Preface

This guide discusses how to use Netscape Server Application Programmer’s Interface (NSAPI) to build plug-ins that define Server Application Functions (SAFs) to extend and modify Sun Java™ System Web Server 6.1. The guide also provides a reference of the NSAPI functions you can use to define new plug-ins.

This preface contains the following topics:
- “Who Should Use This Guide” on page 17
- “Using the Documentation” on page 17
- “How This Guide Is Organized” on page 19
- “Documentation Conventions” on page 20
- “Product Support” on page 21

Who Should Use This Guide

The intended audience for this guide is the person who develops, assembles, and deploys NSAPI plug-ins in a corporate enterprise. This guide assumes you are familiar with the following topics:
- HTTP
- HTML
- NSAPI
- C programming
- Software development processes, including debugging and source code control

Using the Documentation

The Sun Java System Web Server 6.1 SP10 manuals are available as online files in PDF and HTML at: http://docs.sun.com/app/docs/coll/1308.7

The following table lists the tasks and concepts described in the Sun Java System Web Server manuals.
## Table P-1  Sun Java System Web Server Documentation Roadmap

How This Guide Is Organized

This guide has the following chapters:

- **Chapter 1, Syntax and Use of obj.conf**
  This chapter describes the configuration file `obj.conf`. The chapter discusses the syntax and use of directives in this file, which instruct the server how to process HTTP requests.

- **Chapter 2, SAFs in the magnus.conf File**
  This chapter discusses the SAFs you can set in the configuration file `magnus.conf` to configure the Sun Java System Web Server during initialization.

- **Chapter 3, Creating Custom SAFs**
  This chapter discusses how to create your own plug-ins that define new SAFs to modify or extend the way the server handles requests.

- **Chapter 4, Creating Custom Filters**
  This chapter discusses how to create your own custom filters that you can use to intercept, and potentially modify, incoming content presented to or generated by another function.

- **Chapter 5, Examples of Custom SAFs and Filters**
  This chapter describes examples of custom SAFs to use at each stage in the request-handling process.

- **Chapter 6, Creating Custom Server-parsed HTML Tags**
  This chapter explains how to create custom server-parsed HTML tags.

- **Chapter 7, NSAPI Function Reference**

---

| TABLE P-1 Sun Java System Web Server Documentation Roadmap (Continued) |
| --- | --- |
| **For Information About** | **See the Following** |
| Using programming technologies and APIs to do the following: | *Programmer's Guide* |
| - Extend and modify Sun Java System Web Server | |
| - Dynamically generate content in response to client requests | |
| - Modify the content of the server | |
| Creating custom Netscape Server Application Programmer's Interface (NSAPI) plug-ins | *NSAPI Programmer's Guide* |
| Implementing servlets and JavaServer Pages™ (JSP™) technology in Sun Java System Web Server | *Programmer's Guide to Web Applications* |
| Editing configuration files | *Administrator's Configuration File Reference* |
| Tuning Sun Java System Web Server to optimize performance | *Performance Tuning, Sizing, and Scaling Guide* |
This chapter presents a reference of the NSAPI functions. You use NSAPI functions to define SAFs.

- **Chapter 8, Data Structure Reference**
  This chapter discusses some of the commonly used NSAPI data structures.

- **Chapter 9, Using Wildcard Patterns**
  This chapter lists the wildcard patterns you can use when specifying values in obj.conf and various predefined SAFs.

- **Chapter 10, Time Formats**
  This chapter lists time formats.

- **Chapter 11, Dynamic Results Caching Functions**
  This chapter explains how to create a results caching plug-in.

- **Chapter 12, Hypertext Transfer Protocol**
  This chapter gives an overview of HTTP.

- **Appendix A, Alphabetical List of NSAPI Functions and Macros**
  This appendix provides an alphabetical list of NSAPI functions and macros.

### Documentation Conventions

This section describes the types of conventions used throughout this guide.

- **File and directory paths**
  These are given in UNIX® format (with forward slashes separating directory names). For Windows versions, the directory paths are the same, except that backslashes are used to separate directories.

- **URLs** are given in the format:

  http://server.domain/path/file.html

  In these URLs, server is the server name where applications are run; domain is your Internet domain name; path is the server's directory structure; and file is an individual file name. Italic items in URLs are placeholders.

- **Font conventions** include:
  - The monospace font is used for sample code and code listings, API and language elements (such as function names and class names), file names, path names, directory names, and HTML tags.
  - Italic monospace type is used for code variables.
  - *Italic* type is also used for book titles, emphasis, variables and placeholders, and words used in the literal sense.
Bold type is used as either a paragraph lead-in or to indicate words used in the literal sense.

Installation root directories are indicated by install_dir in this guide.

By default, the location of install_dir is as follows:
- On UNIX-based platforms: /opt/SUNWwbsvr/
- On Windows: C:\Sun\WebServer6.1

Product Support

If you have problems with your system, contact customer support using one of the following mechanisms:
- The online support web site at:
- The telephone dispatch number associated with your maintenance contract

Please have the following information available prior to contacting support. This helps to ensure that our support staff can best assist you in resolving problems.
- Description of the problem, including the situation where the problem occurs and its impact on your operation.
- Machine type, operating system version, and product version, including any patches and other software that might be affecting the problem.
- Detailed steps on the methods you have used to reproduce the problem.
- Any error logs or core dumps.
The `obj.conf` configuration file contains directives that instruct the Sun Java System Web Server how to handle HTTP and HTTPS requests from clients and service web server content such as native server plug-ins and CGI programs. You can modify and extend the request-handling process by adding or changing the instructions in `obj.conf`.

All `obj.conf` files are located in the `instance_dir/config` directory, where `instance_dir` is the path to the installation directory of the server instance. There is one `obj.conf` file for each virtual server class, unless several virtual server classes are configured to share an `obj.conf` file. Whenever this guide refers to "the `obj.conf` file," it refers to all `obj.conf` files or to the `obj.conf` file for the virtual server class being described.

By default, the `obj.conf` file for the initial virtual server class is named `obj.conf`, and the `obj.conf` files for the administrator-defined virtual server classes are named `virtual_server_class_id.obj.conf`. Editing one of these files directly or through the Administration interface changes the configuration of a virtual server class.

This chapter discusses server instructions in `obj.conf`, the use of `OBJECT` tags, the use of variables, the flow of control in `obj.conf`, the syntax rules for editing `obj.conf`, and a note about example directives.

**Note** – For detailed information about the standard directives and predefined Server Application Functions (SAFs) that are used in the `obj.conf` file, see the *Sun Java System Web Server 6.1 SP10 Administrator’s Configuration File Reference*.

This chapter has the following sections:

- “How the Server Handles Requests from Clients” on page 24
- “Dynamic Reconfiguration” on page 27
- “Server Instructions in obj.conf” on page 27
- “Configuring HTTP Compression” on page 31
- “The Object and Client Tags” on page 32
How the Server Handles Requests from Clients

Sun Java System Web Server is a web server that accepts and responds to Hypertext Transfer Protocol (HTTP) requests. Browsers such as Netscape Communicator communicate using several protocols including HTTP and FTP. The Sun Java System Web Server handles HTTP specifically.

For more information about the HTTP protocol, refer to Chapter 12, Hypertext Transfer Protocol specification.

HTTP Basics

As a quick summary, the HTTP/1.1 protocol works as follows:

- The client (usually a browser) opens a connection to the server and sends a request.
- The server processes the request, generates a response, and closes the connection if it finds a Connection: Close header.
- The request consists of a line indicating a method such as GET or POST, a Uniform Resource Identifier (URI) indicating which resource is being requested, and an HTTP protocol version separated by spaces.
- This is normally followed by a number of headers, a blank line indicating the end of the headers, and sometimes body data. Headers may provide various information about the request or the client body data. Headers are typically only sent for POST and PUT methods.
- The example request shown below would be sent by a Netscape browser to request the server foo.com to send back the resource in /index.html. In this example, no body data is sent because the method is GET (the point of the request is to get some data, not to send it).

```
GET /index.html HTTP/1.0
User-agent: Mozilla
Accept: text/html, text/plain, image/jpeg, image/gif, */*
Host: foo.com
```

The server receives the request and processes it. It handles each request individually, although it may process many requests simultaneously. Each request is broken down into a series of steps that together make up the request-handling process.
The server generates a response that includes the HTTP protocol version, HTTP status code, and a reason phrase separated by spaces. This is normally followed by a number of headers. The end of the headers is indicated by a blank line. The body data of the response follows. A typical HTTP response might look like this:

```
HTTP/1.0 200 OK
Server: Sun-Java System-Web-Server/6.1
content-type: text/html
Content-length: 83

<html>
<head><title>Hello World</title></head>
<body>Hello World</body>
</html>
```

The status code and reason phrase tell the client how the server handled the request. Normally the status code 200 is returned, indicating that the request was handled successfully and the body data contains the requested item. Other result codes indicate redirection to another server or the browser's cache, or various types of HTTP errors such as 404 Not Found.

**NSAPI Filters**

In previous versions of the Web Server, the NSAPI API allowed multiple SAFs to interact in request processing. For example, one SAF could be used to authenticate the client after which a second SAF would generate the content.

In addition to the existing NSAPI interfaces, Sun Java System Web Server introduces NSAPI filters that enable a function to intercept (and potentially modify) the content presented to or generated by another function.

For more information on NSAPI filters in Sun Java System Web Server 6.1, see Chapter 4, Creating Custom Filters.

Two new NSAPI stages, Input and Output, can be used to insert filters in `obj.conf`. The Input and Output stages are described later in this chapter.

**Request-handling Process**

When the server first starts up it performs some initialization and then waits for an HTTP request from a client (such as a browser). When it receives a request, it first selects a virtual server. For details about how the virtual server is determined, see the Sun Java System Web Server 6.1 SP10 Administrator's Configuration File Reference.

After the virtual server is selected, the `obj.conf` file for the virtual server class specifies how the request is handled in the following steps:
To handle request

1. **AuthTrans** (authorization translation)
   Verify any authorization information (such as name and password) sent in the request.

2. **NameTrans** (name translation)
   Translate the logical URI into a local filesystem path.

3. **PathCheck** (path checking)
   Check the local filesystem path for validity and check that the requestor has access privileges to
   the requested resource on the filesystem.

4. **ObjectType** (object typing)
   Determine the MIME-type (Multi-purpose Internet Mail Encoding) of the requested resource
   (for example, text/html, image/gif, and so on).

5. **Input** (prepare to read input)
   Select filters that will process incoming request data read by the Service step.

6. **Output** (prepare to send output)
   Select filters that will process outgoing response data generated by the Service step.

7. **Service** (generate the response)
   Generate and return the response to the client.

8. **AddLog** (adding log entries)
   Add entries to log file(s).

9. **Error** (service)
   This step is executed only if an error occurs in the previous steps. If an error occurs, the server
   logs an error message and aborts the process.

### Directives for Handling Requests

The file `obj.conf` contains a series of instructions, known as directives, that tell the Sun Java System Web Server what to do at each stage in the request-handling process. Each directive invokes a SAF with one or more arguments. Each directive applies to a specific stage in the request-handling process. The stages are AuthTrans, NameTrans, PathCheck, ObjectType, Input, Output, Service, and AddLog.
For example, the following directive applies during the NameTrans stage. It calls the \texttt{document-root} function with the root argument set to \texttt{D://Sun/WebServer61/server1/docs}. (The \texttt{document-root} function translates the \texttt{http://server_name/} part of the URL to the document root, which in this example is \texttt{D://Sun/WebServer61/server1/docs}).

\begin{verbatim}
NameTrans fn="document-root" root="D:/Sun/WebServer61/server1/docs"
\end{verbatim}

The functions invoked by the directives in \texttt{obj.conf} are known as SAFs.

**Dynamic Reconfiguration**

You do not need to restart the server for changes to certain configuration files to take effect (for example, \texttt{obj.conf}, \texttt{mime.types}, \texttt{server.xml}, and virtual server-specific ACL files). All you need to do is apply the changes by clicking the Apply link and then clicking the Load Configuration Files button on the Apply Changes screen. If there are errors in installing the new configuration, the previous configuration is restored.

When you edit \texttt{obj.conf} and apply the changes, a new configuration is loaded into memory that contains all of the information from the dynamically configurable files.

Every new connection references the newest configuration. Once the last session referencing a configuration ends, the now unused old configuration is deleted.

**Server Instructions in \texttt{obj.conf}**

The \texttt{obj.conf} file contains directives that instruct the server how to handle requests received from clients such as browsers. These directives appear inside \texttt{OBJECT} tags.

Each directive calls a function, indicating when to call it and specifying arguments for it.

The syntax of each directive is:

\begin{verbatim}
Directive fn=func-name name1=value1\ldots nameN=valueN
\end{verbatim}

For example:

\begin{verbatim}
NameTrans fn="document-root" root="D:/Sun/WebServer61/server1/docs"
\end{verbatim}

\texttt{Directive} indicates when this instruction is executed during the request-handling process. The value is one of \texttt{AuthTrans}, \texttt{NameTrans}, \texttt{PathCheck}, \texttt{ObjectType}, \texttt{Service}, \texttt{AddLog}, and \texttt{Error}.

The value of the \texttt{fn} argument is the name of the SAF to execute. All directives must supply a value for the \texttt{fn} parameter; if there's no function, the instruction won't do anything.
The remaining parameters are the arguments needed by the function, and they vary from
function to function.

Sun Java System Web Server is shipped with a set of built-in SAFs that you can use to create and
modify directives in obj.conf. For more information about these predefined SAFs, see the Sun
Java System Web Server 6.1 SP10 Administrator’s Configuration File Reference. You can also
define new SAFs, as discussed in Chapter 3, Creating Custom SAFs.

The magnus.conf file contains Init directive SAFs that initialize the server. For more
information, see Chapter 2, SAFs in the magnus.conf File

Summary of the Directives

Following are the categories of server directives and a description of what each does. Each
category corresponds to a stage in the request-handling process. The section “Flow of Control
in obj.conf” on page 37 explains exactly how the server decides which directive or directives to
execute in each stage.

Note – For detailed information about the standard directives and predefined SAFs that are used
in the obj.conf file, see Sun Java System Web Server 6.1 SP10 Administrator’s Configuration File
Reference.

- “AuthTrans” on page 37
  Verifies any authorization information (normally sent in the Authorization header)
  provided in the HTTP request and translates it into a user and/or a group. Server access
  control occurs in two stages. AuthTrans verifies the authenticity of the user. Later,
  PathCheck tests the user’s access privileges for the requested resource.

  AuthTrans fn=basic-auth userfn=ntauth auth-type=basic userdb=none

  This example calls the basic-auth function, which calls a custom function (in this case
  ntauth, to verify authorization information sent by the client. The Authorization header is
  sent as part of the basic server authorization scheme.

- “NameTrans” on page 37
  Translates the URL specified in the request from a logical URL to a physical file system path
  for the requested resource. This may also result in redirection to another site. For example:

  NameTrans fn="document-root" root=D:/Sun/WebServer61/server1/docs

  This example calls the document-root function with a root argument of
  D:/Sun/WebServer61/server1/docs. The function document-root function translates the
  http://server_name/ part of the requested URL to the document root, which in this case is
  D:/Sun/WebServer61/server1/docs. Thus a request for http://server-name/doc1.html
  is translated to D:/Sun/WebServer61/server1/docs/doc1.html.
“PathCheck” on page 39
Perform tests on the physical path determined by the NameTrans step. In general, these tests determine whether the path is valid and whether the client is allowed to access the requested resource. For example:

```
PathCheck fn="find-index" index-names="index.html,home.html"
```

This example calls the find-index function with an index-names argument of index.html, home.html. If the requested URL is a directory, this function instructs the server to look for a file called either index.html or home.html in the requested directory.

“ObjectType” on page 39
Determines the MIME (Multi-purpose Internet Mail Encoding) type of the requested resource. The MIME type has attributes type (which indicates content type), encoding, and language. The MIME type is sent in the headers of the response to the client. The MIME type also helps determine which Service directive the server should execute.

The resulting type may be:

- A common document type such as text/html or image/gif (for example, the file name extension .gif translates to the MIME type image/gif).
- An internal server type. Internal types always begin with magnus-internal.

For example:

```
ObjectType fn="type-by-extension"
```

This example calls the type-by-extension function, which causes the server to determine the MIME type according to the requested resource's file extension.

“Input” on page 41
Selects filters that will process incoming request data read by the Service step. The Input directive allows you to invoke the insert-filter SAF in order to install filters that process incoming data. All Input directives are executed when the server or a plug-in first attempts to read entity body data from the client. The Input directives are executed at most once per request. For example:

```
Input fn="insert-filter" filter="http-decompression"
```

This directive instructs the insert-filter function to add a filter named http-decompression to the filter stack, which would decompress incoming HTTP request data before passing it to the Service step.

“Output” on page 41
Selects filters that will process outgoing response data generated by the Service step. The Output directive allows you to invoke the insert-filter SAF to install filters that process outgoing data. All Output directives are executed when the server or a plug-in first attempts to write entity body data from the client. The Output directives are executed at most once per request. For example:

```
Output fn="insert-filter" filter="http-compression"
```

This directive instructs the insert-filter function to add a filter named http-compression to the filter stack, which would compress outgoing HTTP response data generated by the Service step.

■ "Service" on page 42

Generates and sends the response to the client. This involves setting the HTTP result status, setting up response headers (such as content-type and Content-Length), and generating and sending the response data. The default response is to invoke the send-file function to send the contents of the requested file along with the appropriate header files to the client. The default Service directive is:

```
Service method="(GET|HEAD|POST)" type="$-magnus-internal/*" fn="send-file"
```

This directive instructs the server to call the send-file function in response to any request whose method is GET, HEAD, or POST, and whose type does not begin with magnus-internal/. (Note the use of the special characters $- to mean “does not match.”)

Another example is:

```
Service method="(GET|HEAD)" type="magnus-internal/imagemap" fn="imagemap"
```

In this case, if the method of the request is either GET or HEAD, and the type of the requested resource is magnus-internal/imagemap, the function imagemap is called.

■ "AddLog" on page 44

Adds an entry to a log file to record information about the transaction. For example:

```
AddLog fn="$flex-log" name="access"
```

This example calls the flex-log function to log information about the current request in the log file named access.

■ "Error" on page 44

Handles an HTTP error. This directive is invoked if a previous directive results in an error. Typically the server handles an error by sending a custom HTML document to the user describing the problem and possible solutions.

For example:
Error fn="send-error" reason="Unauthorized"
path="D:/Sun/WebServer61/server1/errors/unauthorized.html"

In this example, the server sends the file in
D:/Sun/WebServer61/server1/errors/unauthorized.html whenever a client requests a
resource that it is not authorized to access.

**Configuring HTTP Compression**

When compression is enabled in the server, an entry gets added to the obj.conf file. A sample
entry is shown below:

Output fn="insert-filter" filter="http-compression" type="text/*"

Depending on the options specified, this line might also contain these options:

```
 vary="on" compression-level="9"
```

To restrict compression to documents of only a particular type, or to exclude browsers that
don’t work well with compressed content, you would need to edit the obj.conf file, as discussed
below.

The option that appears as:

```
type="text/*"
```

restricts compression to documents that have a MIME type of text/* (for example,
text/ascii, text/css, text/html, and so on). This can be modified to compress only certain
types of documents. If you want to compress only HTML documents, for example, you would
change the option to:

```
type="text/html"
```

Alternatively, you can specifically exclude browsers that are known to misbehave when they
receive compressed content (but still request it anyway) by using the <Client> tag as follows:

```
<Client match="none">
 browsers="*MSIE [1-3]*"
 browsers="*MSIE [1-5]"Mac*"
 browser="Mozilla/[1-4]*Nav">
 Output fn="insert-filter" filter="http-compression" type="text/*"
 </Client>
```

This restricts compression to browsers that are not any of the following:

- Internet Explorer for Windows earlier than version 4
The Object and Client Tags

- Internet Explorer for Macintosh earlier than version 6
- Netscape Navigator/Communicator earlier than version 6

Internet Explorer on Windows earlier than version 4 may request compressed data at times, but does not correctly support it. Internet Explorer on Macintosh earlier than version 6 does the same. Netscape Communicator version 4.x requests compression, but only correctly handles compressed HTML. It will not correctly handle linked CSS or JavaScript from the compressed HTML, so administrators often simply prevent their servers from sending any compressed content to that browser (or earlier).

For more information about the `<Client>` tag, see the “The Client Tag” on page 34.

The Object and Client Tags

This section discusses the use of `<Object>` and `<Client>` tags in the file `obj.conf`.

`<Object>` tags group directives that apply to requests for particular resources, while `<Client>` tags group directives that apply to requests received from specific clients.

These tags are described in the following topics:

- “The Object Tag” on page 32
- “The Client Tag” on page 34

The Object Tag

Directives in the `obj.conf` file are grouped into objects that begin with an `<Object>` tag and end with an `</Object>` tag. The default object provides instructions to the server about how to process requests by default. Each new object modifies the default object's behavior.

An `<Object>` tag may have a `name` attribute or a `ppath` attribute. Either parameter may be a wildcard pattern. For example:

```xml
<Object name="cgi">
   - or -

<Object ppath="/usr/sun/webserver61/server1/docs/private/*">
```

The server always starts handling a request by processing the directives in the default object. However, the server switches to processing directives in another object after the `NameTrans` stage of the default object if either of the following conditions is true:

- The successful `NameTrans` directive specifies a name argument.
- The physical path name that results from the `NameTrans` stage matches the `ppath` attribute of another object.
When the server has been alerted to use an object other than the default object, it processes the directives in the other object before processing the directives in the default object. For some steps in the process, the server stops processing directives in that particular stage (such as the Service stage) as soon as one is successfully executed, whereas for other stages the server processes all directives in that stage, including the ones in the default object as well as those in the additional object. For more details, see "Flow of Control in obj.conf" on page 37.

**Objects that Use the name Attribute**

If a NameTrans directive in the default object specifies a name argument, the server switches to processing the directives in the object of that name before processing the remaining directives in the default object.

For example, the following NameTrans directive in the default object assigns the name cgi to any request whose URL starts with http://server_name/cgi/:

```xml
<Object name="default">
    NameTrans fn="pfx2dir" from="/cgi"
dir="D:/sun/webserver61/server1/docs/mycgi"
    name="cgi"...
</Object>
```

When that NameTrans directive is executed, the server starts processing directives in the object named cgi:

```xml
<Object name="cgi">
    more directives...
</Object>
```

**Objects that Use the ppath Attribute**

When the server finishes processing the NameTrans directives in the default object, the logical URL of the request will have been converted to a physical path name. If this physical path name matches the ppath attribute of another object in obj.conf, the server switches to processing the directives in that object before processing the remaining ones in the default object.

For example, the following NameTrans directive translates the http://server_name/ part of the requested URL to D:/Sun/WebServer61/server1/docs/ (which is the document root directory):

```xml
<Object name="default">
    NameTrans fn="document-root"
    root="D:/Sun/WebServer61/server1/docs"
    ...
</Object>
```
The URL \url{http://server_name/internalplan1.html} would be translated to
\texttt{D:/Sun/WebServer61/server1/docs/internalplan1.html}. However, suppose that \texttt{obj.conf}
contains the following additional object:

\begin{verbatim}
<Object ppath="*internal*">
    more directives...
</Object>
\end{verbatim}

In this case, the partial path \texttt{*internal*} matches the path
\texttt{D:/Sun/WebServer61/server1/docs/internalplan1.html}. So now the server starts
processing the directives in this object before processing the remaining directives in the default
object.

## The Client Tag

The \texttt{<Client>} tag is used to limit execution of a set of directives to requests received from
specific clients. Directives listed between the \texttt{<Client>} and \texttt{</Client>} tags are executed only
when information in the client request matches the parameter values specified.

### Client Tag Parameters

The following table lists the \texttt{<Client>} tag parameters.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>browser</td>
<td>User-agent string sent by a browser to the Web Server</td>
</tr>
<tr>
<td>chunked</td>
<td>Boolean value set by a client requesting chunked encoding</td>
</tr>
<tr>
<td>code</td>
<td>HTTP response code</td>
</tr>
<tr>
<td>dns</td>
<td>DNS name of the client</td>
</tr>
<tr>
<td>internal</td>
<td>Boolean value indicating internally generated request</td>
</tr>
<tr>
<td>ip</td>
<td>IP address of the client</td>
</tr>
<tr>
<td>keep-alive</td>
<td>Boolean value indicating the client has requested a keep-alive connection</td>
</tr>
<tr>
<td>keysize</td>
<td>Key size used in an SSL transaction</td>
</tr>
<tr>
<td>match</td>
<td>Match mode for the \texttt{&lt;Client&gt;} tag; valid values are all, any, and none</td>
</tr>
<tr>
<td>method</td>
<td>HTTP method used by the browser</td>
</tr>
<tr>
<td>name</td>
<td>Name of an object as specified in a previous \texttt{NameTrans} statement</td>
</tr>
</tbody>
</table>
The <Client> tag parameters provide greater control over when and if directives are executed. In the following example, use of the odds parameter gives a request a 25% chance of being redirected:

```xml
<Client odds="25%">
  NameTrans fn="redirect" from="/Pogues"
  url-prefix="http://pogues.example.com"
</Client>
```

One or more wildcard patterns can be used to specify Client tag parameter values.

Wildcards can also be used to exclude clients that match the parameter value specified in the <Client> tag. In the following example, the <Client> tag and the AddLog directive are combined to direct the Web Server to log access requests from all clients except those from the specified subnet:

```xml
<Client variable-headers="\%Weferer:SKVFVWRKJZCMHVIBGDA\%Service type=\"image/*\%fn=deny-existence"
</Client>
```
Using the ~ wildcard negates the expression, so the Web Server excludes clients from the specified subnet.

You can also create a negative match by setting the match parameter of the Client tag to none. In the following example, access requests from the specified subnet are excluded, as are all requests to the virtual server www.sunone.com:

```xml
<Client match="none" ip="192.85.250.*" urlhost="www.sunone.com">AddLog fn="flex-log" name="access"></Client>
```

For more information about wildcard patterns, see Chapter 9, Using Wildcard Patterns.

**Variables Defined in server.xml**

You can define variables in the `server.xml` file and reference them in an `obj.conf` file. For example, the following `server.xml` code defines and uses a variable called `docroot`:

```xml
<property name="docroot" value="/opt/SUNWwbsvr/docs"/>
```

You can reference the variable in `obj.conf` as follows:

```conf
NameTrans fn=document-root root="$docroot"
```

Using this `docroot` variable saves you from having to define document roots for virtual server classes in the `obj.conf` files. It also allows you to define different document roots for different virtual servers within the same virtual server class.

**Note** — Variable substitution is allowed only in an `obj.conf` file. It is not allowed in any other Sun Java System Web Server configuration files. Any variable referenced in an `obj.conf` file must be defined in the `server.xml` file.
Flow of Control in obj.conf

Before the server can process a request, it must direct the request to the correct virtual server. For details about how the virtual server is determined, see the *Sun Java System Web Server 6.1 SP10 Administrator's Configuration File Reference*.

After the virtual server is determined, the server executes the obj.conf file for the virtual server class to which the virtual server belongs. This section discusses how the server decides which directives to execute in obj.conf.

**AuthTrans**

When the server receives a request, it executes the AuthTrans directives in the default object to check that the client is authorized to access the server.

If there is more than one AuthTrans directive, the server executes them all (unless one of them results in an error). If an error occurs, the server skips all other directives except for Error directives.

**NameTrans**

Next, the server executes a NameTrans directive in the default object to map the logical URL of the requested resource to a physical path name on the server's file system. The server looks at each NameTrans directive in the default object in turn, until it finds one that can be applied.

If there is more than one NameTrans directive in the default object, the server considers each directive until one succeeds.

The NameTrans section in the default object must contain exactly one directive that invokes the document-root function. This function translates the http://server_name part of the requested URL to a physical directory that has been designated as the server's document root. For example:

```
NameTrans fn="document-root" root="D:/Sun/WebServer61/server1/docs"
```

The directive that invokes document-root must be the last directive in the NameTrans section so that it is executed if no other NameTrans directive is applicable.

