Index 315
Preface

Both novice users and those familiar with the SunOS operating system can use online man pages to obtain information about the system and its features. A man page is intended to answer concisely the question “What does it do?” The man pages in general comprise a reference manual. They are not intended to be a tutorial.

Overview

The following contains a brief description of each man page section and the information it references:

- Section 1 describes, in alphabetical order, commands available with the operating system.
- Section 1M describes, in alphabetical order, commands that are used chiefly for system maintenance and administration purposes.
- Section 2 describes all of the system calls. Most of these calls have one or more error returns. An error condition is indicated by an otherwise impossible returned value.
- Section 3 describes functions found in various libraries, other than those functions that directly invoke UNIX system primitives, which are described in Section 2.
- Section 4 outlines the formats of various files. The C structure declarations for the file formats are given where applicable.
- Section 5 contains miscellaneous documentation such as character-set tables.
- Section 6 contains available games and demos.
- Section 7 describes various special files that refer to specific hardware peripherals and device drivers. STREAMS software drivers, modules and the STREAMS-generic set of system calls are also described.
Section 9 provides reference information needed to write device drivers in the kernel environment. It describes two device driver interface specifications: the Device Driver Interface (DDI) and the Driver/Kernel Interface (DKI).

Section 9E describes the DDI/DKI, DDI-only, and DKI-only entry-point routines a developer can include in a device driver.

Section 9F describes the kernel functions available for use by device drivers.

Section 9S describes the data structures used by drivers to share information between the driver and the kernel.

Below is a generic format for man pages. The man pages of each manual section generally follow this order, but include only needed headings. For example, if there are no bugs to report, there is no BUGS section. See the intro pages for more information and detail about each section, and man(1) for more information about man pages in general.

NAME
This section gives the names of the commands or functions documented, followed by a brief description of what they do.

SYNOPSIS
This section shows the syntax of commands or functions. When a command or file does not exist in the standard path, its full path name is shown. Options and arguments are alphabetized, with single letter arguments first, and options with arguments next, unless a different argument order is required.

The following special characters are used in this section:

[ ] Brackets. The option or argument enclosed in these brackets is optional. If the brackets are omitted, the argument must be specified.

... Ellipses. Several values can be provided for the previous argument, or the previous argument can be specified multiple times, for example, "filename ...".

| Separator. Only one of the arguments separated by this character can be specified at a time.

{ } Braces. The options and/or arguments enclosed within braces are interdependent, such that everything enclosed must be treated as a unit.
PROTOCOL
This section occurs only in subsection 3R to indicate the protocol description file.

DESCRIPTION
This section defines the functionality and behavior of the service. Thus it describes concisely what the command does. It does not discuss OPTIONS or cite EXAMPLES. Interactive commands, subcommands, requests, macros, and functions are described under USAGE.

IOCTL
This section appears on pages in Section 7 only. Only the device class that supplies appropriate parameters to the ioctl(2) system call is called ioctl and generates its own heading. ioctl calls for a specific device are listed alphabetically (on the man page for that specific device). ioctl calls are used for a particular class of devices all of which have an io ending, such as mtcio(7).

OPTIONS
This section lists the command options with a concise summary of what each option does. The options are listed literally and in the order they appear in the SYNOPSIS section. Possible arguments to options are discussed under the option, and where appropriate, default values are supplied.

OPERANDS
This section lists the command operands and describes how they affect the actions of the command.

OUTPUT
This section describes the output – standard output, standard error, or output files – generated by the command.

RETURN VALUES
If the man page documents functions that return values, this section lists these values and describes the conditions under which they are returned. If a function can return only constant values, such as 0 or -1, these values are listed in tagged paragraphs. Otherwise, a single paragraph describes the return values of each function. Functions declared void do not return values, so they are not discussed in RETURN VALUES.

ERRORS
On failure, most functions place an error code in the global variable errno indicating why they failed. This section lists alphabetically all error codes a function can generate and describes the conditions that cause each error. When more than
one condition can cause the same error, each condition is described in a separate paragraph under the error code.

**USAGE**
This section lists special rules, features, and commands that require in-depth explanations. The subsections listed here are used to explain built-in functionality:

- Commands
- Modifiers
- Variables
- Expressions
- Input Grammar

**EXAMPLES**
This section provides examples of usage or of how to use a command or function. Wherever possible a complete example including command-line entry and machine response is shown. Whenever an example is given, the prompt is shown as `example%`, or if the user must be superuser, `example#`. Examples are followed by explanations, variable substitution rules, or returned values. Most examples illustrate concepts from the SYNOPSIS, DESCRIPTION, OPTIONS, and USAGE sections.

**ENVIROMENT VARIABLES**
This section lists any environment variables that the command or function affects, followed by a brief description of the effect.

**EXIT STATUS**
This section lists the values the command returns to the calling program or shell and the conditions that cause these values to be returned. Usually, zero is returned for successful completion, and values other than zero for various error conditions.

**FILES**
This section lists all file names referred to by the man page, files of interest, and files created or required by commands. Each is followed by a descriptive summary or explanation.

**ATTRIBUTES**
This section lists characteristics of commands, utilities, and device drivers by defining the attribute type and its corresponding value. See attributes(5) for more information.

**SEE ALSO**
This section lists references to other man pages, in-house documentation, and outside publications.

Threads and Realtime Library Functions
# aiocancel(3AIO)

## NAME
aiocancel – cancel an asynchronous operation

## SYNOPSIS
cancel an asynchronous operation

```
#include <sys/asynch.h>

int aiocancel(aio_result_t *resultp);
```

## DESCRIPTION
aiocancel() cancels the asynchronous operation associated with the result buffer pointed to by resultp. It may not be possible to immediately cancel an operation which is in progress and in this case, aiocancel() will not wait to cancel it.

Upon successful completion, aiocancel() returns 0 and the requested operation is cancelled. The application will not receive the SIGIO completion signal for an asynchronous operation that is successfully cancelled.

## RETURN VALUES
Upon successful completion, aiocancel() returns 0. Upon failure, aiocancel() returns −1 and sets errno to indicate the error.

## ERRORS
aiocancel() will fail if any of the following are true:

- **EACCES**
  The parameter resultp does not correspond to any outstanding asynchronous operation, although there is at least one currently outstanding.

- **EFAULT**
  resultp points to an address outside the address space of the requesting process. See NOTES.

- **EINVAL**
  There are not any outstanding requests to cancel.

## ATTRIBUTES
See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>MT-Level</td>
<td>Safe</td>
</tr>
</tbody>
</table>

## SEE ALSO
aioread(3AIO), aiowait(3AIO), attributes(5)

## NOTES
Passing an illegal address as resultp will result in setting errno toEFAULT only if it is detected by the application process.
aio_cancel – cancel asynchronous I/O request

#include <aio.h>

int aio_cancel(int fildes, struct aiocb *aiocbp);

The aio_cancel() function attempts to cancel one or more asynchronous I/O requests currently outstanding against file descriptor fildes. The aiocbp argument points to the asynchronous I/O control block for a particular request to be canceled. If aiocbp is NULL, then all outstanding cancelable asynchronous I/O requests against fildes are canceled.

Normal asynchronous notification occurs for asynchronous I/O operations that are successfully canceled. If there are requests that cannot be canceled, then the normal asynchronous completion process takes place for those requests when they are completed.

For requested operations that are successfully canceled, the associated error status is set to ECANCELED and the return status is −1. For requested operations that are not successfully canceled, the aiocbp is not modified by aio_cancel().

If aiocbp is not NULL, then if fildes does not have the same value as the file descriptor with which the asynchronous operation was initiated, unspecified results occur.

The aio_cancel() function returns the value AIO_CANCELED to the calling process if the requested operation(s) were canceled. The value AIO_NOTCANCELED is returned if at least one of the requested operation(s) cannot be canceled because it is in progress. In this case, the state of the other operations, if any, referenced in the call to aio_cancel() is not indicated by the return value of aio_cancel(). The application may determine the state of affairs for these operations by using aio_error(3RT). The value AIO_ALLDONE is returned if all of the operations have already completed. Otherwise, the function returns −1 and sets errno to indicate the error.

The aio_cancel() function will fail if:

EBADF The fildes argument is not a valid file descriptor.
ENOSYS The aio_cancel() function is not supported.

The aio_cancel() function has a transitional interface for 64-bit file offsets. See lf64(5).

See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>MT-Level</td>
<td>MT-Safe</td>
</tr>
</tbody>
</table>
Solaris 2.6 was the first release to support the Asynchronous Input and Output option. Prior to this release, this function always returned -1 and set errno to ENOSYS.
aio_error(3RT)

NAME
aio_error – retrieve errors status for an asynchronous I/O operation

SYNOPSIS
cce [ flag... ] file... -lrt [ library... ]
#include <aio.h>

int aio_error(const struct aiocb *aiocbp);

DESCRIPTION
The aio_error() function returns the error status associated with the aiocb structure referenced by the aiocbp argument. The error status for an asynchronous I/O operation is the errno value that would be set by the corresponding read(2), write(2), or fsync(3C) operation. If the operation has not yet completed, then the error status will be equal to EINPROGRESS.

RETURN VALUES
If the asynchronous I/O operation has completed successfully, then 0 is returned. If the asynchronous operation has completed unsuccessfully, then the error status, as described for read(2), write(2), and fsync(3C), is returned. If the asynchronous I/O operation has not yet completed, then EINPROGRESS is returned.

ERRORS
The aio_error() function will fail if:
ENOSYS The aio_error() function is not supported by the system.

The aio_error() function may fail if:
EINVAL The aiocbp argument does not refer to an asynchronous operation whose return status has not yet been retrieved.

USAGE
The aio_error() function has a transitional interface for 64-bit file offsets. See lfd64(5).

EXAMPLES
EXAMPLE 1 The following is an example of an error handling routine using the aio_error() function.
#include <aio.h>
#include <errno.h>
#include <signal.h>
struct aiocb my_aiocb;
struct sigaction my_sigaction;
void my_aio_handler(int, siginfo_t *, void *);
...
my_sigaction.sa_flags = SA_SIGINFO;
my_sigaction.sa_sigaction = my_aio_handler;
sigemptyset(&my_sigaction.sa_mask);
(void) sigaction(SIGRTMIN, &my_sigaction, NULL);
...
my_aiocb.aio_sigevent.sigev_notify = SIGEV_SIGNAL;
my_aiocb.aio_sigevent.sigev_signo = SIGRTMIN;
my_aiocb.aio_sigevent.sigev_value.sival_ptr = &my_aiocb;
...
(void) aio_read(&my_aiocb);
...
void
my_aio_handler(int signo, siginfo_t *siginfo, void *context) {
  int my_errno;
  struct aiocb *my_aiocbp;
}
The following is an example of an error handling routine using the `aio_error()` function.  (Continued)

```c
my_aiocbp = siginfo->si_value.sival_ptr;
    if ((my_errno = aio_error(my_aiocb)) != EINPROGRESS) {
        int my_status = aio_return(my_aiocb);
        if (my_status >= 0) { /* start another operation */
            ...
        } else { /* handle I/O error */
            ...
        }
    }
```

**NOTES**  Solaris 2.6 was the first release to support the Asynchronous Input and Output option. Prior to this release, this function always returned −1 and set `errno` to ENOSYS.
NAME  aio_fsync - asynchronous file synchronization

SYNOPSIS

```c
#include <aio.h>

int aio_fsync(int op, struct aiocb *aiocbp);
```

DESCRIPTION

The `aio_fsync()` function asynchronously forces all I/O operations associated with the file indicated by the file descriptor `aio_fildes` member of the `aiocb` structure referenced by the `aiocbp` argument and queued at the time of the call to `aio_fsync()` to the synchronized I/O completion state. The function call returns when the synchronization request has been initiated or queued to the file or device (even when the data cannot be synchronized immediately).

If `op` is `O_DSYNC`, all currently queued I/O operations are completed as if by a call to `fdatasync(3RT)`; that is, as defined for synchronized I/O data integrity completion. If `op` is `O_SYNC`, all currently queued I/O operations are completed as if by a call to `fsync(3C)`; that is, as defined for synchronized I/O file integrity completion. If the `aio_fsync()` function fails, or if the operation queued by `aio_fsync()` fails, then, as for `fsync(3C)` and `fdatasync(3RT)`, outstanding I/O operations are not guaranteed to have been completed.

If `aio_fsync()` succeeds, then it is only the I/O that was queued at the time of the call to `aio_fsync()` that is guaranteed to be forced to the relevant completion state. The completion of subsequent I/O on the file descriptor is not guaranteed to be completed in a synchronized fashion.

The `aiocbp` argument refers to an asynchronous I/O control block. The `aiocbp` value may be used as an argument to `aio_error(3RT)` and `aio_return(3RT)` in order to determine the error status and return status, respectively, of the asynchronous operation while it is proceeding. When the request is queued, the error status for the operation is `EINPROGRESS`. When all data has been successfully transferred, the error status will be reset to reflect the success or failure of the operation. If the operation does not complete successfully, the error status for the operation will be set to indicate the error. The `aio_sigevent` member determines the asynchronous notification to occur when all operations have achieved synchronized I/O completion. All other members of the structure referenced by `aiocbp` are ignored. If the control block referenced by `aiocbp` becomes an illegal address prior to asynchronous I/O completion, then the behavior is undefined.

If the `aio_fsync()` function fails or the `aiocbp` indicates an error condition, data is not guaranteed to have been successfully transferred.

If `aiocbp` is `NULL`, then no status is returned in `aiocbp`, and no signal is generated upon completion of the operation.

RETURN VALUES

The `aio_fsync()` function returns 0 to the calling process if the I/O operation is successfully queued; otherwise, the function returns −1 and sets `errno` to indicate the error.

ERRORS

The `aio_fsync()` function will fail if:
The requested asynchronous operation was not queued due to temporary resource limitations.

The `aio_fildes` member of the `aiocb` structure referenced by the `aiocbp` argument is not a valid file descriptor open for writing.

The system does not support synchronized I/O for this file.

A value of `op` other than `O_DSYNC` or `O_SYNC` was specified.

The `aio_fsync()` function is not supported by the system.

In the event that any of the queued I/O operations fail, `aio_fsync()` returns the error condition defined for `read(2)` and `write(2)`. The error will be returned in the error status for the asynchronous `fsync(3C)` operation, which can be retrieved using `aio_error(3RT)`.

The `aio_fsync()` function has a transitional interface for 64-bit file offsets. See `lf64(5)`.

See `attributes(5)` for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>MT-Level</td>
<td>MT-Safe</td>
</tr>
</tbody>
</table>

Solaris 2.6 was the first release to support the Asynchronous Input and Output option. Prior to this release, this function always returned -1 and set `errno` to `ENOSYS`. 

SEE ALSO `fcntl(2), open(2), read(2), write(2), aio_error(3RT), aio_return(3RT), fdatasync(3RT), fsync(3C), attributes(5), fcntl(3HEAD), aio(3HEAD), lf64(5), signal(3HEAD)`
aioread(3AIO)

NAME
aioread, aiowrite – read or write asynchronous I/O operations

SYNOPSIS
cc [ flag ... ] file ... -laio [ library ... ]
#include <sys/types.h>
#include <sys/asynch.h>

int aioread(int fd, char *bufp, int bufs, off_t offset, int whence, aio_result_t *resultp);
int aiowrite(int fd, const char *bufp, int bufs, off_t offset, int whence, aio_result_t *resultp);

DESCRIPTION
aioread() initiates one asynchronous read(2) and returns control to the calling program. The read() continues concurrently with other activity of the process. An attempt is made to read bufs bytes of data from the object referenced by the descriptor fd into the buffer pointed to by bufp.

aiowrite() initiates one asynchronous write(2) and returns control to the calling program. The write() continues concurrently with other activity of the process. An attempt is made to write bufs bytes of data from the buffer pointed to by bufp to the object referenced by the descriptor fd.

On objects capable of seeking, the I/O operation starts at the position specified by whence and offset. These parameters have the same meaning as the corresponding parameters to the lseek(2) function. On objects not capable of seeking the I/O operation always start from the current position and the parameters whence and offset are ignored. The seek pointer for objects capable of seeking is not updated by aioread() or aiowrite(). Sequential asynchronous operations on these devices must be managed by the application using the whence and offset parameters.

The result of the asynchronous operation is stored in the structure pointed to by resultp:

int aio_return; /* return value of read() or write() */
int aio_errno; /* value of errno for read() or write() */

Upon completion of the operation both aio_return and aio_errno are set to reflect the result of the operation. AIO_INPROGRESS is not a value used by the system so the client may detect a change in state by initializing aio_return to this value.

The application supplied buffer bufp should not be referenced by the application until after the operation has completed. While the operation is in progress, this buffer is in use by the operating system.

Notification of the completion of an asynchronous I/O operation may be obtained synchronously through the aiowait(3AIO) function, or asynchronously by installing a signal handler for the SIGIO signal. Asynchronous notification is accomplished by sending the process a SIGIO signal. If a signal handler is not installed for the SIGIO signal, asynchronous notification is disabled. The delivery of this instance of the SIGIO signal is reliable in that a signal delivered while the handler is executing is not lost. If the client ensures that aiowait(3AIO) returns nothing (using a polling
aioread(3AIO)

Before returning from the signal handler, no asynchronous I/O notifications are lost. The aiowait(3AIO) function is the only way to dequeue an asynchronous notification. Note: SIGIO may have several meanings simultaneously: for example, that a descriptor generated SIGIO and an asynchronous operation completed. Further, issuing an asynchronous request successfully guarantees that space exists to queue the completion notification.

close(2), exit(2) and execve() (see exec(2)) will block until all pending asynchronous I/O operations can be canceled by the system.

It is an error to use the same result buffer in more than one outstanding request. These structures may only be reused after the system has completed the operation.

RETURN VALUES
Upon successful completion, aioread() and aiowrite() return 0. Upon failure, aioread() and aiowrite() return -1 and set errno to indicate the error.

ERRORS
aioread() and aiowrite() will fail if any of the following are true:

- **EAGAIN**: The number of asynchronous requests that the system can handle at any one time has been exceeded.
- **EBADF**: fildes is not a valid file descriptor open for reading.
- **EFAULT**: At least one of bufp points to an address outside the address space of the requesting process. See NOTES.
- **EINVAL**: The parameter resultp is currently being used by an outstanding asynchronous request.
- **EINVAL**: offset is not a valid offset for this file system type.
- **ENOMEM**: Memory resources are unavailable to initiate request.

USAGE
The aioread() and aiowrite() functions have transitional interfaces for 64-bit file offsets. See lfs64(5).

ATTRIBUTES
See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>MT-Level</td>
<td>Safe</td>
</tr>
</tbody>
</table>

SEE ALSO
close(2), exec(2), exit(2), l1seek(2), lseek(2), open(2), read(2), write(2), aiocancel(3AIO), aiowait(3AIO), sigvec(3UCB), attributes(5), lfs64(5)

NOTES
Passing an illegal address to bufp will result in setting errno to EFAULT only if it is detected by the application process.
The `aio_read()` function allows the calling process to read `aiocb->aio_nbytes` from the file associated with `aiocb->aio_fildes` into the buffer pointed to by `aiocb->aio_buf`. The function call returns when the read request has been initiated or queued to the file or device (even when the data cannot be delivered immediately). If `_POSIX_PRIORITIZED_IO` is defined and prioritized I/O is supported for this file, then the asynchronous operation is submitted at a priority equal to the scheduling priority of the process minus `aiocb->aio_reqprio`. The `aiocb` value may be used as an argument to `aio_error` (3RT) and `aio_return` (3RT) in order to determine the error status and return status, respectively, of the asynchronous operation while it is proceeding. If an error condition is encountered during queuing, the function call returns without having initiated or queued the request. The requested operation takes place at the absolute position in the file as given by `aio_offset`, as if `lseek(2)` were called immediately prior to the operation with an offset equal to `aio_offset` and a whence equal to `SEEK_SET`. After a successful call to enqueue an asynchronous I/O operation, the value of the file offset for the file is unspecified.

The `aiocb->aio_lio_opcode` field is ignored by `aio_read()`.

The `aiocb` argument points to an `aiocb` structure. If the buffer pointed to by `aiocb->aio_buf` or the control block pointed to by `aiocb` becomes an illegal address prior to asynchronous I/O completion, then the behavior is undefined.

Simultaneous asynchronous operations using the same `aiocb` produce undefined results.

If `_POSIX_SYNCHRONIZED_IO` is defined and synchronized I/O is enabled on the file associated with `aiocb->aio_fildes`, the behavior of this function is according to the definitions of synchronized I/O data integrity completion and synchronized I/O file integrity completion.

For any system action that changes the process memory space while an asynchronous I/O is outstanding to the address range being changed, the result of that action is undefined.

For regular files, no data transfer will occur past the offset maximum established in the open file description associated with `aiocb->aio_fildes`.

The `aio_read()` function returns 0 to the calling process if the I/O operation is successfully queued; otherwise, the function returns -1 and sets `errno` to indicate the error.

The `aio_read()` function will fail if:
The requested asynchronous I/O operation was not queued due to system resource limitations.

The aio_read() function is not supported by the system.

Each of the following conditions may be detected synchronously at the time of the call to aio_read(), or asynchronously. If any of the conditions below are detected synchronously, the aio_read() function returns -1 and sets errno to the corresponding value. If any of the conditions below are detected asynchronously, the return status of the asynchronous operation is set to -1, and the error status of the asynchronous operation will be set to the corresponding value.

The aiocbp->aio_fildes argument is not a valid file descriptor open for reading.

The file offset value implied by aiocbp->aio_offset would be invalid, aiocbp->aio_reqprio is not a valid value, or aiocbp->aio_nbytes is an invalid value.

In the case that the aio_read() successfully queues the I/O operation but the operation is subsequently canceled or encounters an error, the return status of the asynchronous operation is one of the values normally returned by the read(2) function call. In addition, the error status of the asynchronous operation will be set to one of the error statuses normally set by the read() function call, or one of the following values:

The aiocbp->aio_fildes argument is not a valid file descriptor open for reading.

The requested I/O was canceled before the I/O completed due to an explicit aio_cancel(3RT) request.

The file offset value implied by aiocbp->aio_offset would be invalid.

The file is a regular file, aiocbp->aio_nbytes is greater than 0 and the starting offset in aiocbp->aio_offset is before the end-of-file and is at or beyond the offset maximum in the open file description associated with aiocbp->aio_fildes.

For portability, the application should set aiocb->aio_reqprio to 0.

The aio_read() function has a transitional interface for 64-bit file offsets. See lf64(5).

Solaris 2.6 was the first release to support the Asynchronous Input and Output option. Prior to this release, this function always returned -1 and set errno to ENOSYS.
aio_return(3RT)

NAME aio_return – retrieve return status of an asynchronous I/O operation

SYNOPSIS

cc [ flag... ] file... -lrt [ library... ]
#include <aio.h>

ssize_t aio_return(struct aiocb *aiocbp);

DESCRIPTION

The aio_return() function returns the return status associated with the aiocb
structure referenced by the aiocbp argument. The return status for an asynchronous
I/O operation is the value that would be returned by the corresponding read(2),
write(2), or fsync(3C) function call. If the error status for the operation is equal to
EINPROGRESS, then the return status for the operation is undefined. The
aio_return() function may be called exactly once to retrieve the return status of a
given asynchronous operation; thereafter, if the same aiocb structure is used in a call
to aio_return() or aio_error(3RT), an error may be returned. When the aiocb
structure referred to by aiocbp is used to submit another asynchronous operation, then
aio_return() may be successfully used to retrieve the return status of that
operation.

RETURN VALUES

If the asynchronous I/O operation has completed, then the return status, as described
for read(2), write(2), and fsync(3C), is returned. If the asynchronous I/O operation
has not yet completed, the results of aio_return() are undefined.

ERRORS

The aio_return() function will fail if:

EINVAL    The aiocbp argument does not refer to an asynchronous operation
           whose return status has not yet been retrieved.

ENOSYS    The aio_return() function is not supported by the system.

USAGE

The aio_return() function has a transitional interface for 64-bit file offsets. See
lf64(5).

NOTES

Solaris 2.6 was the first release to support the Asynchronous Input and Output option.
Prior to this release, this function always returned −1 and set errno to ENOSYS.
aio_suspend(3RT)

NAME
aio_suspend – wait for asynchronous I/O request

SYNOPSIS
cc [ flag... ] file... -lrt [ library... ]
#include <aio.h>

int aio_suspend(const struct aiocb * const list[], int nent, const struct timespec *timeout);

DESCRIPTION
The aio_suspend() function suspends the calling thread until at least one of the asynchronous I/O operations referenced by the list argument has completed, until a signal interrupts the function, or, if timeout is not NULL, until the time interval specified by timeout has passed. If any of the aiocb structures in the list correspond to completed asynchronous I/O operations (that is, the error status for the operation is not equal to EINPROGRESS) at the time of the call, the function returns without suspending the calling thread. The list argument is an array of pointers to asynchronous I/O control blocks. The nent argument indicates the number of elements in the array. Each aiocb structure pointed to will have been used in initiating an asynchronous I/O request via aio_read(3RT), aio_write(3RT), orlio_listio(3RT). This array may contain null pointers, which are ignored. If this array contains pointers that refer to aiocb structures that have not been used in submitting asynchronous I/O, the effect is undefined.

If the time interval indicated in the timespec structure pointed to by timeout passes before any of the I/O operations referenced by list are completed, then
aio_suspend() returns with an error.

RETURN VALUES
If aio_suspend() returns after one or more asynchronous I/O operations have completed, it returns 0. Otherwise, it returns −1, and sets errno to indicate the error.

The application may determine which asynchronous I/O completed by scanning the associated error and return status using aio_error(3RT) and aio_return(3RT), respectively.

ERRORS
The aio_suspend() function will fail if:

EAGAIN
No asynchronous I/O indicated in the list referenced by list completed in the time interval indicated by timeout.

EINTR
A signal interrupted the aio_suspend() function. Note that, since each asynchronous I/O operation may possibly provoke a signal when it completes, this error return may be caused by the completion of one (or more) of the very I/O operations being awaited.

EINVAL
The timespec structure pointed to by timeout is not properly set because tv_sec is less than 0 or tv_nsec is either less than 0 or greater than 10⁹.

ENOMEM
There is currently not enough available memory; the application can try again later.

ENOSYS
The aio_suspend() function is not supported by the system.
aio_suspend(3RT)

**USAGE**
The `aio_suspend()` function has a transitional interface for 64-bit file offsets. See `lf64(5)`. See `attributes(5)` for descriptions of the following attributes:

**NOTES**
Solaris 2.6 was the first release to support the Asynchronous Input and Output option. Prior to this release, this function always returned -1 and set `errno` to ENOSYS.
NAME
aiowait – wait for completion of asynchronous I/O operation

SYNOPSIS
cc [ flag... ] file... -laioc [ library... ]
#include <sys/asynch.h>
#include <sys/time.h>

aio_result_t *aiowait(const struct timeval *timeout);

DESCRIPTION
The aiowait() function suspends the calling process until one of its outstanding
asynchronous I/O operations completes, providing a synchronous method of
notification.

If timeout is a non-zero pointer, it specifies a maximum interval to wait for the
completion of an asynchronous I/O operation. If timeout is a zero pointer, aiowait() blocks indefinitely. To effect a poll, the timeout parameter should be non-zero, pointing
to a zero-valued timeval structure.

The timeval structure is defined in <sys/time.h> and contains the following
members:

long tv_sec; /* seconds */
long tv_usec; /* and microseconds */

RETURN VALUES
Upon successful completion, aiowait() returns a pointer to the result structure used
when the completed asynchronous I/O operation was requested. Upon failure, aiowait() returns −1 and sets errno to indicate the error. aiowait() returns 0 if
the time limit expires.

ERRORS
The aiowait() function will fail if:

EFAULT The timeout argument points to an address outside the address
space of the requesting process. See NOTES.

EINTR The execution of aiowait() was interrupted by a signal.

EINVAL There are no outstanding asynchronous I/O requests.

ATTRIBUTES
See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>MT-Level</td>
<td>Safe</td>
</tr>
</tbody>
</table>

SEE ALSO
aiocancel(3AIO), aioread(3AIO), attributes(5)

NOTES
The aiowait() function is the only way to dequeue an asynchronous notification. It
can be used either inside a SIGIO signal handler or in the main program. One SIGIO
signal can represent several queued events.

Passing an illegal address as timeout will result in setting errno to EFAULT only if
detected by the application process.
NAME  aio_waitn – wait for completion of asynchronous I/O operations

SYNOPSIS  

```c
#include <aio.h>

int aio_waitn(struct aiocb *list[], uint_t nent, uint_t *nwait, const struct timespec *timeout);
```

DESCRIPTION  The aio_waitn() function suspends the calling thread until at least the number of requests specified by nwait have completed, until a signal interrupts the function, or if timeout is not NULL, until the time interval specified by timeout has passed.

To effect a poll, the timeout argument should be non-zero, pointing to a zero-valued timespec structure.

The list argument is an array of uninitialized I/O completion block pointers to be filled in by the system before aio_waitn() returns. The nent argument indicates the maximum number of elements that can be placed in list[].

The nwait argument points to the minimum number of requests aio_waitn() should wait for. Upon returning, the content of nwait is set to the actual number of requests in the aiocb list, which can be greater than the initial value specified in nwait. The aio_waitn() function attempts to return as many requests as possible, up to the number of outstanding asynchronous I/Os but less than or equal to the maximum specified by the nent argument. As soon as the number of outstanding asynchronous I/O requests becomes 0, aio_waitn() returns with the current list of completed requests.

The aiocb structures returned will have been used in initiating an asynchronous I/O request from any thread in the process with aio_read(3RT), aio_write(3RT), or lio_listio(3RT).

If the time interval expires before the expected number of I/O operations specified by nwait are completed, aio_waitn() returns the number of completed requests and the content of the nwait pointer is updated with that number.

If aio_waitn() is interrupted by a signal, nwait is set to the number of completed requests.

The application can determine the status of the completed asynchronous I/O by checking the associated error and return status using aio_error(3RT) and aio_return(3RT), respectively.

RETURN VALUES  Upon successful completion, aio_waitn() returns. Otherwise, it returns -1 and sets errno to indicate the error.

ERRORS  The aio_waitn() function will fail if:

- **EAGAIN**  There are no outstanding asynchronous I/O requests.
- **EFAULT**  The list[], nwait, or timeout argument points to an address outside the address space of the process.
The execution of `aio_waitn()` was interrupted by a signal.

`EINVAL` The `timeout` element `tv_sec` or `tv_nsec` is `<0`, `nent` is set to `0`, or `nwait` is either set to `0` or is `>` `nent`.

`ENOMEM` There is currently not enough available memory. The application can try again later.

`ETIME` The time interval expired before `nwait` outstanding requests have completed.

**SEE ALSO**

`aio(3HEAD), aio_error(3RT), aio_read(3RT), aio_write(3RT), lio_listio(3RT), aio_return(3RT), attributes (5)`
The `aio_write()` function allows the calling process to write `aiocbp->aio_nbytes` to the file associated with `aiocbp->aio_fildes` from the buffer pointed to by `aiocbp->aio_buf`. The function call returns when the write request has been initiated or, at a minimum, queued to the file or device. If `_POSIX_PRIORITIZED_IO` is defined and prioritized I/O is supported for this file, then the asynchronous operation is submitted at a priority equal to the scheduling priority of the process minus `aiocbp->aio_reqprio`. The `aiocbp` may be used as an argument to `aio_error(3RT)` and `aio_return(3RT)` in order to determine the error status and return status, respectively, of the asynchronous operation while it is proceeding.

The `aiocbp` argument points to an `aiocb` structure. If the buffer pointed to by `aiocbp->aio_buf` or the control block pointed to by `aiocbp` becomes an illegal address prior to asynchronous I/O completion, then the behavior is undefined.

If `O_APPEND` is not set for the file descriptor `aio_fildes`, then the requested operation takes place at the absolute position in the file as given by `aio_offset`, as if `lseek(2)` were called immediately prior to the operation with an `offset` equal to `aio_offset` and a `whence` equal to `SEEK_SET`. If `O_APPEND` is set for the file descriptor, write operations append to the file in the same order as the calls were made. After a successful call to enqueue an asynchronous I/O operation, the value of the file offset for the file is unspecified.

The `aiocbp-> aio_lio_opcode` field is ignored by `aio_write()`.

Simultaneous asynchronous operations using the same `aiocbp` produce undefined results.

If `_POSIX_SYNCHRONIZED_IO` is defined and synchronized I/O is enabled on the file associated with `aiocbp->aio_fildes`, the behavior of this function shall be according to the definitions of synchronized I/O data integrity completion and synchronized I/O file integrity completion.

For any system action that changes the process memory space while an asynchronous I/O is outstanding to the address range being changed, the result of that action is undefined.

For regular files, no data transfer will occur past the offset maximum established in the open file description associated with `aiocbp->aio_fildes`.

The `aio_write()` function returns 0 to the calling process if the I/O operation is successfully queued; otherwise, the function returns -1 and sets `errno` to indicate the error.

The `aio_write()` function will fail if:

---

**NAME**
aio_write – asynchronous write to a file

**SYNOPSIS**
```c
#include <aio.h>

int aio_write(struct aiocb *aiocbp);
```

**DESCRIPTION**

The `aio_write()` function allows the calling process to write `aiocbp->aio_nbytes` to the file associated with `aiocbp->aio_fildes` from the buffer pointed to by `aiocbp->aio_buf`. The function call returns when the write request has been initiated or, at a minimum, queued to the file or device. If `_POSIX_PRIORITIZED_IO` is defined and prioritized I/O is supported for this file, then the asynchronous operation is submitted at a priority equal to the scheduling priority of the process minus `aiocbp->aio_reqprio`. The `aiocbp` may be used as an argument to `aio_error(3RT)` and `aio_return(3RT)` in order to determine the error status and return status, respectively, of the asynchronous operation while it is proceeding.

The `aiocbp` argument points to an `aiocb` structure. If the buffer pointed to by `aiocbp->aio_buf` or the control block pointed to by `aiocbp` becomes an illegal address prior to asynchronous I/O completion, then the behavior is undefined.

If `O_APPEND` is not set for the file descriptor `aio_fildes`, then the requested operation takes place at the absolute position in the file as given by `aio_offset`, as if `lseek(2)` were called immediately prior to the operation with an `offset` equal to `aio_offset` and a `whence` equal to `SEEK_SET`. If `O_APPEND` is set for the file descriptor, write operations append to the file in the same order as the calls were made. After a successful call to enqueue an asynchronous I/O operation, the value of the file offset for the file is unspecified.

The `aiocbp->aio_lio_opcode` field is ignored by `aio_write()`.

Simultaneous asynchronous operations using the same `aiocbp` produce undefined results.

If `_POSIX_SYNCHRONIZED_IO` is defined and synchronized I/O is enabled on the file associated with `aiocbp->aio_fildes`, the behavior of this function shall be according to the definitions of synchronized I/O data integrity completion and synchronized I/O file integrity completion.

For any system action that changes the process memory space while an asynchronous I/O is outstanding to the address range being changed, the result of that action is undefined.

For regular files, no data transfer will occur past the offset maximum established in the open file description associated with `aiocbp->aio_fildes`.

The `aio_write()` function returns 0 to the calling process if the I/O operation is successfully queued; otherwise, the function returns -1 and sets `errno` to indicate the error.

The `aio_write()` function will fail if:

---

**RETURN VALUES**
The `aio_write()` function returns 0 to the calling process if the I/O operation is successfully queued; otherwise, the function returns -1 and sets `errno` to indicate the error.

**ERRORS**
The `aio_write()` function will fail if:
The requested asynchronous I/O operation was not queued due to system resource limitations.

The aio_write() function is not supported by the system.

Each of the following conditions may be detected synchronously at the time of the call to aio_write(), or asynchronously. If any of the conditions below are detected synchronously, the aio_write() function returns −1 and sets errno to the corresponding value. If any of the conditions below are detected asynchronously, the return status of the asynchronous operation is set to −1, and the error status of the asynchronous operation will be set to the corresponding value.

The aiocbp->aio_fildes argument is not a valid file descriptor open for writing.

The file offset value implied by aiocbp->aio_offset would be invalid, aiocbp->aio_reqprio is not a valid value, or aiocbp->aio_nbytes is an invalid value.

In the case that the aio_write() successfully queues the I/O operation, the return status of the asynchronous operation will be one of the values normally returned by the write(2) function call. If the operation is successfully queued but is subsequently canceled or encounters an error, the error status for the asynchronous operation contains one of the values normally set by the write() function call, or one of the following:

The aiocbp->aio_fildes argument is not a valid file descriptor open for writing.

The file offset value implied by aiocbp->aio_offset would be invalid.

The requested I/O was canceled before the I/O completed due to an explicit aio_cancel(3RT) request.

The file is a regular file, aiocbp->aio_nbytes is greater than 0 and the starting offset in aiocbp->aio_offset is at or beyond the offset maximum in the open file description associated with aiocbp->aio_fildes.

The aio_write() function has a transitional interface for 64-bit file offsets. See lfs64(5).

Cancellation

Thread cancellation allows a thread to terminate the execution of any application thread in the process. Cancellation is useful when further operations of one or more threads are undesirable or unnecessary.

An example of a situation that could benefit from using cancellation is an asynchronously-generated cancel condition such as a user requesting to close or exit some running operation. Another example is the completion of a task undertaken by a number of threads, such as solving a maze. While many threads search for the solution, one of the threads might solve the puzzle while the others continue to operate. Since they are serving no purpose at that point, they should all be canceled.

Planning Steps

Planning and programming for most cancellations follow this pattern:

1. Identify which threads you want to cancel, and insert pthread_cancel(3THR) statements.
2. Identify system-defined cancellation points where a thread that might be canceled could have changed system or program state that should be restored. See the Cancellation Points for a list.
3. When a thread changes the system or program state just before a cancellation point, and should restore that state before the thread is canceled, place a cleanup handler before the cancellation point with pthread_cleanup_push(3THR). Wherever a thread restores the changed state, pop the cleanup handler from the cleanup stack with pthread_cleanup_pop(3THR).
4. Know whether the threads you are canceling call into cancel-unsafe libraries, and disable cancellation with pthread_setcancelstate(3THR) before the call into the library. See Cancellation State and Cancel-Safe.
5. To cancel a thread in a procedure that contains no cancellation points, insert your own cancellation points with pthread_testcancel(3THR). pthread_testcancel(3THR) creates cancellation points by testing for pending cancellations and performing those cancellations if they are found. Push and pop cleanup handlers around the cancellation point, if necessary (see Step 3, above).
The system defines certain points at which cancellation can occur (cancellation points), and you can create additional cancellation points in your application with `pthread_testcancel(3THR)`.

The following cancellation points are defined by the system (system-defined cancellation points): `aio_suspend(3RT)`, `close(2)`, `creats(2)`, `getmsg(2)`, `getpmsg(2)`, `lockf(3C)`, `mq_receive(3RT)`, `mq_send(3RT)`, `msgsnd(2)`, `msync(3C)`, `nanosleep(3RT)`, `open(2)`, `pause(2)`, `poll(2)`, `pread(2)`, `pthread_cond_timedwait(3THR)`, `pthread_cond_wait(3THR)`, `pthread_join(3THR)`, `pthread_testcancel(3THR)`, `putmsg(2)`, `putpmsg(2)`, `pwrite(2)`, `read(2)`, `readv(2)`, `select(3C)`, `sem_wait(3RT)`, `sigpause(3C)`, `sigwaitinfo(3RT)`, `sigsuspend(2)`, `sigtimedwait(3RT)`, `sigwait(2)`, `sleep(3C)`, `sync(2)`, `system(3C)`, `tcdrain(3C)`, `usleep(3C)`, `wait(2)`, `waitid(2)`, `waitpid(2)`, `wait3(3C)`, `write(2)`, `writev(2)`, and `fcntl(2)`, when specifying `F_SETLKW` as the command.

When cancellation is asynchronous, cancellation can occur at any time (before, during, or after the execution of the function defined as the cancellation point). When cancellation is deferred (the default case), cancellation occurs only within the scope of a function defined as a cancellation point (after the function is called and before the function returns). See `Cancellation Type` for more information about deferred and asynchronous cancellation.

Choosing where to place cancellation points and understanding how cancellation affects your program depend upon your understanding of both your application and of cancellation mechanics.

Typically, any call that might require a long wait should be a cancellation point. Operations need to check for pending cancellation requests when the operation is about to block indefinitely. This includes threads waiting in `pthread_cond_wait(3THR)` and `pthread_cond_timedwait(3THR)`, threads waiting for the termination of another thread in `pthread_join(3THR)`, and threads blocked on `sigwait(2)`.

A mutex is explicitly *not* a cancellation point and should be held for only the minimal essential time.

Most of the dangers in performing cancellations deal with properly restoring invariants and freeing shared resources. For example, a carelessly canceled thread might leave a mutex in a locked state, leading to a deadlock. Or it might leave a region of memory allocated with no way to identify it and therefore no way to free it.

When a thread is canceled, it should release resources and clean up the state that is shared with other threads. So, whenever a thread that might be canceled changes the state of the system or of the program, be sure to push a cleanup handler with `pthread_cleanup_push(3THR)` before the cancellation point.
When a thread is canceled, all the currently-stacked cleanup handlers are executed in
last-in-first-out (LIFO) order. Each handler is run in the scope in which it was pushed.
When the last cleanup handler returns, the thread-specific data destructor functions
are called. Thread execution terminates when the last destructor function returns.

When, in the normal course of the program, an uncanceled thread restores state that it
had previously changed, be sure to pop the cleanup handler (that you had set up
where the change took place) using pthread_cleanup_pop(3THR). That way, if the
thread is canceled later, only currently-changed state will be restored by the handlers
that are left in the stack.

Be sure to pop the handler in the same scope in which it was pushed. Also, make sure
that each push statement has a matching pop statement, or compiler errors will be
generated.

Cancellation State
Most programmers will use only the default cancellation state of
PTHREAD_CANCEL_ENABLE, but can choose to change the state by using
pthread_setcancelstate(3THR), which determines whether a thread is
cancelable at all. With the default state of PTHREAD_CANCEL_ENABLE, cancellation is
enabled, and the thread is cancelable at points determined by its cancellation type. See
Cancellation Type.

If the state is PTHREAD_CANCEL_DISABLE, cancellation is disabled, the thread is not
cancelable at any point, and all cancellation requests to it are held pending.

You might want to disable cancellation before a call to a cancel-unsafe library,
restoring the old cancel state when the call returns from the library. See Cancel-Safe
for explanations of cancel safety.

Cancellation Type
A thread’s cancellation type is set with pthread_setcanceltype(3THR), and
determines whether the thread can be canceled anywhere in its execution, or only at
cancellation points.

With the default type of PTHREAD_CANCEL_DEFERRED, the thread is cancelable only
at cancellation points, and then only when cancellation is enabled.

If the type is PTHREAD_CANCEL_ASYNCHRONOUS, the thread is cancelable at any
point in its execution (assuming, of course, that cancellation is enabled). Try to limit
regions of asynchronous cancellation to sequences with no external dependencies that
could result in dangling resources or unresolved state conditions. Using asynchronous
cancellation is discouraged because of the danger involved in trying to guarantee
correct cleanup handling at absolutely every point in the program.

</tr>
</tbody>
</table>

### Cancel-Safe

With the arrival of POSIX cancellation, the cancel-safe level has been added to the list of MT-Safety levels. See Intro(3). An application or library is cancel-safe whenever it has arranged for cleanup handlers to restore system or program state wherever cancellation can occur. The application or library is specifically Deferred-cancel-safe when it is cancel-safe for threads whose cancellation type is PTHREAD_CANCEL_DEFERRED. See Cancellation State. It is specifically Asynchronous-cancel-safe when it is cancel-safe for threads whose cancellation type is PTHREAD_CANCEL_ASYNCHRONOUS.

Obviously, it is easier to arrange for deferred cancel safety, as this requires system and program state protection only around cancellation points. In general, expect that most applications and libraries are not Asynchronous-cancel-safe.

### POSIX Threads Only

Note: The cancellation functions described in this reference page are available for POSIX threads, only (the Solaris threads interfaces do not provide cancellation functions).

### EXAMPLES

**EXAMPLE 1 Cancellation example**

The following short C++ example shows the pushing/popping of cancellation handlers, the disabling/enabling of cancellation, the use of pthread_testcancel(), and so on. The free_res() cancellation handler in this example is a dummy function that simply prints a message, but that would free resources in a real application. The function f2() is called from the main thread, and goes deep into its call stack by calling itself recursively.

Before f2() starts running, the newly created thread has probably posted a cancellation on the main thread since the main thread calls thr_yield() right after creating thread2. Because cancellation was initially disabled in the main thread, through a call to pthread_setcancelstate(), the call to f2() from main() continues and constructs X at each recursive call, even though the main thread has a pending cancellation.
EXAMPLE 1 Cancellation example  (Continued)

When \( f2() \) is called for the fifty-first time (when \( i == 50 \)), \( f2() \) enables cancellation by calling \texttt{pthread_setcancelstate()}. It then establishes a cancellation point for itself by calling \texttt{pthread_testcancel()}. (Because a cancellation is pending, a call to a cancellation point such as \texttt{read(2)} or \texttt{write(2)} would also cancel the caller here.)

After the \texttt{main()} thread is canceled at the fifty-first iteration, all the cleanup handlers that were pushed are called in sequence; this is indicated by the calls to \texttt{free_res()} and the calls to the destructor for \( X \). At each level, the C++ runtime calls the destructor for \( X \) and then the cancellation handler, \texttt{free_res()}. The print messages from \texttt{free_res()} and \( X \)'s destructor show the sequence of calls.

At the end, the main thread is joined by thread2. Because the main thread was canceled, its return status from \texttt{pthread_join()} is \texttt{PTHREAD_CANCELED}. After the status is printed, thread2 returns, killing the process (since it is the last thread in the process).

```c
#include <pthread.h>
#include <sched.h>
extern "C" void thr_yield(void);
extern "C" void printf(...);

struct X {
    int x;
    X(int i){x = i; printf("X(%d) constructed.\n", i);}  
    -X(){ printf("X(%d) destroyed.\n", x);}};

void free_res(void *i) {
    printf("Freeing \$d\n",i);
}

char* f2(int i) {
    try {
        X dummy(i);
        pthread_cleanup_push(free_res, (void *)i);
        if (i == 50) {
            pthread_setcancelstate(PTHREAD_CANCEL_ENABLE, NULL);
            pthread_testcancel();
        }
        f2(i+1);
        pthread_cleanup_pop(0);
    } catch (int) {
        printf("Error: In handler.\n");
    } return "f2";
}
```

Threads and Realtime Library Functions  41
EXAMPLE 1 Cancellation example  (Continued)

thread2(void *tid)
{
    void *sts;
    printf("I am new thread :%d\n", pthread_self());
    pthread_cancel((pthread_t)tid);
    pthread_join((pthread_t)tid, &sts);
    printf("main thread cancelled due to %d\n", sts);
    return (sts);
}

main()
{
    pthread_setcancelstate(PTHREAD_CANCEL_DISABLE, NULL);
    pthread_create(NULL, NULL, thread2, (void *)pthread_self());
    thr_yield();
    printf("Returned from %s\n", f2(0));
}

The `clock_settime()` function sets the specified clock, `clock_id`, to the value specified by `tp`. Time values that are between two consecutive non-negative integer multiples of the resolution of the specified clock are truncated down to the smaller multiple of the resolution.

The `clock_gettime()` function returns the current value `tp` for the specified clock, `clock_id`.

The resolution of any clock can be obtained by calling `clock_getres()`. Clock resolutions are system-dependent and cannot be set by a process. If the argument `res` is not NULL, the resolution of the specified clock is stored in the location pointed to by `res`. If `res` is NULL, the clock resolution is not returned. If the time argument of `clock_settime()` is not a multiple of `res`, then the value is truncated to a multiple of `res`.

A clock may be systemwide (that is, visible to all processes) or per-process (measuring time that is meaningful only within a process).

A `clock_id` of `CLOCK_REALTIME` is defined in `<time.h>`. This clock represents the realtime clock for the system. For this clock, the values returned by `clock_gettime()` and specified by `clock_settime()` represent the amount of time (in seconds and nanoseconds) since the Epoch. Additional clocks may also be supported. The interpretation of time values for these clocks is unspecified.

A `clock_id` of `CLOCK_HIGHRES` represents the non-adjustable, high-resolution clock for the system. For this clock, the value returned by `clock_gettime(3RT)` represents the amount of time (in seconds and nanoseconds) since some arbitrary time in the past; it is not correlated in any way to the time of day, and thus is not subject to resetting or drifting by way of `adjtime(2), ntp_adjtime(2), settimeofday(3C)`, or `clock_settime()`. The time source for this clock is the same as that for `gethrtime(3C)`.

Additional clocks may also be supported. The interpretation of time values for these clocks is unspecified.

Upon successful completion, 0 is returned. Otherwise, -1 is returned and `errno` is set to indicate the error.

The `clock_settime()`, `clock_gettime()` and `clock_getres()` functions will fail if:
The clock_id argument does not specify a known clock.

