to <code>ypfiles(4)</code> for an overview of the NIS name service.	
OPTIONS	-c	Do not send a "Clear current map" request to the local ypserv process. Use this flag if ypserv is not running locally at the time you are running ypxfr . Otherwise, ypxfr complains that it cannot communicate with the local ypserv , and the transfer fails.
	-f	Force the transfer to occur even if the version at the master is not more recent than the local version.
	-C <i>tid prog server</i>	This option is for use <i>only</i> by ypserv . When ypserv starts ypxfr , it specifies that ypxfr should call back a yppush process at the host <i>server</i> , registered as program number <i>prog</i> , and waiting for a response to transaction <i>tid</i> .
	-d <i>ypdomain</i>	Specify a domain other than the default domain.
	-h <i>host</i>	Get the map from <i>host</i> , regardless of the master. If <i>host</i> is not specified, ypxfr asks the NIS service for the name of the master, and tries to get the map from there. <i>host</i> must be a valid host name.

ypxfr(1M)

-s *ypdomain* Specify a source domain from which to transfer a map that should be the same across domains.

NAME	zdump – time zone dumper						
SYNOPSIS	zdump [-v] [-c <i>cutoffyear</i>] [<i>zonename</i> ...]						
DESCRIPTION	The zdump command prints the current time for each time zone (<i>zonename</i>) listed on the command line. Specify <i>zonename</i> as the name of the time zone database file relative to <code>/usr/share/lib/zoneinfo</code>. Specifying an invalid time zone (<i>zonename</i>) to zdump does not return an error, rather zdump uses GMT. This is consistent with the behavior of the library calls; zdump reflects the same behavior of the time routines in libc. See <code>ctime(3C)</code> and <code>mktime(3C)</code>.						
OPTIONS	The following options are supported: -v Displays the entire contents of the time zone database file for <i>zonename</i>. Prints the time at the lowest possible time value; the time one day after the lowest possible time value; the times both one second before and exactly at each time at which the rules for computing local time change; the time at the highest possible time value; and the time at one day less than the highest possible time value. See <code>mktime(3C)</code> and <code>ctime(3C)</code> for information regarding time value (<code>time_t</code>). Each line of output ends with <code>isdst=1</code> if the given time is Daylight Saving Time, or <code>isdst=0</code> otherwise. -c <i>cutoffyear</i> Cuts off the verbose output near the start of the year <i>cutoffyear</i>.						
EXIT STATUS	The following exit values are returned: 0 Successful completion. 1 An error occurred.						
FILES	<code>/usr/share/lib/zoneinfo</code>	Standard zone information directory					
ATTRIBUTES	See <code>attributes(5)</code> for descriptions of the following attributes:

zic(1M)

NAME	zic – time zone compiler																		
SYNOPSIS	zic [-s] [-v] [-l <i>localtime</i>] [-p <i>posixrules</i>] [-d <i>directory</i>] [-y <i>yearistype</i>] [<i>filename...</i>]																		
DESCRIPTION	zic reads text from the file(s) named on the command line and creates the time conversion information files specified in this input. If a <i>filename</i> is '-', the standard input is read. Input lines are made up of fields. Fields are separated by any number of white space characters. Leading and trailing white space on input lines is ignored. A pound sign (#) indicates a comment that extends to the end of the line. White space characters and pound signs can be enclosed within double quotes (" ") if they are to be used as part of a field. Any line that is blank (after comment stripping) is ignored. Non-blank lines are expected to be of one of three types: rule lines, zone lines, or link lines.																		
Rule	A rule line has the form: For example: <pre>Rule NAME FROM TO TYPE IN ON AT SAVE LETTER/S</pre> The fields that make up a rule line are: <pre>Rule USA 1969 1973 - Apr lastSun 2:00 1:00 D</pre> <table><tr><td>NAME</td><td>Gives the (arbitrary) name of the set of rules this rule is part of.</td></tr><tr><td>FROM</td><td>Gives the first year in which the rule applies. The word minimum (or an abbreviation) means the minimum year with a representable time value. The word maximum (or an abbreviation) means the maximum year with a representable time value.</td></tr><tr><td>TO</td><td>Gives the final year in which the rule applies. In addition to minimum and maximum (as above), the word only (or an abbreviation) can be used to repeat the value of the FROM field.</td></tr><tr><td>TYPE</td><td>Gives the type of year in which the rule applies. If TYPE is: <table><tr><td>'_'</td><td>The rule applies in all years between FROM and TO, inclusive.</td></tr><tr><td>uspres</td><td>The rule applies in U.S. Presidential election years.</td></tr><tr><td>nonpres</td><td>The rule applies in years other than U.S. Presidential election years.</td></tr><tr><td>even</td><td>The rule applies to even-numbered years.</td></tr><tr><td>odd</td><td>The rule applies to odd-numbered years.</td></tr></table></td></tr></table>	NAME	Gives the (arbitrary) name of the set of rules this rule is part of.	FROM	Gives the first year in which the rule applies. The word minimum (or an abbreviation) means the minimum year with a representable time value. The word maximum (or an abbreviation) means the maximum year with a representable time value.	TO	Gives the final year in which the rule applies. In addition to minimum and maximum (as above), the word only (or an abbreviation) can be used to repeat the value of the FROM field.	TYPE	Gives the type of year in which the rule applies. If TYPE is: <table><tr><td>'_'</td><td>The rule applies in all years between FROM and TO, inclusive.</td></tr><tr><td>uspres</td><td>The rule applies in U.S. Presidential election years.</td></tr><tr><td>nonpres</td><td>The rule applies in years other than U.S. Presidential election years.</td></tr><tr><td>even</td><td>The rule applies to even-numbered years.</td></tr><tr><td>odd</td><td>The rule applies to odd-numbered years.</td></tr></table>	'_'	The rule applies in all years between FROM and TO, inclusive.	uspres	The rule applies in U.S. Presidential election years.	nonpres	The rule applies in years other than U.S. Presidential election years.	even	The rule applies to even-numbered years.	odd	The rule applies to odd-numbered years.
NAME	Gives the (arbitrary) name of the set of rules this rule is part of.																		
FROM	Gives the first year in which the rule applies. The word minimum (or an abbreviation) means the minimum year with a representable time value. The word maximum (or an abbreviation) means the maximum year with a representable time value.																		
TO	Gives the final year in which the rule applies. In addition to minimum and maximum (as above), the word only (or an abbreviation) can be used to repeat the value of the FROM field.																		
TYPE	Gives the type of year in which the rule applies. If TYPE is: <table><tr><td>'_'</td><td>The rule applies in all years between FROM and TO, inclusive.</td></tr><tr><td>uspres</td><td>The rule applies in U.S. Presidential election years.</td></tr><tr><td>nonpres</td><td>The rule applies in years other than U.S. Presidential election years.</td></tr><tr><td>even</td><td>The rule applies to even-numbered years.</td></tr><tr><td>odd</td><td>The rule applies to odd-numbered years.</td></tr></table>	'_'	The rule applies in all years between FROM and TO, inclusive.	uspres	The rule applies in U.S. Presidential election years.	nonpres	The rule applies in years other than U.S. Presidential election years.	even	The rule applies to even-numbered years.	odd	The rule applies to odd-numbered years.								
'_'	The rule applies in all years between FROM and TO, inclusive.																		
uspres	The rule applies in U.S. Presidential election years.																		
nonpres	The rule applies in years other than U.S. Presidential election years.																		
even	The rule applies to even-numbered years.																		
odd	The rule applies to odd-numbered years.																		

	If TYPE is something else, then <code>zic</code> will attempt to execute the command <pre>yearistype year type</pre> to check the type of a year: an exit status of 0 means that the year is of the given type; an exit status of 1 means that the year is not of the given type. The <code>yearistype</code> command is not currently provided in the Solaris environment.										
IN	Names the month in which the rule takes effect. Month names can be abbreviated.										
ON	Gives the day on which the rule takes effect. Recognized forms include: <table> <tr> <td>5</td><td>the fifth day of the month</td></tr> <tr> <td>lastSun</td><td>The last Sunday in the month</td></tr> <tr> <td>lastMon</td><td>The last Monday in the month</td></tr> <tr> <td>Sun>=8</td><td>First Sunday on or after the eighth</td></tr> <tr> <td>Sun<=25</td><td>Last Sunday on or before the 25th</td></tr> </table> Names of days of the week can be abbreviated or spelled out in full. Note: There cannot be spaces within the ON field.	5	the fifth day of the month	lastSun	The last Sunday in the month	lastMon	The last Monday in the month	Sun>=8	First Sunday on or after the eighth	Sun<=25	Last Sunday on or before the 25th
5	the fifth day of the month										
lastSun	The last Sunday in the month										
lastMon	The last Monday in the month										
Sun>=8	First Sunday on or after the eighth										
Sun<=25	Last Sunday on or before the 25th										
AT	Gives the time of day at which the rule takes effect. Recognized forms include: <table> <tr> <td>2</td><td>Time in hours</td></tr> <tr> <td>2:00</td><td>Time in hours and minutes</td></tr> <tr> <td>15:00</td><td>24-hour format time (for times after noon)</td></tr> <tr> <td>1:28:14</td><td>Time in hours, minutes, and seconds, where hour 0 is midnight at the start of the day and hour 24 is midnight at the end of the day.</td></tr> </table> Any of these forms can be followed by the letter <code>w</code> if the given time is local “wall clock” time; <code>s</code> if the given time is local “standard” time; or <code>u</code> (or <code>g</code> or <code>z</code>) if the given time is universal time. In the absence of an indicator, wall clock time is assumed.	2	Time in hours	2:00	Time in hours and minutes	15:00	24-hour format time (for times after noon)	1:28:14	Time in hours, minutes, and seconds, where hour 0 is midnight at the start of the day and hour 24 is midnight at the end of the day.		
2	Time in hours										
2:00	Time in hours and minutes										
15:00	24-hour format time (for times after noon)										
1:28:14	Time in hours, minutes, and seconds, where hour 0 is midnight at the start of the day and hour 24 is midnight at the end of the day.										
SAVE	Gives the amount of time to be added to local standard time when the rule is in effect. This field has the same format as the AT field (without the <code>w</code> and <code>s</code> suffixes).										
LETTER/S	Gives the “variable part” (for example, the “S” or “D” in “EST” or “EDT” of time zone abbreviations to be used when this rule is in effect. If this field is ‘-’, the variable part is null.										

zic(1M)

Zone

A zone line has the form:

```
Zone  NAME                      GMTOFF  RULES/SAVE  FORMAT  [UNTIL]
```

For example:

```
Zone Australia/SouthWest  9:30      -          CST      1992 Mar 15 12:00
                        8:30      Aus         CST
```

The fields that make up a zone line are:

NAME	The name of the time zone. This is the name used in creating the time conversion information file for the zone.
GMTOFF	The amount of time to add to UTC to get standard time in this zone. This field has the same format as the AT and SAVE fields of rule lines; begin the field with a minus sign to subtract time from UTC.
RULES/SAVE	The name of the rule(s) that apply in the time zone or, alternately, an amount of time to add to local standard time. If this field is '-', then standard time always applies in the time zone.
FORMAT	The format for time zone abbreviations in this time zone. The pair of characters %s is used to show where the "variable part" of the time zone abbreviation goes. Alternately, a slash (/) separates standard and daylight abbreviations.
UNTIL	The time at which the UTC offset or the rule(s) change for a location. It is specified as a year, a month, a day, and a time of day. The time of day has the same format as the AT field of rule lines. If this is specified, the time zone information is generated from the given UTC offset and rule change until the time specified. The month, day, and time of day have the same format as the IN, ON, and AT columns of a rule; trailing columns can be omitted, and default to the earliest possible value for the missing columns. The next line must be a "continuation" line. This line has the same form as a zone line except that the string "Zone" and the name are omitted. The continuation line places information starting at the time specified as the UNTIL field in the previous line in the file used by the previous line. Continuation lines can contain an UNTIL field, just as zone lines do, indicating that the next line is a further continuation.