The pfx2dir (prefix to directory) function is used to set up additional mappings between URLs and directories. For example, the following directive translates the URL http://server_name/cgi/ into the directory path name D:/Sun/WebServer61/server1/docs/mycgi/:
NameTrans fn="pfx2dir" from="/cgi" dir="D:/Sun/WebServer61/server1/docs/mycgi"

Notice that if this directive appeared after the one that calls document-root, it would never be executed, with the result that the resultant directory path name would be D:/Sun/WebServer61/server1/docs/cgi/ (not mycgi). This illustrates why the directive that invokes document-root must be the last one in the NameTrans section.

How and When the Server Processes Other Objects

As a result of executing a NameTrans directive, the server might start processing directives in another object. This happens if the NameTrans directive that was successfully executed specifies a name or generates a partial path that matches the name or ppath attribute of another object.

If the successful NameTrans directive assigns a name by specifying a name argument, the server starts processing directives in the named object (defined with the OBJECT tag) before processing directives in the default object for the rest of the request-handling process.

For example, the following NameTrans directive in the default object assigns the name cgi to any request whose URL starts with http://server_name/cgi/.

<Object name="default">
  ...
  NameTrans fn="pfx2dir" from="/cgi"
  dir="D:/Sun/WebServer61/server1/docs/mycgi" name="cgi"
  ...
</Object>

When that NameTrans directive is executed, the server starts processing directives in the object named cgi:

<Object name="cgi">
  more directives...
</Object>

When a NameTrans directive has been successfully executed, there will be a physical path name associated with the requested resource. If the resultant path name matches the ppath (partial path) attribute of another object, the server starts processing directives in the other object before processing directives in the default object for the rest of the request-handling process.

For example, suppose obj.conf contains an object as follows:

<Object ppath="*internal*">
  more directives...
</Object>

Now suppose the successful NameTrans directive translates the requested URL to the path name D:/Sun/WebServer61/server1/docs/internalplan1.html. In this case, the partial path...
*internal* matches the path D:/Sun/WebServer61/server1/docs/internalplan1.html. So now the server would start processing the directives in this object before processing the remaining directives in the default object.

**PathCheck**

After converting the logical URL of the requested resource to a physical path name in the NameTrans step, the server executes PathCheck directives to verify that the client is allowed to access the requested resource.

If there is more than one PathCheck directive, the server executes all of the directives in the order in which they appear, unless one of the directives denies access. If access is denied, the server switches to executing directives in the Error section.

If the NameTrans directive assigned a name or generated a physical path name that matches the name or ppath attribute of another object, the server first applies the PathCheck directives in the matching object before applying the directives in the default object.

**ObjectType**

Assuming that the PathCheck directives all approve access, the server next executes the ObjectType directives to determine the MIME type of the request. The MIME type has three attributes: type, encoding, and language. When the server sends the response to the client, the type, language, and encoding values are transmitted in the headers of the response. The type also frequently helps the server to determine which Service directive to execute to generate the response to the client.

If there is more than one ObjectType directive, the server applies all of the directives in the order in which they appear. However, once a directive sets an attribute of the MIME type, further attempts to set the same attribute are ignored. The reason that all ObjectType directives are applied is that one directive may set one attribute, for example type, while another directive sets a different attribute, such as language.

As with the PathCheck directives, if another object has been matched to the request as a result of the NameTrans step, the server executes the ObjectType directives in the matching object before executing the ObjectType directives in the default object.

**Setting the Type By File Extension**

Usually the default way the server figures out the MIME type is by calling the type-by-extension function. This function instructs the server to look up the MIME type according to the requested resource’s file extension in the MIME types table. This table was created during virtual server initialization by the MIME types file (which is usually called mime.types).
For example, the entry in the MIME types table for the extensions .html and .htm is usually:

```
type=text/html  exts=htm,html
```

which says that all files with the extension .htm or .html are text files formatted as HTML, and the type is text/html.

Note that if you make changes to the MIME types file, you must reconfigure the server before those changes can take effect.

For more information about MIME types, see Sun Java System Web Server 6.1 SP10 Administrator's Configuration File Reference.

**Forcing the Type**

If no previous ObjectType directive has set the type, and the server does not find a matching file extension in the MIME types table, the type still has no value even after type-by-expression has been executed. Usually if the server does not recognize the file extension, it is a good idea to force the type to be text/plain, so that the content of the resource is treated as plain text. There are also other situations where you might want to set the type regardless of the file extension, such as forcing all resources in the designated CGI directory to have the MIME type magnus-internal/cgi.

The function that forces the type is force-type.

For example, the following directives first instruct the server to look in the MIME types table for the MIME type, then if the type attribute has not been set (that is, the file extension was not found in the MIME types table), set the type attribute to text/plain.

```
ObjectType fn="type-by-extension"
ObjectType fn="force-type" type="text/plain"
```

If the server receives a request for a file abc.dogs, it looks in the MIME types table, does not find a mapping for the extension .dogs, and consequently does not set the type attribute. Since the type attribute has not already been set, the second directive is successful, forcing the type attribute to text/plain.

The following example illustrates another use of force-type. In this example, the type is forced to magnus-internal/cgi before the server gets a chance to look in the MIME types table. In this case, all requests for resources in `http://server_name/cgi/` are translated into requests for resources in the directory D:/Sun/WebServer61/server1/docs/mycgi/. Since a name is assigned to the request, the server processes ObjectType directives in the object named cgi before processing the ones in the default object. This object has one ObjectType directive, which forces the type to be magnus-internal/cgi.

```
NameTrans fn="pfx2dir"
  from="/cgi" dir="/D:/Sun/WebServer61/server1/docs/mycgi"
  name="cgi"
```
The server continues processing all ObjectType directives including those in the default object, but since the type attribute has already been set, no other directive can set it to another value.

**Input**

The Input directive selects filters that will process incoming request data read by the Service step. It allows you to invoke the insert-filter SAF in order to install filters that process incoming data.

The Input directives are executed at most once per request.

You can define the appropriate position of a specific filter within the filter stack. For example, filters that translate content from XML to HTML are placed higher in the filter stack than filters that compress data for transmission. You can use the filter_create function to define the filter's position in the filter stack, and init-filter-order to override the defined position.

When two or more filters are defined to occupy the same position in the filter stack, filters that were inserted later will appear higher than filters that were inserted earlier. That is, the order of Input fn="insert-filter" and Output fn="insert-filter" directives in obj.conf becomes important.

For more information, see Chapter 4, Creating Custom Filters.

**Output**

The Output directive selects filters that will process outgoing response data generated by the Service step. The Output directive allows you to invoke the insert-filter SAF to install filters that process outgoing data. All Output directives are executed when the server or a plug-in first attempts to write entity body data from the client.

The Output directives are executed at most once per request.

You can define the appropriate position of a specific filter within the filter stack. For example, filters that translate content from XML to HTML are placed higher in the filter stack than filters that compress data for transmission. You can use the filter_create function to define the filter's position in the filter stack, init-filter-order to override the defined position.

When two or more filters are defined to occupy the same position in the filter stack, filters that were inserted later will appear higher than filters that were inserted earlier. That is, the order of Input fn="insert-filter" and Output fn="insert-filter" directives in obj.conf becomes important.
For more information, see Chapter 4, Creating Custom Filters.

**Service**

Next, the server needs to execute a Service directive to generate the response to send to the client. The server looks at each Service directive in turn, to find the first one that matches the type, method and query string. If a Service directive does not specify type, method, or query string, then the unspecified attribute matches anything.

If there is more than one Service directive, the server applies the first one that matches the conditions of the request, and ignores all remaining Service directives.

As with the PathCheck and ObjectType directives, if another object has been matched to the request as a result of the NameTrans step, the server considers the Service directives in the matching object before considering the ones in the default object. If the server successfully executes a Service directive in the matching object, it will not get around to executing the Service directives in the default object, since it only executes one Service directive.

**Service Examples**

For an example of how Service directives work, consider what happens when the server receives a request for the URL D:/server_name/jos.html. In this case, all directives executed by the server are in the default object.

- The following NameTrans directive translates the requested URL to D:/Sun/WebServer61/server1/docs/jos.html:

  NameTrans fn="document-root" root="D:/Sun/WebServer61/server1/docs"

- Assume that the PathCheck directives all succeed.

- The following ObjectType directive tells the server to look up the resource’s MIME type in the MIME types table:

  ObjectType fn="type-by-extension"

- The server finds the following entry in the MIME types table, which sets the type attribute to text/html:

  type=text/html exts=htm,html

- The server invokes the following Service directive. The value of the type parameter matches anything that does not begin with magnus-internal/. (For a list of all wildcard patterns, see Chapter 9, Using Wildcard Patterns client.)

  Service method="(GET|HEAD|POST)" type="*~magnus-internal/*" fn="send-file"
Here is an example that involves using another object:

- The following NameTrans directive assigns the name personnel to the request.

```plaintext
NameTrans fn=assign-name name=personnel from=/personnel
```

- As a result of the name assignment, the server switches to processing the directives in the object named personnel. This object is defined as:

```plaintext
<Object name="personnel">
Service fn="index-simple"
</Object>
```

- The personnel object has no PathCheck or ObjectType directives, so the server processes the PathCheck and ObjectType directives in the default object. Let’s assume that all PathCheck and ObjectType directives succeed.

- When processing Service directives, the server starts by considering the Service directive in the personnel object, which is:

```plaintext
Service fn="index-simple"
```

- The server executes this Service directive, which calls the index-simple function.

Since a Service directive has now been executed, the server does not process any other Service directives. (However, if the matching object had not had a Service directive that was executed, the server would continue looking at Service directives in the default object.)

### Default Service Directive

There is usually a Service directive that does the default task (sends a file) if no other Service directive matches a request sent by a browser. This default directive should come last in the list of Service directives in the default object, to ensure it only gets called if no other Service directives have succeeded. The default Service directive is usually:

```plaintext
Service method=(GET|HEAD|POST) type="*~magnus-internal/*" fn="send-file"
```

This directive matches requests whose method is GET, HEAD, or POST, which covers nearly virtually all requests sent by browsers. The value of the type argument uses special pattern-matching characters. For complete information about the special pattern-matching characters, see Chapter 9, Using Wildcard Patterns

The characters "*~" mean "anything that doesn’t match the following characters," so the expression *~magnus-internal/ means "anything that doesn’t match magnus-internal/."
asterisk by itself matches anything, so the whole expression *-magnus-internal/* matches anything that does not begin with magnus-internal/.

So if the server has not already executed a Service directive when it reaches this directive, it executes the directive so long as the request method is GET, HEAD or POST, and the value of the type attribute does not begin with magnus-internal/. The invoked function is send-file, which simply sends the contents of the requested file to the client.

**AddLog**

After the server generates the response and sends it to the client, it executes AddLog directives to add entries to the log files.

All AddLog directives are executed. The server can add entries to multiple log files.

Depending on which log files are used and which format they use, the Init section in magnus.conf may need to have directives that initialize the logs. For example, if one of the AddLog directives calls flex-log, which uses the extended log format, the Init section must contain a directive that invokes flex-init to initialize the flexible logging system.

For more information about initializing logs, see the discussion of the functions "flex-init" on page 54 and "init-clf" on page 61 in Chapter 2, SAFs in the magnus.conf File

For more information about flex-log, see information about predefined SAFs in the obj.conf file in the Sun Java System Web Server 6.1 SP10 Administrator’s Configuration File Reference

**Error**

If an error occurs during the request-handling process, such as if a PathCheck or AuthTrans directive denies access to the requested resource, or the requested resource does not exist, the server immediately stops executing all other directives and immediately starts executing the Error directives.

**Changes in Function Flow**

There are times when the function flow changes from the normal request-handling process. This happens during internal redirects, restarts, and URI translation functions.

**Internal Redirects**

An example of an internal redirect is a servlet include or forward. In this case, because there is no exposed NSAPI function to handle an internal redirect, when an internal redirect occurs, the request structure is copied into rq->orig_rq. For more information on the request data structure, see "Request" on page 244
Restarts

A restart occurs when a REQ_RESTART is returned from a PathCheck or Service function. For example, when a CGI is redirected using a relative path.

On a restart, much of the request is cleared. Some elements of the HTTP request (rq->reqpb), the server’s “working” variables (rq->vars), and response headers (rq->srvhdrs) are cleared. The method, protocol, and clf_request variables from rq->reqpb are saved. The saved variables are put back into the data structure. The new URI is inserted (and if there is a query string in the new URI, that too is inserted) into rq->reqpb. The parameter rq->rq_attr.req_restarted is set to 1. For more information on the request data structure, see “Request” on page 244.

URI Translation

At times it is necessary to find the physical path for a URI without actually running a request. The function “request_translate_uri” on page 196 does this. A new request structure is created and run through the AuthTrans and NameTrans stages to get the physical path. Thereafter, the new request is freed.

Syntax Rules for Editing obj.conf

Several rules are important in the obj.conf file. Be very careful when editing this file. Simple mistakes can make the server fail to start or operate correctly.

Caution – Do not remove any directives from any obj.conf file that are present in the obj.conf file that exists when you first install Sun Java System Web Server. The server may not function properly.

Order of Directives

The order of directives is important, since the server executes them in the order they appear in obj.conf. The outcome of some directives affect the execution of other directives.

For PathCheck directives, the order within the PathCheck section is not so important, since the server executes all PathCheck directives. However, the order within the ObjectType section is very important, because if an ObjectType directive sets an attribute value, no other ObjectType directive can change that value. For example, if the default ObjectType directives were listed in the following order (which is the wrong way around), every request would have its type value set to text/plain, and the server would never have a chance to set the type according to the extension of the requested resource.
Similarly, the order of directives in the Service section is very important. The server executes the first Service directive that matches the current request and does not execute any others.

**Parameters**

The number and names of parameters depends on the function. The order of parameters on the line is not important.

**Case Sensitivity**

Items in the obj.conf file are case-sensitive including function names, parameter names, many parameter values, and path names.

**Separators**

The C language allows function names to be composed only of letters, digits, and underscores. You may use the hyphen (-) character in the configuration file in place of underscore (_) for your C code function names. This is only true for function names.

**Quotes**

Quotes (") are only required around value strings when there is a space in the string. Otherwise they are optional. Each open-quote must be matched by a close-quote.

**Spaces**

- Spaces are not allowed at the beginning of a line except when continuing the previous line.
- Spaces are not allowed before or after the equal (=) sign that separates the name and value.
- Spaces are not allowed at the end of a line or on a blank line.

**Line Continuation**

A long line may be continued on the next line by beginning the next line with a space or tab.
Path Names

Always use forward slashes (/) rather than backslashes (\) in path names under Windows. Backslash escapes the next character.

Comments

Comments begin with a pound (#) sign. If you manually add comments to obj.conf, then use the Server Manager interface to make changes to your server, the Server Manager will wipe out your comments when it updates obj.conf.

About obj.conf Directive Examples

Every line in the obj.conf file begins with one of the following keywords:

AuthTrans
NameTrans
PathCheck
ObjectType
Input
Output
Service
AddLog
Error
<Object
</Object>

If any line of any example begins with a different word in the manual, the line is wrapping in a way that it does not in the actual file. In some cases this is due to line length limitations imposed by the PDF and HTML formats of the manuals.

For example, the following directive is all on one line in the actual obj.conf file:

NameTrans fn="pfx2dir" from="/cgi"
dir="D:/Sun/WebServer61/server1/docs/mycgi"
name="cgi"
SAFs in the magnus.conf File

When the Sun Java System Web Server starts up, it looks in a file called magnus.conf in the server-id/config directory to establish a set of global variable settings that affect the server’s behavior and configuration. Sun Java System Web Server executes all of the directives defined in magnus.conf. The order of the directives is not important.

**Note** – When you edit the magnus.conf file, you must restart the server for the changes to take effect.

### Init SAFs

This section the Init SAFs that can be specified in magnus.conf in Sun Java System Web Server 6.1. For information about the other, non-SAF directives in magnus.conf, see the Sun Java System Web Server 6.1 SP10 Administrator's Configuration File Reference

The Init directives initialize the server (for example they load and initialize additional modules and plug-ins, and initialize log files).

The Init directives are SAFs, like obj.conf directives, and have SAF syntax rather than the simpler variable value syntax of other magnus.conf directives.

They are located in magnus.conf because, like other magnus.conf directives, they are executed only once at server startup.

Each Init directive has an optional LateInit parameter. For the UNIX platform, if LateInit is set to yes, the function is executed by the child process after it is forked from the parent. If LateInit is set to no or is not provided, the function is executed by the parent process before the fork. When the server is started up by user root but runs as another user, any activities that must be performed as the user root (such as writing to a root-owned file) must be done before the fork. Functions that create threads, with the exception of thread-pool-init, should execute after the fork (that is, the relevant Init directive should have LateInit=yes set).
For all platforms, any function that requires access to a fully parsed configuration should have `LateInit=yes` set on its `Init` directive.

Upon failure, `Init`-class functions return `REQ_ABORTED`. The server logs the error according to the instructions in the `Error` directives in `obj.conf`, and terminates. Any other result code is considered a success.

## Syntax

`Init` functions have the following syntax:

```
Init fn=function param1="value1" ... paramN="valueN"
```

Directives have the following syntax:

```
directive value
```

The following `Init`-class functions and their parameters are described in detail in this chapter:

- **“cindex-init” on page 51** changes the default characteristics for fancy indexing.
- **“define-perf-bucket” on page 52** creates a performance bucket.
- **“dns-cache-init” on page 53** configures DNS caching.
- **“flex-init” on page 54** initializes the flexible logging system.
- **“flex-rotate-init” on page 58** enables rotation for flexible logs.
- **“init-cgi” on page 60** changes the default settings for CGI programs.
- **“init-clf” on page 61** initializes the Common Log subsystem.
- **“init-dav” on page 62** initializes the WebDAV subsystem.
- **“init-filter-order” on page 62** controls the position of specific filters within filter stacks.
- **“init-j2ee” on page 64** initializes the Java subsystem.
- **“init-uhome” on page 64** loads user home directory information.
- **“load-modules” on page 65** loads shared libraries into the server.
- **“nt-console-init” on page 66** enables the Windows console, which is the command-line shell that displays standard output and error streams.
- **“perf-init” on page 66** enables system performance measurement via performance buckets.
- **“pool-init” on page 67** configures pooled memory allocation.
- **“register-http-method” on page 68** lets you extend the HTTP protocol by registering new HTTP methods.
- **“stats-init” on page 69** enables reporting of performance statistics in XML format.
- **“thread-pool-init” on page 69** configures an additional thread pool.
cindex-init function, if present, is ignored.

**cindex-init**

Applicable in Init-class directives.

The function `cindex-init` sets the default settings for common indexing. Common indexing (also known as fancy indexing) is performed by the Service function `index-common`. Indexing occurs when the requested URL translates to a directory that does not contain an index file or home page, or no index file or home page has been specified.

In common (fancy) indexing, the directory list shows the name, last modified date, size, and description for each indexed file or directory.

**Parameters**

The following table describes parameters for the `cindex-init` function.

<table>
<thead>
<tr>
<th><strong>Parameter</strong></th>
<th><strong>Description</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>opts</strong></td>
<td>(Optional) String of letters specifying the options to activate. Currently there is only one possible option: <code>s</code> tells the server to scan each HTML file in the directory being indexed for the contents of the HTML <code>&lt;TITLE&gt;</code> tag to display in the description field. The <code>&lt;TITLE&gt;</code> tag must be within the first 255 characters of the file. This option is off by default.&lt;br&gt;The search for <code>&lt;TITLE&gt;</code> is not case-sensitive.</td>
</tr>
<tr>
<td><strong>widths</strong></td>
<td>(Optional) Specifies the width for each column in the indexing display. The string is a comma-separated list of numbers that specify the column widths in characters for name, last-modified date, size, and description, respectively.&lt;br&gt;The default values for the widths parameter are 22, 18, 8, 33.&lt;br&gt;The final three values (corresponding to last-modified date, size, and description, respectively) can each be set to 0 to turn the display for that column off. The name column cannot be turned off. The minimum size of a column (if the value is nonzero) is specified by the length of its title. For example, the minimum size of the date column is 5 (the length of “Date” plus one space). If you set a nonzero value for a column that is less than the length of its title, the width defaults to the minimum required to display the title.</td>
</tr>
</tbody>
</table>
TABLE 2–1  index-init parameters  (Continued)

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>timezone</td>
<td>(Optional) Indicates whether the last-modified time is shown in local time or in Greenwich Mean Time. The values are GMT or local. The default is local.</td>
</tr>
<tr>
<td>format</td>
<td>(Optional) Parameter determines the format of the last modified date display. It uses the format specification for the UNIX function strftime(). The default is %d-%b-%Y %H:%M.</td>
</tr>
<tr>
<td>ignore</td>
<td>(Optional) Specifies a wildcard pattern for file names the server should ignore while indexing. File names starting with a period (.) are always ignored. The default is to only ignore file names starting with a period (.).</td>
</tr>
<tr>
<td>icon-uri</td>
<td>(Optional) Specifies the URI prefix the index-common function uses when generating URLs for file icons (.gif files). By default, it is /mc-icons/. If icon-uri is different from the default, the px2dir function in the NameTrans directive must be changed so that the server can find these icons.</td>
</tr>
</tbody>
</table>

Example

Init fn=index-init widths=50,1,1,0
Init fn=index-init ignore=*private*
Init fn=index-init widths=22,0,0,50

define-perf-bucket

Applicable in Init-class directives.

The define-perf-bucket function creates a performance bucket, which you can use to measure the performance of SAFs in obj.conf (for more information about predefined SAFs that are used in obj.conf, see Sun Java System Web Server 6.1 SP10 Administrator’s Configuration File Reference).

For more information about performance buckets, see the Sun Java System Web Server 6.1 SP10 Performance Tuning, Sizing, and Scaling Guide.

Parameters

The following table describes parameters for the define-perf-bucket function.
Table 2-2  define-perf-bucket parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>Name for the bucket (for example, cgi-bucket).</td>
</tr>
<tr>
<td>description</td>
<td>Description of what the bucket measures (for example, CGI Stats).</td>
</tr>
</tbody>
</table>

Example

Init fn="define-perf-bucket" name="cgi-bucket" description="CGI Stats"

See Also

"perf-init" on page 66

dns-cache-init

Applicable in Init-class directives.

The dns-cache-init function specifies that DNS lookups should be cached when DNS lookups are enabled. If DNS lookups are cached, then when the server gets a client’s host name information, it stores that information in the DNS cache. If the server needs information about the client in the future, the information is available in the DNS cache.

You may specify the size of the DNS cache and the time it takes before a cache entry becomes invalid. The DNS cache can contain 32 to 32768 entries; the default value is 1024 entries. Values for the time it takes for a cache entry to expire (specified in seconds) can range from 1 second to 1 year; the default value is 1200 seconds (20 minutes).

Parameters

The following table describes parameters for the dns-cache-init function.

Table 2-3  dns-cache-init parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>cache-size</td>
<td>(Optional) Specifies how many entries are contained in the cache. Acceptable values are 32 to 32768; the default value is 1024.</td>
</tr>
</tbody>
</table>
### TABLE 2-3  dns-cache-init parameters  (Continued)

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>expire</td>
<td>(Optional) Specifies how long (in seconds) it takes for a cache entry to expire. Acceptable values are 1 to 31536000 (1 year); the default is 1200 seconds (20 minutes).</td>
</tr>
</tbody>
</table>

#### Example

```
Init fn="dns-cache-init" cache-size="2140" expire="600"
```

---

### flex-init

Applicable in `Init-class` directives.

The `flex-init` function opens the named log file to be used for flexible logging and establishes a record format for it. The log format is recorded in the first line of the log file. You cannot change the log format while the log file is in use by the server.

The `flex-log` function (applicable in `AddLog-class` directives) writes entries into the log file during the `AddLog` stage of the request-handling process.

The log file stays open until the server is shut down or restarted (at which time all logs are closed and reopened).

---

**Note** – If the server has `AddLog-stage` directives that call `flex-log`, the flexible log file must be initialized by `flex-init` during server initialization.

For more information about `flex-log`, see information about predefined SAFs in the `obj.conf` file in the *Sun Java System Web Server 6.1 SP10 Administrator’s Configuration File Reference*.

You may specify multiple log file names in the same `flex-init` function call. Then use multiple `AddLog` directives with the `flex-log` function to log transactions to each log file.

The `flex-init` function may be called more than once. Each new log file name and format will be added to the list of log files.

If you move, remove, or change the currently active log file without shutting down or restarting the server, client accesses might not be recorded. To save or backup the currently active log file, you need to rename the file and then restart the server. The server first looks for the log file by name, and if it doesn’t find it, creates a new one (the renamed original log file is left for you to use).

For information on rotating log files, see “flex-rotate-init” on page 58.
The `flex-init` function has three parameters: one that names the log file, one that specifies the format of each record in that file, and one that specifies the logging mode.

**Parameters**

The following table describes parameters for the `flex-init` function.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
</table>
| `logFileName`    | Name of the parameter is the name of the log file. The value of the parameter specifies either the full path to the log file or a file name relative to the server's logs directory. For example: access=\"/usr/netscape/server4/https-servername/logs/access\"mylogfile = \"log1\"
You will use the log file name later, as a parameter to the `flex-log` function (applicable in `AddLog-class` directives). |
| `buffer-size`    | Specifies the size of the global log buffer. The default is 8192. See the third `flex-init` example below. |
| `buffers-per-file` | Specifies the number of buffers for a given log file. The default value is determined by the server. Access log entries can be logged in strict chronological order by using a single buffer per log file. To accomplish this, add `buffers-per-file=1` to the `Init fn=\"flex-log-init\"` line in `magnus.conf`. This ensures that requests are logged in chronological order. Note that this approach will result in decreased performance when the server is under heavy load. |
| `format.logFileName` | Specifies the format of each log entry in the log file. For information about the format, see the "flex-init" on page 54 |
| `%duration%`     | This `flex-log` format variable, records the time in microseconds, spent by the server in processing requests. Statistics must be enabled for the server instance before `%duration%` is used. See Sun Java System Web Server 6.1 SP10 Administrator's Guide for information on enabling statistics. For more information on log file formats, see Sun Java System Web Server 6.1 SP10 Administrator's Guide. |

**More on Log Format**

The `flex-init` function recognizes anything contained between percent signs (%) as the name portion of a name-value pair stored in a parameter block in the server. (The one exception to this rule is the `%SYSDATE%` component, which delivers the current system date.) `%SYSDATE%` is formatted using the time format `%d/%b/%Y: %H:%M:%S` plus the offset from GMT.
(See Chapter 3, Creating Custom SAFs for more information about parameter blocks, and Chapter 7, NSAPI Function Reference.)

Any additional text is treated as literal text, so you can add to the line to make it more readable. Typical components of the formatting parameter are listed in the following table “flex-init” on page 54. Certain components might contain spaces, so they should be bounded by escaped quotes (\”).

If no format parameter is specified for a log file, the common log format is used:

```
%Ses->client.ip% - %Req->vars.auth-user% [%SYSDATE%]
\"%Req->reqpb.clf-request\" %Req->srvhdrs.clf-status%
%Req->srvhdrs.content-length%
```

You can now log cookies by logging the Req->headers.cookie.name component.

In the following table, the components that are enclosed in escaped double quotes (\”) are the ones that could potentially resolve to values that have white spaces.