The functions clock_settime(), clock_gettime(), and clock_getres() are not supported by this implementation.

The clock_settime() function will fail if:

- EINVAL The tp argument to clock_settime() is outside the range for the given clock ID; or the tp argument specified a nanosecond value less than zero or greater than or equal to 1000 million.

The clock_settime() function may fail if:

- EPERM The requesting process does not have the appropriate privilege to set the specified clock.

```

**DESCRIPTION**

Condition variables and mutexes should be global. Condition variables that are allocated in writable memory can synchronize threads among processes if they are shared by the cooperating processes (see `mmap(2)`) and are initialized for this purpose.

The scope of a condition variable is either intra-process or inter-process. This is dependent upon whether the argument is passed implicitly or explicitly to the initialization of that condition variable. A condition variable does not need to be explicitly initialized. A condition variable is initialized with all zeros, by default, and its scope is set to within the calling process. For inter-process synchronization, a condition variable must be initialized once, and only once, before use.

A condition variable must not be simultaneously initialized by multiple threads or re-initialized while in use by other threads.

Attributes of condition variables can be set to the default or customized at initialization.

The `cond_init()` function initializes the condition variable pointed to by `cvp`. A condition variable can have several different types of behavior, specified by `type`. No current type uses `arg` although a future type may specify additional behavior parameters with `arg`. The `type` argument can take one of the following values:

- **USYNC_THREAD**: The condition variable can synchronize threads only in this process. This is the default.
- **USYNC_PROCESS**: The condition variable can synchronize threads in this process and other processes. Only one process should initialize the condition variable. The object initialized with this attribute must be allocated in memory shared between processes, either in System V shared memory (see `shmop(2)`) or in memory mapped to a file (see `mmap(2)`).
cond_init(3THR)

mmap(2)). It is illegal to initialize the object this way and to not allocate it in such shared memory.

Initializing condition variables can also be accomplished by allocating in zeroed memory, in which case, a type of USYNC_THREAD is assumed.

If default condition variable attributes are used, statically allocated condition variables can be initialized by the macro DEFAULTTCV.

Default condition variable initialization (intra-process):

```c
cond_t cvp;
cond_init(&cvp, NULL, NULL); /*initialize condition variable with default*/
```

or

```c
cond_init(&cvp, USYNC_THREAD, NULL);
```

or

```c
cond_t cond = DEFAULTTCV;
```

Customized condition variable initialization (inter-process):

```c
cond_init(&cvp, USYNC_PROCESS, NULL); /* initialize cv with inter-process scope */
```

Condition Wait

The condition wait interface allows a thread to wait for a condition and atomically release the associated mutex that it needs to hold to check the condition. The thread waits for another thread to make the condition true and that thread’s resulting call to signal and wakeup the waiting thread.

The `cond_wait()` function atomically releases the mutex pointed to by `mp` and causes the calling thread to block on the condition variable pointed to by `cvp`. The blocked thread may be awakened by `cond_signal()`, `cond_broadcast()`, or when interrupted by delivery of a UNIX signal or a `fork()`.

The `cond_wait()`, `cond_timedwait()`, and `cond_reltimedwait()` functions always return with the mutex locked and owned by the calling thread even when returning an error, except when the mutex is of USYNC_PROCESS_ROBUST type and has been left irrecoverable by the mutex’s last owner. The `cond_wait()`, `cond_timedwait()`, and `cond_reltimedwait()` functions return the appropriate error value if they fail to internally reacquire the mutex.

A condition signal allows a thread to unblock a single thread waiting on the condition variable, whereas a condition broadcast allows a thread to unblock all threads waiting on the condition variable.

The `cond_signal()` function unblocks one thread that is blocked on the condition variable pointed to by `cvp`. 
The `cond_broadcast()` function unblocks all threads that are blocked on the condition variable pointed to by `cvp`.

If no threads are blocked on the condition variable, then `cond_signal()` and `cond_broadcast()` have no effect.

Both functions should be called under the protection of the same mutex that is used with the condition variable being signaled. Otherwise, the condition variable may be signaled between the test of the associated condition and blocking in `cond_wait()`. This can cause an infinite wait.

Destroy

The condition destroy functions destroy any state, but not the space, associated with the condition variable.

The `cond_destroy()` function destroys any state associated with the condition variable pointed to by `cvp`. The space for storing the condition variable is not freed.

RETURN VALUES

Upon successful completion, these functions return 0. Otherwise, a non-zero value is returned to indicate the error.

ERRORS

These functions may fail if:

- **EFAULT**
  The `cond`, `attr`, `cvp`, `arg`, `abstime`, or `mutex` argument points to an illegal address.

- **EINVAL**
  Invalid argument. For `cond_init()`, `type` is not a recognized type. For `cond_timedwait()`, the specified number of seconds, `abstime`, is greater than `current_time + 100,000,000`, where `current_time` is the current time, or the number of nanoseconds is greater than or equal to `1,000,000,000`.

- **EINVAL**
  The last owner of this mutex unmapped the mutex while holding the mutex. This mutex is now owned by the caller. See the description of the `mutex_lock()` function on the `mutex_init(3THR)` manual page.

- **EINVAL**
  The mutex pointed to by `mp` is protecting the state that has been left irrecoverable when the mutex’s last owner was not able to clean up the state. The mutex has not been acquired. See the description of the `mutex_lock()` function on the `mutex_init(3THR)` manual page.

- **EINVAL**
  The last owner of the mutex pointed to by `mp` died while holding the mutex. The mutex has been acquired. See the description of the `mutex_lock()` function on the `mutex_init(3THR)` manual page.

The `cond_timedwait()` and `cond_reltimedwait()` functions will fail if:
The time specified by `abstime` or `reltime` has passed.

The `cond_wait()` function may fail if:

**EINTR** Interrupted. The calling thread was awakened by the delivery of a UNIX signal.

**EXAMPLE 1** Use `cond_wait()` in a loop to test some condition.

The `cond_wait()` function is normally used in a loop testing some condition, as follows:

```c
(void) mutex_lock(mp);
while (cond == FALSE) {
    (void) cond_wait(cvp, mp);
}
(void) mutex_unlock(mp);
```

**EXAMPLE 2** Use `cond_timedwait()` in a loop to test some condition.

The `cond_timedwait()` function is normally used in a loop testing some condition. It uses an absolute timeout value as follows:

```c
timestruc_t to;
...
(void) mutex_lock(mp);
    to.tv_sec = time(NULL) + TIMEOUT;
    to.tv_nsec = 0;
    while (cond == FALSE) {
        err = cond_timedwait(cvp, mp, &to);
        if (err == ETIME) {
            /* timeout, do something */
            break;
        }
    }
(void) mutex_unlock(mp);
```

**EXAMPLE 3** Use `cond_reltimedwait()` in a loop to test some condition.

The `cond_reltimedwait()` function is normally used in a loop testing in some condition. It uses a relative timeout value as follows:

```c
timestruc_t to;
...
(void) mutex_lock(mp);
    while (cond == FALSE) {
        to.tv_sec = TIMEOUT;
        to.tv_nsec = 0;
        err = cond_reltimedwait(cvp, mp, &to);
        if (err == ETIME) {
            /* timeout, do something */
            break;
        }
    }
```
EXAMPLE 3 Use cond_reltimedwait() in a loop to test some condition.  (Continued)

```c
(void) mutex_unlock(mp);
```

**NOTES**

The only policy currently supported is SCHED_OTHER. In Solaris, under the SCHED_OTHER policy, there is no established order in which threads are unblocked.

If more than one thread is blocked on a condition variable, the order in which threads are unblocked is determined by the scheduling policy. When each thread, unblocked as a result of a cond_signal() or cond_broadcast(), returns from its call to cond_wait() or cond_timedwait(), the thread owns the mutex with which it called cond_wait(), cond_timedwait(), or cond_reltimedwait(). The thread(s) that are unblocked compete for the mutex according to the scheduling policy and as if each had called mutex_lock(3THR).

When cond_wait() returns the value of the condition is indeterminate and must be reevaluated.

The cond_timedwait() and cond_reltimedwait() functions are similar to cond_wait(), except that the calling thread will not wait for the condition to become true past the absolute time specified by abstime or the relative time specified by reltime. Note that cond_timedwait() or cond_reltimedwait() might continue to block as it tries to reacquire the mutex pointed to by mp, which may be locked by another thread. If either cond_timedwait() or cond_reltimedwait() returns because of a timeout, it returns the error value ETIME.
Occasionally, a thread running within a mutex needs to wait for an event, in which case it blocks or sleeps. When a thread is waiting for another thread to communicate its disposition, it uses a condition variable in conjunction with a mutex. Although a mutex is exclusive and the code it protects is sharable (at certain moments), condition variables enable the synchronization of differing events that share a mutex, but not necessarily data. Several condition variables may be used by threads to signal each other when a task is complete, which then allows the next waiting thread to take ownership of the mutex.

A condition variable enables threads to atomically block and test the condition under the protection of a mutual exclusion lock (mutex) until the condition is satisfied. If the condition is false, a thread blocks on a condition variable and atomically releases the mutex that is waiting for the condition to change. If another thread changes the condition, it may wake up waiting threads by signaling the associated condition variable. The waiting threads, upon awakening, reacquire the mutex and re-evaluate the condition.

Condition variables and mutexes should be global. Condition variables that are allocated in writable memory can synchronize threads among processes if they are shared by the cooperating processes (see `mmap(2)` and are initialized for this purpose.

The scope of a condition variable is either intra-process or inter-process. This is dependent upon whether the argument is passed implicitly or explicitly to the initialization of that condition variable. A condition variable does not need to be explicitly initialized. A condition variable is initialized with all zeros, by default, and its scope is set to within the calling process. For inter-process synchronization, a condition variable must be initialized once, and only once, before use.

A condition variable must not be simultaneously initialized by multiple threads or re-initialized while in use by other threads.

Condition variables attributes may be set to the default or customized at initialization. POSIX threads even allow the default values to be customized. Establishing these attributes varies depending upon whether POSIX or Solaris threads are used. Similar to the distinctions between POSIX and Solaris thread creation, POSIX condition variables implement the default, intra-process, unless an attribute object is modified for inter-process prior to the initialization of the condition variable. Solaris condition variables also implement as the default, intra-process; however, they set this attribute according to the argument, `type`, passed to their initialization function.

The condition wait interface allows a thread to wait for a condition and atomically release the associated mutex that it needs to hold to check the condition. The thread waits for another thread to make the condition true and that thread’s resulting call to signal and wakeup the waiting thread.

A condition signal allows a thread to unblock the next thread waiting on the condition variable, whereas, a condition broadcast allows a thread to unblock all threads waiting on the condition variable.
The condition destroy functions destroy any state, but not the space, associated with the condition variable.

**ATTRIBUTES**

**NOTES**

If more than one thread is blocked on a condition variable, the order in which threads are unblocked is determined by the scheduling policy.

USYNC_THREAD does not support multiple mappings to the same logical synch object. If you need to mmap() a synch object to different locations within the same address space, then the synch object should be initialized as a shared object USYNC_PROCESS for Solaris, and PTHREAD_PROCESS_PRIVATE for POSIX.
**NAME**
door_bind, door_unbind – bind or unbind the current thread with the door server pool

**SYNOPSIS**
```c
cc -mt [ flag ... ] file ... -ldoor [ library ... ]
#include <door.h>

int door_bind(int did);
int door_unbind();
```

**DESCRIPTION**
The `door_bind()` function associates the current thread with a door server pool. A door server pool is a private pool of server threads that is available to serve door invocations associated with the door `did`.

The `door_unbind()` function breaks the association of `door_bind()` by removing any private door pool binding that is associated with the current thread.

Normally, door server threads are placed in a global pool of available threads that invocations on any door can use to dispatch a door invocation. A door that has been created with `DOOR_PRIVATE` only uses server threads that have been associated with the door by `door_bind()`. It is therefore necessary to bind at least one server thread to doors created with `DOOR_PRIVATE`.

The server thread create function, `door_server_create()`, is initially called by the system during a `door_create()` operation. See `door_server_create(3DOOR)` and `door_create(3DOOR)`.

The current thread is added to the private pool of server threads associated with a door during the next `door_return()` (that has been issued by the current thread after an associated `door_bind()`). See `door_return(3DOOR)`. A server thread performing a `door_bind()` on a door that is already bound to a different door performs an implicit `door_unbind()` of the previous door.

If a process containing threads that have been bound to a door calls `fork(2)`, the threads in the child process will be bound to an invalid door, and any calls to `door_return(3DOOR)` will result in an error.

**RETURN VALUES**
Upon successful completion, a 0 is returned. Otherwise, −1 is returned and `errno` is set to indicate the error.

**ERRORS**
The `door_bind()` and `door_unbind()` functions fail if:

- **EBADF** The `did` argument is not a valid door.
- **EBADF** The `door_unbind()` function was called by a thread that is currently not bound.
- **EINVAL** `did` was not created with the `DOOR_PRIVATE` attribute.
EXAMPLE 1 Use door_bind() to create private server pools for two doors.

The following example shows the use of door_bind() to create private server pools for two doors, d1 and d2. Function my_create() is called when a new server thread is needed; it creates a thread running function, my_server_create(), which binds itself to one of the two doors.

```c
#include <door.h>
#include <thread.h>
#include <pthread.h>

thread_key_t door_key;
int d1 = -1;
int d2 = -1;
cond_t cv; /* statically initialized to zero */
mutex_t lock; /* statically initialized to zero */

extern foo(); extern bar();

static void *
my_server_create(void *arg)
{
    /* wait for d1 & d2 to be initialized */
    mutex_lock(&lock);
    while (d1 == -1 || d2 == -1)
        cond_wait(&cv, &lock);
    mutex_unlock(&lock);

    if (arg == (void *)foo){
        /* bind thread with pool associated with d1 */
        thr_setspecific(door_key, (void *)foo);
        if (door_bind(d1) < 0) {
            perror("door_bind"); exit (-1);
        }
    } else if (arg == (void *)bar) {
        /* bind thread with pool associated with d2 */
        thr_setspecific(door_key, (void *)bar);
        if (door_bind(d2) < 0) {
            /* bind thread to d2 thread pool */
            perror("door_bind"); exit (-1);
        }
    }

    pthread_setcancelstate(POSIX_CANCEL_DISABLE, NULL);
    door_return(NULL, 0, NULL, 0); /* Wait for door invocation */
}

static void
my_create(door_info_t *dip)
{
    /* Pass the door identity information to create function */
    thr_create(NULL, 0, my_server_create, (void *)dip->di_proc,
               THR_BOUND | THR_DETACHED, NULL);
}

main( )
{
    (void)door_server_create(my_create);
    mutex_lock(&lock);
}
```

door_call(3DOOR)

NAME
door_call – invoke the function associated with a door descriptor

SYNOPSIS
cce [ flag ... ] file ... -ldoor [ library ... ]

#include <door.h>

typedef struct {
    char *data_ptr; /* Argument/result buf ptr */
    size_t data_size; /* Argument/result buf size */
    door_desc_t *desc_ptr; /* Argument/result descriptors */
    uint_t desc_num; /* Argument/result num desc */
    char *rbuf; /* Result buffer */
    size_t rsize; /* Result buffer size */
} door_arg_t;

int door_call(int d, door_arg_t *params);

DESCRIPTION

The door_call() function invokes the function associated with the door descriptor d, and passes the arguments (if any) specified in params. All of the params members are treated as in/out parameters during a door invocation and may be updated upon returning from a door call. Passing NULL for params indicates there are no arguments to be passed and no results expected.

Arguments are specified using the data_ptr and desc_ptr members of params. The size of the argument data in bytes is passed in data_size and the number of argument descriptors is passed in desc_num.

Results from the door invocation are placed in the buffer, rbuf. See door_return(3DOOR). The data_ptr and desc_ptr members of params are updated to reflect the location of the results within the rbuf buffer. The size of the data results and number of descriptors returned are updated in the data_size and desc_num members. It is acceptable to use the same buffer for input argument data and results, so door_call() may be called with data_ptr and desc_ptr pointing to the buffer rbuf.

If the results of a door invocation exceed the size of the buffer specified by rsize, the system automatically allocates a new buffer in the caller’s address space and updates the rbuf and rsize members to reflect this location. In this case, the caller is responsible for reclaiming this area using munmap(rbuf, rsize) when the buffer is no longer required. See munmap(2).

Descriptors passed in a door_desc_t structure are identified by the d_attributes member. The client marks the d_attributes member with the type of object being passed by logically OR-ing the value of object type. Currently, the only object type that can be passed or returned is a file descriptor, denoted by the DOOR_DESCRIPTOR attribute. Additionally, the DOOR_RELEASE attribute can be set, causing the descriptor to be closed in the caller’s address space after it is passed to the target. The descriptor will be closed even if door_call() returns an error, unless that error is EFAULT or EBADF.

The door_desc_t structure includes the following members:
typedef struct {
    door_attr_t d_attributes; /* Describes the parameter */
    union {
        struct {
            int d_descriptor; /* Descriptor */
            door_id_t d_id; /* Unique door id */
        } d_desc;
    } d_data;
} door_desc_t;

When file descriptors are passed or returned, a new descriptor is created in the target address space and the d_descriptor member in the target argument is updated to reflect the new descriptor. In addition, the system passes a system-wide unique number associated with each door in the door_id member and marks the d_attributes member with other attributes associated with a door including the following:

- **DOOR_LOCAL**: The door received was created by this process using door_create(). See door_create(3DOOR).
- **DOOR_PRIVATE**: The door received has a private pool of server threads associated with the door.
- **DOOR_UNREF**: The door received is expecting an unreferenced notification.
- **DOOR_UNREF_MULTI**: Similar to DOOR_UNREF, except multiple unreferenced notifications may be delivered for the same door.
- **DOOR_REVOKED**: The door received has been revoked by the server.

The door_call() function is not a restartable system call. It returns EINTR if a signal was caught and handled by this thread. If the door invocation is not idempotent the caller should mask any signals that may be generated during a door_call() operation. If the client aborts in the middle of a door_call(), the server thread is notified using the POSIX (see standards(5)) thread cancellation mechanism. See cancellation(3THR).

The descriptor returned from door_create() is marked as close on exec (FD_CLOEXEC). Information about a door is available for all clients of a door using door_info(). Applications concerned with security should not place secure information in door data that is accessible by door_info(). In particular, secure data should not be stored in the data item cookie. See door_info(3DOOR).

**RETURN VALUES**

Upon successful completion, 0 is returned. Otherwise, -1 is returned and errno is set to indicate the error.

**ERRORS**

The door_call() function will fail if:

- **EBADF**: Invalid door descriptor was passed.
- **EINVAL**: Bad arguments were passed.
- **EFAULT**: Argument pointers pointed outside the allocated address space.
door_call(3DOOR)

E2BIG     Arguments were too big for server thread stack.
EOVERFLOW System could not create overflow area in caller for results.
EAGAIN    Server was out of available resources.
EINTR     Signal was caught in the client during the invocation.
EMFILE    The client or server has too many open descriptors.

SEE ALSO munmap(2), cancellation(3THR), door_create(3DOOR), door_info(3DOOR), door_return(3DOOR), attributes(5), standards(5)
The `door_create()` function creates a door descriptor that describes the procedure specified by the function `server_procedure`. The data item, `cookie`, is associated with the door descriptor, and is passed as an argument to the invoked function `server_procedure` during `door_call(3DOOR)` invocations. Other arguments passed to `server_procedure` from an associated `door_call()` are placed on the stack and include `argp` and `dp`. The `argp` argument points to `arg_size` bytes of data and the `dp` argument points to `n_desc` `door_desc_t` structures. The `attributes` argument specifies attributes associated with the newly created door. Valid values for `attributes` are constructed by OR-ing one or more of the following values:

- **DOOR_UNREF**
  - Delivers a special invocation on the door when the number of descriptors that refer to this door drops to one. In order to trigger this condition, more than one descriptor must have referred to this door at some time. `DOOR_UNREF_DATA` designates an unreferenced invocation, as the `argp` argument passed to `server_procedure`. In the case of an unreferenced invocation, the values for `arg_size`, `dp` and `n_desc` are 0. Only one unreferenced invocation is delivered on behalf of a door.

- **DOOR_UNREF_MULTI**
  - Similar to `DOOR_UNREF`, except multiple unreferenced invocations can be delivered on the same door if the number of descriptors referring to the door drops to one more than once. Since an additional reference may have been passed by the time an unreferenced invocation arrives, the `DOOR_IS_UNREF` attribute returned by the `door_info(3DOOR)` call can be used to determine if the door is still unreferenced.

- **DOOR_PRIVATE**
  - Maintains a separate pool of server threads on behalf of the door. Server threads are associated with a door’s private server pool using `door_bind(3DOOR)`.

The descriptor returned from `door_create()` will be marked as close on exec (`FD_CLOEXEC`). Information about a door is available for all clients of a door using `door_info(3DOOR)`. Applications concerned with security should not place secure information in door data that is accessible by `door_info()`. In particular, secure data should not be stored in the data item `cookie`. 
By default, additional threads are created as needed to handle concurrent `door_call(3DOOR)` invocations. See `door_server_create(3DOOR)` for information on how to change this behavior.

**RETURN VALUES**

Upon successful completion, `door_create()` returns a non-negative value. Otherwise, `door_create` returns −1 and sets `errno` to indicate the error.

**ERRORS**

The `door_create()` function will fail if:

- **EINVAL** Invalid attributes are passed.
- **EMFILE** The process has too many open descriptors.

door_cred(3DOOR)

NAME  door_cred – return credential information associated with the client

SYNOPSIS  
```c
#include <door.h>

int door_cred(door_cred_t *info);
```

DESCRIPTION  The `door_cred()` function returns credential information associated with the client (if any) of the current door invocation.

The contents of the `info` argument include the following fields:

```c
uid_t dc_euid; /* Effective uid of client */
gid_t dc_egid; /* Effective gid of client */
uid_t dc_ruid; /* Real uid of client */
gid_t dc_rgid; /* Real gid of client */
pid_t dc_pid; /* pid of client */
```

The credential information associated with the client refers to the information from the immediate caller; not necessarily from the first thread in a chain of door calls.

RETURN VALUES  Upon successful completion, `door_cred()` returns 0. Otherwise, `door_cred()` returns −1 and sets `errno` to indicate the error.

ERRORS  The `door_cred()` function will fail if:

- **EFAULT** The address of the `info` argument is invalid.
- **EINVAL** There is no associated door client.

</tr>
</tbody>
</table>

SEE ALSO  `door_call(3DOOR)`, `door_create(3DOOR)`, `attributes(5)`
The `door_info()` function returns information associated with a door descriptor. It obtains information about the door descriptor `d` and places the information that is relevant to the door in the structure pointed to by the `info` argument.

The `door_info` structure pointed to by the `info` argument contains the following members:

- `pid_t di_target; /* door server pid */`
- `door_ptr_t di_proc; /* server function */`
- `door_ptr_t di_data; /* data cookie for invocation */`
- `door_attr_t di_attributes; /* door attributes */`
- `door_id_t di_uniquifier; /* unique id among all doors */`

The `di_target` member is the process ID of the door server, or −1 if the door server process has exited.

The values for `di_attributes` may be composed of the following:

- `DOOR_LOCAL`: The door descriptor refers to a service procedure in this process.
- `DOOR_UNREF`: The door has requested notification when all but the last reference has gone away.
- `DOOR_UNREF_MULTI`: Similar to `DOOR_UNREF`, except multiple unreferenced notifications may be delivered for this door.
- `DOOR_IS_UNREF`: There is currently only one descriptor referring to the door.
- `DOOR_REVOKED`: The door descriptor refers to a door that has been revoked.
- `DOOR_PRIVATE`: The door has a separate pool of server threads associated with it.

The `di_proc` and `di_data` members are returned as `door_ptr_t` objects rather than `void*` pointers to allow clients and servers to interoperate in environments where the pointer sizes may vary in size (for example, 32-bit clients and 64-bit servers). Each door has a system-wide unique number associated with it that is set when the door is created by `door_create()`. This number is returned in `di_uniquifier`.

Upon successful completion, 0 is returned. Otherwise, −1 is returned and `errno` is set to indicate the error.

The `door_info()` function will fail if:
door_info(3DOOR)

EFAULT The address of argument info is an invalid address.
EBADF d is not a door descriptor.

SEE ALSO door_bind(3DOOR), door_create(3DOOR), door_server_create(3DOOR)
door_return(3DOOR)

NAME  door_return — return from a door invocation

SYNOPSIS  
```
cc -mt [ flags ... ] file ... -ldoor [ library ... ]
#include <door.h>

int door_return(char *data_ptr, size_t data_size, door_desc_t *desc_ptr,
                uint_t num_desc);
```

DESCRIPTION  The `door_return()` function returns from a door invocation. It returns control to the thread that issued the associated `door_call()` and blocks waiting for the next door invocation. See `door_call(3DOOR)`. Results, if any, from the door invocation are passed back to the client in the buffers pointed to by `data_ptr` and `desc_ptr`. If there is not a client associated with the `door_return()`, the calling thread discards the results, releases any passed descriptors with the `DOOR_RELEASE` attribute, and blocks waiting for the next door invocation.

RETURN VALUES  Upon successful completion, `door_return()` does not return to the calling process. Otherwise, `door_return()` returns `-1` to the calling process and sets `errno` to indicate the error.

ERRORS  The `door_return()` function fails and returns to the calling process if:

- **E2BIG** Arguments were too big for client.
- **EFAULT** The address of `data_ptr` or `desc_ptr` is invalid.
- **EINVAL** Invalid `door_return()` arguments were passed or a thread is bound to a door that no longer exists.
- **EMFILE** The client has too many open descriptors.

door_revoke(3DOOR)

NAME  door_revoke – revoke access to a door descriptor
SYNOPSIS  cc -mt [ flag ... ] file ... -ldoor [ library ... ]
#include <door.h>

int door_revoke(int d);

DESCRIPTION  The door_revoke() function revokes access to a door descriptor. Door descriptors
are created with door_create(3DOOR). The door_revoke() function performs an
implicit call to close(2), marking the door descriptor d as invalid.

A door descriptor can only be revoked by the process that created it. Door invocations
that are in progress during a door_revoke() invocation are allowed to complete
normally.

RETURN VALUES  Upon successful completion, door_revoke() returns 0. Otherwise,
                 door_revoke() returns -1 and sets errno to indicate the error.

ERRORS  The door_revoke() function will fail if:

    EBADF   An invalid door descriptor was passed.
    EPERM   The door descriptor was not created by this process (with
door_create(3DOOR)).

door_server_create(3DOOR)

NAME
door_server_create – specify an alternative door server thread creation function

SYNOPSIS
cc -mt [ flag ... ] file ... -ldoor [ library ... ]
#include <door.h>

void (*) () door_server_create(void (*create_proc) (door_info_t*));

DESCRIPTION
Normally, the doors library creates new door server threads in response to incoming concurrent door invocations automatically. There is no pre-defined upper limit on the number of server threads that the system creates in response to incoming invocations (1 server thread for each active door invocation). These threads are created with the default thread stack size and POSIX (see standards(5)) threads cancellation disabled. The created threads also have the THR_BOUND | THR_DETACHED attributes for Solaris threads and the PTHREAD_SCOPE_SYSTEM | PTHREAD_CREATE_DETACHED attributes for POSIX threads. The signal disposition, and scheduling class of the newly created thread are inherited from the calling thread (initially from the thread calling door_create(), and subsequently from the current active door server thread).

The door_server_create() function allows control over the creation of server threads needed for door invocations. The procedure create_proc is called every time the available server thread pool is depleted. In the case of private server pools associated with a door (see the DOOR_PRIVATE attribute in door_create()), information on which pool is depleted is passed to the create function in the form of a door_info_t structure. The di_proc and di_data members of the door_info_t structure can be used as a door identifier associated with the depleted pool. The create_proc procedure may limit the number of server threads created and may also create server threads with appropriate attributes (stack size, thread-specific data, POSIX thread cancellation, signal mask, scheduling attributes, and so forth) for use with door invocations.

The specified server creation function should create user level threads using thr_create() with the THR_BOUND flag, or in the case of POSIX threads, pthread_create() with the PTHREAD_SCOPE_SYSTEM attribute. The server threads make themselves available for incoming door invocations on this process by issuing a door_return(NULL, 0, NULL, 0). In this case, the door_return() arguments are ignored. See door_return(3DOOR) and thr_create(3THR).

The server threads created by default are enabled for POSIX thread cancellations which may lead to unexpected thread terminations while holding resources (such as locks) if the client aborts the associated door_call(). See door_call(3DOOR). Unless the server code is truly interested in notifications of client aborts during a door invocation and is prepared to handle such notifications using cancellation handlers, POSIX thread cancellation should be disabled for server threads using pthread_setcancelstate (PTHREAD_CANCEL_DISABLE, NULL).

The create_proc procedure need not create any additional server threads if there is at least one server thread currently active in the process (perhaps handling another door invocation) or it may create as many as seen fit each time it is called. If there are no available server threads during an incoming door invocation, the associated door_call() blocks until a server thread becomes available. The create_proc procedure must be MT-Safe.
Upon successful completion, `door_server_create()` returns a pointer to the previous server creation function. This function has no failure mode (it cannot fail).

**EXAMPLE 1** Creating door server threads.

The following example creates door server threads with cancellation disabled and an 8k stack instead of the default stack size:

```c
#include <door.h>
#include <pthread.h>
#include <thread.h>

void *
my_thread(void *arg)
{
    pthread_setcancelstate(PTHREAD_CANCEL_DISABLE, NULL);
    door_return(NULL, 0, NULL, 0);
}

void
my_create(door_info_t *dip)
{
    thr_create(NULL, 8192, my_thread, NULL,
               THR_BOUND | THR_DETACHED, NULL);
}
main()
{
    (void)door_server_create(my_create);
    ...
}
```

NAME
fdatasync – synchronize a file’s data

SYNOPSIS
cc [ flag... ] file... -lrt [ library... ]
#include <unistd.h>

int fdatasync(int fildes);

DESCRIPTION
The fdatasync() function forces all currently queued I/O operations associated
with the file indicated by file descriptor fildes to the synchronized I/O completion
state.

The functionality is as described for fsync(3C) (with the symbol _XOPEN_REALTIME
defined), with the exception that all I/O operations are completed as defined for
synchronised I/O data integrity completion.

RETURN VALUES
If successful, the fdatasync() function returns 0. Otherwise, the function returns −1
and sets errno to indicate the error. If the fdatasync() function fails, outstanding
I/O operations are not guaranteed to have been completed.

ERRORS
The fdatasync() function will fail if:

EBADF The fildes argument is not a valid file descriptor open for writing.
EINVAL The system does not support synchronized I/O for this file.
ENOSYS The function fdatasync() is not supported by the system.

In the event that any of the queued I/O operations fail, fdatasync() returns the
error conditions defined for read(2) and write(2).

libthread_db(3THR)
The libthread_db library provides support for monitoring and manipulating threads-related aspects of a multithreaded program. There are at least two processes involved, the controlling process and one or more target processes. The controlling process is the libthread_db client, which links with libthread_db and uses libthread_db to inspect or modify threads-related aspects of one or more target processes. The target processes must be multithreaded processes that use libthread or libpthread. The controlling process may or may not be multithreaded itself.

The most commonly anticipated use for libthread_db is that the controlling process will be a debugger for a multithreaded program, hence the "db" in libthread_db.

libthread_db is dependent on the internal implementation details of libthread. It is a "friend" of libthread in the C++ sense, which is precisely the "value added" by libthread_db. It encapsulates the knowledge of libthread internals that a debugger needs in order to manipulate the threads-related state of a target process.

To be able to inspect and manipulate target processes, libthread_db makes use of certain process control primitives that must be provided by the process using libthread_db. The imported interfaces are defined in proc_service(3PROC). In other words, the controlling process is linked with libthread_db, and it calls routines in libthread_db.libthread_db in turn calls certain routines that it expects the controlling process to provide. These process control primitives allow libthread_db to:

- Look up symbols in a target process.
- Stop and continue individual lightweight processes (LWPs) within a target process.
Stop and continue an entire target process.
Read and write memory and registers in a target process.

Initially, a controlling process obtains a handle for a target process. Through that handle it can then obtain handles for the component objects of the target process, its threads, its synchronization objects, and its thread-specific-data keys.

When libthread_db needs to return sets of handles to the controlling process, for example, when returning handles for all the threads in a target process, it uses an iterator function. An iterator function calls back a client-specified function once for each handle to be returned, passing one handle back on each call to the callback function. The calling function also passes another parameter to the iterator function, which the iterator function passes on to the callback function. This makes it easy to build a linked list of thread handles for a particular target process. The additional parameter is the head of the linked list, and the callback function simply inserts the current handle into the linked list.

Callback functions are expected to return an integer. Iteration terminates early if a callback function returns a non-zero value. Otherwise, iteration terminates when there are no more handles to pass back.

libthread_db relies on an "agent thread" in the target process for some of its operations. The "agent thread" is a system thread started when libthread_db attaches to a process through td_ta_new(3THR). In the current implementation, a brief window exists after the agent thread has been started, but before it has completed its initialization, in which libthread_db routines that require the agent thread will fail, returning a TD_NOCAPAB error status. This is particularly troublesome if the target process was stopped when td_ta_new() was called, so that the agent thread cannot be initialized. To avoid this problem, the target process must be allowed to make some forward progress after td_ta_new() is called. This limitation will be removed in a future release.

attributes(5)
The `lio_listio` function allows the calling process, LWP, or thread, to initiate a list of I/O requests within a single function call.

The `mode` argument takes one of the values `LIO_WAIT` or `LIO_NOWAIT` declared in `<aio>` and determines whether the function returns when the I/O operations have been completed, or as soon as the operations have been queued. If the `mode` argument is `LIO_WAIT`, the function waits until all I/O is complete and the `sig` argument is ignored.

If the `mode` argument is `LIO_NOWAIT`, the function returns immediately, and asynchronous notification occurs, according to the `sig` argument, when all the I/O operations complete. If `sig` is `NULL`, or the `sigev_signo` member of the `sigevent` structure referenced by `sig` is zero, then no asynchronous notification occurs. If `sig` is not `NULL`, asynchronous notification occurs when all the requests in `list` have completed. If `sig->sigev_notify` is `SIGEV_NONE`, then no signal will be posted upon I/O completion, but the error status and the return status for the operation will be set appropriately. If `sig->sigev_notify` is `SIGEV_SIGNAL`, then the signal specified in `sig->sigev_signo` will be sent to the process. If the `SA_SIGINFO` flag is set for that signal number, then the signal will be queued to the process and the value specified in `sig->sigev_value` will be the `si_value` component of the generated signal (see `siginfo(3HEAD)`).

The I/O requests enumerated by `list` are submitted in an unspecified order.

The `list` argument is an array of pointers to `aiocb` structures. The array contains `nent` elements. The array may contain null elements, which are ignored.

The `aio_lio_opcode` field of each `aiocb` structure specifies the operation to be performed. The supported operations are `LIO_READ`, `LIO_WRITE`, and `LIO_NOP`; these symbols are defined in `<aio>`. The `LIO_NOP` operation causes the list entry to be ignored. If the `aio_lio_opcode` element is equal to `LIO_READ`, then an I/O operation is submitted as if by a call to `aio_read(3RT)` with the `aiocb` equal to the address of the `aiocb` structure. If the `aio_lio_opcode` element is equal to `LIO_WRITE`, then an I/O operation is submitted as if by a call to `aio_write(3RT)` with the `aiocb` equal to the address of the `aiocb` structure.

The `aio_fildes` member specifies the file descriptor on which the operation is to be performed.

The `aio_buf` member specifies the address of the buffer to or from which the data is to be transferred.

The `aio_nbytes` member specifies the number of bytes of data to be transferred.
lio_listio(3RT)

The members of the aiocb structure further describe the I/O operation to be performed, in a manner identical to that of the corresponding aiocb structure when used by the aio_read(3RT) and aio_write(3RT) functions.

The nent argument specifies how many elements are members of the list, that is, the length of the array.

The behavior of this function is altered according to the definitions of synchronized I/O data integrity completion and synchronized I/O file integrity completion if synchronized I/O is enabled on the file associated with aio_fildes. (see fcntl(3HEAD) definitions of O_DSYNC and O_SYNC.)

For regular files, no data transfer will occur past the offset maximum established in the open file description associated with aiocbp->aio_fildes.

RETURN VALUES

If the mode argument has the value LIO_NOWAIT, and the I/O operations are successfully queued, lio_listio() returns 0; otherwise, it returns -1, and sets errno to indicate the error.

If the mode argument has the value LIO_WAIT, and all the indicated I/O has completed successfully, lio_listio() returns 0; otherwise, it returns -1, and sets errno to indicate the error.

In either case, the return value only indicates the success or failure of the lio_listio() call itself, not the status of the individual I/O requests. In some cases, one or more of the I/O requests contained in the list may fail. Failure of an individual request does not prevent completion of any other individual request. To determine the outcome of each I/O request, the application must examine the error status associated with each aiocb control block. Each error status so returned is identical to that returned as a result of an aio_read(3RT) or aio_write(3RT) function.

ERRORS

The lio_listio() function will fail if:

EAGAIN The resources necessary to queue all the I/O requests were not available. The error status for each request is recorded in the aio_error member of the corresponding aiocb structure, and can be retrieved using aio_error(3RT).

EAGAIN The number of entries indicated by nent would cause the system-wide limit AIO_MAX to be exceeded.

EINVAL The mode argument is an improper value, or the value of nent is greater than AIO_LISTIO_MAX.

EINTR A signal was delivered while waiting for all I/O requests to complete during an LIO_WAIT operation. Note that, since each I/O operation invoked by lio_listio() may possibly provoke a signal when it completes, this error return may be caused by the completion of one (or more) of the very I/O operations being awaited. Outstanding I/O requests are not canceled, and the application can use aio_fsync(3RT) to determine if any request
lio_listio(3RT)

was initiated; aio_return(3RT) to determine if any request has completed; or aio_error(3RT) to determine if any request was canceled.

EIO

One or more of the individual I/O operations failed. The application can use aio_error(3RT) to check the error status for each aiocb structure to determine the individual request(s) that failed.

ENOSYS

The lio_listio() function is not supported by the system.

In addition to the errors returned by the lio_listio() function, if the lio_listio() function succeeds or fails with errors of EAGAIN, EINTR, or EIO, then some of the I/O specified by the list may have been initiated. If the lio_listio() function fails with an error code other than EAGAIN, EINTR, or EIO, no operations from the list have been initiated. The I/O operation indicated by each list element can encounter errors specific to the individual read or write function being performed. In this event, the error status for each aiocb control block contains the associated error code. The error codes that can be set are the same as would be set by a read(2) or write(2) function, with the following additional error codes possible:

EAGAIN

The requested I/O operation was not queued due to resource limitations.

ECANCELED

The requested I/O was canceled before the I/O completed due to an explicit aio_cancel(3RT) request.

EFTBIG

The aiocbp->aio_lio_opcode is LIO_WRITE, the file is a regular file, aiocbp->aio_nbytes is greater than 0, and the aiocbp->aio_offset is greater than or equal to the offset maximum in the open file description associated with aiocbp->aio_fildes.

EINPROGRESS

The requested I/O is in progress.

EOVERFLOW

The aiocbp->aio_lio_opcode is LIO_READ, the file is a regular file, aiocbp->aio_nbytes is greater than 0, and the aiocbp->aio_offset is before the end-of-file and is greater than or equal to the offset maximum in the open file description associated with aiocbp->aio_fildes.

USAGE

The lio_listio() function has a transitional interface for 64-bit file offsets. See lff64(5).

SEE ALSO

Solaris 2.6 was the first release to support the Asynchronous Input and Output option. Prior to this release, this function always returned −1 and set errno to ENOSYS.
**mq_close(3RT)**

**NAME**
mq_close – close a message queue

**SYNOPSIS**
```c
#include <mqueue.h>
int mq_close(mqd_t mqdes);
```

**DESCRIPTION**
The `mq_close()` function removes the association between the message queue descriptor, `mqdes`, and its message queue. The results of using this message queue descriptor after successful return from this `mq_close()`, and until the return of this message queue descriptor from a subsequent `mq_open(3RT)`, are undefined.

If the process (or thread) has successfully attached a notification request to the message queue via this `mqdes`, this attachment is removed and the message queue is available for another process to attach for notification.

**RETURN VALUES**
Upon successful completion, `mq_close()` returns 0; otherwise, the function returns -1 and sets `errno` to indicate the error condition.

**ERRORS**
The `mq_close()` function will fail if:

- **EBADF** The `mqdes` argument is an invalid message queue descriptor.
- **ENOSYS** The `mq_open()` function is not supported by the system.

**ATTRIBUTES**

**NOTES**
Solaris 2.6 was the first release to support the Asynchronous Input and Output option. Prior to this release, this function always returned -1 and set `errno` to ENOSYS.
mq_getattr(3RT)

NAME
mq_getattr – get message queue attributes

SYNOPSIS
cc [ flag... ] file... -lrt [ library... ]
#include <mqueue.h>

int mq_getattr(mqd_t mqdes, struct mq_attr *mqstat);

DESCRIPTION
The mqdes argument specifies a message queue descriptor. The mq_getattr() function is used to get status information and attributes of the message queue and the open message queue description associated with the message queue descriptor. The results are returned in the mq_attr structure referenced by the mqstat argument.

Upon return, the following members will have the values associated with the open message queue description as set when the message queue was opened and as modified by subsequent mq_setattr(3RT) calls:

- mq_flags message queue flags
- mq_maxmsg maximum number of messages
- mq_msgsize maximum message size
- mq_curmsgs number of messages currently on the queue.

RETURN VALUES
Upon successful completion, the mq_getattr() function returns 0. Otherwise, the function returns −1 and sets errno to indicate the error.

ERRORS
The mq_getattr() function will fail if:

- EBADF The mqdes argument is not a valid message queue descriptor.
- ENOSYS The mq_getattr() function is not supported by the system.

ATTRIBUTES

### NAME
mq_notify – notify process (or thread) that a message is available on a queue

### SYNOPSIS
```c
#include <mqueue.h>

int mq_notify(mqd_t mqdes, const struct sigevent *notification);
```

### DESCRIPTION
The `mq_notify()` function provides an asynchronous mechanism for processes to receive notice that messages are available in a message queue, rather than synchronously blocking (waiting) in `mq_receive(3RT)`.

If `notification` is not `NULL`, this function registers the calling process to be notified of message arrival at an empty message queue associated with the message queue descriptor, `mqdes`. The notification specified by `notification` will be sent to the process when the message queue transitions from empty to non-empty. At any time, only one process may be registered for notification by a specific message queue. If the calling process or any other process has already registered for notification of message arrival at the specified message queue, subsequent attempts to register for that message queue will fail.

The `notification` argument points to a structure that defines both the signal to be generated and how the calling process will be notified upon I/O completion. If `notification->sigev_notify` is `SIGEV_NONE`, then no signal will be posted upon I/O completion, but the error status and the return status for the operation will be set appropriately. If `notification->sigev_notify` is `SIGEV_SIGNAL`, then the signal specified in `notification->sigev_signo` will be sent to the process. If the `SA_SIGINFO` flag is set for that signal number, then the signal will be queued to the process and the value specified in `notification->sigev_value` will be the `si_value` component of the generated signal (see `siginfo(3HEAD)`).

If `notification` is `NULL` and the process is currently registered for notification by the specified message queue, the existing registration is removed. The message queue is then available for future registration.

When the notification is sent to the registered process, its registration is removed. The message queue is then be available for registration.

If a process has registered for notification of message arrival at a message queue and some processes is blocked in `mq_receive(3RT)` waiting to receive a message when a message arrives at the queue, the arriving message will be received by the appropriate `mq_receive(3RT)`, and no notification will be sent to the registered process. The resulting behavior is as if the message queue remains empty, and this notification will not be sent until the next arrival of a message at this queue.

Any notification registration is removed if the calling process either closes the message queue or exits.

### RETURN VALUES
Upon successful completion, `mq_notify()` returns 0; otherwise, it returns -1 and sets `errno` to indicate the error.

### ERRORS
The `mq_notify()` function will fail if:

---

Threads and Realtime Library Functions  81
mq_notify(3RT)

EBADF      The *mqdes* argument is not a valid message queue descriptor.

EBUSY      A process is already registered for notification by the message queue.

ENOSYS     The *mq_notify()* function is not supported by the system.

NOTES       Solaris 2.6 was the first release to support the Asynchronous Input and Output option. Prior to this release, this function always returned −1 and set *errno* to ENOSYS.
### NAME
mq_open – open a message queue

### SYNOPSIS
```c
#include <mqueue.h>

mqd_t mq_open(const char *name, int oflag, /* unsigned long mode,
               mq_attr attr */ ...);
```

### DESCRIPTION
The `mq_open()` function establishes the connection between a process and a message queue with a message queue descriptor. It creates an open message queue description that refers to the message queue, and a message queue descriptor that refers to that open message queue description. The message queue descriptor is used by other functions to refer to that message queue.

The `name` argument points to a string naming a message queue. The `name` argument must conform to the construction rules for a path-name. If `name` is not the name of an existing message queue and its creation is not requested, `mq_open()` fails and returns an error. The first character of `name` must be a slash (\`) character and the remaining characters of `name` cannot include any slash characters. For maximum portability, `name` should include no more than 14 characters, but this limit is not enforced.

The `oflag` argument requests the desired receive and/or send access to the message queue. The requested access permission to receive messages or send messages is granted if the calling process would be granted read or write access, respectively, to a file with the equivalent permissions.

The value of `oflag` is the bitwise inclusive OR of values from the following list. Applications must specify exactly one of the first three values (access modes) below in the value of `oflag`:

- **O_RDONLY**: Open the message queue for receiving messages. The process can use the returned message queue descriptor with `mq_receive(3RT)`, but not `mq_send(3RT)`. A message queue may be open multiple times in the same or different processes for receiving messages.

- **O_WRONLY**: Open the queue for sending messages. The process can use the returned message queue descriptor with `mq_send(3RT)` but not `mq_receive(3RT)`. A message queue may be open multiple times in the same or different processes for sending messages.

- **O_RDWR**: Open the queue for both receiving and sending messages. The process can use any of the functions allowed for `O_RDONLY` and `O_WRONLY`. A message queue may be open multiple times in the same or different processes for sending messages.

Any combination of the remaining flags may additionally be specified in the value of `oflag`:

- **O_CREAT**: This option is used to create a message queue, and it requires two additional arguments: `mode`, which is of type `mode_t`, and `attr`, which is of type `mq_attr_t`. The `mode` argument specifies the file mode mask for the new file, and the `attr` argument contains additional attributes for the message queue description.

Threads and Realtime Library Functions  83
mq_open(3RT)

which is pointer to a mq_attr structure. If the pathname, name, has already been used to create a message queue that still exists, then this flag has no effect, except as noted under O_EXCL (see below). Otherwise, a message queue is created without any messages in it.

The user ID of the message queue is set to the effective user ID of process, and the group ID of the message queue is set to the effective group ID of the process. The file permission bits are set to the value of mode, and modified by clearing all bits set in the file mode creation mask of the process (see umask(2)).

If attr is non-NULL and the calling process has the appropriate privilege on name, the message queue mq_maxmsg and mq_msgsize attributes are set to the values of the corresponding members in the mq_attr structure referred to by attr. If attr is non-NULL, but the calling process does not have the appropriate privilege on name, the mq_open() function fails and returns an error without creating the message queue.

O_EXCL If both O_EXCL and O_CREAT are set, mq_open() will fail if the message queue name exists. The check for the existence of the message queue and the creation of the message queue if it does not exist are atomic with respect to other processes executing mq_open() naming the same name with both O_EXCL and O_CREAT set. If O_EXCL and O_CREAT are not set, the result is undefined.

O_NONBLOCK The setting of this flag is associated with the open message queue description and determines whether a mq_send(3RT) or mq_receive(3RT) waits for resources or messages that are not currently available, or fails with errno set to EAGAIN. See mq_send(3RT) and mq_receive(3RT) for details.

RETURN VALUES Upon successful completion, mq_open() returns a message queue descriptor; otherwise the function returns (mqd_t)-1 and sets errno to indicate the error condition.

ERRORS The mq_open() function will fail if:

EACCESS The message queue exists and the permissions specified by oflag are denied, or the message queue does not exist and permission to create the message queue is denied.

EXISTS O_CREAT and O_EXCL are set and the named message queue already exists.

EINTR The mq_open() operation was interrupted by a signal.
mq_open(3RT)

EINVAL

The mq_open() operation is not supported for the given name, or O_CREAT was specified in oflag, the value of attr is not NULL, and either mq_maxmsg or mq_msgsize was less than or equal to zero.

EMFILE

The number of open message queue descriptors in this process exceeds MQ_OPEN_MAX, of the number of open file descriptors in this process exceeds OPEN_MAX.

ENAMETOOLONG

The length of the name string exceeds PATH_MAX, or a pathname component is longer than NAME_MAX while _POSIX_NO_TRUNC is in effect.

ENFILE

Too many message queues are currently open in the system.

ENOENT

O_CREAT is not set and the named message queue does not exist.

ENOSPC

There is insufficient space for the creation of the new message queue.

ENOSYS

The mq_open() function is not supported by the system.

USAGE

When a UFS file system is mounted with logging enabled, file system transactions that free blocks from files might not actually add those freed blocks to the file system’s free list until some unspecified time in the future. This behavior improves file system performance but does not conform to the POSIX, Single UNIX Specification, SPARC Conformance Definition, System V Application Binary Interface, System V Interface Definition, and X/Open Portability Guide Standards, which require that freed space be available immediately. To enable standards conformance regarding file deletions or to address the problem of not being able to grow files on a relatively full UFS file system even after files have been deleted, disable UFS logging (see mount_ufs(1M)).

ATTRIBUTES

See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>MT-Level</td>
<td>MT-Safe</td>
</tr>
</tbody>
</table>

SEE ALSO

mount_ufs(1M), exec(2), exit(2), umask(2), mq_close(3RT), mq_receive(3RT), mq_send(3RT), mq_setattr(3RT), mq_unlink(3RT), sysconf(3C), attributes(5), mqueue(3HEAD)

NOTES

Due to the manner in which message queues are implemented, they should not be considered secure and should not be used in security-sensitive applications.

Solaris 2.6 was the first release to support the Asynchronous Input and Output option. Prior to this release, this function always returned −1 and set errno to ENOSYS.
### NAME
mq_receive – receive a message from a message queue

### SYNOPSIS
```c
#include <mqueue.h>