Link

A link line has the form:

```
Link  LINK-FROM  LINK-TO
```

For example:

```
Link    Europe/Istanbul Asia/Istanbul
```

The LINK-FROM field should appear as the NAME field in some zone line; the LINK-TO field is used as an alternate name for that zone.

Except for continuation lines, lines can appear in any order in the input.

OPTIONS

- d *directory* Creates time conversion information files in the directory *directory* rather than in the standard directory `/usr/share/lib/zoneinfo`.
- l *localtime* Uses the given time zone as local time *localtime*. `zic` acts as if the file contained a link line of the form:

Link *localtime* *localtime*
- p *posixrules* Uses the rules of the given time zone *posixrules* when handling POSIX-format time zone environment variables. `zic` acts as if the input contained a link line of the form:

Link *posixrules* *posixrules*

This option is not used by `ctime(3C)` and `mktime(3C)` in the Solaris environment.
- s Limits time values stored in output files to values that are the same whether they are taken to be signed or unsigned. You can use this option to generate SVVS-compatible files.
- v Complains if a year that appears in a data file is outside the range of years representable by system time values (0:00:00 a.m. UTC, January 1, 1970, to 3:14:07 a.m. UTC, January 19, 2038).
- y *yearistype* Uses the given command *yearistype* rather than `yearistype` when checking year types (see Rules under DESCRIPTION).

OPERANDS

- filename* A file containing input lines that specify the time conversion information files to be created. If a *filename* is '-', the standard input is read.

FILES

- `/usr/share/lib/zoneinfo` Standard directory used for created files
- `/usr/share/lib/zoneinfo/src` Directory containing source files

zic(1M)

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

SEE ALSO `time(1)`, `zdump(1M)`, `ctime(3C)`, `mktime(3C)`, `attributes(5)`

NOTES For areas with more than two types of local time, you might need to use local standard time in the AT field of the earliest transition time's rule to ensure that the earliest transition time recorded in the compiled file is correct.

NAME	zuludaemon – load microcode for Sun XVR-4000 Graphics Accelerator device				
SYNOPSIS	/usr/sbin/zuludaemon [-dev <i>zulu_device</i>]				
DESCRIPTION	The zuludaemon is a daemon, started and stopped from a script in <code>/etc/init.d</code>, that loads the microcode and provides other support functions for the Sun XVR-4000 Graphics Accelerator device. Do not kill this process. This daemon is essential to the zulu(7D) driver. The zuludaemon process is not configurable.				
OPTIONS	-dev <i>zulu_device</i> name of the Sun XVR-4000 Graphics Accelerator device				
FILES	/usr/sbin/zuludaemon daemon executable /usr/lib/zulu.ucode file containing microcode used by zuludaemon /etc/init.d/zuluinit startup/kill script for zuludaemon				
ATTRIBUTES	See attributes(5) for descriptions of the following attributes:				
	<table border="1"> <thead> <tr> <th>ATTRIBUTE TYPE</th><th>ATTRIBUTE VALUE</th></tr> </thead> <tbody> <tr> <td>Availability</td><td>SUNWzuluc</td></tr> </tbody> </table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	Availability	SUNWzuluc

acct — miscellaneous accounting
commands, 35

acctadm — configure extended accounting
facility, 38

acctcms — command summary from process
accounting records, 41

acctcon — create summary of connect
records, 43

acctcon1 — create summary of connect
records, 43

acctcon2 — create summary of connect
records, 43

acctdisk — create disk usage records, 35

acctdusg — compute disk usage by login, 35

acctmerg — merge or add total disk accounting
files, 45

accton — turn on process accounting, 35

acctprc — summary of process accounting, 46

acctprc1 — summary of process accounting, 46

acctprc2 — summary of process accounting, 46

acctsh — shell procedures for accounting, 48

acctwtmp — create connect accounting record
in /var/adm/wtmp, 35

adb scripts, generate — adbgen, 51

adbgen — generate adb script, 51

add (create) a new group definition on the system — groupadd, 501
 add a new device driver to the system — add_drv, 56
 add_drv — add a new device driver to the system, 56
 add_install_client — scripts used to install the Solaris software, 669
 add_to_install_server — scripts used to install the Solaris software, 669
 addbadsec — map out defective disk blocks, 54
 address resolution display and control — arp, 75
 adds an application to the Solstice application registry — soladdapp, 1742
 administer a new project on the system — projadd, 1400
 administer a new role account on the system — roleadd, 1468
 administer disk space used for caching file systems with the Cache File-System (CacheFS) — cfsadmin, 217
 administer files available as block devices through lofi — lofiadm, 809
 administer flash archives — flar, 393
 administer FTP Server enhanced group access file — privatepw, 1380
 administer NIS+ aliases, — aliasadm, 70
 administer ramdisk pseudo device — ramdiskadm, 1445
 administration program for the Sun Enterprise Network Array (SENA), RSM, SPARCstorage Array (SSA) subsystems, Sun Fire 880 internal storage subsystem, and individual Fiber Channel Arbitrated Loop (FC_AL) devices — luxadm, 915
 admintool — system administration tool with a graphical interface, 60
 afbconfig — configure the AFB Graphics Accelerator, 62
 aliasadm — administer NIS+ aliases, 70
 ancillary agent for inbound zone transfers — named-xfer, 1124
 answerbook2_admin — bring up AnswerBook2 administration tool GUI, 72
 AnswerBook2 administration tool GUI — answerbook2_admin, 72
 apache — Apache hypertext transfer protocol server overview, 73
 Apache hypertext transfer protocol server overview — apache, 73
 apply a patch package to a Solaris 2 system — patchadd, 1259
 arp — address resolution display and control, 75
 ASET
 monitors or restricts accesses to system files and directories — aset, 77
 prints tasks status — taskstat, 1852
 aset.restore — restore files and directories to the state before ASET was installed, 83
 audit — maintain audit trail, 84
 audit records, select or merge from audit trail files — auditreduce, 93
 audit_startup shell script, 101
 audit statistics report — auditstat, 102
 audit trail file, select records from — auditreduce, 93
 audit_warn — audit daemon warning script, 104
 auditconfig — get and set kernel audit parameters, 85
 auditd — audit daemon, 91
 auditreduce — select or merge audit records from audit trail files, 93
 auditstat — display kernel audit statistics, 102
 autoboot procedures — boot, 662
 autofs, automatically mount file systems — automount, 106
 Autofs, mount/unmount request server — automountd, 113
 Automated conversational exchange tool — chat, 223
 Automated Security Enhancement Tool, *See* ASET
 automated volume creation utility to support Solaris Volume Manager — metassist, 996
 automount — automatically mount file systems, 106
 automountd — Autofs mount/unmount request server, 113
 autopush — configures lists of automatically pushed STREAMS modules, 114

B

backup NIS+ directories — nisbackup, 1174
Basic Security Module, enable — bsmconv, bsmunconv, 140
Basic Security Module commands
 — audit, 84
 — audit_startup, 101
 — audit_warn, 104
 — auditconfig, 85
 — auditd, 91
 — auditreduce, 93
 — auditstat, 102
bdconfig — configures the bd (buttons and dials) stream, 116
become superuser or another user — su, 1771
snmpXwbemd — SNMP Adapter Subagent for WBEM, 1727
boot — bootstrap procedures, 118
boot parameter server — rpc.bootparamd, 1485
boot — system startup procedures, 662
bootconchk — verify the integrity of a network boot configuration file, 139
BOOTP
 DHCP network table management utility — pntadm, 1320
 administration — dhtadm, 300
 server — in.dhcpd, 591
 service — dhcpconfig, 291
bootstrap procedures — boot, 662
bootstrap PROM monitor program — monitor, 1075
Bootstrap Protocol, *See* 'DHCP'
Bourne shell, — rsh, 1519
broadcast message
 network wall server — rpc.rwalld, 1506
 write to all users — wall, 1942
 write to all users of a group — wall, 1942
 write to all users over a network — rwall, 1527
bsmconv — enable Solaris system to use Basic Security Module, 140
bsmrecord — display Solaris audit record formats, 142
bsmunconv — enable Solaris system to use Basic Security Module, 140
build class list and compile Solaris Management Console service beans for remote use — smccompile, 1627

busstat — report bus-related performance statistics, 145

C

Cache File System statistics — cachefsstat, 154
cachefs
 cachefslog — Cache File System logging, 150
 cachefswssize — Determine working set size for cachefs, 156
 cfsadmin — administer disk space used for caching file systems with the Cache File-System (CacheFS), 217
 fsck_cachefs — check integrity of data cached with CacheFS, 441
 mount_cachefs — mount CacheFS file systems, 1092
CacheFS daemon — cachefsd, 149
cachebsd — CacheFS daemon, 149
cachefspack — pack files and file systems in the cache, 152
cachefsstat — Cache File System statistics, 154
captainfo — convert termcap description to terminfo description, 158
catman — create formatted files for manual pages, 159
CD-ROM, packages on — pkgadd, 1295
CD-ROM, managing, — rmmount, 1463
CD-ROM, mounting, — rmmount, 1463
cfgadm — configuration administration, 163
cfgadm_ac — EXX00 memory system administration, 174
cfgadm_scsi — SCSI hardware specific commands for cfgadm, 197
cfgadm_sysctrl — EXX00 system board administration, 203
cfgadm_usb — USB hardware-specific commands for cfgadm, 207
cfs, *See* cachefs
cfsadmin — administer disk space used for caching file systems with the Cache File-System (CacheFS), 217
 CacheFS Resource Parameters, 218
cg14config — configure the cgfourteen device, 221
change processor operational status — psradm, 1419