### TABLE 2–5 Typical Components of flex-init Formatting

<table>
<thead>
<tr>
<th>Flex-log Option</th>
<th>Component</th>
</tr>
</thead>
<tbody>
<tr>
<td>Client host name (unless iponly is specified in flex-log or DNS name is not available) or IP address</td>
<td>%Ses-&gt;client.ip%</td>
</tr>
<tr>
<td>Client DNS name</td>
<td>%Ses-&gt;client.dns%</td>
</tr>
<tr>
<td>System date</td>
<td>%SYSDATE%</td>
</tr>
<tr>
<td>Full HTTP request line</td>
<td>&quot;%Req-&gt;reqpb.clf-request&quot;</td>
</tr>
<tr>
<td>Status</td>
<td>%Req-&gt;srvhdrs.clf-status%</td>
</tr>
<tr>
<td>Response content length</td>
<td>%Req-&gt;srvhdrs.content-length%</td>
</tr>
<tr>
<td>Response content type</td>
<td>%Req-&gt;srvhdrs.content-type%</td>
</tr>
<tr>
<td>Referer header</td>
<td>&quot;%Req-&gt;headers.referer&quot;</td>
</tr>
<tr>
<td>User-agent header</td>
<td>&quot;%Req-&gt;headers.user-agent&quot;</td>
</tr>
<tr>
<td>HTTP method</td>
<td>%Req-&gt;reqpb.method%</td>
</tr>
<tr>
<td>HTTP URI</td>
<td>%Req-&gt;reqpb.uri%</td>
</tr>
<tr>
<td>HTTP query string</td>
<td>%Req-&gt;reqpb.query%</td>
</tr>
<tr>
<td>HTTP protocol version</td>
<td>%Req-&gt;reqpb.protocol%</td>
</tr>
</tbody>
</table>
TABLE 2-5  Typical Components of flex-init Formatting  (Continued)

<table>
<thead>
<tr>
<th>Flex-log Option</th>
<th>Component</th>
</tr>
</thead>
<tbody>
<tr>
<td>Accept header</td>
<td>%Req-&gt;headers.accept%</td>
</tr>
<tr>
<td>Date header</td>
<td>%Req-&gt;headers.date%</td>
</tr>
<tr>
<td>If-Modified-Since header</td>
<td>%Req-&gt;headers.if-modified-since%</td>
</tr>
<tr>
<td>Authorization header</td>
<td>%Req-&gt;headers.authorization%</td>
</tr>
<tr>
<td>Any header value</td>
<td>%Req-&gt;headers.headername%</td>
</tr>
<tr>
<td>Name of authorized user</td>
<td>%Req-&gt;vars.auth-user%</td>
</tr>
<tr>
<td>Value of a cookie</td>
<td>%Req-&gt;headers.cookie.name%</td>
</tr>
<tr>
<td>Value of any variable in</td>
<td>%Req-&gt;vars.varname%</td>
</tr>
<tr>
<td>Req-&gt;vars</td>
<td></td>
</tr>
<tr>
<td>Virtual server ID</td>
<td>%vsid%</td>
</tr>
<tr>
<td>Duration</td>
<td>%duration%</td>
</tr>
</tbody>
</table>

Record the time in microseconds the server spent handling the request. Statistics must be enabled for the server instance before %duration% can be used. For information about enabling statistics, see Sun Java System Web Server 6.1 SP10 Administrator’s Guide.

Examples

The first example below initializes flexible logging into the file
/usr/sun/webserver61/server1/https-servername/logs/access.

Init fn=flex-init access="/usr/sun/webserver61/server1/https-servername/logs/access" format.access="%Ses->client.ip% - %Req->vars.auth-user% [%SYSDATE%] "%\Req->reqpb.clf-request%" %Req->srvhdrs.clf-status% %Req->srvhdrs.content-length%"

This will record the following items:
- IP or host name, followed by the three characters " . "
- User name, followed by the two characters " [ "
- System date, followed by the two characters " ] "
- Full HTTP request in quotes, followed by a single space
- HTTP result status in quotes, followed by a single space
- Content length
  This is the default format, which corresponds to the Common Log Format (CLF).
It is advisable that the first six elements of any log always be in exactly this format, because a number of log analyzers expect that as output.

The second example initializes flexible logging into the file /usr/sun/webserver61/server1/https-servername/logs/extended.

```
Init fn=flex-init extended="/usr/sun/webserver61/server1/https-servername/logs/extended"
format.extended="%Ses->client.ip% - %Req->vars.auth-user% [SYSDATE ly] "%Req->reqpb.clf-request%% %Req->srvhdrs.clf-status% %Req->srvhdrs.content-length% %Req->headers.referer% "%Req->headers.user-agent% %Req->reqpb.method% %Req->reqpb.uri% %Req->reqpb.query% %Req->reqpb.protocol%"
```

The third example shows how logging can be tuned to prevent request handling threads from making blocking calls when writing to log files, instead delegating these calls to the log flush thread.

Doubling the size of the buffer-size and num-buffers parameters from their defaults and lowering the value of the LogFlushInterval magnus.conf directive to 4 seconds (see Chapter 2, SAFs in the magnus.conf File)

```
Init fn=flex-init buffer-size=16384 num-buffers=2000
access="/usr/sun/webserver61/server1/https-servername/logs/access"
format.access="%Ses->client.ip% - %Req->vars.auth-user% [SYSDATE ly] "%Req->reqpb.clf-request%% %Req->srvhdrs.clf-status% %Req->srvhdrs.content-length%"
```

See Also

“flex-rotate-init” on page 58

**flex-rotate-init**

Applicable in Init-class directives.

The **flex-rotate-init** function configures log rotation for all log files on the server, including error logs and the common-log, flex-log, and record-useragent AddLog SAFs. Call this function in the Init section of magnus.conf before calling “flex-init” on page 54. The **flex-rotate-init** function allows you to specify a time interval for rotating log files. At the specified time interval, the server moves the log file to a file whose name indicates the time of moving. The log functions in the AddLog stage in obj.conf then start logging entries in a new log file. The server does not need to be shut down while the log files are being rotated.
Note – The server keeps all rotated log files forever, so you will need to clean them up as necessary to free disk space.

By default, log rotation is disabled.

Parameters

The following table describes parameters for the `flex-rotate-init` function.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>rotate-start</td>
<td>Indicates the time to start rotation. This value is a four-digit string indicating the time in 24-hour format. For example, 0900 indicates 9 a.m., while 1800 indicates 9 p.m.</td>
</tr>
<tr>
<td>rotate-interval</td>
<td>Indicates the number of minutes to elapse between each log rotation.</td>
</tr>
<tr>
<td>rotate-access</td>
<td>(Optional) Determines whether <code>common-log</code>, <code>flex-log</code>, and <code>record-useragent</code> logs are rotated (AddLog SAFs). Values are <code>yes</code> (the default), and <code>no</code>.</td>
</tr>
<tr>
<td>rotate-error</td>
<td>(Optional) Determines whether error logs are rotated. Values are <code>yes</code> (the default), and <code>no</code>.</td>
</tr>
<tr>
<td>rotate-callback</td>
<td>(Optional) Specifies the file name of a user-supplied program to execute following log file rotation. The program is passed the post-rotation name of the rotated log file as its parameter.</td>
</tr>
</tbody>
</table>

Example

This example enables log rotation, starting at midnight and occurring every hour.

```ini
Init fn=flex-rotate-init rotate-start=2400 rotate-interval=60
```

See Also

“flex-init” on page 54
Applicable in Init-class directives.

The `init-cgi` function performs certain initialization tasks for CGI execution. Two options are provided: timeout of the execution of the CGI script, and establishment of environment variables.

### Parameters

The following table describes parameters for the `init-cgi` function.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>timeout</code></td>
<td>(Optional) Specifies how many seconds the server waits for CGI output. If the CGI script has not delivered any output in that many seconds, the server terminates the script. The default is 300 seconds.</td>
</tr>
<tr>
<td><code>cgistub-path</code></td>
<td>(Optional) Specifies the path to the CGI stub binary. If not specified, Sun Java System Web Server looks in the following directories in the following order, relative to the server instance's config directory: <code>./private/Cgistub</code>, then <code>../bin/https/bin/Cgistub</code>. Use the first directory to house an suid Cgistub (that is, a Cgistub owned by root that has the set-user-ID-on-exit bit set). Use the second directory to house a non-suid Cgistub. The second directory is the location used by Sun Java System Web Server 4.x servers. If present, the <code>./private</code> directory must be owned by the server user and have permissions <code>d??x------</code>. This prevents other users (for example, users with shell accounts or CGI access) from using Cgistub to set their uid. For information about installing a suid Cgistub, see the <em>Sun Java System Web Server 6.1 SP10 Programmer’s Guide</em>.</td>
</tr>
<tr>
<td><code>env-variable</code></td>
<td>(Optional) Specifies the name and value for an environment variable that the server places into the environment for the CGI. You can set any number of environment variables in a single <code>init-cgi</code> function.</td>
</tr>
</tbody>
</table>

### Example

```
Init fn=init-cgi LD_LIBRARY_PATH=/usr/lib;/usr/local/lib
```
**init-clf**

Applicable in **Init-class directives**.

The *init-clf* function opens the named log files to be used for common logging. The *common-log* function writes entries into the log files during the *AddLog* stage of the request-handling process. The log files stay open until the server is shut down (at which time the log files are closed) or restarted (at which time the log files are closed and reopened).

**Note** – If the server has an *AddLog*-stage directive that calls *common-log*, common log files must be initialized by *init-clf* during initialization.

**Note** – This function should only be called once. If it is called again, the new call will replace log file names from all previous calls.

If you move, remove, or change the log file without shutting down or restarting the server, client accesses might not be recorded. To save or backup a log file, you need to rename the file (and for UNIX, send the -HUP signal), and then restart the server. The server first looks for the log file by name, and if it doesn’t find it, creates a new one (the renamed original log file is left for you to use).

For information on rotating log files, see “flex-rotate-init” on page 58.

**Parameters**

The following table describes parameters for the *init-clf* function.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>logFileName</td>
<td>Name of the parameter is the name of the log file. The value of the parameter specifies either the full path to the log file or a file name relative to the server’s logs directory. For example:</td>
</tr>
<tr>
<td></td>
<td>access=&quot;/usr/netscape/server4/https-servername/logs/access&quot;mylogfile = &quot;log1&quot;</td>
</tr>
<tr>
<td></td>
<td>You will use the log file name later, as a parameter to the <em>common-log</em> function (applicable in <em>AddLog</em>-class directives).</td>
</tr>
</tbody>
</table>
init-dav

Examples

Init fn=init-clf access=/usr/netscape/server4/https-boots/logs/access
Init fn=init-clf templog=/tmp/mytemplog templog2=/tmp/mytemplog2

See Also

"flex-rotate-init" on page 58

init-dav

Applicable in Init-class directives.

The init-dav function performs initialization tasks to load the WebDAV plug-in.

Parameters

This function requires a LateInit=yes parameter.

Example

Init fn="load-modules" shlib="/s1ws6.1/lib/libdavplug-in.so"
func="init-dav,ntrans-dav,service-dav"
shlib_flags="(global|now)"
Init fn="init-dav" LateInit=yes

Example

Init fn=init-cgi LD_LIBRARY_PATH=/usr/lib;/usr/local/lib

init-filter-order

Applicable in Init-class directives.

The init-filter-order Init SAF can be used to control the position of specific filters within filter stacks. For example, init-filter-order can be used to ensure that a filter that converts outgoing XML to XHTML is inserted above a filter that converts outgoing XHTML to HTML.

Filters that appear higher in the filter stack are given an earlier opportunity to process outgoing data, and filters that appear lower in the filter stack are given an earlier opportunity to process incoming data.
The appropriate position of a specific filter within the filter stack is defined by the filter developer. For example, filters that translate content from XML to HTML are placed higher in the filter stack than filters that compress data for transmission. Filter developers use the “filter_create” function to define the filter's position in the filter stack. init-filter-order can be used to override the position defined by the filter developer.

When two or more filters are defined to occupy the same position in the filter stack, filters that were inserted later will appear higher than filters that were inserted earlier. That is, the order of Input fn="insert-filter" and Output fn="insert-filter" directives in obj.conf becomes important. For example, consider two filters, xhtml-to-html and xml-to-xhtml, which convert XHTML to HTML and XML to XHTML, respectively. Since both filters transform data from one format to another, they may be defined to occupy the same position in the filter stack. To transform XML documents to XHTML and then to HTML before sending the data to the client, Output fn="insert-filter" directives in obj.conf would appear in the following order:

Output fn="insert-filter" filter="xhtml-to-html"
Output fn="insert-filter" filter="xml-to-xhtml"

In general, administrators should use the order of Input fn="insert-filter" and Output fn="insert-filter" directives in obj.conf to control the position of filters in the filter stack. init-filter-order should only be used to address specific filter interoperability problems.

**Note**—The load-module SAFs that create the filters should be called before init-filter-order attempts to order them.

**Parameters**

The following table describes parameters for the init-filter-order function.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>filters</td>
<td>Comma-separated list of filters in the order they should appear within a filter stack, listed from highest to lowest.</td>
</tr>
</tbody>
</table>

**Example**

Init fn="init-filter-order" filters="xml-to-xhtml,xhtml-to-html,http-compression"
init-j2ee

Applicable in Init-class directives.

The init-j2ee function initializes the Java subsystem.

Parameters

This function requires a LateInit=yes parameter.

Example

Init fn="load-modules" shlib="install_dir/lib/j2eeplug-in.so"
funcs="init-j2ee,ntrans-j2ee,service-j2ee,error-j2ee" shlib_flags="(global|now)"
Init fn="init-j2ee" LateInit=yes

init-uhome

Applicable in Init-class directives.

UNIX Only. The init-uhome function loads information about the system’s user home directories into internal hash tables. This increases memory usage slightly, but improves performance for servers that have a lot of traffic to home directories.

Parameters

The following table describes parameters for the init-uhome function.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pwfile</td>
<td>(Optional) Specifies the full file system path to a file other than /etc/passwd. If not provided, the default UNIX path (/etc/passwd) is used.</td>
</tr>
</tbody>
</table>

Examples

Init fn=init-uhome
Init fn=init-uhome pwfile=/etc/passwd-http
load-modules

Applicable in Init-class directives.

The load-modules function loads a shared library or dynamic-link library (DLL) into the server code. Specified functions from the library can then be executed from any subsequent directives. Use this function to load new plug-ins or SAFs.

If you define your own SAFs, you get the server to load them by using the load-modules function and specifying the shared library or DLL to load.

Parameters

The following table describes parameters for the load-modules function.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>shlib</td>
<td>Specifies either the full path to the shared library or DLL, or a file name relative to the server configuration directory.</td>
</tr>
<tr>
<td>funcs</td>
<td>Comma-separated list of the names of the functions in the shared library or DLL to be made available for use by other Init directives or by Service directives in obj.conf. The list should not contain any spaces. The dash (-) character may be used in place of the underscore (_) character in function names.</td>
</tr>
<tr>
<td>NativeThread</td>
<td>(Optional) Specifies which threading model to use.</td>
</tr>
<tr>
<td></td>
<td>no causes the routines in the library to use user-level threading.</td>
</tr>
<tr>
<td></td>
<td>yes enables kernel-level threading. The default is yes.</td>
</tr>
<tr>
<td>pool</td>
<td>Name of a custom thread pool, as specified in &quot;thread-pool-init&quot; on page 69.</td>
</tr>
</tbody>
</table>

Examples

Init fn=load-modules shlib="C:/mysrvfns/corpfns.dll"
funcs="moveit"

Init fn=load-modules shlib="/mysrvfns/corpfns.so"
funcs="myinit,myservice"
Init fn=myinit
nt-console-init

Applicable in Init-class directives.

The `nt-console-init` function enables the Windows console, which is the command-line shell that displays standard output and error streams.

**Parameters**

The following table describes parameters for the `nt-console-init` function.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>stderr</td>
<td>Directs error messages to the Windows console. The required and only value is <code>console</code>.</td>
</tr>
<tr>
<td>stdout</td>
<td>Directs output to the Windows console. The required and only value is <code>console</code>.</td>
</tr>
</tbody>
</table>

**Example**

```ini
Init fn="nt-console-init" stdout=console stderr=console
```

perf-init

Applicable in Init-class directives.

The `perf-init` function enables system performance measurement via performance buckets.

For more information about performance buckets, see the *Sun Java System Web Server 6.1 SP10 Performance Tuning, Sizing, and Scaling Guide*.

**Parameters**

The following table describes parameters for the `perf-init` function.
TABLE 2–13  perf-init parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>disable</td>
<td>Flag to disable the use of system performance measurement via performance buckets. Should have a value of true or false. Default value is true.</td>
</tr>
</tbody>
</table>

Example

Init fn=perf-init disable=false

See Also

“define-perf-bucket” on page 52

pool-init

Applicable in Init-class directives.

The pool-init function changes the default values of pooled memory settings. The size of the free block list may be changed or pooled memory may be entirely disabled.

Memory allocation pools allow the server to run significantly faster. If you are programming with the NSAPI, note that MALLOC, REALLOC, CALLOC, STRDUP, and FREE work slightly differently if pooled memory is disabled. If pooling is enabled, the server automatically cleans up all memory allocated by these routines when each request completes. In most cases, this will improve performance and prevent memory leaks. If pooling is disabled, all memory is global and there is no clean-up.

If you want persistent memory allocation, add the prefix PERM_ to the name of each routine (PERM_MALLOC, PERM_REALLOC, PERM_CALLOC, PERM_STRDUP, and PERM_FREE).

Note – Any memory you allocate from Init-class functions will be allocated as persistent memory, even if you use MALLOC. The server cleans up only the memory that is allocated while processing a request, and because Init-class functions are run before processing any requests, their memory is allocated globally.

Parameters

The following table describes parameters for the pool-init function.
TABLE 2–14  pool-init parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>free-size</td>
<td>(Optional) Maximum size in bytes of free block list. May not be greater than 1048576.</td>
</tr>
<tr>
<td>disable</td>
<td>(Optional) Flag to disable the use of pooled memory. Should have a value of true or false. Default value is false.</td>
</tr>
</tbody>
</table>

Example

Init fn=pool-init disable=true

register-http-method

Applicable in Init-class directives.

This function lets you extend the HTTP protocol by registering new HTTP methods. (You do not need to register the default HTTP methods.)

Upon accepting a connection, the server checks if the method it received is known to it. If the server does not recognize the method, it returns a “501 Method Not Implemented” error message.

Parameters

The following table describes parameters for the register-http-method function.

TABLE 2–15  register-http-method parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>methods</td>
<td>Comma-separated list of the names of the methods you are registering.</td>
</tr>
</tbody>
</table>

Example

The following example shows the use of register-http-method and a Service function for one of the methods.

Init fn="register-http-method" methods="MY_METHOD1,MY_METHOD2"
Service fn="MyHandler" method="MY_METHOD1"
stats-init

Applicable in Init-class directives.

The stats-init function enables reporting of performance statistics in XML format. The actual report is generated by the stats-xml function in obj.conf.

Parameters

The following table describes parameters for the stats-init function.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>update-interval</td>
<td>Period in seconds between statistics updates within the server. Set higher for better performance, lower for more frequent updates. The minimum value is 1; the default is 5.</td>
</tr>
<tr>
<td>virtual-servers</td>
<td>Maximum number of virtual servers for which statistics are tracked. This number should be set higher than the number of virtual servers configured. Smaller numbers result in lower memory usage. The minimum value is 1; the default is 1000.</td>
</tr>
<tr>
<td>profiling</td>
<td>Enables NSAPI performance profiling using buckets if set to yes. This can also be enabled through the &quot;perf-init&quot; on page 66 Init SAF. The default is no, which results in slightly better server performance.</td>
</tr>
</tbody>
</table>

Example

Init fn="stats-init" update-interval="5" virtual-servers="2000" profiling="yes"

thread-pool-init

Applicable in Init-class directives.

The thread-pool-init function creates a new pool of user threads. A pool must be declared before it is used. To tell a plug-in to use the new pool, specify the pool parameter when loading the plug-in with the Init-class function "load-modules" on page 65.

One reason to create a custom thread pool would be if a plug-in is not thread-aware, in which case you can set the maximum number of threads in the pool to 1.

The older parameter NativeThread=yes always engages one default native pool, called NativePool.
The native pool on UNIX is normally not engaged, as all threads are OS-level threads. Using native pools on UNIX may introduce a small performance overhead, as they’ll require an additional context switch; however, they can be used to localize the jvm.stickyAttach effect or for other purposes, such as resource control and management, or to emulate single-threaded behavior for plug-ins.

On Windows, the default native pool is always being used and Sun Java System Web Server uses fibers (user-scheduled threads) for initial request processing. Using custom additional pools on Windows introduces no additional overhead.

In addition, native thread pool parameters can be added to the magnus.conf file for convenience. For more information, see “Native Thread Pools” in the chapter “Syntax and Use of magnus.conf” in the Sun Java System Web Server 6.1 SP10 Administrator’s Configuration File Reference.

Parameters

The following table describes parameters for the thread-pool-init function.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>Name of the thread pool.</td>
</tr>
<tr>
<td>maxthreads</td>
<td>Maximum number of threads in the pool.</td>
</tr>
<tr>
<td>minthreads</td>
<td>Minimum number of threads in the pool.</td>
</tr>
<tr>
<td>queueSize</td>
<td>Size of the queue for the pool. If all threads in the pool are busy, further request-handling threads that want to get a thread from the pool will wait in the pool queue. The number of request-handling threads that can wait in the queue is limited by the queue size. If the queue is full, the next request-handling thread that comes to the queue is turned away, with the result that the request is turned down, but the request-handling thread remains free to handle another request instead of becoming locked up in the queue.</td>
</tr>
<tr>
<td>stackSize</td>
<td>Stack size of each thread in the native (kernel) thread pool.</td>
</tr>
</tbody>
</table>

Example

Init fn=thread-pool-init name="my-custom-pool"
maxthreads=5 minthreads=1 queueSize=200
Init fn=load-modules shlib="C:/mydir/myplugin.dll"
funcs="tracker" pool="my-custom-pool"

"load-modules" on page 65
Creating Custom SAFs

This chapter describes how to write your own NSAPI plug-ins that define custom Server Application Functions (SAFs). Creating plug-ins allows you to modify or extend the Sun Java System Web Server’s built-in functionality. For example, you can modify the server to handle user authorization in a special way or generate dynamic HTML pages based on information in a database.

This chapter has the following sections:
- “Future Compatibility Issues” on page 74
- “The SAF Interface” on page 74
- “SAF Parameters” on page 74
- “Result Codes” on page 76
- “Creating and Using Custom SAFs” on page 77
- “Overview of NSAPI C Functions” on page 84
- “Required Behavior of SAFs for Each Directive” on page 88
- “CGI to NSAPI Conversion” on page 91

Before writing custom SAFs, you should familiarize yourself with the request-handling process, as described in general in “Request-handling Process” on page 25 and in greater detail in the Sun Java System Web Server 6.1 Administrator's Configuration File Reference. Also, before writing a custom SAF, check to see if a built-in SAF already accomplishes the tasks you have in mind.

See Chapter 2, SAFs in the magnus.conf File for a list of the predefined Init SAFs. For information about predefined SAFs used in the obj.conf file, see the Sun Java System Web Server 6.1 SP10 Administrator's Configuration File Reference.

For a complete list of the NSAPI routines for implementing custom SAFs, see Chapter 7, NSAPI Function Reference.
Future Compatibility Issues

The NSAPI interface may change in a future version of Sun Java System Web Server. To keep your custom plug-ins upgradable, do the following:

- Make sure plug-in users know how to edit the configuration files (such as magnus.conf and obj.conf) manually. The plug-in installation software should not be used to edit these configuration files.
- Keep the source code so you can recompile the plug-in.

The SAF Interface

All SAFs (custom and built-in) have the same C interface regardless of the request-handling step for which they are written. They are small functions designed for a specific purpose within a specific request-response step. They receive parameters from the directive that invokes them in the obj.conf file, from the server, and from previous SAFs.

Here is the C interface for a SAF:

```c
int function(pblock *pb, Session *sn, Request *rq);
```

The next section discusses the parameters in detail.

The SAF returns a result code that indicates whether and how it succeeded. The server uses the result code from each function to determine how to proceed with processing the request. See “Result Codes” on page 76 for details of the result codes.

SAF Parameters

This section discusses the SAF parameters in detail. The parameters are:

- "pb (parameter block)" on page 74 -- contains the parameters from the directive that invokes the SAF in the obj.conf file.
- “sn (session)” on page 75 -- contains information relating to a single TCP/IP session.
- “rq (request)” on page 75 -- contains information relating to the current request.

pb (parameter block)

The pb parameter is a pointer to a pbblock data structure that contains values specified by the directive that invokes the SAF. A pbblock data structure contains a series of name-value pairs.

For example, a directive that invokes the basic-nsca function might look like:
AuthTrans fn=basic-ncsa auth-type=basic dbm=/sun/server61/userdb/rs

In this case, the pb parameter passed to basic-ncsa contains name-value pairs that correspond to auth-type=basic and dbm=/Sun/WebServer61/server1/userdb/rs.

NSAPI provides a set of functions for working with pblock data structures. For example, pblock_findval() returns the value for a given name in a pblock. See “Parameter Block Manipulation Routines” on page 84 working with parameter blocks.

**sn (session)**

The sn parameter is a pointer to a session data structure. This parameter contains variables related to an entire session (that is, the time between the opening and closing of the TCP/IP connection between the client and the server). The same sn pointer is passed to each SAF called within each request for an entire session. The following list describes the most important fields in this data structure (see Chapter 7, NSAPI Function Reference NSAPI routines for manipulating the session data structure).

- sn->client
  Pointer to a pblock containing information about the client such as its IP address, DNS name, or certificate. If the client does not have a DNS name or if it cannot be found, it will be set to -none.

- sn->csd
  Platform-independent client socket descriptor. You will pass this to the routines for reading from and writing to the client.

**rq (request)**

The rq parameter is a pointer to a request data structure. This parameter contains variables related to the current request, such as the request headers, URI, and local file system path. The same request pointer is passed to each SAF called in the request-response process for an HTTP request.

The following list describes the most important fields in this data structure (see Chapter 7, NSAPI Function Reference for information about NSAPI routines for manipulating the request data structure).

- rq->vars
Pointer to a pblock containing the server’s “working” variables. This includes anything not specifically found in the following three pblocks. The contents of this pblock vary depending on the specific request and the type of SAF. For example, an AuthTrans SAF may insert an auth-user parameter into rq->vars which can be used subsequently by a PathCheck SAF.

- rq->reqpb
  Pointer to a pblock containing elements of the HTTP request. This includes the HTTP method (GET, POST, and so on), the URI, the protocol (normally HTTP/1.0), and the query string. This pblock does not normally change throughout the request-response process.

- rq->headers
  Pointer to a pblock containing all of the request headers (such as User-Agent, If-Modified-Since, and so on) received from the client in the HTTP request. See Chapter 12, Hypertext Transfer Protocol for more information about request headers. This pblock does not normally change throughout the request-response process.

- rq->srvhdrs
  Pointer to a pblock containing the response headers (such as Server, Date, content-type, Content-Length, and so on) to be sent to the client in the HTTP response. See Chapter 12, Hypertext Transfer Protocol

The rq parameter is the primary mechanism for passing along information throughout the request-response process. On input to a SAF, rq contains whatever values were inserted or modified by previously executed SAFs. On output, rq contains any modifications or additional information inserted by the SAF. Some SAFs depend on the existence of specific information provided at an earlier step in the process. For example, a PathCheck SAF retrieves values in rq->vars that were previously inserted by an AuthTrans SAF.

Result Codes

Upon completion, a SAF returns a result code. The result code indicates what the server should do next. The result codes are:

- REQ_PROCEED
  Indicates that the SAF achieved its objective. For some request-response steps (AuthTrans, NameTrans, Service, and Error), this tells the server to proceed to the next request-response step, skipping any other SAFs in the current step. For the other request-response steps (PathCheck, ObjectType, and AddLog), the server proceeds to the next SAF in the current step.

- REQ_NOACTION
  Indicates that the SAF took no action. The server continues with the next SAF in the current server step.

- REQ_ABORTED
Indicates that an error occurred and an HTTP response should be sent to the client to indicate the cause of the error. A SAF returning `REQ_ABORTED` should also set the HTTP response status code. If the server finds an `Error` directive matching the status code or reason phrase, it executes the SAF specified. If not, the server sends a default HTTP response with the status code and reason phrase plus a short HTML page reflecting the status code and reason phrase for the user. The server then goes to the first `AddLog` directive.

- `REQ_EXIT`

  Indicates the connection to the client was lost. This should be returned when the SAF fails in reading or writing to the client. The server then goes to the first `AddLog` directive.

### Creating and Using Custom SAFs

Custom SAFs are functions in shared libraries that are loaded and called by the server.

#### To create a custom SAF

1. **Write the Source Code** on page 77 using the NSAPI functions. Each SAF is written for a specific directive.