ssize_t mq_receive(mqd_t mqdes, char *msg_ptr, size_t msg_len,
                   unsigned int *msg_prio);
```

### DESCRIPTION
The `mq_receive()` function is used to receive the oldest of the highest priority message(s) from the message queue specified by `mqdes`. If the size of the buffer in bytes, specified by `msg_len`, is less than the `mq_msgsize` member of the message queue, the function fails and returns an error. Otherwise, the selected message is removed from the queue and copied to the buffer pointed to by `msg_ptr`.

If `msg_prio` is not `NULL`, the priority of the selected message is stored in the location referenced by `msg_prio`.

If the specified message queue is empty and `O_NONBLOCK` is not set in the message queue description associated with `mqdes`, (see `mq_open(3RT)` and `mq_setattr(3RT)`), `mq_receive()` blocks, waiting until a message is enqueued on the message queue, or until `mq_receive()` is interrupted by a signal. If more than one process (or thread) is waiting to receive a message when a message arrives at an empty queue, then the process of highest priority that has been waiting the longest is selected to receive the message. If the specified message queue is empty and `O_NONBLOCK` is set in the message queue description associated with `mqdes`, no message is removed from the queue, and `mq_receive()` returns an error.

### RETURN VALUES
Upon successful completion, `mq_receive()` returns the length of the selected message in bytes and the message is removed from the queue. Otherwise, no message is removed from the queue, the function returns a value of `-1`, and sets `errno` to indicate the error condition.

### ERRORS
The `mq_receive()` function will fail if:

- **EAGAIN** `O_NONBLOCK` was set in the message description associated with `mqdes`, and the specified message queue is empty.
- **EBADF** The `mqdes` argument is not a valid message queue descriptor open for reading.
- **EMSGSIZE** The specified message buffer size, `msg_len`, is less than the message size member of the message queue.
- **EINTR** The `mq_receive()` function operation was interrupted by a signal.
- **ENOSYS** The `mq_receive()` function is not supported by the system.

The `mq_receive()` function may fail if:

- **EBADMSG** A data corruption problem with the message has been detected.

NOTES Solaris 2.6 was the first release to support the Asynchronous Input and Output option. Prior to this release, this function always returned −1 and set errno to ENOSYS.
The `mq_send()` function adds the message pointed to by the argument `msg_ptr` to the message queue specified by `mqdes`. The `msg_len` argument specifies the length of the message in bytes pointed to by `msg_ptr`. The value of `msg_len` is less than or equal to the `mq_msgsize` attribute of the message queue, or `mq_send()` fails.

If the specified message queue is not full, `mq_send()` behaves as if the message is inserted into the message queue at the position indicated by the `msg_prio` argument. A message with a larger numeric value of `msg_prio` is inserted before messages with lower values of `msg_prio`. A message will be inserted after other messages in the queue, if any, with equal `msg_prio`. The value of `msg_prio` must be greater than zero and less than or equal to `MQ_PRIO_MAX`.

If the specified message queue is full and `O_NONBLOCK` is not set in the message queue description associated with `mqdes` (see `mq_open(3RT)` and `mq_setattr(3RT)`), `mq_send()` blocks until space becomes available to enqueue the message, or until `mq_send()` is interrupted by a signal. If more than one thread is waiting to send when space becomes available in the message queue, then the thread of the highest priority which has been waiting the longest is unblocked to send its message. Otherwise, it is unspecified which waiting thread is unblocked. If the specified message queue is full and `O_NONBLOCK` is set in the message queue description associated with `mqdes`, the message is not queued and `mq_send()` returns an error.

Upon successful completion, `mq_send()` returns 0; otherwise, no message is enqueued, the function returns -1, and `errno` is set to indicate the error.

The `mq_send()` function will fail if:

- **EAGAIN**: The `O_NONBLOCK` flag is set in the message queue description associated with `mqdes`, and the specified message queue is full.
- **EBADF**: The `mqdes` argument is not a valid message queue descriptor open for writing.
- **EINTR**: A signal interrupted the call to `mq_send()`.
- **EINVAL**: The value of `msg_prio` was outside the valid range.
- **EMSGSIZE**: The specified message length, `msg_len`, exceeds the message size attribute of the message queue.
- **ENOSYS**: The `mq_send()` function is not supported by the system.

mq_setattr() - set/get message queue attributes

#include <mqueue.h>

int mq_setattr(mqd_t mqdes, const struct mq_attr *mqstat, struct mq_attr *omqstat);

DESCRIPTION

The mq_setattr() function is used to set attributes associated with the open message queue description referenced by the message queue descriptor specified by mqdes.

The message queue attributes corresponding to the following members defined in the mq_attr structure are set to the specified values upon successful completion of mq_setattr():

mq_flags The value of this member is either 0 or O_NONBLOCK.

The values of mq_maxmsg, mq_msgsize, and mq_curmsgs are ignored by mq_setattr().

If omqstat is non-NULL, mq_setattr() stores, in the location referenced by omqstat, the previous message queue attributes and the current queue status. These values are the same as would be returned by a call to mq_getattr() at that point.

RETURN VALUES

Upon successful completion, mq_setattr() returns 0 and the attributes of the message queue will have been changed as specified. Otherwise, the message queue attributes are unchanged, and the function returns -1 and sets errno to indicate the error.

ERRORS

The mq_setattr() function will fail if:

EBADF The mqdes argument is not a valid message queue descriptor.

ENOSYS The mq_setattr() function is not supported by the system.

mq_unlink(3RT)

NAME
mq_unlink – remove a message queue

SYNOPSIS
cc [ flag... ] file... -lrt [ library... ]
#include <mqueue.h>

    int mq_unlink(const char *name);

DESCRIPTION
The mq_unlink() function removes the message queue named by the pathname name. After a successful call to mq_unlink() with name, a call to mq_open(3RT) with name fails if the flag O_CREAT is not set in flags. If one or more processes have the message queue open when mq_unlink() is called, destruction of the message queue is postponed until all references to the message queue have been closed. Calls to mq_open(3RT) to re-create the message queue may fail until the message queue is actually removed. However, the mq_unlink() call need not block until all references have been closed; it may return immediately.

RETURN VALUES
Upon successful completion, mq_unlink() returns 0; otherwise, the named message queue is not changed by this function call, the function returns −1 and sets errno to indicate the error.

ERRORS
The mq_unlink() function will fail if:

EACCESS Permission is denied to unlink the named message queue.
ENAMETOOLONG The length of the name string exceeds PATH_MAX, or a pathname component is longer than NAME_MAX while _POSIX_NO_TRUNC is in effect.
ENOENT The named message queue, name, does not exist.
ENOSYS mq_unlink() is not supported by the system.

NOTES
Solaris 2.6 was the first release to support the Asynchronous Input and Output option. Prior to this release, this function always returned −1 and set errno to ENOSYS.
Mutexes are either intra-process or inter-process, depending upon the argument passed implicitly or explicitly to the initialization of that mutex. A statically allocated mutex does not need to be explicitly initialized; by default, a statically allocated mutex is initialized with all zeros and its scope is set to be within the calling process.

For inter-process synchronization, a mutex needs to be allocated in memory shared between these processes. Since the memory for such a mutex must be allocated dynamically, the mutex needs to be explicitly initialized with the appropriate attribute that indicates inter-process use.

A critical section of code is enclosed by a call to lock the mutex and the call to unlock the mutex to protect it from simultaneous access by multiple threads. Only one thread at a time may possess mutually exclusive access to the critical section of code that is enclosed by the mutex-locking call and the mutex-unlocking call, whether the mutex’s
scope is intra-process or inter-process. A thread calling to lock the mutex either gets exclusive access to the code starting from the successful locking until its call to unlock the mutex, or it waits until the mutex is unlocked by the thread that locked it.

Mutexes have ownership, unlike semaphores. Only the thread that locked a mutex, (that is, the owner of the mutex), should unlock it.

If a thread waiting for a mutex receives a signal, upon return from the signal handler, the thread resumes waiting for the mutex as if there was no interrupt.

**Caveats**

Mutexes are almost like data – they can be embedded in data structures, files, dynamic or static memory, and so forth. Hence, they are easy to introduce into a program. However, too many mutexes can degrade performance and scalability of the application. Because too few mutexes can hinder the concurrency of the application, they should be introduced with care. Also, incorrect usage (such as recursive calls, or violation of locking order, and so forth) can lead to deadlocks, or worse, data inconsistencies.

**ATTRIBUTES**

See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>

**NOTES**

In the current implementation of threads, pthread_mutex_lock(), pthread_mutex_unlock(), mutex_lock() mutex_unlock(), pthread_mutex_trylock(), and mutex_trylock() do not validate the mutex type. Therefore, an uninitialized mutex or a mutex with an invalid type does not return EINVAL. Interfaces for mutexes with an invalid type have unspecified behavior.

By default, if multiple threads are waiting for a mutex, the order of acquisition is undefined.

USYNC_THREAD does not support multiple mappings to the same logical synch object. If you need to mmap() a synch object to different locations within the same address space, then the synch object should be initialized as a shared object USYNC_PROCESS for Solaris, and PTHREAD_PROCESS_PRIVATE for POSIX.
mutual exclusion locks

#include <thread.h>
#include <synch.h>

int mutex_init (mutex_t *mp, int type, void *arg);
int mutex_lock (mutex_t *mp);
int mutex_trylock (mutex_t *mp);
int mutex_unlock (mutex_t *mp);
int mutex_destroy (mutex_t *mp);

Mutual exclusion locks (mutexes) prevent multiple threads from simultaneously executing critical sections of code which access shared data (that is, mutexes are used to serialize the execution of threads). All mutexes must be global. A successful call for a mutex lock by way of mutex_lock() will cause another thread that is also trying to lock the same mutex to block until the owner thread unlocks it by way of mutex_unlock(). Threads within the same process or within other processes can share mutexes.

Mutexes can synchronize threads within the same process or in other processes. Mutexes can be used to synchronize threads between processes if the mutexes are allocated in writable memory and shared among the cooperating processes (see mmap(2)), and have been initialized for this task.

Initialize

Mutexes are either intra-process or inter-process, depending upon the argument passed implicitly or explicitly to the initialization of that mutex. A statically allocated mutex does not need to be explicitly initialized; by default, a statically allocated mutex is initialized with all zeros and its scope is set to be within the calling process.

For inter-process synchronization, a mutex needs to be allocated in memory shared between these processes. Since the memory for such a mutex must be allocated dynamically, the mutex needs to be explicitly initialized using mutex_init().

The mutex_init() function initializes the mutex referenced by mp with the type specified by type. Upon successful initialization the state of the mutex becomes initialized and unlocked. No current type uses arg although a future type may specify additional behavior parameters by way of arg. The type argument can be one of the following:

USYNC_THREAD The mutex can synchronize threads only in this process. The arg argument is ignored.

USYNC_PROCESS The mutex can synchronize threads in this process and other processes. The arg argument is ignored. The object initialized with this attribute must be allocated in memory shared between processes, either in System V shared memory (see shmop(2)) or in memory
The mutex can synchronize threads in this process and other processes robustly. At the time of process death, if the lock is held by the process, it is unlocked. The next owner of this mutex will acquire it with an error return of EOWNERDEAD. The application must always check the return value from mutex_lock() for a mutex of this type. The new owner of this mutex should then attempt to make the state protected by the mutex consistent, since this state could have been left inconsistent when the last owner died. If the new owner is able to make the state consistent, it should reinitialize the mutex by calling mutex_init() and then unlock the mutex. Only the new owner can make the mutex consistent. If another process then calls mutex_init(), the call will return EBUSY. If for any reason the new owner is not able to make the state consistent, it should not reinitialize the mutex but should simply unlock the mutex. All waiting processes will be awakened and all subsequent calls to mutex_lock() will fail in acquiring the mutex with an error value of ENOTRECOVERABLE. The mutex can be reused by uninitialized the mutex with mutex_destroy() and reinitializing it with mutex_init(). If the process that acquired the lock with EOWNERDEAD died, the next owner will acquire the lock with an error value of EOWNERDEAD. The arg argument is ignored. The object initialized with this attribute must be allocated in memory shared between processes, either in System V shared memory (see shmem(2)) or in memory mapped to a file (see mmap(2)) and memory must be zeroed before initialization. All the processes interested in the robust lock must call mutex_init() at least once to register robust mutex with the system and potentially initialize it. If the object is not allocated in such shared memory, it will not be shared between processes. If mutex_init() is called on a previously initialized mutex, mutex_init() will not reinitialize the mutex and will return the error value EBUSY.

If type is either USYNC_THREAD or USYNC_PROCESS, it can be augmented by the bitwise-inclusive-OR of one or both of the following flags:
**LOCK_RECURSIVE**  
A thread attempting to relock this mutex without first unlocking it will succeed in locking the mutex.

**LOCK_ERRORCHECK**  
Unless **LOCK_RECURSIVE** is also set, a thread attempting to relock this mutex without first unlocking it will return with an error rather than deadlocking itself. A thread attempting to unlock this mutex without first owning it will return with an error.

See `pthread_mutexattr_settype(3THR)` for more information on recursive and error checking mutex types. The combination (**LOCK_RECURSIVE** | **LOCK_ERRORCHECK**) is the same as the POSIX `PTHREAD_MUTEX_RECURSIVE` type.

Initializing mutexes can also be accomplished by allocating in zeroed memory (default), in which case a *type* of `USYNC_THREAD` is assumed. In general, the following rules apply to mutex initialization:

- The same mutex must not be simultaneously initialized by multiple threads.
- A mutex lock must not be reinitialized while in use by other threads.

These rules do not apply to `USYNC_PROCESS_ROBUST` mutexes. See the description for `USYNC_PROCESS_ROBUST` above. If default mutex attributes are used, the macro `DEFAULTMUTEX` can be used to initialize mutexes that are statically allocated.

**Default mutex initialization (intra-process):**

```c
mutex_t mp;
mutex_init(&mp, NULL, NULL);
```

or

```c
mutex_init(&mp, USYNC_THREAD, NULL);
```

or

```c
mutex_t mp = DEFAULTMUTEX;
```

or

```c
mutex_t mp;
mp = calloc(1, sizeof (mutex_t));
```

or

```c
mutex_t mp;
mp = malloc(sizeof (mutex_t));
memset(mp, 0, sizeof (mutex_t));
```

**Customized mutex initialization (inter-process):**

```c
mutex_init(&mp, USYNC_PROCESS, NULL);
```

**Customized mutex initialization (inter-process):**

---
mutex_init(3THR)

mutex_init(&mp, USYNC_PROCESS_ROBUST, NULL);

Statically allocated mutexes can also be initialized with macros specifying
LOCK_RECURSIVE and/or LOCK_ERRORCHECK:

mutex_t mp = RECURSIVEMUTEX;
    Same as (USYNC_THREAD | LOCK_RECURSIVE)
mutex_t mp = ERRORCHECKMUTEX;
    Same as (USYNC_THREAD | LOCK_ERRORCHECK)
mutex_t mp = RECURSIVE_ERRORCHECKMUTEX;
    Same as (USYNC_THREAD | LOCK_RECURSIVE | LOCK_ERRORCHECK)

Lock and Unlock

A critical section of code is enclosed by a the call to lock the mutex and the call to
unlock the mutex to protect it from simultaneous access by multiple threads. Only one
thread at a time may possess mutually exclusive access to the critical section of code
that is enclosed by the mutex-locking call and the mutex-unlocking call, whether the
mutex’s scope is intra-process or inter-process. A thread calling to lock the mutex
either gets exclusive access to the code starting from the successful locking until its call
to unlock the mutex, or it waits until the mutex is unlocked by the thread that locked
it.

Mutexes have ownership, unlike semaphores. Although any thread, within the scope
of a mutex, can get an unlocked mutex and lock access to the same critical section of
code, only the thread that locked a mutex should unlock it.

If a thread waiting for a mutex receives a signal, upon return from the signal handler,
the thread resumes waiting for the mutex as if there was no interrupt. A mutex
protects code, not data; therefore, strongly bind a mutex with the data by putting both
within the same structure, or at least within the same procedure.

A call to mutex_lock() locks the mutex object referenced by mp. If the mutex is
already locked, the calling thread blocks until the mutex is freed; this will return with
the mutex object referenced by mp in the locked state with the calling thread as its
owner. If the current owner of a mutex tries to relock the mutex, it will result in
deadlock.

The mutex_trylock() function is the same as mutex_lock(), respectively, except
that if the mutex object referenced by mp is locked (by any thread, including the
current thread), the call returns immediately with an error.

The mutex_unlock() function are called by the owner of the mutex object
referenced by mp to release it. The mutex must be locked and the calling thread must
be the one that last locked the mutex (the owner). If there are threads blocked on
the mutex object referenced by mp when mutex_unlock() is called, the mp is freed, and
the scheduling policy will determine which thread gets the mutex. If the calling thread
is not the owner of the lock, no error status is returned, and the behavior of the
program is undefined.
### Destroy

The `mutex_destroy()` function destroys the mutex object referenced by `mp`. The mutex object becomes uninitialized. The space used by the destroyed mutex variable is not freed. It needs to be explicitly reclaimed.

### Return Values

If successful, these functions return 0. Otherwise, an error number is returned.

### Errors

These functions may fail if:

- **EFAULT** The `mp` argument points to an illegal address.

The `mutex_init()` function will fail if:

- **EINVAL** The value specified by `type` is invalid.

The `mutex_init()` function will fail for `USYNC_PROCESS_ROBUST` type mutex if:

- **EBUSY** The mutex pointed to by `mp` was already initialized. An attempt to reinitialize a mutex previously initialized, but not yet destroyed.

The `mutex_trylock()` function will fail if:

- **EBUSY** The mutex pointed to by `mp` was already locked.

The `mutex_lock()` and `mutex_trylock()` functions will fail for a `LOCK_RECURSIVE` mutex if:

- **EAGAIN** The mutex could not be acquired because the maximum number of recursive locks for the mutex has been reached.

The `mutex_lock()` function will fail for a `LOCK_ERRORCHECK` and non-`LOCK_RECURSIVE` mutex if:

- **EDEADLK** The current thread already owns the mutex.

The `mutex_unlock()` function will fail for a `LOCK_ERRORCHECK` mutex if:

- **EPERM** The current thread does not own the mutex.

The `mutex_lock()` or `mutex_trylock()` functions will fail for `USYNC_PROCESS_ROBUST` type mutex if:

- **EOWNERDEAD** The last owner of this mutex died while holding the mutex. This mutex is now owned by the caller. The caller must now attempt to make the state protected by the mutex consistent. If it is able to clean up the state, then it should reinitialize the mutex by calling `mutex_init()` and unlock the mutex. Subsequent calls to `mutex_lock()` will behave normally, as before. If the caller is not able to clean up the state, the mutex should not be reinitialized but it should be unlocked. Subsequent calls to `mutex_lock()` will fail to acquire the mutex, returning with the error value **ENOTRECOVERABLE**. If the owner who acquired the
lock with OWNERDEAD died, the next owner will acquire the lock with OWNERDEAD.

ELOCKUNMAPPED

The last owner of this mutex unmaped the mutex while holding the mutex. This mutex is now owned by the caller. The caller must now attempt to make the state protected by the mutex consistent. If it is able to clean up the state, it should reinitialize and unlock the mutex. Subsequent calls to mutex_lock() will behave normally, as before. If the caller is not able to clean up the state, the mutex should not be reinitialized. Subsequent calls to mutex_lock() will fail to acquire the mutex and return the error value ENOTRECOVERABLE.

ENOTRECOVERABLE

The mutex trying to be acquired is protecting the state that has been left irrecoverable when the mutex’s last owner could not make the state protected by the mutex consistent. The mutex has not been acquired. This condition can occur when the lock was previously acquired with OWNERDEAD or ELOCKUNMAPPED and the owner was not able to clean up the state and unlocked the mutex without making the mutex consistent.

EXAMPLES

Single Gate

The following example uses one global mutex as a gate-keeper to permit each thread exclusive sequential access to the code within the user-defined function "change_global_data." This type of synchronization will protect the state of shared data, but it also prohibits parallelism.

```c
/* cc thisfile.c -lthread */
#define _REENTRANT
#include <stdio.h>
#include <thread.h>
#define NUM_THREADS 12
void *change_global_data(void *);
/* for thr_create() */
main(int argc,char * argv[])
{
  int i=0;
  for (i=0; i< NUM_THREADS; i++)
  { 
    thr_create(NULL, 0, change_global_data, NULL, 0, NULL);
  }

  while ((thr_join(NULL, NULL, NULL) == 0));
}

void * change_global_data(void *null){
  static mutex_t Global_mutex;
  static int Global_data = 0;
  mutex_lock(&Global_mutex);  
  Global_data++;
  sleep(1);
}

mutex_init(3THR)
```

Threads and Realtime Library Functions 99
The previous example, the mutex, the code it owns, and the data it protects was enclosed in one function. The next example uses C++ features to accommodate many functions that use just one mutex to protect one data:

```c
#include <stdio.h>

extern void *change_global_data(void *);

class Mutected {
public:
    static int add_to_global_data(void);
    static int subtract_from_global_data(void);
private:
    static mutex_t Global_mutex;
    static int Global_data;
};

int Mutected::Global_data = 0;
mutex_t Mutected::Global_mutex;

int Mutected::add_to_global_data() {
    mutex_lock(&Global_mutex);
    Global_data++;
    mutex_unlock(&Global_mutex);
    return Global_data;
}

int Mutected::subtract_from_global_data() {
    mutex_lock(&Global_mutex);
    Global_data--;
    mutex_unlock(&Global_mutex);
    return Global_data;
}

void * change_global_data(void *) {
    // Mutex initialization and manipulation
    // Function to perform global data manipulation
}
```

The previous example, the mutex, the code it owns, and the data it protects was enclosed in one function. The next example uses C++ features to accommodate many functions that use just one mutex to protect one data.
A mutex can protect data that is shared among processes. The mutex would need to be initialized as `USYNC_PROCESS`. One process initializes the process-shared mutex and writes it to a file to be mapped into memory by all cooperating processes (see `mmap`). Afterwards, other independent processes can run the same program (whether concurrently or not) and share mutex-protected data.

```c
#include <sys/types.h>
#include <sys/mman.h>
#include <sys/stat.h>
#include <fcntl.h>
#include <stdio.h>
#include <thread.h>
#define INTERPROCESS_FILE "ipc-sharedfile"
#define NUM_ADDTHREADS 12
#define NUM_SUBTRACTTHREADS 10
#define INCREMENT '0'
#define DECREMENT '1'
typedef struct {
    mutex_t Interprocess_mutex;
    int Interprocess_data;
} buffer_t;
buffer_t *buffer;
void *add_interprocess_data(), *subtract_interprocess_data();
void create_shared_memory(), test_argv();
int zeroed[sizeof(buffer_t)];
int ipc_fd, i = 0;
void main(int argc, char * argv[]){
    test_argv(argv[1]);
    switch (*argv[1]) {
    case INCREMENT: /* Initializes the process-shared mutex */ /* Should be run prior to running a DECREMENT process */
        create_shared_memory();
        ipc_fd = open(INTERPROCESS_FILE, O_RDWR);
        buffer = (buffer_t *)mmap(NULL, sizeof(buffer_t),
        PROT_READ|PROT_WRITE, MAP_SHARED, ipc_fd, 0);
        buffer->Interprocess_data = 0;
        mutex_init(&buffer->Interprocess_mutex, USYNC_PROCESS, 0);
        for (i = 0; i < NUM_ADDTHREADS; i++)
            thr_create(NULL, 0, add_interprocess_data, argv[1],
```
**mutex_init(3THR)**

```c
mutex_init(3THR)

0, NULL);
break;

case DECREMENT:
    /* Should be run after the INCREMENT process has run. */
    while(ipc_fd = open(INTERPROCESS_FILE, O_RDWR)) == -1)
        sleep(1);
    buffer = (buffer_t *)mmap(NULL, sizeof(buffer_t),
        PROT_READ|PROT_WRITE, MAP_SHARED, ipc_fd, 0);
    for (i=0; i< NUM_SUBTRACTTHREADS; i++)
        thr_create(NULL, 0, subtract_interprocess_data, argv[1],
            0, NULL);
    break;
} /* end switch */

while ((thr_join(NULL,NULL,NULL) == 0));
} /* end main */

void *add_interprocess_data(char argv_1[]){
    mutex_lock(&buffer->Interprocess_mutex);
    buffer->Interprocess_data++;
    sleep(2);
    printf("%d is add-interprocess data, and \%c is argv1\n", 
        buffer->Interprocess_data, argv_1[0]);
    mutex_unlock(&buffer->Interprocess_mutex);
    return NULL;
}

void *subtract_interprocess_data(char argv_1[]){
    mutex_lock(&buffer->Interprocess_mutex);
    buffer->Interprocess_data--;
    sleep(2);
    printf("%d is subtract-interprocess data, and \%c is argv1\n", 
        buffer->Interprocess_data, argv_1[0]);
    mutex_unlock(&buffer->Interprocess_mutex);
    return NULL;
}

void create_shared_memory(){
    int i;
    ipc_fd = creat(INTERPROCESS_FILE, O_CREAT|O_RDWR );
    for (i=0; i<sizeof(buffer_t); i++){
        zeroed[i] = 0;
        write(ipc_fd, &zeroed[i],2);
    }
    close(ipc_fd);
    chmod(INTERPROCESS_FILE, S_IRWXU|S_IRWXG|S_IRWXO);
}

void test_argv(char argv1[]){
    if (argv1 == NULL) {
        printf("use 0 as arg1 for initial process\n or use 1 as argv1 for the second process\n\n");
        exit(NULL);
    }
}
```
A mutex can protect data that is shared among processes robustly. The mutex would need to be initialized as USYNC_PROCESS_ROBUST. One process initializes the robust process-shared mutex and writes it to a file to be mapped into memory by all cooperating processes (see mmap(2)). Afterwards, other independent processes can run the same program (whether concurrently or not) and share mutex-protected data.

The following example shows how to use a USYNC_PROCESS_ROBUST type mutex.

```c
/* cc thisfile.c -lthread */
/* To execute, run the command line “a.out & a.out 1” */
#include <sys/types.h>
#include <sys/mman.h>
#include <fcntl.h>
#include <stdio.h>
#include <thread.h>
#define INTERPROCESS_FILE "ipc-sharedfile"

typedef struct {
    mutex_t Interprocess_mutex;
    int    Interprocess_data;
} buffer_t;
buffer_t *buffer;
int make_data_consistent();
void create_shared_memory();
int zeroed[sizeof(buffer_t)];
int ipc_fd, i=0;
main(int argc,char * argv[]) {
    int rc;
    if (argc > 1) {
        while((ipc_fd = open(INTERPROCESS_FILE, O_RDWR)) == -1)
            sleep(1);
        buffer = (buffer_t *)mmap(NULL, sizeof(buffer_t),
                PROT_READ|PROT_WRITE, MAP_SHARED, ipc_fd, 0);
        mutex_init(&buffer->Interprocess_mutex,
                USYNC_PROCESS_ROBUST,0);
    } else {
        create_shared_memory();
        ipc_fd = open(INTERPROCESS_FILE, O_RDWR);
        buffer = (buffer_t *)mmap(NULL, sizeof(buffer_t),
                PROT_READ|PROT_WRITE, MAP_SHARED, ipc_fd, 0);
        buffer->Interprocess_data = 0;
        mutex_init(&buffer->Interprocess_mutex,
                USYNC_PROCESS_ROBUST,0);
    }
    for(;;) {
        rc = mutex_lock(&buffer->Interprocess_mutex);
        switch (rc) {
            case EOWNERDEAD:
                /* lock acquired.
                 * last owner died holding the lock, try to make
                 * the state associated with the mutex consistent.
                 * If so, make the robust lock consistent by
                 * reinitializing it.
                 */
                if (make_data_consistent())
                    mutex_init(&buffer->Interprocess_mutex,
                            USYNC_PROCESS_ROBUST,0);
            default:
                break;
            }
        } 
```
mutex_init(3THR)

```c
mutex_unlock(&buffer->Interprocess_mutex);
case ENOTRECOVERABLE:
    /* lock not acquired. *
   * last owner got the mutex with EOWNERDEAD *
   * mutex is not consistent (and data?), *
   * so return from here */
    exit(1);
    break;
case 0:
    /* no error - data is consistent */
    /* do something with data */
    mutex_unlock(&buffer->Interprocess_mutex);
    break;
}
} /* end main */

void create_shared_memory() {
    int i;
    ipc_fd = creat(INTERPROCESS_FILE, O_CREAT|O_RDWR);
    for (i=0; i<sizeof(buffer_t); i++) {
        zeroed[i] = 0;
        write(ipc_fd, &zeroed[i],2);
    }
    close(ipc_fd);
    chmod(INTERPROCESS_FILE, S_IRWXU|S_IRWXG|S_IRWXO);
}

/* return 1 if able to make data consistent, otherwise 0. */
int make_data_consistent () {
    buffer->Interprocess_data = 0;
    return (1);
}
```

The following example allocates and frees memory in which a mutex is embedded.

```c
struct record {
    int field1;
    int field2;
} *r;
r = malloc(sizeof(struct record));
mutex_init(&r->m, USYNC_THREAD, NULL);
/*
 * The fields in this record are accessed concurrently
 * by acquiring the embedded lock.
 */
```

The thread execution in this example is as follows:

**Thread 1 executes:**
```c
... mutex_lock(&r->m); r->field1++; mutex_unlock(&r->m);
```

**Thread 2 executes:**
```c
... mutex_lock(&r->m); localvar = r->field1;
```

Dynamically Allocated Mutexes

104 man pages section 3: Threads and Realtime Library Functions • Last Revised 18 Dec 2001
Later, when a thread decides to free the memory pointed to by \( r \), the thread should call `mutex_destroy()` on the mutexes in this memory.

In the following example, the main thread can do a `thr_join()` on both of the above threads. If there are no other threads using the memory in \( r \), the main thread can now safely free \( r \):

```c
for (i = 0; i < 2; i++)
    thr_join(0, 0, 0);
mutex_destroy(&r->m); /* first destroy mutex */
free(r); /* then free memory */
```

If the mutex is not destroyed, the program could have memory leaks.

### NOTES

The only supported policy is `SCHED_OTHER`. In Solaris under the `SCHED_OTHER` policy, there is no established order in which threads are unblocked.

The `mutex_lock()`, `mutex_unlock()`, and `mutex_trylock()` functions do not validate the mutex type. An uninitialized mutex or a mutex with an invalid type does not return `EINVAL`. Interfaces for mutexes with an invalid type have unspecified behavior.

Uninitialized mutexes that are allocated locally could contain junk data. Such mutexes need to be initialized using `mutex_init()`.

By default, if multiple threads are waiting for a mutex, the order of acquisition is undefined.
NAME | nanosleep – high resolution sleep

SYNOPSIS | `include <time.h>

int nanosleep(const struct timespec *rqtp, struct timespec *rmtp);

DESCRIPTION | The `nanosleep()` function causes the current thread to be suspended from execution until either the time interval specified by the `rqtp` argument has elapsed or a signal is delivered to the calling thread and its action is to invoke a signal-catching function or to terminate the process. The suspension time may be longer than requested because the argument value is rounded up to an integer multiple of the sleep resolution or because of the scheduling of other activity by the system. But, except for the case of being interrupted by a signal, the suspension time will not be less than the time specified by `rqtp`, as measured by the system clock, `CLOCK_REALTIME`.

The use of the `nanosleep()` function has no effect on the action or blockage of any signal.

RETURN VALUES | If the `nanosleep()` function returns because the requested time has elapsed, its return value is 0.

If the `nanosleep()` function returns because it has been interrupted by a signal, the function returns a value of −1 and sets `errno` to indicate the interruption. If the `rmtp` argument is non-NULL, the `timespec` structure referenced by it is updated to contain the amount of time remaining in the interval (the requested time minus the time actually slept). If the `rmtp` argument is NULL, the remaining time is not returned.

If `nanosleep()` fails, it returns −1 and sets `errno` to indicate the error.

ERRORS | The `nanosleep()` function will fail if:

- `EINTR` The `nanosleep()` function was interrupted by a signal.
- `EINVAL` The `rqtp` argument specified a nanosecond value less than zero or greater than or equal to 1000 million.
- `ENOSYS` The `nanosleep()` function is not supported by this implementation.

DESCRIPTION

Every program that links libthread_db or librtld_db must provide a set of process control primitives that will allow libthread_db and librtld_db to access memory and registers in the target process, to start and to stop the target process, and to look up symbols in the target process. See libthread_db(3THR). For information on librtld_db, refer to the Linker and Libraries Guide

Refer to the individual reference manual pages that describe these routines for a functional specification that clients of libthread_db and librtld_db can use to implement this required interface. `<proc_service.h>` lists the C declarations of these routines

FUNCTIONS

<table>

</tr>
<tr>
<td>ps_pdwrite()</td>
<td>Identical to ps_pwrite().</td>
</tr>
<tr>
<td>ps_ptread()</td>
<td>Identical to ps_pread().</td>
</tr>
<tr>
<td>ps_ptwrite()</td>
<td>Identical to ps_pwrite().</td>
</tr>
<tr>
<td>ps_pstop()</td>
<td>Stops the target process.</td>
</tr>
<tr>
<td>ps_pcontinue()</td>
<td>Resumes target process.</td>
</tr>
</tbody>
</table>
ps_lstop()  
Stops a single lightweight process (LWP) within the target process.

ps_lcontinue()  
Resumes a single LWP within the target process.

ps_lgetregs()  
Gets the general registers of the LWP.

ps_lsetregs()  
Sets the general registers of the LWP.

ps_lgetfpregs()  
Gets the LWP's floating point register set.

ps_lsetfpregs()  
Sets the LWP's floating point register set.

ps_pauxv()  
Returns a pointer to a read-only copy of the target process's auxiliary vector.

ps_kill()  
Sends signal to target process.

ps_lrolltoaddr()  
Rolls the LWP out of a critical section when the process is stopped.

ps_plog()  
Logs a message.

SPARC  
ps_lgetxregsize()  
Returns the size of the architecture-dependent extra state registers.

ps_lgetxregs()  
Gets the extra state registers of the LWP.

ps_lsetxregs()  
Sets the extra state registers of the LWP.

x86  
ps_lgetLDT()  
Reads the local descriptor table of the LWP.

ps_lgetregs(3PROC)

NAME

ps_lgetregs, ps_lsetregs, ps_lgetfpregs, ps_lsetfpregs, ps_lgetxregsize, ps_lgetxregs, ps_lsetxregs – routines that access the target process register in libthread_db

SYNOPSIS

#include <proc_service.h>

ps_err_e ps_lgetregs(struct ps_prochandle *ph, lwpid_t lid, prgregset_t *gregset);
ps_err_e ps_lsetregs(struct ps_prochandle *ph, lwpid_t lid, static prgregset_t *gregset);
ps_err_e ps_lgetfpregs(struct ps_prochandle *ph, lwpid_t lid, prfpregset_t *fpregs);
ps_err_e ps_lsetfpregs(struct ps_prochandle *ph, lwpid_t lid, static prfpregset_t *fpregs);
ps_err_e ps_lgetxregsize(struct ps_prochandle *ph, lwpid_t lid, int *xregsize);
ps_err_e ps_lgetxregs(struct ps_prochandle *ph, lwpid_t lid, caddr_t xregset);
ps_err_e ps_lsetxregs(struct ps_prochandle *ph, lwpid_t lid, caddr_t xregset);

DESCRIPTION

ps_lgetregs(), ps_lsetregs(), ps_lgetfpregs(), ps_lsetfpregs(), ps_lgetxregsize(), ps_lgetxregs(), ps_lsetxregs() read and write register sets from lightweight processes (LWPs) within the target process identified by ph.

ps_lgetregs() gets the general registers of the LWP identified by lid, and ps_lsetregs() sets them. ps_lgetfpregs() gets the LWP’s floating point register set, while ps_lsetfpregs() sets it.

SPARC Only

ps_lgetxregsize(), ps_lgetxregs(), and ps_lsetxregs() are SPARC-specific. They do not need to be defined by a controlling process on non-SPARC architecture.

ps_lgetxregsize() returns in *xregsize the size of the architecture-dependent extra state registers. ps_lgetxregs() gets the extra state registers, and ps_lsetxregs() sets them.

RETURN VALUES

PS_OK The call returned successfully.
PS_NOFPREGS Floating point registers are neither available for this architecture nor for this process.
PS_NOXREGS Extra state registers are not available on this architecture.
PS_ERR The function did not return successfully.

ps_pglobal_lookup(3PROC)

NAME
ps_pglobal_lookup, ps_pglobal_sym – look up a symbol in the symbol table of the
load object in the target process

SYNOPSIS
#include <proc_service.h>

ps_err_e ps_pglobal_lookup(struct ps_prochandle *ph, const char
*object_name, const char *sym_name, psaddr_t *sym_addr);

ps_err_e ps_pglobal_sym(struct ps_prochandle *ph, const char
*object_name, const char *sym_name, ps_sym_t *sym);

DESCRIPTION
ps_pglobal_lookup() looks up the symbol sym_name in the symbol table of the
load object object_name in the target process identified by ph. It returns the symbol’s
value as an address in the target process in *sym_addr.

ps_pglobal_sym() looks up the symbol sym_name in the symbol table of the load
object object_name in the target process identified by ph. It returns the symbol table
entry in *sym. The value in the symbol table entry is the symbol’s value as an address
in the target process.

RETURN VALUES
PS_OK The call completed successfully.
PS_NOSYM The specified symbol was not found.
PS_ERR The function did not return successfully.

ATTRIBUTES
See attributes(5) for description of the following attributes:

SEE ALSO
kill(2), libthread_db(3LIB), libthread_db(3THR), proc_service(3PROC),
threads(3THR), attributes(5)
These routines copy data between the target process’s address space and the controlling process. `ps_pread()` copies `size` bytes from address `addr` in the target process into `buf` in the controlling process. `ps_pwrite()` is like `ps_pread()` except that the direction of the copy is reversed; data is copied from the controlling process to the target process.

`ps_pdread()` and `ps_ptread()` behave identically to `ps_pread()`. `ps_pdwrite()` and `ps_ptwrite()` behave identically to `ps_pwrite()`. These functions can be implemented as simple aliases for the corresponding primary functions. They are artifacts of history that must be maintained.

**RETURN VALUES**

- **PS_OK** The call returned successfully. `size` bytes were copied.
- **PS_BADADDR** Some part of the address range from `addr` through `addr+size-1` is not part of the target process’s address space.
- **PS_ERR** The function did not return successfully.

ps_pstop(3PROC)

NAME
   ps_pstop, ps_pcontinue, ps_lstop, ps_lcontinue, ps_lrolltoaddr, ps_kill – process and
   LWP control in libthread_db

SYNOPSIS
   #include <proc_service.h>

   ps_err_e ps_pstop(struct ps_prochandle *ph);
   ps_err_e ps_pcontinue(struct ps_prochandle *ph);
   ps_err_e ps_lstop(struct ps_prochandle *ph, lwpid_t lwpid);
   ps_err_e ps_lcontinue(struct ps_prochandle *ph, lwpid_t lwpid);
   ps_err_e ps_lrolltoaddr(struct ps_prochandle *ph, lwpid_t lwpid,
                          psaddr_t go_addr, psaddr_t stop_addr);
   ps_err_e ps_kill(struct ps_prochandle *ph, int signum);

DESCRIPTION
   The ps_pstop() function stops the target process identified by ph, while the
   ps_pcontinue() function allows it to resume.

   The libthread_db() function uses ps_pstop() to freeze the target process while it
   is under inspection. Within the scope of any single call from outside libthread_db
   to a libthread_db routine, libthread_db will call ps_pstop(), at most once. If it
   does, it will call ps_pcontinue() within the scope of the same routine.

   The controlling process may already have stopped the target process when it calls
   libthread_db. In that case, it is not obligated to resume the target process when
   libthread_db calls ps_pcontinue(). In other words, ps_pstop() is mandatory,
   while ps_pcontinue() is advisory. After ps_pstop(), the target process must be
   stopped; after ps_pcontinue(), the target process may be running.

   The ps_lstop() and ps_lcontinue() functions stop and resume a single
   lightweight process (LWP) within the target process ph.

   The ps_lrolltoaddr() function is used to roll an LWP forward out of a critical
   section when the process is stopped. It is also used to run the libthread_db_agent
   thread on behalf of libthread. The ps_lrolltoaddr() function is always called
   with the target process stopped, that is, there has been a preceding call to
   ps_pstop(). The specified LWP must be continued at the address go_addr, or at its
   current address if go_addr is NULL. It should then be stopped when its execution
   reaches stop_addr. This routine does not return until the LWP has stopped at stop_addr.

   The ps_kill() function directs the signal signum to the target process for which the
   handle is ph. It has the same semantics as kill(2).

RETURN VALUES
   PS_OK       The call completed successfully. In the case of ps_pstop(), the
               target process is stopped.
   PS_BADLID   For ps_lstop(), ps_lcontinue() and ps_lrolltoaddr();
               there is no LWP with id lwpid in the target process.
   PS_ERR      The function did not return successfully.

NAME  pthread_attr_getdetachstate, pthread_attr_setdetachstate — get or set detachstate attribute

SYNOPSIS  cc -mt [ flag... ] file... -lpthread [ -lrt library... ]
#include <pthread.h>

int pthread_attr_setdetachstate(pthread_attr_t *attr, int detachstate);

int pthread_attr_getdetachstate(const pthread_attr_t *attr, int *detachstate);

DESCRIPTION  The detachstate attribute controls whether the thread is created in a detached state. If the thread is created detached, then use of the ID of the newly created thread by the pthread_detach() or pthread_join() function is an error.

The pthread_attr_setdetachstate() and pthread_attr_getdetachstate() functions, respectively, set and get the detachstate attribute in the attr object.

The detachstate can be set to either PTHREAD_CREATE_DETACHED or PTHREAD_CREATE_JOINABLE. A value of PTHREAD_CREATE_DETACHED causes all threads created with attr to be in the detached state, whereas using a value of PTHREAD_CREATE_JOINABLE causes all threads created with attr to be in the joinable state. The default value of the detachstate attribute is PTHREAD_CREATE_JOINABLE.

RETURN VALUES  Upon successful completion, pthread_attr_setdetachstate() and pthread_attr_getdetachstate() return a value of 0. Otherwise, an error number is returned to indicate the error.

The pthread_attr_getdetachstate() function stores the value of the detachstate attribute in detachstate if successful.

ERRORS  The pthread_attr_setdetachstate() or pthread_attr_getdetachstate() functions may fail if:

EINVAL  attr or detachstate is invalid.

SEE ALSO  pthread_attr_init(3THR), pthread_attr_setstackaddr(3THR), pthread_attr_setstacksize(3THR), pthread_create(3THR), attributes(5), standards(5)
The guardsize attribute controls the size of the guard area for the created thread’s stack. The guardsize attribute provides protection against overflow of the stack pointer. If a thread’s stack is created with guard protection, the implementation allocates extra memory at the overflow end of the stack as a buffer against stack overflow of the stack pointer. If an application overflows into this buffer an error results (possibly in a SIGSEGV signal being delivered to the thread).

The guardsize attribute is provided to the application for two reasons:

1. Overflow protection can potentially result in wasted system resources. An application that creates a large number of threads, and which knows its threads will never overflow their stack, can save system resources by turning off guard areas.

2. When threads allocate large data structures on the stack, large guard areas may be needed to detect stack overflow.

The pthread_attr_getguardsize() function gets the guardsize attribute in the attr object. This attribute is returned in the guardsize parameter.

The pthread_attr_setguardsize() function sets the guardsize attribute in the attr object. The new value of this attribute is obtained from the guardsize parameter. If guardsize is 0, a guard area will not be provided for threads created with attr. If guardsize is greater than 0, a guard area of at least size guardsize bytes is provided for each thread created with attr.

A conforming implementation is permitted to round up the value contained in guardsize to a multiple of the configurable system variable PAGESIZE. If an implementation rounds up the value of guardsize to a multiple of PAGESIZE, a call to pthread_attr_getguardsize() specifying attr will store in the guardsize parameter the guard size specified by the previous pthread_attr_setguardsize() function call.

The default value of the guardsize attribute is PAGESIZE bytes. The actual value of PAGESIZE is implementation-dependent and may not be the same on all implementations.
If the `stackaddr` attribute has been set (that is, the caller is allocating and managing its own thread stacks), the `guardsize` attribute is ignored and no protection will be provided by the implementation. It is the responsibility of the application to manage stack overflow along with stack allocation and management in this case.

**RETURN VALUES**
If successful, the `pthread_attr_getguardsize()` and `pthread_attr_setguardsize()` functions return 0. Otherwise, an error number is returned to indicate the error.

**ERRORS**
The `pthread_attr_getguardsize()` and `pthread_attr_setguardsize()` functions will fail if:

- **EINVAL** The attribute `attr` is invalid.
- **EINVAL** The parameter `guardsize` is invalid.
- **EINVAL** The parameter `guardsize` contains an invalid value.

**ATTRIBUTES**
See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>MT-Level</td>
<td>MT-Safe</td>
</tr>
</tbody>
</table>

**SEE ALSO**
`sysconf(3C), pthread_attr_init(3THR), attributes(5)`
The functions `pthread_attr_setinheritsched()` and `pthread_attr_getinheritsched()` respectively set and get the `inheritsched` attribute in the `attr` argument.

When the attribute objects are used by `pthread_create()`, the `inheritsched` attribute determines how the other scheduling attributes of the created thread are to be set:

- **PTHREAD_INHERIT_SCHED**
  Specifies that the scheduling policy and associated attributes are to be inherited from the creating thread, and the scheduling attributes in this `attr` argument are to be ignored.

- **PTHREAD_EXPLICIT_SCHED**
  Specifies that the scheduling policy and associated attributes are to be set to the corresponding values from this attribute object.

The symbols `PTHREAD_INHERIT_SCHED` and `PTHREAD_EXPLICIT_SCHED` are defined in the header `<pthread.h>`.

If successful, the `pthread_attr_setinheritsched()` and `pthread_attr_getinheritsched()` functions return 0. Otherwise, an error number is returned to indicate the error.

The `pthread_attr_setinheritsched()` or `pthread_attr_getinheritsched()` functions may fail if:

- **EINVAL**
  `attr` or `inheritsched` is invalid.

After these attributes have been set, a thread can be created with the specified attributes using `pthread_create()`. Using these routines does not affect the current running thread.

See `attributes(5)` for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>

         pthread_setsched_param(3THR), attributes(5), standards(5)
### NAME

pthread_attr_getschedparam, pthread_attr_setschedparam – get or set schedparam attribute

### SYNOPSIS