chargefee — accounting shell procedure, 48
 chat — Automated conversational exchange tool, 223
 check — scripts used to install the Solaris software, 669
 check-hostname — check if sendmail can determine the system's fully-qualified host name, 231
 check if sendmail can determine the system's fully-qualified host name — check-hostname, 231
 check integrity of data cached with CacheFS — fsck_cachefs, 441
 check-permissions — check permissions on mail rerouting files, 232
 check permissions on mail rerouting files — check-permissions, 232
 chown — change owner of file, 233
 chroot — change root directory for a command, 234
 CIM Boot Manager, starting, 620
 CIM Object Manager, stopping, 620
 ckpacct — accounting shell procedure, 48
 clear inode
 — cli, 239
 — dcopy, 239
 clear_locks — clear locks held on behalf of an NFS client, 237
 clear locks held on behalf of an NFS client — clear_locks, 237
 client configuration daemon — dhcpagent, 287
 clinfo — display cluster information, 238
 close down the FTP Servers at a given time — ftpshut, 483
 closewtmp — puts a false DEAD_PROCESS record in /var/adm/wtmpx file, 35
 cli — clear inode, 239
 command used to launch the MQ
 Administration Console, a graphical user interface for performing MQ administration tasks — imqadmin, 559
 command utility for managing a Message Queue user repository — imqusermgr, 587
 compile MOF files into CIM classes — mofcomp, 1069
 configuration applications, execute or define — sysidconfig, 1837
 configure the AFB Graphics Accelerator — afbconfig, 62
 configure the FFB Graphics Accelerator — ffbconfig, 384
 configure the M64 Graphics Accelerator — m64config, 931
 configure the PGX32 Graphics Accelerator — pgxconfig, 1283
 configure the Raptor GFX Graphics Accelerator — GFXconfig, 1283
 configure
 cgfourteen device — cg14config, 221
 contiguous memory for sx video — sxconfig, 1816
 undo system configuration — sys-unconfig, 1846
 configure and administer a smart card — smartcard, 1610
 configure extended accounting facility — acctadm, 38
 configure Mobility IP Agent — mipagentconfig, 1040
 configure operating system crash dump — dumpadm, 352
 configure or unconfigure mouse, keyboard, display — kdmconfig, 749
 configure resource capping daemon — rcapadm, 1447
 configure shared disksets — metaset, 988
 configure system wide IPsec policy — ipsecconf, 701
 Configure the power management system — pmconfig, 1318
 configure the Solaris Management Console — smcconf, 1631
 configure the XVR-1000 Graphics Accelerator — SUNWgfb_config, 1776
 configure transport providers for use by sockets — soconfig, 1740
 configures the bd (buttons and dials) stream — bdconfig, 116
 connect accounting
 — acctcon, 43
 — fwtmpt, 487
 — utmp2wtmpt, 35
 — wtmpfix, 487
 consadm — select or display devices used as auxiliary console devices, 240

- construct a FAT file system — mkfs_pcfs, 1054
- construct a udfs file system — mkfs_udfs, 1058
- control and query bindings of processes to processors — pbind, 1276
- conv_lp — convert LP configuration, 242
- conv_lpd — convert LPD configuration, 243
- convert a JavaSpaces datastore to the newer Reliable Log datastore format — wbemconfig, 1954
- convert LP configuration — conv_lp, 242
- convert LPD configuration — conv_lpd, 243
- convert name server configuration files — named-bootconf, 1123
- copy FNS contexts — fncopy, 410
- coradm — core file administration, 245
- core file administration — coradm, 245
- CPU PROM monitor, program — monitor, 1075
- cpustat — monitor system behavior using CPU performance counters, 249
- create, NIS dbm file — makedbm, 938
- create a flash archive from a master system — flarcreate, 401
- create a new boot environment — lucreate, 872
- create a temporary snapshot of a UFS file system — fssnap_ufs, 473
- create an FNS context — fncreate, 412
- create and delete replicas of the metadvice state database — metadb, 949
- create and display client and server keys for WAN booting — wanboot_keygen, 1944
- create FNS file system contexts — fncreate_fs, 419
- create LDAP entries from corresponding /etc files — ldapaddent, 773
- create new printers in the FNS namespace — fncreate_printer, 424
- create or modify fixed disk partition table — fdisk, 376
- create temporary snapshots of a file system — fssnap, 471
- creates /dev entries for tape drives attached to the system — tapes, 1848
- creation and management of processor sets — psrset, 1424
- cron — clock daemon, 252
- cvcd — virtual console daemon, 254

D

- daemon, distributed system administration — sadmind, 1535
- daemon for DHCP client configuration — dhcagent, 287
- daemon for the Internet Key Exchange (IKE) — in.iked, 613
- daemon to monitor metadevices — mdmonitord, 944
- daemons
 - clock daemon — cron, 252
 - Internet Trivial File Transfer Protocol — in.tftpd, 682
 - kernel statistics — rpc.rstatd, 1504
 - network router discovery daemon — in.rdisc, 639
 - network username server — rpc.rusersd, 1505
 - network wall server — rpc.rwall, 1506
 - network status monitor — statd, 1763
 - NFS — nfsd, 1151
 - NIS+ service — rpc.nisd, 1494
 - remote quota — rquotad, 1518
 - RPC-based remote execution — rpc.rexd, 1502
 - server which records packets sent by spray — rpc.sprayd, 1508
- date, set system date from a remote host — rdate, 1453
- dcopy — clear inode, 239
- dcs — domain configuration server, 255
- dd — convert and copy a file, 257
- debug tools, generate adb script — adbgen, 51
- delete a project from the system — projdel, 1402
- delete a user's login from the system — roledel, 1472
- destroy an FNS context — fndestroy, 427
- devattr — displays the values for a device's attributes, 263
- devfsadm — administration command for /dev and /devices, 265
- devfsadmd — administration daemon for /dev and /devices, 265
- device access, verifies accessibility — getvol, 497
- device_maps, display entries — dminfo, 343

devices
 add, modify remove device entry from table
 — putdev, 1428
 add, remove and change device group table
 — putdgrp, 1431
 adds /dev entries for miscellaneous devices
 and pseudo-devices — devlinks, 268
 cgfourteen — configure the cgfourteen
 device, 221
 display access control entries from
 device_maps, 343
 display attributes — devattr, 263
 group list — getdgrp, 490
 list — getdev, 488
 lists members of a group — listdgrp, 789
 name — devnm, 272
 print information about disk devices —
 devinfo, 267
 release from exclusive use — devfree, 264
 remove a device driver from the system —
 rm_drv, 1456
 reserve for exclusive use — devfree, 273
 /devices directory, configure — drvconfig, 349
 devinfo — print device specific
 information, 267
 df — display amount of used and available disk
 space, 275
 df_ufs — display amount of space occupied by
 ufs, 286
 dfmounts — displays information on resources
 shared through DFS, 280
 dfmounts_nfs — displays information on
 resources shared through NFS, 282
 DFS
 display information on resources shared —
 dfmounts, 280
 list available resources from remote or local
 systems — dfshares, 283
 dfshares — list available resources from remote
 or local systems, 283
 dfshares_nfs — list available resources from
 remote systems, 284
 DHCP
 network table management utility —
 pntadm, 1320
 administration — dhtadm, 300
 server — in.dhcpd, 591
 service — dhcpconfig, 291
 DHCP client configuration daemon —
 dhcagent, 287
 DHCP service lock daemon — dsvclockd, 351
 dhcagent — daemon for DHCP client
 configuration, 287
 dhcpconfig — DHCP service configuration
 utility, 291
 dhcpmgr — graphical interface for managing
 DHCP service, 298
 dhtadm — DHCP configuration table
 management utility, 300
 Diffie-Hellman key pair, 1149
 directories, move — mvdir, 1122
 directoryserver — front end for the Directory
 Server (DS), 314
 disk accounting
 — acctdisk, 35
 — acctdusg, 35
 — acctmerg, 45
 disk blocks, display free ones — df, 275
 disk quotas, remote quota daemon —
 rquotad, 1518
 disk quotas and usage, display for a user's ufs
 file system — quota, 1438
 diskettes, packages on — pkgadd, 1295
 disks — adds /dev entries for hard disks
 attached to the system, 330
 disks, partitioning and maintenance utility —
 format, 431
 diskscan — perform surface analysis, 334
 display
 system configuration information —
 prtconf, 1411
 system diagnostic information —
 prtdiag, 1413
 display cluster information — clinfo, 238
 SNMP Adapter Subagent for WBEM —
 snmpXwbemd, 1727
 display kernel statistics — kstat, 762
 display or modify global state of system
 resource controls — rctldm, 1451
 display or set boot environment description —
 ludesc, 891
 display Solaris audit record formats —
 bsmrecord, 142
 displays information about processors —
 psrinfo, 1422
 Distributed File System, *See* DFS

dmesg — create error log from system diagnostic messages, 338
 dmi_cmd — DMI command line interface utility, 339
 DMI command line interface utility — dmi_cmd, 339
 DMI command line retrieval utility — dmiget, 342
 dmiget — DMI command line retrieval utility, 342
 dminfo — display device_maps entries, 343
 dmispd — Sun Solstice Enterprise DMI Service Provider, 345
 DNS test shell — nstest, 1234
 DoD Internet, host table — gettable, 494
 DoD Internet format host table, convert — htable, 515
 dodisk — accounting shell procedure, 48
 domain configuration server — dcs, 255
 domainname — display name of current domain, 348
 domainname — set name of current domain, 348
 driver statistics from a synchronous serial link, report — syncstat, 1826
 drvconfig — configure /devices, 349
 dsvclockd — DHCP service lock daemon, 351
 dumpadm — configure operating system crash dump, 352
 Dynamic Host Configuration Protocol, *See* 'DHCP'