2. **Compile and Link** on page 78 the source code to create a shared library (`.so`, `.sl`, or `.dll`) file.

3. **Load and Initialize the SAF** on page 81 by editing the `magnus.conf` file to:
   - Load the shared library file containing your custom SAF(s)
   - Initialize the SAF if necessary

4. **Instruct the Server to Call the SAFs** on page 82 by editing `obj.conf` to call your custom SAF(s) at the appropriate time.

5. **Restart the Server** on page 83.

6. **Test the SAF** on page 84 by accessing your server from a browser with a URL that triggers your function.

The following sections describe these steps in greater detail.

### Write the Source Code

Write your custom SAFs using NSAPI functions. For a summary of some of the most commonly used NSAPI functions, see "Overview of NSAPI C Functions" on page 84 available routines, see Chapter 7, NSAPI Function Reference
For examples of custom SAFs, see nsapi/examples/ in the server root directory, and also see Chapter 5, Examples of Custom SAFs and Filters.

The signature for all SAFs is:

```c
int function(pblock *pb, Session *sn, Request *rq);
```

For more details on the parameters, see “SAF Parameters” on page 74.

The Sun Java System Web Server runs as a multi-threaded single process. On UNIX platforms there are actually two processes (a parent and a child), for historical reasons. The parent process performs some initialization and forks the child process. The child process performs further initialization and handles all of the HTTP requests.

Keep the following in mind when writing your SAF:

- Write thread-safe code
- Blocking may affect performance
- Write small functions with parameters and configure them in obj.conf
- Carefully check and handle all errors (and log them so you can determine the source of problems and fix them)

If necessary, write an initialization function that performs initialization tasks required by your new SAFs. The initialization function has the same signature as other SAFs:

```c
int function(pblock *pb, Session *sn, Request *rq);
```

SAFs expect to be able to obtain certain types of information from their parameters. In most cases, parameter block (pblock) data structures provide the fundamental storage mechanism for these parameters. A pblock maintains its data as a collection of name-value pairs. For a summary of the most commonly used functions for working with pblock structures, see “Parameter Block Manipulation Routines” on page 84.

When defining a SAF, you do not specifically state which directive it is written for. However, each SAF must be written for a specific directive (such as AuthTrans, Service, and so on). Each directive expects its SAFs to behave in particular ways, and your SAF must conform to the expectations of the directive for which it was written. For details of what each directive expects of its SAFs, see “Required Behavior of SAFs for Each Directive” on page 88.

**Compile and Link**

Compile and link your code with the native compiler for the target platform. For UNIX, use the gmake command. For Windows, use the nmake command. For Windows, use Microsoft Visual C++ 6.0 or newer. You must have an import list that specifies all global variables and functions to access from the server binary. Use the correct compiler and linker flags for your platform. Refer to the example Makefile in the server_root/plugins/nsapi/examples directory.
Adhere to the following guidelines for compiling and linking.

**Include Directory and nsapi.h File**
Add the `server_root/plugins/include` (UNIX) or `server_root\plugins\include` (Windows) directory to your makefile to include the `nsapi.h` file.

**Libraries**
Add the `server_root/bin/https/lib` (UNIX) or `server_root\bin\https\bin` (Windows) library directory to your linker command.

The following table lists the library that you need to link to.

<table>
<thead>
<tr>
<th>Platform</th>
<th>Library</th>
</tr>
</thead>
<tbody>
<tr>
<td>Windows</td>
<td>ns-httpd40.dll (in addition to the standard Windows libraries)</td>
</tr>
<tr>
<td>HP-UX</td>
<td>libns-httpd40.sl</td>
</tr>
<tr>
<td>All other UNIX platforms</td>
<td>libns-httpd40.so</td>
</tr>
</tbody>
</table>

**Linker Commands and Options for Generating a Shared Object**
To generate a shared library, use the commands and options listed in the following table.

<table>
<thead>
<tr>
<th>Platform</th>
<th>Options</th>
</tr>
</thead>
<tbody>
<tr>
<td>Solaris™ Operating System (SPARC® Platform Edition)</td>
<td>ld -G or cc -G</td>
</tr>
<tr>
<td>Windows</td>
<td>link -LD</td>
</tr>
<tr>
<td>HP-UX</td>
<td>cc +Z -b -Wl,+s -Wl,-B,symbolic</td>
</tr>
<tr>
<td>AIX</td>
<td>cc -p 0 -berok -blibpath:$LD_RPATH</td>
</tr>
<tr>
<td>Compaq</td>
<td>cc -shared</td>
</tr>
<tr>
<td>Linux</td>
<td>gcc -shared</td>
</tr>
<tr>
<td>IRIX</td>
<td>cc -shared</td>
</tr>
</tbody>
</table>

**Additional Linker Flags**
Use the linker flags in the following table to specify which directories should be searched for shared objects during runtime to resolve symbols.
TABLE 3–3  Linker Flags

<table>
<thead>
<tr>
<th>Platform</th>
<th>Flags</th>
</tr>
</thead>
<tbody>
<tr>
<td>Solaris SPARC</td>
<td>-R dir:dir</td>
</tr>
<tr>
<td>Windows</td>
<td>(no flags, but the ns-httpd40.dll file must be in the system PATH variable)</td>
</tr>
<tr>
<td>HP-UX</td>
<td>-Wl,+b,dir:dir</td>
</tr>
<tr>
<td>AIX</td>
<td>-blibpath:dir:dir</td>
</tr>
<tr>
<td>Compaq</td>
<td>-rpath dir:dir</td>
</tr>
<tr>
<td>Linux</td>
<td>-Wl,-rpath,dir:dir</td>
</tr>
<tr>
<td>IRIX</td>
<td>-Wl,-rpath,dir:dir</td>
</tr>
</tbody>
</table>

On UNIX, you can also set the library search path using the LD_LIBRARY_PATH environment variable, which must be set when you start the server.

**Compiler Flags**

The following table lists the flags and defines you need to use for compilation of your source code.

TABLE 3–4  Compiler Flags and Defines

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Solaris SPARC</td>
<td>-DXP_UNIX -D_REENTRANT -KPIC -DSOLARIS</td>
</tr>
<tr>
<td>Windows</td>
<td>-DXP_WIN32 -DWIN32 /MD</td>
</tr>
<tr>
<td>HP-UX</td>
<td>-DXP_UNIX -D_REENTRANT -DHPUX</td>
</tr>
<tr>
<td>AIX</td>
<td>-DXP_UNIX -D_REENTRANT -DAIX $(DEBUG)</td>
</tr>
<tr>
<td>Compaq</td>
<td>-DXP_UNIX -KPIC</td>
</tr>
<tr>
<td>Linux</td>
<td>-DLINUX -D_REENTRANT -fPIC</td>
</tr>
<tr>
<td>IRIX</td>
<td>-o32 -exceptions -DXP_UNIX -KPIC</td>
</tr>
<tr>
<td>All platforms</td>
<td>-MCC_HTTPD -NET_SSL</td>
</tr>
</tbody>
</table>

The following table lists the optional flags and defines you can use.
### Compiling 3.x Plugins on AIX

For AIX only, plug-ins built for 3.x versions of the server must be relinked to work with 4.x and 6.x versions. The files you need, which are in the server_root/plugins/nsapi/examples/ directory, are as follows:

- The Makefile file has the -G option instead of the old -bM:SRE -berk -brtl -bnoentry options.
- A script, relink_36plugin, modifies a plug-in built for 3.x versions of the server to work with 4.x and 6.x versions. The script’s comments explain its use.

Sun Java System Web Server 4.x and 6.x versions are built on AIX 4.2, which natively supports runtime-linking. Because of this, NSAPI plug-ins, which reference symbols in the ns-httpd main executable, must be built with the -G option, which specifies that symbols must be resolved at runtime.

Previous versions of Sun Java System Web Server, however, were built on AIX 4.1, which did not support native runtime-linking. Sun Java System Web Server had specific additional software to enable plug-ins. No special runtime-linking directives were required to build plug-ins. Because of this, plug-ins that have been built for previous server versions on AIX will not work with Sun Java System Web Server 4.x and 6.x versions as they are.

However, they can easily be relinked to work with Sun Java System Web Server 4.x and 6.x versions. The relink_36plugin script relinks existing plug-ins. Only the existing plug-in itself is required for the script; original source and .o files are not needed. More specific comments are in the script itself. Since all AIX versions from 4.2 onward natively support runtime-linking, no plug-ins for Sun Java System Web Server versions 4.x and later will need to be relinked.

### Load and Initialize the SAF

For each shared library (plug-in) containing custom SAFs to be loaded into the Sun Java System Web Server, add an Init directive that invokes the load-modules SAF to magnus.conf.

The syntax for a directive that calls load-modules is:

```
Init fn=load-modules shlib=[path]sharedlibname funcs="SAF1,...,SAFn"
```

- `shlib` is the local file system path to the shared library (plug-in).

---

**TABLE 3–5** Optional Flags and Defines

<table>
<thead>
<tr>
<th>Flag/Define</th>
<th>Platforms</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-DSPAPI20</td>
<td>All</td>
<td>Needed for the proxy utilities function include file putil.h</td>
</tr>
</tbody>
</table>
funcs is a comma-separated list of function names to be loaded from the shared library. Function names are case-sensitive. You may use dash (\-) in place of an underscore (\_\_) in function names. There should be no spaces in the function name list.

If the new SAFs require initialization, be sure that the initialization function is included in the \texttt{funcs} list.

For example, if you created a shared library \texttt{animations.so} that defines two SAFs \texttt{do_small_anim()} and \texttt{do_big_anim()} and also defines the initialization function \texttt{init_my_animations}, you would add the following directive to load the plug-in:

\begin{verbatim}
Init fn=load-modules shlib=animations.so
funcs="do_small_anim,do_big_anim,init_my_animations"
\end{verbatim}

If necessary, also add an \texttt{Init} directive that calls the initialization function for the newly loaded plug-in. For example, if you defined the function \texttt{init\_my\_new\_SAF()} to perform an operation on the \texttt{maxAnimLoop} parameter, you would add a directive such as the following to \texttt{magnus.conf}:

\begin{verbatim}
Init fn=init_my_animations maxAnimLoop=5
\end{verbatim}

\section*{Instruct the Server to Call the SAFs}

Next, add directives to \texttt{obj.conf} to instruct the server to call each custom SAF at the appropriate time. The syntax for directives is:

\textit{Directive } \texttt{fn=function-name [name1=value1] ... [nameN=valueN]}

- \textit{Directive} is one of the server directives, such as \texttt{AuthTrans}, \texttt{Service}, and so on.
- \textit{function-name} is the name of the SAF to execute.
- \textit{nameN=valueN} are the names and values of parameters which are passed to the SAF.

Depending on what your new SAF does, you might need to add just one directive to \texttt{obj.conf}, or you might need to add more than one directive to provide complete instructions for invoking the new SAF.

For example, if you define a new \texttt{AuthTrans} or \texttt{PathCheck} SAF, you could just add an appropriate directive in the default object. However, if you define a new \texttt{Service} SAF to be invoked only when the requested resource is in a particular directory or has a new kind of file extension, you would need to take extra steps.

If your new \texttt{Service} SAF is to be invoked only when the requested resource has a new kind of file extension, you might need to add an entry to the MIME types file so that the type value gets set properly during the \texttt{ObjectType} stage. Then you could add a \texttt{Service} directive to the default object that specifies the desired type value.
If your new Service SAF is to be invoked only when the requested resource is in a particular directory, you might need to define a NameTrans directive that generates a name or path value that matches another object, and then in the new object you could invoke the new Service function.

For example, suppose your plug-in defines two new SAFs, do_small_anim() and do_big_anim(), which both take speed parameters. These functions run animations. All files to be treated as small animations reside in the directory D:/Sun/WebServer61/server1/docs/animations/small, while all files to be treated as full-screen animations reside in the directory D:/Sun/WebServer61/server1/docs/animations/fullscreen.

To ensure that the new animation functions are invoked whenever a client sends a request for either a small or full-screen animation, you would add NameTrans directives to the default object to translate the appropriate URLs to the corresponding path names and also assign a name to the request.

```
NameTrans fn=pfx2dir from="/animations/small" dir="D:/Sun/WebServer61/server1/docs/animations/small" name="small_anim"
NameTrans fn=pfx2dir from="/animations/fullscreen" dir="D:/Sun/WebServer61/server1/docs/animations/fullscreen" name="fullscreen_anim"
```

You also need to define objects that contain the Service directives that run the animations and specify the speed parameter.

```
<Object name="small_anim">
  Service fn=do_small_anim speed=40
</Object>
<Object name="fullscreen_anim">
  Service fn=do_big_anim speed=20
</Object>
```

**Restart the Server**

After modifying obj.conf, you need to restart the server. A restart is required for all plug-ins that implement SAFs and/or filters.
Test the SAF

Test your SAF by accessing your server from a browser with a URL that triggers your function. For example, if your new SAF is triggered by requests to resources in http://server-name/animations/small, try requesting a valid resource that starts with that URI.

You should disable caching in your browser so that the server is sure to be accessed. In Netscape Navigator you may hold the shift key while clicking the Reload button to ensure that the cache is not used. (Note that the shift-reload trick does not always force the client to fetch images from source if the images are already in the cache.)

You may also wish to disable the server cache using the cache-init SAF.

Examine the access log and error log to help with debugging.

Overview of NSAPI C Functions

NSAPI provides a set of C functions that are used to implement SAFs. They serve several purposes. They provide platform independence across Sun Java System Web Server operating system and hardware platforms. They provide improved performance. They are thread-safe which is a requirement for SAFs. They prevent memory leaks. And they provide functionality necessary for implementing SAFs. You should always use these NSAPI routines when defining new SAFs.

This section provides an overview of the function categories available and some of the more commonly used routines. All of the public routines are detailed in Chapter 7, NSAPI Function Reference.

The main categories of NSAPI functions are:

- "Parameter Block Manipulation Routines" on page 84
- "Protocol Utilities for Service SAFs" on page 85
- "Memory Management" on page 85
- "File I/O" on page 86
- "Network I/O" on page 86
- "Threads" on page 86
- "Utilities" on page 87
- "Virtual Server" on page 87

Parameter Block Manipulation Routines

The parameter block manipulation functions provide routines for locating, adding, and removing entries in a pblock data structure:

- "pblock_findval" on page 178 returns the value for a given name in a pblock.
“pblock_nvinsert” on page 179 adds a new name-value entry to a pblock.
“pblock_remove” on page 182 removes a pblock entry by name from a pblock. The entry is not disposed. Use “param_free” on page 175 to free the memory used by the entry.
“param_free” on page 175 frees the memory for the given pblock entry.
“pblock_pblock2str” on page 181 creates a new string containing all of the name-value pairs from a pblock in the form “name=value name=value.” This can be a useful function for debugging.

Protocol Utilities for Service SAFs

Protocol utilities provide functionality necessary to implement Service SAFs:
“request_header” on page 194 returns the value for a given request header name, reading the headers if necessary. This function must be used when requesting entries from the browser header pblock (rq->headers).
“protocol_status” on page 189 sets the HTTP response status code and reason phrase.
“protocol_start_response” on page 188 sends the HTTP response and all HTTP headers to the browser.

Memory Management

Memory management routines provide fast, platform-independent versions of the standard memory management routines. They also prevent memory leaks by allocating from a temporary memory (called “pooled” memory) for each request, and then disposing the entire pool after each request. There are wrappers for standard memory routines for using permanent memory. To disable pooled memory for debugging, see the built-in SAF “pool-init” on page 67 in Chapter 2, SAFs in the magnus.conf File
“MALLOC” on page 164
“FREE” on page 159
“PERM_STRDUP” on page 186
“REALLOC” on page 193
“CALLOC” on page 144
“PERM_MALLOC” on page 184
“PERM_FREE” on page 184
“PERM_STRDUP” on page 186
“PERM_REALLOC” on page 185
“PERM_CALLOC” on page 183
**File I/O**

The file I/O functions provide platform-independent, thread-safe file I/O routines.

- “system_fopenRO” on page 204 opens a file for read-only access.
- “system_fopenRW” on page 204 opens a file for read-write access, creating the file if necessary.
- “system_fopenWA” on page 205 opens a file for write-append access, creating the file if necessary.
- “system_fclose” on page 203 closes a file.
- “system_fread” on page 205 reads from a file.
- “system_fwrite” on page 206 writes to a file.
- “system_fwrite_atomic” on page 207 locks the given file before writing to it. This avoids interference between simultaneous writes by multiple processes or threads.

**Network I/O**

Network I/O functions provide platform-independent, thread-safe network I/O routines. These routines work with SSL when it’s enabled.

- “netbuf_grab” on page 171 reads from a network buffer’s socket into the network buffer.
- “netbuf_getc” on page 171 gets a character from a network buffer.
- “net_flush” on page 164 flushes buffered data.
- “net_read” on page 166 reads bytes from a specified socket into a specified buffer.
- “net_sendfile” on page 166 sends the contents of a specified file to a specified socket.
- “net_write” on page 168 writes to the network socket.

**Threads**

Thread functions include functions for creating your own threads that are compatible with the server’s threads. There are also routines for critical sections and condition variables.

- “systhread_start” on page 214 creates a new thread.
- “systhread_sleep” on page 213 puts a thread to sleep for a given time.
- “crit_init” on page 148 creates a new critical section variable.
- “crit_enter” on page 147 gains ownership of a critical section.
- “crit_exit” on page 148 surrenders ownership of a critical section.
- “crit_terminate” on page 149 disposes of a critical section variable.
- “condvar_init” on page 145 creates a new condition variable.
- “condvar_notify” on page 146 awakens any threads blocked on a condition variable.
- “condvar_wait” on page 147 blocks on a condition variable.
- “condvar_terminate” on page 146 disposes of a condition variable.
- “prepare_nsapi_thread” on page 187 allows threads that are not created by the server to act like server-created threads.

Utilities

Utility functions include platform-independent, thread-safe versions of many standard library functions (such as string manipulation), as well as new utilities useful for NSAPI.

- “daemon_atrestart” on page 149 (UNIX only) registers a user function to be called when the server is sent a restart signal (HUP) or at shutdown.
- “condvar_init” on page 145 gets the next line (up to a LF or CRLF) from a buffer.
- “util_hostname” on page 221 gets the local host name as a fully qualified domain name.
- “utilLater_than” on page 223 compares two dates.
- “util_sprintf” on page 225 is the same as the standard library routine sprintf().
- “util_strftime” on page 226 is the same as the standard library routine strftime().
- “util_uri_escape” on page 227 converts the special characters in a string into URI-escaped format.
- “util_uri_unescape” on page 229 converts the URI-escaped characters in a string back into special characters.

Note – You cannot use an embedded null in a string, because NSAPI functions assume that a null is the end of the string. Therefore, passing unicode-encoded content through an NSAPI plug-in doesn’t work.

Virtual Server

The virtual server functions provide routines for retrieving information about virtual servers.

- “request_get_vs” on page 194 finds the virtual server to which a request is directed.
- “vs_alloc_slot” on page 231 allocates a new slot for storing a pointer to data specific to a certain virtual server.
- “vs_get_data” on page 231 finds the value of a pointer to data for a given virtual server and slot.
- “vs_get_default_httpd_object” on page 232 obtains a pointer to the default (or root) object from the virtual server’s virtual server class configuration.
- “vs_get_doc_root” on page 232 finds the document root for a virtual server.
Required Behavior of SAFs for Each Directive

When writing a new SAF, you should define it to do certain things, depending on which stage of the request-handling process will invoke it. For example, SAFs to be invoked during the Init stage must conform to different requirements than SAFs to be invoked during the Service stage.

The rq parameter is the primary mechanism for passing along information throughout the request-response process. On input to a SAF, rq contains whatever values were inserted or modified by previously executed SAFs. On output, rq contains any modifications or additional information inserted by the SAF. Some SAFs depend on the existence of specific information provided at an earlier step in the process. For example, a PathCheck SAF retrieves values in rq->vars that were previously inserted by an AuthTrans SAF.

This section outlines the expected behavior of SAFs used at each stage in the request-handling process.

- “Init SAFs” on page 89
- “AuthTrans SAFs” on page 89
- “NameTrans SAFs” on page 89
- “PathCheck SAFs” on page 90
- “ObjectType SAFs” on page 90
- “Input SAFs” on page 90
- “Output SAFs” on page 90
- “Service SAFs” on page 90
- “Error SAFs” on page 91
For more detailed information about these SAFs, see the *Sun Java System Web Server 6.1 SP10 Administrator’s Configuration File Reference*.

**Init SAFs**

- Purpose: Initialize at startup.
- Called at server startup and restart.
- rq and sn are NULL.
- Initialize any shared resources such as files and global variables.
- Can register callback function with `daemon_atrestart()` to clean up.
- On error, insert `error` parameter into `pb` describing the error and return `REQ_ABORTED`.
- If successful, return `REQ_PROCEED`.

**AuthTrans SAFs**

- Purpose: Verify any authorization information. Only basic authorization is currently defined in the HTTP/1.0 specification.
- Check for `Authorization` header in `rq->headers` that contains the authorization type and uu-encoded user and password information. If header was not sent, return `REQ_NOACTION`.
- If header exists, check authenticity of user and password.
- If authentic, create `auth-type`, plus `auth-user` and/or `auth-group` parameter in `rq->vars` to be used later by `PathCheck` SAFs.
- Return `REQ_PROCEED` if the user was successfully authenticated, `REQ_NOACTION` otherwise.

**NameTrans SAFs**

- Purpose: Convert logical URI to physical path.
- Perform operations on logical path (`ppath` in `rq->vars`) to convert it into a full local file system path.
- Return `REQ_PROCEED` if `ppath` in `rq->vars` contains the full local file system path, or `REQ_NOACTION` if not.
- To redirect the client to another site, change `ppath` in `rq->vars` to `/URL`. Add `url` to `rq->vars` with full URL (for example, `http://home.netscape.com/`). Return `REQ_PROCEED`. 
PathCheck SAFs

- Purpose: Check path validity and user's access rights.
- Check auth-type, auth-user, and/or auth-group in rq->vars.
- Return REQ_PROCEED if user (and group) is authorized for this area (ppath in rq->vars).
- If not authorized, insert WWW-Authenticate to rq->srvhdrs with a value such as: Basic; Realm="Our private area". Call protocol_status() to set HTTP response status to PROTOCOL_UNAUTHORIZED. Return REQ_ABORTED.

ObjectType SAFs

- Purpose: Determine content-type of data.
- If content-type in rq->srvhdrs already exists, return REQ_NOACTION.
- Determine the MIME type and create content-type in rq->srvhdrs
- Return REQ_PROCEED if content-type is created, REQ_NOACTION otherwise.

Input SAFs

- Purpose: Insert filters that process incoming (client-to-server) data.
- Input SAFs are executed when a plug-in or the server first attempts to read entity body data from the client.
- Input SAFs are executed at most once per request.
- Return REQ_PROCEED to indicate success, or REQ_NOACTION to indicate it performed no action.

Output SAFs

- Purpose: Insert filters that process outgoing (server-to-client) data.
- Output SAFs are executed when a plug-in or the server first attempts to write entity body data from the client.
- Output SAFs are executed at most once per request.
- Return REQ_PROCEED to indicate success, or REQ_NOACTION to indicate it performed no action.

Service SAFs

- Purpose: Generate and send the response to the client.
• A Service SAF is only called if each of the optional parameters type, method, and query specified in the directive in obj.conf match the request.
• Remove existing content-type from rq->srvhdrs. Insert correct content-type in rq->srvhdrs.
• Create any other headers in rq->srvhdrs.
• Call "protocol_status" on page 189 to set HTTP response status.
• Call "protocol_start_response" on page 188 to send HTTP response and headers.
• Generate and send data to the client using "net_write" on page 168.
• Return REQ_PROCEED if successful, REQ_EXIT on write error, REQ_ABORTED on other failures.

Error SAFs

• Purpose: Respond to an HTTP status error condition.
• The Error SAF is only called if each of the optional parameters code and reason specified in the directive in obj.conf match the current error.
• Error SAFs do the same as Service SAFs, but only in response to an HTTP status error condition.

AddLog SAFs

• Purpose: Log the transaction to a log file.
• AddLog SAFs can use any data available in pb, sn, or rq to log this transaction.
• Return REQ_PROCEED.

CGI to NSAPI Conversion

You may have a need to convert a CGI variable into an SAF using NSAPI. Since the CGI environment variables are not available to NSAPI, you’ll retrieve them from the NSAPI parameter blocks. The table below indicates how each CGI environment variable can be obtained in NSAPI.

Keep in mind that your code must be thread-safe under NSAPI. You should use NSAPI functions that are thread-safe. Also, you should use the NSAPI memory management and other routines for speed and platform independence.
<table>

Creating Custom Filters

This chapter describes how to create custom filters that can be used to intercept and possibly modify the content presented to or generated by another function.

This chapter has the following sections:

- “Future Compatibility Issues” on page 95
- “The NSAPI Filter Interface” on page 96
- “Filter Methods” on page 96
- “Position of Filters in the Filter Stack” on page 99
- “Filters that Alter Content-Length” on page 101
- “Creating and Using Custom Filters” on page 102
- “Overview of NSAPI Functions for Filter Development” on page 104

Future Compatibility Issues

The NSAPI interface may change in a future version of Sun Java System Web Server. To keep your custom plug-ins upgradable, do the following:

- Make sure plug-in users know how to edit the configuration files (such as magnus.conf and obj.conf) manually. The plug-in installation software should not be used to edit these configuration files.
- Keep the source code so you can recompile the plug-in.
The NSAPI Filter Interface

Sun Java System Web Server 6.1 extends NSAPI by introducing a new filter interface that complements the existing Server Application Function (SAF) interface. Filters make it possible to intercept and possibly modify data sent to and from the server. The server communicates with a filter by calling the filter’s filter methods. Each filter implements one or more filter methods. A filter method is a C function that performs a specific operation, such as processing data sent by the server.

Filter Methods

This section describes the filter methods that a filter can implement. To create a filter, a filter developer implements one or more of these methods. This section describes the following filter methods:

- “insert” on page 97
- “remove” on page 97
- “flush” on page 98
- “read” on page 98
- “write” on page 98
- “writev” on page 99
- “sendfile” on page 99

For more information about these methods, see Chapter 7, NSAPI Function Reference

C Prototypes for Filter Methods

Following is a list of C prototypes for the filter methods:

```c
int insert(FilterLayer *layer, pblock *pb);
void remove(FilterLayer *layer);
int flush(FilterLayer *layer);
int read(FilterLayer *layer, void *buf, int amount, int timeout);
int write(FilterLayer *layer, const void *buf, int amount);
int writev(FilterLayer *layer, const struct iovec *iov, int iov_size);
int sendfile(FilterLayer *layer, sendfiledata *sfd);
```

The `layer` parameter is a pointer to a FilterLayer data structure, which contains variables related to a particular instance of a filter. Following is a list of the most important fields in the FilterLayer data structure:

- `context->sn`: Contains information relating to a single TCP/IP session (the same `sn` pointer that’s passed to SAFs).
Filter Methods

- `context->rq`: Contains information relating to the current request (the same rq pointer that's passed to SAFs).
- `context->data`: Pointer to filter-specific data.
- `lower`: A platform-independent socket descriptor used to communicate with the next filter in the stack.

The meaning of the `context->data` field is defined by the filter developer. Filters that must maintain state information across filter method calls can use `context->data` to store that information.

For more information about FilterLayer, see "FilterLayer" on page 246

**insert**

The `insert` filter method is called when an SAF such as `insert-filter` calls the `filter_insert` function to request that a specific filter be inserted into the filter stack. Each filter must implement the `insert` filter method.

When `insert` is called, the filter can determine whether it should be inserted into the filter stack. For example, the filter could inspect the `content-type` header in the `rq->srvhdrs` pblock to determine whether it is interested in the type of data that will be transmitted. If the filter should not be inserted, the `insert` filter method should indicate this by returning `REQ_NOACTION`.

If the filter should be inserted, the `insert` filter method provides an opportunity to initialize this particular instance of the filter. For example, the `insert` method could allocate a buffer with `MALLOC` and store a pointer to that buffer in `layer->context->data`.