```c
#include <pthread.h>

int pthread_attr_setschedparam(pthread_attr_t *attr, const struct sched_param *param);

int pthread_attr_getschedparam(const pthread_attr_t *attr, struct sched_param *param);
```

### DESCRIPTION

The functions `pthread_attr_setschedparam()` and `pthread_attr_getschedparam()`, respectively, set and get the scheduling parameter attributes in the `attr` argument. The contents of the `param` structure are defined in `<sched.h>`. For the SCHED_FIFO and SCHED_RR policies, the only required member of `param` is `sched_priority`.

### RETURN VALUES

If successful, the `pthread_attr_setschedparam()` and `pthread_attr_getschedparam()` functions return 0. Otherwise, an error number is returned to indicate the error.

### ERRORS

The `pthread_attr_setschedparam()` function may fail if:

- **EINVAL** `attr` is invalid.

The `pthread_attr_getschedparam()` function may fail if:

- **EINVAL** `attr` or `param` is invalid.

### USAGE

After these attributes have been set, a thread can be created with the specified attributes using `pthread_create()`. Using these routines does not affect the current running thread.

### ATTRIBUTES

See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>MT-Level</td>
<td>MT-Safe</td>
</tr>
</tbody>
</table>

### SEE ALSO

pthread_attr_init(3THR), pthread_attr_setscope(3THR), pthread_attr_setinheritsched(3THR), pthread_attr_setschedpolicy(3THR), pthread_create(3THR), pthread_setschedparam(3THR), attributes(5), standards(5)
The functions `pthread_attr_setschedpolicy()` and `pthread_attr_getschedpolicy()` set and get the `schedpolicy` attribute in the `attr` argument.

The supported values of `policy` include `SCHED_FIFO`, `SCHED_RR` and `SCHED_OTHER`, which are defined by the header `<sched.h>`. When threads executing with the scheduling policy `SCHED_FIFO` or `SCHED_RR` are waiting on a mutex, they acquire the mutex in priority order when the mutex is unlocked.

If successful, the `pthread_attr_setschedpolicy()` and `pthread_attr_getschedpolicy()` functions return 0. Otherwise, an error number is returned to indicate the error.

The `pthread_attr_setschedpolicy()` function may fail if:

- `EINVAL` `attr` or `policy` is invalid.

After these attributes have been set, a thread can be created with the specified attributes using `pthread_create()`. Using these routines does not affect the current running thread.

See `attributes(5)` for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>MT-Level</td>
<td>MT-Safe</td>
</tr>
</tbody>
</table>

SEE ALSO `pthread_attr_init(3THR)`, `pthread_attr_setscope(3THR)`, `pthread_attr_setinheritsched(3THR)`, `pthread_attr_setschedparam(3THR)`, `pthread_create(3THR)`, `attributes(5)`, `standards(5)`
The `pthread_attr_setscope()` and `pthread_attr_getscope()` functions are used to set and get the `contentionscope` attribute in the `attr` object.

The `contentionscope` attribute can have the value `PTHREAD_SCOPE_SYSTEM`, signifying system scheduling contention scope, or `PTHREAD_SCOPE_PROCESS`, signifying process scheduling contention scope.

The symbols `PTHREAD_SCOPE_SYSTEM` and `PTHREAD_SCOPE_PROCESS` are defined by the header `<pthread.h>`.

If successful, the `pthread_attr_setscope()` and `pthread_attr_getscope()` functions return 0. Otherwise, an error number is returned to indicate the error.

The `pthread_attr_setscope()`, or `pthread_attr_getscope()`, function may fail if:

- `EINVAL` `attr` or `contentionscope` is invalid.

After these attributes have been set, a thread can be created with the specified attributes using `pthread_create()`. Using these routines does not affect the current running thread.

See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>MT-Level</td>
<td>MT-Safe</td>
</tr>
</tbody>
</table>

See also:

The functions `pthread_attr_setstackaddr()` and `pthread_attr_getstackaddr()` respectively, set and get the thread creation `stackaddr` attribute in the `attr` object. The `stackaddr` default is `NULL`. See `pthread_create(3THR)`.

The `stackaddr` attribute specifies the location of storage to be used for the created thread’s stack. The size of the storage is at least `PTHREAD_STACK_MIN`.

Upon successful completion, `pthread_attr_setstackaddr()` and `pthread_attr_getstackaddr()` return a value of 0. Otherwise, an error number is returned to indicate the error.

If successful, the `pthread_attr_getstackaddr()` function stores the `stackaddr` attribute value in `stackaddr`.

The `pthread_attr_setstackaddr()` function may fail if:

- `EINVAL` `attr` is invalid.

The `pthread_attr_getstackaddr()` function may fail if:

- `EINVAL` `attr` or `stackaddr` is invalid.

See `attributes(5)` for descriptions of the following attributes:

- **MT-Level**: MT-Safe

**See Also**

- `pthread_attr_init(3THR)`, `pthread_attr_setdetachstate(3THR)`, `pthread_attr_setstacksize(3THR)`, `pthread_create(3THR)`, `attributes(5)`, `standards(5)`
The functions `pthread_attr_setstacksize()` and `pthread_attr_getstacksize()`, respectively, set and get the thread creation stack size attribute in the `attr` object.

The `stacksize` attribute defines the minimum stack size (in bytes) allocated for the created threads stack. When the `stacksize` argument is `NULL`, the default stack size becomes 1 megabyte for 32-bit processes and 2 megabytes for 64-bit processes.

Upon successful completion, `pthread_attr_setstacksize()` and `pthread_attr_getstacksize()` return a value of 0. Otherwise, an error number is returned to indicate the error. The `pthread_attr_getstacksize()` function stores the `stacksize` attribute value in `stacksize` if successful.

The `pthread_attr_setstacksize()` or `pthread_attr_getstacksize()` function may fail if:

**EINVAL** `attr` or `stacksize` is invalid.

See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>MT-Level</td>
<td>MT-Safe</td>
</tr>
</tbody>
</table>

NAME
pthread_attr_init, pthread_attr_destroy – initialize or destroy threads attribute object

SYNOPSIS
cc -mt [ flag... ] file... -lpthread [ -lrt library... ]
#include <pthread.h>

int pthread_attr_init(pthread_attr_t *attr);
int pthread_attr_destroy(pthread_attr_t *attr);

DESCRIPTION
The function pthread_attr_init() initializes a thread attributes object attr with the default value for all of the individual attributes used by a given implementation.

The resulting attribute object (possibly modified by setting individual attribute values), when used by pthread_create(), defines the attributes of the thread created. A single attributes object can be used in multiple simultaneous calls to pthread_create().

The pthread_attr_init() function initializes a thread attributes object (attr) with the default value for each attribute as follows:

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Default Value</th>
<th>Meaning of Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>contentionscope</td>
<td>PTHREAD_SCOPE_PROCESS</td>
<td>resource competition within process</td>
</tr>
<tr>
<td>detachstate</td>
<td>PTHREAD_CREATE_JOINABLE</td>
<td>joinable by other threads</td>
</tr>
<tr>
<td>stackaddr</td>
<td>NULL</td>
<td>stack allocated by system</td>
</tr>
<tr>
<td>stacksize</td>
<td>NULL</td>
<td>1 or 2 megabyte</td>
</tr>
<tr>
<td>priority</td>
<td>0</td>
<td>priority of the thread</td>
</tr>
<tr>
<td>policy</td>
<td>SCHED_OTHER</td>
<td>determined by system</td>
</tr>
<tr>
<td>inheritsched</td>
<td>PTHREAD_EXPLICIT_SCHED</td>
<td>scheduling policy and parameters not inherited but explicitly defined by the attribute object</td>
</tr>
<tr>
<td>guardsize</td>
<td>PAGESIZE</td>
<td>size of guard area for a thread’s created stack</td>
</tr>
</tbody>
</table>

The pthread_attr_destroy() function destroys a thread attributes object (attr), which cannot be reused until it is reinitialized. An implementation may cause pthread_attr_destroy() to set attr to an implementation-dependent invalid value. The behavior of using the attribute after it has been destroyed is undefined.

RETURN VALUES
Upon successful completion, pthread_attr_init() and pthread_attr_destroy() return a value of 0. Otherwise, an error number is returned to indicate the error.

ERRORS
The pthread_attr_init() function will fail if:

126 man pages section 3: Threads and Realtime Library Functions • Last Revised 28 Apr 1998
ENOMEM
Insufficient memory exists to initialize the thread attributes object.

The pthread_attr_destroy() function may fail if:

EINVAL 
attr is invalid.

### pthread_cancel(3THR)

**NAME**
thread_cancel – cancel execution of a thread

**SYNOPSIS**
```c
#include <pthread.h>

int pthread_cancel(pthread_t target_thread);
```

**DESCRIPTION**
The `pthread_cancel()` function requests that `target_thread` be canceled.

By default, cancellation is deferred until `target_thread` reaches a cancellation point. See `cancellation(3THR)`.

Cancellation cleanup handlers for `target_thread` are called when the cancellation is acted on. Upon return of the last cancellation cleanup handler, the thread-specific data destructor functions are called for `target_thread`. `target_thread` is terminated when the last destructor function returns.

The cancellation processing in `target_thread` runs asynchronously with respect to the calling thread returning from `pthread_cancel()`.

**RETURN VALUES**
If successful, the `pthread_cancel()` function returns 0. Otherwise, an error number is returned to indicate the error.

**ERRORS**
The `pthread_cancel()` function may fail if:

- **ESRCH**
  
  No thread was found with an ID corresponding to that specified by the given thread ID, `target_thread`.

**ATTRIBUTES**
See `attributes(5)` for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>MT-Level</td>
<td>MT-Safe</td>

NAME
pthread_cleanup_pop – pop a thread cancellation cleanup handler

SYNOPSIS
cc -mt [ flag... ] file... -lpthread [ -lrt library... ]
#include <pthread.h>
void pthread_cleanup_pop(int execute);

DESCRIPTION
pthread_cleanup_pop() removes the cleanup handler routine at the top of the
cancellation cleanup stack of the calling thread and executes it if execute is non-zero.

When the thread calls pthread_cleanup_pop() with a non-zero execute argument,
the argument at the top of the stack is popped and executed. An argument of 0 pops
the handler without executing it.

The Solaris system generates a compile time error if pthread_cleanup_push() does not have a matching pthread_cleanup_pop().

Be aware that using longjmp() or siglongjmp() to jump into or out of a push/pop pair can lead to trouble, as either the matching push or the matching pop statement might not get executed.

RETURN VALUES
The pthread_cleanup_pop() function returns no value.

ERRORS
No errors are defined.

The pthread_cleanup_pop() function will not return an error code of EINTR.

ATTRIBUTES
See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>MT-Level</td>
<td>MT-Safe</td>
</tr>
</tbody>

pthread_cleanup_push(3THR)

NAME
pthread_cleanup_push – push a thread cancellation cleanup handler

SYNOPSIS
cc -mt [ flag... ] file... -lpthread [ -lrt library... ]
#include <pthread.h>

void pthread_cleanup_push(void (*handler, void *), void *arg);

DESCRIPTION
pthread_cleanup_push() pushes the specified cancellation cleanup handler
routine, handler, onto the cancellation cleanup stack of the calling thread.

When a thread exits or is canceled and its cancellation cleanup stack is not empty, the
cleanup handlers are invoked with the argument arg in last in, first out (LIFO) order
from the cancellation cleanup stack.

The Solaris system generates a compile time error if pthread_cleanup_push() does not have a matching
pthread_cleanup_pop().

Be aware that using longjmp() or siglongjmp() to jump into or out of a push/pop
pair can lead to trouble, as either the matching push or the matching pop statement
might not get executed.

RETURN VALUES
The pthread_cleanup_push() function returns no value.

ERRORS
No errors are defined.

The pthread_cleanup_push() function will not return an error code of EINTR.

ATTRIBUTES
See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>MT-Level</td>
<td>MT-Safe</td>
</tr>
</tbody>
</table>

pthread_join(3THR), pthread_setcancelstate(3THR),
pthread_setcanceltype(3THR), pthread_testcancelt(3THR), attributes(5)

NOTES
See cancellation(3THR) for a discussion of cancellation concepts.
The `pthread_condattr_getpshared()` function obtains the value of the process-shared attribute from the attributes object referenced by `attr`. The `pthread_condattr_setpshared()` function is used to set the process-shared attribute in an initialized attributes object referenced by `attr`.

The process-shared attribute is set to `PTHREAD_PROCESS_SHARED` to permit a condition variable to be operated upon by any thread that has access to the memory where the condition variable is allocated, even if the condition variable is allocated in memory that is shared by multiple processes. If the process-shared attribute is `PTHREAD_PROCESS_PRIVATE`, the condition variable will only be operated upon by threads created within the same process as the thread that initialized the condition variable; if threads of differing processes attempt to operate on such a condition variable, the behavior is undefined. The default value of the attribute is `PTHREAD_PROCESS_PRIVATE`.

Additional attributes, their default values, and the names of the associated functions to get and set those attribute values are implementation-dependent.

**RETURN VALUES**

If successful, the `pthread_condattr_setpshared()` function returns 0. Otherwise, an error number is returned to indicate the error.

If successful, the `pthread_condattr_getpshared()` function returns 0 and stores the value of the process-shared attribute of `attr` into the object referenced by the `pshared` parameter. Otherwise, an error number is returned to indicate the error.

**ERRORS**

The `pthread_condattr_getpshared()` and `pthread_condattr_setpshared()` functions may fail if:

- **EINVAL** The value specified by `attr` is invalid.

The `pthread_condattr_setpshared()` function will fail if:

- **EINVAL** The new value specified for the attribute is outside the range of legal values for that attribute.

**ATTRIBUTES**

See `attributes(5)` for descriptions of the following attributes:
**SEE ALSO**  
`pthread_condattr_init(3THR)`, `pthread_create(3THR)`,  
`pthread_mutex_init(3THR)`, `pthread_cond_init(3THR)`, `attributes(5)`
The `pthread_condattr_init()` function initializes a condition variable attributes object `attr` with the default value for all of the attributes defined by the implementation.

At present, the only attribute available is the scope of condition variables. The default scope of the attribute is `PTHREAD_PROCESS_PRIVATE`.

Attempts to initialize previously initialized condition variable attributes object will leave the storage allocated by the previous initialization unallocated.

After a condition variable attributes object has been used to initialize one or more condition variables, any function affecting the attributes object (including destruction) does not affect any previously initialized condition variables.

The `pthread_condattr_destroy()` function destroys a condition variable attributes object; the object becomes, in effect, uninitialized. An implementation may cause `pthread_condattr_destroy()` to set the object referenced by `attr` to an invalid value. A destroyed condition variable attributes object can be re-initialized using `pthread_condattr_init()`; the results of otherwise referencing the object after it has been destroyed are undefined.

Additional attributes, their default values, and the names of the associated functions to get and set those attribute values are implementation-dependent.

If successful, the `pthread_condattr_init()` and `pthread_condattr_destroy()` functions return 0. Otherwise, an error number is returned to indicate the error.

The `pthread_condattr_init()` function will fail if:

- **ENOMEM**: Insufficient memory exists to initialize the condition variable attributes object.

The `pthread_condattr_destroy()` function may fail if:

- **EINVAL**: The value specified by `attr` is invalid.

See `attributes(5)` for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>MT-Level</td>
<td>MT-Safe</td>
</tr>
</tbody>
</table>
pthread_condattr_init(3THR)

SEE ALSO

pthread_condattr_getpshared(3THR),
 pthread_condattr_setpshared(3THR), pthread_cond_init(3THR),
 pthread_create(3THR), pthread_mutex_init(3THR), attributes(5)
**NAME**

pthread_cond_init, pthread_cond_destroy – initialize or destroy condition variables

**SYNOPSIS**

```c
#include <pthread.h>

int pthread_cond_init(pthread_cond_t *cond, const pthread_condattr_t *attr);

int pthread_cond_destroy(pthread_cond_t *cond);

pthread_cond_t cond = PTHREAD_COND_INITIALIZER;
```

**DESCRIPTION**

The function `pthread_cond_init()` initializes the condition variable referenced by `cond` with attributes referenced by `attr`. If `attr` is NULL, the default condition variable attributes are used; the effect is the same as passing the address of a default condition variable attributes object. See `pthread_condattr_init(3THR)`. Upon successful initialization, the state of the condition variable becomes initialized.

Attempting to initialize an already initialized condition variable results in undefined behavior.

The function `pthread_cond_destroy()` destroys the given condition variable specified by `cond`; the object becomes, in effect, uninitialized. An implementation may cause `pthread_cond_destroy()` to set the object referenced by `cond` to an invalid value. A destroyed condition variable object can be re-initialized using `pthread_cond_init();` the results of otherwise referencing the object after it has been destroyed are undefined.

It is safe to destroy an initialized condition variable upon which no threads are currently blocked. Attempting to destroy a condition variable upon which other threads are currently blocked results in undefined behavior.

In cases where default condition variable attributes are appropriate, the macro `PTHREAD_COND_INITIALIZER` can be used to initialize condition variables that are statically allocated. The effect is equivalent to dynamic initialization by a call to `pthread_cond_init()` with parameter `attr` specified as NULL, except that no error checks are performed.

**RETURN VALUES**

If successful, the `pthread_cond_init()` and `pthread_cond_destroy()` functions return 0. Otherwise, an error number is returned to indicate the error. The `EBUSY` and `EINVAL` error checks, if implemented, act as if they were performed immediately at the beginning of processing for the function and caused an error return prior to modifying the state of the condition variable specified by `cond`.

**ERRORS**

The `pthread_cond_init()` function will fail if:

- `EAGAIN` The system lacked the necessary resources (other than memory) to initialize another condition variable.
- `ENOMEM` Insufficient memory exists to initialize the condition variable.

The `pthread_cond_init()` function may fail if:

Threads and Realtime Library Functions 135
EBUSY The implementation has detected an attempt to re-initialize the object referenced by \textit{cond}, a previously initialized, but not yet destroyed, condition variable.

EINVAL The value specified by \textit{attr} is invalid.

The \texttt{pthread_cond_destroy()} function may fail if:

EBUSY The implementation has detected an attempt to destroy the object referenced by \textit{cond} while it is referenced (for example, while being used in a \texttt{pthread_cond_wait()} or \texttt{pthread_cond_timedwait()}) by another thread.

EINVAL The value specified by \textit{is} is invalid. This condition is not reported.

\textbf{SEE ALSO} condition(3THR), \texttt{pthread_cond_signal(3THR)}, \texttt{pthread_cond_broadcast(3THR)}, \texttt{pthread_cond_wait(3THR)}, \texttt{pthread_cond_timedwait(3THR)}, \texttt{pthread_condattr_init(3THR)}, attributes(5), standards(5)
pthread_cond_signal, pthread_cond_broadcast — signal or broadcast a condition

SYNOPSIS

cc -mt [ flag... ] file... -lpthread [ -lrt library... ]
#include <pthread.h>

int pthread_cond_signal(pthread_cond_t *cond);
int pthread_cond_broadcast(pthread_cond_t *cond);

DESCRIPTION

These two functions are used to unblock threads blocked on a condition variable.

The pthread_cond_signal() call unblocks at least one of the threads that are
blocked on the specified condition variable cond (if any threads are blocked on cond).

The pthread_cond_broadcast() call unblocks all threads currently blocked on the
specified condition variable cond.

If more than one thread is blocked on a condition variable, the scheduling policy
determines the order in which threads are unblocked. When each thread unblocked as
a result of a pthread_cond_signal() or pthread_cond_broadcast() returns
from its call to pthread_cond_wait() or pthread_cond_timedwait(), the
thread owns the mutex with which it called pthread_cond_wait() or
pthread_cond_timedwait(). The thread(s) that are unblocked contend for the
mutex according to the scheduling policy (if applicable), and as if each had called
pthread_mutex_lock().

The pthread_cond_signal() or pthread_cond_broadcast() functions may be
called by a thread whether or not it currently owns the mutex that threads calling
pthread_cond_wait() or pthread_cond_timedwait() have associated with the
condition variable during their waits; however, if predictable scheduling behavior is
required, then that mutex is locked by the thread calling pthread_cond_signal()
or pthread_cond_broadcast().

The pthread_cond_signal() and pthread_cond_broadcast() functions have
no effect if there are no threads currently blocked on cond.

RETURN VALUES

If successful, the pthread_cond_signal() and pthread_cond_broadcast() functions return 0. Otherwise, an error number is returned to indicate the error.

ERRORS

The pthread_cond_signal() and pthread_cond_broadcast() function may fail if:

EINVAL

The value cond does not refer to an initialized condition variable.

ATTRIBUTES

See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Interface Stability</td>
<td>Standard</td>
</tr>
<tr>
<td>MT-Level</td>
<td>MT-Safe</td>
</tr>
</tbody>
</table>
The `pthread_cond_wait()` function is used to block on a condition variable. It is called with `mutex` locked by the calling thread or undefined behavior will result. These functions atomically release `mutex` and cause the calling thread to block on the condition variable `cond`; atomically here means “atomically with respect to access by another thread to the mutex and then the condition variable”. That is, if another thread is able to acquire the mutex after the about-to-block thread has released it, then a subsequent call to `pthread_cond_signal()` or `pthread_cond_broadcast()` in that thread behaves as if it were issued after the about-to-block thread has blocked.

Upon successful return, the mutex has been locked and is owned by the calling thread.

When using condition variables there is always a boolean predicate, an invariant, associated with each condition wait that must be true before the thread should proceed. Spurious wakeups from the `pthread_cond_wait()`, `pthread_cond_timedwait()`, or `pthread_cond_reltimedwait_np()` functions may occur. Since the return from `pthread_cond_wait()`, `pthread_cond_timedwait()`, or `pthread_cond_reltimedwait_np()` does not imply anything about the value of this predicate, the predicate should always be re-evaluated.

The order in which blocked threads are awakened by `pthread_cond_signal()` or `pthread_cond_broadcast()` is determined by the scheduling policy. See `pthreads(3THR)`.

The effect of using more than one mutex for concurrent `pthread_cond_wait()`, `pthread_cond_timedwait()`, or `pthread_cond_reltimedwait_np()` operations on the same condition variable will result in undefined behavior.

A condition wait (whether timed or not) is a cancellation point. When the cancelability enable state of a thread is set to `PTHREAD_CANCEL_DEFERRED`, a side effect of acting upon a cancellation request while in a condition wait is that the mutex is re-acquired before calling the first cancellation cleanup handler.
A thread that has been unblocked because it has been canceled while blocked in a call to `pthread_cond_wait()` or `pthread_cond_timedwait()` does not consume any condition signal that may be directed concurrently at the condition variable if there are other threads blocked on the condition variable.

The `pthread_cond_timedwait()` function is the same as `pthread_cond_wait()` except that an error is returned if the absolute time specified by `abstime` passes (that is, system time equals or exceeds `abstime`) before the condition `cond` is signaled or broadcasted, or if the absolute time specified by `abstime` has already been passed at the time of the call. When such time-outs occur, `pthread_cond_timedwait()` will nonetheless release and reacquire the mutex referenced by `mutex`. The function `pthread_cond_timedwait()` is also a cancellation point.

The `pthread_cond_reltimedwait_np()` function is a non-standard extension provided by the Solaris version of pthreads as indicated by the "_np" (non-portable) suffix. The `pthread_cond_reltimedwait_np()` function is the same as `pthread_cond_timedwait()` except that the `reltime` argument specifies a non-negative time relative to the current system time rather than an absolute time. An error value is returned if the relative time passes (that is, system time equals or exceeds the starting system time plus the relative time) before the condition `cond` is signaled or broadcasted. When such timeouts occur, `pthread_cond_reltimedwait_np()` releases and reacquires the mutex referenced by `mutex`. The `pthread_cond_reltimedwait_np()` function is also a cancellation point.

If a signal is delivered to a thread waiting for a condition variable, upon return from the signal handler the thread resumes waiting for the condition variable as if it was not interrupted, or it returns 0 due to spurious wakeup.

**RETURN VALUES**

Except in the case of `ETIMEDOUT`, all these error checks act as if they were performed immediately at the beginning of processing for the function and cause an error return, in effect, prior to modifying the state of the mutex specified by `mutex` or the condition variable specified by `cond`.

Upon successful completion, 0 is returned. Otherwise, an error value is returned to indicate the error.

**ERRORS**

The `pthread_cond_timedwait()` function will fail if:

- `ETIMEDOUT`  The absolute time specified by `abstime` to `pthread_cond_timedwait()` has passed.

The `pthread_cond_reltimedwait_np()` function will fail if:

- `EINVAL`  The value specified by `reltime` is invalid.
- `ETIMEDOUT`  The relative time specified by `reltime` to `pthread_cond_reltimedwait_np()` has passed.

The `pthread_cond_wait()` and `pthread_cond_timedwait()` functions may fail if:
EINVAL The value specified by abstime is invalid.
EINVAL The value specified by cond or mutex is invalid.
EINVAL Different mutexes were supplied for concurrent pthread_cond_wait() or pthread_cond_timedwait(), operations on the same condition variable.
EINVAL The mutex was not owned by the current thread at the time of the call.

When a thread makes a call to pthread_cond_wait(), pthread_cond_timedwait(), or pthread_cond_reltimedwait_np(), if the symbol _POSIX_THREAD_PRIO_INHERIT is defined and the mutex is initialized with the protocol attribute having the value PTHREAD_PRIO_INHERIT and the robustness attribute having the value PTHREAD_MUTEX_ROBUST_NP (see pthread_mutexattr_getrobust_np(3THR)), the pthread_cond_wait(), pthread_cond_timedwait(), and pthread_cond_reltimedwait_np() functions will fail if:

EOWNERDEAD The last owner of this mutex died while holding the mutex. This mutex is now owned by the caller. The caller must now attempt to make the state protected by the mutex consistent. If it is able to clean up the state, then it should call pthread_mutex_consistent_np() for the mutex and unlock the mutex. Subsequent calls to pthread_cond_wait(), pthread_cond_timedwait(), and pthread_cond_reltimedwait_np() will behave normally, as before. If the caller is not able to clean up the state, pthread_mutex_consistent_np() should not be called for the mutex, but it should be unlocked. Subsequent calls to pthread_cond_wait(), pthread_cond_timedwait(), and pthread_cond_reltimedwait_np() will fail to acquire the mutex with the error value ENOTRECOVERABLE. If the owner who acquired the lock with EOWNERDEAD dies, the next owner will acquire the lock with EOWNERDEAD.

ENOTRECOVERABLE The mutex trying to be acquired is protecting the state that has been left irrecoverable by the mutex's last owner, who died while holding the lock. The mutex has not been acquired. This condition can occur when the lock was previously acquired with EOWNERDEAD, and the owner was not able to clean up the state and unlocked the mutex without making the mutex consistent.

SEE ALSO
condition(3THR), pthread_cond_signal(3THR), pthread_cond_broadcast(3THR), attributes(5), standards(5)
The `pthread_create()` function is used to create a new thread, with attributes specified by `attr`, within a process. If `attr` is `NULL`, the default attributes are used. (See `pthread_attr_init(3THR)`). If the attributes specified by `attr` are modified later, the thread’s attributes are not affected. Upon successful completion, `pthread_create()` stores the ID of the created thread in the location referenced by `thread`.

The thread is created executing `start_routine` with `arg` as its sole argument. If the `start_routine` returns, the effect is as if there was an implicit call to `pthread_exit()` using the return value of `start_routine` as the exit status. Note that the thread in which `main()` was originally invoked differs from this. When it returns from `main()`, the effect is as if there was an implicit call to `exit()` using the return value of `main()` as the exit status.

The signal state of the new thread is initialised as follows:

- The signal mask is inherited from the creating thread.
- The set of signals pending for the new thread is empty.

Default thread creation:

```c
pthread_t tid;
void *(*start_func(void *), *arg);

pthread_create(&tid, NULL, start_func, arg);
```

This would have the same effect as:

```c
pthread_attr_t attr;

pthread_attr_init(&attr); // * initialize attr with default attributes */
pthread_create(&tid, &attr, start_func, arg);
```

User-defined thread creation: To create a thread that is scheduled on a system-wide basis, use:

```c
pthread_attr_init(&attr); // * initialize attr with default attributes */
pthread_attr_setscope(&attr, PTHREAD_SCOPE_SYSTEM); // * system-wide contention */

pthread_create(&tid, &attr, start_func, arg);
```

To customize the attributes for POSIX threads, see `pthread_attr_init(3THR)`.

A new thread created with `pthread_create()` uses the stack specified by the `stackaddr` attribute, and the stack continues for the number of bytes specified by the `stacksize` attribute. By default, the stack size is 1 megabyte for 32-bit processes and 2 megabyte for 64-bit processes (see `pthread_attr_setstacksize(3THR)`). If the
default is used for both the `stackaddr` and `stacksize` attributes, `pthread_create()` creates a stack for the new thread with at least 1 megabyte for 32-bit processes and 2 megabyte for 64-bit processes. (For customizing stack sizes, see NOTES).

If `pthread_create()` fails, no new thread is created and the contents of the location referenced by `thread` are undefined.

**RETURN VALUES**

If successful, the `pthread_create()` function returns 0. Otherwise, an error number is returned to indicate the error.

**ERRORS**

The `pthread_create()` function will fail if:

- **EAGAIN** The system lacked the necessary resources to create another thread, or the system-imposed limit on the total number of threads in a process PTHREAD_THREADS_MAX would be exceeded.
- **EINVAL** The value specified by `attr` is invalid.
- **EPERM** The caller does not have appropriate permission to set the required scheduling parameters or scheduling policy.

**EXAMPLES**

**EXAMPLE 1** Example of concurrency with multithreading

The following is an example of concurrency with multithreading. Since POSIX threads and Solaris threads are fully compatible even within the same process, this example uses `pthread_create()` if you execute `a.out 0`, or `thr_create()` if you execute `a.out 1`.

Five threads are created that simultaneously perform a time-consuming function, `sleep(10)`. If the execution of this process is timed, the results will show that all five individual calls to `sleep` for ten-seconds completed in about ten seconds, even on a uniprocessor. If a single-threaded process calls `sleep(10)` five times, the execution time will be about 50-seconds.

The command-line to time this process is:

```
/usr/bin/time a.out 0 (for POSIX threading)
```

or

```
/usr/bin/time a.out 1 (for Solaris threading)
```

```c
/* cc thisfile.c -lthread -lpthread */
#define _REENTRANT /* basic 3-lines for threads */
#include <pthread.h>
#include <thread.h>

#define NUM_THREADS 5
#define SLEEP_TIME 10

void *sleeping(void *); /* thread routine */
int i;
thread_t tid[NUM_THREADS]; /* array of thread IDs */
```
EXAMPLE 1 Example of concurrency with multithreading  (Continued)

```c
int main(int argc, char *argv[]) {
    if (argc == 1) {
        printf("use 0 as arg1 to use pthread_create( )\n");
        printf("or use 1 as arg1 to use thr_create( )\n");
        return (1);
    }
    switch (*argv[1]) {
    case '0': /* POSIX */
        for (i = 0; i < NUM_THREADS; i++)
            pthread_create(&tid[i], NULL, sleeping, (void *)SLEEP_TIME);
        for (i = 0; i < NUM_THREADS; i++)
            pthread_join(tid[i], NULL);
        break;
    case '1': /* Solaris */
        for (i = 0; i < NUM_THREADS; i++)
            thr_create(NULL, 0, sleeping, (void *)SLEEP_TIME, 0,
                       &tid[i]);
        while (thr_join(NULL, NULL) == 0)
            break;
    } /* switch */
    printf("main( ) reporting that all %d threads have terminated\n", i);
    return (0);
} /* main */

void *sleeping(void *arg)
{
    int sleep_time = (int)arg;
    printf("thread %d sleeping %d seconds ...\n", thr_self(), sleep_time);
    sleep(sleep_time);
    printf("\nthread %d awakening\n", thr_self());
    return (NULL);
}
```

If `main()` had not waited for the completion of the other threads (using `pthread_join(3THR)` or `thr_join(3THR)`), it would have continued to process concurrently until it reached the end of its routine and the entire process would have exited prematurely (see `exit(2)`).

**ATTRIBUTES**

See attributes(5) for descriptions of the following attributes:
Multithreaded application threads execute independently of each other, thus their relative behavior is unpredictable. Therefore, it is possible for the thread executing `main()` to finish before all other user application threads.

`pthread_join(3THR)`, on the other hand, must specify the terminating thread (IDs) for which it will wait.

A user-specified stack size must be greater than the value `PTHREAD_STACK_MIN`. A minimum stack size may not accommodate the stack frame for the user thread function `start_func`. If a stack size is specified, it must accommodate `start_func` requirements and the functions that it may call in turn, in addition to the minimum requirement.

It is usually very difficult to determine the runtime stack requirements for a thread. `PTHREAD_STACK_MIN` specifies how much stack storage is required to execute a NULL `start_func`. The total runtime requirements for stack storage are dependent on the storage required to do runtime linking, the amount of storage required by library runtimes (as `printf()`) that your thread calls. Since these storage parameters are not known before the program runs, it is best to use default stacks. If you know your runtime requirements or decide to use stacks that are larger than the default, then it makes sense to specify your own stacks.
The **pthread_detach()** function is used to indicate to the implementation that storage for the thread *thread* can be reclaimed when that thread terminates. In other words, **pthread_detach()** dynamically resets the *detachstate* attribute of the thread to PTHREAD_CREATE_DETACHED. After a successful call to this function, it would not be necessary to reclaim the thread using pthread_join(). See pthread_join(3THR). If *thread* has not terminated, pthread_detach() will not cause it to terminate. The effect of multiple pthread_detach() calls on the same target thread is unspecified.

If successful, pthread_detach() returns 0. Otherwise, an error number is returned to indicate the error.

The pthread_detach() function will fail if:

- **EINVAL** The implementation has detected that the value specified by *thread* does not refer to a joinable thread.
- **ESRCH** No thread could be found corresponding to that specified by the given thread ID.

**SEE ALSO**pthread_create(3THR), pthread_join(3THR), attributes(5), standards(5)
#include <pthread.h>

int pthread_equal(pthread_t t1, pthread_t t2);

The `pthread_equal()` function compares the thread IDs `t1` and `t2`. The `pthread_equal()` function returns a non-zero value if `t1` and `t2` are equal. Otherwise, 0 is returned.

If `t1` or `t2` is an invalid thread ID, the behavior is undefined.

No errors are defined.

</tr>
</thead>
<tbody>
<tr>
<td>MT-Level</td>
<td>MT-Safe</td>
</tr>
</tbody>
</table>

Solaris thread IDs do not require an equivalent function because the `thread_t` structure is an unsigned int.
The `pthread_exit()` function terminates the calling thread, in a similar way that `exit(3C)` terminates the calling process. If the thread is not detached, the exit status specified by `value_ptr` is made available to any successful join with the terminating thread. See `pthread_join(3THR)`. Any cancellation cleanup handlers that have been pushed and not yet popped are popped in the reverse order that they were pushed and then executed. After all cancellation cleanup handlers have been executed, if the thread has any thread-specific data, appropriate destructor functions will be called in an unspecified order. Thread termination does not release any application visible process resources, including, but not limited to, mutexes and file descriptors, nor does it perform any process level cleanup actions, including, but not limited to, calling any `atexit()` routines that may exist.

An implicit call to `pthread_exit()` is made when a thread other than the thread in which `main()` was first invoked returns from the start routine that was used to create it. The function’s return value serves as the thread’s exit status.

The behavior of `pthread_exit()` is undefined if called from a cancellation cleanup handler or destructor function that was invoked as a result of either an implicit or explicit call to `pthread_exit()`.

After a thread has terminated, the result of access to local (auto) variables of the thread is undefined. Thus, references to local variables of the exiting thread should not be used for the `pthread_exit()` `value_ptr` parameter value.

The process exits with an exit status of 0 after the last thread has been terminated. The behavior is as if the implementation called `exit()` with a 0 argument at thread termination time.

The `pthread_exit()` function cannot return to its caller.

No errors are defined.

NAME

 pthread_getconcurrency, pthread_setconcurrency – get or set level of concurrency

SYNOPSIS

 cc -mt [ flag... ] file... -lpthread [ -lrt library... ]
 #include <pthread.h>

 int pthread_getconcurrency(void);
 int pthread_setconcurrency(int new_level);

DESCRIPTION

 Unbound threads in a process may or may not be required to be simultaneously active. By default, the threads implementation ensures that a sufficient number of threads are active so that the process can continue to make progress. While this conserves system resources, it may not produce the most effective level of concurrency.

 The pthread_setconcurrency() function allows an application to inform the threads implementation of its desired concurrency level, new_level. The actual level of concurrency provided by the implementation as a result of this function call is unspecified.

 If new_level is 0, it causes the implementation to maintain the concurrency level at its discretion as if pthread_setconcurrency() was never called.

 The pthread_getconcurrency() function returns the value set by a previous call to the pthread_setconcurrency() function. If the pthread_setconcurrency() function was not previously called, this function returns 0 to indicate that the implementation is maintaining the concurrency level.

 When an application calls pthread_setconcurrency() it is informing the implementation of its desired concurrency level. The implementation uses this as a hint, not a requirement.

 If an implementation does not support multiplexing of user threads on top of several kernel scheduled entities, the pthread_setconcurrency() and pthread_getconcurrency() functions will be provided for source code compatibility but they will have no effect when called. To maintain the function semantics, the new_level parameter will be saved when pthread_setconcurrency() is called so that a subsequent call to pthread_getconcurrency() returns the same value.

RETURN VALUES

 If successful, the pthread_setconcurrency() function returns 0. Otherwise, an error number is returned to indicate the error.

 The pthread_getconcurrency() function always returns the concurrency level set by a previous call to pthread_setconcurrency(). If the pthread_setconcurrency() function has never been called, pthread_getconcurrency() returns 0.

ERRORS

 The pthread_setconcurrency() function will fail if:

EINVAL The value specified by new_level is negative.
EAGAIN

The value specified by `new_level` would cause a system resource to be exceeded.

ATTRIBUTES

The `pthread_getschedparam()` and `pthread_setschedparam()` functions allow the scheduling policy and scheduling parameters of individual threads within a multithreaded process to be retrieved and set. Supported policies are `SCHED_FIFO`, `SCHED_RR`, and `SCHED_OTHER`. See `pthreads(3THR)`. For `SCHED_FIFO`, `SCHED_RR`, and `SCHED_OTHER`, the affected scheduling parameter is the `sched_priority` member of the `sched_param` structure.

The `pthread_getschedparam()` function retrieves the scheduling policy and scheduling parameters for the thread whose thread ID is given by `thread` and stores those values in `policy` and `param`, respectively. The priority value returned from `pthread_getschedparam()` is the value specified by the most recent `pthread_setschedparam()` or `pthread_create()` call affecting the target thread, and reflects any temporary adjustments to its priority as a result of any priority inheritance or ceiling functions. The `pthread_setschedparam()` function sets the scheduling policy and associated scheduling parameters for the thread whose thread ID is given by `thread` to the policy and associated parameters provided in `policy` and `param`, respectively.

If the `pthread_setschedparam()` function fails, no scheduling parameters will be changed for the target thread.

If successful, the `pthread_getschedparam()` and `pthread_setschedparam()` functions return `0`. Otherwise, an error number is returned to indicate the error.

The `pthread_getschedparam()` function may fail if:

- **ESRCH**: The value specified by `thread` does not refer to a existing thread.

The `pthread_setschedparam()` function may fail if:

- **EINVAL**: The value specified by `policy` or one of the scheduling parameters associated with the scheduling policy `policy` is invalid.
- **EPERM**: The caller does not have the appropriate permission to set either the scheduling parameters or the scheduling policy of the specified thread.
- **ESRCH**: The value specified by `thread` does not refer to a existing thread.

**NAME**

pthread_getspecific, pthread_setspecific – manage thread-specific data

**SYNOPSIS**