E

edquota — edit user quotas for ufs file system, 359
 EEPROM display and load program — eeprom, 361
 efdaemon — embedded FCode interpreter daemon, 370
 embedded FCode interpreter daemon — efdaemon, 370
 encryption keys, server for storing private keys — keyserv, 755
 environment variables, convert termcap description into terminfo description — captainfo, 158

error log, create from system diagnostic messages — dmesg, 338
 etrn — send ETRN commands to start mail queue, 371
 EXX00 memory system administration — cfgadm_ac, 174
 EXX00 system board administration — cfgadm_sysctrl, 203

F

fbconfig — Frame Buffer configuration utility, 373
 fbconfig module for configuring Sun XVR-4000 Graphics Accelerator — SUNWzulu_config, 1798
 fbconfig module for configuring XVR-100 Graphics Accelerator — SUNWpfb_config, 1792
 fdetach — detach a name from STREAMS-based file descriptor, 375
 fdisk — create or modify fixed disk partition table, 376
 Menu Options, 376
 ffbconfig — configure the FFB Graphics Accelerator, 384
 FIFO, make FIFO special file — mkfifo, 1050
 FIFO, make — mknod, 1065
 File Transfer Protocol Server — ftpd, 605
 File Transfer Protocol Server — in.ftpd, 605
 file system
 cache file systems
 See cacheefs
 change the dynamic parameters — tuneufs, 1890
 check and repair — fsck, 437
 check and repair ufs — fsck_ufs, 447
 construct — mkfs, 1052
 construct UFS — mkfs_ufs, 1060
 create new — newfs, 1143
 debugger — fsdb, 451
 display amount of used disk space occupied by ufs — df_ufs, 286
 display amount of used and available disk space — df, 275
 grow — growfs, 506

file system (Continued)

- link and unlink files and directories —
 - link, 788
- list file names and statistics — `ff`, 382
- list file names and statistics for ufs —
 - `ff_ufs`, 392
- loopback — `mount`, 1087
- make literal copy — `volcopy`, 1937
- `mount` — `mount`, 1087
- `mount` — `mountall`, 1090
- `mount ufs` — `mount_ufs`, 1112
- move directory — `mvdir`, 1122
- provide labels — `labelit`, 767
- provide labels for ufs — `labelit_ufs`, 772
- report processes using file or file structure —
 - `fuser`, 485
- share multiple resources — `shareall`, 1595
- ufs, make image copy — `volcopy_ufs`, 1939
- `umount` — `umount`, 1087
- `umount` — `umountall`, 1090
- unshare multiple resources —
 - `unshareall`, 1595

file system consistency check and interactive —
`fsck_pcfs`, 442

file system type, determine — `fstyp`, 478

files

- change ownership — `chown`, 233
- convert and copy — `dd`, 257

`flar` — administer flash archives, 393

`flarcreate` — create a flash archive from a master system, 401

floppy, managing, — `rmmount`, 1463

floppy, mounting, — `rmmount`, 1463

flush disk activity — `sync`, 1819

FMLI-based interface to Live Upgrade functions — `lu`, 863

`fmthard` — populate Volume Table of Contents on hard disks, 406

`fnccopy` — copy FNS contexts, 410

`fncreate` — create an FNS context, 412

`fncreate_fs` — create FNS file system contexts, 419

`fncreate_printer` — create new printers in the FNS namespace, 424

`fndestroy` — destroy an FNS context, 427

FNS

- copy FNS contexts — `fnccopy`, 410
- create context — `fncreate`, 412

FNS (Continued)

- create FNS file system contexts —
 - `fncreate_fs`, 419
- select naming service for FNS Initial Context —
 - `fnselect`, 428

`fnselect` — select naming service for FNS Initial Context, 428

`format` — disk partitioning and maintenance utility, 431

Frame Buffer configuration utility —

- `fbconfig`, 373

front end for the Directory Server (DS) —

- `directoryserver`, 314

`fruadm` — prints and updates customer data associated with FRUs, 435

`fsck_cacheefs` — check integrity of data cached with CacheFS, 441

`fsck` — check and repair file systems, 437

`fsck_pcfs` — file system consistency check and interactive, 442

`fsck_ufs` — check and repair ufs, 447

`fsdb` — file system debugger, 451

`fsdb_ufs` — ufs file system debugger, 460

- Commands, 463
- Expressions, 461
- Formatted Output, 466
- Inode Commands, 465

`fsirand` — install random inode generation numbers, 470

`fssnap` — create temporary snapshots of a file system, 471

`fssnap_ufs` — create a temporary snapshot of a UFS file system, 473

`fstyp` — determine file system type, 478

`ftpaddhost` — set up a virtual FTP host, 479

`ftpconfig` — set up anonymous FTP, 481

`ftpd` — File Transfer Protocol Server, 605

`ftprestart` — restart previously shutdown FTP Servers, 482

`ftpsht` — close down the FTP Servers at a given time, 483

`fuser` — identify processes using file or file structure, 485

`fwtmp` — convert connect accounting records to ASCII, 487

G

generate a self-signed certificate for secure communication — `imqkeytool`, 576
generate message IDs — `msgid`, 1121
get printer configuration — `lpget`, 851
`getdev` — lists devices that match given criteria, 488
`getdgrp` — lists device groups which contain devices that match given criteria, 490
`getent` — gets a list of entries from administrative databases, 492
`gettable` — get DoD Internet host table, 494
`getty` — set terminal type, modes, speed, and line discipline, 495
`getvol` — verifies device accessibility, 497
`GFXconfig` — configure the Raptor GFX Graphics Accelerator, 1283
graphical interface for managing DHCP service — `dhcpgmgr`, 298
group file, check for inconsistencies — `grpck`, 1433
`groupadd` — add (create) a new group definition on the system, 501
`groupdel` — delete a group definition on the system, 503
`groupmod` — modify a group definition on the system, 504
`growfs` — grow file system, 506

H

`halt` — stop the processor, 512
hard disks, populate Volume Table of Contents — `fmthard`, 406
`hostconfig` — configure a system's host parameters, 513
`hsfs`
 labels for `hsfs` file systems, provide and print — `labelit_hsfs`, 769
 mount — `mount_hsfs`, 1096
`htable` — convert DoD Internet format host table, 515

I

I/O statistics report — `iostat`, 687

`ickey` — install a client key for WAN boot, 516
ICMP, router discovery daemon — `in.rdisc`, 639
`id` — return user identity, 517
`idsconfig` — prepare an iPlanet Directory Server (iDS) to be populated with data and serve LDAP clients, 520
`ifconfig` — configure network interface parameters, 522
`ikeadm` — manipulate Internet Key Exchange (IKE) parameters and state, 544
`ikecert` — manipulates the machine's on-filesystem public-key certificate databases, 552
`imports` disk sets into existing Solaris Volume Manager configurations — `metainport`, 961
`imqadmin` — command used to launch the MQ Administration Console, a graphical user interface for performing MQ administration tasks, 559
`imqbrokerd` — start a Message Queue broker instance, 560
`imqcmd` — manage Message Queue brokers, 564
`imqdbmgr` — manage a plugged-in JDBC-compliant Message Queue data store, 573
`imqkeytool` — generate a self-signed certificate for secure communication, 576
`imqobjmgr` — manage Message Queue administered objects, 578
`imqusermgr` — command utility for managing a Message Queue user repository, 587
`in.comsat` — biff server, 590
`in.dhcpd` — DHCP server, 591
`in.fingerd` — remote user information server, 600
`in.ftpd` — File Transfer Protocol Server, 605
`in.iked` — daemon for the Internet Key Exchange (IKE), 613
`in.lpd` — print job listener, 624
`in.rarpd` — Reverse Address Resolution Protocol server, 637
`in.rdisc` — ICMP router discovery daemon, 639
`in.rexecd` — remote execution server, 641
`in.ripngd` — network routing daemon for IPv6, 643
`in.rlogind` — remote login server, 646
`in.routed` — network routing daemon, 649

- in.rshd — remote shell server, 655
- in.rwhod — system status server, 658
- in.talkd — talk server, 678
- in.telnetd — DARPA TELNET virtual terminal protocol server, 679
- in.tftpd — Internet Trivial File Transfer Protocol server, 682
- in.tnamed — DARPA trivial name server, 684
- in.uucpd — UUCP server, 685
- incremental file system dump —
 ufsdump, 1894
- inetd — Internet services daemon, 596
- init — process control initialization, 615
 - /etc/defaults/init file, 616
 - init and System Booting, 615
 - inittab Additions, 616
 - Run Level Changes, 616
 - Run Level Defined, 615
 - telinit, 616
- init.wbem — start CIM Boot Manager, 620
- init.wbem — stop CIM Object Manager, 620
- initialize LDAP client machine or output an LDAP client profile in LDIF format —
 ldapclient, 779
- inode, clear — chri, 239
- insert and extract keys —
 wanboot_keymgmt, 1946
- install — install commands, 660
- install, SunOS/SVR4 — suninstall, 1775
- install a client key for WAN boot — ickey, 516
- install_scripts — scripts used to install the Solaris software, 669
- installboot procedures — boot, 662
- installer — Solaris Web Start installer utility, 664
- installf — add a file to software installation database, 665
- Internet
 - biff server — in.comsat, 590
 - DARPA TELNET virtual terminal protocol server — in.telnetd, 679
 - DARPA trivial name server —
 in.tnamed, 684
 - DHCP server — in.dhcpd, 591
 - DHCP service configuration —
 dhcpconfig, 291
 - ICMP router discovery daemon —
 in.rdisc, 639

Internet (Continued)

- network routing daemon — in.routed, 649
- query domain name servers —
 nslookup, 1225
- RARP server — in.rarpd, 637
- remote user information server —
 in.fingerd, 600
- send ICMP ECHO_REQUEST packets to network hosts — ping, 1290
- server for talk program — in.talkd, 678
- services daemon — inetd, 596
- system status server — in.rwhod, 658
- Trivial File Transfer Protocol server —
 in.tftpd, 682
- Internet Control Message Protocol, *See* ICMP
- Internet Protocol, to Ethernet addresses —
 arp, 75
- Interprocess Communication, make FIFO special file — mkfifo, 1050
- iostat — report I/O statistics, 687
- ipseconf — configure system wide IPsec policy, 701
- ipseckey — manually manipulate an IPsec Security Association Database (SABD), 717