The filter is not part of the filter stack until after `insert` returns. As a result, the `insert` method should not attempt to read from, write to, or otherwise interact with the filter stack.

**See Also**

"insert" on page 162 in Chapter 7, NSAPI Function Reference

**remove**

The `remove` filter method is called when a filter stack is destroyed (that is, when the corresponding socket descriptor is closed), when the server finishes processing the request the filter was associated with, or when an SAF such as `remove-filter` calls the `filter_remove` function. The `remove` filter method is optional.

The `remove` method can be used to clean up any data the filter allocated in `insert` and to pass any buffered data to the next filter by calling `net_write(layer->lower, ...)`. 
Filter Methods

See Also
“remove” on page 193 in Chapter 7, NSAPI Function Reference

flush
The flush filter method is called when a filter or SAF calls the net_flush function. The flush method should pass any buffered data to the next filter by calling net_write(layer->lower, ...). The flush method is optional, but it should be implemented by any filter that buffers outgoing data.

See Also
“flush” on page 158 in Chapter 7, NSAPI Function Reference

read
The read filter method is called when a filter or SAF calls the net_read function. Filters that are interested in incoming data (data sent from a client to the server) implement the read filter method.

Typically, the read method will attempt to obtain data from the next filter by calling net_read(layer->lower, ...). The read method may then modify the received data before returning it to its caller.

See Also
“read” on page 192 in Chapter 7, NSAPI Function Reference

write
The write filter method is called when a filter or SAF calls the net_write function. Filters that are interested in outgoing data (data sent from the server to a client) implement the write filter method.

Typically, the write method will pass data to the next filter by calling net_write(layer->lower, ...). The write method may modify the data before calling net_write. For example, the http-compression filter compresses data before passing it on to the next filter.

If a filter implements the write filter method but does not pass the data to the next layer before returning to its caller (that is, if the filter buffers outgoing data), the filter should also implement the flush method.
See Also
"write" on page 237 in Chapter 7, NSAPI Function Reference

writev

The writev filter method performs the same function as the write filter method, but the format of its parameters is different. It is not necessary to implement the writev filter method; if a filter implements the write filter method but not the writev filter method, the server uses the write method instead of the writev method. A filter should not implement the writev method unless it also implements the write method.

Under some circumstances, the server may run slightly faster when filters that implement the write filter method also implement the writev filter method.

See Also
"writev" on page 238 in Chapter 7, NSAPI Function Reference

sendfile

The sendfile filter method performs a function similar to the writev filter method, but it sends a file directly instead of first copying the contents of the file into a buffer. It is not necessary to implement the sendfile filter method; if a filter implements the write filter method but not the sendfile filter method, the server will use the write method instead of the sendfile method. A filter should not implement the sendfile method unless it also implements the write method.

Under some circumstances, the server may run slightly faster when filters that implement the write filter method also implement the sendfile filter method.

See Also
"sendfile" on page 197 in Chapter 7, NSAPI Function Reference

Position of Filters in the Filter Stack

All data sent to the server (such as the result of an HTML form) or sent from the server (such as the output of a JSP page) is passed through a set of filters known as a filter stack. The server creates a separate filter stack for each connection. While processing a request, individual filters can be inserted into and removed from the stack.
Different types of filters occupy different positions within a filter stack. Filters that deal with application-level content (such filters that translates a page from XHTML to HTML) occupy a higher position than filters that deal with protocol-level issues (such as filters that format HTTP responses). When two or more filters are defined to occupy the same position in the filter stack, filters that were inserted later will appear higher than filters that were inserted earlier.

Filters positioned higher in the filter stack are given an earlier opportunity to process outgoing data, while filters positioned lower in the stack are given an earlier opportunity to process incoming data. For example, in the following figure, the xml-to-xhtml filter is given an earlier opportunity to process outgoing data than the xhtml-to-html filter.

When you create a filter with the `filter_create` function, you specify what position your filter should occupy in the stack. You can also use the `init-filter-order` Init SAF to control the position of specific filters within filter stacks. For example, `init-filter-order` can be used to ensure that a filter that converts outgoing XML to XHTML is inserted above a filter that converts outgoing XHTML to HTML.

For more information, see “filter_create” on page 155 and “init-filter-order” on page 62.
Filters that Alter Content-Length

Filters that can alter the length of an incoming request body or outgoing response body must take special steps to ensure interoperability with other filters and SAFs.

Filters that process incoming data are referred to as input filters. If an input filter can alter the length of the incoming request body (for example, if a filter decompresses incoming data) and there is a Content-Length header in the rq->headers pblock, the filter’s insert filter method should remove the Content-Length header and replace it with a Transfer-encoding: identity header as follows:

```c
pb_param *pp;

pp = pblock_remove("content-length", layer->context->rq->headers);
if (pp != NULL) {
    param_free(pp);
    pblock_nvinsert("transfer-encoding", "identity", layer->context->rq->headers);
}
```

Because some SAFs expect a Content-Length header when a request body is present, before calling the first Service SAF the server will insert all relevant filters, read the entire request body, and compute the length of the request body after it has been passed through all input filters. However, by default, the server will read at most 8192 bytes of request body data. If the request body exceeds 8192 bytes after being passed through the relevant input filters, the request will be cancelled. For more information, see the description of ChunkedRequestBufferSize in the "Syntax and Use of magnus.conf" chapter in the Sun Java System Web Server 6.1 SP10 Administrator's Configuration File Reference.

Filters that process outgoing data are referred to as output filters. If an output filter can alter the length of the outgoing response body (for example, if the filter compresses outgoing data), the filter’s insert filter method should remove the Content-Length header from rq->srvhdrs as follows:

```c
pb_param *pp;

pp = pblock_remove("content-length", layer->context->rq->srvhdrs);
if (pp != NULL) {
    param_free(pp);
```
Creating and Using Custom Filters

Custom filters are defined in shared libraries that are loaded and called by the server.

▼ To create a custom filter

2. “Compile and Link” on page 103 the source code to create a shared library (.so, .sl, or .dll) file.
3. “Load and Initialize the Filter” on page 103 by editing the magnus.conf file.
4. “Instruct the Server to Insert the Filter” on page 103 by editing the obj.conf file to insert your custom filter(s) at the appropriate time.
5. “Restart the Server” on page 104.
6. “Test the Filter” on page 104 by accessing your server from a browser with a URL that triggers your filter.

These steps are described in greater detail in the following sections.

Write the Source Code

Write your custom filter methods using NSAPI functions. For a summary of the NSAPI functions specific to filter development, see “Overview of NSAPI Functions for Filter Development” on page 104 "Filter Methods” on page 96 for the filter method prototypes.

The filter must be created by a call to filter_create. Typically, each plug-in defines an nsapi_module_init function that is used to call filter_create and perform any other initialization tasks. See “nsapi_module_init” on page 172 and “filter_create” on page 155 for more information.

Filter methods are invoked whenever the server or an SAF calls certain NSAPI functions such as net_write or filter_insert. As a result, filter methods can be invoked from any thread and should only block using NSAPI functions (for example, crit_enter and net_read). If a filter method blocks using other functions (for example, the Windows WaitForMultipleObjects and ReadFile functions), the server may hang. Also, shared objects that define filters should be loaded with the NativeThread="no" flag, as described in "Load and Initialize the Filter” on page 103.
If a filter method must block using a non-NSAPI function, KernelThreads 1 should be set in magnus.conf. For more information about KernelThreads, see the description in the chapter "Syntax and Use of magnus.conf" in the Sun Java System Web Server 6.1 SP10 Administrator's Configuration File Reference.

Keep the following in mind when writing your filter:

- Write thread-safe code
- IO should only be performed using the NSAPI functions documented in “File I/O” on page 86
- Thread synchronization should only be performed using NSAPI functions documented in “Threads” on page 86
- Blocking may affect performance.
- Carefully check and handle all errors

For examples of custom filters, see server_root/plugins/nsapi/examples and also Chapter 5, Examples of Custom SAFs and Filters

**Compile and Link**

Filters are compiled and linked in the same way as SAFs. See “Compile and Link” on page 78

**Load and Initialize the Filter**

For each shared library (plug-in) containing custom SAFs to be loaded into the Sun Java System Web Server, add an Init directive that invokes the load-modules SAF to magnus.conf. The syntax for a directive that loads a filter plug-in is:

```
Init fn=load-modules shlib=[path]sharedlibname NativeThread="no"
```

- shlib is the local file system path to the shared library (plug-in).
- NativeThread indicates whether the plug-in requires native threads. Filters should be written to run on any type of thread (see “Write the Source Code” on page 102)

When the server encounters such a directive, it calls the plug-in's nsapi_module_init function to initialize the filter.

**Instruct the Server to Insert the Filter**

Add an Input or Output directive to obj.conf to instruct the server to insert your filter into the filter stack. The format of the directive is as follows:

```
Directive fn=insert-filter filter="filter-name" [name1="value1"]...[nameN="valueN"]
```
Directive is Input or Output.
filter-name is the name of the filter, as passed to filter_create, to insert.
nameN="valueN" are the names and values of parameters that are passed to the filter's insert filter method.
Filters that process incoming data should be inserted using an Input directive. Filters that process outgoing data should be inserted using an Output directive.
To ensure that your filter is inserted whenever a client sends a request, add the Input or Output directive to the default object. For example, the following portion of obj.conf instructs the server to insert a filter named example-replace and pass it two parameters, from and to:

```
<Object name="default">
  Output fn=insert-filter
    filter="example-replace"
    from="Old String"
    to="New String"
...
</Object>
```

**Restart the Server**

For the server to load your plug-in, you must restart the server. A restart is required for all plug-ins that implement SAFs and/or filters.

**Test the Filter**

Test your SAF by accessing your server from a browser. You should disable caching in your browser so that the server is sure to be accessed. In Netscape Navigator, you can hold the shift key while clicking the Reload button to ensure that the cache is not used. (Note that the shift-reload trick does not always force the client to fetch images from source if the images are already in the cache.) Examine the access and error logs to help with debugging.

**Overview of NSAPI Functions for Filter Development**

NSAPI provides a set of C functions that are used to implement SAFs and filters. This section lists the functions that are specific to the development of filters. All of the public routines are described in detail in Chapter 7, NSAPI Function Reference.

The NSAPI functions specific to the development of filters are:

- "filter_create" on page 155 creates a new filter
Overview of NSAPI Functions for Filter Development

- “filter_insert” on page 156 inserts the specified filter into a filter stack
- “filter_remove” on page 158 removes the specified filter from a filter stack
- “filter_name” on page 158 returns the name of the specified filter
- “filter_find” on page 156 finds an existing filter given a filter name
- “filter_layer” on page 157 returns the layer in a filter stack that corresponds to the specified filter
Examples of Custom SAFs and Filters

This chapter provides examples of custom Sever Application Functions (SAFs) and filters for each directive in the request-response process. You may wish to use these examples as the basis for implementing your own custom SAFs and filters. For more information about creating your own custom SAFs, see Chapter 3, Creating Custom SAFs and Chapter 4, Creating Custom Filters.

Before writing custom SAFs, you should be familiar with the request-response process and the role of the configuration file obj.conf (this file is discussed in the Sun Java System Web Server 6.1 Administrator's Configuration File Reference).

Before writing your own SAF, check to see if an existing SAF serves your purpose. The predefined SAFs are discussed in the Sun Java System Web Server 6.1 SP10 Administrator's Configuration File Reference.

For a list of the NSAPI functions for creating new SAFs, see Chapter 7, NSAPI Function Reference.

This chapter has the following sections:

- “Examples in the Build” on page 108
- “AuthTrans Example” on page 108
- “NameTrans Example” on page 111
- “PathCheck Example” on page 114
- “ObjectType Example” on page 117
- “Output Example” on page 119
- “Service Example” on page 125
- “AddLog Example” on page 127
- “Quality of Service Example” on page 130
Examples in the Build

The nsapi/examples/ or plugins/nsapi/examples subdirectory within the server installation directory contains examples of source code for SAFs.

You can use the example.mak makefile in the same directory to compile the examples and create a library containing the functions in all of the example files.

To test an example, load the examples shared library into the Sun Java System Web Server by adding the following directive in the Init section of magnus.conf:

```
Init fn=load-modules shlib=examples.so/dll
funcs=function1,function2,function3
```

The funcs parameter specifies the functions to load from the shared library.

If the example uses an initialization function, be sure to specify the initialization function in the funcs argument to load-modules, and also add an Init directive to call the initialization function.

For example, the PathCheck example implements the restrict-by-acf function, which is initialized by the acf-init function. The following directive loads both these functions:

```
Init fn=load-modules yourlibrary funcs=acf-init,restrict-by-acf
```

The following directive calls the acf-init function during server initialization:

```
Init fn=acf-init file=extra-arg
```

To invoke the new SAF at the appropriate step in the response handling process, add an appropriate directive in the object to which it applies, for example:

```
PathCheck fn=restrict-by-acf
```

After adding new Init directives to magnus.conf, you always need to restart the Sun Java System Web Server to load the changes, since Init directives are only applied during server initialization.

AuthTrans Example

This simple example of an AuthTrans function demonstrates how to use your own custom ways of verifying that the user name and password that a remote client provided is accurate. This program uses a hard-coded table of user names and passwords and checks a given user's password against the one in the static data array. The userdb parameter is not used in this function.
AuthTrans directives work in conjunction with PathCheck directives. Generally, an AuthTrans function checks if the user name and password associated with the request are acceptable, but it does not allow or deny access to the request; it leaves that to a PathCheck function.

AuthTrans functions get the user name and password from the headers associated with the request. When a client initially makes a request, the user name and password are unknown so the AuthTrans function and PathCheck function work together to reject the request, since they can not validate the user name and password. When the client receives the rejection, the usual response is for it to present a dialog box asking the user for their user name and password. The client submits the request again, this time including the user name and password in the headers.

In this example, the hardcoded-auth function, which is invoked during the AuthTrans step, checks if the user name and password correspond to an entry in the hard-coded table of users and passwords.

**Installing the Example**

To install the function on the Sun Java System Web Server, add the following Init directive to magnus.conf to load the compiled function:

```ini
Init fn=load-modules shlib=yourlibrary funcs=hardcoded-auth
```

Inside the default object in obj.conf, add the following AuthTrans directive:

```ini
AuthTrans fn=basic-auth auth-type="basic" userfn=hardcoded-auth userdb=unused
```

Note that this function does not actually enforce authorization requirements, it only takes given information and tells the server if it's correct or not. The PathCheck function require-auth performs the enforcement, so add the following PathCheck directive as well:

```ini
PathCheck fn=require-auth realm="test realm" auth-type="basic"
```

**Source Code**

The source code for this example is in the auth.c file in the nsapi/examples/ or plugins/nsapi/examples subdirectory of the server root directory.

```c
#include "nsapi.h"
typedef struct {
    char *name;
    char *pw;
} user_s;
```
static user_s user_set[] = {
    "joe", "shmoe",
    "suzy", "creamcheese",
    {NULL, NULL}
};

#include "frame/log.h"

#ifdef __cplusplus
extern "C"
#endif
NSAPI_PUBLIC int hardcoded_auth(pblock *param, Session *sn, Request *rq)
{
    /* Parameters given to us by auth-basic */
    char *pwfile = pblock_findval("userdb", param);
    char *user = pblock_findval("user", param);
    char *pw = pblock_findval("pw", param);

    /* Temp variables */
    register int x;

    for(x = 0; user_set[x].name != NULL; ++x) {
        /* If this isn't the user we want, keep going */
        if(strcmp(user, user_set[x].name) != 0) continue;

        /* Verify password */
        if(strcmp(pw, user_set[x].pw)) {
            log_error(LOG_SECURITY, "hardcoded-auth", sn, rq,
                "user %s entered wrong password", user);
            /* This will cause the enforcement function to ask */
            return REQ_NOACTION;
        }
        /* If we return REQ_PROCEED, the username will be accepted */
        return REQ_PROCEED;
    }

    /* No match, have it ask them again */
    log_error(LOG_SECURITY, "hardcoded-auth", sn, rq,
        "unknown user %s", user);
    return REQ_NOACTION;
}
NameTrans Example

The ntrans.c file in the nsapi/examples/ or plugins/nsapi/examples subdirectory of the server root directory contains source code for two example NameTrans functions:

- explicit_pathinfo
  This example allows the use of explicit extra path information in a URL.
- https_redirect
  This example redirects the URL if the client is a particular version of Netscape Navigator.

This section discusses the first example. Look at the source code in ntrans.c for the second example.

Note – A NameTrans function is used primarily to convert the logical URL in ppath in rq->vars to a physical path name. However, the example discussed here, explicit_pathinfo, does not translate the URL into a physical path name; it changes the value of the requested URL. See the second example, https_redirect, in ntrans.c for an example of a NameTrans function that converts the value of ppath in rq->vars from a URL to a physical path name.

The explicit_pathinfo example allows URLs to explicitly include extra path information for use by a CGI program. The extra path information is delimited from the main URL by a specified separator, such as a comma.

For example:

http://server-name/cgi/marketing,/jan/releases/hardware

In this case, the URL of the requested resource (which would be a CGI program) is http://server-name/cgi/marketing, and the extra path information to give to the CGI program is /jan/releases/hardware.

When choosing a separator, be sure to pick a character that will never be used as part of the real URL.

The explicit_pathinfo function reads the URL, strips out everything following the comma, and puts it in the path-info field of the vars field in the request object (rq->vars). CGI programs can access this information through the PATH_INFO environment variable.

One side effect of explicit_pathinfo is that the SCRIPT_NAME CGI environment variable has the separator character tacked onto the end.

NameTrans directives usually return REQ_PROCEED when they change the path, so that the server does not process any more NameTrans directives. However, in this case we want name translation to continue after we have extracted the path info, since we have not yet translated the URL to a physical path name.
Installing the Example

To install the function on the Sun Java System Web Server, add the following `Init` directive to `magnus.conf` to load the compiled function:

```
Init fn=load-modules shlib=yourlibrary func=explicit-pathinfo
```

Inside the default object in `obj.conf`, add the following `NameTrans` directive:

```
NameTrans fn=explicit-pathinfo separator="","
```

This `NameTrans` directive should appear before other `NameTrans` directives in the default object.

Source Code

This example is in the `ntrans.c` file in the `nsapi/examples/` or `plugins/nsapi/examples` subdirectory of the server root directory.

```c
#include "nsapi.h"
#include "string.h"    /* strchr */
#include "frame/log.h" /* log_error */
#ifndef __cplusplus
extern "C"
#endif

NSAPI_PUBLIC int explicit_pathinfo(pblock *pb, Session *sn, Request *rq)
{
    /* Parameter: The character to split the path by */
    char *sep = pbblock_findval("separator", pb);
    /* Server variables */
    char *ppath = pbblock_findval("ppath", rq->vars);
    /* Temp var */
    char *t;
    /* Verify correct usage */
    if(!sep) {
        log_error(LOG_MISC, "explicit-pathinfo", sn, rq,
            "missing parameter (need root)");
        /* When we abort, the default status code is 500 Server Error */
        return REQ_ABORTED;
    }
    /* Check for separator. If not there, don't do anything */
    t = strchr(ppath, sep[0]);
    if(!t) {
        return REQ_NOACTION;
    }
    /* Truncate path at the separator */
    *t++ = '\0';
}
```
/* Assign path information */
pblock_nvinsert("path-info", t, rq->vars);
/* Normally NameTrans functions return REQ_PROCEED when they
change the path. However, we want name translation to
continue after we’re done. */
return REQ_NOACTION;
}
#include "base/util.h"    /* is_mozilla */
#include "frame/protocol.h"    /* protocol_status */
#include "base/shexp.h"    /* shexp_cmp */
#endif
extern "C"
#endif
NSAPI_PUBLIC int https_redirect(pblock *pb, Session *sn, Request *rq)
{
    /* Server Variable */
    char *ppath = pblock_findval("ppath", rq->vars);
    /* Parameters */
    char *from = pblock_findval("from", pb);
    char *url = pblock_findval("url", pb);
    char *alt = pblock_findval("alt", pb);
    /* Work vars */
    char *ua;
    /* Check usage */
    if(!(from || (!url))) {
        log_error(LOG_MISCONFIG, "https-redirect", sn, rq,
                  "missing parameter {need from, url}");
        return REQ_ABORTED;
    }
    /* Use wildcard match to see if this path is one we should
redirect */
    if(shexp_cmp(ppath, from) != 0)
        return REQ_NOACTION;    /* no match */
    /* Sigh. The only way to check for SSL capability is to
check UA */
    if(request_header("user-agent", &ua, sn, rq) == REQ_ABORTED)
        return REQ_ABORTED;
    /* The is_mozilla function checks for Mozilla version 0.96
or greater */
    if(util_is_mozilla(ua, "0", "96")) {
        /* Set the return code to 302 Redirect */
        protocol_status(sn, rq, PROTOCOL_REDIRECT, NULL);
        /* The error handling functions use this to set the
Location: */
        pblock_nvinsert("url", url, rq->vars);
        return REQ_ABORTED;
    }
    /* No match. Old client. */
/* If there is an alternate document specified, use it. */
if(alt) {
    pb_param *pp = pblock_find("ppath", rq->vars);
    /* Trash the old value */
    FREE(pp->value);
    /* We must dup it because the library will later free
    this pblock */
    pp->value = STRDUP(alt);
    return REQ_PROCEED;
}
/* Else do nothing */
return REQ_NOACTION;

PathCheck Example

The example in this section demonstrates how to implement a custom SAF for performing path checks. This example simply checks if the requesting host is on a list of allowed hosts.

The Init function acf-init loads a file containing a list of allowable IP addresses with one IP address per line. The PathCheck function restrict_by_acf gets the IP address of the host that is making the request and checks if it is on the list. If the host is on the list, it is allowed access; otherwise, access is denied.

For simplicity, the studio library is used to scan the IP addresses from the file.

Installing the Example

To load the shared object containing your functions, add the following line in the Init section of the magnus.conf file:

```
Init fn=load-modules yourlibrary funcs=acf-init,restrict-by-acf
```

To call the function, acf-init for reading the list of allowable hosts, add the following line to the Init section in magnus.conf. (This line must come after the one that loads the library containing acf-init).

```
Init fn=acf-init file=fileContainingHostsList
```

To execute your custom SAF during the request-response process for some object, add the following line to that object in the obj.conf file:

```
PathCheck fn=restrict-by-acf
```
Source Code

The source code for this example is in `pcheck.c` in the `nsapi/examples/` or `plugins/nsapi/examples` subdirectory within the server root directory.

```c
#include "nsapi.h"
/* Set to NULL to prevent problems with people not calling
   acf-init */
static char **hosts = NULL;
#include <stdio.h>
#include "base/daemon.h"
#include "base/util.h" /* util_sprintf */
#include "frame/log.h" /* log_error */
#include "frame/protocol.h" /* protocol_status */
/* The longest line we'll allow in an access control file */
#define MAX_ACF_LINE 256
/* Used to free static array on restart */
#ifdef __cplusplus
extern "C"
#endif
NSAPI_PUBLIC void acf_free(void *unused)
{
    register int x;
    for(x = 0; hosts[x]; ++x)
        FREE(hosts[x]);
    FREE(hosts);
    hosts = NULL;
}
#ifdef __cplusplus
extern "C"
#endif
NSAPI_PUBLIC int acf_init(pblock *pb, Session *sn, Request *rq)
{
    /* Parameter */
    char *acf_file = pblock_findval("file", pb);
    /* Working variables */
    int num_hosts;
    FILE *f;
    char err[MAGNUS_ERROR_LEN];
    char buf[MAX_ACF_LINE];
    /* Check usage. Note that Init functions have special
       error logging */
    if(!acf_file) {
        util_sprintf(err, "missing parameter to acf_init
                        (need file)");
        pblock_nvinsert("error", err, pb);
        return REQ_ABORTED;
    }
```
f = fopen(acf_file, "r");
/* Did we open it? */
if(!f) {
  util_sprintf(err, "can't open access control file %s (%s)",
    acf_file, system_errmsg());
  pblock_nvinsert("error", err, pb);
  return REQ_ABORTED;
}
/* Initialize hosts array */
num_hosts = 0;
hosts = (char **) MALLOC(1 * sizeof(char *));
hosts[0] = NULL;
while(fgets(buf, MAX_ACF_LINE, f)) {
  /* Blast linefeed that stdio helpfully leaves on there */
  buf[strlen(buf) - 1] = '\'0';
  hosts = (char **) REALLOC(hosts, (num_hosts + 2) *
    sizeof(char *));
  hosts[num_hosts++] = STRDUP(buf);
  hosts[num_hosts] = NULL;
}
fclose(f);
/* At restart, free hosts array */
daemon_atrestart(acf_free, NULL);
return REQ_PROCEED
#endif
NSAPI_PUBLIC int restrict_by_acf(pblock *pb, Session *sn, Request *rq) {
  /* No parameters */
  /* Working variables */
  char *remip = pblock_findval("ip", sn->client);
  register int x;
  if(!hosts) {
    log_error(LOG_MISCONFIG, "restrict-by-acf", sn, rq,
      "restrict-by-acf called without call to acf-init");
    /* When we abort, the default status code is 500 Server Error */
    return REQ_ABORTED;
  }
  for(x = 0; hosts[x] != NULL; ++x) {
    /* If they're on the list, they're allowed */
    if(!strcmp(remip, hosts[x])
      return REQ_NOACTION;
  }
  /* Set response code to forbidden and return an error. */
  protocol_status(sn, rq, PROTOCOL_FORBIDDEN, NULL);
ObjectType Example

The example in this section demonstrates how to implement html2shtml, a custom SAF that instructs the server to treat a .html file as a .shtml file if a .shtml version of the requested file exists.

A well-behaved ObjectType function checks if the content type is already set, and if so, does nothing except return REQ_NOACTION.

```c
if(pblock_findval("content-type", rq->srvhdrs))
    return REQ_NOACTION;
```

The primary task an ObjectType directive needs to perform is to set the content type (if it is not already set). This example sets it to magnus-internal/parsed-html in the following lines:

```c
/* Set the content-type to magnus-internal/parsed-html */
pblock_nvinsert("content-type", "magnus-internal/parsed-html",
                 rq->srvhdrs);
```

The html2shtml function looks at the requested file name. If it ends with .html, the function looks for a file with the same base name, but with the extension .shtml instead. If it finds one, it uses that path and informs the server that the file is parsed HTML instead of regular HTML. Note that this requires an extra stat call for every HTML file accessed.

Installing the Example

To load the shared object containing your function, add the following line in the Init section of the magnus.conf file:

```conf
Init fn=load-modules shlib=yourlibrary funcs=html2shtml
```

To execute the custom SAF during the request-response process for some object, add the following line to that object in the obj.conf file:

```conf
ObjectType fn=html2shtml
```

Source Code

The source code for this example is in otype.c in the nsapi/examples/ or plugins/nsapi/examples subdirectory within the server root directory.
#include "nsapi.h"

    if(stat(npath, &finfo) == -1) {
        FREE(npath);
        return REQ_NOACTION;
    }

    /* Got it, do the switch */
    FREE(path->value);
    path->value = npath;

    /* The server caches the stat() of the current path. Update it. */
    (void) request_stat_path(NULL, rq);

    pblock_nvinsert("content-type", "magnus-internal/parsed-html",
        rq->srvhdrs);
    return REQ_PROCEED;
}
Output Example

This section describes an example NSAPI filter named example-replace, which examines outgoing data and substitutes one string for another. It shows how you can create a filter that intercepts and modifies outgoing data.

Installing the Example

To load the filter, add the following line in the Init section of the magnus.conf file:

```
Init fn="load-modules" shlib="<path>/replace.ext"
NativeThread="no"
```

To execute the filter during the request-response process for some object, add the following line to that object in the obj.conf file:

```
Output fn="insert-filter" type="text/*" filter="example-replace"
from="iPlanet" to="Sun Java System"
```

Source Code

The source code for this example is in the replace.c file in the plugins/nsapi/examples subdirectory of the server root directory.

```c
#define NSAPI_PUBLIC __declspec(dllexport)
#include "nsapi.h"

/* ExampleReplaceData will be used to store information between filter method invocations. Each instance of the example-replace filter will have its own ExampleReplaceData object. */
```
typedef struct ExampleReplaceData ExampleReplaceData;

struct ExampleReplaceData {
    char *from; /* the string to replace */
    int fromlen; /* length of "from" */
    char *to; /* the string to replace "from" with */
    int tolen; /* length of "to" */
    int matched; /* number of "from" chars matched */
};

/* -------------- example_replace_insert ------------------------ */

/* example_replace_insert implements the example-replace filter's
 insert method. The insert filter method is called before the
 server adds the filter to the filter stack. */

#ifdef __cplusplus

Service Example

This section discusses a very simple Service function called simple_service. All this function does is send a message in response to a client request. The message is initialized by the init_simple_service function during server initialization.