```c
#include <pthread.h>

int pthread_setspecific(pthread_key_t key, const void *value);
void *pthread_getspecific(pthread_key_t key);
```

**DESCRIPTION**

The `pthread_setspecific()` function associates a thread-specific value with a key obtained by way of a previous call to `pthread_key_create()`. Different threads may bind different values to the same key. These values are typically pointers to blocks of dynamically allocated memory that have been reserved for use by the calling thread.

The `pthread_getspecific()` function returns the value currently bound to the specified key on behalf of the calling thread.

The effect of calling `pthread_setspecific()` or `pthread_getspecific()` with a key value not obtained from `pthread_key_create()` or after key has been deleted with `pthread_key_delete()` is undefined.

Both `pthread_setspecific()` and `pthread_getspecific()` may be called from a thread-specific data destructor function. However, calling `pthread_setspecific()` from a destructor may result in lost storage or infinite loops.

**RETURN VALUES**

The `pthread_getspecific()` function returns the thread-specific data value associated with the given key. If no thread-specific data value is associated with key, then the value `NULL` is returned.

Upon successful completion, the `pthread_setspecific()` function returns 0. Otherwise, an error number is returned to indicate the error.

**ERRORS**

The `pthread_setspecific()` function will fail if:

- **ENOMEM** Insufficient memory exists to associate the value with the key.

The `pthread_setspecific()` function may fail if:

- **EINVAL** The key value is invalid.

The `pthread_getspecific()` function does not return errors.

**ATTRIBUTES**

See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>MT-Level</td>
<td>MT-Safe</td>
</tr>
</tbody>
</table>

**SEE ALSO**

`pthread_key_create(3THR)` attributes(5), standards(5)
The `pthread_join()` function suspends processing of the calling thread until the target thread completes. `thread` must be a member of the current process and it cannot be a detached thread. See `pthread_create(3THR)`.

If two or more threads wait for the same thread to complete, all will suspend processing until the thread has terminated, and then one thread will return successfully and the others will return with an error of `ESRCH`. The `pthread_join()` function will not block processing of the calling thread if the target thread has already terminated.

If a `pthread_join()` call returns successfully with a non-null `status` argument, the value passed to `pthread_exit(3THR)` by the terminating thread will be placed in the location referenced by `status`.

If the `pthread_join()` calling thread is cancelled, then the target thread will remain joinable by `pthread_join()`. However, the calling thread may set up a cancellation cleanup handler on `thread` prior to the join call, which may detach the target thread by calling `pthread_detach(3THR)`. See `pthread_detach(3THR)` and `pthread_cancel(3THR)`.

If successful, `pthread_join()` returns 0. Otherwise, an error number is returned to indicate the error.

**ERRORS**
- **EDEADLK** A joining deadlock would occur, such as when a thread attempts to wait for itself.
- **EINVAL** The thread corresponding to the given thread ID is a detached thread.
- **ESRCH** No thread could be found corresponding to the given thread ID.

**ATTRIBUTES**
See `attributes(5)` for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>MT-Level</td>
<td>MT-Safe</td>
</tr>
</tbody>
</table>

**SEE ALSO**
- `wait(2)`, `pthread_cancel(3THR)`, `pthread_create(3THR)`, `pthread_detach(3THR)`, `pthread_exit(3THR)`, `attributes(5)`, `standards(5)`

**NOTES**
The `pthread_join(3THR)` function must specify the `thread` ID for whose termination it will wait.
Calling `pthread_join()` also "detaches" the thread; that is, `pthread_join()` includes the effect of the `pthread_detach()` function. If a thread were to be cancelled when blocked in `pthread_join()`, an explicit detach would have to be performed in the cancellation cleanup handler. The `pthread_detach()` function exists primarily for this purpose.
This function creates a thread-specific data key visible to all threads in the process. Key values provided by `pthread_key_create()` are opaque objects used to locate thread-specific data. Although the same key value may be used by different threads, the values bound to the key by `pthread_setspecific()` are maintained on a per-thread basis and persist for the life of the calling thread.

Upon key creation, the value `NULL` is associated with the new key in all active threads. Upon thread creation, the value `NULL` is associated with all defined keys in the new thread.

An optional destructor function may be associated with each key value. At thread exit, if a key value has a non-NULL destructor pointer, and the thread has a non-NULL value associated with that key, the function pointed to is called with the current associated value as its sole argument. Destructors can be called in any order.

If, after all the destructors have been called for all keys with non-NULL values, there are still some keys with non-NULL values, the process will be repeated. If, after at least `PTHREAD_DESTRUCTOR_ITERATIONS` iterations of destructor calls for outstanding non-NULL values, there are still some keys with non-NULL values, the process is continued, even though this might result in an infinite loop.

If successful, the `pthread_key_create()` function stores the newly created key value at `*key` and returns `0`. Otherwise, an error number is returned to indicate the error.

The `pthread_key_create()` function will fail if:

- `EAGAIN` The system lacked the necessary resources to create another thread-specific data key, or the system-imposed limit on the total number of keys per process `PTHREAD_KEYS_MAX` has been exceeded.
- `ENOMEM` Insufficient memory exists to create the key.

The `pthread_key_create()` function will not return an error code of `EINVAL`.

See `attributes(5)` for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>MT-Level</td>
<td>MT-Safe</td>
</tr>
</tbody>
</table>
SEE ALSO  pthread_getspecific(3THR), pthread_setspecific(3THR),
          pthread_key_delete(3THR), attributes(5), standards(5)
#include <pthread.h>

int pthread_key_delete(pthread_key_t key);

The `pthread_key_delete()` function deletes a thread-specific data key previously returned by `pthread_key_create()`. The thread-specific data values associated with `key` need not be NULL at the time `pthread_key_delete()` is called. It is the responsibility of the application to free any application storage or perform any cleanup actions for data structures related to the deleted key or associated thread-specific data in any threads; this cleanup can be done either before or after `pthread_key_delete()` is called. Any attempt to use `key` following the call to `pthread_key_delete()` results in undefined behaviour.

The `pthread_key_delete()` function is callable from within destructor functions. No destructor functions will be invoked by `pthread_key_delete()`. Any destructor function that may have been associated with `key` will no longer be called upon thread exit.

If successful, the `pthread_key_delete()` function returns 0. Otherwise, an error number is returned to indicate the error.

The `pthread_key_delete()` function may fail if:

- **EINVAL**: The `key` value is invalid.

The `pthread_key_delete()` function will not return an error code of **EINTR**.

The `pthread_kill()` function is used to request that a signal be delivered to the specified thread.

As in `kill()`, if `sig` is 0, error checking is performed but no signal is actually sent.

Upon successful completion, the function returns a value of 0. Otherwise the function returns an error number. If the `pthread_kill()` function fails, no signal is sent.

The `pthread_kill()` function will fail if:

- **ESRCH**  No thread could be found corresponding to that specified by the given thread ID.
- **EINVAL**  The value of the `sig` argument is an invalid or unsupported signal number.

The `pthread_mutexattr_getprioceiling()` and `pthread_mutexattr_setprioceiling()` functions, respectively, get and set the priority ceiling attribute of a mutex attribute object pointed to by `attr`, which was previously created by the `pthread_mutexattr_init()` function.

The `prioceiling` attribute contains the priority ceiling of initialized mutexes. The values of `prioceiling` must be within the maximum range of priorities defined by `SCHED_FIFO`.

The `prioceiling` attribute defines the priority ceiling of initialized mutexes, which is the minimum priority level at which the critical section guarded by the mutex is executed. In order to avoid priority inversion, the priority ceiling of the mutex must be set to a priority higher than or equal to the highest priority of all the threads that may lock that mutex. The values of `prioceiling` must be within the maximum range of priorities defined under the `SCHED_FIFO` scheduling policy.

The ceiling value should be drawn from the range of priorities for the `SCHED_FIFO` policy. When a thread acquires such a mutex, the policy of the thread at mutex acquisition should match that from which the ceiling value was derived (`SCHED_FIFO`, in this case). If a thread changes its scheduling policy while holding a ceiling mutex, the behavior of `pthread_mutex_lock()` and `pthread_mutex_unlock()` on this mutex is undefined. See `pthread_mutex_lock(3THR)`.

The ceiling value should not be treated as a persistent value resident in a `pthread_mutex_t` that is valid across upgrades of Solaris. The semantics of the actual ceiling value are determined by the existing priority range for the `SCHED_FIFO` policy, as returned by the `sched_get_priority_min()` and `sched_get_priority_max()` functions (see `sched_get_priority_min(3RT)`) when called on the version of Solaris on which the ceiling value is being utilized.

Upon successful completion, the `pthread_mutexattr_getprioceiling()` and `pthread_mutexattr_setprioceiling()` functions return 0. Otherwise, an error number is returned to indicate the error.

The `pthread_mutexattr_getprioceiling()` and `pthread_mutexattr_setprioceiling()` functions will fail if:
The _POSIX_THREAD_PRIO_PROTECT option is not defined and the system does not support the function.

The pthread_mutexattr_getprioceiling() function will fail if:

EINVAL The value specified by attr is NULL.

The pthread_mutexattr_setprioceiling() functions will fail if:

EINVAL The value specified by attr is NULL or prioceiling is invalid.

The pthread_mutexattr_getprioceiling() and pthread_mutexattr_setprioceiling() functions may fail if:

EINVAL The value specified by attr or prioceiling is invalid.

EPERM The caller does not have the privilege to perform the operation.

sched_get_priority_min(3RT), attributes(5), standards(5)
The `pthread_mutexattr_setprotocol()` and `pthread_mutexattr_getprotocol()` functions, respectively, set and get the protocol attribute of a mutex attribute object pointed to by `attr`, which was previously created by the `pthread_mutexattr_init()` function.

The `protocol` attribute defines the protocol to be followed in utilizing mutexes. The value of `protocol` may be one of `PTHREAD_PRIO_NONE`, `PTHREAD_PRIO_INHERIT`, or `PTHREAD_PRIO_PROTECT`, which are defined by the header `<pthread.h>`.

When a thread owns a mutex with the `PTHREAD_PRIO_NONE` protocol attribute, its priority and scheduling are not affected by its mutex ownership.

When a thread is blocking higher priority threads because of owning one or more mutexes with the `PTHREAD_PRIO_INHERIT` protocol attribute, it executes at the higher of its priority or the priority of the highest priority thread waiting on any of the mutexes owned by this thread and initialized with this protocol.

When a thread owns one or more mutexes initialized with the `PTHREAD_PRIO_PROTECT` protocol, it executes at the higher of its priority or the highest of the priority ceilings of all the mutexes owned by this thread and initialized with this attribute, regardless of whether other threads are blocked on any of these mutexes.

While a thread is holding a mutex that has been initialized with the `PRIO_INHERIT` or `PRIO_PROTECT` protocol attributes, it will not be subject to being moved to the tail of the scheduling queue at its priority in the event that its original priority is changed, such as by a call to `sched_setparam()`. Likewise, when a thread unlocks a mutex that has been initialized with the `PRIO_INHERIT` or `PRIO_PROTECT` protocol attributes, it will not be subject to being moved to the tail of the scheduling queue at its priority in the event that its original priority is changed.

If a thread simultaneously owns several mutexes initialized with different protocols, it will execute at the highest of the priorities that it would have obtained by each of these protocols.

When a thread makes a call to `pthread_mutex_lock()`, if the symbol `_POSIX_THREAD_PRIO_INHERIT` is defined and the mutex was initialized with the protocol attribute having the value `PTHREAD_PRIO_INHERIT`, when the calling thread is blocked because the mutex is owned by another thread, that owner thread...
The implementation updates its execution priority to the maximum of its assigned priority and all its inherited priorities. Furthermore, if this owner thread becomes blocked on another mutex, the same priority inheritance effect will be propagated to the other owner thread, in a recursive manner.

If the symbol `_POSIX_THREAD_PRIO_INHERIT` is defined, when a mutex initialized with the protocol attribute having the value `PTHREAD_PRIO_INHERIT` dies, the behavior depends on the robustness attribute of the mutex. See `pthread_mutexattr_getrobust_np(3THR)`.

A thread that uses mutexes initialized with the `PTHREAD_PRIO_INHERIT` or `PTHREAD_PRIO_PROTECT` protocol attribute values should have its `contentionscope` attribute equal to `PTHREAD_SCOPE_SYSTEM` (see `pthread_attr_getscope(3THR)`) and its scheduling policy equal to `SCHED_FIFO` or `SCHED_RR` (see `pthread_attr_getschedparam(3THR)` and `pthread_getschedparam(3THR)`).

If a thread with `contentionscope` attribute equal to `PTHREAD_SCOPE_PROCESS` and/or its scheduling policy equal to `SCHED_OTHER` uses a mutex initialized with the `PTHREAD_PRIO_INHERIT` or `PTHREAD_PRIO_PROTECT` protocol attribute value, the effect on the thread’s scheduling and priority is unspecified.

The `_POSIX_THREAD_PRIO_INHERIT` and `_POSIX_THREAD_PRIO_PROTECT` options are designed to provide features to solve priority inversion due to mutexes. A priority inheritance or priority ceiling mutex is designed to minimize the dispatch latency of a high priority thread when a low priority thread is holding a mutex required by the high priority thread. This is a specific need for the realtime application domain.

Threads created by realtime applications need to be such that their priorities can influence their access to system resources (CPU resources, at least), in competition with all threads running on the system.

**RETURN VALUES**

Upon successful completion, the `pthread_mutexattr_getprotocol()` and `pthread_mutexattr_setprotocol()` functions return 0. Otherwise, an error number is returned to indicate the error.

**ERRORS**

The `pthread_mutexattr_getprotocol()` and `pthread_mutexattr_setprotocol()` functions will fail if:

- **EINVAL** The value specified by `attr` is NULL.
- **ENOSYS** Neither of the options `POSIX_THREAD_PRIO_PROTECT` and `_POSIX_THREAD_PRIO_INHERIT` is defined and the system does not support the function.
- **ENOTSUP** The value specified by `protocol` is an unsupported value.

The `pthread_mutexattr_getprotocol()` and `pthread_mutexattr_setprotocol()` functions may fail if:
EINVAL The value specified by attr or protocol is invalid.

EPERM The caller does not have the privilege to perform the operation.

pthread_cond_init(3THR), pthread_mutexattr_getrobust_np(3THR),
attributes(5), standards(5)
The `pthread_mutexattr_getpshared()` function obtains the value of the process-shared attribute from the attributes object referenced by `attr`. The `pthread_mutexattr_setpshared()` function is used to set the process-shared attribute in an initialized attributes object referenced by `attr`.

The process-shared attribute is set to `PTHREAD_PROCESS_SHARED` to permit a mutex to be operated upon by any thread that has access to the memory where the mutex is allocated, even if the mutex is allocated in memory that is shared by multiple processes. If the process-shared attribute is `PTHREAD_PROCESS_PRIVATE`, the mutex will only be operated upon by threads created within the same process as the thread that initialized the mutex; if threads of differing processes attempt to operate on such a mutex, the behavior is undefined. The default value of the attribute is `PTHREAD_PROCESS_PRIVATE`.

Upon successful completion, `pthread_mutexattr_getpshared()` returns 0 and stores the value of the process-shared attribute of `attr` into the object referenced by the `pshared` parameter. Otherwise, an error number is returned to indicate the error.

Upon successful completion, `pthread_mutexattr_setpshared()` returns 0. Otherwise, an error number is returned to indicate the error.

The `pthread_mutexattr_getpshared()` and `pthread_mutexattr_setpshared()` functions may fail if:

- **EINVAL** The value specified by `attr` is invalid.

The `pthread_mutexattr_setpshared()` function may fail if:

- **EINVAL** The new value specified for the attribute is outside the range of legal values for that attribute.

The following applies only if the symbol \_POSIX_THREAD_PRIO_INHERIT is defined, and the mutex attributes object \textit{attr} should be used only to initialize mutexes that will also be initialized with the protocol attribute having the value PTHREAD_PRIO_INHERIT. See \textit{pthread_mutexattr_getprotocol(3THR)}.

The \textbf{pthread_mutexattr_setrobust_np()} and \textbf{pthread_mutexattr_getrobust_np()} functions set and get the \textit{robustness} attribute of a mutex attribute object pointed to by \textit{attr} that was previously created by the function \textit{pthread_mutexattr_init(3THR)}.

The \textit{robustness} attribute defines the behavior when the owner of a mutex dies. The value of\textit{ robustness} may be either \textbf{PTHREAD_MUTEX_ROBUST_NP} or \textbf{PTHREAD_MUTEX_STALLED_NP}, which are defined by the header \texttt{<pthread.h>}. The default value of the \textit{robustness} attribute is \textbf{PTHREAD_MUTEX_STALLED_NP}.

When the owner of a mutex with the \textbf{PTHREAD_MUTEX_STALLED_NP} \textit{robustness} attribute dies, all future calls to \textbf{pthread_mutex_lock(3THR)} for this mutex will be blocked from progress in an unspecified manner.

When the owner of a mutex with the \textbf{PTHREAD_MUTEX_ROBUST_NP} \textit{robustness} attribute dies, the mutex is unlocked. The next owner of this mutex acquires it with an error value of \textbf{EOWNERDEAD}. Note that the application must always check the return value from \textbf{ pthread_mutex_lock()} for a mutex initialized with the \textbf{PTHREAD_MUTEX_ROBUST_NP} \textit{robustness} attribute. The new owner of this mutex should then attempt to make the state protected by the mutex consistent, since this state could have been left inconsistent when the last owner died. If the new owner is able to make the state consistent, it should call \textbf{pthread_mutex_consistent_np(3THR)} for the mutex and then unlock the mutex. If for any reason the new owner is not able to make the state consistent, it should not call \textbf{pthread_mutex_consistent_np()} for the mutex, but should simply unlock the mutex. In the latter scenario, all waiters will be awakened and all subsequent calls to \textbf{pthread_mutex_lock()} will fail in acquiring the mutex with an error value of \textbf{ENOTRECOVERABLE}. The mutex can then be made consistent by uninitializing the mutex with the \textbf{pthread_mutex_destroy()} function and reinitializing it with the \textbf{ pthread_mutex_init()} function. If the thread that acquired the lock with \textbf{EOWNERDEAD} dies, the next owner will acquire the lock with an error value of \textbf{EOWNERDEAD}. 

**NAME**

\texttt{pthread_mutexattr_getrobust_np(3THR)}

\texttt{pthread_mutexattr_setrobust_np(3THR)}

**SYNOPSIS**

\begin{verbatim}
cc -mt [ flag... ] file... -lpthread [ -lrt library... ]
#include <pthread.h>

int pthread_mutexattr_getrobust_np(const pthread_mutexattr_t *attr, int *robustness);

int pthread_mutexattr_setrobust_np(pthread_mutexattr_t *attr, int robustness);
\end{verbatim}

**DESCRIPTION**

The \textbf{pthread_mutexattr_setrobust_np()} and \textbf{pthread_mutexattr_getrobust_np()} functions set and get the \textit{robustness} attribute of a mutex attribute object pointed to by \textit{attr} that was previously created by the function \textit{pthread_mutexattr_init(3THR)}.

The \textit{robustness} attribute defines the behavior when the owner of a mutex dies. The value of \textit{robustness} may be either \textbf{PTHREAD_MUTEX_ROBUST_NP} or \textbf{PTHREAD_MUTEX_STALLED_NP}, which are defined by the header \texttt{<pthread.h>}. The default value of the \textit{robustness} attribute is \textbf{PTHREAD_MUTEX_STALLED_NP}.

When the owner of a mutex with the \textbf{PTHREAD_MUTEX_STALLED_NP} \textit{robustness} attribute dies, all future calls to \textbf{pthread_mutex_lock(3THR)} for this mutex will be blocked from progress in an unspecified manner.

When the owner of a mutex with the \textbf{PTHREAD_MUTEX_ROBUST_NP} \textit{robustness} attribute dies, the mutex is unlocked. The next owner of this mutex acquires it with an error value of \textbf{EOWNERDEAD}. Note that the application must always check the return value from \textbf{ pthread_mutex_lock()} for a mutex initialized with the \textbf{PTHREAD_MUTEX_ROBUST_NP} \textit{robustness} attribute. The new owner of this mutex should then attempt to make the state protected by the mutex consistent, since this state could have been left inconsistent when the last owner died. If the new owner is able to make the state consistent, it should call \textbf{pthread_mutex_consistent_np(3THR)} for the mutex and then unlock the mutex. If for any reason the new owner is not able to make the state consistent, it should not call \textbf{ pthread_mutex_consistent_np()} for the mutex, but should simply unlock the mutex. In the latter scenario, all waiters will be awakened and all subsequent calls to \textbf{ pthread_mutex_lock()} will fail in acquiring the mutex with an error value of \textbf{ENOTRECOVERABLE}. The mutex can then be made consistent by uninitializing the mutex with the \textbf{pthread_mutex_destroy()} function and reinitializing it with the \textbf{ pthread_mutex_init()} function. If the thread that acquired the lock with \textbf{EOWNERDEAD} dies, the next owner will acquire the lock with an error value of \textbf{EOWNERDEAD}. 

168  man pages section 3: Threads and Realtime Library Functions • Last Revised 4 Oct 1999
Note that the mutex may be in memory shared between processes or in memory private to a process, i.e. the "owner" referenced above is a thread, either within or outside the requestor’s process.

The mutex memory must be zeroed before initialization.

**RETURN VALUES**

Upon successful completion, the `pthread_mutexattr_getrobust_np()` and `pthread_mutexattr_setrobust_np()` functions return 0. Otherwise, an error number is returned to indicate the error.

**ERRORS**

The `pthread_mutexattr_getrobust_np()` and `pthread_mutexattr_setrobust_np()` functions will fail if:

- **EINVAL** The value specified by `attr` or `robustness` is invalid.
- **ENOSYS** The option `_POSIX_THREAD_PRIO_INHERIT` is not defined and the implementation does not support the function.
- **ENOTSUP** The value specified by `robustness` is unsupported value.

**ATTRIBUTES**

See `attributes(5)` for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>MT-Level</td>
<td>MT-Safe</td>
</tr>
</tbody>
</table>

**SEE ALSO**

`mutex(3THR), pthread_mutex_lock(3THR), pthread_mutex_consistent_np(3THR), pthread_mutexattr_getprotocol(3THR), attributes(5), standards(5)`
The `pthread_mutexattr_gettype()` and `pthread_mutexattr_settype()` functions respectively get and set the mutex type attribute. This attribute is set in the `type` parameter to these functions. The default value of the `type` attribute is `PTHREAD_MUTEX_DEFAULT`.

The type of mutex is contained in the `type` attribute of the mutex attributes. Valid mutex types include:

- **PTHREAD_MUTEX_NORMAL**: This type of mutex does not detect deadlock. A thread attempting to relock this mutex without first unlocking it will deadlock. Attempting to unlock a mutex locked by a different thread results in undefined behavior. Attempting to unlock an unlocked mutex results in undefined behavior.

- **PTHREAD_MUTEX_ERRORCHECK**: This type of mutex provides error checking. A thread attempting to relock this mutex without first unlocking it will return with an error. A thread attempting to unlock a mutex that another thread has locked will return with an error. A thread attempting to unlock an unlocked mutex will return with an error.

- **PTHREAD_MUTEX_RECURSIVE**: A thread attempting to relock this mutex without first unlocking it will succeed in locking the mutex. The relocking deadlock that can occur with mutexes of type `PTHREAD_MUTEX_NORMAL` cannot occur with this type of mutex. Multiple locks of this mutex require the same number of unlocks to release the mutex before another thread can acquire the mutex. A thread attempting to unlock a mutex that another thread has locked will return with an error. A thread attempting to unlock an unlocked mutex will return with an error. This type of mutex is only supported for mutexes whose process shared attribute is `PTHREAD_PROCESS_PRIVATE`.

Attempting to recursively lock a mutex of this type results in undefined behavior. Attempting to unlock a mutex of this type that was not locked by the calling thread results in undefined behavior. Attempting to unlock a mutex of this type that is not locked results in undefined behavior. An implementation is allowed to map this mutex to one of the other mutex types.

Upon successful completion, the `pthread_mutexattr_settype()` function returns 0. Otherwise, an error number is returned to indicate the error.

Upon successful completion, the `pthread_mutexattr_gettype()` function returns 0 and stores the value of the `type` attribute of `attr` in the object referenced by the `type` parameter. Otherwise an error number is returned to indicate the error.

The `pthread_mutexattr_gettype()` and `pthread_mutexattr_settype()` functions will fail if:

- `EINVAL` The value `type` is invalid.

The `pthread_mutexattr_gettype()` and `pthread_mutexattr_settype()` functions may fail if:

- `EINVAL` The value specified by `attr` is invalid.

See `attributes(5)` for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>MT-Level</td>
<td>MT-Safe</td>
</tr>
</tbody>
</table>

It is advised that an application should not use a `PTHREAD_MUTEX_RECURSIVE` mutex with condition variables `PTHREAD_MUTEX_RECURSIVE` because the implicit unlock performed for `pthread_cond_wait()` or `pthread_cond_timedwait()` will not actually release the mutex (if it had been locked multiple times). If this occurs, no other thread can satisfy the condition of the predicate.
The `pthread_mutexattr_init()` function initializes a mutex attributes object `attr` with the default value for all of the attributes defined by the implementation. The effect of initializing an already initialized mutex attributes object is undefined.

After a mutex attributes object has been used to initialize one or more mutexes, any function affecting the attributes object (including destruction) does not affect any previously initialized mutexes.

The `pthread_mutexattr_destroy()` function destroys a mutex attributes object; the object becomes, in effect, uninitialized. An implementation may cause `pthread_mutexattr_destroy()` to set the object referenced by `attr` to an invalid value. A destroyed mutex attributes object can be re-initialized using `pthread_mutexattr_init()`; the results of otherwise referencing the object after it has been destroyed are undefined.

Upon successful completion, `pthread_mutexattr_init()` and `pthread_mutexattr_destroy()` return 0. Otherwise, an error number is returned to indicate the error.

The `pthread_mutexattr_init()` function may fail if:

- **ENOMEM** Insufficient memory exists to initialize the mutex attributes object.

The `pthread_mutexattr_destroy()` function may fail if:

- **EINVAL** The value specified by `attr` is invalid.

See `attributes(5)` for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>MT-Level</td>
<td>MT-Safe</td>
</tr>
</tbody>
</table>

NAME
pthread_mutex_consistent_np – make a mutex consistent after owner death

SYNOPSIS
cc -mt [ flag... ] file... -lpthread [ -lrt library... ]
#include <pthread.h>

int pthread_mutex_consistent_np(pthread_mutex_t *mutex);

DESCRIPTION
The following applies only if the symbol _POSIX_THREAD_PRIO_INHERIT is defined, and for mutexes that have been initialized with the protocol attribute having the value PTHREAD_PRIO_INHERIT. See pthread_mutexattr_getprotocol(3THR).

The mutex object referenced by mutex is made consistent by calling pthread_mutex_consistent_np().

A consistent mutex becomes inconsistent and is unlocked if its owner dies while holding it. A subsequent owner of the mutex will acquire the mutex with pthread_mutex_lock(3THR), which will return EOWNERDEAD to indicate that the acquired mutex is inconsistent.

The pthread_mutex_consistent_np() function should be called while holding the mutex acquired by a previous call to pthread_mutex_lock() that returned EOWNERDEAD.

Since the critical section protected by the mutex could have been left in an inconsistent state by the dead owner, the caller should make the mutex consistent only if it is able to make the critical section protected by the mutex consistent.

Calls to pthread_mutex_lock(), pthread_mutex_unlock(), and pthread_mutex_trylock() for a consistent mutex will behave in the normal manner.

The behavior of pthread_mutex_consistent_np() for a mutex which is not inconsistent, or which is not held, is undefined.

RETURN VALUES
Upon successful completion, the pthread_mutexattr_consistent_np() function returns 0. Otherwise, an error number is returned to indicate the error.

ERRORS
The pthread_mutex_consistent_np() function will fail if:

ENOSYS The option _POSIX_THREAD_PRIO_INHERIT is not defined and the implementation does not support the function.

The pthread_mutex_consistent_np() function may fail if:

EINVAL The value specified by mutex is invalid, or the mutex does not have the appropriate attributes.
See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>MT-Level</td>
<td>MT-Safe</td>
</tr>
</tbody>
</table>

SEE ALSO mutex(3THR), pthread_mutex_lock(3THR),
        pthread_mutexattr_getprotocol(3THR),
        pthread_mutexattr_getrobust_np(3THR), attributes(5), standards(5)
The `pthread_mutex_setprioceiling()` function either locks the mutex if it is unlocked, or blocks until it can successfully lock the mutex, then it changes the mutex's priority ceiling and releases the mutex. When the change is successful, the previous value of the priority ceiling is returned in `old_ceiling`. The process of locking the mutex need not adhere to the priority protect protocol.

If the `pthread_mutex_setprioceiling()` function fails, the mutex priority ceiling is not changed.

The ceiling value should be drawn from the range of priorities for the SCHED_FIFO policy. When a thread acquires such a mutex, the policy of the thread at mutex acquisition should match that from which the ceiling value was derived (SCHED_FIFO, in this case). If a thread changes its scheduling policy while holding a ceiling mutex, the behavior of `pthread_mutex_lock()` and `pthread_mutex_unlock()` on this mutex is undefined. See `pthread_mutex_lock(3THR)`.

The ceiling value should not be treated as a persistent value resident in a `pthread_mutex_t` that is valid across upgrades of Solaris. The semantics of the actual ceiling value are determined by the existing priority range for the SCHED_FIFO policy, as returned by the `sched_get_priority_min()` and `sched_get_priority_max()` functions (see `sched_get_priority_min(3RT)`) when called on the version of Solaris on which the ceiling value is being utilized.

Upon successful completion, the `pthread_mutex_getprioceiling()` and `pthread_mutex_setprioceiling()` functions return 0. Otherwise, an error number is returned to indicate the error.

The `pthread_mutex_getprioceiling()` and `pthread_mutex_setprioceiling()` functions will fail if:

- `ENOSYS` The option `_POSIX_THREAD_PRIO_PROTECT` is not defined and the system does not support the function. Since `_POSIX_THREAD_PRIO_PROTECT` is defined, this condition is not reported.
The `pthread_mutex_setprioceiling()` function will fail if:

- **EINVAL** The mutex was not initialized with its `protocol` attribute having the value of `PTHREAD_PRIO_PROTECT`.

The `pthread_mutex_getprioceiling()` and `pthread_mutex_setprioceiling()` functions may fail if:

- **EINVAL** The value specified by `mutex` does not refer to a currently existing mutex.
- **ENOSYS** The system does not support the priority ceiling protocol for mutexes.
- **EPERM** The caller does not have the privilege to perform the operation.

The `pthread_mutex_getprioceiling()` function may fail if:

- **EINVAL** The priority requested by `prioceiling` is out of range.

The `pthread_mutex_setprioceiling()` function may fail if:

- **EINVAL** The priority requested by `prioceiling` is out of range.

**ATTRIBUTES** See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>

NAME
pthread_mutex_init, pthread_mutex_destroy – initialize or destroy a mutex

SYNOPSIS
cc -mt [ flag...] file... -lpthread [ -lrt library...] 
#include <pthread.h>

int pthread_mutex_init(pthread_mutex_t *mutex, const
pthread_mutexattr_t *attr);

int pthread_mutex_destroy(pthread_mutex_t *mutex);

pthread_mutex_t mutex = PTHREAD_MUTEX_INITIALIZER

DESCRIPTION
The pthread_mutex_init() function initializes the mutex referenced by mutex
with attributes specified by attr. If attr is NULL, the default mutex attributes are used;
the effect is the same as passing the address of a default mutex attributes object. Upon
successful initialization, the state of the mutex becomes initialized and unlocked.

Attempting to initialize an already initialized mutex results in undefined behavior.

The pthread_mutex_destroy() function destroys the mutex object referenced by
mutex; the mutex object becomes, in effect, uninitialized. A destroyed mutex object can
be re-initialized using pthread_mutex_init(); the results of otherwise referencing
the object after it has been destroyed are undefined.

It is safe to destroy an initialized mutex that is unlocked. Attempting to destroy a
locked mutex results in undefined behavior.

In cases where default mutex attributes are appropriate, the macro
PTHREAD_MUTEX_INITIALIZER can be used to initialize mutexes that are statically
allocated. The effect is equivalent to dynamic initialization by a call to
pthread_mutex_init() with parameter attr specified as NULL, except that no error
checks are performed.

RETURN VALUES
If successful, the pthread_mutex_init() and pthread_mutex_destroy() functions return 0. Otherwise, an error number is returned to indicate the error.

ERRORS
The pthread_mutex_init() function will fail if:

EINVAL
An attempt was made to initialize mutex to be robust and not
PTHREAD_PRIO_INHERIT.

EAGAIN
The system lacked the necessary resources (other than memory) to
initialize another mutex.

EBUSY
An attempt was detected to re-initialize the object referenced by
mutex, a robust mutex previously initialized but not yet destroyed.

EINVAL
The value specified by attr has not been initialized using
pthread_mutexattr_init(3THR).

EINVAL
An attempt was made to initialize mutex to be robust and not
PTHREAD_PRIO_INHERIT.
pthread_mutex_init(3THR)

EINVAL An attempt was made to initialize mutex to be
PTHREAD_PRIO_INHERIT or PTHREAD_PRIO_PROTECT and the
type of the mutex to be PTHREAD_MUTEX_ERRORCHECK or
PTHREAD_MUTEX_RECURSIVE.

EINVAL An attempt was made to initialize mutex to be
PTHREAD_PROCESS_SHARED and the type of the mutex to be
PTHREAD_MUTEX_RECURSIVE.

EINVAL The process-shared attribute associated with attr is invalid.

ENOMEM Insufficient memory exists to initialize the mutex.

EPERM The caller does not have the privilege to perform the operation.

The pthread_mutex_init() function may fail if:

EBUSY An attempt was detected to re-initialize the object referenced by
mutex, a mutex previously initialized but not yet destroyed.

EINVAL The value specified by attr or mutex is invalid.

The pthread_mutex_destroy() function may fail if:

EBUSY An attempt was detected to destroy the object referenced by mutex
while it is locked or referenced (for example, while being used in a
pthread_cond_wait(3THR) or
pthread_cond_timedwait(3THR)) by another thread.

EINVAL The value specified by mutex is invalid.

NAME
pthread_mutex_lock, pthread_mutex_trylock, pthread_mutex_unlock – lock or unlock a mutex

SYNOPSIS
cc -mt [ flag... ] file... -lpthread [ -lrt library... ]
#include <pthread.h>

int pthread_mutex_lock(pthread_mutex_t *mutex);
int pthread_mutex_trylock(pthread_mutex_t *mutex);
int pthread_mutex_unlock(pthread_mutex_t *mutex);

DESCRIPTION
The mutex object referenced by mutex is locked by calling pthread_mutex_lock().
If the mutex is already locked, the calling thread blocks until the mutex becomes available.
This operation returns with the mutex object referenced by mutex in the locked state with the
calling thread as its owner.

If the mutex type is PTHREAD_MUTEX_NORMAL, deadlock detection is not provided.
Attempting to relock the mutex causes deadlock. If a thread attempts to unlock a mutex
that it has not locked or a mutex that is unlocked, undefined behavior results.

If the mutex type is PTHREAD_MUTEX_ERRORCHECK, then error checking is provided.
If a thread attempts to relock a mutex that it has already locked, an error will be
returned. If a thread attempts to unlock a mutex that it has not locked or a mutex
which is unlocked, an error will be returned.

If the mutex type is PTHREAD_MUTEX_RECURSIVE, then the mutex maintains the
concept of a lock count. When a thread successfully acquires a mutex for the first time,
the lock count is set to 1. Every time a thread relocks this mutex, the lock count is
incremented by one. Each time the thread unlocks the mutex, the lock count is
decremented by one. When the lock count reaches 0, the mutex becomes available for
other threads to acquire. If a thread attempts to unlock a mutex that it has not locked or
a mutex that is unlocked, an error will be returned.

If the mutex type is PTHREAD_MUTEX_DEFAULT, attempting to recursively lock the
mutex results in undefined behavior. Attempting to unlock the mutex if it was not
locked by the calling thread results in undefined behavior. Attempting to unlock the
mutex if it is not locked results in undefined behavior.

The pthread_mutex_trylock() function is identical to pthread_mutex_lock() except that
if the mutex object referenced by mutex is currently locked (by any thread,
including the current thread), the call returns immediately.

The pthread_mutex_unlock() function releases the mutex object referenced by
mutex. The manner in which a mutex is released is dependent upon the mutex’s type
attribute. If there are threads blocked on the mutex object referenced by mutex when
pthread_mutex_unlock() is called, resulting in the mutex becoming available, the
scheduling policy is used to determine which thread will acquire the mutex. (In the
case of PTHREAD_MUTEX_RECURSIVE mutexes, the mutex becomes available when
the count reaches 0 and the calling thread no longer has any locks on this mutex.)
If a signal is delivered to a thread waiting for a mutex, upon return from the signal handler the thread resumes waiting for the mutex as if it was not interrupted.

**RETURN VALUES**

If successful, the `pthread_mutex_lock()` and `pthread_mutex_unlock()` functions return 0. Otherwise, an error number is returned to indicate the error.

The `pthread_mutex_trylock()` function returns 0 if a lock on the mutex object referenced by `mutex` is acquired. Otherwise, an error number is returned to indicate the error.

**ERRORS**

The `pthread_mutex_lock()` and `pthread_mutex_trylock()` functions will fail if:

- **EINVAL** The `mutex` was created with the protocol attribute having the value `PTHREAD_PRIO_PROTECT` and the calling thread’s priority is higher than the mutex’s current priority ceiling.

The `pthread_mutex_trylock()` function will fail if:

- **EBUSY** The `mutex` could not be acquired because it was already locked.

The `pthread_mutex_lock()`, `pthread_mutex_trylock()` and `pthread_mutex_unlock()` functions may fail if:

- **EINVAL** The value specified by `mutex` does not refer to an initialized mutex object.

- **EAGAIN** The mutex could not be acquired because the maximum number of recursive locks for `mutex` has been exceeded.

The `pthread_mutex_lock()` function may fail if:

- **EDEADLK** The current thread already owns the mutex.

The `pthread_mutex_unlock()` function may fail if:

- **EPERM** The current thread does not own the mutex.

When a thread makes a call to `pthread_mutex_lock()` or `pthread_mutex_trylock()`, if the symbol `_POSIX_THREAD_PRIO_INHERIT` is defined and the mutex is initialized with the protocol attribute having the value `PTHREAD_PRIO_INHERIT` and the robustness attribute having the value `PTHREAD_MUTEX_ROBUST_NP` (see `pthread_mutexattr_getrobust_np(3THR)`), the `pthread_mutex_lock()` and `pthread_mutex_trylock()` functions will fail if:

- **EOWNERDEAD** The last owner of this mutex died while holding the mutex. This mutex is now owned by the caller. The caller must now attempt to make the state protected by the mutex consistent. If it is able to clean up the state, then it should call `pthread_mutex_consistent_np()` for the mutex and unlock the mutex. Subsequent
calls to pthread_mutex_lock() and
pthread_mutex_trylock() will behave normally,
as before. If the caller is not able to clean up the state,
 pthread_mutex_consistent_np() should not be
called for the mutex, but it should be unlocked.
Subsequent calls to pthread_mutex_lock() and
pthread_mutex_trylock() will fail to acquire the
mutex with the error value ENOTRECOVERABLE. If the
owner who acquired the lock with EOWNERDEAD dies,
the next owner will acquire the lock with EOWNERDEAD.

ENOTRECOVERABLE
The mutex trying to be acquired is protecting the state
that has been left irrecoverable by the mutex’s last
owner, who died while holding the lock. The mutex
has not been acquired. This condition can occur when
the lock was previously acquired with EOWNERDEAD,
and the owner was not able to clean up the state and
unlocked the mutex without making the mutex
consistent.

ENOMEM
The limit on the number of simultaneously held
mutexes has been exceeded.

ATTRIBUTES

 pthread_mutex_init(3THR), pthread_mutex_destroy(3THR),
 pthread_mutex_consistent_np(3THR),
 pthread_mutexattr_getrobust_np(3THR), attributes(5), standards(5)

NOTES
In the current implementation of threads, pthread_mutex_lock(),
 pthread_mutex_unlock(), mutex_lock(), mutex_unlock(),
 pthread_mutex_trylock(), and mutex_trylock() do not validate the mutex
type. Therefore, an uninitialized mutex or a mutex with an invalid type does not
return EINVAL. Interfaces for mutexes with an invalid type have unspecified behavior.

Uninitialized mutexes that are allocated locally may contain junk data. Such mutexes
need to be initialized using pthread_mutex_init() or mutex_init().
pthread_once(3THR)

NAME          pthread_once — initialize dynamic package

SYNOPSIS      cc -mt [ flag... ] file... -lpthread [ -lrt library... ]

#include <pthread.h>
pthread_once_t once_control = PTHREAD_ONCE_INIT;
int pthread_once(pthread_once_t *once_control, void (*init_routine, void));

DESCRIPTION    If any thread in a process with a once_control parameter makes a call to
                pthread_once(), the first call will summon the init_routine(), but subsequent
                calls will not. The once_control parameter determines whether the associated
                initialization routine has been called. The init_routine() is complete upon return
                of pthread_once().

                pthread_once() is not a cancellation point; however, if the function
                init_routine() is a cancellation point and is canceled, the effect on once_control is
                the same as if pthread_once() had never been called.

                The constant PTHREAD_ONCE_INIT is defined in the <pthread.h> header.

                If once_control has automatic storage duration or is not initialized by
                PTHREAD_ONCE_INIT, the behavior of pthread_once() is undefined.

RETURN VALUES  Upon successful completion, pthread_once() returns 0. Otherwise, an error
                number is returned to indicate the error.

ERRORS         EINVAL        once_control or init_routine is NULL.

ATTRIBUTES     See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>MT-Level</td>
<td>MT-Safe</td>
</tr>
</tbody>
</table>

SEE ALSO       attributes(5)

NOTES          Solaris threads do not offer this functionality.
The `pthread_rwlockattr_getpshared()` function obtains the value of the process-shared attribute from the initialised attributes object referenced by `attr`. The `pthread_rwlockattr_setpshared()` function is used to set the process-shared attribute in an initialised attributes object referenced by `attr`.

**RETURN VALUES**

If successful, the `pthread_rwlockattr_setpshared()` function returns 0. Otherwise, an error number is returned to indicate the error.

Upon successful completion, the `pthread_rwlockattr_getpshared()` returns 0 and stores the value of the process-shared attribute of `attr` into the object referenced by the `pshared` parameter. Otherwise an error number is returned to indicate the error.

**ERRORS**

The `pthread_rwlockattr_getpshared()` and `pthread_rwlockattr_setpshared()` functions will fail if:

- `EINVAL` The value specified by `attr` or `pshared` is invalid.

**NAME**

pthread_rwlockattr_init, pthread_rwlockattr_destroy – initialize or destroy read-write lock attributes object

**SYNOPSIS**

cc -mt [ flag... ] file... -lpthread [ -lrt library... ]

#include <pthread.h>

int pthread_rwlockattr_init(pthread_rwlockattr_t *attr);

int pthread_rwlockattr_destroy(pthread_rwlockattr_t *attr);

**DESCRIPTION**

The pthread_rwlockattr_init() function initializes a read-write lock attributes object *attr* with the default value for all of the attributes defined by the implementation.

Results are undefined if pthread_rwlockattr_init() is called specifying an already initialized read-write lock attributes object.

After a read-write lock attributes object has been used to initialize one or more read-write locks, any function affecting the attributes object (including destruction) does not affect any previously initialized read-write locks.

The pthread_rwlockattr_destroy() function destroys a read-write lock attributes object. The effect of subsequent use of the object is undefined until the object is re-initialized by another call to pthread_rwlockattr_init(). An implementation may cause pthread_rwlockattr_destroy() to set the object referenced by *attr* to an invalid value.

**RETURN VALUES**

If successful, the pthread_rwlockattr_init() and pthread_rwlockattr_destroy() functions return 0. Otherwise, an error number is returned to indicate the error.

**ERRORS**

The pthread_rwlockattr_init() function will fail if:

EINVAL

The value specified by *attr* is invalid.

NAME
pthread_rwlock_init, pthread_rwlock_destroy – initialize or destroy a read-write lock object
SYNOPSIS
cc -mt [ flag... ] file... -lpthread [ -lrt library... ]
#include <pthread.h>

int pthread_rwlock_init(pthread_rwlock_t *rwlock, const
pthread_rwlockattr_t *attr);

int pthread_rwlock_destroy(pthread_rwlock_t *rwlock);
pthread_rwlock_t rwlock=PTHREAD_RWLOCK_INITIALIZER;

DESCRIPTION
The pthread_rwlock_init() function initializes the read-write lock referenced by
rwlock with the attributes referenced by attr. If attr is NULL, the default read-write lock
attributes are used; the effect is the same as passing the address of a default read-write
lock attributes object. Once initialized, the lock can be used any number of times
without being re-initialized. Upon successful initialization, the state of the read-write
lock becomes initialized and unlocked. Results are undefined if
pthread_rwlock_init() is called specifying an already initialized read-write lock.
Results are undefined if a read-write lock is used without
first being initialized.

If the pthread_rwlock_init() function fails, rwlock is not initialized and the
contents of rwlock are undefined.

The pthread_rwlock_destroy() function destroys the read-write lock object
referenced by rwlock and releases any resources used by the lock. The effect of
subsequent use of the lock is undefined until the lock is re-initialized by another call to
pthread_rwlock_init(). An implementation may cause
pthread_rwlock_destroy() to set the object referenced by rwlock to an invalid
value. Results are undefined if pthread_rwlock_destroy() is called when any
thread holds rwlock. Attempting to destroy an uninitialized read-write lock results in
undefined behaviour. A destroyed read-write lock object can be re-initialized using
pthread_rwlock_init(); the results of otherwise referencing the read-write lock
object after it has been destroyed are undefined.

In cases where default read-write lock attributes are appropriate, the macro
PTHREAD_RWLOCK_INITIALIZER can be used to initialize read-write locks that are
statically allocated. The effect is equivalent to dynamic initialization by a call to
pthread_rwlock_init() with the parameter attr specified as NULL, except that no
error checks are performed.

RETURN VALUES
If successful, the pthread_rwlock_init() and pthread_rwlock_destroy() functions return 0. Otherwise, an error number is returned to indicate the error.

ERRORS
The pthread_rwlock_init() and pthread_rwlock_destroy() functions will fail if:

EINVAL The value specified by attr is invalid.
EINVAL The value specified by rwlock is invalid.
pthread_rwlock_init(3THR)

SEE ALSO

pthread_rwlock_rdlock(3THR), pthread_rwlock_unlock(3THR),
pthread_rwlock_wrlock(3THR), pthread_rwlockattr_init(3THR),
attributes(5)
The `pthread_rwlock_rdlock()` function applies a read lock to the read-write lock referenced by `rwlock`. The calling thread acquires the read lock if a writer does not hold the lock and there are no writers blocked on the lock. It is unspecified whether the calling thread acquires the lock when a writer does not hold the lock and there are writers waiting for the lock. If a writer holds the lock, the calling thread will not acquire the read lock. If the read lock is not acquired, the calling thread blocks (that is, it does not return from the `pthread_rwlock_rdlock()` call) until it can acquire the lock. Results are undefined if the calling thread holds a write lock on `rwlock` at the time the call is made.

Implementations are allowed to favor writers over readers to avoid writer starvation. The current implementation favors writers over readers.

A thread may hold multiple concurrent read locks on `rwlock` (that is, successfully call the `pthread_rwlock_rdlock()` function n times). If so, the thread must perform matching unlocks (that is, it must call the `pthread_rwlock_unlock()` function n times).

The function `pthread_rwlock_tryrdlock()` applies a read lock as in the `pthread_rwlock_rdlock()` function with the exception that the function fails if any thread holds a write lock on `rwlock` or there are writers blocked on `rwlock`.

Results are undefined if any of these functions are called with an uninitialized read-write lock.

If a signal is delivered to a thread waiting for a read-write lock for reading, upon return from the signal handler the thread resumes waiting for the read-write lock for reading as if it was not interrupted.

**RETURN VALUES**

If successful, the `pthread_rwlock_rdlock()` function returns 0. Otherwise, an error number is returned to indicate the error.

The function `pthread_rwlock_tryrdlock()` returns 0 if the lock for reading on the read-write lock object referenced by `rwlock` is acquired. Otherwise an error number is returned to indicate the error.

**ERRORS**

The `pthread_rwlock_tryrdlock()` function will fail if:

**EBUSY**

The read-write lock could not be acquired for reading because a writer holds the lock or was blocked on it.

**NAME**

pthread_rwlock_unlock – unlock a read-write lock object

**SYNOPSIS**

```c
cc -mt [...flags...] file... -lpthread [... -lrt library...] 
#include <pthread.h>

int pthread_rwlock_unlock(pthread_rwlock_t *rwlock);
```

**DESCRIPTION**

The pthread_rwlock_unlock() function is called to release a lock held on the read-write lock object referenced by `rwlock`. Results are undefined if the read-write lock `rwlock` is not held by the calling thread.

If this function is called to release a read lock from the read-write lock object and there are other read locks currently held on this read-write lock object, the read-write lock object remains in the read locked state. If this function releases the calling thread’s last read lock on this read-write lock object, then the calling thread is no longer one of the owners of the object. If this function releases the last read lock for this read-write lock object, the read-write lock object will be put in the unlocked state with no owners.

If this function is called to release a write lock for this read-write lock object, the read-write lock object will be put in the unlocked state with no owners.

If the call to the pthread_rwlock_unlock() function results in the read-write lock object becoming unlocked and there are multiple threads waiting to acquire the read-write lock object for writing, the scheduling policy is used to determine which thread acquires the read-write lock object for writing. If there are multiple threads waiting to acquire the read-write lock object for reading, the scheduling policy is used to determine the order in which the waiting threads acquire the read-write lock object for reading. If there are multiple threads blocked on `rwlock` for both read locks and write locks, it is unspecified whether the readers acquire the lock first or whether a writer acquires the lock first.

Results are undefined if any of these functions are called with an uninitialized read-write lock.

**RETURN VALUES**

If successful, the pthread_rwlock_unlock() function returns 0. Otherwise, an error number is returned to indicate the error.

### DESCRIPTION

`pthread_setcancelstate()` atomically sets the calling thread’s cancellation state to the specified `state` and if `oldstate` is not NULL, stores the previous cancellation state in `oldstate`.

The `state` can be either of the following:

- **PTHREAD_CANCEL_ENABLE**: This is the default. When cancellation is deferred (deferred cancellation is also the default), cancellation occurs when the target thread reaches a cancellation point and a cancel is pending. When cancellation is asynchronous, receipt of a `pthread_cancel(3THR)` call causes immediate cancellation.

- **PTHREAD_CANCEL_DISABLE**: When cancellation is deferred, all cancellation requests to the target thread are held pending. When cancellation is asynchronous, all cancellation requests to the target thread are held pending; as soon as cancellation is re-enabled, pending cancellations are executed immediately.

See `cancellation(3THR)` for the definition of a cancellation point and a discussion of cancellation concepts. See `pthread_setcanceltype(3THR)` for explanations of deferred and asynchronous cancellation.

`pthread_setcancelstate()` is a cancellation point when it is called with `PTHREAD_CANCEL_ENABLE` and the cancellation type is `PTHREAD_CANCELASYNCHRONOUS`.

### RETURN VALUES

Upon successful completion, `pthread_setcancelstate()`, returns 0. Otherwise, an error number is returned to indicate the error.

### ERRORS

The `pthread_setcancelstate()` function will fail if:

- **EINVAL**: The specified `state` is not `PTHREAD_CANCEL_ENABLE` or `PTHREAD_CANCEL_DISABLE`.

NAME

pthread_setcanceltype – set the cancellation type of a thread

SYNOPSIS

cc -mt [ flag... ] file... -lpthread [ -lrt library... ]

#include <pthread.h>

int pthread_setcanceltype(int type, int *oldtype);

DESCRIPTION

pthread_setcanceltype() atomically sets the calling thread’s cancellation type to the specified type and, if oldtype is not NULL, stores the previous cancellation type in oldtype. The type can be either of the following:

PTHREAD_CANCEL_DEFERRED

This is the default. When cancellation is enabled (enabled cancellation is also the default), cancellation occurs when the target thread reaches a cancellation point and a cancel is pending. When cancellation is disabled, all cancellation requests to the target thread are held pending.

PTHREAD_CANCELASYNCHRONOUS

When cancellation is enabled, receipt of a pthread_cancel(3THR) call causes immediate cancellation. When cancellation is disabled, all cancellation requests to the target thread are held pending; as soon as cancellation is re-enabled, pending cancellations are executed immediately.

See cancellation(3THR) for the definition of a cancellation point and a discussion of cancellation concepts. See pthread_setcancelstate(3THR) for explanations of enabling and disabling cancellation.

pthread_setcanceltype() is a cancellation point if type is called with PTHREAD_CANCELASYNCHRONOUS and the cancellation state is PTHREAD_CANCELENABLE.

RETURN VALUES

Upon successful completion, the pthread_setcanceltype() function returns 0. Otherwise, an error number is returned to indicate the error.

ERRORS

The pthread_setcanceltype() function will fail if:

EINVAL

The specified type is not PTHREAD_CANCEL_DEFERRED or PTHREAD_CANCELASYNCHRONOUS.

attributes(5)
The `pthread_sigmask()` function changes or examines a calling thread’s signal mask. Each thread has its own signal mask. A new thread inherits the calling thread’s signal mask and priority; however, pending signals are not inherited. Signals pending for a new thread will be empty.

If the value of the argument `set` is not `NULL`, `set` points to a set of signals that can modify the currently blocked set. If the value of `set` is `NULL`, the value of `how` is insignificant and the thread’s signal mask is unmodified; thus, `pthread_sigmask()` can be used to inquire about the currently blocked signals.

The value of the argument `how` specifies the method in which the set is changed and takes one of the following values:

- **SIG_BLOCK** `set` corresponds to a set of signals to block. They are added to the current signal mask.
- **SIG_UNBLOCK** `set` corresponds to a set of signals to unblock. These signals are deleted from the current signal mask.
- **SIG_SETMASK** `set` corresponds to the new signal mask. The current signal mask is replaced by `set`.

If the value of `oset` is not `NULL`, it points to the location where the previous signal mask is stored.

Upon successful completion, the `pthread_sigmask()` function returns 0. Otherwise, it returns a non-zero value.

The `pthread_sigmask()` function will fail if:

- **EINVAL** The value of `how` is not defined and `oset` is `NULL`.

**EXAMPLE 1** The following example shows how to create a default thread that can serve as a signal catcher/handler with its own signal mask. `new` will have a different value from the creator’s signal mask.

As POSIX threads and Solaris threads are fully compatible even within the same process, this example uses `pthread_create(3THR)` if you execute `a.out 0`, or `thr_create(3THR)` if you execute `a.out 1`.

In this example:
- `sigemptyset(3C)` initializes a null signal set, `new`. `sigaddset(3C)` packs the signal, `SIGINT`, into that new set.
The following example shows how to create a default thread that can serve as a signal catcher/handler with its own signal mask. new will have a different value from the creator’s signal mask. (Continued)

- Either pthread_sigmask() or thr_sigsetmask() is used to mask the signal, SIGINT (CTRL-C), from the calling thread, which is main(). The signal is masked to guarantee that only the new thread will receive this signal.
- pthread_create() or thr_create() creates the signal-handling thread.
- Using pthread_join(3THR) or thr_join(3THR), main() then waits for the termination of that signal-handling thread, whose ID number is user_threadID; after which, main() will sleep(3C) for 2 seconds, and then the program terminates.
- The signal-handling thread, handler:
  - Assigns the handler interrupt() to handle the signal SIGINT, by the call to sigaction(2).
  - Resets its own signal set to *not block* the signal, SIGINT.
  - Sleeps for 8 seconds to allow time for the user to deliver the signal, SIGINT, by pressing the CTRL-C.

```c
/* cc thisfile.c -lthread -lpthread */
#define _REENTRANT /* basic first 3-lines for threads */
#include <pthread.h>
#include <thread.h>
thread_t user_threadID;
sigset_t new;

void *handler( ), interrupt( );

main( int argc, char *argv[] ) {
    test_argv(argv[1]);
    sigemptyset(&new);
    sigaddset(&new, SIGINT);
    switch(*argv[1]) {
    case '0': /* POSIX */
        pthread_sigmask(SIG_BLOCK, &new, NULL);
        pthread_create(&user_threadID, NULL, handler, argv[1]);
        pthread_join(user_threadID, NULL);
        break;
    case '1': /* Solaris */
        thr_sigsetmask(SIG_BLOCK, &new, NULL);
        thr_create(NULL, 0, handler, argv[1], 0, &user_threadID);
        thr_join(user_threadID, NULL, NULL);
        break;
    } /* switch */
    printf("thread handler, # %d, has exited\n", user_threadID);
    sleep(2);
    printf("main thread, # %d is done\n", thr_self( ));
} /* end main */
```
EXAMPLE 1 The following example shows how to create a default thread that can serve as a signal catcher/handler with its own signal mask. new will have a different value from the creator’s signal mask.  