K

- kadb — a kernel debugger, 726
- kdb5_util — Kerberos Database maintenance utility, 747
- kdmconfig — configure or unconfigure keyboard, display, and mouse options, 749
- Kerberos Database maintenance utility —
 kdb5_util, 747
- Kerberos warning daemon — ktkd_warnd, 766
- kernel — UNIX system executable file containing basic operating system services, 752
- kernel
 - debugger — kadb, 726
 - display status of loaded modules —
 modload, 1066
 - load a module — modload, 1067
- kernel — UNIX system executable file containing basic operating system services SPARC Only, 752, 754

- kernel
 - unload a module — modunload, 1068
- kernel debugger — kadb, 726
- Kernel Symbolic Debugging for OpenBoot
 - Firmware — obpsym, 1253
- kernel system event command invocation
 - daemon — syseventconfd, 1834
- kernel system event notification daemon — syseventd, 1835
- keyserv — server for storing private encryption keys, 755
- killall — kill all active processes, 757
- kstat — display kernel statistics, 762
- ktkt_warnd — Kerberos warning daemon, 766

L

- labelit — provide labels for file systems, 767
- labelit_hfs — provide and print labels for hfs file systems, 769
- labelit_ufs — provide labels for ufs, 772
- lastlogin — accounting shell procedure, 48
- ldapaddent — create LDAP entries from corresponding /etc files, 773
- ldapclient — initialize LDAP client machine or output an LDAP client profile in LDIF format, 779
- link — link and unlink files and directories, 788
- listdgrp — lists members of a device group, 789
- listen — network listener daemon, 790
- llc2_loop — loopback diagnostics to test the driver, adapter and network., 792
- lock, — lockstat, 801
- lockd — network lock daemon, 796
- lockfs — lock file system, 798
- lockstat — report kernel lock and profiling statistics, 801
- lofiadm — administer files available as block devices through lofi, 809
- log files and system log daemon — syslogd, 1843
- logadm — manage endlessly growing log files, 814
- logins — list user and system login information, 823

- loopback diagnostics to test the driver, adapter and network. — llc2_loop, 792
- loopback file system, mount — mount, 1087
- LP print services
 - administer filters — lpfilter, 838
 - administer forms — lpforms, 844
 - configure — lpadmin, 825
 - register remote systems — lpssystem, 860
 - set printing queue priorities — lpusers, 861
- lpadmin — configure LP print service, 825
- lpfilter — administer filters used with LP print service, 838
- lpforms — administer forms used with LP print service, 844
- lpforms — administer forms used with the LP print service
 - Adding or Changing a Form, 844
 - Allowing and Denying Access to a Form, 847
- lpforms — administer forms used with the, Deleting a Form, 846
- lpforms — administer forms used with the LP print service
 - Listing Form Attributes, 847
 - Listing the Current Alert, 849
 - Removing an Alert Definition, 849
 - Setting an Alert to Mount a Form, 847
 - Terminating an Active Alert, 849
- lpget — get printer configuration, 851
- lpmove — moves print requests that are queued, 853
- lpsched — start the LP print service, 855
- lpset — set printing configuration, 856
- lpshut — stop the LP print service, 859
- lpssystem — register remote systems with LP print service, 860
- lpusers — set printing queue priorities, 861
- lu — FMLI-based interface to Live Upgrade functions, 863
- lu, 863
- luactivate, 866
- lucancel, 868
- lucompare, 869
- lucreate — create a new boot environment, 872
- lucurr, 887
- ludelete, 889
- ludesc — display or set boot environment description, 891

- ludesc, 891
- lufslst, 894
- lumake, 896
- lumount, 898
- lurename, 901
- lustatus, 903
- luupgrade, 905
- luxadm — administration program for the Sun Enterprise Network Array (SENA), RSM, SPARCstorage Array (SSA) subsystems, Sun Fire 880 internal storage subsystem, and individual Fiber Channel Arbitrated Loop (FC_AL) devices, 915
- luxadm — administration program for the Sun Enterprise Network Array (SENA), RSM and SPARCstorage Array (SSA) subsystems Enclosure, 917
- Enclosure Services Card Subcommands, 925
- Other Expert Mode Subcommands, 926
- Pathname, 915
- SENA Expert Mode Subcommands, 925
- SPARCstorage Array Subcommands, 924
- Subcommands, 918
- usr/sbin, 929

M

- m64config — configure the M64 Graphics Accelerator, 931
- mail delivery server — sendmail, 1569
- mail.local — store mail in a mailbox, 936
- mail utilities
 - biff server — in.comsat, 590
 - create aliases database — newaliases, 1141
- make device_allocate entries — mkdevalloc, 1048
- make device_maps entries — mkdevmaps, 1049
- make FIFO — mknod, 1065
- make FIFO special file — mkfifo, 1050
- make local NFS file systems available for mounting by remote systems — share_nfs, 1596
- make named pipe — mkfifo, 1050
- make named pipe — mknod, 1065
- make special file — mknod, 1065
- makedbm — make NIS ndbm file, 938

- manage a plugged-in JDBC-compliant Message Queue data store — imqdbmgr, 573
- manage and view WBEM log files — smlog, 1671
- manage bulk operations on user accounts — smmultiuser, 1679
- manage diskless client support for a server — smdiskless, 1657
- manage email alias entries — smmaillist, 1675
- manage endlessly growing log files — logadm, 814
- manage entries in the exec_attr database — smexec, 1663
- manage group entries — smgroup, 1667
- manage jobs in the crontab database — smcron, 1648
- manage keys and certificates for WAN booting — wanbootutil, 1949
- manage Message Queue administered objects — imqobjmgr, 578
- manage Message Queue brokers — imqcmd, 564
- manage OS services — smoservice, 1684
- manage packaging and patching system — pkgadm, 1301
- manage patches — smpatch, 1689
- manage profiles in the prof_attr and exec_attr databases — smprofile, 1696
- manage roles and users in role accounts — smrole, 1701
- manage serial port — smserialport, 1708
- manage user entries — smuser, 1714
- manage WCI RSM controller configurations — wrsmconf, 1961
- manipulate Internet Key Exchange (IKE) parameters and state — ikeadm, 544
- manipulates the machine's on-filesystem public-key certificate databases — ikecert, 552
- manual pages, create formatted files for — catman, 159
- manually manipulate an IPsec Security Association Database (SABD) — ipseckey, 717
- map out defective disk blocks — addbadsec, 54
- mdmonitord — daemon to monitor metadevices, 944
- medstat command, 945

metaclear command, 947
 metadb — create and delete replicas of the
 metadevice state database, 949
 metadetach command, 1007
 metadevadm command, 954
 metahs command, 957
 metaimport — imports disk sets into existing
 Solaris Volume Manager configurations, 961
 metainit command, 963
 metaoffline command, 973
 metaonline command, 973
 metaparam command, 975
 metarecover — recover soft partition
 information, 977
 metarename command, 979
 metareplace command, 983
 metaroot command, 986
 metaset — configure shared disksets, 988
 metassist — automated volume creation utility
 to support Solaris Volume Manager, 996
 metastat command, 1001
 metasync command, 1005
 metattach command, 1007
 mibiisa — Sun SNMP Agent, 1014
 mipagent — Mobile IP agent, 1037
 mipagentconfig — configure Mobility IP
 Agent, 1040
 mipagentstat — show Mobile IP Mobility Agent
 status, 1046
 mkdevalloc — make device_allocate
 entries, 1048
 mkdevmaps — make device_maps
 entries, 1049
 mkfifo — make FIFO special file, 1050
 mkfile — create a file, 1051
 mkfs — make file system, 1052
 mkfs_pcfs — construct a FAT file system, 1054
 mkfs_udfs — construct a udfs file system, 1058
 mkfs_ufs — construct UFS, 1060
 mknod — make special file, 1065
 Mobile IP agent — mipagent, 1037
 modify a project's information on the system —
 projmod, 1403
 modify a role's login information on the system
 — rolemod, 1474
 modify device driver attributes —
 update_drv, 1910
 modify_install_server — scripts used to install
 the Solaris software, 669
 modinfo — display status of loaded kernel
 modules, 1066
 modload — load a kernel module, 1067
 modunload — unload a kernel module, 1068
 mofcomp — compile MOF files into CIM
 classes, 1069
 monacct — accounting shell procedure, 48
 monitor program — monitor, 1075
 monitor system behavior using CPU
 performance counters — cpustat, 249
 mount — mount filesystems and remote
 resources, 1087
 mount, show all remote mounts —
 showmount, 1603
 mount_cacheofs — mount CacheFS file
 systems, 1092
 mount_hfs — mount hfs file systems, 1096
 mount hfs file systems — mount_hfs, 1096
 mount_nfs — mount remote NFS
 resources, 1098
 mount_pcfs — mount pcfs file systems, 1106
 mount pcfs file systems — mount_pcfs, 1106
 mount_tmpfs — mount tmpfs, 1108
 mount_ufs — mount ufs, 1112
 mount_xmemfs — mount xmemfs file
 systems, 1117
 mount xmemfs file systems —
 mount_xmemfs, 1117
 mountall — mount multiple filesystems, 1090
 mountd — NFS mount request server, 1095
 mouse, keyboard, display, configure or
 unconfigure — kdmconfig, 749
 mpstat — report per-processor statistics, 1119
 msgid — generate message IDs, 1121
 mvdir — move a directory, 1122

N

name service cache daemon — nscd, 1223
 named-bootconf — convert name server
 configuration files, 1123
 named pipe, make — mkfifo, 1050
 named pipe, make — mknod, 1065
 named-xfer — ancillary agent for inbound zone
 transfers, 1124

- ncaconfd — Solaris Network Cache and Accelerator (NCA) configuration daemon, 1126
- ncheck — generate a list of path names vs i-numbers of all files on special, 1127
- ncheck_ufs — generate a list of pathnames vs i-numbers for ufs, 1129
- ndd — get and set driver configuration parameters, 1132
- netstat — show network status, 1134
- netstat — display network status
 - Active Sockets (First Form), 1137
 - DHCP Interface Information (Sixth Form), 1139
 - Interface Status (Third Form), 1138
 - Multicast Routing Tables (Fifth Form), 1139
 - Network Data Structures (Second Form), 1137
 - Routing Table (Fourth Form), 1139
 - TCP Sockets, 1137
- network routing daemon — in.routed, 649
- network
 - listener daemon — listen, 790
 - lock daemon — lockd, 796
 - test connections to hosts using ICMP — ping, 1290
- Network File System, *See* NFS
- network interface parameters, configure — ifconfig, 522
- network listener service, administration — nlsadmin, 1217
- network packets capture and inspection — snoop, 1729
- network routing daemon for IPv6 — in.ripngd, 643
- Network Time Protocol daemon — xntpd, 1966
- newaliases — make mail aliases database, 1141
- newfs — make new file system, 1143
- newkey — create a new key in publickey database, 1149
- NFS
 - crash and recovery functions for locking services — statd, 1763
 - create files for use as NFS mounted swap areas — mkfile, 1051
 - daemon — nfsd, 1151
 - display information on resources shared — dfmounts_nfs, 282