For a more complex example, see the file service.c in the examples directory, which is discussed in “More Complex Service Example” on page 127.

Installing the Example

To load the shared object containing your functions, add the following line in the Init section of the magnus.conf file:

`Init fn=load-modules shlib=yourlibrary funcs=simple-service-init,simple-service`

To call the function, simple-service-init function for initializing the message representing the generated output, add the following line to the Init section in magnus.conf. (This line must come after the one that loads the library containing simple-service-init.)

`Init fn=simple-service-init
generated-output="<H1>Generated output msg</H1>"
`

To execute the custom SAF during the request-response process for some object, add the following line to that object in the obj.conf file:

`Service type="text/html" fn=simple-service`

The type="text/html" argument indicates that this function is invoked during the Service stage only if the content-type has been set to text/html.
Source Code

#include <nsapi.h>

static char *simple_msg = "default customized content";

/* This is the initialization function.
 * It gets the value of the generated-output parameter
 * specified in the Init directive in magnus.conf
 */

NSAPI_PUBLIC int init-simple-service(pblock *pb, Session *sn, Request *rq)
{
    /* Get the message from the parameter in the directive in
     * magnus.conf
     */
    simple_msg = pblock_findval("generated-output", pb);
    return REQ_PROCEED;
}

/* This is the customized Service SAF.
 * It sends the "generated-output" message to the client.
 */

NSAPI_PUBLIC int simple-service(pblock *pb, Session *sn, Request *rq)
{
    int return_value;
    char msg_length[8];
    /* Use the protocol_status function to set the status of the
     * response before calling protocol_start_response.
     */
    protocol_status(sn, rq, PROTOCOL_OK, NULL);
    /* Although we would expect the ObjectType stage to
     * set the content-type, set it here just to be
     * completely sure that it gets set to text/html.
     */
    param_free(pblock_remove("content-type", rq->srvhdrs));
    pblock_nvinsert("content-type", "text/html", rq->srvhdrs);
    /* If you want to use keepalive, need to set content-length header.
     * The util_itoa function converts a specified integer to a
     * string, and returns the length of the string. Use this
     * function to create a textual representation of a number.
     */
    util_itoa(strlen(simple_msg), msg_length);
    pblock_nvinsert("content-length", msg_length, rq->srvhdrs);
    /* Send the headers to the client*/
    return_value = protocol_start_response(sn, rq);
    if (return_value == REQ_NOACTION) {
        /* HTTP HEAD instead of GET */
        return REQ_PROCEED;
    }
    /* Write the output using net_write*/
return_value = net_write(sn->csd, simple_msg, 
strlen(simple_msg));
if (return_value == IO_ERROR) {
    return REQ_EXIT;
}
return REQ_PROCEED;

**More Complex Service Example**

The `send-images` function is a custom SAF that replaces the `doit.cgi` demonstration available on the iPlanet home pages. When a file is accessed as `/dir1/dir2/something.picgroup`, the `send-images` function checks if the file is being accessed by a Mozilla/1.1 browser. If not, it sends a short error message. The file `something.picgroup` contains a list of lines, each of which specifies a file name followed by a content-type (for example, `one.gif image/gif`).

To load the shared object containing your function, add the following line at the beginning of the `magnus.conf` file:

```
Init fn=load-modules shlib=yourlibrary funcs=send-images
```

Also, add the following line to the `mime.types` file:

```
type=magnus-internal/picgroup exts=picgroup
```

To execute the custom SAF during the request-response process for some object, add the following line to that object in the `obj.conf` file (`send-images` takes an optional parameter, `delay`, which is not used for this example):

```
Service method=(GET|HEAD) type=magnus-internal/picgroup fn=send-images
```

The source code is in `service.c` in the `nsapi/examples/` or `plugins/nsapi/examples` subdirectory within the server root directory.

**AddLog Example**

The example in this section demonstrates how to implement `brief-log`, a custom SAF for logging only three items of information about a request: the IP address, the method, and the URI (for example, `198.93.95.99 GET /jocelyn/dogs/homesneeded.html`).
**Installing the Example**

To load the shared object containing your functions, add the following line in the Init section of the magnus.conf file:

```
Init fn=load-modules shlib=yourlibrary funcs=brief-init,brief-log
```

To call brief-init to open the log file, add the following line to the Init section in magnus.conf. (This line must come after the one that loads the library containing brief-init.)

```
Init fn=brief-init file=/tmp/brief.log
```

To execute your custom SAF during the AddLog stage for some object, add the following line to that object in the obj.conf file:

```
AddLog fn=brief-log
```

**Source Code**

The source code is in addlog.c file in the nsapi/examples/ or plugins/nsapi/examples subdirectory within the server root directory.

```c
#include "nsapi.h"
#include "base/daemon.h" /* daemon_atrestart */
#include "base/file.h" /* system_fopenWA, system_fclose */
#include "base/util.h" /* sprintf */

/* File descriptor to be shared between the processes */
static SYS_FILE logfd = SYS_ERROR_FD;

#ifdef __cplusplus
extern "C"
#endif
NSAPI_PUBLIC void brief_terminate(void *parameter)
{
    system_fclose(logfd);
    logfd = SYS_ERROR_FD;
}

#ifdef __cplusplus
extern "C"
#endif
NSAPI_PUBLIC int brief_init(pblock *pb, Session *sn, Request *rq)
{
```

/ Parameter */
char *fn = pblock_findval("file", pb);

if(!fn) {
    pblock_nvinsert("error", "brief-init: please supply a file name", pb);
    return REQ_ABORTED;
}

logfd = system_fopenWA(fn);
if(logfd == SYS_ERROR_FD) {
    pblock_nvinsert("error", "brief-init: please supply a file name", pb);
    return REQ_ABORTED;
}

/* Close log file when server is restarted */
daemon_atrestart(brief_terminate, NULL);
return REQ_PROCEED;

#endif
extern "C"
#endif
NSAPI_PUBLIC int brief_log(pblock *pb, Session *sn, Request *rq)
{
    /* No parameters */

    /* Server data */
    char *method = pblock_findval("method", rq->reqpb);
    char *uri = pblock_findval("uri", rq->reqpb);
    char *ip = pblock_findval("ip", sn->client);

    /* Temp vars */
    char *logmsg;
    int len;

    logmsg = (char *)
        MALLOC(strlen(ip)+1+strlen(method)+1+strlen(uri)+1+1);
    len = util_sprintf(logmsg, "%s %s %s\n", ip, method, uri);
    /* The atomic version uses locking to prevent interference */
    system_fwrite_atomic(logfd, logmsg, len);
    FREE(logmsg);

    return REQ_PROCEED;
}
Quality of Service Example

The code for the qos-handler (AuthTrans) and qos-error (Error) SAFs is provided as an example in case you want to define your own SAFs for quality of service handling.

For more information about predefined SAFs, see the Sun Java System Web Server 6.1 SP10 Administrator’s Configuration File Reference.

Installing the Example

Inside the default object in obj.conf, add the following AuthTrans and Error directives:

```
AuthTrans fn=qos-handler
...
Error fn=qos-error code=503
```

Source Code

The source code for this example is in the qos.c file in the plugins/nsapi/examples subdirectory of the server root directory.

```
#include "nspr.h"
#include "base/pblock.h"
#include "frame/log.h"
#include "frame/http.h"

/*- decode : internal function used for parsing of QOS values in pblock */
#define decode : internal function used for parsing of QOS values in pblock

void decode(const char* val, PInt32* var, pblock* pb)
{
    char* pbval;
    if ( (!var) || (!val) || (!pb) )
        return;
    pbval = pblock_findval(val, pb);
    if (!pbval)
        return;
    *var = atoi(pbval);
}
```

qos_error_sample
This function is meant to be an error handler for an HTTP 503 error code, which is returned by qos_handler when QOS limits are exceeded and enforced.

This sample function just prints out a message about which limits were exceeded.

---

qos_handler_sample
This is an NSAPI AuthTrans function.

It examines the QOS values in the request and compares them to the QOS limits.

It does several things:
1) It will log errors if the QOS limits are exceeded.
2) It will return REQ_ABORTED with a 503 error code if the QOS limits are exceeded, and the QOS limits are set to be enforced. Otherwise

Chapter 5 • Examples of Custom SAFs and Filters 133
it will return REQ_PROCEED.

NSAPI_PUBLIC int qos_handler_sample(pblock *pb, Session *sn, Request *rq)
{
    PRBool ok = PR_TRUE;

    PRInt32 vs_bw = 0, vs_bwlim = 0, vs_bw_ef = 0,

Creating Custom Server-parsed HTML Tags

HTML files can contain tags that are executed on the server. For general information about server-parsed HTML tags, see the *Sun Java System Web Server 6.1 SP10 Programmer’s Guide to Web Applications*.

In Sun Java System Web Server 6.1, you can define your own server-side tags. For example, you could define the tag *HELLO* to invoke a function that prints "Hello World!" You could have the following code in your *hello.shtml* file:

```html
<html>
<head>
<title>shtml custom tag example</title>
</head>
<body>
<!--#HELLO-->
</body>
</html>
```

When the browser displays this code, each occurrence of the *HELLO* tag calls the function.

1. “Define the Functions that Implement the Tag” on page 138.
   You must define the tag execution function. You must also define other functions that are called on tag loading and unloading, and on page loading and unloading.
2. “Write an Initialization Function” on page 141.
   Write an initialization function that registers the tag using the *shtml_add_tag* function.
Define the Functions that Implement the Tag

Define the functions that implement the tags in C, using NSAPI.

- Include the header `shtml_public.h`, which is in the directory `install_dir/include/shtml`.
- Link against the SHTML shared library. On Windows, `shtml.dll` is in `install_dir/bin`. On UNIX platforms, `libshtml.so` or `sl` is in `install_dir/lib`.

`ShtmlTagExecuteFunc` is the actual tag handler. It gets called with the usual NSAPI `pblock`, `Session`, and `Request` variables. In addition, it also gets passed the `TagUserData` created from the result of executing the tag loading and page loading functions (if defined) for that tag.

The signature for the tag execution function is:

```
typedef int (*ShtmlTagExecuteFunc)(pblock*, Session*, Request*, TagUserData, TagUserData);
```

Write the body of the tag execution function to generate the output to replace the tag in the `.shtml` page. Do this in the usual NSAPI way, using the `net_write` NSAPI function, which writes a specified number of bytes to a specified socket from a specified buffer.

For more information about writing NSAPI plug-ins, see Chapter 3, Creating Custom SAFs.

For more information about `net_write` and other NSAPI functions, see Chapter 7, NSAPI Function Reference.

The tag execution function must return an int that indicates whether the server should proceed to the next instruction in `obj.conf`, which is one of:

- `REQ_PROCEED` -- the execution was successful
- `REQ_NOACTION` -- nothing happened
- `REQ_ABORTED` -- an error occurred
- `REQ_EXIT` -- the connection was lost

The other functions you must define for your tag are:

- `ShtmlTagInstanceLoad`
  This is called when a page containing the tag is parsed. It is not called if the page is retrieved from the browser’s cache. It basically serves as a constructor, the result of which is cached and is passed into `ShtmlTagExecuteFunc` whenever the execution function is called.

- `ShtmlTagInstanceUnload`
  This is basically a destructor for cleaning up whatever was created in the `ShtmlTagInstanceLoad` function. It gets passed the result that was originally returned from the `ShtmlTagInstanceLoad` function.

- `ShtmlTagPageLoadFunc`
This is called when a page containing the tag is executed, regardless of whether the page is still in the browser's cache. This provides a way to make information persistent between occurrences of the same tag on the same page.

- **ShtmlTagPageUnLoadFn**

  This is called after a page containing the tag has executed. It provides a way to clean up any allocations done in a ShtmlTagPageLoadFunc and hence gets passed the result returned from the ShtmlTagPageLoadFunc.

  The signatures for these functions are:

  ```
  #define TagUserData void*
  typedef TagUserData (*ShtmlTagInstanceLoad)(
    const char* tag, pblock*, const char*, size_t);
  typedef void (*ShtmlTagInstanceUnload)(TagUserData);
  typedef int (*ShtmlTagExecuteFunc)(
    pblock*, Session*, Request*, TagUserData, TagUserData);
  typedef TagUserData (*ShtmlTagPageLoadFunc)(
    pblock* pb, Session*, Request*);
  typedef void (*ShtmlTagPageUnLoadFunc)(TagUserData);
  ```

Here is the code that implements the HELLO tag:

```c
#include "nsapi.h"
#include "shtml/shtml_public.h"

/* FUNCTION : mytag_con */
/* DESCRIPTION: ShtmlTagInstanceLoad function */
#else __cplusplus
extern "C"
#endif
TagUserData
mytag_con(const char* tag, pblock* pb, const char* c1, size_t t1)
{
    return NULL;
}

/* FUNCTION : mytag_des */
/* DESCRIPTION: ShtmlTagInstanceUnload */
#else __cplusplus
extern "C"
#endif
void
```
mytag_des(TagUserData v1)
{
}
/* FUNCTION : mytag_load
 * DESCRIPTION: ShtmlTagPageLoadFunc
*/
#endif
TagUserData
mytag_load(pblock *pb, Session *sn, Request *rq)
{
    return NULL;
}
/* FUNCTION : mytag_unload
 * DESCRIPTION: ShtmlTagPageUnloadFunc
*/
#endif
void
mytag_unload(TagUserData v2)
{
}
/* FUNCTION : mytag
 * DESCRIPTION: ShtmlTagExecuteFunc
*/
#endif
int
mytag(pblock* pb, Session* sn, Request* rq, TagUserData t1, TagUserData t2)
{
    char* buf;
    int length;
    char* client;
    buf = (char *) MALLOC(100*sizeof(char));
    length = util_sprintf(buf, "<h1>Hello World! </h1>", client);
    if (net_write(sn->csd, buf, length) == IO_ERROR)
    {
        FREE(buf);
        return REQ_ABORTED;
    }
    FREE(buf);
    return REQ_PROCEED;
}
write an initialization function

in the initialization function for the shared library that defines the new tag, register the tag using the function shtml_add_tag. the signature is:

NSAPI_PUBLIC int shtml_add_tag ( const char* tag, ShtmlTagInstanceLoad ctor, ShtmlTagInstanceUnLoad dtor, ShtmlTagExecuteFunc execFn, ShtmlTagPageLoadFunc pageLoadFn, ShtmlTagPageUnLoadFunc pageUnLoadFn);

any of these arguments can return NULL except for the tag and execFn.

load the new tag into the server

after creating the shared library that defines the new tag, you load the library into the sun java system web server in the usual way for NSAPI plug-ins. Add the following directives to the configuration file magnus.conf:

Add an Init directive whose fn parameter is load-modules and whose shlib parameter is the shared library to load. For example, if you compiled your tag into the shared object install_dir/hello.so, it would be:
Init funcs="mytag,mytag_init" shlib="install_dir/hello.so"
fn="load-modules"

Add another Init directive whose fn parameter is the initialization function in the shared library that uses shtml_add_tag to register the tag. For example:

Init fn="mytag_init"
This chapter lists all of the public C functions and macros of the Netscape Server Applications Programming Interface (NSAPI) in alphabetic order. These are the functions you use when writing your own Server Application Functions (SAFs).

See Chapter 2, SAFs in the magnus.conf File for a list of the predefined Init SAFs. For more information about the other predefined SAFs used in obj.conf, see the Sun Java System Web Server 6.1 SP10 Administrator’s Configuration File Reference.

Each function provides the name, syntax, parameters, return value, a description of what the function does, and sometimes an example of its use and a list of related functions.

For more information on data structures, see Chapter 8, Data Structure Reference include directory in the build for Sun Java System Web Server 6.1.

**NSAPI Functions (in Alphabetical Order)**

For an alphabetical list of function names, see Appendix A, “Alphabetical List of NSAPI Functions and Macros”
CALLOC

The CALLOC macro is a platform-independent substitute for the C library routine calloc. It allocates num*size bytes from the request's memory pool. If pooled memory has been disabled in the configuration file (with the pool-init built-in SAF), PERM_CALLOC and CALLOC both obtain their memory from the system heap.

Syntax

void *CALLOC(int size)

Returns

A void pointer to a block of memory.

Parameters

int size is the size in bytes of each element.

Example

char *name;name = (char *) CALLOC(100);

See Also

“FREE” on page 159, “REALLOC” on page 193, “STRDUP” on page 201, “PERM_MALLOC” on page 184, “PERM_FREE” on page 184, “PERM_REALLOC” on page 185, “PERM_STRDUP” on page 186

cinfo_find

The cinfo_find() function uses the MIME types information to find the type, encoding, and/or language based on the extension(s) of the URI or local file name. Use this information to send headers (rq->srvhdrs) to the client indicating the content-type, content-encoding, and content-language of the data it will be receiving from the server.

The name used is everything after the last slash (/) or the whole string if no slash is found. File name extensions are not case-sensitive. The name may contain multiple extensions separated by period(.) to indicate type, encoding, or language. For example, the URI a/b/filename.jp.txt.zip could represent a Japanese language, text/plain type, zip encoded file.
Syntax

cinfo *cinfo_find(char *uri);

Returns

A pointer to a newly allocated cinfo structure if content info was found, or NULL if no content was found.

The cinfo structure that is allocated and returned contains pointers to the content-type, content-encoding, and content-language, if found. Each is a pointer into static data in the types database, or NULL if not found. Do not free these pointers. You should free the cinfo structure when you are done using it.

Parameters

char *uri is a URI or local file name. Multiple file name extensions should be separated by periods (.)

condvar_init

The condvar_init function is a critical-section function that initializes and returns a new condition variable associated with a specified critical-section variable. You can use the condition variable to prevent interference between two threads of execution.

Syntax

CONDVAR condvar_init(CRITICAL id);

Returns

A newly allocated condition variable (CONDVAR).

Parameters

CRITICAL id is a critical-section variable.

See Also

condvar_notify

The condvar_notify function is a critical-section function that activates threads that are blocked on the given critical-section variable. Use this function to awaken threads of execution of a given critical section. First, use crit_enter to gain ownership of the critical section. Then use the returned critical-section variable to call condvar_notify to awaken the threads. Finally, when condvar_notify returns, call crit_exit to surrender ownership of the critical section.

Syntax

void condvar_notify(CONDVAR cv);

Returns

void

Parameters

CONDVAR cv is a condition variable.

See Also

condvar_terminate

The condvar_terminate function is a critical-section function that frees a condition variable. Use this function to free a previously allocated condition variable.

Warning

Terminating a condition variable that is in use can lead to unpredictable results.

Syntax

void condvar_terminate(CONDVAR cv);

Returns

void

Parameters

CONDVAR cv is a condition variable.
See Also

condvar_wait
The condvar_wait function is a critical-section function that blocks on a given condition variable. Use this function to wait for a critical section (specified by a condition variable argument) to become available. The calling thread is blocked until another thread calls condvar_notify with the same condition variable argument. The caller must have entered the critical section associated with this condition variable before calling condvar_wait.

Syntax
void condvar_wait(CONDVAR cv);

Returns
void

Parameters
CONDVAR cv is a condition variable.

See Also

crit_enter
The crit_enter function is a critical-section function that attempts to enter a critical section. Use this function to gain ownership of a critical section. If another thread already owns the section, the calling thread is blocked until the first thread surrenders ownership by calling crit_exit.

Syntax
void crit_enter(CRITICAL crvar);

Returns
void
Parameters
CRITICAL crvar is a critical-section variable.

See Also
“crit_init” on page 148, “crit_exit” on page 148, “crit_terminate” on page 149

crit_exit
The crit_exit function is a critical-section function that surrenders ownership of a critical section. Use this function to surrender ownership of a critical section. If another thread is blocked waiting for the section, the block will be removed and the waiting thread will be given ownership of the section.

Syntax
void crit_exit(CRITICAL crvar);

Returns
void

Parameters
CRITICAL crvar is a critical-section variable.

See Also
“crit_init” on page 148, “crit_enter” on page 147, “crit_terminate” on page 149

crit_init
The crit_init function is a critical-section function that creates and returns a new critical-section variable (a variable of type CRITICAL). Use this function to obtain a new instance of a variable of type CRITICAL (a critical-section variable) to be used in managing the prevention of interference between two threads of execution. At the time of its creation, no thread owns the critical section.

Warning
Threads must not own or be waiting for the critical section when crit_terminate is called.

Syntax
CRITICAL crit_init(void);
**Returns**
A newly allocated critical-section variable (CRITICAL).

**Parameters**
none

**See Also**
“crit_enter” on page 147, “crit_exit” on page 148, “crit_terminate” on page 149

**crit_terminate**
The crit_terminate function is a critical-section function that removes a previously allocated critical-section variable (a variable of type CRITICAL). Use this function to release a critical-section variable previously obtained by a call to crit_init.

**Syntax**
void crit_terminate(CRITICAL crvar);

**Returns**
void

**Parameters**
CRITICAL crvar is a critical-section variable.

**See Also**
“crit_init” on page 148, “crit_enter” on page 147, “crit_exit” on page 148

**daemon_atrestart**
The daemon_atrestart function lets you register a callback function named by fn to be used when the server terminates. Use this function when you need a callback function to deallocate resources allocated by an initialization function. The daemon_atrestart function is a generalization of the magnus_atrestart function.
The magnus.conf directives TerminateTimeout and ChildRestartCallback also affect the callback of NSAPI functions.

Syntax

```c
void daemon_atrestart(void (*fn)(void *), void *data);
```

Returns

void

Parameters

void (* fn) (void *) is the callback function.

void *data is the parameter passed to the callback function when the server is restarted.

Example

```c
/* Register the log_close function, passing it NULL */
   /* to close *a log file when the server is */
   /* reassembled or shutdown. */
   daemon_atrestart(log_close, NULL);

NSAPI_PUBLIC void log_close(void *parameter)
   {system_fclose(global_logfd);}
```

fc_open

The fc_open function returns a pointer to PRFileDesc that refers to an open file (fileName). The fileName must be the full path name of an existing file. The file is opened in read-only mode. The application calling this function should not modify the currency of the file pointed to by the PRFileDesc * unless the DUP_FILE_DESC is also passed to this function. In other words, the application (at minimum) should not issue a read operation based on this pointer that would modify the currency for the PRFileDesc *. If such a read operation is required (that may change the currency for the PRFileDesc *), then the application should call this function with the argument DUP_FILE_DESC.

On a successful call to this function, a valid pointer to PRFileDesc is returned and the handle 'FcHdl' is properly initialized. The size information for the file is stored in the 'fileSize' member of the handle.

Syntax

```c
PRFileDesc *fc_open(const char *fileName,
                    FcHdl *hDl, PRUint32 flags, Session *sn, Request *rq);
```
Returns
Pointer to PRFileDesc, or NULL on failure.

Parameters
const char *fileName is the full path name of the file to be opened.
FcHdl *hDl is a valid pointer to a structure of type FcHdl.
PRUint32 flags can be 0 or DUP_FILE_DESC.
Session *sn is a pointer to the session.
Request *rq is a pointer to the request.

fc_close
The fc_close function closes a file opened using fc_open. This function should only be called with files opened using fc_open.

Syntax
void fc_close(PRFileDesc *fd, FcHdl *hDl);

Returns
void

Parameters
PRFileDesc *fd is a valid pointer returned from a prior call to fc_open.
FcHdl *hDl is a valid pointer to a structure of type FcHdl. This pointer must have been initialized by a prior call to fc_open.

filebuf_buf2sd
The filebuf_buf2sd function sends a file buffer to a socket (descriptor) and returns the number of bytes sent.
Use this function to send the contents of an entire file to the client.

Syntax
int filebuf_buf2sd(filebuf *buf, SYS_NETFD sd);
Returns
The number of bytes sent to the socket if successful, or the constant IO_ERROR if the file buffer could not be sent.

Parameters
filebuf *buf is the file buffer that must already have been opened.

SYS_NETFD sd is the platform-independent socket descriptor. Normally this will be obtained from the csd (client socket descriptor) field of the sn (session) structure.

Example
if (filebuf_buf2sd(buf, sn->csd) == IO_ERROR) return(REQ_EXIT);

See Also
"filebuf_close" on page 152, "filebuf_open" on page 153, "filebuf_open_nostat" on page 154, "filebuf_getc" on page 153

filebuf_close
The filebuf_close function deallocates a file buffer and closes its associated file.

Generally, use filebuf_open first to open a file buffer, and then filebuf_getc to access the information in the file. After you have finished using the file buffer, use filebuf_close to close it.

Syntax
void filebuf_close(filebuf *buf);

Returns
void

Parameters
filebuf *buf is the file buffer previously opened with filebuf_open.

Example
filebuf_close(buf);

See Also
"filebuf_open" on page 153, "filebuf_open_nostat" on page 154, "filebuf_buf2sd" on page 151, "filebuf_getc" on page 153
**filebuf_getc**

The `filebuf_getc` function retrieves a character from the current file position and returns it as an integer. It then increments the current file position.

Use `filebuf_getc` to sequentially read characters from a buffered file.

**Syntax**

```c
filebuf_getc(filebuf b);
```

**Returns**

An integer containing the character retrieved, or the constant `IO_EOF` or `IO_ERROR` upon an end of file or error.

**Parameters**

`filebuf b` is the name of the file buffer.

**See Also**

“filebuf_close” on page 152, “filebuf_buf2sd” on page 151, “filebuf_open” on page 153, “filter_create” on page 155

**filebuf_open**

The `filebuf_open` function opens a new file buffer for a previously opened file. It returns a new buffer structure. Buffered files provide more efficient file access by guaranteeing the use of buffered file I/O in environments where it is not supported by the operating system.

**Syntax**

```c
filebuf *filebuf_open(SYS_FILE fd, int sz);
```

**Returns**

A pointer to a new buffer structure to hold the data if successful, or NULL if no buffer could be opened.

**Parameters**

`SYS_FILE fd` is the platform-independent file descriptor of the file which has already been opened.

`int sz` is the size, in bytes, to be used for the buffer.
Example

```c
filebuf *buf = filebuf_open_nostat(fd, FILE_BUFFERSIZE); if (!buf) {
    system_fclose(fd);
}
```

See Also

“filebuf_getc” on page 153, “filebuf_buf2sd” on page 151, “filebuf_close” on page 152,
“filebuf_open_nostat” on page 154

**filebuf_open_nostat**

The `filebuf_open_nostat` function opens a new file buffer for a previously opened file. It returns a new buffer structure. Buffered files provide more efficient file access by guaranteeing the use of buffered file I/O in environments where it is not supported by the operating system.

This function is the same `filebuf_open`, but is more efficient, since it does not need to call the `request_stat_path` function. It requires that the stat information be passed in.

**Syntax**

```c
filebuf* filebuf_open_nostat(SYS_FILE fd, int sz, struct stat *finfo);
```

**Returns**

A pointer to a new buffer structure to hold the data if successful, or NULL if no buffer could be opened.

**Parameters**

- `SYS_FILE fd` is the platform-independent file descriptor of the file that has already been opened.
- `int sz` is the size, in bytes, to be used for the buffer.
- `struct stat *finfo` is the file information of the file. Before calling the `filebuf_open_nostat` function, you must call the `request_stat_path` function to retrieve the file information.

Example

```c
filebuf *buf = filebuf_open_nostat(fd, FILE_BUFFERSIZE, &finfo);
if (!buf) {
    system_fclose(fd);
}
```

“filebuf_close” on page 152, “filebuf_open” on page 153, “filebuf_getc” on page 153,
“filebuf_buf2sd” on page 151
The `filter_create` function defines a new filter.

The name parameter specifies a unique name for the filter. If a filter with the specified name already exists, it will be replaced.