```c
struct sigaction act;
void *
handler(char argv1[])
{
    act.sa_handler = interrupt;
    sigaction(SIGINT, &act, NULL);
    switch(*argv1) {
        case '0': /* POSIX */
            pthread_sigmask(SIG_UNBLOCK, &new, NULL);
            break;
        case '1': /* Solaris */
            thrSigsetmask(SIG_UNBLOCK, &new, NULL);
            break;
    }
    printf("\n Press CTRL-C to deliver SIGINT signal to the process\n");
    sleep(8); /* give user time to hit CTRL-C */
}

void
interrupt(int sig)
{
    printf("thread %d caught signal %d\n", thr_self(), sig);
}

void test_argv(char argv1[])
{
    if(argv1 == NULL) {
        printf("use 0 as arg1 to use thr_create( );

 or use 1 as arg1 to use pthread_create( )\n");
        exit(NULL);
    }
}
```

EXAMPLE 2 Rewriting the subroutines in the previous example.

In the last example, the handler thread served as a signal-handler while also taking care of activity of its own (in this case, sleeping, although it could have been some other activity). A thread could be completely dedicated to signal-handling simply by waiting for the delivery of a selected signal by blocking with sigwait(2). The two subroutines in the previous example, handler() and interrupt(), could have been replaced with the following routine:

```c
void *
handler()
{
    int signal;
    printf("thread %d is waiting for you to press the CTRL-C keys\n", thr_self());
    sigwait(&new, &signal);
    printf("thread %d has received the signal %d \n", thr_self(), signal);
```
EXAMPLE 2 Rewriting the subroutines in the previous example. (Continued)

} /* \* pthread_create() and thr_create() would use NULL instead of argv[1] for the arg passed to handler() */

In this routine, one thread is dedicated to catching and handling the signal specified by the set new, which allows main() and all of its other sub-threads, created after pthread_sigmask() or thr_sigsetmask() masked that signal, to continue uninterrupted. Any use of sigwait(2) should be such that all threads block the signals passed to sigwait(2) at all times. Only the thread that calls sigwait() will get the signals. The call to sigwait(2) takes two arguments.

For this type of background dedicated signal-handling routine, you may wish to use a Solaris daemon thread by passing the argument, THR_DAEMON, to thr_create(3THR).

NOTES

It is not possible to block signals that cannot be ignored (see sigaction(2)). If using the threads library, it is not possible to block or unblock the signals SIGWAITING, SIGLWP, or SIGCANCEL. This restriction is quietly enforced by the threads library.

Using sigwait(2) in a dedicated thread allows asynchronously generated signals to be managed synchronously; however, sigwait(2) should never be used to manage synchronously generated signals.

Synchronously generated signals are exceptions that are generated by a thread and are directed at the thread causing the exception. Since sigwait() blocks waiting for signals, the blocking thread cannot receive a synchronously generated signal.

If sigprocmask(2) is used in a multi-threaded program, it will be the same as if pthread_sigmask() has been called. POSIX leaves the semantics of the call to sigprocmask(2) unspecified in a multi-threaded process, so programs that care about POSIX portability should not depend on this semantic.

If a signal is delivered while a thread is waiting on a condition variable, the cond_wait(3THR) function will be interrupted and the handler will be executed. The state of the lock protecting the condition variable is undefined while the thread is executing the signal handler.
Although `pthread_sigmask()` is Async-Signal-Safe with respect to the Solaris environment, this safeness is not guaranteed to be portable to other POSIX domains.

Signals that are generated synchronously should not be masked. If such a signal is blocked and delivered, the receiving process is killed.
The `pthread_testcancel()` function forces testing for cancellation. This is useful when you need to execute code that runs for long periods without encountering cancellation points; such as a library routine that executes long-running computations without cancellation points. This type of code can block cancellation for unacceptable long periods of time. One strategy for avoiding blocking cancellation for long periods, is to insert calls to `pthread_testcancel()` in the long-running computation code and to setup a cancellation handler in the library code, if required.

The `pthread_testcancel()` function returns a void.

The `pthread_testcancel()` function does not return errors.

See `cancellation(3THR)` for an example of using `pthread_testcancel()` to force testing for cancellation and a discussion of cancellation concepts.

See `attributes(5)` for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>MT-Level</td>
<td>MT-Safe</td>
</tr>
</tbody>
</table>

It is possible to kill a thread when it is holding a resource, such as lock or allocated memory. If that thread has not setup a cancellation cleanup handler to release the held resource, the application is "cancel-unsafe". See `attributes(5)` for a discussion of Cancel-Safety, Deferred-Cancel-Safety, and Asynchronous-Cancel-Safety.
Many threads can have simultaneous read-only access to data, while only one thread can have write access at any given time. Multiple read access with single write access is controlled by locks, which are generally used to protect data that is frequently searched.

Readers/writer locks can synchronize threads in this process and other processes if they are allocated in writable memory and shared among cooperating processes (see `mmap(2)`), and are initialized for this purpose.

Additionally, readers/writer locks must be initialized prior to use. `rwlock_init()` The readers/writer lock pointed to by `rwlp` is initialized by `rwlock_init()`. A readers/writer lock is capable of having several types of behavior, which is specified by `type`. `arg` is currently not used, although a future type may define new behavior parameters by way of `arg`.

type may be one of the following:

**USYNC_PROCESS**

The readers/writer lock can synchronize threads in this process and other processes. The readers/writer lock should be initialized by only one process. `arg` is ignored. A readers/writer lock initialized with this type, must be allocated in memory shared between processes, i.e. either in Sys V shared memory (see `shmop(2)`) or in memory mapped to a file (see `mmap(2)`). It is illegal to initialize the object this way and to not allocate it in such shared memory.

**USYNC_THREAD**

The readers/writer lock can synchronize threads in this process, only. `arg` is ignored.
Additionally, readers/writer locks can be initialized by allocation in zeroed memory. A type of USYNC_THREAD is assumed in this case. Multiple threads must not simultaneously initialize the same readers/writer lock. And a readers/writer lock must not be re-initialized while in use by other threads.

The following are default readers/writer lock initialization (intra-process):

```c
rwlock_t rwlp;
rwlock_init(&rwlp, NULL, NULL);
OR
rwlock_init(&rwlp, USYNC_THREAD, NULL);
OR
rwlock_t rwlp = DEFAULT_RWLOCK;
```

The following is a customized readers/writer lock initialization (inter-process):

```c
rwlock_init(&rwlp, USYNC_PROCESS, NULL);
```

Any state associated with the readers/writer lock pointed to by `rwlp` are destroyed by `rwlock_destroy()` and the readers/writer lock storage space is not released.

`rw_rdlock()` gets a read lock on the readers/writer lock pointed to by `rwlp`. If the readers/writer lock is currently locked for writing, the calling thread blocks until the write lock is freed. Multiple threads may simultaneously hold a read lock on a readers/writer lock.

`rw_tryrdlock()` tries to get a read lock on the readers/writer lock pointed to by `rwlp`. If the readers/writer lock is locked for writing, it returns an error; otherwise, the read lock is acquired.

`rw_wrlock()` gets a write lock on the readers/writer lock pointed to by `rwlp`. If the readers/writer lock is currently locked for reading or writing, the calling thread blocks until all the read and write locks are freed. At any given time, only one thread may have a write lock on a readers/writer lock.

`rw_trywrlock()` tries to get a write lock on the readers/writer lock pointed to by `rwlp`. If the readers/writer lock is currently locked for reading or writing, it returns an error.

`rw_unlock()` unlocks a readers/writer lock pointed to by `rwlp`, if the readers/writer lock is locked and the calling thread holds the lock for either reading or writing. One of the other threads that is waiting for the readers/writer lock to be freed will be unblocked, provided there is other waiting threads. If the calling thread does not hold the lock for either reading or writing, no error status is returned, and the program’s behavior is unknown.

**RETURN VALUES**

If successful, these functions return 0. Otherwise, a non-zero value is returned to indicate the error.

**ERRORS**

The `rwlock_init()` function will fail if:

- EINVAL type is invalid.
The `rw_tryrdlock()` or `rw_trywrlock()` functions will fail if:

- **EBUSY**: The reader or writer lock pointed to by `rwlp` was already locked.

These functions may fail if:

- **EFAULT**: `rwlp` or `arg` points to an illegal address.

### NOTES

These interfaces also available by way of:

```c
#include <thread.h>
```

If multiple threads are waiting for a readers/writer lock, the acquisition order is random by default. However, some implementations may bias acquisition order to avoid depriving writers. The current implementation favors writers over readers.
These functions provide limited control over the scheduling of a lightweight process (LWP). They allow a running LWP to give a hint to the kernel that preemptions of that LWP should be avoided. The most likely use for these functions is to block preemption while holding a spinlock. Improper use of this facility, including attempts to block preemption for sustained periods of time, may result in reduced performance.

The `schedctl_init()` function initializes preemption control for the calling LWP and returns a pointer used to refer to the data. If `schedctl_init()` is called more than once by the same LWP, the most recently returned pointer is the only valid one.

The `schedctl_lookup()` function returns the currently allocated preemption control data associated with the calling LWP that was previously returned by `schedctl_init()`. This can be useful in programs where it is difficult to maintain local state for each LWP.

The `schedctl_exit()` function removes the preemption control data associated with the calling LWP.

The `schedctl_start()` macro gives a hint to the kernel scheduler that preemption should be avoided on the current LWP. The pointer passed to the macro must be the same as the pointer returned by the call to `schedctl_init()` by the current LWP. The behavior of the program when other values are passed is undefined.

The `schedctl_stop()` macro removes the hint that was set by `schedctl_start()`. As with `schedctl_start()`, the pointer passed to the macro must be the same as the pointer returned by the call to `schedctl_init()` by the current LWP.

The `schedctl_start()` and `schedctl_stop()` macros are intended to be used to bracket short critical sections, such as the time spent holding a spinlock. Other uses, including the failure to call `schedctl_stop()` soon after calling `schedctl_start()`, might result in poor performance.

The `schedctl_init()` function returns a pointer to a `schedctl_t` structure if the initialization was successful, or `NULL` otherwise. The `schedctl_lookup()` function returns a pointer to a `schedctl_t` structure if the data for that LWP was found, or `NULL` otherwise.
No errors are returned.

**SEE ALSO**  
`priocntl(1)`, `exec(2)`, `fork(2)`, `priocntl(2)`, `thr_create(3THR)`

**NOTES**  
Preemption control is intended for use by LWPs belonging to the time-sharing (TS), interactive (IA), fair-share (FSS), and fixed-priority (FX) scheduling classes. If used by LWPs in other scheduling classes, such as real-time (RT), no errors will be returned but `schedctl_start()` and `schedctl_stop()` will not have any effect.

Use of preemption control by unbound threads in multithreaded applications (see `thr_create(3THR)`) is not supported and will result in undefined behavior.

The data used for preemption control are not copied in the child of a `fork(2)`. Thus, if a process containing LWPs using preemption control calls `fork` and the child does not immediately call `exec(2)`, each LWP in the child must call `schedctl_init()` again prior to any future uses of `schedctl_start()` and `schedctl_stop()`. Failure to do so will result in undefined behavior.
sched_getparam(3RT)

NAME sched_getparam – get scheduling parameters

SYNOPSIS

    cc [ flag... ] file... -lrt [ library... ]
    #include <sched.h>

    int sched_getparam(pid_t pid, struct sched_param *param);

DESCRIPTION

The sched_getparam() function returns the scheduling parameters of a process
specified by pid in the sched_param structure pointed to by param.

If a process specified by pid exists and if the calling process has permission, the
scheduling parameters for the process whose process ID is equal to pid will be
returned.

If pid is 0, the scheduling parameters for the calling process will be returned. The
behavior of the sched_getparam() function is unspecified if the value of pid is
negative.

RETURN VALUES

Upon successful completion, the sched_getparam() function returns 0. If the call to
sched_getparam() is unsuccessful, the function returns -1 and sets errno to
indicate the error.

ERRORS

The sched_getparam() function will fail if:

- ENOSYS The sched_getparam() function is not supported by the system.
- EPERM The requesting process does not have permission to obtain the
  scheduling parameters of the specified process.
- ESRCH No process can be found corresponding to that specified by pid.

NOTES

Solaris 2.6 was the first release to support libposix4/librt. Prior to this release,
this function always returned -1 and set errno to ENOSYS.
The `sched_get_priority_max()` and `sched_get_priority_min()` functions return the appropriate maximum or minimum, respectfully, for the scheduling policy specified by `policy`.

The value of `policy` is one of the scheduling policy values defined in `<sched.h>`.

If successful, the `sched_get_priority_max()` and `sched_get_priority_min()` functions return the appropriate maximum or minimum values, respectively. If unsuccessful, they return −1 and set `errno` to indicate the error.

The `sched_get_priority_max()` and `sched_get_priority_min()` functions will fail if:

- **EINVAL** The value of the `policy` parameter does not represent a defined scheduling policy.
- **ENOSYS** The `sched_get_priority_max()`, `sched_get_priority_min()` and `sched_rr_get_interval(3RT)` functions are not supported by the system.

Solaris 2.6 was the first release to support `libposix4/librt`. Prior to this release, this function always returned −1 and set `errno` to ENOSYS.
sched_getscheduler(3RT)

NAME sched_getscheduler – get scheduling policy

SYNOPSIS

cc [ flag... ] file... -lrt [ library... ]
#include <sched.h>

int sched_getscheduler(pid_t pid);

DESCRIPTION

The sched_getscheduler() function returns the scheduling policy of the process
specified by pid. If the value of pid is negative, the behavior of the
sched_getscheduler() function is unspecified.

The values that can be returned by sched_getscheduler() are defined in the
header <sched.h> and described on the sched_setscheduler(3RT) manual page.

If a process specified by pid exists and if the calling process has permission, the
scheduling policy will be returned for the process whose process ID is equal to pid.

If pid is 0, the scheduling policy will be returned for the calling process.

RETURN VALUES

Upon successful completion, the sched_getscheduler() function returns the
scheduling policy of the specified process. If unsuccessful, the function returns −1 and
sets errno to indicate the error.

ERRORS

The sched_getscheduler() function will fail if:

ENOSYS The sched_getscheduler() function is not supported by the
system.

EPERM The requesting process does not have permission to determine the
scheduling policy of the specified process.

ESRCH No process can be found corresponding to that specified by pid.

ATTRIBUTES

librt(3LIB), sched(3HEAD), sched_getparam(3RT), sched_setparam(3RT),
sched_setscheduler(3RT), attributes(5)

NOTES

Solaris 2.6 was the first release to support libposix4/librt. Prior to this release,
this function always returned −1 and set errno to ENOSYS.
The `sched_rr_get_interval()` function updates the `timespec` structure referenced by the `interval` argument to contain the current execution time limit (that is, time quantum) for the process specified by `pid`. If `pid` is 0, the current execution time limit for the calling process will be returned.

### Errors
The `sched_rr_get_interval()` function will fail if:

- **ENOSYS** The `sched_get_priority_max(3RT)`, `sched_get_priority_min(3RT)`, and `sched_rr_get_interval()` functions are not supported by the system.
- **ESRCH** No process can be found corresponding to that specified by `pid`.

### NOTES
Solaris 2.6 was the first release to support `libposix4/librt`. Prior to this release, this function always returned −1 and set `errno` to ENOSYS.
The `sched_setparam()` function sets the scheduling parameters of the process specified by `pid` to the values specified by the `sched_param` structure pointed to by `param`. The value of the `sched_priority` member in the `sched_param` structure is any integer within the inclusive priority range for the current scheduling policy of the process specified by `pid`. Higher numerical values for the priority represent higher priorities. If the value of `pid` is negative, the behavior of the `sched_setparam()` function is unspecified.

If a process specified by `pid` exists and if the calling process has permission, the scheduling parameters will be set for the process whose process ID is equal to `pid`. The real or effective user ID of the calling process must match the real or saved (from `exec(2)`) user ID of the target process unless the effective user ID of the calling process is 0. See `intro(2)`.

If `pid` is zero, the scheduling parameters will be set for the calling process.

The target process, whether it is running or not running, resumes execution after all other runnable processes of equal or greater priority have been scheduled to run.

If the priority of the process specified by the `pid` argument is set higher than that of the lowest priority running process and if the specified process is ready to run, the process specified by the `pid` argument preempts a lowest priority running process. Similarly, if the process calling `sched_setparam()` sets its own priority lower than that of one or more other non-empty process lists, then the process that is the head of the highest priority list also preempts the calling process. Thus, in either case, the originating process might not receive notification of the completion of the requested priority change until the higher priority process has executed.

If the current scheduling policy for the process specified by `pid` is not `SCHED_FIFO` or `SCHED_RR`, including `SCHED_OTHER`, the result is equal to `priocntl(P_PID, pid, PC_SETPARMS, &pcparam)`, where `pcparam` is an image of `*param`.

The effect of this function on individual threads is dependent on the scheduling contention scope of the threads:

- For threads with system scheduling contention scope, these functions have no effect on their scheduling.
- For threads with process scheduling contention scope, the threads' scheduling parameters will not be affected. However, the scheduling of these threads with respect to threads in other processes may be dependent on the scheduling parameters of their process, which are governed using these functions.
If an implementation supports a two-level scheduling model in which library threads are multiplexed on top of several kernel scheduled entities, then the underlying kernel scheduled entities for the system contention scope threads will not be affected by these functions.

The underlying kernel scheduled entities for the process contention scope threads will have their scheduling parameters changed to the value specified in `param`. Kernel scheduled entities for use by process contention scope threads that are created after this call completes inherit their scheduling policy and associated scheduling parameters from the process.

This function is not atomic with respect to other threads in the process. Threads are allowed to continue to execute while this function call is in the process of changing the scheduling policy for the underlying kernel scheduled entities used by the process contention scope threads.

If successful, the `sched_setparam()` function returns 0.

If the call to `sched_setparam()` is unsuccessful, the priority remains unchanged, and the function returns −1 and sets `errno` to indicate the error.

The `sched_setparam()` function will fail if:

- **EINVAL** One or more of the requested scheduling parameters is outside the range defined for the scheduling policy of the specified `pid`.
- **ENOSYS** The `sched_setparam()` function is not supported by the system.
- **EPERM** The requesting process does not have permission to set the scheduling parameters for the specified process, or does not have the appropriate privilege to invoke `sched_setparam()`.
- **ESRCH** No process can be found corresponding to that specified by `pid`.

</tr>
</tbody>
</table>

**SEE ALSO**

intro(2), exec(2), librt(3LIB), sched(3HEAD), sched_getparam(3RT), sched_getscheduler(3RT), sched_setscheduler(3RT), attributes(5)

**NOTES**

Solaris 2.6 was the first release to support libposix4/librt. Prior to this release, this function always returned −1 and set `errno` to ENOSYS.
The sched_setscheduler() function sets the scheduling policy and scheduling parameters of the process specified by pid to policy and the parameters specified in the sched_param structure pointed to by param, respectively. The value of the sched_priority member in the sched_param structure is any integer within the inclusive priority range for the scheduling policy specified by policy. The sched_setscheduler() function ignores the other members of the sched_param structure. If the value of pid is negative, the behavior of the sched_setscheduler() function is unspecified.

The possible values for the policy parameter are defined in the header <sched.h> (see sched(3HEAD)).

If a process specified by pid exists and if the calling process has permission, the scheduling policy and scheduling parameters are set for the process whose process ID is equal to pid. The real or effective user ID of the calling process must match the real or saved (from exec(2)) user ID of the target process unless the effective user ID of the calling process is 0. See intro(2).

If pid is 0, the scheduling policy and scheduling parameters are set for the calling process.

To change the policy of any process to either of the real time policies SCHED_FIFO or SCHED_RR, the calling process must either have the SCHED_FIFO or SCHED_RR policy or have an effective user ID of 0.

The sched_setscheduler() function is considered successful if it succeeds in setting the scheduling policy and scheduling parameters of the process specified by pid to the values specified by policy and the structure pointed to by param, respectively.

The effect of this function on individual threads is dependent on the scheduling contention scope of the threads:

- For threads with system scheduling contention scope, these functions have no effect on their scheduling.
- For threads with process scheduling contention scope, the threads’ scheduling policy and associated parameters will not be affected. However, the scheduling of these threads with respect to threads in other processes may be dependent on the scheduling parameters of their process, which are governed using these functions.

The system supports a two-level scheduling model in which library threads are multiplexed on top of several kernel scheduled entities. The underlying kernel scheduled entities for the system contention scope threads will not be affected by these functions.
The underlying kernel scheduled entities for the process contention scope threads will have their scheduling policy and associated scheduling parameters changed to the values specified in policy and param, respectively. Kernel scheduled entities for use by process contention scope threads that are created after this call completes inherit their scheduling policy and associated scheduling parameters from the process.

This function is not atomic with respect to other threads in the process. Threads are allowed to continue to execute while this function call is in the process of changing the scheduling policy and associated scheduling parameters for the underlying kernel scheduled entities used by the process contention scope threads.

RETURN VALUES
Upon successful completion, the function returns the former scheduling policy of the specified process. If the sched_setscheduler() function fails to complete successfully, the policy and scheduling parameters remain unchanged, and the function returns −1 and sets errno to indicate the error.

ERRORS
The sched_setscheduler() function will fail if:

EINVAL The value of policy is invalid, or one or more of the parameters contained in param is outside the valid range for the specified scheduling policy.
ENOSYS The sched_setscheduler() function is not supported by the system.
EPERM The requesting process does not have permission to set either or both of the scheduling parameters or the scheduling policy of the specified process.
ESRCH No process can be found corresponding to that specified by pid.

NOTES
Solaris 2.6 was the first release to support libposix4/librt. Prior to this release, this function always returned −1 and set errno to ENOSYS.
The `sched_yield()` function forces the running thread to relinquish the processor until the process again becomes the head of its process list. It takes no arguments.

If successful, `sched_yield()` returns 0, otherwise, it returns −1, and sets `errno` to indicate the error condition.

No errors are defined.

NAME
semaphore, sema_init, sema_destroy, sema_wait, sema_trywait, sema_post – semaphores

SYNOPSIS
cc [ flag... ] file... -lthread -lc [ library... ]
#include <synch.h>

int sema_init(sema_t *sp, unsigned int count, int type, void * arg);
int sema_destroy(sema_t *sp);
int sema_wait(sema_t *sp);
int sema_trywait(sema_t *sp);
int sema_post(sema_t *sp);

DESCRIPTION
A semaphore is a non-negative integer count and is generally used to coordinate access to resources. The initial semaphore count is set to the number of free resources, then threads slowly increment and decrement the count as resources are added and removed. If the semaphore count drops to 0, which means no available resources, threads attempting to decrement the semaphore will block until the count is greater than 0.

Semaphores can synchronize threads in this process and other processes if they are allocated in writable memory and shared among the cooperating processes (see mmap(2)), and have been initialized for this purpose.

Semaphores must be initialized before use; semaphores pointed to by sp to count are initialized by sema_init(). The type argument can assign several different types of behavior to a semaphore. No current type uses arg, although it may be used in the future.

The type argument may be one of the following:

USYNC_PROCESS
The semaphore can synchronize threads in this process and other processes. Initializing the semaphore should be done by only one process. A semaphore initialized with this type must be allocated in memory shared between processes, either in Sys V shared memory (see shmop(2)), or in memory mapped to a file (see mmap(2)). It is illegal to initialize the object this way and not allocate it in such shared memory. arg is ignored.

USYNC_THREAD
The semaphore can synchronize threads only in this process. The arg argument is ignored. USYNC_THREAD does not support multiple mappings to the same logical synch object. If you need to mmap() a synch object to different locations within the same address space, then the synch object should be initialized as a shared object USYNC_PROCESS for Solaris threads and PTHREAD_PROCESS_PRIVATE for POSIX threads.
A semaphore must not be simultaneously initialized by multiple threads, nor re-initialized while in use by other threads.

Default semaphore initialization (intra-process):

```c
sema_t sp;
int count = 1;
sema_init(&sp, count, NULL, NULL);
```
or

```c
sema_init(&sp, count, USYNC_THREAD, NULL);
```

Customized semaphore initialization (inter-process):

```c
sema_t sp;
int count = 1;
sema_init(&sp, count, USYNC_PROCESS, NULL);
```

The `sema_destroy()` function destroys any state related to the semaphore pointed to by `sp`. The semaphore storage space is not released.

The `sema_wait()` function blocks the calling thread until the semaphore count pointed to by `sp` is greater than 0, and then it atomically decrements the count.

The `sema_trywait()` function atomically decrements the semaphore count pointed to by `sp`, if the count is greater than 0; otherwise, it returns an error.

The `sema_post()` function atomically increments the semaphore count pointed to by `sp`. If there are any threads blocked on the semaphore, one will be unblocked.

The semaphore functionality described on this man page is for the Solaris threads implementation. For the POSIX-compliant semaphore interface documentation, see `sem_open(3RT)`, `sem_init(3RT)`, `sem_wait(3RT)`, `sem_post(3RT)`, `sem_getvalue(3RT)`, `sem_unlink(3RT)`, `sem_close(3RT)`, `sem_destroy(3RT)`.

**RETURN VALUES**

Upon successful completion, 0 is returned; otherwise, a non-zero value indicates an error.

**ERRORS**

These functions will fail if:

- **EINVAL** The `sp` argument does not refer to a valid semaphore.
- **EFAULT** Either the `sp` or `arg` argument points to an illegal address.

The `sema_wait()` function will fail if:

- **EINTR** The wait was interrupted by a signal or `fork()`.

The `sema_trywait()` function will fail if:

- **EBUSY** The semaphore pointed to by `sp` has a 0 count.

The `sema_post()` function will fail if:
The semaphore value pointed to by\texttt{sp} exceeds \texttt{SEM\_VALUE\_MAX}.

\textbf{EXAMPLE 1}  The customer waiting-line in a bank is analogous to the synchronization scheme of a semaphore using \texttt{sema\_wait()} and \texttt{sema\_trywait()}:

\begin{verbatim}
/* cc [ flag ... ] file ... -lthread [ library ... ] */
#include <errno.h>
define TELLERS 10
sema_t tellers; /* semaphore */
int banking_hours(), deposit_withdrawal;
void*customer(), do_business(), skip_banking_today();
...
sema_init(&tellers, TELLERS, USYNC_THREAD, NULL);
/* 10 tellers available */
while(banking_hours())
  pthread_create(NULL, NULL, customer, deposit_withdrawal);
...
void *
customer(int deposit_withdrawal)
{
  int this_customer, in_a_hurry = 50;
  this_customer = rand() % 100;
  if (this_customer == in_a_hurry) {
    if (sema_trywait(&tellers) != 0)
      if (errno == EBUSY){ /* no teller available */
        skip_banking_today(this_customer);
        return;
      } /* else go immediately to available teller and
         decrement tellers */
  }
  else
    sema_wait(&tellers); /* wait for next teller, then proceed,
                      and decrement tellers */
    do_business(deposit_withdrawal);
    sema_post(&tellers); /* increment tellers; 
     this_customer's teller
    is now available */
}
\end{verbatim}

sem\_init(3RT), sem\_open(3RT), sem\_post(3RT), sem\_unlink(3RT),
sem\_wait(3RT), attributes(5), standards(5)
These functions are also available by way of:

```c
#include <thread.h>
```

By default, there is no defined order of unblocking for multiple threads waiting for a semaphore.
The `sem_close()` function is used to indicate that the calling process is finished using the named semaphore indicated by `sem`. The effects of calling `sem_close()` for an unnamed semaphore (one created by `sem_init(3RT)`) are undefined. The `sem_close()` function deallocates (that is, make available for reuse by a subsequent `sem_open(3RT)` by this process) any system resources allocated by the system for use by this process for this semaphore. The effect of subsequent use of the semaphore indicated by `sem` by this process is undefined. If the semaphore has not been removed with a successful call to `sem_unlink(3RT)`, then `sem_close()` has no effect on the state of the semaphore. If the `sem_unlink(3RT)` function has been successfully invoked for `name` after the most recent call to `sem_open(3RT)` with `O_CREAT` for this semaphore, then when all processes that have opened the semaphore close it, the semaphore is no longer be accessible.

If successful, `sem_close()` returns 0, otherwise it returns -1 and sets `errno` to indicate the error.

The `sem_close()` function will fail if:

- **EINVAL** The `sem` argument is not a valid semaphore descriptor.
- **ENOSYS** The `sem_close()` function is not supported by the system.

The `sem_close()` function should not be called for an unnamed semaphore initialized by `sem_init(3RT)`. See `attributes(5)` for descriptions of the following attributes:

<table>

<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>MT-Level</td>
<td>MT-Safe</td>
</tr>
</tbody>
</table>

Solaris 2.6 was the first release to support the Asynchronous Input and Output option. Prior to this release, this function always returned -1 and set `errno` to ENOSYS.
sem_destroy(3RT)

NAME
sem_destroy – destroy an unnamed semaphore

SYNOPSIS
cc [ flag... ] file... -lrt [ library... ]
#include <semaphore.h>

int sem_destroy(sem_t *sem);

DESCRIPTION
The sem_destroy() function is used to destroy the unnamed semaphore indicated by sem. Only a semaphore that was created using sem_init(3RT) may be destroyed using sem_destroy(); the effect of calling sem_destroy() with a named semaphore is undefined. The effect of subsequent use of the semaphore sem is undefined until sem is re-initialized by another call to sem_init(3RT).

It is safe to destroy an initialized semaphore upon which no threads are currently blocked. The effect of destroying a semaphore upon which other threads are currently blocked is undefined.

RETURN VALUES
If successful, sem_destroy() returns 0, otherwise it returns −1 and sets errno to indicate the error.

ERRORS
The sem_destroy() function will fail if:

EINVAL
The sem argument is not a valid semaphore.

ENOSYS
The sem_destroy() function is not supported by the system.

The sem_destroy() function may fail if:

EBUSY
There are currently processes (or LWPs or threads) blocked on the semaphore.

NAME  sem_getvalue – get the value of a semaphore

SYNOPSIS  
```c
#include <semaphore.h>

int sem_getvalue(sem_t *sem, int *sval);
```

DESCRIPTION  The `sem_getvalue()` function updates the location referenced by the `sval` argument to have the value of the semaphore referenced by `sem` without affecting the state of the semaphore. The updated value represents an actual semaphore value that occurred at some unspecified time during the call, but it need not be the actual value of the semaphore when it is returned to the calling process.

If `sem` is locked, then the value returned by `sem_getvalue()` is either zero or a negative number whose absolute value represents the number of processes waiting for the semaphore at some unspecified time during the call.

The value set in `sval` may be 0 or positive. If `sval` is 0, there may be other processes (or LWPs or threads) waiting for the semaphore; if `sval` is positive, no process is waiting.

RETURN VALUES  Upon successful completion, `sem_getvalue()` returns 0. Otherwise, it returns -1 and sets `errno` to indicate the error.

ERRORS  The `sem_getvalue()` function will fail if:

- `EINVAL` The `sem` argument does not refer to a valid semaphore.
- `ENOSYS` The `sem_getvalue()` function is not supported by the system.

sem_init – initialize an unnamed semaphore

```c
#include <semaphore.h>

int sem_init(sem_t *sem, int pshared, unsigned int value);
```

The `sem_init()` function is used to initialize the unnamed semaphore referred to by `sem`. The value of the initialized semaphore is `value`. Following a successful call to `sem_init()`, the semaphore may be used in subsequent calls to `sem_wait(3RT)`, `sem_trywait(3RT)`, `sem_post(3RT)`, and `sem_destroy(3RT)`. This semaphore remains usable until the semaphore is destroyed.

If the `pshared` argument has a non-zero value, then the semaphore is shared between processes; in this case, any process that can access the semaphore `sem` can use `sem` for performing `sem_wait(3RT)`, `sem_trywait(3RT)`, `sem_post(3RT)`, and `sem_destroy(3RT)` operations.

Only `sem` itself may be used for performing synchronization. The result of referring to copies of `sem` in calls to `sem_wait(3RT)`, `sem_trywait(3RT)`, `sem_post(3RT)`, and `sem_destroy(3RT)`, is undefined.

If the `pshared` argument is zero, then the semaphore is shared between threads of the process; any thread in this process can use `sem` for performing `sem_wait(3RT)`, `sem_trywait(3RT)`, `sem_post(3RT)`, and `sem_destroy(3RT)` operations. The use of the semaphore by threads other than those created in the same process is undefined.

Attempting to initialize an already initialized semaphore results in undefined behavior.

Upon successful completion, the function initializes the semaphore in `sem`. Otherwise, it returns -1 and sets `errno` to indicate the error.

The `sem_init()` function will fail if:

- **EINVAL**: The `value` argument exceeds `SEM_VALUE_MAX`.
- **ENOMEM**: A resource required to initialize the semaphore has been exhausted, or the resources have reached the limit on semaphores (`SEM_NSEMS_MAX`).
- **ENOSYS**: The `sem_init()` function is not supported by the system.
- **EPERM**: The process lacks the appropriate privileges to initialize the semaphore.

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>MT-Level</td>
<td>MT-Safe</td>
</tr>
</tbody>
</table>
sem_init(3RT)

SEE ALSO  sem_destroy(3RT), sem_post(3RT), sem_wait(3RT), attributes(5)
The `sem_open()` function establishes a connection between a named semaphore and a process (or LWP or thread). Following a call to `sem_open()` with semaphore name `name`, the process may reference the semaphore associated with `name` using the address returned from the call. This semaphore may be used in subsequent calls to `sem_wait(3RT)`, `sem_trywait(3RT)`, `sem_post(3RT)`, and `sem_close(3RT)`. The semaphore remains usable by this process until the semaphore is closed by a successful call to `sem_close(3RT)`, `_exit(2)`, or one of the `exec` functions.

The `oflag` argument controls whether the semaphore is created or merely accessed by the call to `sem_open()`. The following flag bits may be set in `oflag`:

- `O_CREAT` This flag is used to create a semaphore if it does not already exist. If `O_CREAT` is set and the semaphore already exists, then `O_CREAT` has no effect, except as noted under `O_EXCL`. Otherwise, `sem_open()` creates a named semaphore. The `O_CREAT` flag requires a third and a fourth argument: `mode`, which is of type `mode_t`, and `value`, which is of type `unsigned int`. The semaphore is created with an initial value of `value`. Valid initial values for semaphores are less than or equal to `SEM_VALUE_MAX`.

The user ID of the semaphore is set to the effective user ID of the process; the group ID of the semaphore is set to a system default group ID or to the effective group ID of the process. The permission bits of the semaphore are set to the value of the `mode` argument except those set in the file mode creation mask of the process (see `umask(2)`). When bits in `mode` other than the file permission bits are specified, the effect is unspecified.

After the semaphore named `name` has been created by `sem_open()` with the `O_CREAT` flag, other processes can connect to the semaphore by calling `sem_open()` with the same value of `name`.

- `O_EXCL` If `O_EXCL` and `O_CREAT` are set, `sem_open()` fails if the semaphore `name` exists. The check for the existence of the semaphore and the creation of the semaphore if it does not exist are atomic with respect to other processes executing `sem_open()` with `O_EXCL` and `O_CREAT` set. If `O_EXCL` is set and `O_CREAT` is not set, the effect is undefined.

If flags other than `O_CREAT` and `O_EXCL` are specified in the `oflag` parameter, the effect is unspecified.
The `name` argument points to a string naming a semaphore object. It is unspecified whether the name appears in the file system and is visible to functions that take pathnames as arguments. The `name` argument conforms to the construction rules for a pathname. The first character of `name` must be a slash (/) character and the remaining characters of `name` cannot include any slash characters. For maximum portability, `name` should include no more than 14 characters, but this limit is not enforced.

If a process makes multiple successful calls to `sem_open()` with the same value for `name`, the same semaphore address is returned for each such successful call, provided that there have been no calls to `sem_unlink(3RT)` for this semaphore.

References to copies of the semaphore produce undefined results.

**RETURN VALUES**

Upon successful completion, the function returns the address of the semaphore. Otherwise, it will return a value of `SEM_FAILED` and set `errno` to indicate the error. The symbol `SEM_FAILED` is defined in the header `<semaphore.h>`. No successful return from `sem_open()` will return the value `SEM_FAILED`.

**ERRORS**

If any of the following conditions occur, the `sem_open()` function will return `SEM_FAILED` and set `errno` to the corresponding value:

- **EACCES**
  The named semaphore exists and the `O_RDWR` permissions are denied, or the named semaphore does not exist and permission to create the named semaphore is denied.

- **EEXIST**
  `O_CREAT` and `O_EXCL` are set and the named semaphore already exists.

- **EINTR**
  The `sem_open()` function was interrupted by a signal.

- **EINVAL**
  The `sem_open()` operation is not supported for the given name, or `O_CREAT` was set in `o`flag and `value` is greater than `SEM_VALUE_MAX`.

- **EMFILE**
  The number of open semaphore descriptors in this process exceeds `SEM_NSEMS_MAX`, or the number of open file descriptors in this process exceeds `OPEN_MAX`.

- **ENAMETOOLONG**
  The length of `name` string exceeds `PATH_MAX`, or a pathname component is longer than `NAME_MAX` while `_POSIX_NO_TRUNC` is in effect.

- **ENFILE**
  Too many semaphores are currently open in the system.

- **ENOENT**
  `O_CREAT` is not set and the named semaphore does not exist.

- **ENOSPC**
  There is insufficient space for the creation of the new named semaphore.
The \texttt{sem_open()} function is not supported by the system.

\textbf{ATTRIBUTES} See attributes(5) for descriptions of the following attributes:

sem_post(3RT)

NAME
sem_post – increment the count of a semaphore

SYNOPSIS
cc [ flag... ] file... -lrt [ library... ]
#include <semaphore.h>

int sem_post(sem_t *sem);

DESCRIPTION
The sem_post() function unlocks the semaphore referenced by sem by performing a
semaphore unlock operation on that semaphore.

If the semaphore value resulting from this operation is positive, then no threads were
blocked waiting for the semaphore to become unlocked; the semaphore value is
simply incremented.

If the value of the semaphore resulting from this operation is 0, then one of the threads
blocked waiting for the semaphore will be allowed to return successfully from its call
to sem_wait(3RT). If the symbol _POSIX_PRIORITY_SCHEDULING is defined, the
thread to be unblocked will be chosen in a manner appropriate to the scheduling
policies and parameters in effect for the blocked threads. In the case of the schedulers
SCHED_FIFO and SCHED_RR, the highest priority waiting thread will be unblocked,
and if there is more than one highest priority thread blocked waiting for the
semaphore, then the highest priority thread that has been waiting the longest will be
unblocked. If the symbol _POSIX_PRIORITY_SCHEDULING is not defined, the choice
of a thread to unblock is unspecified.

RETURN VALUES
If successful, sem_post() returns 0; otherwise it returns -1 and sets errno to
indicate the error.

ERRORS
The sem_post() function will fail if:

EINVAL The sem argument does not refer to a valid semaphore.
ENOSYS The sem_post() function is not supported by the system.
EOVERFLOW The semaphore value exceeds SEM_VALUE_MAX.

USAGE
The sem_post() function is reentrant with respect to signals and may be invoked
from a signal-catching function. The semaphore functionality described on this
manual page is for the POSIX (see standards(5)) threads implementation. For the
documentation of the Solaris threads interface, see semaphore(3THR)).

EXAMPLES
See sem_wait(3RT).

NAME
sem_unlink – remove a named semaphore

SYNOPSIS
cc [ flag... ] file... -lrt [ library... ]
#include <semaphore.h>

    int sem_unlink(const char *name);

DESCRIPTION
The sem_unlink() function removes the semaphore named by the string name. If the
semaphore named by name is currently referenced by other processes, then
sem_unlink() has no effect on the state of the semaphore. If one or more processes
have the semaphore open when sem_unlink() is called, destruction of the
semaphore is postponed until all references to the semaphore have been destroyed by
calls to sem_close(3RT), _exit(2), or one of the exec functions (see exec(2)). Calls
to sem_open(3RT) to re-create or re-connect to the semaphore refer to a new
semaphore after sem_unlink() is called. The sem_unlink() call does not block
until all references have been destroyed; it returns immediately.

RETURN VALUES
Upon successful completion, sem_unlink() returns 0. Otherwise, the semaphore is
not changed and the function returns a value of −1 and sets errno to indicate the
error.

ERRORS
The sem_unlink() function will fail if:

EACCES Permission is denied to unlink the named semaphore.
ENAMETOOLONG The length of name string exceeds PATH_MAX, or a
pathname component is longer than NAME_MAX while
_POSIX_NO_TRUNC is in effect.
ENOENT The named semaphore does not exist.
ENOSYS The sem_unlink() function is not supported by the
system.

ATTRIBUTES
See attributes(5) for descriptions of the following attributes:

<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>MT-Level</td>
<td>MT-Safe</td>
</tr>
</tbody>
</table>

SEE ALSO
exec(2), exit(2), sem_close(3RT), sem_open(3RT), attributes(5)

NOTES
Solaris 2.6 was the first release to support the Asynchronous Input and Output option.
Prior to this release, this function always returned −1 and set errno to ENOSYS.
sem_wait(3RT)

NAME
sem_wait, sem_trywait – acquire or wait for a semaphore

SYNOPSIS
cc [ flag... ] file... -lrt [ library... ]
#include <semaphore.h>

int sem_wait(sem_t *sem);
int sem_trywait(sem_t *sem);

DESCRIPTION
The sem_wait() function locks the semaphore referenced by sem by performing a
semaphore lock operation on that semaphore. If the semaphore value is currently zero,
then the calling thread will not return from the call to sem_wait() until it either
locks the semaphore or the call is interrupted by a signal. The sem_trywait() function locks the semaphore referenced by sem only if the semaphore is currently not
locked; that is, if the semaphore value is currently positive. Otherwise, it does not lock
the semaphore.

Upon successful return, the state of the semaphore is locked and remains locked until
the sem_post(3RT) function is executed and returns successfully.

The sem_wait() function is interruptible by the delivery of a signal.

RETURN VALUES
The sem_wait() and sem_trywait() functions return 0 if the calling process
successfully performed the semaphore lock operation on the semaphore designated by
sem. If the call was unsuccessful, the state of the semaphore is unchanged, and the
function returns -1 and sets errno to indicate the error.

ERRORS
The sem_wait() and sem_trywait() functions will fail if:
EINVAL The sem function does not refer to a valid semaphore.
ENOSYS The sem_wait() and sem_trywait() functions are not
supported by the system.

The sem_trywait() function will fail if:
EAGAIN The semaphore was already locked, so it cannot be immediately
locked by the sem_trywait() operation.

The sem_wait() and sem_trywait() functions may fail if:
EDEADLK A deadlock condition was detected; that is, two separate processes are
waiting for an available resource to be released via a
semaphore "held" by the other process.

EINTR A signal interrupted this function.

USAGE
Realtime applications may encounter priority inversion when using semaphores. The
problem occurs when a high priority thread "locks" (that is, waits on) a semaphore
that is about to be "unlocked" (that is, posted) by a low priority thread, but the low
priority thread is preempted by a medium priority thread. This scenario leads to
priority inversion; a high priority thread is blocked by lower priority threads for an
unlimited period of time. During system design, realtime programmers must take into
account the possibility of this kind of priority inversion. They can deal with it in a number of ways, such as by having critical sections that are guarded by semaphores execute at a high priority, so that a thread cannot be preempted while executing in its critical section.

**EXAMPLE 1** The customer waiting-line in a bank may be analogous to the synchronization scheme of a semaphore utilizing `sem_wait()` and `sem_trywait()`:

```c
#include <errno.h>
define TELLERS 10
sem_t bank_line; /* semaphore */
int banking_hours(), deposit_withdrawal;
void *customer(), do_business(), skip_banking_today();
thread_t tid;

sem_init(&bank_line,TRUE,TELLERS); /* 10 tellers available */
while(banking_hours())
    thr_create(NULL, NULL, customer, (void *)deposit_withdrawal,
                THREAD_NEW_LWP, &tid);

void *
customer(deposit_withdrawal)
void *deposit_withdrawal;
{
    int this_customer, in_a_hurry = 50;
    this_customer = rand() % 100;
    if (this_customer == in_a_hurry) {
        if (sem_trywait(&bank_line) != 0)
            if (errno == EAGAIN) { /* no teller available */
                skip_banking_today(this_customer);
                return;
            } /*else go immediately to available teller & decrement bank_line*/
    } /*else go immediately to available teller & decrement bank_line*/
    sem_wait(&bank_line); /* wait for next teller, then proceed, and decrement bank_line */
    do_business((int *)deposit_withdrawal);
    sem_getvalue(&bank_line,&num_tellers);
    sem_post(&bank_line); /* increment bank_line; this_customer’s teller is now available */
}
```

shm_open – open a shared memory object

SYNOPSIS

```c
#include <sys/mman.h>

int shm_open(const char *name, int oflag, mode_t mode);
```

DESCRIPTION

The `shm_open()` function establishes a connection between a shared memory object and a file descriptor. It creates an open file description that refers to the shared memory object and a file descriptor that refers to that open file description. The file descriptor is used by other functions to refer to that shared memory object. The `name` argument points to a string naming a shared memory object. It is unspecified whether the name appears in the file system and is visible to other functions that take pathnames as arguments. The `name` argument conforms to the construction rules for a pathname. The first character of `name` must be a slash (/) character and the remaining characters of `name` cannot include any slash characters. For maximum portability, `name` should include no more than 14 characters, but this limit is not enforced.

If successful, `shm_open()` returns a file descriptor for the shared memory object that is the lowest numbered file descriptor not currently open for that process. The open file description is new, and therefore the file descriptor does not share it with any other processes. It is unspecified whether the file offset is set. The `FD_CLOEXEC` file descriptor flag associated with the new file descriptor is set.

The file status flags and file access modes of the open file description are according to the value of `oflag`. The `oflag` argument is the bitwise inclusive OR of the following flags defined in the header `<fcntl.h>`. Applications specify exactly one of the first two values (access modes) below in the value of `oflag`:

- `O_RDONLY` Open for read access only.
- `O_RDWR` Open for read or write access.

Any combination of the remaining flags may be specified in the value of `oflag`:

- `O_CREAT` If the shared memory object exists, this flag has no effect, except as noted under `O_EXCL` below. Otherwise the shared memory object is created; the user ID of the shared memory object will be set to the effective user ID of the process; the group ID of the shared memory object will be set to a system default group ID or to the effective group ID of the process. The permission bits of the shared memory object will be set to the value of the `mode` argument except those set in the file mode creation mask of the process. When bits in `mode` other than the file permission bits are set, the effect is unspecified. The `mode` argument does not affect whether the shared memory object is opened for reading, for writing, or for both. The shared memory object has a size of zero.

- `O_EXCL` If `O_EXCL` and `O_CREAT` are set, `shm_open()` fails if the shared memory object exists. The check for the existence of the shared memory object and the creation of the object if it does not exist is
atomic with respect to other processes executing `shm_open()` naming the same shared memory object with `O_EXCL` and `O_CREAT` set. If `O_EXCL` is set and `O_CREAT` is not set, the result is undefined.

`O_TRUNC` If the shared memory object exists, and it is successfully opened `O_RDWR`, the object will be truncated to zero length and the mode and owner will be unchanged by this function call. The result of using `O_TRUNC` with `O_RDONLY` is undefined.

When a shared memory object is created, the state of the shared memory object, including all data associated with the shared memory object, persists until the shared memory object is unlinked and all other references are gone. It is unspecified whether the name and shared memory object state remain valid after a system reboot.

Upon successful completion, the `shm_open()` function returns a non-negative integer representing the lowest numbered unused file descriptor. Otherwise, it returns -1 and sets `errno` to indicate the error condition.

The `shm_open()` function will fail if:

- **EACCES** The shared memory object exists and the permissions specified by `oflag` are denied, or the shared memory object does not exist and permission to create the shared memory object is denied, or `O_TRUNC` is specified and write permission is denied.

- **EEXIST** `O_CREAT` and `O_EXCL` are set and the named shared memory object already exists.

- **EINVAL** The `shm_open()` operation is not supported for the given name.

- **EMFILE** Too many file descriptors are currently in use by this process.

- **ENAMETOOLONG** The length of the `name` string exceeds `PATH_MAX`, or a pathname component is longer than `NAME_MAX` while `_POSIX_NO_TRUNC` is in effect.

- **ENOFILE** Too many shared memory objects are currently open in the system.

- **ENOENT** `O_CREAT` is not set and the named shared memory object does not exist.

- **ENOSPC** There is insufficient space for the creation of the new shared memory object.
The `shm_open()` function is not supported by the system.

When a UFS file system is mounted with logging enabled, file system transactions that free blocks from files might not actually add those freed blocks to the file system’s free list until some unspecified time in the future. This behavior improves file system performance but does not conform to the POSIX, Single UNIX Specification, SPARC Conformance Definition, System V Application Binary Interface, System V Interface Definition, and X/Open Portability Guide Standards, which require that freed space be available immediately. To enable standards conformance regarding file deletions or to address the problem of not being able to grow files on a relatively full UFS file system even after files have been deleted, disable UFS logging (see `mount_ufs(1M)`).

</tbody>
</table>

Solaris 2.6 was the first release to support the Asynchronous Input and Output option. Prior to this release, this function always returned −1 and set `errno` to `ENOSYS`. 
shm_unlink – remove a shared memory object

#include <sys/mman.h>

int shm_unlink(const char *name);

The shm_unlink() function removes the name of the shared memory object named by the string pointed to by name. If one or more references to the shared memory object exists when the object is unlinked, the name is removed before shm_unlink() returns, but the removal of the memory object contents will be postponed until all open and mapped references to the shared memory object have been removed.

Upon successful completion, shm_unlink() returns 0. Otherwise it returns -1 and sets errno to indicate the error condition, and the named shared memory object is not affected by this function call.

The shm_unlink() function will fail if:

- **EACCES** Permission is denied to unlink the named shared memory object.
- **ENAMETOOLONG** The length of the name string exceeds PATH_MAX, or a pathname component is longer than NAME_MAX while _POSIX_NO_TRUNC is in effect.
- **ENOENT** The named shared memory object does not exist.
- **ENOSYS** The shm_unlink() function is not supported by the system.

Solaris 2.6 was the first release to support the Asynchronous Input and Output option. Prior to this release, this function always returned -1 and set errno to ENOSYS.
**NAME**
sigqueue – queue a signal to a process

**SYNOPSIS**
```c
c [ flag... ] file... -lrt [ library... ]
#include <sys/types.h>
#include <signal.h>
int sigqueue(pid_t pid, int signo, const union sigval value);
```

**DESCRIPTION**
The `sigqueue()` function causes the signal specified by `signo` to be sent with the value specified by `value` to the process specified by `pid`. If `signo` is 0 (the null signal), error checking is performed but no signal is actually sent. The null signal can be used to check the validity of `pid`.

The conditions required for a process to have permission to queue a signal to another process are the same as for the `kill(2)` function.

The `sigqueue()` function returns immediately. If `SA_SIGINFO` is set for `signo` and if the resources were available to queue the signal, the signal is queued and sent to the receiving process. If `SA_SIGINFO` is not set for `signo`, then `signo` is sent at least once to the receiving process; it is unspecified whether `value` will be sent to the receiving process as a result of this call.

If the value of `pid` causes `signo` to be generated for the sending process, and if `signo` is not blocked for the calling thread and if no other thread has `signo` unblocked or is waiting in a `sigwait(2)` function for `signo`, either `signo` or at least the pending, unblocked signal will be delivered to the calling thread before the `sigqueue()` function returns. Should any of multiple pending signals in the range `SIGRTMIN` to `SIGRTMAX` be selected for delivery, it will be the lowest numbered one. The selection order between realtime and non-realtime signals, or between multiple pending non-realtime signals, is unspecified.

**RETURN VALUES**
Upon successful completion, the specified signal will have been queued, and the `sigqueue()` function returns 0. Otherwise, the function returns -1 and sets `errno` to indicate the error.

**ERRORS**
The `sigqueue()` function will fail if:

- **EAGAIN** No resources are available to queue the signal. The process has already queued `SIGQUEUE_MAX` signals that are still pending at the receiver(s), or a system wide resource limit has been exceeded.
- **EINVAL** The value of `signo` is an invalid or unsupported signal number.
- **ENOSYS** The `sigqueue()` function is not supported by the system.
- **EPERM** The process does not have the appropriate privilege to send the signal to the receiving process.
- **ESRCH** The process `pid` does not exist.

</tbody>
</table>

SEE ALSO

kill(2), sigwaitinfo(3RT), attributes(5), siginfo(3HEAD), signal(3HEAD)
# sigwaitinfo(3RT)

## NAME

sigwaitinfo, sigtimedwait – wait for queued signals

## SYNOPSIS