NFS (Continued)

- display statistics — nfsstat, 1156
- list available resources from remote systems — dfshares_nfs, 284
- make local NFS filesystem unavailable for mounting by remote systems — unshare_nfs, 1909
- mount — mount_nfs, 1098
- mount request server — mountd, 1095
- NFS, secure, create a new key in publickey database — newkey, 1149
- NFS security, server for storing private encryption keys — keyserv, 755
- nfsstat — display NFS statistics, 1156
- NIS
 - binder process — ypbind, 1990
 - make ndbm file — makedbm, 938
 - point binder process ypbind at a particular server — ypset, 2004
 - rebuild database — ypmake, 1993
 - return current version of a NIS map at a NIS server host — yppoll, 1997
 - transfer NIS map from a NIS server to host — ypxfr, 2007
- NIS+
 - add /etc files and NIS maps into their corresponding NIS+ tables — nisaddent, 1167
 - client and root server initialization utility — nisinit, 1184
 - credential creation tool — nisaddcred, 1161
 - display the contents of the NIS+ transaction log — nislog, 1192
 - initialize a domain to store system administration information — nissetup, 1211
 - nisping — ping NIS+ servers, 1193
 - nissetup — initialize a NIS+ domain to serve clients, 1211
 - nisstat — report NIS+ server statistics, 1213
 - service daemon — rpc.nisd, 1494
 - update public keys in NIS+ directory object — nisupdkeys, 1215
 - utility to cache location information about NIS+ servers — nis_cachemgr, 1177
 - utility to print out the contents of the shared cache file — nisshowcache, 1212

- NIS+ credentials for NIS+ principals, initialize
 - nisclient, 1179
- NIS+ password update daemon
 - nispasswd, 1500
 - rpc.nispasswd, 1500
- NIS+ servers, set up — nisserver, 1208
- NIS+ utility to set server preferences for NIS+ clients — nisprefadm, 1201
- NIS server and binder processes
 - ypserv, 2000
 - ypxfrd, 2000
- NIS services, start, — ypstart, 2006
- NIS services, stop, — ypstop, 2006
- nisaddcred — create NIS+ credentials, 1161
- nisaddent — add /etc files and NIS maps into their corresponding NIS+ tables, 1167
- nisbackup — backup NIS+ directories, 1174
- nisclient — initialize NIS+ credentials for NIS+ principals, 1179
- nislmaptest — test NIS+ and LDAP mapping configuration files, 1188
- nispasswd — NIS+ password update daemon, 1500
- nisping — ping NIS+ servers, 1193
- nispopulate — populate the NIS+ tables in a NIS+ domain, 1196
- nisprefadm — NIS+ utility to set server preferences for NIS+ clients, 1201
- nisrestore — restore NIS+ directory backup, 1205
- nisserver — set up NIS+ servers, 1208
- nissetup — initialize a domain to serve clients, 1211
- nisshowcache — NIS+ utility to print out the contents of the shared cache file, 1212
- nisstat — report NIS+ server statistics, 1213
- nscd — name service cache daemon, 1223
- nslookup — query Internet domain name servers, 1225
- nstest — DNS test shell, 1234
- nsupdate — update Internet name servers interactively, 1238
- ntpdate — set the date and time by way of NTP, 1241
- ntpq — standard Network Time Protocol query program, 1244
 - Control Message Commands, 1246
 - Interactive Commands, 1245

- ntptrace — trace a chain of NTP hosts back to their master time source, 1251
- nulladm — accounting shell procedure, 48

O

- obpsym — Kernel Symbolic Debugging for OpenBoot Firmware, 1253
 - Kernel Symbolic Name Syntax, 1253
- OCF server — ocfserv, 1255
- ocfserv — OCF server, 1255
- operating system
 - install SunOS/SVR4 — suninstall, 1775
 - save core dump — savecore, 1558
- operating system, bootable, load and execute — boot, 118
- output system definition, display current — sysdef, 1828
- owner of file, change — chown, 233

P

- pack files and file systems in the cache — cachefspack, 152
- packages, install, upgrade, and remove software — swmtool, 1815
- parse clustertoc file based on dynamic entries — parse_dynamic_clustertoc, 1256
- parse_dynamic_clustertoc — parse clustertoc file based on dynamic entries, 1256
- passmgmt — password files management, 1257
- password file, check for inconsistencies — pwck, 1433
- passwords
 - installs and updates /etc/shadow with information from /etc/passwd — pwconv, 1434
 - management — passmgmt, 1257
- patchadd — apply a patch package to a Solaris 2 system, 1259
- patchrm — remove a Solaris patch package and restore previously saved files, 1270
- pbind — control and query bindings of processes to processors, 1276
- pcfs, mount — mount_pcfs, 1106
- PCMCIA user daemon — pcmciad, 1278

pcmciad — PCMCIA user daemon, 1278
 per-processor statistics report — mpstat, 1119
 perform surface analysis — diskscan, 334
 pfinstall — tests installation profiles, 1279
 pgxconfig — configure the PGX32 Graphics Accelerator, 1283
 PICL daemon — picld, 1288
 picld — PICL daemon, 1288
 pkgadd — transfer software packages to system, 1295
 pkgadm — manage packaging and patching system, 1301
 pkgask — stores answers to an interactive software package, 1305
 pkgchk — check package installation accuracy, 1307
 pkgrm — remove package from system, 1310
 pmconfig — Configure the power management system, 1318
 pntadm — DHCP network table management utility, 1320
 Point to point protocol daemon — pppd, 1340
 pool administration utility — pooladm, 1327
 pool binding command — poolbind, 1329
 pooladm — pool administration utility, 1327
 poolbind — pool binding command, 1329
 populate security attribute databases in a name service — smattrpop, 1618
 populate the NIS+ tables in a NIS+ domain — nispopulate, 1196
 ports
 add or remove a service — pmadm, 1313
 create /dev entries and inittab entries for serial lines — ports, 1335
 enable or disable a service — pmadm, 1313
 install or replace a service configuration script — pmadm, 1313
 print requested service information — pmadm, 1313
 service administration — pmadm, 1313
 power manager daemon — powerd, 1339
 powerd — power manager daemon, 1339
 poweroff — stop the processor, 512
 PPP tunneling driver utility — sppptun, 1745
 pppd — Point to point protocol daemon, 1340
 PPPoE chat utility — pppoec, 1365
 PPPoE server daemon — pppoed, 1368
 pppoec — PPPoE chat utility, 1365
 pppoed — PPPoE server daemon, 1368
 pppstats — Print PPP statistics, 1373
 praudit — print contents of an audit trail file, 1376
 prctmp — accounting shell procedure, 48
 prdaily — accounting shell procedure, 48
 prepare an iPlanet Directory Server (iDS) to be populated with data and serve LDAP clients — idsconfig, 520
 print contents of an audit trail file — praudit, 1376
 print device specific information — devinfo, 267
 print FRUID-specific information about the FRUs on a system or domain — prtfru, 1414
 print PICL tree — prtpicl, 1415
 Print PPP statistics, 1373
 print queue, accept or reject requests — accept, reject, 33
 print requests, accept or reject — accept, reject, 33
 print service, LP, — lpmove, 853
 printer filters
 add and change — lpfilter, 838
 list attributes — lpfilter, 838
 remove — lpfilter, 838
 printer forms
 add or change — lpforms, 844
 delete — lpforms, 846
 list attributes — lpforms, 847
 listing the current alert — lpforms, 849
 provide access — lpforms, 847
 removing an alert definition — lpforms, 849
 setting an alert to mount a form — lpforms, 847
 terminating an active alert — lpforms, 849
 printers
 add and change printers — lpadmin, 825
 define alerts for printer faults — lpadmin, 825
 mount printer wheels — lpadmin, 825
 remove printers — lpadmin, 825
 set or change system default destination — lpadmin, 825
 setting priorities — lpusers, 861
 printmgr.lm — Solaris Print Manager is a graphical user interface for managing printers in a network, 1378

- prints and updates customer data associated with FRUs — fruadm, 435
- privatepw — administer FTP Server enhanced group access file, 1380
- process accounting
 - acctcms, 41
 - accton, 35
 - acctprc, 46
- process scheduler, administration — dispadmin, 335
- processes
 - initialization — init, 615
 - kill all active processes — killall, 757
 - using file or file structure — fuser, 485
- program, standalone, load and execute — boot, 118
- programming tools, install — install commands, 660
- projadd — administer a new project on the system, 1400
- projdel — delete a project from the system, 1402
- projmod — modify a project's information on the system, 1403
- PROM monitor program — monitor, 1075
- PROM monitor program, display and load program — eeprom, 361
- prstat — report active process statistics, 1405
- prtacct — accounting shell procedure, 48
- prtconf — print system configuration information, 1411
- prtdiag — print system diagnostic information, 1413
- prtfru — print FRUID-specific information about the FRUs on a system or domain, 1414
- prtpicl — print PICL tree, 1415
- prtvoc — report information about a disk geometry and partitioning, 1416
- psradm — change processor operational status, 1419
- psrinfo — displays information about processors, 1422
- psrset — creation and management of processor sets, 1424
- putdev — add, modify remove device entry from table, 1428
- putdgrep — add, remove and change device group table, 1431

Q

- query routing daemons for their routing tables — rtquery, 1522
- quick halt, — halt, 512
- quota, remote quota daemon — rquotad, 1518
- quotas
 - check file system quota for inconsistencies — quotacheck, 1439
 - display a user's disk quota and usage — quota, 1438
 - displays number of blocks in filesystem currently owned by each user — quot, 1436
 - summarize quotas for a file system — repquota, 1459
 - turn off file system quotas — quotaoff, 1440
 - turn on file system quotas — quotaon, 1440
- quotas, user, edit — edquota, 359