Names beginning with `magnus-` or `server-` are reserved by the server.

The order parameter indicates the position of the filter in the filter stack by specifying what class of functionality the filter implements.

The following table describes parameters allowed order constants and their associated meanings for the `filter_create` function. The left column lists the name of the constant, the middle column describes the functionality the filter implements, and the right column lists the position the filter occupies in the filter stack.

<table>
<thead>
<tr>
<th>Constant</th>
<th>Functionality Filter Implements</th>
<th>Position in Filter Stack</th>
</tr>
</thead>
<tbody>
<tr>
<td>FILTER_CONTENT_TRANSLATION</td>
<td>Translates content from one form to another (for example, XSLT)</td>
<td>Top</td>
</tr>
<tr>
<td>FILTER_CONTENT_CODING</td>
<td>Encodes content (for example, HTTP gzip compression)</td>
<td>Middle</td>
</tr>
<tr>
<td>FILTER_TRANSFER_CODING</td>
<td>Encodes entity bodies for transmission (for example, HTTP chunking)</td>
<td>Bottom</td>
</tr>
</tbody>
</table>

The methods parameter specifies a pointer to a `FilterMethods` structure. Before calling `filter_create`, you must first initialize the "FilterMethods" on page 246 structure using the `FILTER_METHODS_INITIALIZER` macro, and then assign function pointers to the individual `FilterMethods` members (for example, `insert`, `read`, `write`, and so on) that correspond to the filter methods the filter will support.

`filter_create` returns `const Filter *`, a pointer to an opaque representation of the filter. This value may be passed to `filter_insert` to insert the filter in a particular filter stack.

**Syntax**

```c
const Filter *filter_create(const char *name, int order, const FilterMethods *methods);
```

**Returns**

The `const Filter *` that identifies the filter or NULL if an error occurred.
Parameters

const char *name is the name of the filter.

int order is one of the order constants above.

const FilterMethods *methods contains pointers to the filter methods the filter supports.

Example

FilterMethods methods = FILTER_METHODS_INITIALIZER;
const Filter *filter;
/* This filter will only support the "read" filter method */
methods.read = my_input_filter_read;
/* Create the filter */
filter = filter_create("my-input-filter", FILTERCONTENT_TRANSLATION,
&methods);

filter_find

The filter_find function finds the filter with the specified name.

Syntax

const Filter *filter_find(const char *name);

Returns

The const Filter * that identifies the filter, or NULL if the specified filter does not exist.

Parameters

const char *name is the name of the filter of interest.

filter_insert

The filter_insert function inserts a filter into a filter stack, creating a new filter layer and installing the filter at that layer. The filter layer’s position in the stack is determined by the order value specified when “filter_create” on page 155 was called, and any explicit ordering configured by “init-filter-order” on page 62. If a filter layer with the same order value already exists in the stack, the new layer is inserted above that layer.

Parameters may be passed to the filter using the pb and data parameters. The semantics of the data parameter are defined by individual filters. However, all filters must be able to handle a data parameter of NULL.
When possible, plug-in developers should avoid calling `filter_insert` directly, and instead use the `insert-filter SAF` (applicable in Input-class directives).

**Syntax**

```c
int filter_insert(SYS_NETFD sd, pblock *pb, Session *sn, Request *rq, void *data, const Filter *filter);
```

**Returns**

Returns `REQ_PROCEED` if the specified filter was inserted successfully, or `REQ_NOACTION` if the specified filter was not inserted because it was not required. Any other return value indicates an error.

**Parameters**

- `SYS_NETFD sd` is NULL (reserved for future use).
- `pblock *pb` is a set of parameters to pass to the specified filter's init method.
- `Session *sn` is the Session.
- `Request *rq` is the Request.
- `void *data` is filter-defined private data.
- `const Filter *filter` is the filter to insert.

**filter_layer**

The `filter_layer` function returns the layer in a filter stack that corresponds to the specified filter.

**Syntax**

```c
FilterLayer *filter_layer(SYS_NETFD sd, const Filter *filter);
```

**Returns**

The topmost `FilterLayer *` associated with the specified filter, or NULL if the specified filter is not part of the specified filter stack.

**Parameters**

- `SYS_NETFD sd` is the filter stack to inspect.
- `const Filter *filter` is the filter of interest.
filter_name

The filter_name function returns the name of the specified filter. The caller should not free the returned string.

Syntax

```c
const char *filter_name(const Filter *filter);
```

Returns

The name of the specified filter, or NULL if an error occurred.

Parameters

const Filter *filter is the filter of interest.

filter_remove

The filter_remove function removes the specified filter from the specified filter stack, destroying a filter layer. If the specified filter was inserted into the filter stack multiple times, only that filter's topmost filter layer is destroyed.

When possible, plug-in developers should avoid calling filter_remove directly, and instead use the remove-filter SAF (applicable in Input-, Output-, Service-, and Error-class directives).

Syntax

```c
int filter_remove(SYS_NETFD sd, const Filter *filter);
```

Returns

Returns REQ_PROCEED if the specified filter was removed successfully or REQ_NOACTION if the specified filter was not part of the filter stack. Any other return value indicates an error.

Parameters

SYS_NETFD sd is the filter stack, sn->csd.

const Filter *filter is the filter to remove.

flush

The flush filter method is called when buffered data should be sent. Filters that buffer outgoing data should implement the flush filter method.
Upon receiving control, a flush implementation must write any buffered data to the filter layer immediately below it. Before returning success, a flush implementation must successfully call the “net_flush” on page 164 function:

\[\text{net\_flush}(\text{layer}\rightarrow\text{lower}).\]

**Syntax**

\[
\text{int flush(FilterLayer *layer);}\]

**Returns**

0 on success or -1 if an error occurred.

**Parameters**

FilterLayer *layer is the filter layer the filter is installed in.

**Example**

\[
\text{int myfilter\_flush(FilterLayer *layer)}\]
\[
\{
  \text{MyFilterContext context = (MyFilterContext *)layer}\rightarrow\text{context}\rightarrow\text{data};
  \text{if (context}\rightarrow\text{buf.count) }\{
    \text{int rv;}
    \text{rv = net\_write(layer}\rightarrow\text{lower, context}\rightarrow\text{buf.data, context}\rightarrow\text{buf.count);}
    \text{if (rv !}\Rightarrow\text{context}\rightarrow\text{buf.count)}
      \text{return -1; /* failed to flush data */}
    \text{context}\rightarrow\text{buf.count} = 0;
  \}
  \text{return net\_flush(layer}\rightarrow\text{lower);}\]
\]

**See Also**

“net_flush” on page 164

**FREE**

The FREE macro is a platform-independent substitute for the C library routine free. It deallocates the space previously allocated by MALLOC, CALLOC, or STRDUP from the request’s memory pool.

**Syntax**

\[
\text{FREE(void *ptr);}\]
**Returns**

void

**Parameters**

void *ptr is a (void *) pointer to a block of memory. If the pointer is not one created by MALLOC, CALLOC, or STRDUP, the behavior is undefined.

**Example**

char *name; name = (char *) MALLOC(256);...FREE(name);

**See Also**

"CALLOC" on page 144, "REALLOC" on page 193, "STRDUP" on page 201, "PERM_MALLOC" on page 184, "PERM_FREE" on page 184, "PERM_REALLOC" on page 185, "PERM_STRDUP" on page 186

**func_exec**

The func_exec function executes the function named by the fn entry in a specified pblock. If the function name is not found, it logs the error and returns REQ_ABORTED.

You can use this function to execute a built-in SAF by identifying it in the pbloc.

**Syntax**

int func_exec(pblock *pb, Session *sn, Request *rq);

**Returns**

The value returned by the executed function, or the constant REQ_ABORTED if no function was executed.

**Parameters**

pblock pb is the pblock containing the function name (fn) and parameters.

Session *sn is the Session.

Request *rq is the Request.

The Session and Request parameters are the same as the ones passed into your SAF.

**See Also**

"log_error" on page 163
**func_find**

The `func_find` function returns a pointer to the function specified by `name`. If the function does not exist, it returns NULL.

**Syntax**

```c
FuncPtr func_find(char *name);
```

**Returns**

A pointer to the chosen function, suitable for dereferencing, or NULL if the function could not be found.

**Parameters**

`char *name` is the name of the function.

**Example**

```c
/* this block of code does the same thing as func_exec */
char *afunc = pblock_findval("afunction", pb); FuncPtr afnptr = func_find(afunc);
if (afnptr) return (afnptr)(pb, sn, rq);
```

**See Also**

“func_exec” on page 160

**func_insert**

The `func_insert` function dynamically inserts a named function into the server's table of functions. This function should only be called during the Init stage.

**Syntax**

```c
FuncStruct *func_insert(char *name, FuncPtr fn);
```

**Returns**

Returns the `FuncStruct` structure that identifies the newly inserted function. The caller should not modify the contents of the `FuncStruct` structure.

**Parameters**

`char *name` is the name of the function.

`FuncPtr fn` is the pointer to the function.
**Example**

```c
func_insert("my-service-saf", &my_service_saf);
```

**See Also**

“func_exec” on page 160, “func_find” on page 161

---

**insert**

The `insert` filter method is called when a filter is inserted into a filter stack by the “filter_insert” on page 156 function or insert-filter SAF (applicable in Input-class directives).

**Syntax**

```c
int insert(FilterLayer *layer, pblock *pb);
```

**Returns**

Returns `REQ_PROCEED` if the filter should be inserted into the filter stack, `REQ_NOACTION` if the filter should not be inserted because it is not required, or `REQ_ABORTED` if the filter should not be inserted because of an error.

**Parameters**

- `FilterLayer *layer` is the filter layer at which the filter is being inserted.
- `pblock *pb` is the set of parameters passed to `filter_insert` or specified by the `fn="insert-filter"` directive.

**Example**

```c
FilterMethods myfilter_methods = FILTER_METHODS_INITIALIZER;const Filter
    *myfilter;int myfilter_insert(FilterLayer *layer, pblock *pb)
    {if (pblock_findval("dont-insert-filter", pb))
        return REQ_NOACTION;return REQ_PROCEED;}
    myfilter_methods.insert = &myfilter_insert;
    myfilter = filter_create("myfilter", &myfilter_methods);
```
The log_error function creates an entry in an error log, recording the date, the severity, and a specified text.

**Syntax**

```c
int log_error(int degree, char *func, Session *sn, Request *rq, char *fmt, ...);
```

**Returns**

0 if the log entry was created, or -1 if the log entry was not created.

**Parameters**

- `int degree` specifies the severity of the error. It must be one of the following constants:
  - `LOG_WARN` -- warning
  - `LOG_MISCONFIG` -- a syntax error or permission violation
  - `LOG_SECURITY` -- an authentication failure or 403 error from a host
  - `LOG_FAILURE` -- an internal problem
  - `LOG_CATASTROPHE` -- a nonrecoverable server error
  - `LOG_INFORM` -- an informational message

- `char *func` is the name of the function where the error has occurred.

- `Session *sn` is the Session.

- `Request *rq` is the Request.

The Session and Request parameters are the same as the ones passed into your SAF.

- `char *fmt` specifies the format for the printf function that delivers the message.

  ... represents a sequence of parameters for the printf function.

**Example**

```c
log_error(LOG_WARN, "send-file", sn, rq,
          "error opening buffer from %s (%s)", path,
          system_errmsg(fd));
```

**See Also**

"func_exec" on page 160
M

MALLOC

The MALLOC macro is a platform-independent substitute for the C library routine malloc. It normally allocates from the request’s memory pool. If pooled memory has been disabled in the configuration file (with the pool-init built-in SAF), PERM_MALLOC and MALLOC both obtain their memory from the system heap.

Syntax

void *MALLOC(int size)

Returns

A void pointer to a block of memory.

Parameters

int size is the number of bytes to allocate.

Example

/* Allocate 256 bytes for a name */char *name; name = (char *) MALLOC(256);

See Also

"FREE" on page 159, "CALLOC" on page 144, "REALLOC" on page 193, "STRDUP" on page 201, "PERM_MALLOC" on page 184, "PERM_FREE" on page 184, "PERM_CALLOC" on page 183, "PERM_REALLOC" on page 185, "PERM_STRDUP" on page 186

N

net_flush

The net_flush function flushes any buffered data. If you require that data be sent immediately, call net_flush after calling network output functions such as net_write or net_sendfile.

Syntax

int net_flush(SYS_NETFD sd);
Returns

0 on success, or a negative value if an error occurred.

Parameters

SYS_NETFD sd is the socket to flush.

Example

```c
net_write(sn->csd, "Please wait...", 15);
net_flush(sn->csd);
/* Perform some time-intensive operation */
...net_write(sn->csd, "Thank you.\n", 11);
```

See Also

“net_write” on page 168, “net_sendfile” on page 166

net_ip2host

The net_ip2host function transforms a textual IP address into a fully-qualified domain name and returns it.

Note – This function works only if the DNS directive is enabled in the magnus.conf file. For more information, see Chapter 2, SAFs in the magnus.conf File.

Syntax

```c
char *net_ip2host(char *ip, int verify);
```

Returns

A new string containing the fully-qualified domain name if the transformation was accomplished, or NULL if the transformation was not accomplished.

Parameters

char *ip is the IP address as a character string in dotted-decimal notation: nnn.nnn.nnn.nnn
int verify, if nonzero, specifies that the function should verify the fully-qualified domain name. Though this requires an extra query, you should use it when checking access control.
net_read

The net_read function reads bytes from a specified socket into a specified buffer. The function waits to receive data from the socket until either at least one byte is available in the socket or the specified time has elapsed.

Syntax

```c
int net_read (SYS_NETFD sd, char *buf, int sz, int timeout);
```

Returns

The number of bytes read, which will not exceed the maximum size, sz. A negative value is returned if an error has occurred, in which case errno is set to the constant ETIMEDOUT if the operation did not complete before timeout seconds elapsed.

Parameters

- SYS_NETFD sd is the platform-independent socket descriptor.
- char *buf is the buffer to receive the bytes.
- int sz is the maximum number of bytes to read.
- int timeout is the number of seconds to allow for the read operation before returning. The purpose of timeout is not to return because not enough bytes were read in the given time, but to limit the amount of time devoted to waiting until some data arrives.

See Also

- "net_write" on page 168

net_sendfile

The net_sendfile function sends the contents of a specified file to a specified socket. Either the whole file or a fraction may be sent, and the contents of the file may optionally be preceded and/or followed by caller-specified data.

Parameters are passed to net_sendfile in the sendfiledata structure. Before invoking net_sendfile, the caller must initialize every sendfiledata structure member.

Syntax

```c
int net_sendfile(SYS_NETFD sd, const sendfiledata *sfd);
```
**Returns**

A positive number indicates the number of bytes successfully written, including the headers, file contents, and trailers. A negative value indicates an error.

**Parameters**

SYS_NETFD sd is the socket to write to.

cnst sendfiledata *sfd identifies the data to send.

**Example**

The following Service SAF sends a file bracketed by the strings "begin" and "end."

```c
#include <string.h>
#include "nsapi.h"

NSAPI_PUBLIC int service_net_sendfile(pblock *pb, Session *sn, Request *rq) {
    char *path;
    SYS_FILE fd;
    struct sendfiledata sfd;
    int rv;

    path = pblock_findval("path", rq->vars);
    fd = system_fopenRO(path);
    if (!fd) {
        log_error(LOG_MISCONFIG, "service-net-sendfile", sn, rq,
            "Error opening %s (%s)", path, system_errmsg());
        return REQ_ABORTED;
    }
    sfd.fd = fd; /* file to send */
    sfd.offset = 0; /* start sending from the beginning */
    sfd.len = 0; /* send the whole file */
    sfd.header = "begin"; /* header data to send before the file */
    sfd.hlen = strlen(sfd.header); /* length of header data */
    sfd.trailer = "end"; /* trailer data to send after the file */
    sfd.tlen = strlen(sfd.trailer); /* length of trailer data */

    /* send the headers, file, and trailers to the client */
    rv = net_sendfile(sn->csd, &sfd);
    system_fclose(fd);

    if (rv < 0) {
        log_error(LOG_INFORM, "service-net-sendfile", sn, rq,"Error sending %s
See Also

“net_flush” on page 164

net_write

The net_write function writes a specified number of bytes to a specified socket from a specified buffer.

Syntax

```
int net_write(SYS_NETFD sd, char *buf, int sz);
```

Returns

The number of bytes written, which may be less than the requested size if an error occurred.

Parameters

SYS_NETFD sd is the platform-independent socket descriptor.

char *buf is the buffer containing the bytes.

int sz is the number of bytes to write.

Example

```
if (net_write(sn->csd, FIRSTMSG, strlen(FIRSTMSG)) == IO_ERROR) return REQ_EXIT;
```

See Also

“net_read” on page 166

netbuf_buf2sd

The netbuf_buf2sd function sends a buffer to a socket. You can use this function to send data from IPC pipes to the client.
Syntax

```c
int netbuf_buf2sd(netbuf *buf, SYS_NETFD sd, int len);
```

Returns

The number of bytes transferred to the socket, if successful, or the constant `IO_ERROR` if unsuccessful.

Parameters

- `netbuf *buf` is the buffer to send.
- `SYS_NETFD sd` is the platform-independent identifier of the socket.
- `int len` is the length of the buffer.

See Also

- "netbuf_close” on page 169, "netbuf_getc” on page 171, "netbuf_grab” on page 171, "netbuf_open” on page 172, "netbuf_getbytes” on page 170

**netbuf_close**

The `netbuf_close` function deallocates a network buffer and closes its associated files. Use this function when you need to deallocate the network buffer and close the socket.

You should never close the `netbuf` parameter in a session structure.

Syntax

```c
void netbuf_close(netbuf *buf);
```

Returns

`void`

Parameters

`netbuf *buf` is the buffer to close.

See Also

- "netbuf_buf2sd” on page 168, "netbuf_getc” on page 171, "netbuf_grab” on page 171, "netbuf_open” on page 172, "netbuf_getbytes” on page 170
netbuf_getbytes

The netbuf_getbytes function reads bytes from a network buffer into a caller-supplied buffer. If the network buffer is empty, the function waits to receive data from the network buffer’s socket until either at least one byte is available from the socket or the network buffer’s timeout has elapsed.

Syntax

```c
int netbuf_getbytes(netbuf *buf, char *buffer, int sz);
```

Returns

The number of bytes placed into buffer (between 1 and sz) if the operation is successful, the constant NETBUF_EOF on end of file, or the constant NETBUF_ERROR if an error occurred.

Parameters

- `netbuf *buf` is the buffer from which to retrieve bytes.
- `char *buffer` is the caller-supplied buffer that receives the bytes.
- `int sz` is the maximum number of bytes to read.

Example

```c
int cl = 0;

* Read the entire request body */
for (;;) {
    char mybuf[1024];
    int rv;

    rv = netbuf_getbytes(sn->inbuf, mybuf, sizeof(mybuf));
    if (rv == NETBUF_EOF) {
        log_error(LOG_INFORM, "mysaf", sn, rq,
                 "Received %d byte(s)",
                 cl);
        break;
    }
    if (rv == NETBUF_ERROR) {
        log_error(LOG_FAILURE, "mysaf", sn, rq,
                 "Error reading request body (%s)",
                 cl, system_errmsg());
        break;  }

    cl += rv;
}
```
See Also

"netbuf_buf2sd" on page 168, "netbuf_close" on page 169, "netbuf_getc" on page 171, "netbuf_grab" on page 171, "netbuf_open" on page 172

netbuf_getc

The netbuf_getc function retrieves a character from the cursor position of the network buffer specified by b.

Syntax

netbuf_getc(netbuf b);

Returns

The integer representing the character if one was retrieved, or the constant IO_EOF or IO_ERROR for end of file or error.

Parameters

netbuf b is the buffer from which to retrieve one character.

See Also

"netbuf_buf2sd" on page 168, "netbuf_close" on page 169, "netbuf_grab" on page 171, "netbuf_open" on page 172, "netbuf_getbytes" on page 170

netbuf_grab

The netbuf_grab function reads sz number of bytes from the network buffer’s (buf) socket into the network buffer. If the buffer is not large enough it is resized. The data can be retrieved from buf->inbuf on success.

This function is used by the function netbuf_buf2sd.

Syntax

int netbuf_grab(netbuf *buf, int sz);

Returns

The number of bytes actually read (between 1 and sz) if the operation was successful, or the constant IO_EOF or IO_ERROR for end of file or error.
**Parameters**

netbuf *buf is the buffer to read into.

int sz is the number of bytes to read.

**See Also**

"netbuf_buf2sd" on page 168, "netbuf_close" on page 169, "netbuf_grab" on page 171, "netbuf_open" on page 172, "netbuf_getbytes" on page 170

**netbuf_open**

The `netbuf_open` function opens a new network buffer and returns it. You can use `netbuf_open` to create a `netbuf` structure and start using buffered I/O on a socket.

**Syntax**

```c
netbuf* netbuf_open(SYS_NETFD sd, int sz);
```

**Returns**

A pointer to a new `netbuf` structure (network buffer).

**Parameters**

SYS_NETFD sd is the platform-independent identifier of the socket.

int sz is the number of characters to allocate for the network buffer.

**See Also**

"netbuf_buf2sd" on page 168, "netbuf_close" on page 169, "netbuf_getc" on page 171, "netbuf_grab" on page 171, "netbuf_getbytes" on page 170

**nsapi_module_init**

Plugin developers may define an `nsapi_module_init` function, which is a module initialization entry point that enables a plug-in to create filters when it is loaded. When an NSAPI module contains an `nsapi_module_init` function, the server will call that function immediately after loading the module. The `nsapi_module_init` presents the same interface as an `Init` SAF, and it must follow the same rules.

The `nsapi_module_init` function may be used to register SAFs with `func_insert`, create filters with "filter_create" on page 155, register virtual server initialization/destruction callbacks with "vs_register_cb" on page 235, and perform other initialization tasks.
Syntax

int nsapi_module_init(pblock *pb, Session *sn, Request *rq);

Returns

REQ_PROCEED on success, or REQ_ABORTED on error.

Parameters

pblock *pb is a set of parameters specified by the fn="load-modules" directive.

Session *sn (the Session) is NULL.

Request *rq (the Request) is NULL.

NSAPI_RUNTIME_VERSION

The NSAPI_RUNTIME_VERSION macro defines the NSAPI version available at runtime. This is the same as the highest NSAPI version supported by the server the plug-in is running in. The NSAPI version is encoded as in USE_NSAPI_VERSION.

The value returned by the NSAPI_RUNTIME_VERSION macro is valid only in iPlanet™ Web Server 6.0, Netscape Enterprise Server 6.0, and Sun Java System Web Server 6.1. That is, the server must support NSAPI 3.1 for this macro to return a valid value. Additionally, to use NSAPI_RUNTIME_VERSION, you must compile against an nsapi.h header file that supports NSAPI 3.2 or higher.

Plugin developers should not attempt to set the value of the NSAPI_RUNTIME_VERSION macro directly. Instead, see the USE_NSAPI_VERSION macro.

Syntax

int NSAPI_RUNTIME_VERSION

Example

NSAPI_PUBLIC int log_nsapi_runtime_version(pblock *pb, Session *sn, Request *rq) {
    log_error(LOG_INFORM, "log-nsapi-runtime-version", sn, rq,
             "Server supports NSAPI version %d.%d\n",
             NSAPI_RUNTIME_VERSION / 100,
             NSAPI_RUNTIME_VERSION % 100);
    return REQ_PROCEED;
}

See Also

"NSAPI_VERSION" on page 174,"USE_NSAPI_VERSION" on page 215
NSAPI_VERSION

The NSAPI_VERSION macro defines the NSAPI version used at compile time. This value is determined by the value of the USE_NSAPI_VERSION macro. If the plug-in developer did not define USE_NSAPI_VERSION, by the highest NSAPI version supported by the nsapi.h header the plug-in was compiled against. The NSAPI version is encoded as in USE_NSAPI_VERSION.

Plugin developers should not attempt to set the value of the NSAPI_VERSION macro directly. Instead, see the USE_NSAPI_VERSION macro.

Syntax

int NSAPI_VERSION

Example

NSAPI_PUBLIC int log_nsapi_compile_time_version(pblock *pb, Session *sn, Request *rq) {
    log_error(LOG_INFORM, "log-nsapi-compile-time-version", sn, rq,
        "Plugin compiled against NSAPI version %d.%d\n",
        NSAPI_VERSION / 100,
        NSAPI_VERSION % 100);
    return REQ_PROCEED;
}

See Also

“NSAPI_RUNTIME_VERSION” on page 173, “USE_NSAPI_VERSION” on page 215

param_create

The param_create function creates a pb_param structure containing a specified name and value. The name and value are copied. Use this function to prepare a pb_param structure to be used in calls to pblock routines such as pblock_insert.

Syntax

pb_param *param_create(char *name, char *value);

Returns

A pointer to a new pb_param structure.
**Parameters**

char *name is the string containing the name.
char *value is the string containing the value.

**Example**

```c
pb_param *newpp = param_create("content-type", "text/plain");
pblock_pinsert(newpp, rq->srvhdrs);
```

**See Also**

"param_free" on page 175, "pblock_pinsert" on page 181, "pblock_remove" on page 182

**param_free**

The param_free function frees the pb_param structure specified by pp and its associated structures. Use the param_free function to dispose a pb_param after removing it from a pblock with pblock_remove.

**Syntax**

```c
int param_free(pb_param *pp);
```

**Returns**

1 if the parameter was freed or 0 if the parameter was NULL.

**Parameters**

pb_param *pp is the name-value pair stored in a pblock.

**Example**

```c
if (param_free(pblock_remove("content-type", rq-srvhdrs)))
    return; /* we removed it */
```

**See Also**

"param_create" on page 174, "pblock_pinsert" on page 181, "pblock_remove" on page 182

**pblock_copy**

The pblock_copy function copies the entries of the source pblock and adds them into the destination pblock. Any previous entries in the destination pblock are left intact.
**Syntax**

```c
void pblock_copy(pblock *src, pblock *dst);
```

**Returns**

```c
void
```

**Parameters**

- `pblock *src` is the source `pblock`.
- `pblock *dst` is the destination `pblock`.

Names and values are newly allocated so that the original `pblock` may be freed, or the new `pblock` changed without affecting the original `pblock`.

**See Also**

- "pblock_create" on page 176,
- "pblock_dup" on page 177,
- "pblock_free" on page 178,
- "pblock_find" on page 177,
- "pblock_findval" on page 178,
- "pblock_remove" on page 182,
- "pblock_nvinsert" on page 179

**pblock_create**

The `pblock_create` function creates a new `pblock`. The `pblock` maintains an internal hash table for fast name-value pair lookups.

**Syntax**

```c
pblock *pblock_create(int n);
```

**Returns**

A pointer to a newly allocated `pblock`.

**Parameters**

- `int n` is the size of the hash table (number of name-value pairs) for the `pblock`.

**See Also**

- "pblock_copy" on page 175,
- "pblock_dup" on page 177,
- "pblock_find" on page 177,
- "pblock_findval" on page 178,
- "pblock_free" on page 178,
- "pblock_nvinsert" on page 179,
- "pblock_remove" on page 182
pblock_dup

The pblock_dup function duplicates a pblock. It is equivalent to a sequence of pblock_create and pblock_copy.

Syntax

pblock *pblock_dup(pblock *src);

Returns

A pointer to a newly allocated pblock.

Parameters

pblock *src is the source pblock.

See Also

"pblock_create" on page 176, "pblock_find" on page 177, "pblock_findval" on page 178, "pblock_free" on page 178, "pblock_nvinsert" on page 179, "pblock_remove" on page 182

pblock_find

The pblock_find function finds a specified name-value pair entry in a pblock, and returns the pb_param structure. If you only want the value associated with the name, use the pblock_findval function.

This function is implemented as a macro.

Syntax

pb_param *pblock_find(char *name, pblock *pb);

Returns

A pointer to the pb_param structure if one was found, or NULL if name was not found.

Parameters

char *name is the name of a name-value pair.

pblock *pb is the pblock to be searched.

See Also

"pblock_copy" on page 175, "pblock_dup" on page 177, "pblock_findval" on page 178, "pblock_free" on page 178, "pblock_nvinsert" on page 179, "pblock_remove" on page 182
**pblock_findval**

The `pblock_findval` function finds the value of a specified name in a `pblock`. If you just want the `pb_param` structure of the `pblock`, use the `pblock_find` function.

The pointer returned is a pointer into the `pblock`. Do not FREE it. If you want to modify it, do a `STRDUP` and modify the copy.

**Syntax**