```
cc [ flag... ] file... -lrt [ library... ]
#include <signal.h>

int sigwaitinfo(const sigset_t *set, siginfo_t *info);
int sigtimedwait(const sigset_t *set, siginfo_t *info, const struct
timespec *timeout);
```

## DESCRIPTION

The `sigwaitinfo()` function selects the pending signal from the set specified by `set`. Should any of multiple pending signals in the range SIGRTMIN to SIGRTMAX be selected, it will be the lowest numbered one. The selection order between realtime and non-realtime signals, or between multiple pending non-realtime signals, is unspecified. If no signal in `set` is pending at the time of the call, the calling thread is suspended until one or more signals in `set` become pending or until it is interrupted by an unblocked, caught signal.

The `sigwaitinfo()` function behaves the same as the `sigwait(2)` function if the `info` argument is `NULL`. If the `info` argument is non-`NULL`, the `sigwaitinfo()` function behaves the same as `sigwait(2)`, except that the selected signal number is stored in the `si_signo` member, and the cause of the signal is stored in the `si_code` member. If any value is queued to the selected signal, the first such queued value is dequeued and, if the `info` argument is non-`NULL`, the value is stored in the `si_value` member of `info`. The system resource used to queue the signal will be released and made available to queue other signals. If no value is queued, the content of the `si_value` member is undefined. If no further signals are queued for the selected signal, the pending indication for that signal will be reset. If the value of the `si_code` member is `SI_NOINFO`, only the `si_signo` member of `siginfo_t` is meaningful, and the value of all other members is unspecified.

The `sigtimedwait()` function behaves the same as `sigwaitinfo()` except that if none of the signals specified by `set` are pending, `sigtimedwait()` waits for the time interval specified in the `timespec` structure referenced by `timeout`. If the `timespec` structure pointed to by `timeout` is zero-valued and if none of the signals specified by `set` are pending, then `sigtimedwait()` returns immediately with an error. If `timeout` is the `NULL` pointer, the behavior is unspecified.

If, while `sigwaitinfo()` or `sigtimedwait()` is waiting, a signal occurs which is eligible for delivery (that is, not blocked by the process signal mask), that signal is handled asynchronously and the wait is interrupted.

## RETURN VALUES

Upon successful completion (that is, one of the signals specified by `set` is pending or is generated) `sigwaitinfo()` and `sigtimedwait()` will return the selected signal number. Otherwise, the function returns −1 and sets `errno` to indicate the error.

## ERRORS

The `sigwaitinfo()` and `sigtimedwait()` functions will fail if:

- **EINTR**: The wait was interrupted by an unblocked, caught signal.
- **ENOSYS**: The `sigwaitinfo()` and `sigtimedwait()` functions are not supported.
The `sigtimedwait()` function will also fail if:

**EAGAIN**  
No signal specified by `set` was generated within the specified timeout period.

The `sigtimedwait()` function may also fail if:

**EINVAL**  
The `timeout` argument specified a `tv_nsec` value less than zero or greater than or equal to 1000 million. The system only checks for this error if no signal is pending in `set` and it is necessary to wait.

NAME

td_init – performs initialization for libthread_db library of interfaces

SYNOPSIS

cc [ flag ... ] file ... -lthread_db [ library ... ]

#include <proc_service.h>
#include <thread_db.h>

#include <proc_service.h>
#include <thread_db.h>

td_err_e td_init();

DESCRIPTION

td_init() is the global initialization function for the libthread_db() library of interfaces. It must be called exactly once by any process using the libthread_db() library before any other libthread_db function can be called.

RETURN VALUES

TD_OK The libthread_db() library of interfaces successfully initialized.

TD_ERR Initialization failed.

Synchronization objects include mutexes, condition variables, semaphores, and reader-writer locks. In the same way that thread operations use a thread handle of type `td_thrhandle_t`, operations on synchronization objects use a synchronization object handle of type `td_synchandle_t`.

The controlling process obtains synchronization object handles either by calling the function `td_ta sync iter()` to obtain handles for all synchronization objects of the target process that are known to the `libthread_db` library of interfaces, or by mapping the address of a synchronization object in the address space of the target process to a handle by calling `td ta map addr2sync(3THR)`.

Not all synchronization objects that a process uses may be known to the `libthread_db` library and returned by `td ta sync iter(3THR)`. A synchronization object is known to `libthread_db` only if it has been the target of a synchronization primitive in the process (such as `mutex lock()`, described on the `mutex init(3THR)` manual page) after `td ta new(3THR)` has been called to attach to the process and `td ta sync tracking enable()` has been called to enable synchronization object tracking.

The `td ta sync tracking enable()` function turns synchronization object tracking on or off for the process identified by `ta_p`, depending on whether `on_off` is 0 (off) or non-zero (on).

The `td sync get info()` function fills in the `td syncinfo_t` structure `*si_p` with values for the synchronization object identified by `sh_p`. The `td syncinfo_t` structure contains the following fields:
<table>
<thead>
<tr>
<th>Variable Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>td_thragent_t *si_ta_p</code></td>
<td>The internal process handle identifying the target process through which this synchronization object handle was obtained. Synchronization objects may be process-private or process-shared. In the latter case, the same synchronization object may have multiple handles, one for each target process’s “view” of the synchronization object.</td>
</tr>
<tr>
<td><code>psaddr_t si_sv_addr</code></td>
<td>The address of the synchronization object in this target process’s address space.</td>
</tr>
<tr>
<td><code>td_sync_type_e si_type</code></td>
<td>The type of the synchronization variable: mutex, condition variable, semaphore, or readers-writer lock.</td>
</tr>
<tr>
<td><code>int si_shared_type</code></td>
<td>If the USYNC_PROCESS or USYNC_PROCESS_ROBUST bit is set in <code>si_shared_type</code>, this synchronization object is process-shared, otherwise it is process-private.</td>
</tr>
<tr>
<td><code>td_sync_flags_t si_flags</code></td>
<td>Flags dependent on the type of the synchronization object.</td>
</tr>
<tr>
<td><code>int si_state.sema_count</code></td>
<td>Semaphores only. The current value of the semaphore.</td>
</tr>
<tr>
<td><code>int si_state.nreaders</code></td>
<td>Readers-writer locks only. The number of readers currently holding the lock, or -1, if a writer is currently holding the lock.</td>
</tr>
<tr>
<td><code>int si_state.mutex_locked</code></td>
<td>For mutexes only. Non-zero if and only if the mutex is currently locked.</td>
</tr>
<tr>
<td><code>int si_size</code></td>
<td>The size of the synchronization object.</td>
</tr>
<tr>
<td><code>uint8_t si_has_waiters</code></td>
<td>Non-zero if and only if at least one thread is blocked on this synchronization object.</td>
</tr>
<tr>
<td><code>uint8_t si_is_wlocked</code></td>
<td>For reader-writer locks only. The value is non-zero if and only if this lock is held by a writer.</td>
</tr>
<tr>
<td><code>uint8_t si_rcount</code></td>
<td>PTHREAD_MUTEX_RECURSIVE mutexes only. If the mutex is held, the recursion count.</td>
</tr>
<tr>
<td><code>uint8_t si_prioceiling</code></td>
<td>PTHREAD_PRIO_PROTECT protocol mutexes only. The priority ceiling.</td>
</tr>
</tbody>
</table>
td_thrhandle_t si_owner

Mutexes and readers-writer locks only. This is the thread holding the mutex, or the write lock, if this is a reader-writer lock. The value is NULL if no one holds the mutex or write-lock.

pid_t si_ownerpid

Mutexes only. For a locked process-shared mutex, this is the process-ID of the process containing the owning thread.

The `td_sync_get_stats()` function fills in the `td_syncstats_t` structure `*ss_p` with values for the synchronization object identified by `sh_p`. The `td_syncstats_t` structure contains an embedded `td_syncinfo_t` structure that is filled in as described above for `td_sync_get_info()`. In addition, usage statistics gathered since `td_ta_sync_tracking_enable()` was called to enable synchronization object tracking are returned in the `ss_un.mutex`, `ss_un.cond`, `ss_un.rwlock`, or `ss_un.sema` members of the `td_syncstats_t` structure, depending on the type of the synchronization object.

The `td_sync_setstate` function modifies the state of synchronization object `si_p`, depending on the synchronization object type. For mutexes, `td_sync_setstate` is unlocked if the value is 0. Otherwise it is locked. For semaphores, the semaphore’s count is set to the value. For reader-writer locks, the reader count set to the value if value is >0. The count is set to write-locked if value is –1. It is set to unlocked if the value is 0. Setting the state of a synchronization object from a libthread_db interface may cause the synchronization object’s semantics to be violated from the point of view of the threads in the target process. For example, if a thread holds a mutex, and `td_sync_setstate` is used to set the mutex to unlocked, then a different thread will also be able to subsequently acquire the same mutex.

The `td_sync_waiters` function iterates over the set of thread handles of threads blocked on `sh_p`. The callback function `cb` is called once for each such thread handle, and is passed the thread handle and `cb_data_p`. If the callback function returns a non-zero value, iteration is terminated early. See `td_ta_thr_iter(3THR)`.

**RETURN VALUES**

- **TD_OK** The call returned successfully.
- **TD_BADTH** An invalid thread handle was passed in.
- **TD_DBERR** A call to one of the imported interface routines failed.
- **TD_ERR** A libthread_db-internal error occurred.

**ATTRIBUTES**

See `attributes(5)` for descriptions of the following attributes:

Threads and Realtime Library Functions 247
td_sync_get_info(3THR)

SEE ALSO libthread_db(3LIB), libthread_db(3THR), mutex_init(3THR),
      td_ta_map_addr2sync(3THR), td_ta_sync_iter(3THR),
      td_ta_thr_iter(3THR), attributes(5)
The controlling process can request the collection of certain statistics about a target process. Statistics gathering is disabled by default. Each target process has a td_ta_stats_t structure that contains current values when statistic gathering is enabled.

The td_ta_enable_stats() function turns statistics gathering on or off for the process identified by ta_p, depending on whether or not on_off is non-zero. When statistics gathering is turned on, all statistics are implicitly reset as though td_ta_reset_stats() had been called. Statistics are not reset when statistics gathering is turned off. Except for nthreads and r_concurrency, the values do not change further, but they remain available for inspection by way of td_ta_get_stats().

The td_ta_reset_stats() function resets all counters in the td_ta_stats_t structure to zero for the target process.

The td_ta_get_stats() function returns the structure for the process in tstats.

The td_ta_stats_t structure is defined in <thread_db.h> and contains the following members:

```c
typedef struct {
    int nthreads;        /* total number of threads in use */
    int r_concurrency;   /* requested concurrency level */
    int nrunnable_num;   /* numerator of avg runnable threads */
    int nrunnable_den;   /* denominator of avg runnable threads */
    int a_concurrency_num; /* numerator, avg achieved concurrency */
    int a_concurrency_den; /* denominator, avg achieved concurrency */
    int nlwps_num;       /* numerator, avg number of LWPs in use */
    int nlwps_den;       /* denominator, avg number of LWPs in use */
    int nidle_num;       /* numerator, avg number of idling LWPs */
    int nidle_den;       /* denominator, avg number of idling LWPs */
} td_ta_stats_t;
```

The nthreads member is the number of threads that are currently part of the target process. The r_concurrency member is the current requested concurrency level, such as would be returned by thr_setconcurrency(3THR). The remaining members are averages over time, each expressed as a fraction with an integral numerator and denominator. The nrunnable_num and nrunnable_den members
td_ta_enable_stats(3THR)

represent the average number of runnable threads. The a_concurrency_num and a_concurrency_den members represent the average achieved concurrency, the number of actually running threads. The a_concurrency_num and a_concurrency_den members are less than or equal to nrunnable_num and nrunnable_den, respectively. The nlwps_num and nlwps_den members represent the average number of lightweight processes (LWPs) participating in this process. They must be greater than or equal to a_concurrency_num and a_concurrency_den, respectively, since every running thread is assigned to an LWP, but there can at times be additional idling LWPs with no thread assigned to them. The nidle_num and nidle_den members represent the average number of idle LWPs.

RETURN VALUES

TD_OK The call completed successfully.
TD_BADTA An invalid internal process handle was passed in.
TD_DBERR A call to one of the imported interface routines failed.
TD_ERR Something else went wrong.

ATTRIBUTES

See attributes(5) for description of the following attributes:

SEE ALSO

libthread_db(3THR), thr_getconcurrency(3THR), libthread_db(3LIB), attributes(5)
These routines comprise the thread event facility for libthread_db(3THR). This facility allows the controlling process to be notified when certain thread-related events occur in a target process and to retrieve information associated with these events. An event consists of an event type, and optionally, some associated event data, depending on the event type. See the section titled "Event Set Manipulation Macros" that follows.

The event type and the associated event data, if any, constitute an "event message." "Reporting an event" means delivering an event message to the controlling process by way of libthread_db.
Several flags can control event reporting, both a per-thread and per event basis. Event reporting may further be enabled or disabled for a thread. There is not only a per-thread event mask that specifies which event types should be reported for that thread, but there is also a global event mask that applies to all threads.

An event is reported, if and only if, the executing thread has event reporting enabled, and either the event type is enabled in the executing thread’s event mask, or the event type is enabled in the global event mask.

Each thread has associated with it an event buffer in which it stores the most recent event message it has generated, the type of the most recent event that it reported, and, depending on the event type, some additional information related to that event. See the section titled “Event Set Manipulation Macros” for a description of the td_thr_events_e and td_event_msg_t types and a list of the event types and the values reported with them. The thread handle, type td_thrhndlte_t, the event type, and the possible value, together constitute an event message. Each thread’s event buffer holds at most one event message.

Each event type has an event reporting address associated with it. A thread reports an event by writing the event message into the thread’s event buffer and having control reach the event reporting address for that event type.

Typically, the controlling process sets a breakpoint at the event reporting address for one or more event types. When the breakpoint is hit, the controlling process knows that an event of the corresponding type has occurred.

The event types, and the additional information, if any, reported with each event, are:

- **TD_READY** The thread became ready to execute.
- **TD_SLEEP** The thread has blocked on a synchronization object.
- **TD_SWITCHTO** A runnable thread is being assigned to LWP.
- **TD_SWITCHFROM** A running thread is being removed from its LWP.
- **TD_LOCK_TRY** A thread is trying to get an unavailable lock.
- **TD_CATCHSIG** A signal was posted to a thread.
- **TD_IDLE** An LWP is becoming idle.
- **TD_CREATE** A thread is being created.
- **TD_DEATH** A thread has terminated.
- **TD_PREEMPT** A thread is being preempted.
- **TD_PRI_INHERIT** A thread is inheriting an elevated priority from another thread.
- **TD_REAP** A thread is being reaped.
- **TD_CONCURRENCY** The number of LWPs is changing.
A condition-variable timed wait expired.

The controlling process may then set a breakpoint at that address. If a thread hits that breakpoint, it reports an event of type event.

Enables or disables event reporting for thread th_p. If a thread has event reporting disabled, it will not report any events. Threads are started with event reporting disabled. Event reporting is enabled if on_off is non-zero; otherwise, it is disabled. To find out whether or not event reporting is enabled on a thread, call td_thr_getinfo() for the thread and examine the ti_trace_field of the td_thrinfo_t structure it returns.

Set and clear, respectively, a set of event types in the event mask associated with the thread th_p. To inspect a thread’s event mask, call td_thr_getinfo() for the thread, and examine the ti_events field of the td_thrinfo_t structure it returns.

td_thr_set_event() and td_thr_clear_event() are just like td_ta_set_event() and td_ta_clear_event(), respectively, except that the target process’s global event mask is modified. There is no provision for inspecting the value of a target process’s global event mask.

Returns in *msg the event message associated with thread th_p. Reading a thread’s event message consumes the message, emptying the thread’s event buffer. As noted above, each thread’s event buffer holds at most one event message; if a thread reports a second event before the first event message has been read, the second event message overwrites the first.

Passed a process handle rather than a thread handle. It selects some thread that has an event message buffered, and it returns that thread’s message. The thread selected is undefined, except that as long as at least one thread has an event message buffered, it will return an event message from some such thread.

Several macros are provided for manipulating event sets of type td_thr_events_t:

- **td_event_emptyset**: Sets its argument to the NULL event set.
- **td_event_fillset**: Sets its argument to the set of all events.
- **td_event_addset**: Adds a specific event type to an event set.
- **td_event_delset**: Deletes a specific event type from an event set.
- **td_eventismember**: Tests whether a specific event type is a member of an event set.
- **td_eventisempty**: Tests whether an event set is the NULL set.

The following values may be returned for all thread event routines:
td_ta_event_addr(3THR)

NAME

td_ta_get_nthreads – gets the total number of threads in a process for libthread_db

SYNOPSIS

cc [ flag ... ] file ... -lthread_db [ library ... ]

#include <proc_service.h>
#include <thread_db.h>

td_err_e td_ta_get_nthreads (const td_thragent_t *ta_p, int *

nthread_p);

DESCRIPTION

The td_ta_get_nthreads() function returns the total number of threads in process

\textit{ta}_p, including any system threads. System threads are those created by \texttt{libthread}

or \texttt{libthread_db} on its own behalf. The number of threads is written into \*\textit{nthread}_p.

RETURN VALUES

TD_OK The call completed successfully.

TD_BADTA An invalid internal process handle was passed in.

TD_BADPH There is a NULL external process handle associated with this

internal process handle.

TD_DBERR A call to one of the imported interface routines failed.

TD_ERR \textit{nthread}_p was NULL, or a \texttt{libthread_db} internal error occurred.

td_ta_map_addr2sync(3THR)

NAME  td_ta_map_addr2sync – get a synchronization object handle from a synchronization object’s address

SYNOPSIS  cc [ flag ... ] file ... -lthread_db [ library ... ]

#include <proc_service.h>
#include <thread_db.h>

td_ta_map_addr2sync(const td_thragent_t *ta_p, psaddr_t addr, td_synchandle_t *sh_p);

DESCRIPTION  td_ta_map_addr2sync() produces the synchronization object handle of type td_synchandle_t that corresponds to the address of the synchronization object (mutex, semaphore, condition variable, or reader/writer lock). Some effort is made to validate addr and verify that it does indeed point at a synchronization object. The handle is returned in *sh_p.

RETURN VALUES  
TD_OK The call completed successfully.
TD_BADTA An invalid internal process handle was passed in.
TD_BADPH There is a NULL external process handle associated with this internal process handle.
TD_BADSH sh_p is NULL, or addr does not appear to point to a valid synchronization object.
TD_DBERR A call to one of the imported interface routines failed.
TD_ERR addr is NULL, or a libthread_db internal error occurred.

ATTRIBUTES  See attributes(5) for description of the following attributes:

td_ta_map_id2thr(3THR)

NAME
td_ta_map_id2thr, td_ta_map_lwp2thr – convert a thread id or LWP id to a thread handle

SYNOPSIS
cc [ flag ... ] file ... -lthread_db [ library ... ]
#include <proc_service.h>
#include <thread_db.h>
td_ta_map_id2thr(const td_thragent_t *ta_p, thread_t tid, td_thrhandle_t *th_p);
td_ta_map_lwp2thr(const td_thragent_t *ta_p, lwpid_t lwpid, td_thrhandle_t *th_p);

DESCRIPTION
td_ta_map_id2thr() produces the td_thrhandle_t thread handle that corresponds to a particular thread id, as returned by thr_create(3THR) or thr_self(3THR). The thread handle is returned in *th_p.

td_ta_map_lwp2thr() produces the td_thrhandle_t thread handle for the thread that is currently executing on the light weight process (LWP) and has an id of lwpid.

RETURN VALUES
TD_OK The call completed successfully.
TD_BADTA An invalid internal process handle was passed in.
TD_BADPH There is a NULL external process handle associated with this internal process handle.
TD_DBERR A call to one of the imported interface routines failed.
TD_NOTHR Either there is no thread with the given thread id (td_ta_map_id2thr) or no thread is currently executing on the given LWP (td_ta_map_lwp2thr).
TD_ERR The call did not complete successfully.

ATTRIBUTES See attributes(5) for description of the following attributes:

NAME
td_ta_new, td_ta_delete, td_ta_get_ph – allocate and deallocate process handles for
libthread_db

SYNOPSIS
cc [ flag ... ] file ... -lthread_db [ library ... ]
#include <proc_service.h>
#include <thread_db.h>

td_err_e td_ta_new(const struct ps_prochandle *ph_p,
                   td_thragent_t **ta_pp);

td_err_e td_ta_delete(const td_thragent_t *ta_p);

td_err_e td_ta_get_ph(const td_thragent_t *ta_p, struct
                      ps_prochandle **ph_pp);

DESCRIPTION
td_ta_new() registers a target process with libthread_db and allocates an
internal process handle of type td_thragent_t for this target process. Subsequent
calls to libthread_db can use this handle to refer to this target process.

There are actually two process handles, an internal process handle assigned by
libthread_db and an external process handle assigned by the libthread_db
client. There is a one-to-one correspondence between the two handles. When the client
calls a libthread_db routine, it uses the internal process handle. When
libthread_db calls one of the client-provided routines listed in
proc_service(3PROC), it uses the external process handle.

ph is the external process handle that libthread_db should use to identify this target
process to the controlling process when it calls routines in the imported interface.

If this call is successful, the value of the newly allocated td_thragent_t handle is
returned in *ta_pp. td_ta_delete() deregisters a target process with
libthread_db, which deallocates its internal process handle and frees any other
resources libthread_db has acquired with respect to the target process. ta_p
specifies the target process to be deregistered.

td_ta_get_ph() returns in *ph_pp the external process handle that corresponds to
the internal process handle ta_p. This is useful for checking internal consistency.

RETURN VALUES
TD_OK The call completed successfully.
TD_BADPH A NULL external process handle was passed in to
td_ta_new.
TD_ERR ta_pp is NULL, or an internal error occurred.
TD_DBERR A call to one of the imported interface routines failed.
TD_MALLOC Memory allocation failure.
TD_NOLIBTHREAD The target process does not appear to be
multithreaded.

libthread_db(3THR), proc_service(3PROC), libthread_db(3LIB), attributes(5)
td_ta_setconcurrency(3THR)

NAME  td_ta_setconcurrency – set concurrency level for target process

SYNOPSIS

cc [ flag ... ] file ... -lthread_db [ library ... ]

#include <proc_service.h>
#include <thread_db.h>

td_err_e td_ta_setconcurrency(const td_thragent_t *ta_p, int level);

DESCRIPTION

td_ta_setconcurrency() sets the desired concurrency level for the process identified by ta_p to level, just as if a thread within the process had called thr_setconcurrency(). See thr_setconcurrency(3THR).

RETURN VALUES

TD_OK The call completed successfully.
TD_BADTA An invalid internal process handle was passed in.
TD_BADPH There is a NULL external process handle associated with this internal process handle. TD_NOCAPAB The client did not implement the ps_kill() routine in the imported interface. See ps_kill(3PROC).
TD_DBERR A call to one of the imported interface routines failed.
TD_ERR A libthread_db internal error occurred.

SEE ALSO

libthread_db(3THR), ps_kill(3PROC), thr_setconcurrency(3THR), libthread_db(3LIB), attributes(5)
The td_ta_sync_iter(), td_ta_thr_iter(), and td_ta_tsd_iter() functions are iterator functions that when given a target process handle as an argument, return sets of handles for objects associated with the target process. The method is to call back a client-provided function once for each associated object, passing back a handle as well as the client-provided pointer cb_data_p. This enables a client to easily build a linked list of the associated objects. If the client-provided function returns non-zero, the iteration terminates, even if there are members remaining in the set of associated objects.

The td_ta_sync_iter() function returns handles of synchronization objects (mutexes, readers-writer locks, semaphores, and condition variables) associated with a process. Some synchronization objects might not be known to libthread_db and will not be returned. If the process has initialized the synchronization object (by calling mutex_init(3THR), for example) or a thread in the process has called a synchronization primitive (mutex_lock(), for example) using this object after td_ta_new(3THR) was called to attach to the process and td_ta_sync_tracking_enable() (see td_sync_get_info(3THR)) was called to enable synchronization object tracking, then a handle for the synchronization object will be passed to the callback function. See td_sync_get_info(3THR) for operations that can be performed on synchronization object handles.
The `td_ta_thr_iter()` function returns handles for threads that are part of the target process. For `td_ta_thr_iter()`, the caller specifies several criteria to select a subset of threads for which the callback function should be called. Any of these selection criteria may be wild-carded. If all of them are wild-carded, then handles for all threads in the process will be returned.

The selection parameters and corresponding wild-card values are:

- **state (TD_THR_ANY_STATE):**
  Select only threads whose state matches `state`. See `td_thr_get_info(3THR)` for a list of thread states.

- **ti_pri (TD_THR_LOWEST_PRIORITY):**
  Select only threads for which the priority is at least `ti_pri`.

- **ti_sigmask_p (TD_SIGNO_MASK):**
  Select only threads whose signal mask exactly matches `*ti_sigmask_p`.

- **ti_user_flags (TD_THR_ANY_USER_FLAGS):**
  Select only threads whose user flags (specified at thread creation time) exactly match `ti_user_flags`.

The `td_ta_tsd_iter()` function returns the thread-specific data keys in use by the current process. Thread-specific data for a particular thread and key can be obtained by calling `td_thr_tsd(3THR)`.

### RETURN VALUES

- **TD_OK** The call completed successfully.
- **TD_BADTA** An invalid process handle was passed in.
- **TD_DBERR** A call to one of the imported interface routines failed.
- **TD_ERR** The call did not complete successfully.

td_thr_dbsuspend(3THR)

NAME

td_thr_dbsuspend, td_thr_dbresume – suspend and resume threads in libthread_db

SYNOPSIS

cc [ flag ... ] file ... -lthread_db [ library ... ]

#include <proc_service.h>
#include <thread_db.h>

td_err_e td_thr_dbsuspend(const td_thrhandle_t *th_p);

td_err_e td_thr_dbresume(const td_thrhandle_t *th_p);

DESCRIPTION

These operations suspend and resume the thread identified by th_p. A thread that has
been suspended with td_thr_dbsuspend() is said to be in the "dbsuspended" state.
A thread whose "dbsuspended" flag is set will not execute. If an unbound thread
enters the "dbsuspended" state and is currently assigned to a lightweight process (LWP),
then the LWP becomes available for assignment to a different thread.

A thread’s "dbsuspended" state is independent of the suspension state controlled by
calls to thr_suspend(3THR) and thr_continue(3THR) from within the target
process. Calling thr_continue(3THR) within the target process on a thread that has
been suspended during a call to td_thr_dbsuspend() will not cause that thread to
resume execution; only a call to td_thr_dbresume() will do that.

RETURN VALUES

TD_OK The call completed successfully.

TD_BADTH An invalid thread handle was passed in.

TD_DBERR A call to one of the imported interface routines failed.

TD_NOCAPAB The "agent thread" in the target process has not completed
initialization, so this operation cannot be performed. The operation
can be performed after the target process has been allowed to
make some forward progress. See also libthread_db(3THR)

TD_ERR A libthread_db internal error occurred.

ATTRIBUTES

NAME

td_thr_getgregs, td_thr_setgregs, td_thr_getfpregs, td_thr_setfpregs,
td_thr_getxregsize, td_thr_getxregs, td_thr_setxregs

DESCRIPTION

These routines read and write the register sets associated with thread \texttt{th.p}.
\texttt{td_thr_getgregs()} and \texttt{td_thr_setgregs()} get and set, respectively, the
general registers of thread \texttt{th.p}. \texttt{td_thr_getfpregs()} and \texttt{td_thr_setfpregs()} get
and set, respectively, the thread’s floating point register set.
\texttt{td_thr_getxregsize()}, \texttt{td_thr_getxregs()}, and \texttt{td_thr_setxregs()} are
SPARC-specific. \texttt{td_thr_getxregsize()} returns an \texttt{xregsize} of the
architecture-dependent extra state registers. \texttt{td_thr_getxregs()} and
\texttt{td_thr_setxregs()} get and set, respectively, those extra state registers. On
non-SPARC architectures, these routines return TD_NOXREGS.

If thread \texttt{th.p} is currently executing on a lightweight process (LWP), these routines
will read or write, respectively, the appropriate register set to the LWP using the
imported interface. If the thread is not currently executing on a LWP, then the floating
point and extra state registers may not be read or written. Some of the general
registers may also not be readable or writable, depending on the architecture. In this
case, \texttt{td_thr_getfpregs()} and \texttt{td_thr_setfpregs()} will return
TD_NOFPREGS, and \texttt{td_thr_getxregs()} and \texttt{td_thr_setxregs()} will return
TD_NOXREGS. Calls to \texttt{td_thr_getgregs()} and \texttt{td_thr_setgregs()} will
succeed, but values returned for unreadable registers will be undefined, and values

SYNOPSIS

cc \{ flag ... \} file ... -lthread_db \{ library ... \}

#include <proc_service.h>
#include <thread_db.h>

td_err_e td_thr_getgregs(const td_thrhandle_t *th_p,
prggregset_t *gregset);

td_err_e td_thr_setgregs(const td_thrhandle_t *th_p,
prggregset_t *gregset);

td_err_e td_thr_getfpregs(const td_thrhandle_t *th_p,
prfgregset_t *fpregset);

td_err_e td_thr_setfpregs(const td_thrhandle_t *th_p,
prfgregset_t *fpregset);

td_err_e td_thr_getxregsize(const td_thrhandle_t *th_p, int
*xregsize);

td_err_e td_thr_getxregs(const td_thrhandle_t *th_p, prxregset_t
*xregset);

td_err_e td_thr_setxregs(const td_thrhandle_t *th_p, prxregset_t
*xregset);
specified for unwritable registers will be ignored. In this instance, a value of
TD_PARTIALREGS will be returned. See the architecture-specific notes that follow
regarding the registers that may be read and written for a thread not currently
executing on a LWP.

SPARC On a thread not currently assigned to a LWP, only %i0-%i7, %l0-%l7, %g7, %pc, and
%sp (%o6) may be read or written. %pc and %sp refer to the program counter and
stack pointer that the thread will have when it resumes execution.

x86 Architecture On a thread not currently assigned to a LWP, only %pc, %sp, %ebp, %edi, %edi, and
%ebx may be read.

RETURN VALUES

TD_OK The call completed successfully.
TD_BADTH An invalid thread handle was passed in.
TD_DBERR A call to one of the imported interface routines failed.
TD_PARTIALREGS Because the thread is not currently assigned to a LWP,
not all registers were read or written. See
DESCRIPTION for a discussion about which registers
are not saved when a thread is not assigned to an LWP.

TD_NOPREGS Floating point registers could not be read or written,
either because the thread is not currently assigned to an
LWP, or because the architecture does not have such
registers.

TD_NOXREGS Architecture-dependent extra state registers could not
be read or written, either because the thread is not
currently assigned to an LWP, or because the
architecture does not have such registers, or because
the architecture is not a SPARC architecture.

TD_ERR A libthread_db internal error occurred.

td_thr_get_info(3THR)

NAME
td_thr_get_info – get thread information in libthread_db library of interfaces

SYNOPSIS

cc [ flag ... ] file ... -lthread_db [ library ... ]

#include <proc_service.h>
#include <thread_db.h>

td_err_e td_thr_get_info(const td_thrhandle_t *th_p, td_thrinfo_t *ti_p);

DESCRIPTION

The td_thr_get_info() function fills in the td_thrinfo_t structure *ti_p with values for the thread identified by th_p.

The td_thrinfo_t structure contains the following fields:

typedef struct td_thrinfo_t {
    td_thragent_t *ti_ta_p /* internal process handle */
    unsigned ti_user_flags; /* value of flags parameter */
    thread_t ti_tid; /* thread identifier */
    char *ti_tls; /* pointer to thread-local storage*/
    paddr ti_startfunc; /* address of function at which thread
        execution began*/
    paddr ti_stkbase; /* base of thread’s stack area*/
    int ti_stksize; /* size in bytes of thread’s allocated
        stack region*/
    paddr ti_ro_area; /* address of uthread_t structure*/
    int ti_ro_size /* size of the uthread_t structure in
        bytes */
    td_thr_state_e ti_state /* state of the thread */
    uchar_t ti_db_suspended /* non-zero if thread suspended by
        td_thr_dbsuspend*/
    td_thr_type_e ti_type /* type of the thread*/
    int ti_pc /* value of thread’s program counter*/
    int ti_sp /* value of thread’s stack counter*/
    short ti_flags /* set of special flags used by
        libthread*/
    int ti_pri /* priority of thread returned by
        thr_getprio(3T)*/
    lwpid_t ti_lid /* id of light weight process (LWP)
        executing this thread*/
    sigset_t ti_sigmask /* thread’s signal mask. See
        thr_sigsetmask(3T)*/
    u_char ti_traceeme /* non-zero if event tracing is on*/
    u_char_t ti_premptflag /* non-zero if thread preempted when
        last active*/
    u_char_t ti_pirecflag /* non-zero if thread runs priority
        beside regular */
    sigset_t ti_pending /* set of signals pending for this
        thread*/
    td_thr_events_t ti_events /* bitmap of events enabled for this
        thread*/
} ;

td_thragent_t *ti_ta_p is the internal process handle identifying the process of which the thread is a member.

266 man pages section 3: Threads and Realtime Library Functions • Last Revised 20 Oct 1998
unsigned int ti_user_flags is the value of the flags parameter passed to thr_create(3THR) when the thread was created.

thread_t ti_tid is the thread identifier for the thread returned by libthread when created with thr_create(3THR).

cchar *ti_tls is the thread’s pointer to thread-local storage.

psaddr_t ti_startfunc is the address of the function at which thread execution began, as specified when the thread was created with thr_create(3THR).

psaddr_t ti_stkbase is the base of the thread’s stack area.

int ti_stksize is the size in bytes of the thread’s allocated stack region.

psaddr_t ti_ro_area is the address of the libthread-internal uthread_t structure for this thread. Since accessing the uthread_t structure directly violates the encapsulation provided by libthread_db, this field should generally not be used. However, it may be useful as a prototype for extensions.

td_thr_state_e ti_state is the state in which the thread is. The td_thr_state_e enumeration type may contain the following values:

<table>
<thead>
<tr>
<th>td_thr_state_e</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>TD_THR_ANY_STATE</td>
<td>Never returned by td_thr_get_info. TD_THR_ANY_STATE is used as a wildcard</td>
</tr>
<tr>
<td></td>
<td>to select threads in td_ta_thr_iter().</td>
</tr>
<tr>
<td>TD_THR_UNKNOWN</td>
<td>libthread_db cannot determine the state of the thread.</td>
</tr>
<tr>
<td>TD_THR_STOPPED</td>
<td>The thread has been stopped by a call to thr_suspend(3THR).</td>
</tr>
<tr>
<td>TD_THR_RUN</td>
<td>The thread is runnable, but it is not currently assigned to a LWP.</td>
</tr>
<tr>
<td>TD_THR_ACTIVE</td>
<td>The thread is currently executing on a LWP.</td>
</tr>
<tr>
<td>TD_THR_ZOMBIE</td>
<td>The thread has exited, but it has not yet been deallocated by a call to</td>
</tr>
<tr>
<td></td>
<td>thr_join(3THR).</td>
</tr>
<tr>
<td>TD_THR_SLEEP</td>
<td>The thread is not currently runnable.</td>
</tr>
<tr>
<td>TD_THR_STOPPED_ASLEEP</td>
<td>The thread is both blocked by TD_THR_SLEEP, and stopped by a call to</td>
</tr>
<tr>
<td></td>
<td>td_thr_dbsuspend(3THR).</td>
</tr>
</tbody>
</table>

uchar_t ti_db_suspended is non-zero if and only if this thread is currently suspended because the controlling process has called td_thr_dbsuspend on it.
td_thr_get_info(3THR)

- **td_thr_type** is a type of thread. It will be either `TD_THR_USER` for a user thread (one created by the application), or `TD_THR_SYSTEM` for one created by `libthread`.

- `int ti_pc` is the value of the thread's program counter, provided that the thread's `ti_state` value is `TD_THR_SLEEP`, `TD_THR_STOPPED`, or `TD_THR_STOPPED_ASLEEP`. Otherwise, the value of this field is undefined.

- `int ti_sp` is the value of the thread's stack pointer, provided that the thread's `ti_state` value is `TD_THR_SLEEP`, `TD_THR_STOPPED`, or `TD_THR_STOPPED_ASLEEP`. Otherwise, the value of this field is undefined.

- `short ti_flags` is a set of special flags used by `libthread`, currently of use only to those debugging `libthread`.

- `int ti_pri` is the thread's priority, as it would be returned by `thr_getprio(3THR)`.

- `lwpid_t ti_lid` is the ID of the LWP executing this thread, or the ID of the LWP that last executed this thread, if this thread is not currently assigned to a LWP.

- `sigset_t ti_sigmask` is this thread's signal mask. See `thr_sigsetmask(3THR)`.

- `uchar_t ti_traceflag` is non-zero if and only if event tracing for this thread is on.

- `uchar_t ti_preemptflag` is non-zero if and only if the thread was preempted the last time it was active.

- `uchar_t ti_pirecflag` is non-zero if and only if due to priority inheritance the thread is currently running at a priority other than its regular priority.

- `td_thr_events_t ti_events` is the bitmap of events enabled for this thread.

### RETURN VALUES

- **TD_OK** The call completed successfully.
- **TD_BADTH** An invalid thread handle was passed in.
- **TD_DBERR** A call to one of the imported interface routines failed.
- **TD_ERR** The call did not complete successfully.

td_thr_lockowner(3THR)

NAME
td_thr_lockowner – iterate over the set of locks owned by a thread

SYNOPSIS
cc [ flag ... ] file ... -lthread_db [ library ... ]

#include <proc_service.h>
#include <thread_db.h>

td_err_e td_thr_lockowner(const td_thrhandle_t *th_p,
    td_sync_iter_f *cb, void *cb_data_p);

DESCRIPTION
td_thr_lockowner() calls the iterator function cb once for every mutex that is held
by the thread whose handle is th_p. The synchronization handle and the pointer
cb_data_p are passed to the function. See td_ta_thr_iter(3THR) for a similarly
structured function.

Iteration terminates early if the callback function cb returns a non-zero value.

RETURN VALUES

TD_OK The call completed successfully.

TD_BADTH An invalid thread handle was passed in.

TD_BADPH There is a NULL external process handle associated with this
internal process handle.

TD_DBERR A call to one of the imported interface routines failed.

TD_ERR A libthread_db internal error occurred.

ATTRIBUTES

Threads and Realtime Library Functions 269
td_thr_setprio(3THR)

NAME    td_thr_setprio – set the priority of a thread

SYNOPSIS  cc [ flag ... ] file ... -lthread_db [ library ... ]

#include <proc_service.h>
#include <thread_db.h>

td_err_e td_thr_setprio(const td_thrhandle_t *th_p, const int new_prio);

DESCRIPTION  td_thr_setprio() sets thread th_p’s priority to new_prio, just as if a thread within
the process had called thr_setprio(.). See thr_setprio(3THR).

RETURN VALUES
TD_OK         The call completed successfully.
TD_BADTH     An invalid thread handle was passed in.
TD_DBERR     A call to one of the imported interface routines failed.
TD_ERR       new_prio is an illegal value (out of range).

ATTRIBUTES  See attributes(5) for description of the following attributes:

NAME

td_thr_setsigpending, td_thr_sigsetmask – manage thread signals for libthread_db

SYNOPSIS

cc [ flag ... ] file ... -lthread_db [ library ... ]

#include <proc_service.h>
#include <thread_db.h>

td_err_e td_thr_setsigpending(const td_thrhandle_t *th_p, const uchar_t ti_sigpending_flag, const sigset_t ti_sigmask);

td_err_e td_thr_sigsetmask(const td_thrhandle_t *th_p, const sigset_t ti_sigmask);

DESCRIPTION

The td_thr_setsigpending() and td_thr_setsigmask() operations affect the signal state of the thread identified by th_p.

td_thr_setsigpending() sets the set of pending signals for thread th_p to ti_sigpending. The value of the libthread-internal field that indicates whether a thread has any signal pending is set to ti_sigpending_flag. To be consistent, ti_sigpending_flag should be zero if and only if all of the bits in ti_sigpending are zero.

td_thr_sigsetmask() sets the signal mask of the thread th_p as if the thread had set its own signal mask by way of thr_sigsetmask(3THR). The new signal mask is the value of ti_sigmask.

There is no equivalent to the SIG_BLOCK or SIG_UNBLOCK operations of thr_sigsetmask(3THR), which mask or unmask specific signals without affecting the mask state of other signals. To block or unblock specific signals, either stop the whole process, or the thread, if necessary, by td_thr_dbsuspend(). Then determine the thread’s existing signal mask by calling td_thr_get_info() and reading the ti_sigmask field of the td_thrinfo_t structure returned. Modify it as desired, and set the new signal mask with td_thr_sigsetmask().

RETURN VALUES

TD_OK The call completed successfully.
TD_BADTH An invalid thread handle was passed in.
TD_DBERR A call to one of the imported interface routines failed.
TD_ERR A libthread_db internal error occurred.

### NAME

td_thr_sleepinfo(3THR)

#### SYNOPSIS

```c
cc [ flag ... ] file ... -lthread_db [ library ... ]

#include <proc_service.h>
#include <thread_db.h>

td_err_e td_thr_sleepinfo(const td_thrhandle_t *th_p,
    td_synchandle_t *sh_p);
```

#### DESCRIPTION

td_thr_sleepinfo() returns in *sh_p the handle of the synchronization object on which a sleeping thread is blocked.

#### RETURN VALUES

- **TD_OK**: The call completed successfully.
- **TD_BADTH**: An invalid thread handle was passed in.
- **TD_DBERR**: A call to one of the imported interface routines failed.
- **TD_ERR**: The thread th_p is not blocked on a synchronization object, or a libthread_db internal error occurred.

#### ATTRIBUTES

See attributes(5) for description of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>

NAME       td_thr_tsd – get a thread’s thread-specific data for libthread_db library of interfaces

SYNOPSIS   cc [ flag ... ] file ... -lthread_db [ library ... ]

#include <proc_service.h>
#include <thread_db.h>

td_err_e td_thr_tsd(const td_thrhandle_t, const thread_key_t key,
        void *data_pp);

DESCRIPTION td_thr_tsd() returns in *data_pp the thread-specific data pointer for the thread
identified by th_p and the thread-specific data key key. This is the same value that
thread th_p would obtain if it called thr_getspecific(3THR).

To find all the thread-specific data keys in use in a given target process, call
td_ta_tsd_iter(3THR).

RETURN VALUES

TD_OK       The call completed successfully.
TD_BADTH    An invalid thread handle was passed in.
TD_DBERR    A call to one of the imported interface routines failed.
TD_ERR      A libthread_db internal error occurred.

ATTRIBUTES  See attributes(5) for description of the following attributes:

td_thr_validate(3THR)

NAME  td_thr_validate – test a thread handle for validity

SYNOPSIS  cc [ flag ... ] file ... -lthread_db [ library ... ]
#include <proc_service.h>
#include <thread_db.h>

td_err_e td_thr_validate(const td_thrhandle_t *th_p);

DESCRIPTION  td_thr_validate() tests whether th_p is a valid thread handle. A valid thread handle may become invalid if its thread exits.

RETURN VALUES  
TD_OK  The call completed successfully. th_p is a valid thread handle.

TD_BADTH  th_p was NULL.

TD_DBERR  A call to one of the imported interface routines failed.

TD_NOTHR  th_p is not a valid thread handle.

TD_ERR  A libthread_db internal error occurred.

ATTRIBUTES  See attributes(5) for description of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>MT-Level</td>
<td>Safe</td>
</tr>
</tbody>
</table>

SEE ALSO  libthread_db(3THR), libthread_db(3LIB), attributes(5)
Thread creation adds a new thread of control to the current process. The procedure main() is a single thread of control. Each thread executes concurrently with all other threads within the calling process and with other threads from other active processes. Although a newly created thread shares all of the calling process’s global data with the other threads in the process, it has its own set of attributes and private execution stack. The new thread inherits the calling thread’s signal mask, possibly, and scheduling priority. Pending signals for a new thread are not inherited and will be empty.

The call to create a thread takes the address of a user-defined function, specified by start_func, as one of its arguments. This function is the complete execution routine for the new thread.

The lifetime of a thread begins with the successful return from thr_create(), which calls start_func() and ends with one of the following:

- the normal completion of start_func(),
- the return from an explicit call to thr_exit(3THR), or
- the conclusion of the calling process (see exit(2)).

The new thread performs by calling the function defined by start_func with only one argument, arg. If more than one argument needs to be passed to start_func, the arguments can be packed into a structure, the address of which can be passed to arg.

If start_func returns, the thread terminates with the exit status set to the start_func return value (see thr_exit(3THR)).

When the thread from which main() originated returns, the effect is the same as if an implicit call to exit() were made using the return value of main() as the exit status. This behavior differs from a start_func return. If main() calls thr_exit(3THR), only the main thread exits, not the entire process.

If the thread creation fails, a new thread is not created and the contents of the location referenced by the pointer to the new thread are undefined.

The flags argument specifies which attributes are modifiable for the created thread. The value in flags is determined by the bitwise inclusive-OR of the following:

- **THR_BOUND**: This flag affects the contentionscope attribute of the thread. The new thread is created permanently bound to an LWP (that is, it is a bound thread.)
- **THR_DETACHED**: This flag affects the detachstate attribute of the thread. The new thread is created detached. The exit status of a detached thread is
thr_create(3THR)

not accessible to other threads. Its thread ID and other resources
may be re-used as soon as the thread terminates.
thr_join(3THR) will not wait for a detached thread.

THR_NEW_LWP This flag is obsolete and is maintained for compatibility.

THR_SUSPENDED This flag affects the suspended attribute of the thread. The new
thread is created suspended and will not execute start_func until it
is started by thr_continue().

THR_DAEMON This flag affects the daemon attribute of the thread. In addition to
being created detached (THR_DAEMON implies THR_DETACHED),
the thread is marked as a daemon. Daemon threads do not
interfere with the exit conditions for a process. A process will
terminate when the last non-daemon thread exits or the process
calls exit(2). Also, a thread that is waiting in thr_join() for any
thread to terminate will return EDEADLK when all remaining
threads in the process are either daemon threads or other threads
waiting in thr_join(). Daemon threads are most useful in
libraries that want to use threads.

Default thread creation:

thread_t tid;
void *start_func(void *), *arg;
thr_create(NULL, NULL, start_func, arg, NULL, &tid);

User-defined thread creation (create a bound permanently to an LWP, that is, a bound
thread):

thr_create(NULL, NULL, start_func, arg, THR_BOUND, &tid);

With thr_create(), the new thread uses the stack beginning at the address
specified by stack_base and continuing for stack_size bytes. The stack_size argument
must be greater than the value returned by thr_min_stack(3THR). If stack_base is
NULL, thr_create() allocates a stack for the new thread with at least stack_size
bytes. If stack_size is 0, a default size is used. If stack_size is not 0, it must be greater
than the value returned by thr_min_stack(3THR) See NOTES.

When new_thread_ID is not NULL, it points to a location where the ID of the new
thread is stored if thr_create() is successful. The ID is only valid within the calling
process.

RETURN VALUES
If successful, the thr_create() function returns 0. Otherwise, an error value is
returned to indicate the error. If the application is not linked with the threads library,
-1 is returned.

ERRORS
EAGAIN The system-imposed limit on the total number of threads in a
process has been exceeded or some system resource has been
exceeded (for example, too many LWPs were created).
EINVAL

The stack_base argument is not NULL and stack_size is less than the value returned by thr_min_stack(3THR), or the stack_base argument is NULL and stack_size is not 0 and is less than the value returned by thr_min_stack(3THR).

ENOMEM

The system cannot allocate stack for the thread.

The thr_create() function may use mmap() to allocate thread stacks from MAP_PRIVATE, MAP_NORESERVE, and MAP_ANON memory mappings if stack_base is NULL, and consequently may return upon failure the relevant error values returned by mmap(). See the mmap(2) manual page for these error values.

EXAMPLES

EXAMPLE 1 This is an example of concurrency with multi-threading. Since POSIX threads and Solaris threads are fully compatible even within the same process, this example uses pthread_create() if you execute a.out 0, or thr_create() if you execute a.out 1.

Five threads are created that simultaneously perform a time-consuming function, sleep(10). If the execution of this process is timed, the results will show that all five individual calls to sleep for ten-seconds completed in about ten seconds, even on a uniprocessor. If a single-threaded process calls sleep(10) five times, the execution time will be about 50-seconds.

The command-line to time this process is:

/usr/bin/time a.out 0 (for POSIX threading)

or

/usr/bin/time a.out 1 (for Solaris threading)

/* cc thisfile.c -lthread -lpthread */
#define _REENTRANT /* basic 3-lines for threads */
#include <pthread.h>
#include <thread.h>
#define NUM_THREADS 5
#define SLEEP_TIME 10

void *sleeping(void *); /* thread routine */
int i;
thread_t tid[NUM_THREADS]; /* array of thread IDs */

int
main(int argc, char *argv[])
{
    if (argc == 1) {
        printf("use 0 as arg1 to use pthread_create( )\n");
        printf("or use 1 as arg1 to use thr_create( )\n");
        return (1);
    }

    switch (*argv[1]) {
    case '0': /* POSIX */
        for (i = 0; i < NUM_THREADS; i++)
            pthread_create(&tid[i], NULL, sleeping,

threads and Realtime Library Functions 277
EXAMPLE 1
This is an example of concurrency with multi-threading. Since POSIX threads and Solaris threads are fully compatible even within the same process, this example uses pthread_create() if you execute a.out 0, or thr_create() if you execute a.out 1.