R

- RAID hardware utility — raidctl, 1442
- raidctl — RAID hardware utility, 1442
- ramdiskadm — administer ramdisk pseudo device, 1445
- RARP, server — in.rarpd, 637
- rcapadm — configure resource capping daemon, 1447
- rctladm — display or modify global state of system resource controls, 1451
- re-preinstall — restore a system to its original factory condition, 1460
- real-time clock and GMT-lag management, provide — rtc, 1521
- reboot — restart the operating system, 1454
- rebuild NIS database — ypmake, 1993
- recover soft partition information — metarecover, 977
- reject — reject print requests, 33
- remote execution server — in.rexecd, 641
- remote login server — in.rlogind, 646
- remote shell server — in.rshd, 655
- remote shell server — rshd, 655
- remote system with debugging on, try to contact — Uutry, 1931
- remote login server — in.rlogind, rlogind, 646

remote system with debugging on, try to
 contact — `Uutry`, `uutry`, 1931

remote magtape protocol server — `rmt`, 1466

Remote Program Load Server, *See* `rpld`

remote resources

- mount or unmount — `mount`, 1087
- mount NFS — `mount_nfs`, 1098

remote system

- execute remote command requests —
`uuxqt`, 1932
- make local resource unavailable for
 mounting — `unshare`, 1908
- register with LP print service —
`lpssystem`, 860
- set system date — `rdate`, 1453
- user information server — `in.fingerd`, 600

removable media device server —
`rpc.smserverd`, 1507

removable media mounter for CD-ROM and
 floppy — `rmmount`, 1463

remove a Solaris patch package and restore
 previously saved files — `patchrm`, 1270

`removef` — remove a file from software
 database, 1457

removes an application from the Solstice
 application registry — `soldelapp`, 1743

report active process statistics — `prstat`, 1405

report bus-related performance statistics —
`busstat`, 145

report I/O statistics — `iostat`, 687

report information about a disk geometry and
 partitioning — `prtvtoc`, 1416

report trap statistics — `trapstat`, 1874

report WCI RSM driver statistics —
`wrsmstat`, 1963

restart previously shutdown FTP Servers —
`ftprestart`, 482

restore, incremental file system restore —
`ufsrestore`, 1901

restore NIS+ directory backup —
`nisrestore`, 1205

return user identity — `id`, 517

Reverse Address Resolution Protocol, *See* `RARP`

`rlogind` — remote login server, 646

`rm_drv` — remove a device driver from the
 system, 1456

`rm_install_client` — scripts used to install the
 Solaris software, 669

`rmmount` — removable media mounter for
 CD-ROM and floppy, 1463

`rmt` — remote magtape protocol server, 1466

`roleadd` — administer a new role account on the
 system, 1468

`roledel` — delete a user's login from the
 system, 1472

`rolemod` — modify a role's login information on
 the system, 1474

`root` directory, change for a command —
`chroot`, 234

`route` — manually manipulate routing
 tables, 1477

RPC

- kernel statistics server — `rpc.rstatd`, 1504
- network username server —
`rpc.rusersd`, 1505
- network wall server — `rpc.rwall`, 1506
- NIS+ service daemon — `rpc.nisd`, 1494
- program number to universal addresses
 mapping — `rpcbind`, 1483
- remote execution server — `rpc.rexd`, 1502
- remote quota daemon — `rquotad`, 1518
- report information — `rpcinfo`, 1486
- sends one-way stream of packets to host —
`spray`, 1747
- server which records packets sent by spray
 — `rpc.sprayd`, 1508
- server, Autofs mount/unmount requests —
`automountd`, 113
- server, NFS mount requests — `mountd`, 1095

RPC, secure, create a new key in publickey
 database — `newkey`, 1149

`rpc.bootparamd` — boot parameter server, 1485

`rpc.metad` command, 1491

`rpc.metamedd` command, 1492

`rpc.metamhd` command, 1493

`rpc.nisd` — NIS+ service daemon, 1494

- `rpc.nisd_resolv`, 1494, 1499

`rpc.nispasswd` — NIS+ password update
 daemon, 1500

`rpc.rexd` — remote execution daemon, 1502

`rpc.rstatd` — kernel statistics server, 1504

`rpc.ruserd` — network username server, 1505

`rpc.rwalld` — network wall server, 1506

`rpc.smserverd` — removable media device
 server, 1507

- rpc.sprayd — records packets sent by spray, 1508
- rpc.yppupdated — server for changing NIS information, 1512
- rpcbind — converts RPC program numbers to universal addresses, 1483
- rpcinfo — report RPC information, 1486
- rpld — x86 Network Booting RPL (Remote Program Load) Server, 1513
- rquotad — remote quota server, 1518
- rsh — the restricted shell command interpreter, 1519
- rshd — remote shell server, 655
- rtc — provide all real-time clock and GMT-lag management, 1521
- rtquery — query routing daemons for their routing tables, 1522
- runacct — run daily accounting, 1524
- rwall — write to all users over a network, 1527
- rwall daemon, network wall server — rpc.rwalld, 1506

S

- sac — Service Access Controller (SAC), 1528
- sacadm — Service Access Controller administration, 1531
- sadmind — Distributed system administration daemon, 1535
- saf — Service Access Facility (SAF), 1539
- SAF
 - format and output port monitor-specific information — ttyadm, 1885
 - port monitor for terminal ports — ttymon, 1887
- savecore — save OS core dump, 1558
- scheduler, process, administration — dispadmin, 335
- sckmd — Sun Fire High-End system key management daemon, 1567
- scripts used to install the Solaris software — add_install_client, 669
- scripts used to install the Solaris software — add_to_install_server, 669
- scripts used to install the Solaris software — check, 669

- scripts used to install the Solaris software — install_scripts, 669
- scripts used to install the Solaris software — modify_install_server, 669
- scripts used to install the Solaris software — rm_install_client, 669
- scripts used to install the Solaris software — setup_install_server, 669
- SCSI hardware specific commands for cfgadm — cfgadm_scsi, 197
- secure shell daemon — sshd, 1755
- select a time zone — tzselect, 1892
- select naming service for FNS Initial Context — fnselect, 428
- select or display devices used as auxiliary console devices — consadm, 240
- sendmail — mail delivery system, 1569
- set serial line interface, set operating parameters — syncinit, 1820
- server for changing NIS information
 - rpc.yppupdated, 1512
 - yppupdated, 1512
- servers
 - automountd — mount/unmount request server, 113
 - biff server — in.comsat, 590
 - DARPA TELNET virtual terminal protocol server — in.telnetd, 679
 - DARPA trivial name server — in.tnamed, 684
 - DHCP server — in.dhcpd, 591
 - in.rexecd — remote execution server, 641
 - in.uucpd — UUCP server, 685
 - inetd — Internet services daemon, 596
 - mountd — mount request server, 1095
 - RARP server — in.rarpd, 637
 - system status server — in.rwhod, 658
 - talk program server — in.talkd, 678
 - yppasswdd — NIS password server, 1509
- servers, NIS+, location information — nis_cachemgr, 1177
- Service Access Controller, *See* SAC
- Service Access Facility, *See* SAF
- Service Location Protocol Daemon — slpd, 1608
- set printing configuration — lpset, 856
- set the date and time by way of NTP — ntpdate, 1241

set up a virtual FTP host — ftpaddhost, 479
 set up anonymous FTP — ftpconfig, 481
 setuname — changes machine information, 1590
 setup_install_server — scripts used to install the Solaris software, 669
 sf880drc — Sun Fire 880 Dynamic Reconfiguration daemon, 1591
 sftp-server — SFTP server subsystem, 1592
 SFTP server subsystem — sftp-server, 1592
 share — make local resource available for mounting by remote systems, 1593
 share_nfs — make local NFS file system available for mounting by remote systems, 1596
 shareall — multiple resources, 1595
 SHELL variable — rsh, 1519
 shells, the restricted shell command interpreter — rsh, 1519
 show Mobile IP Mobility Agent status — mipagentstat, 1046
 show network status — netstat, 1134
 showmount — display remote mounts, 1603
 showrev — displays revision information for current hardware and software, 1604
 shutacct — accounting shell procedure, 48
 shutdown — shutdown system, change system state, 1606
 slpd — Service Location Protocol Daemon, 1608
 smartcard — configure and administer a smart card, 1610
 smattrpop — populate security attribute databases in a name service, 1618
 smc — start the Solaris Management Console, 1623
 smccompile — build class list and compile Solaris Management Console service beans for remote use, 1627
 smconf — configure the Solaris Management Console, 1631
 smcron — manage jobs in the crontab database, 1648
 smcwebserver — start the Sun Management Center console web server, 1655
 smdiskless — manage diskless client support for a server, 1657
 smexec — manage entries in the exec_attr database, 1663
 smgroup — manage group entries, 1667
 smlog — manage and view WBEM log files, 1671
 smmaillist — manage email alias entries, 1675
 smmultiuser — manage bulk operations on user accounts, 1679
 smossservice — manage OS services, 1684
 smpatch — manage patches, 1689
 smprofile — manage profiles in the prof_attr and exec_attr databases, 1696
 smrole — manage roles and users in role accounts, 1701
 smserialport — manage serial port, 1708
 smuser — manage user entries, 1714
 snmpdx — Sun Solstice Enterprise Master Agent, 1722
 snmpXdmid — Sun Solstice Enterprise SNMP-DMI mapper subagent, 1725
 snoop — capture and inspect network packets, 1729
 soconfig — configure transport providers for use by sockets, 1740
 software package
 add a file to the software installation database — installf, 665
 check installation accuracy — pkgchk, 1307
 remove a file from software database — removef, 1457
 remove package from system — pkgrm, 1310
 stores answers to an interactive package — pkgask, 1305
 soladdapp — adds an application to the Solstice application registry, 1742
 Solaris Network Cache and Accelerator (NCA) configuration daemon — ncaconfd, 1126
 Solaris Print Manager is a graphical user interface for managing printers in a network — printmgr.lm, 1378
 Solaris Web Start installer utility — installer, 664
 soldelapp — removes an application from the Solstice application registry, 1743
 solstice — access system administration tools with a graphical user interface, 1744

SPARCstorage Array, administration program
 — ssaadm, 1748
 special NTP query program — xntpd, 1982
 split a PKCS #12 file into separate certificate and
 key files — wanboot_p12split, 1948
 sppptun — PPP tunneling driver utility, 1745
 spray — sends one-way stream of packets to
 host, 1747
 ssaadm — administration program for the
 SPARCstorage Array, 1748
 sshd — secure shell daemon, 1755
 standard Network Time Protocol query
 program — ntpq, 1244
 start a Message Queue broker instance —
 imqbrokerd, 560
 Start and stop NIS services, — ypstart, 2006
 Start NIS services, — ypstart, 2006
 start Sun WBEM User Manager —
 wbemadmin, 235, 1951
 start the LP print service — lpsched, 855
 start the Solaris Management Console —
 smc, 1623
 start the Sun Management Center console web
 server — smcwebserver, 1655
 start WBEM Log Viewer —
 wbemlogviewer, 1955
 startup — accounting shell procedure, 48
 startup procedures — boot, 662
 statd — network status monitor, 1763
 statistics
 audit — auditstat, 102
 for file system — ff, 382
 for ufs file system — ff, 392
 I/O — iostat, 687
 NFS, display — nfsstat, 1156
 per-processor — mpstat, 1119
 stop the processor — halt, 512
 stop the processor — poweroff, poweroff, 512
 Stop NIS services, — ypstop, 2006
 stop the LP print service — lpshut, 859
 store mail in a mailbox — mail.local, 936
 STREAMS
 automatically pushed modules —
 autopush, 114
 detach a name from file descriptor —
 fdetach, 375
 error logger cleanup program —
 strclean, 1766
 STREAMS (Continued)
 error logger daemon — strerr, 1767
 port monitor for terminal ports —
 ttymon, 1887
 print trace messages — strace, 1764
 su — become superuser or another user, 1771
 sulogin — single-user mode automatically
 invoked when system is first started, 1774
 Sun Fire 880 Dynamic Reconfiguration daemon
 — sf880drd, 1591
 Sun Fire High-End system key management
 daemon — sckmd, 1567
 Sun SNMP Agent — mibiisa, 1014
 Sun Solstice Enterprise DMI Service Provider —
 dmispd, 345
 Sun Solstice Enterprise Master Agent —
 snmpdx, 1722
 Sun Solstice Enterprise SNMP-DMI mapper
 subagent — snmpXdmid, 1725
 SUNWgfb_config — configure the XVR-1000
 Graphics Accelerator, 1776
 suninstall — install SunOS/SVR4, 1775
 SUNWpfb_config — fbconfig module for
 configuring XVR-100 Graphics
 Accelerator, 1792
 SUNWzulu_config — fbconfig module for
 configuring Sun XVR-4000 Graphics
 Accelerator, 1798
 swap — administer the system swap
 areas, 1812
 swmtool — install, upgrade and remove
 software packages, 1815
 sxconfig — configure contiguous memory for sx
 video, 1816
 sync — update super block, 1819
 synchronous serial link, report driver statistics
 — syncstat, 1826
 synchronous serial loopback test program —
 syncloop, 1823
 syncinit — set serial line interface operating
 parameters., 1820
 syncloop — synchronous serial loopback test
 program, 1823
 syncstat — report driver statistics from a
 synchronous serial link., 1826
 sys-unconfig — undo system
 configuration, 1846

- sysdef — displays current system definition, 1828
- sysevent event specification administration — syseventadm, 1830
- syseventadm — sysevent event specification administration, 1830
- syseventconfd — kernel system event command invocation daemon, 1834
- syseventd — kernel system event notification daemon, 1835
- sysidconfig — execute or define configuration applications, 1837
- sysidnet — system configuration, 1840
- sysidpm — system configuration, 1840
- sysidroot — system configuration, 1840
- sysidtool — system configuration, 1840
- syslogd — system log message daemon, 1843
- system activity reports — sar, 1556
- system status server — in.rwhod, 658
- system administration
 - access control lists — admintool, 60
 - add a file to the software installation database — installf, 665
 - control for basic administrative functions — uadmin, 1893
 - create formatted files for manual pages — catman, 159
 - get entries from administrative database — getent, 492
 - install commands — install, 660
 - NIS+ aliases — aliasadm, 70
 - system databases — admintool, 60
- system configuration
 - print information — prtconf, 1411
 - sysidnet, 1840
 - sysidpm, 1840
 - sysidroot, 1840
 - sysidtool, 1840
 - undo — sys-unconfig, 1846
- system definition, display current — sysdef, 1828
- system diagnostic, print information — prtdiag, 1413
- system diagnostic messages, error log — dmesg, 338
- system information, displays revision information for current hardware and software — showrev, 1604

- system log daemon — syslog, 1843
- system parameters, change value — setuname, 1590
- System Performance Analysis Utilities Tools, system activity report package — sar, 1556
- system PROM monitor program — monitor, 1075
- system shutdown, — halt, 512

T

- tapes — creates /dev entries for tape drives attached to the system, 1848
- tcxconfig — configure the default linearity of the 24-bit TrueColor Visual for OpenWindows with an S24 frame buffer system (TCX), 1853
- telinit — process control initialization, 615
- terminal
 - compare or print terminfo descriptions — infocmp, 601
 - set type, modes, speed, and line discipline — getty, 495
- terminfo, compiler — tic, 1865
- test installation profiles — pfinstall, 1279
- test NIS+ and LDAP mapping configuration files — nisldapmaptest, 1188
- time zone
 - compiler — zic, 2010
 - print current time in each named on command line — zdump, 2009
- timed event services, daemon for cron — cron, 252
- tmpfs, mount — mount_tmpfs, 1108
- trace a chain of NTP hosts back to their master time source — ntptrace, 1251
- trace messages, STREAMS — strace, 1764
- transfer software packages to system — pkgadd, 1295
- trapstat — report trap statistics, 1874
- TTY ports, maintain line settings and hunt sequences — sttydefs, 1769
- ttyadm — format and output port monitor-specific information, 1885
- ttymon — port monitor for terminal ports, 1887
- tunefs — tune an existing file system, 1890
- turnacct — accounting shell procedure, 48

tzselect — select a time zone, 1892

U

ufs

check and repair — fsck_ufs, 447

UFS, construct file system — mkfs_ufs, 1060

ufs

display amount of disk space — df_ufs, 286

generate a list of pathnames vs i-numbers —
ncheck_ufs, 1129

incremental file system restore —
ufsrestore, 1901

make image copy of file system—
volcopy_ufs, 1939

mount — mount_ufs, 1112

provide labels for ufs — labelit_ufs, 772

ufs file system debugger — fsdb_ufs, 460

ufsdump — incremental file system
dump, 1894

umount — unmount file systems and remote
resources, 1087

umountall — unmount multiple file
systems, 1090

unconfigure, undo system configuration —
sys-unconfig, 1846

UNIX system executable file containing basic
operating system services — kernel, 752

unshare — make local resource unavailable for
mounting by remote systems, 1908

unshare_nfs — make local NFS filesystem
unavailable for mounting by remote
systems, 1909

unshareall — multiple resources, 1595

update_drv — modify device driver
attributes, 1910

update Internet name servers interactively —
nsupdate, 1238

update super block — sync, 1819

USB hardware-specific commands for cfgadm
— cfgadm_usb, 207

user IDs, administer a new user login on the
system — useradd, 1913

user information, server, remote —
in.fingerd, 600

user quotas, remote quota daemon —
rquotad, 1518

useradd — administer a new user login on the
system, 1913

userdel — delete a user's login from the
system, 1918

usermod — modify a user's login information
on the system, 1920

users

list login information — logins, 823

who is doing what — whodo, 1957

utmp2wtmp — create an entry for each user
logged on in file /var/adm/wtmpx, 35

utmpd — utmpx monitoring daemon, 1924

utmpx monitoring daemon — utmpd, 1924

uuccheck — check the uucp directories and
permissions file, 1925

uucico — file transport program for uucp
system, 1926

uucleanup — uucp spool directory
clean-up, 1928

uucp

check directories and permissions file —
uuccheck, 1925

clean-up of spool directory —
uucleanup, 1928

file transport program — uucico, 1926

scheduler for file transport program —
uusched, 1930

server — in.uucpd, 685

uusched — scheduler for uucp transport
program, 1930

Uutry — try to contact remote system with
debugging on, 1931

uutry — try to contact remote system with
debugging on, 1931

uuxqt — execute remote command
requests, 1932

V

verify the integrity of a network boot
configuration file — bootconfchk, 139

virtual console daemon — cvcd, 254

virtual memory, display statistics —
vmstat, 1933

vmstat — display virtual memory
statistics, 1933

vold — Volume Management daemon to manage CD-ROM and floppy devices, 1940
Volume Management
floppy and CD-ROM management daemon
— vold, 1940
removable media mouter —
rmmount, 1463

W

wall — write to all users, 1942
wanboot_keygen — create and display client and server keys for WAN booting, 1944
wanboot_keymgmt — insert and extract keys, 1946
wanboot_p12split — split a PKCS #12 file into separate certificate and key files, 1948
wanbootutil — manage keys and certificates for WAN booting, 1949
wbemadmin — start Sun WBEM User Manager, 235, 1951
wbemconfig — convert a JavaSpaces datastore to the newer Reliable Log datastore format, 1954
wbemlogviewer — start WBEM Log Viewer, 1955
whodo — who is doing what, 1957
wract — write extended accounting records for active processes and tasks, 1959
write extended accounting records for active processes and tasks — wracct, 1959
wrsmconf — manage WCI RSM controller configurations, 1961
wrsmstat — report WCI RSM driver statistics, 1963
wtmfix — correct connect accounting records date/time stamp, 487

X

x86 Network Booting RPL (Remote Program Load) Server — rpld, 1513
xntpd — Network Time Protocol daemon, 1966
Access Control Commands, 1970
Authentication Commands, 1969
Authentication Key File Format, 1978

xntpd — Network Time Protocol daemon
(Continued)
Configuration Commands, 1967
Miscellaneous Commands, 1977
Monitoring Commands, 1973
Primary Clock Support, 1979
xntpd — special NTP query program, 1982

Y

YP
make ndbm file — makedbm, 938
rebuild database — ypmake, 1993
ypbind — NIS binder process, 1990
ypinit — set up NIS client, 1992
ypmake — rebuild NIS database, 1993
ypoll — return current version of a NIS map at a NIS server host, 1997
yppush — force propagation of changed NIS map, 1998
ypserv — NIS server and binder processes, 2000
ypserv, 2002
ypset — point NIS binder process ypbind at a particular server, 2004
ypstart — Start and stop NIS services, 2006
ypstop — Start and stop NIS services, 2006
ypupdated — server for changing NIS information, 1512
ypxfr — transfer NIS map from a NIS server to host, 2007
ypxfrd — NIS server and binder processes, 2000
yppasswdd — NIS password server, 1509

Z

zdump — prints the current time in each zonename named on command line, 2009
zic — time zone compiler, 2010
zuludaemon — load microcode for Sun XVR-4000 Graphics Accelerator device, 2015