```
(void *)SLEEP_TIME);
for ( i = 0; i < NUM_THREADS; i++)
    pthread_join(tid[i], NULL);
break;

case '1': /* Solaris */
    for ( i = 0; i < NUM_THREADS; i++)
        thr_create(NULL, 0, sleeping, (void *)SLEEP_TIME, 0,
            stdid[i]);
    while (thr_join(0, NULL, NULL) == 0)
        break;
    break;
} /* switch */
printf("main( ) reporting that all %d threads have terminated\n", i);
return (0);
}
``` 

Had main() not waited for the completion of the other threads (using pthread_join(3THR) or thr_join(3THR)), it would have continued to process concurrently until it reached the end of its routine and the entire process would have exited prematurely (see exit(2)).

EXAMPLE 2
Creating a default thread with a new signal mask.

The following example demonstrates how to create a default thread with a new signal mask. The new_mask argument is assumed to have a value different from the creator's signal mask (orig_mask). The new_mask argument is set to block all signals except for SIGINT. The creator's signal mask is changed so that the new thread inherits a different mask, and is restored to its original value after thr_create() returns.

```
thread_t tid;

sigset_t new_mask, orig_mask;
int error;

(void) sigfillset(&new_mask);
```
EXAMPLE 2 Creating a default thread with a new signal mask.  (Continued)

(voi)d sigdelset (&new_mask, SIGINT);
(void) thr_sigsetmask(SIG_SETMASK, &new_mask, &orig_mask);
error = thr_create(NULL, 0, do_func, NULL, 0, &tid);
(void) thr_sigsetmask(SIG_SETMASK, &orig_mask, NULL);

NOTES  Since multithreaded-application threads execute independently of each other, their relative behavior is unpredictable. It is therefore possible for the thread executing main() to finish before all other user-application threads.

Using thr_join(3THR) in the following syntax,

while (thr_join(0, NULL, NULL) == 0);

will cause the invoking thread (which may be main()) to wait for the termination of all non-daemon threads, excluding threads that are themselves waiting in thr_join(); however, the second and third arguments to thr_join() need not necessarily be NULL.

A thread has not terminated until thr_exit() has finished. The only way to determine this is by thr_join(). When thr_join() returns a departed thread, it means that this thread has terminated and its resources are reclaimable. For instance, if a user specified a stack to thr_create(), this stack can only be reclaimed after thr_join() has reported this thread as a departed thread. It is not possible to determine when a detached thread has terminated. A detached thread disappears without leaving a trace.

Typically, thread stacks allocated by thr_create() begin on page boundaries and any specified (a red-zone) size is rounded up to the next page boundary. A page with no access permission is appended to the top of the stack so that most stack overflows will result in a SIGSEGV signal being sent to the offending thread. Thread stacks allocated by the caller are used as is.

Using a default stack size for the new thread, instead of passing a user-specified stack size, results in much better thr_create() performance. The default stack size for a user-thread is 1 megabyte in a 32-bit process and 2 megabyte in a 64-bit process.
A user-specified stack size must be greater than the value THR_MIN_STACK. A minimum stack size may not accommodate the stack frame for the user thread function start_func. If a stack size is specified, it must accommodate start_func requirements and the functions that it may call in turn, in addition to the minimum requirement.

It is usually very difficult to determine the runtime stack requirements for a thread. THR_MIN_STACK specifies how much stack storage is required to execute a NULL start_func. The total runtime requirements for stack storage are dependent on the storage required to do runtime linking, the amount of storage required by library runtimes (like printf()) that your thread calls. Since these storage parameters are not known before the program runs, it is best to use default stacks. If you know your runtime requirements or decide to use stacks that are larger than the default, then it makes sense to specify your own stacks.
Threads and Realtime Library Functions

| NAME | threads, pthreads – concepts related to POSIX pthreads and Solaris threads and the libpthread and libthread libraries |
| SYNOPSIS | |
| POSIX | cc -mt [ flag... ] file... -lpthread [ -lrt library... ]  
#include <pthread.h> |
| Solaris | cc -mt [ flag... ] file...[ library... ]  
#include <sched.h>  
#include <thread.h> |
<p>| DESCRIPTION | POSIX and Solaris threads each have their own implementation of the threads library. The libpthread library is associated with POSIX; the libthread library is associated with Solaris. Both implementations are interoperable, their functionality similar, and can be used within the same application. Only POSIX threads are guaranteed to be fully portable to other POSIX-compliant environments. POSIX and Solaris threads require different source, include files and linking libraries. See SYNOPSIS. |
| Similarities | Most of the functions in the libpthread and libthread, libraries have a counterpart in the other corresponding library. POSIX function names, with the exception of the semaphore names, have a &quot;pthread&quot; prefix. Function names for similar POSIX and Solaris have similar endings. Typically, similar POSIX and Solaris functions have the same number and use of arguments. |
| Differences | POSIX pthreads and Solaris threads differ in the following ways: |
| | - POSIX threads are more portable. |
| | - POSIX threads establish characteristics for each thread according to configurable attribute objects. |
| | - POSIX pthreads implement thread cancellation. |
| | - POSIX pthreads enforce scheduling algorithms. |
| | - POSIX pthreads allow for clean-up handlers for fork(2) calls. |
| | - Solaris threads can be suspended and continued. |
| | - Solaris threads implement an optimized mutex and interprocess robust mutex locks. |
| | - Solaris threads implement daemon threads, for whose demise the process does not wait. |
| Function Comparison | The following table compares the POSIX pthreads and Solaris threads functions. When a comparable interface is not available either in POSIX pthreads or Solaris threads, a hyphen (-) appears in the column. |</p>

Synchronizing multiple threads diminishes their concurrency. The coarser the grain of synchronization, that is, the larger the block of code that is locked, the lesser the concurrency.

If a POSIX threads program calls `fork()`, it implicitly calls `fork1()`, which replicates only the calling thread. Should there be any outstanding mutexes throughout the process, the application should call `pthread_atfork()` to wait for and acquire those mutexes prior to calling `fork()`.

### SCHEDULING

#### POSIX

Scheduling allocation size per thread is greater than one. POSIX supports the following three scheduling policies:

- **SCHED_OTHER**: Timesharing (TS) scheduling policy. It is based on the timesharing scheduling class.
- **SCHED_FIFO**: First-In-First-Out (FIFO) scheduling policy. Threads scheduled to this policy, if not pre-empted by a higher priority, will proceed until completion. Threads whose contention scope is system (PTHREAD_SCOPE_SYSTEM) are in real-time (RT) scheduling class. The calling process must have an effective user ID of 0. 
  - `SCHED_FIFO` for threads whose contention scope’s process (PTHREAD_SCOPE_PROCESS) is based on the TS scheduling class.
- **SCHED_RR**: Round-Robin scheduling policy. Threads scheduled to this policy, if not pre-empted by a higher priority, will execute for a time period determined by the system. Threads whose contention scope is system (PTHREAD_SCOPE_SYSTEM) are in real-time (RT) scheduling class and the calling process must have an effective user ID of 0. 
  - `SCHED_RR` for threads whose contention scope is process (PTHREAD_SCOPE_PROCESS) is based on the TS scheduling class.

#### Solaris

Only scheduling policy supported is `SCHED_OTHER`, which is timesharing, based on the TS scheduling class.
In a multi-threaded application, linked with libpthread or libthread, EINTR may be returned whenever another thread calls fork(2), which calls fork1(2) instead. To ensure proper library linking order, use this option, rather than -lthread, to link with libthread.

**ERRORS**

The -mt compiler option compiles and links for multithreaded code. It compiles source files with -D_REENTRANT and augments the set of support libraries to include -lthread in the required order.

To ensure proper library linking order, use this option rather than -lthread to link with libthread.

Linker and Libraries Guide
thr_exit(3THR)

NAME
thr_exit – terminate the calling thread

SYNOPSIS
c -m [ flag... ] file[ library... ]
#include <thread.h>

void thr_exit(void *status);

DESCRIPTION
The thr_exit() function terminates the calling thread, in a similar way that
exit(3C) terminates the calling process. If the calling thread is not detached, then the
thread’s ID and the exit status specified by status are retained. The value status is then
made available to any successful join with the terminating thread (see
thr_join(3THR)); otherwise, status is disregarded allowing the thread’s ID to be
reclaimed immediately.

Any cancellation cleanup handlers that have been pushed and not yet popped are
popped in the reverse order that they were pushed and then executed. After all
cancellation cleanup handlers have been executed, if the thread has any thread-specific
data, appropriate destructor functions will be called in an unspecified order. Thread
termination does not release any application visible process resources, including, but
not limited to, mutexes and file descriptors, nor does it perform any process level
cleanup actions, including, but not limited to, calling any atexit() routines that may
exist.

If any thread, including the main() thread, calls thr_exit(), only that thread will
exit.

If main() returns or exits (either implicitly or explicitly), or any thread explicitly calls
exit(), the entire process will exit.

The behavior of thr_exit() is undefined if called from a cancellation cleanup
handler or destructor function that was invoked as a result of either an implicit or
explicit call to thr_exit().

After a thread has terminated, the result of access to local (auto) variables of the thread
is undefined. Thus, references to local variables of the exiting thread should not be
used for the thr_exit() status parameter value.

If any thread (except the main() thread) implicitly or explicitly returns, the result is
the same as if the thread called thr_exit() and it will return the value of status as
the exit code.

The process will terminate with an exit status of 0 after the last non-daemon thread
has terminated (including the main() thread). This behavior is the same as if the
application had called exit() with a 0 argument at thread termination time.

RETURN VALUES
The thr_exit() function cannot return to its caller.

ERRORS
No errors are defined.
ATTRIBUTES
See attributes(5) for descriptions of the following attributes:

SEE ALSO
exit(3C), thr_create(3THR), thr_join(3THR), thr_keycreate(3THR), attributes(5), standards(5)

NOTES
Although only POSIX implements cancellation, cancellation can be used with Solaris threads, due to their interoperability.

The status argument should not reference any variables local to the calling thread.
thr_getconcurrency(3THR)

NAME
thr_getconcurrency, thr_setconcurrency — get or set thread concurrency level

SYNOPSIS
cc -mt [ flag... ] file...[ library... ]

#include <thread.h>

int thr_setconcurrency(int new_level);
int thr_getconcurrency(void);

DESCRIPTION
These functions are obsolete and maintained for compatibility only. The
thr_setconcurrency() function updates the desired concurrency level that
libthread maintains for the calling process. This value does not affect the behavior
of the calling process.

The thr_getconcurrency() function returns the current value for the desired
concurrency level.

RETURN VALUES
The thr_getconcurrency() function always returns the current value for the
desired concurrency level.

If successful, the thr_setconcurrency() function returns 0. Otherwise, a non-zero
value is returned to indicate the error.

ERRORS
The thr_setconcurrency() function will fail if:

EAGAIN The specified concurrency level would cause a system resource to
be exceeded.

EINVAL The value for new_level is negative.

ATTRIBUTES
See attributes(5) for descriptions of the following attributes:

</tr>
</thead>
<tbody>
<tr>
<td>MT-Level</td>
<td>MT-Safe</td>
</tr>
</tbody>
</table>

SEE ALSO
thr_create(3THR), attributes(5), standards(5)
The `thr_setprio()` function dynamically changes the priority of the thread specified by `target_thread` within the current process to the priority specified by `priority`. By default, threads contend for synchronization objects based on fixed priorities that range from 0, the least significant, to 127. The `target_thread` will receive precedence by `libthread` over lower priority threads with respect to synchronization object contention.

The `thr_getprio()` function stores the current priority for the thread specified by `target_thread` in the location pointed to by `priority`. Thread priorities regulate the order in which threads unblock from synchronization objects and are different from realtime priorities, which regulate and enforce access to CPU resources. Programs that need access to "real" priorities should use bound threads in the realtime class (see `priocntl(2)`).

If successful, the `thr_getprio()` and `thr_setprio()` return 0. Otherwise, an error number is returned to indicate the error.

For each of the following conditions, these functions return an error number if the condition is detected.

- **ESRCH**                   The value specified by `target_thread` does not refer to an existing thread.

The `thr_getprio()` and `thr_setprio()` functions may fail if:

- **EINVAL**                  The value of `priority` makes no sense for the scheduling class associated with the `target_thread`.

See `attributes(5)` for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>MT-Level</td>
<td>MT-Safe</td>
</tr>
</tbody>
</table>

See also `priocntl(2), sched_setparam(3RT), thr_create(3THR), thr_suspend(3THR), thr_yield(3THR), attributes(5), standards(5)`
The `thr_join()` function suspends processing of the calling thread until the target thread completes. The `thread` argument must be a member of the current process and cannot be a detached thread. See `thr_create(3THR)`.

If two or more threads wait for the same thread to complete, all will suspend processing until the thread has terminated, and then one thread will return successfully and the others will return with an error of ESRCH. The `thr_join()` function will not block processing of the calling thread if the target `thread` has already terminated.

If a `thr_join()` call returns successfully with a non-null `status` argument, the value passed to `thr_exit(3THR)` by the terminating thread will be placed in the location referenced by `status`.

If the target `thread` ID is 0, `thr_join()` finds and returns the status of a terminated undetached thread in the process. If no such thread exists, it suspends processing of the calling thread until a thread for which no other thread is waiting enters that state, at which time it returns successfully, or until all other threads in the process are either daemon threads or threads waiting in `thr_join()`, in which case it returns EDEADLK. See NOTES.

If `departed` is not NULL, it points to a location that is set to the ID of the terminated thread if `thr_join()` returns successfully.

If successful, `thr_join()` returns 0. Otherwise, an error number is returned to indicate the error.

**ERRORS**

- **EDEADLK**: A joining deadlock would occur, such as when a thread attempts to wait for itself, or the calling thread is waiting for any thread to exit and only daemon threads or waiting threads exist in the process.
- **ESRCH**: No undetached thread could be found corresponding to the given thread ID.

**ATTRIBUTES**

See attributes(5) for descriptions of the following attributes:

`wait(2), thr_create(3THR), thr_exit(3THR), attributes(5), standards(5)`
Using `thr_join(3THR)` in the following syntax,

```c
while (thr_join(0, NULL, NULL) == 0);
```

will wait for the termination of all non-daemon threads, excluding threads that are themselves waiting in `thr_join()`.
thr_keycreate(3THR)

NAME  thr_keycreate, thr_setspecific, thr_getspecific – thread-specific-data functions

SYNOPSIS

cc -mt [ flag... ] file... [ library... ]

#include <thread.h>

int thr_keycreate(thread_key_t *keyp, void (*destructor, void *value);
int thr_setspecific(thread_key_t key, void *value);
int thr_getspecific(thread_key_t key, void **valuep);

DESCRIPTION

Create Key

In general, thread key creation allocates a key that locates data specific to each thread in the process. The key is global to all threads in the process, which allows each thread to bind a value to the key once the key has been created. The key independently maintains specific values for each binding thread. The thr_keycreate() function allocates a global key namespace, pointed to by keyp, that is visible to all threads in the process. Each thread is initially bound to a private element of this key, which allows access to its thread-specific data.

Upon key creation, a new key is assigned the value NULL for all active threads. Additionally, upon thread creation, all previously created keys in the new thread are assigned the value NULL.

Optionally, a destructor function, destructor, may be associated with each key. Upon thread exit, if a key has a non-NULL destructor function and the thread has a non-NULL value associated with that key, the destructor function is called with the current associated value. If more than one destructor exists for a thread when it exits, the order of destructor calls is unspecified.

Set Value

Once a key has been created, each thread may bind a new value to the key using thr_setspecific(). The values are unique to the binding thread and are individually maintained. These values continue for the life of the calling thread.

Proper synchronization of key storage and access must be ensured by the caller. The value argument to thr_setspecific() is generally a pointer to a block of dynamically allocated memory reserved by the calling thread for its own use. See EXAMPLES.

At thread exit, the destructor function, which is associated at time of creation, is called and it uses the specific key value as its sole argument.

Get Value

thr_getspecific() stores the current value bound to key for the calling thread into the location pointed to by valuep.

RETURN VALUES

If successful, thr_keycreate(), thr_setspecific() and thr_getspecific() return 0. Otherwise, an error number is returned to indicate the error.

ERRORS

If the following conditions occur, thr_keycreate() returns the corresponding error number.
EAGAIN  The system lacked the necessary resources to create another thread-specific data key.
ENOMEM  Insufficient memory exists to create the key.

If the following conditions occur, `thr_keycreate()` and `thr_setspecific()` return the corresponding error number:
ENOMEM  Insufficient memory exists to associate the value with the key.
The `thr_setspecific()` function returns the corresponding error number:
EINVAL  The key value is invalid.

EXAMPLE 1 In this example, the thread-specific data in this function can be called from more than one thread without special initialization.

For each argument you pass to the executable of this example, a thread is created and privately bound to the string-value of that argument.

```c
/* cc thisfile.c */
#include <thread.h>

#define _REENTRANT
void *thread_specific_data(), free();
#define MAX_ARGC 20
thread_t tid[MAX_ARGC];
int num_threads;

main( int argc, char *argv[] ) {
    int i;
    num_threads = argc - 1;
    for (i = 0; i < num_threads; i++)
        thr_create(NULL, 0, thread_specific_data, argv[i+1], 0, &tid[i]);
    for (i = 0; i < num_threads; i++)
        thr_join(tid[i], NULL, NULL);
} /* end main */

void *thread_specific_data(char private_data[])
{
    static mutex_t keylock; /* static ensures only one copy of keylock */
    static thread_key_t key;
    static int once_per_keyname = 0;
    void *tsd = NULL;

    if (!once_per_keyname) {
        mutex_lock(&keylock);
        if (!once_per_keyname) {
            thr_keycreate(&key, free);
            once_per_keyname++;
        }
        mutex_unlock(&keylock);
    }
    thr_getspecific(key, &tsd);
    if (tsd == NULL) {
EXAMPLE 1 In this example, the thread-specific data in this function can be called from more than one thread without special initialization. (Continued)

```c
  tsd = (void *)malloc(strlen(private_data) + 1);
  strcpy(tsd, private_data);
  thr_setspecific(key, tsd);
  thr_getspecific(key, &tsd);
  printf("tsd for %d = %s\n", thr_self(), tsd);
  thr_getspecific(key, &tsd);
  printf("tsd for %d remains %s\n", thr_self(), tsd);
} /* end thread_specific_data */

void
free(void *v) {
  /* application-specific clean-up function */
}
```

WARNINGS The thr_getspecific() and thr_getspecific() functions may be called either explicitly, or implicitly from a thread-specific data destructor function. Calling thr_setspecific() from a destructor may result in lost storage or infinite loops.
NAME  thr_kill – send a signal to a thread

SYNOPSIS  cc -mt [ flag... ] file... [ library... ]

```
#include <signal.h>
#include <thread.h>

int thr_kill(thread_t thread, int sig);
```

DESCRIPTION  thr_kill() sends the sig signal to the thread designated by thread. thread must be a
member of the same process as the calling thread. sig must be one of the signals listed
in signal(3HEAD); with the exception of SIGLWP, SIGCANCEL, and SIGWAITING
being reserved and off limits to thr_kill(). If sig is 0, a validity check is done for
the existence of the target thread; no signal is sent.

RETURN VALUES  Upon successful completion, thr_kill() returns 0. Otherwise, an error number is
returned. In the event of failure, no signal is sent.

ERRORS  ESRCH  No thread was found that corresponded to the thread designated
by thread ID.

EINVAL  The sig argument value is not zero and is an invalid or an
unsupported signal number.

thr_min_stack – return the minimum-allowable size for a thread’s stack

**SYNOPSIS**

```c
#include <thread.h>
size_t thr_min_stack(void);
```

**DESCRIPTION**

When a thread is created with a user-supplied stack, the user must reserve enough space to run this thread. In a dynamically linked execution environment, it is very hard to know what the minimum stack requirements are for a thread. The function `thr_min_stack()` returns the amount of space needed to execute a null thread. This is a thread that was created to execute a null procedure. A thread that does something useful should have a stack size that is `thr_min_stack()` + `<some increment>`.

Most users should not be creating threads with user-supplied stacks. This functionality was provided to support applications that wanted complete control over their execution environment.

Typically, users should let the threads library manage stack allocation. The threads library provides default stacks which should meet the requirements of any created thread.

`thr_min_stack()` will return the unsigned int `THR_MIN_STACK`, which is the minimum-allowable size for a thread’s stack.

In this implementation the default size for a user-thread’s stack is one mega-byte. If the second argument to `thr_create(3THR)` is NULL, then the default stack size for the newly-created thread will be used. Otherwise, you may specify a stack-size that is at least `THR_MIN_STACK`, yet less than the size of your machine’s virtual memory.

It is recommended that the default stack size be used.

To determine the smallest-allowable size for a thread’s stack, execute the following:

```c
/* cc thisfile.c -lthread */
#define _REENTRANT
#include <thread.h>
#include <stdio.h>
main( ) {
   printf("thr_min_stack( ) returns %u\n",thr_min_stack( ));
}
```

**ATTRIBUTES**

thr_self(3THR)

NAME  thr_self – get calling thread’s ID

SYNOPSIS  cc -mt [ flag... ] file...[ library... ]
           #include <thread.h>
           thread_t thr_self(void);
           typedef(unsigned int thread_t);

DESCRIPTION  thr_self() returns the thread ID of the calling thread.

ERRORS  No errors are defined.

ATTRIBUTES  See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>MT-Level</td>
<td>MT-Safe</td>
</tr>
</tbody>
</table>

SEE ALSO  thr_create(3THR), attributes(5), standards(5)
The `thr_sigsetmask()` function changes or examines a calling thread’s signal mask. Each thread has its own signal mask. A new thread inherits the calling thread’s signal mask and priority; however, pending signals are not inherited. Signals pending for a new thread will be empty.

If the value of the argument `set` is not `NULL`, `set` points to a set of signals that can modify the currently blocked set. If the value of `set` is `NULL`, the value of `how` is insignificant and the thread’s signal mask is unmodified; thus, `thr_sigsetmask()` can be used to inquire about the currently blocked signals.

The value of the argument `how` specifies the method in which the set is changed and takes one of the following values:

- **SIG_BLOCK**: `set` corresponds to a set of signals to block. They are added to the current signal mask.
- **SIG_UNBLOCK**: `set` corresponds to a set of signals to unblock. These signals are deleted from the current signal mask.
- **SIG_SETMASK**: `set` corresponds to the new signal mask. The current signal mask is replaced by `set`.

If the value of `oset` is not `NULL`, it points to the location where the previous signal mask is stored.

Upon successful completion, the `thr_sigsetmask()` function returns 0. Otherwise, it returns a non-zero value.

The `thr_sigsetmask()` function will fail if:

- **EINVAL**: The value of `how` is not defined and `oset` is `NULL`.

### EXAMPLES

**EXAMPLE 1** The following example shows how to create a default thread that can serve as a signal catcher/handler with its own signal mask. `new` will have a different value from the creator’s signal mask.

As POSIX threads and Solaris threads are fully compatible even within the same process, this example uses `pthread_create(3THR)` if you execute `a.out 0` or `thr_create(3THR)` if you execute `a.out 1`.

In this example:

- `sigemptyset(3C)` initializes a null signal set, `new`. `sigaddset(3C)` packs the signal, `SIGINT`, into that new set.
EXAMPLE 1  The following example shows how to create a default thread that can serve as a
signal catcher/handler with its own signal mask.  new will have a different value from the
creator's signal mask.  (Continued)

- Either pthread_sigmask() or thr_setsigmask() is used to mask the signal,
  SIGINT (CTRL-C), from the calling thread, which is main().  The signal is masked
to guarantee that only the new thread will receive this signal.
- pthread_create() or thr_create() creates the signal-handling thread.
- Using pthread_join(3THR) or thr_join(3THR), main() then waits for the
  termination of that signal-handling thread, whose ID number is user_threadID;
after which, main() will sleep(3C) for 2 seconds, and then the program
terminates.
- The signal-handling thread, handler:
  - Assigns the handler interrupt() to handle the signal SIGINT, by the call to
    sigaction(2).
  - Resets its own signal set to not block the signal, SIGINT.
  - Sleeps for 8 seconds to allow time for the user to deliver the signal, SIGINT, by
    pressing the CTRL-C.

/* cc thisfile.c -lthread -lpthread */
define _REENTRANT /* basic first 3-lines for threads */
#include <pthread.h>
#include <thread.h>

thread_t user_threadID;
sigset_t new;
void *handler( ), interrupt( );
main( int argc, char *argv[] ){
  test_argv(argv[1]);

  sigemptyset(&new);
  sigaddset(&new, SIGINT);
  switch(*argv[1]) {
  case '0': /* POSIX */
    pthread_sigmask(SIG_BLOCK, &new, NULL);
    pthread_create(&user_threadID, NULL, handler, argv[1]);
    pthread_join(user_threadID, NULL);
    break;
  case '1': /* Solaris */
    thr_sigsetmask(SIG_BLOCK, &new, NULL);
    thr_create(NULL, 0, handler, argv[1], 0, &user_threadID);
    thr_join(user_threadID, NULL, NULL);
    break;
  } /* switch */

  printf("thread handler, # %d, has exited\n",user_threadID);
  sleep(2);
  printf("main thread, # %d is done\n", thr_self( ));
}
EXAMPLE 1 The following example shows how to create a default thread that can serve as a signal catcher/handler with its own signal mask. new will have a different value from the creator’s signal mask. (Continued)

```c
} /* end main */

struct sigaction act;

void *
handler(char argv1[ ]) {
    act.sa_handler = interrupt;
    sigaction(SIGINT, &act, NULL);
    switch(*argv1){
    case '0': /* POSIX */
        pthread_sigmask(SIG_UNBLOCK, &new, NULL);
        break;
    case '1': /* Solaris */
        thr_sigsetmask(SIG_UNBLOCK, &new, NULL);
        break;
    }
    printf("\n Press CTRL-C to deliver SIGINT signal to the process\n");
    sleep(8); /* give user time to hit CTRL-C */
}

void
interrupt(int sig) {
    printf("thread %d caught signal %d\n", thr_self( ), sig);
}

void test_argv(char argv1[ ]) {
    if(argv1 == NULL) {
        printf("use 0 as arg1 to use thr_create();
    or use 1 as arg1 to use pthread_create();
    exit(NULL);
    }
}

EXAMPLE 2 Rewriting the subroutines in the last example.

In the last example, the handler thread served as a signal-handler while also taking care of activity of its own (in this case, sleeping, although it could have been some other activity). A thread could be completely dedicated to signal-handling simply by waiting for the delivery of a selected signal by blocking with sigwait(2). The two subroutines in the previous example, handler() and interrupt(), could have been replaced with the following routine:

```c
void *
handler( ) {
    int signal;
    printf("thread %d waiting for you to press the CTRL-C keys\n", th_self( ));
    sigwait(&new, &signal);
    printf("thread %d has received the signal %d\n", th_self( ), signal);
```
EXAMPLE 2 Rewriting the subroutines in the last example. (Continued)

} /*pthread_create( ) and thr_create( ) would use NULL instead of
   argv[1] for the arg passed to handler( ) */

In this routine, one thread is dedicated to catching and handling the signal specified
by the set new, which allows main() and all of its other sub-threads, created after
pthread_sigmask() or thr_sigsetmask() masked that signal, to continue
uninterrupted. Any use of sigwait(2) should be such that all threads block the
signals passed to sigwait(2) at all times. Only the thread that calls sigwait() will
get the signals. The call to sigwait(2) takes two arguments.

For this type of background dedicated signal-handling routine, you may wish to use a
Solaris daemon thread by passing the argument THR_DAEMON to thr_create().

NOTES

It is not possible to block signals that cannot be ignored (see sigaction(2)). If using
the threads library, it is not possible to block or unblock the signals SIGWAITING,
SIGLWP, or SIGCANCEL. This restriction is quietly enforced by the threads library.

Using sigwait(2) in a dedicated thread allows asynchronously generated signals to
be managed synchronously; however, sigwait(2) should never be used to manage
synchronously generated signals.

Synchronously generated signals are exceptions that are generated by a thread and are
directed at the thread causing the exception. Since sigwait() blocks waiting for
signals, the blocking thread cannot receive a synchronously generated signal.

If sigprocmask(2) is used in a multi-threaded program, it will be the same as if
thr_sigsetmask() or pthread_sigmask() has been called. POSIX leaves the
semantics of the call to sigprocmask(2) unspecified in a multi-threaded process, so
programs that care about POSIX portability should not depend on this semantic.

If a signal is delivered while a thread is waiting on a condition variable, the
cond_wait(3THR) function will be interrupted and the handler will be executed. The
state of the lock protecting the condition variable is undefined while the thread is
executing the signal handler.
Signals that are generated synchronously should not be masked. If such a signal is blocked and delivered, the receiving process is killed.
thr_stksegment(3THR)

NAME
thr_stksegment – get thread stack address and size

SYNOPSIS
cc -mt [ flag... ] file...[ library... ]
#include <thread.h>
#include <signal.h>

int thr_stksegment(stack_t *ss);

DESCRIPTION
The thr_stksegment() function returns, in its stack_t argument, the address and size of the calling thread’s stack.

The stack_t structure includes the following members:

  void *ss_sp
  size_t ss_size
  int ss_flags

On successful return from thr_stksegment(), ss_sp contains the high address of the caller’s stack and ss_size contains the size of the stack in bytes. The ss_flags member is always 0. Note that the meaning of ss_sp is reversed from other uses of stack_t such as sigaltstack(2) where ss_sp is the low address.

The stack information provided by thr_stksegment() is typically used by debuggers, garbage collectors, and similar applications. Most applications should not require such information.

RETURN VALUES
The thr_stksegment() function returns 0 if the thread stack address and size were successfully retrieved. Otherwise, it returns a non-zero error value.

ERRORS
The thr_stksegment() function will fail if:

  EAGAIN The stack information for the thread is not available because the thread’s initialization is not yet complete, or the thread is an internal thread.

thr_suspend, thr_continue – suspend or continue thread execution

SYNOPSIS

cc -mt [ flag... ] file...[ library... ]
#include <thread.h>

int thr_suspend(thread_t target_thread);
int thr_continue(thread_t target_thread);

DESCRIPTION

The thr_suspend() function immediately suspends the execution of the thread specified by target_thread. On successful return from thr_suspend(), the suspended thread is no longer executing. Once a thread is suspended, subsequent calls to thr_suspend() have no effect.

The thr_continue() function resumes the execution of a suspended thread. Once a suspended thread is continued, subsequent calls to thr_continue() have no effect.

A suspended thread will not be awakened by a signal. The signal stays pending until the execution of the thread is resumed by thr_continue().

RETURN VALUES

If successful, the thr_suspend() and thr_continue() functions return 0. Otherwise, a non-zero value is returned to indicate the error.

ERRORS

The thr_suspend() or thr_continue() functions will fail if:

ESRCH The target_thread cannot be found in the current process.
ECANCELED The target_thread was not suspended because a subsequent thr_continue() occurred before the suspend completed.

thr_yield(3THR)

NAME thr_yield – yield to another thread

SYNOPSIS cc -mt [ flag... ] file...[ library... ]

#include <thread.h>

void thr_yield(void);

DESCRIPTION The thr_yield() function causes the current thread to yield its execution in favor of another thread with the same or greater priority.

RETURN VALUES The thr_yield() function returns nothing and does not set errno.

ATTRIBUTES See attributes(5) for descriptions of the following attributes:

SEE ALSO thr_setprio(3THR), attributes(5), standards(5)
timer_create() function creates a timer using the specified clock, `clock_id`, as the timing base. The `timer_create()` function returns, in the location referenced by `timerid`, a timer ID of type `timer_t` used to identify the timer in timer requests. This timer ID will be unique within the calling process until the timer is deleted. The particular clock, `clock_id`, is defined in `<time.h>`. The timer whose ID is returned will be in a disarmed state upon return from `timer_create()`.

The `evp` argument, if non-null, points to a `sigevent` structure. This structure, allocated by the application, defines the asynchronous notification that will occur when the timer expires. If the `evp` argument is NULL, the effect is as if the `evp` argument pointed to a `sigevent` structure with the `sigev_notify` member having the value `SIGEV_SIGNAL`, the `sigev_signo` having a default signal number, and the `sigev_value` member having the value of the timer ID, `timerid`.

The system defines a set of clocks that can be used as timing bases for per-process timers. The following values for `clock_id` are supported:

- `CLOCK_REALTIME`: wall clock
- `CLOCK_VIRTUAL`: user CPU usage clock
- `CLOCK_PROF`: user and system CPU usage clock
- `CLOCK_HIGHRES`: non-adjustable, high-resolution clock

For timers created with a `clock_id` of `CLOCK_HIGHRES`, the system will attempt to use an optimal hardware source. This may include, but is not limited to, per-CPU timer sources. The actual hardware source used is transparent to the user and may change over the lifetime of the timer. For example, if the caller that created the timer were to change its processor binding or its processor set, the system may elect to drive the timer with a hardware source that better reflects the new binding. Timers based on a `clock_id` of `CLOCK_HIGHRES` are ideally suited for interval timers that have minimal jitter tolerance.

Timers are not inherited by a child process across a `fork(2)` and are disarmed and deleted by a call to one of the `exec` functions (see `exec(2)`).

Upon successful completion, `timer_create()` returns 0 and updates the location referenced by `timerid` to a `timer_t`, which can be passed to the per-process timer calls. If an error occurs, the function returns -1 and sets `errno` to indicate the error. The value of `timerid` is undefined if an error occurs.

The `timer_create()` function will fail if:
timer_create(3RT)

**EAGAIN**  
The system lacks sufficient signal queuing resources to honor the request, or the calling process has already created all of the timers it is allowed by the system.

**EINVAL**  
The specified clock ID, clock_id, is not defined.

**ENOSYS**  
The timer_create() function is not supported by the system.

**EPERM**  
The specified clock ID, clock_id, is CLOCK_HIGHRES and the effective user of the caller is not superuser.

exec(2), fork(2), time(2), clock_settime(3RT), signal(3C), timer_delete(3RT), timer_settime(3RT), attributes(5), standards(5)
NAME | timer_delete – delete a timer  
SYNOPSIS | `cc [ flag... ] file... -lrt [ library... ]`
#include <time.h>

    int timer_delete(timer_t timerid);

DESCRIPTION | The `timer_delete()` function deletes the specified timer, `timerid`, previously created by the `timer_create(3RT)` function. If the timer is armed when `timer_delete()` is called, the behavior will be as if the timer is automatically disarmed before removal. The disposition of pending signals for the deleted timer is unspecified.

RETURN VALUES | If successful, the function returns 0. Otherwise, the function returns -1 and sets `errno` to indicate the error.

ERRORS | The `timer_delete()` function will fail if:

    EINVAL | The timer ID specified by `timerid` is not a valid timer ID.
    ENOSYS | The `timer_delete()` function is not supported by the system.

ATTRIBUTES | See attributes(5) for descriptions of the following attributes:

<table>
<thead>
<tr>
<th>ATTRIBUTE TYPE</th>
<th>ATTRIBUTE VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>MT-Level</td>
<td>MT-Safe with exceptions</td>
</tr>
</tbody>
</table>

SEE ALSO | `timer_create(3RT), attributes(5)`
The `timer_settime()` function sets the time until the next expiration of the timer specified by `timerid` from the `it_value` member of the `value` argument and arm the timer if the `it_value` member of `value` is non-zero. If the specified timer was already armed when `timer_settime()` is called, this call resets the time until next expiration to the `value` specified. If the `it_value` member of `value` is 0, the timer is disarmed. The effect of disarming or resetting a timer on pending expiration notifications is unspecified.

If the flag `TIMER_ABSTIME` is not set in the argument `flags`, `timer_settime()` behaves as if the time until next expiration is set to be equal to the interval specified by the `it_value` member of `value`. That is, the timer expires in `it_value` nanoseconds from when the call is made. If the flag `TIMER_ABSTIME` is set in the argument `flags`, `timer_settime()` behaves as if the time until next expiration is set to be equal to the difference between the absolute time specified by the `it_value` member of `value` and the current value of the clock associated with `timerid`. That is, the timer expires when the clock reaches the value specified by the `it_value` member of `value`. If the specified time has already passed, the function succeeds and the expiration notification is made.

The reload value of the timer is set to the value specified by the `it_interval` member of `value`. When a timer is armed with a non-zero `it_interval`, a periodic (or repetitive) timer is specified.

Time values that are between two consecutive non-negative integer multiples of the resolution of the specified timer will be rounded up to the larger multiple of the resolution. Quantization error will not cause the timer to expire earlier than the rounded time value.

If the argument `ovalue` is not NULL, the function `timer_settime()` stores, in the location referenced by `ovalue`, a value representing the previous amount of time before the timer would have expired or 0 if the timer was disarmed, together with the previous timer reload value. The members of `ovalue` are subject to the resolution of the timer, and they are the same values that would be returned by a `timer_gettime()` call at that point in time.

The `timer_gettime()` function stores the amount of time until the specified timer, `timerid`, expires and the reload value of the timer into the space pointed to by the `value` argument. The `it_value` member of this structure contains the amount of time before
the timer expires, or 0 if the timer is disarmed. This value is returned as the interval until timer expiration, even if the timer was armed with absolute time. The it_interval member of value contains the reload value last set by timer_settime().

Only a single signal will be queued to the process for a given timer at any point in time. When a timer for which a signal is still pending expires, no signal will be queued, and a timer overrun occurs. When a timer expiration signal is delivered to or accepted by a process, the timer_getoverrun() function returns the timer expiration overrun count for the specified timer. The overrun count returned contains the number of extra timer expirations that occurred between the time the signal was generated (queued) and when it was delivered or accepted, up to but not including an implementation-dependent maximum of DELAYTIMER_MAX. If the number of such extra expirations is greater than or equal to DELAYTIMER_MAX, then the overrun count will be set to DELAYTIMER_MAX. The value returned by timer_getoverrun() applies to the most recent expiration signal delivery or acceptance for the timer. If no expiration signal has been delivered for the timer, the meaning of the overrun count returned is undefined.

RETURN VALUES

If the timer_settime() or timer_gettime() functions succeed, 0 is returned. If an error occurs for either of these functions, -1 is returned, and errno is set to indicate the error. If the timer_getoverrun() function succeeds, it returns the timer expiration overrun count as explained above.

ERRORS

The timer_settime(), timer_gettime() and timer_getoverrun() functions will fail if:

EINVAL The timerid argument does not correspond to a timer returned by timer_create(3RT) but not yet deleted by timer_delete(3RT).

ENOSYS The timer_settime(), timer_gettime(), and timer_getoverrun() functions are not supported by the system. The timer_settime() function will fail if:

EINVAL A value structure specified a nanosecond value less than zero or greater than or equal to 1000 million.

ps_kill — process and LWP control in libthread_db, 114
ps_lcontinue — process and LWP control in libthread_db, 114
ps_lgetfpregs — routines that access the target process register in libthread_db, 110
ps_lgetregs — routines that access the target process register in libthread_db, 110
ps_lgetxregs — routines that access the target process register in libthread_db, 110
ps_lgetxregszie — routines that access the target process register in libthread_db, 110
ps_lrolltoaddr — process and LWP control in libthread_db, 114
ps_lsetfpregs — routines that access the target process register in libthread_db, 110

319
ps_lsetregs — routines that access the target process register in libthread_db, 110
ps_lsetxregs — routines that access the target process register in libthread_db, 110
ps_lstop — process and LWP control in libthread_db, 114
ps_pcontinue — process and LWP control in libthread_db, 114
ps_pdread — interfaces in libthread_db that target process memory access, 113
ps_pdwrite — interfaces in libthread_db that target process memory access, 113
ps_pglobal_lookup — look up a symbol in the symbol table of the load object in the target process, 112
ps_pglobal_sym — look up a symbol in the symbol table of the load object in the target process, 112
ps_pstop — process and LWP control in libthread_db, 114
ps_ptread — interfaces in libthread_db that target process memory access, 113
ps_ptwrite — interfaces in libthread_db that target process memory access, 113
pthread_attr_destroy — initialize and destroy threads attribute object, 126
pthread_attr_getdetachstate — get or set detachstate attribute, 116
pthread_attr_getguardsize — get or set the thread guardsize attribute, 117
pthread_attr_getinheritsched — get or set inheritsched attribute, 119
pthread_attr_getschedparam — get or set schedparam attribute, 121
pthread_attr_getschedpolicy — get or set schedpolicy attribute, 122
pthread_attr_getscope — get or set contentionscope attribute, 123
pthread_attr_getsetstackaddr — get or set stackaddr attribute, 124
pthread_attr_getsetstacksize — get or set stacksize attribute, 125
pthread_cleanup_pop — pop a thread cancellation cleanup handler, 129
pthread_cleanup_push — push a thread cancellation cleanup handler, 130
pthread_cond_broadcast — signal or broadcast a condition, 137
pthread_cond_destroy — initialize or destroy condition variables, 135
pthread_cond_init — initialize or destroy condition variables, 135
pthread_cond_reltimedwait_np — wait on a condition, 139
pthread_cond_signal — signal or broadcast a condition, 137
pthread_cond_timedwait — wait on a condition, 139
pthread_cond_wait — wait on a condition, 139
pthread_condattr_destroy — initialize or destroy condition variable attributes object, 133
pthread_condattr_getpshared — get or set the process-shared condition variable attributes, 131
pthread_condattr_init — initialize or destroy condition variable attributes object, 133
pthread_condattr_setpshared — get or set the process-shared condition variable attributes, 131
pthread_create — create a thread, 143
pthread_detach — detach a thread, 147
pthread_equal — compare thread IDs, 148
pthread_exit — terminate calling thread, 149
pthread_getconcurrency — get or set level of thread scheduling parameters, 152

schedctl_init — preemption control, 206
schedctl_lookup — preemption control, 206
schedctl_start — preemption control, 206
schedctl_stop — preemption control, 206
sem_close — close a named semaphore, 221
sem_destroy — destroy an unnamed semaphore, 222
sem_getvalue — get the value of a semaphore, 223
sem_init — initialize an unnamed semaphore, 224
sem_open — initialize/open a named semaphore, 226
sem_post — increment the count of a semaphore, 229
sem_trywait — acquire or wait for a semaphore, 232
sem_unlink — remove a named semaphore, 231
sem_wait — acquire or wait for a semaphore, 232
sema_destroy() — destroy a semaphore, 217
sema_init() — initialize a semaphore, 217
sema_post() — increment a semaphore, 217
sema_trywait() — decrement a semaphore, 217
sema_wait() — decrement a semaphore, 217
semaphore acquire or wait for — sem_wait,
   sem_trywait, 232
semaphore (Continued)
close a named one — sem_close, 221
destroy an unnamed one —
   sem_destroy, 222
get the value — sem_getvalue, 223
increment the count — sem_post, 229
initialize an unnamed one — sem_init, 224
initialize/open a named one —
   sem_open, 226
remove a named one — sem_unlink, 231
set concurrency level for target process —
   td_ta_setconcurrency, 260
set/get scheduling parameters
   — sched_getparam, 212
   — sched_setparam, 212
set scheduling policy and scheduling parameters — sched_setscheduler, 214
set the cancellation type of a thread —
   pthread_setcanceltype, 195
set the priority of a thread —
   td_thr_setprio, 270
shared memory object
   open — shm_open, 235
   remove — shm_unlink, 238
shm_open — open a shared memory object, 235
shm_unlink — remove a shared memory object, 238
signal
   queue one to a process — sigqueue, 239
   wait for queued signals — sigwaitinfo, sigtimedwait, 241
signal or broadcast a condition
   — pthread_cond_broadcast, 137
   — pthread_cond_signal, 137
sigqueue — queue a signal to a process, 239
sigtimedwait — wait for queued signals, 241
sigwaitinfo — wait for queued signals, 241
sleep, high resolution — nanosleep, 106
specify an alternative door server thread creation function — door_server_create, 65
suspend and resume threads in libthread_db
   — td_thr_dbresume, 263
   — td_thr_dbsuspend, 263
synchronize a file’s data, — fsasync, 67

T

T

T
td_ta_new — allocate and deallocate process handles for libthread_db, 258

td_ta_reset_stats — collect target process statistics for libthread_db, 249

td_ta_set_event — thread events in libthread_db, 251

td_ta_setconcurrency — set concurrency level for target process, 260

td_ta_sync_iter — iterator functions on process handles from libthread_db, 261

td_ta_sync_tracking_enable — operations on a synchronization object in libthread_db, 245

td_ta_tsd_iter — iterator functions on process handles from libthread_db, 261

td_thr_clear_event — thread events in libthread_db, 251

td_thr_dbresume — suspend and resume threads in libthread_db, 263

td_thr_dbsuspend — suspend and resume threads in libthread_db, 263

td_thr_event_enable — thread events in libthread_db, 251

td_thr_event_getmsg — thread events in libthread_db, 251

td_thr_get_info — get thread information in libthread_db library of interfaces, 266

td_thr_getfpregs — reading and writing thread registers in libthread_db, 264

td_thr_getgregs — reading and writing thread registers in libthread_db, 264

td_thr_getxregs — reading and writing thread registers in libthread_db, 264

td_thr_getxregsize — reading and writing thread registers in libthread_db, 264

td_thr_lockowner — iterate over the set of locks owned by a thread, 269

td_thr_set_event — thread events in libthread_db, 251

td_thr_setfpregs — reading and writing thread registers in libthread_db, 264

td_thr_setgregs — reading and writing thread registers in libthread_db, 264

td_thr_setprio — set the priority of a thread, 270

td_thr_setsigpending — manage thread signals for libthread_db, 271

td_thr_setxregs — reading and writing thread registers in libthread_db, 264

td_thr_sigsetmask — manage thread signals for libthread_db, 271

td_thr_sleepinfo — return the synchronization handle for the object on which a thread is blocked, 272

td_thr_tsd — get a thread’s thread-specific data for libthread_db library of interfaces, 273

td_thr_validate — test a thread handle for validity, 274

tda_ta_clear_event — thread events in libthread_db, 251

terminate calling thread — pthread_exit, 149

terminate the calling thread — thr_exit, 288

test a thread handle for validity —

  td_thr_validate, 274

thr_continue — continue thread execution, 307

thr_create — create a thread, 275

thr_exit — terminate the calling thread, 288

thr_getconcurrency — get thread concurrency level, 290

thr_getprio — access dynamic thread scheduling, 291

thr_getspecific — thread-specific-data functions, 294

thr_join — wait for thread termination, 292

thr_keycreate — thread-specific-data functions, 294

  Create Key, 294

  Get Value, 294

  Set Value, 294

thr_main — identifies the calling thread as the main thread or not the main thread, 298

thr_self — get calling thread’s ID, 300

thr_setconcurrency — set thread concurrency level, 290

thr_setspec — access dynamic thread scheduling, 291

thr_setspecific — thread-specific-data functions, 294

thr_sigsetmask — change or examine calling thread’s signal mask, 301

thr_stksegment — get thread stack address and size, 306

thr_suspend — suspend thread execution, 307
thr_yield — thread yield to another thread, 308

thread events in libthread_db
— td_event_addset, 251