```c
char *pblock_findval(char *name, pblock *pb);
```

**Returns**

A string containing the value associated with the name or NULL if no match was found.

**Parameters**

- `char *name` is the name of a name-value pair.
- `pblock *pb` is the `pblock` to be searched.

**Example**

see "pblock_nvinsert" on page 179.

**See Also**

"pblock_create" on page 176, "pblock_copy" on page 175, "pblock_find" on page 177, "pblock_free" on page 178, "pblock_nvinsert" on page 179, "pblock_remove" on page 182, "request_header" on page 194

**pblock_free**

The `pblock_free` function frees a specified `pblock` and any entries inside it. If you want to save a variable in the `pblock`, remove the variable using the function `pblock_remove` and save the resulting pointer.

**Syntax**

```c
void pblock_free(pblock *pb);
```

**Returns**

`void`
Parameters

pblock *pb is the pblock to be freed.

See Also

"pblock_copy" on page 175, "pblock_create" on page 176, "pblock_dup" on page 177, "pblock_find" on page 177, "pblock_findval" on page 178, "pblock_nvinsert" on page 179, "pblock_remove" on page 182

pblock_nninsert

The pblock nninsert function creates a new entry with a given name and a numeric value in the specified pblock. The numeric value is first converted into a string. The name and value parameters are copied.

Syntax

pb_param *pblock_nninsert(char *name, int value, pblock *pb);

Returns

A pointer to the new pb_param structure.

Parameters

char *name is the name of the new entry.

int value is the numeric value being inserted into the pblock. This parameter must be an integer. If the value you assign is not a number, then instead use the function pblock_nvinsert to create the parameter.

pblock *pb is the pblock into which the insertion occurs.

See Also

"pblock_copy" on page 175, "pblock_create" on page 176, "pblock_find" on page 177, "pblock_free" on page 178, "pblock_nvinsert" on page 179, "pblock_remove" on page 182, "pblock_str2pblock" on page 182

pblock_nvinsert

The pblock_nvinsert function creates a new entry with a given name and character value in the specified pblock. The name and value parameters are copied.
Syntax

pb_param *pblock_nvinsert(char *name, char *value, pblock *pb);

Returns

A pointer to the newly allocated pb_param structure.

Parameters

char *name is the name of the new entry.
char *value is the string value of the new entry.
pblock *pb is the pblock into which the insertion occurs.

Example

pblock_nvinsert("content-type", "text/html", rq->srvhdrs);

See Also

pblock_pb2env

The pblock_pb2env function copies a specified pblock into a specified environment. The function creates one new environment entry for each name-value pair in the pblock. Use this function to send pblock entries to a program that you are going to execute.

Syntax

char **pblock_pb2env(pblock *pb, char **env);

Returns

A pointer to the environment.

Parameters

pblock *pb is the pblock to be copied.
char **env is the environment into which the pblock is to be copied.
pblock_pblock2str

The pblock_pblock2str function copies all parameters of a specified pblock into a specified string. The function allocates additional non-heap space for the string, if needed.

Use this function to stream the pblock for archival and other purposes.

Syntax

char *pblock_pblock2str(pblock *pb, char *str);

Returns

The new version of the str parameter. If str is NULL, this is a new string; otherwise, it is a reallocated string. In either case, it is allocated from the request’s memory pool.

Parameters

pblock *pb is the pblock to be copied.

char *str is the string into which the pblock is to be copied. It must have been allocated by MALLOC or REALLOC, not by PERM_MALLOC or PERM_REALLOC (which allocate from the system heap).

Each name-value pair in the string is separated from its neighbor pair by a space, and is in the format name="value."

See Also

"pblock_copy" on page 175, “pblock_create” on page 176, “pblock_find” on page 177, “pblock_free” on page 178, “pblock_nvinsert” on page 179, “pblock_remove” on page 182, “pblock_str2pblock” on page 182

pblock_pinsert

The function pblock_pinsert inserts a pb_param structure into a pblock.

Syntax

void pblock_pinsert(pb_param *pp, pblock *pb);

**Returns**

`void`

**Parameters**

`pb_param *pp` is the `pb_param` structure to insert.

`pblock *pb` is the `pblock`.

**See Also**

"pblock_copy" on page 175, "pblock_create" on page 176, "pblock_find" on page 177, "pblock_free" on page 178, "pblock_nvinsert" on page 179, "pblock_remove" on page 182, "pblock_str2pblock" on page 182

**pblock_remove**

The `pblock_remove` function removes a specified name-value entry from a specified `pblock`. If you use this function, you should eventually call `param_free` to deallocate the memory used by the `pb_param` structure.

**Syntax**

```c
pb_param *pblock_remove(char *name, pblock *pb);
```

**Returns**

A pointer to the named `pb_param` structure if it was found, or NULL if the named `pb_param` was not found.

**Parameters**

`char *name` is the name of the `pb_param` to be removed.

`pblock *pb` is the `pblock` from which the name-value entry is to be removed.

**See Also**

"pblock_copy" on page 175, "pblock_create" on page 176, "pblock_find" on page 177, "pblock_free" on page 178, "pblock_nvinsert" on page 179, "param_create" on page 174, "param_free" on page 175

**pblock_str2pblock**

The `pblock_str2pblock` function scans a string for parameter pairs, adds them to a `pblock`, and returns the number of parameters added.
Syntax

```c
int pblock_str2pblock(char *str, pblock *pb);
```

**Returns**
The number of parameter pairs added to the `pblock`, if any, or -1 if an error occurred.

**Parameters**

`char *str` is the string to be scanned.

The name-value pairs in the string can have the format `name=value` or `name="value"`.

All backslashes (`\`) must be followed by a literal character. If string values are found with no unescaped `=` signs (no `name=`, it assumes the names 1, 2, 3, and so on, depending on the string position. For example, if `pblock_str2pblock` finds "some strings together", the function treats the strings as if they appeared in name-value pairs as `1="some" 2="strings" 3="together"`.

`pblock *pb` is the `pblock` into which the name-value pairs are stored.

**See Also**

"pblock_copy" on page 175, "pblock_create" on page 176, "pblock_find" on page 177, "pblock_free" on page 178, "pblock_nvinsert" on page 179, "pblock_remove" on page 182, "pblock_pblock2str" on page 181

**PERM_CALLOC**

The `PERM_CALLOC` macro is a platform-independent substitute for the C library routine `calloc`. It allocates `int size` bytes of memory that persist after the request that is being processed has been completed. If pooled memory has been disabled in the configuration file (with the `pool-init` built-in SAF), `PERM_CALLOC` and `CALLOC` both obtain their memory from the system heap.

**Syntax**

```c
void *PERM_CALLOC(int size)
```

**Returns**

A void pointer to a block of memory.

**Parameters**

`int size` is the size in bytes of each element.
Example
char **name; name = (char **) PERM_CALLOC(100); 

See Also

PERM_FREE
The PERM_FREE macro is a platform-independent substitute for the C library routine free. It deallocates the persistent space previously allocated by PERM_MALLOC, PERM_CALLOC, or PERM_STRDUP. If pooled memory has been disabled in the configuration file (with the pool-init built-in SAF), both PERM_FREE and FREE deallocates memory in the system heap.

Syntax
PERM_FREE(void *ptr);

Returns
void

Parameters
void *ptr is a (void *) pointer to block of memory. If the pointer is not one created by PERM_MALLOC, PERM_CALLOC, or PERM_STRDUP, the behavior is undefined.

Example
char *name; name = (char *) PERM_MALLOC(256); ...PERM_FREE(name);

See Also

PERM_MALLOC
The PERM_MALLOC macro is a platform-independent substitute for the C library routine malloc. It provides allocation of memory that persists after the request that is being processed has been completed. If pooled memory has been disabled in the configuration file (with the pool-init built-in SAF), PERM_MALLOC and MALLOC both obtain their memory from the system heap.
Syntax
void *PERM_MALLOC(int size)

Returns
A void pointer to a block of memory.

Parameters
int size is the number of bytes to allocate.

Example
/* Allocate 256 bytes for a name */char *name; name = (char *) PERM_MALLOC(256);

See Also
"PERM_FREE" on page 184, "PERM_STRDUP" on page 186, "PERM_CALLOC" on page 183, "PERM_REALLOC" on page 185, "MALLOC" on page 164, "FREE" on page 159, "CALLOC" on page 144, "STRDUP" on page 201, "REALLOC" on page 193

PERM_REALLOC

The PERM_REALLOC macro is a platform-independent substitute for the C library routine realloc. It changes the size of a specified memory block that was originally created by MALLOC, CALLOC, or STRDUP. The contents of the object remains unchanged up to the lesser of the old and new sizes. If the new size is larger, the new space is uninitialized.

Warning
Calling PERM_REALLOC for a block that was allocated with MALLOC, CALLOC, or STRDUP will not work.

Syntax
void *PERM_REALLOC(void *ptr, int size)

Returns
A void pointer to a block of memory.

Parameters
void *ptr a void pointer to a block of memory created by PERM_MALLOC, PERM_CALLOC, or PERM_STRDUP.

int size is the number of bytes to which the memory block should be resized.
Example

```c
char *name; name = (char *) PERM_MALLOC(256); if (NotBigEnough())
    name = (char *) PERM_REALLOC(512);
```

See Also

"PERM_MALLOC" on page 184, "PERM_FREE" on page 184, "PERM_CALLOC" on page 183, "PERM_STRDUP" on page 186, "MALLOC" on page 164, "FREE" on page 159, "REALLOC" on page 193

PERM_STRDUP

The PERM_STRDUP macro is a platform-independent substitute for the C library routine strdup. It creates a new copy of a string in memory that persists after the request that is being processed has been completed. If pooled memory has been disabled in the configuration file (with the pool-init built-in SAF), PERM_STRDUP and STRDUP both obtain their memory from the system heap.

The PERM_STRDUP routine is functionally equivalent to:

```c
newstr = (char *) PERM_MALLOC(strlen(str) + 1); strcpy(newstr, str);
```

A string created with PERM_STRDUP should be disposed with PERM_FREE.

Syntax

```c
char *PERM_STRDUP(char *ptr);
```

Returns

A pointer to the new string.

Parameters

`char *ptr` is a pointer to a string.

See Also

"PERM_MALLOC" on page 184, "PERM_FREE" on page 184, "PERM_CALLOC" on page 183, "PERM_REALLOC" on page 185, "MALLOC" on page 164, "FREE" on page 159, "REALLOC" on page 193

**prepare_nsapi_thread**

The `prepare_nsapi_thread` function allows threads that are not created by the server to act like server-created threads. This function must be called before any NSAPI functions are called from a thread that is not server-created.

**Syntax**

```c
void prepare_nsapi_thread(Request *rq, Session *sn);
```

**Returns**

`void`

**Parameters**

- `Request *rq` is the Request.
- `Session *sn` is the Session.

The Request and Session parameters are the same as the ones passed into your SAF.

**See Also**

“protocol_start_response” on page 188

**protocol_dump822**

The `protocol_dump822` function prints headers from a specified `pblock` into a specific buffer, with a specified size and position. Use this function to serialize the headers so that they can be sent, for example, in a mail message.

**Syntax**

```c
char *protocol_dump822(pblock *pb, char *t, int *pos, int tsz);
```

**Returns**

A pointer to the buffer, which will be reallocated if necessary.

The function also modifies `*pos` to the end of the headers in the buffer.

**Parameters**

- `pblock *pb` is the `pblock` structure.
- `char *t` is the buffer, allocated with MALLOC, CALLOC, or STRDUP.
- `int *pos` is the position within the buffer at which the headers are to be dumped.
int tsz is the size of the buffer.

See Also
"protocol_start_response" on page 188, "protocol_status" on page 189

protocol_set_finfo

The protocol_set_finfo function retrieves the content-length and last-modified date from a specified stat structure and adds them to the response headers (rq->srvhdrs). Call protocol_set_finfo before calling protocol_start_response.

Syntax
int protocol_set_finfo(Session *sn, Request *rq, struct stat *finfo);

Returns
The constant REQ_PROCEED if the request can proceed normally, or the constant REQ_ABORTED if the function should treat the request normally but not send any output to the client.

Parameters
Session *sn is the Session.
Request *rq is the Request.
The Session and Request parameters are the same as the ones passed into your SAF.
stat *finfo is the stat structure for the file.
The stat structure contains the information about the file from the file system. You can get the stat structure info using request_stat_path.

See Also
"protocol_start_response" on page 188, "protocol_status" on page 189

protocol_start_response

The protocol_start_response function initiates the HTTP response for a specified session and request. If the protocol version is HTTP/0.9, the function does nothing, because that version has no concept of status. If the protocol version is HTTP/1.0, the function sends a status line followed by the response headers. Use this function to set up HTTP and prepare the client and server to receive the body (or data) of the response.
**Syntax**

```c
int protocol_start_response(Session *sn, Request *rq);
```

**Returns**

The constant `REQ_PROCEED` if the operation succeeded, in which case you should send the data you were preparing to send.

The constant `REQ_NOACTION` if the operation succeeded but the request method was `HEAD`, in which case no data should be sent to the client.

The constant `REQ_ABORTED` if the operation did not succeed.

**Parameters**

- `Session *sn` is the Session.
- `Request *rq` is the Request.

The `Session` and `Request` parameters are the same as the ones passed into your SAF.

**Example**

```c
/* A noaction response from this function means the request was HEAD */
if (protocol_start_response(sn, rq) == REQ_NOACTION)
    filebuf_close(groupbuf); /* close our file*/
    return REQ_PROCEED;
```

**See Also**

"protocol_status" on page 189

---

**protocol_status**

The `protocol_status` function sets the session status to indicate whether an error condition occurred. If the reason string is NULL, the server attempts to find a reason string for the given status code. If it finds none, it returns "Unknown reason." The reason string is sent to the client in the HTTP response line. Use this function to set the status of the response before calling the function `protocol_start_response`.

For the complete list of valid status code constants, please refer to the file "nsapi.h" in the server distribution.

**Syntax**

```c
void protocol_status(Session *sn, Request *rq, int n, char *r);
```
Returns
void, but it sets values in the Session/Request designated by sn/rq for the status code and the reason string.

Parameters
Session *sn is the Session.
Request *rq is the Request.
The Session and Request parameters are the same as the ones passed into your SAF.
int n is one of the status code constants above.
char *r is the reason string.

Example
/* if we find extra path-info, the URL was bad so tell the */
   browser it was not found */if (t = pblock_findval("path-info", rq->vars))
protocol_status(sn, rq, PROTOCOL_NOT_FOUND, NULL);   log_error(LOG_WARN,
"function-name", sn, rq, "%s not found", path);
return REQ_ABORTED;

See Also
"protocol_start_response" on page 188

protocol_uri2url
The protocol_uri2url function takes strings containing the given URI prefix and URI suffix, and creates a newly allocated, fully qualified URL in the form http://(server):(port)(prefix)(suffix). See protocol_uri2url_dynamic.

If you want to omit either the URI prefix or suffix, use "" instead of NULL as the value for either parameter.

Syntax
char *protocol_uri2url(char *prefix, char *suffix);

Returns
A new string containing the URL.
Parameters

char *prefix is the prefix.
char *suffix is the suffix.

See Also

"protocol_start_response" on page 188, "protocol_status" on page 189, "pblock_nvinsert" on page 179, "protocol_uri2url_dynamic" on page 191

protocol_uri2url_dynamic

The protocol_uri2url function takes strings containing the given URI prefix and URI suffix, and creates a newly allocated, fully qualified URL in the form http://(server):(port)(prefix)(suffix).

If you want to omit either the URI prefix or suffix, use "" instead of NULL as the value for either parameter.

The protocol_uri2url_dynamic function is similar to the protocol_uri2url function, but should be used whenever the session and request structures are available. This ensures that the URL it constructs refers to the host that the client specified.

Syntax

char *protocol_uri2url(char *prefix, char *suffix, Session *sn, Request *rq);

Returns

A new string containing the URL.

Parameters

char *prefix is the prefix.
char *suffix is the suffix.
Session *sn is the Session.
Request *rq is the Request.

The Session and Request parameters are the same as the ones passed into your SAF.

See Also

"protocol_start_response" on page 188, "protocol_status" on page 189, "protocol_uri2url_dynamic" on page 191
read

The read filter method is called when input data is required. Filters that modify or consume incoming data should implement the read filter method.

Upon receiving control, a read implementation should fill buf with up to amount bytes of input data. This data may be obtained by calling the “net_read” on page 166 function, as shown in the example below.

Syntax

```c
int read(FilterLayer *layer, void *buf, int amount, int timeout);
```

Returns

The number of bytes placed in buf on success, 0 if no data is available, or a negative value if an error occurred.

Parameters

- FilterLayer *layer is the filter layer in which the filter is installed.
- void *buf is the buffer in which data should be placed.
- int amount is the maximum number of bytes that should be placed in the buffer.
- int timeout is the number of seconds to allow for the read operation before returning. The purpose of timeout is not to return because not enough bytes were read in the given time, but to limit the amount of time devoted to waiting until some data arrives.

Example

```c
int myfilter_read(FilterLayer *layer, void *buf, int amount,
                 int timeout){       return net_read(layer->lower, buf, amount, timeout);}
```

See Also

“net_read” on page 166
REALLOC

The REALLOC macro is a platform-independent substitute for the C library routine realloc. It changes the size of a specified memory block that was originally created by MALLOC, CALLOC, or STRDUP. The contents of the object remains unchanged up to the lesser of the old and new sizes. If the new size is larger, the new space is uninitialized.

Warning

Calling REALLOC for a block that was allocated with PERM_MALLOC, PERM_CALLOC, or PERM_STRDUP will not work.

Syntax

void *REALLOC(void *ptr, int size);

Returns

A pointer to the new space if the request could be satisfied.

Parameters

void *ptr is a (void *) pointer to a block of memory. If the pointer is not one created by MALLOC, CALLOC, or STRDUP, the behavior is undefined.

int size is the number of bytes to allocate.

Example

char *name; name = (char *) MALLOC(256); if (NotBigEnough())
   name = (char *) REALLOC(512);

See Also

"MALLOC" on page 164, "FREE" on page 159, "STRDUP" on page 201, "CALLOC" on page 144, "PERM_MALLOC" on page 184, "PERM_FREE" on page 184, "PERM_REALLOC" on page 185, "PERM_CALLOC" on page 183, "PERM_STRDUP" on page 186

remove

The remove filter method is called when the filter stack is destroyed, or when a filter is removed from a filter stack by the “filter_remove” on page 158 function or remove-filter SAF (applicable in Input-, Output-, Service-, and Error-class directives).

Note that it may be too late to flush buffered data when the remove method is invoked. For this reason, filters that buffer outgoing data should implement the flush filter method.
Syntax
void remove(FilterLayer *layer);

Returns
void

Parameters
FilterLayer *layer is the filter layer the filter is installed in.

See Also
"flush" on page 158

request_get_vs
The request_get_vs function finds the VirtualServer* to which a request is directed.

The returned VirtualServer* is valid only for the current request. To retrieve a virtual server ID that is valid across requests, use "vs_get_id" on page 233.

Syntax
const VirtualServer* request_get_vs(Request* rq);

Returns
The VirtualServer* to which the request is directed.

Parameters
Request *rq is the request for which the VirtualServer* is returned.

See Also
"vs_get_id" on page 233

request_header
The request_header function finds an entry in the pblobk containing the client's HTTP request headers (rq->headers). You must use this function rather than pblobk_findval when accessing the client headers, since the server may begin processing the request before the headers have been completely read.
Syntax

```c
int request_header(char *name, char **value, Session *sn, Request *rq);
```

Returns

A result code, `REQ_PROCEED` if the header was found, `REQ_ABORTED` if the header was not found, `REQ_EXIT` if there was an error reading from the client.

Parameters

- `char *name` is the name of the header.
- `char **value` is the address where the function will place the value of the specified header. If none is found, the function stores a NULL.
- `Session *sn` is the Session.
- `Request *rq` is the Request.

The `Session` and `Request` parameters are the same as the ones passed into your SAF.

See Also

`request_create`, `request_free`

`request_stat_path`

The `request_stat_path` function returns the file information structure for a specified path or, if none is specified, the path entry in the vars pblock in the specified request structure. If the resulting file name points to a file that the server can read, `request_stat_path` returns a new file information structure. This structure contains information on the size of the file, its owner, when it was created, and when it was last modified.

You should use `request_stat_path` to retrieve information on the file you are currently accessing (instead of calling `stat` directly), because this function keeps track of previous calls for the same path and returns its cached information.

Syntax

```c
struct stat *request_stat_path(char *path, Request *rq);
```

Returns

Returns a pointer to the file information structure for the file named by the `path` parameter. Do not free this structure. Returns NULL if the file is not valid or the server cannot read it. In this case, it also leaves an error message describing the problem in `rq->staterr`. 
Parameters
char *path is the string containing the name of the path. If the value of path is NULL, the function uses the path entry in the vars pblock in the request structure denoted by rq.

Request *rq is the request identifier for a Server Application Function call.

Example
fi = request_stat_path(path, rq);

See Also
request_create, request_free, request_header

request_translate_uri
The request_translate_uri function performs virtual to physical mapping on a specified URI during a specified session. Use this function when you want to determine which file would be sent back if a given URI is accessed.

Syntax
char *request_translate_uri(char *uri, Session *sn);

Returns
A path string if it performed the mapping, or NULL if it could not perform the mapping.

Parameters
char *uri is the name of the URI.
Session *sn is the Session parameter that is passed into your SAF.

See Also
request_create, request_free, request_header
**sendfile**

The `sendfile` filter method is called when the contents of a file are to be sent. Filters that modify or consume outgoing data may choose to implement the `sendfile` filter method.

If a filter implements the `write` filter method but not the `sendfile` filter method, the server will automatically translate "`net_sendfile` on page 166" calls to "`net_write` on page 168" calls. As a result, filters interested in the outgoing data stream do not need to implement the `sendfile` filter method. However, for performance reasons, it is beneficial for filters that implement the `write` filter method to also implement the `sendfile` filter method.

**Syntax**

```c
int sendfile(FilterLayer *layer, const sendfiledata *data);
```

**Returns**

The number of bytes consumed, which may be less than the requested amount if an error occurred.

**Parameters**

- `FilterLayer *layer` is the filter layer the filter is installed in.
- `const sendfiledata *sfd` identifies the data to send.

**Example**

```c
int myfilter_sendfile(FilterLayer *layer, const sendfiledata *sfd)
{
    return net_sendfile(layer->lower, sfd);
}
```

**See Also**

---

**session_dns**

The `session_dns` function resolves the IP address of the client associated with a specified session into its DNS name. It returns a newly allocated string. You can use `session_dns` to change the numeric IP address into something more readable.
The `session_maxdns` function verifies that the client is who it claims to be; the `session_dns` function does not perform this verification.

**Note** - This function works only if the DNS directive is enabled in the `magnus.conf` file. For more information, see Chapter 2, SAFs in the `magnus.conf` File

### Syntax

```c
char *session_dns(Session *sn);
```

### Returns

A string containing the host name, or NULL if the DNS name cannot be found for the IP address.

### Parameters

- `Session *sn` is the Session.
- The Session is the same as the one passed to your SAF.

### `session_maxdns`

The `session_maxdns` function resolves the IP address of the client associated with a specified session into its DNS name. It returns a newly allocated string. You can use `session_maxdns` to change the numeric IP address into something more readable.

**Note** - This function works only if the DNS directive is enabled in the `magnus.conf` file. For more information, see Chapter 2, SAFs in the `magnus.conf` File

### Syntax

```c
char *session_maxdns(Session *sn);
```

### Returns

A string containing the host name, or NULL if the DNS name cannot be found for the IP address.

### Parameters

- `Session *sn` is the Session.
- The Session is the same as the one passed to your SAF.
shexp_casecmp

The shexp_casecmp function validates a specified shell expression and compares it with a specified string. It returns one of three possible values representing match, no match, and invalid comparison. The comparison (in contrast to that of the shexp_cmp function) is not case-sensitive.

Use this function if you have a shell expression like *.netscape.com and you want to make sure that a string matches it, such as foo.netscape.com.

Syntax

int shexp_casecmp(char *str, char *exp);

Returns

0 if a match was found.
1 if no match was found.
-1 if the comparison resulted in an invalid expression.

Parameters

char *str is the string to be compared.
char *exp is the shell expression (wildcard pattern) to compare against.

See Also

“shexp_cmp” on page 199, “shexp_match” on page 200, “shexp_valid” on page 201

shexp_cmp

The shexp_casecmp function validates a specified shell expression and compares it with a specified string. It returns one of three possible values representing match, no match, and invalid comparison. The comparison (in contrast to that of the shexp_casecmp function) is case-sensitive.

Use this function if you have a shell expression like *.netscape.com and you want to make sure that a string matches it, such as foo.netscape.com.

Syntax

int shexp_cmp(char *str, char *exp);
Returns

0 if a match was found.

1 if no match was found.

-1 if the comparison resulted in an invalid expression.

Parameters

char *str is the string to be compared.

char *exp is the shell expression (wildcard pattern) to compare against.

Example

/* Use wildcard match to see if this path is one we want */
char *path; char *match = "/usr/netscape/*"; if (shexp_cmp(path, match) != 0)
    return REQ_NOACTION; /* no match */

See Also

"shexp_casecmp" on page 199, "shexp_match" on page 200, "shexp_valid" on page 201

shexp_match

The shexp_match function compares a specified prevalidated shell expression against a
specified string. It returns one of three possible values representing match, no match, and
invalid comparison. The comparison (in contrast to that of the shexp_casecmp function) is
case-sensitive.

The shexp_match function doesn’t perform validation of the shell expression; instead the
function assumes that you have already called shexp_valid.

Use this function if you have a shell expression such as *.netscape.com, and you want to make
sure that a string matches it, such as foo.netscape.com.

Syntax

int shexp_match(char *str, char *exp);

Returns

0 if a match was found.

1 if no match was found.

-1 if the comparison resulted in an invalid expression.
Parameters
char *str is the string to be compared.
char *exp is the prevalidated shell expression (wildcard pattern) to compare against.

See Also
“shexp_casecmp” on page 199, “shexp_cmp” on page 199, “shexp_valid” on page 201

shexp_valid
The shexp_valid function validates a specified shell expression named by exp. Use this function to validate a shell expression before using the function shexp_match to compare the expression with a string.

Syntax
int shexp_valid(char *exp);

Returns
The constant NON_SXP if exp is a standard string.
The constant INVALID_SXP if exp is a shell expression, but invalid.
The constant VALID_SXP if exp is a valid shell expression.

Parameters
char *exp is the shell expression (wildcard pattern) to be validated.

See Also
“shexp_casecmp” on page 199, “shexp_match” on page 200, “shexp_cmp” on page 199

STRDUP
The STRDUP macro is a platform-independent substitute for the C library routine strdup. It creates a new copy of a string in the request's memory pool.

The STRDUP routine is functionally equivalent to:

newstr = (char *) MALLOC(strlen(str) + 1);
strcpy(newstr, str);
A string created with STRDUP should be disposed with FREE.

**Syntax**

```
char *STRDUP(char *ptr);
```

**Returns**

A pointer to the new string.

**Parameters**

*char *ptr* is a pointer to a string.

**Example**

```
char *name1 = "MyName"; char *name2 = STRDUP(name1);
```

**See Also**

"MALLOC" on page 164, "FREE" on page 159, "CALLOC" on page 144, "REALLOC" on page 193, "PERM_MALLOC" on page 184, "PERM_FREE" on page 184, "PERM_CALLOC" on page 183, "PERM_REALLOC" on page 185, "PERM_STRDUP" on page 186

---

**systemErrMsg**

The `systemErrMsg` function returns the last error that occurred from the most recent system call. This function is implemented as a macro that returns an entry from the global array `sys.ErrList`. Use this macro to help with I/O error diagnostics.

**Syntax**

```
char *systemErrMsg(int param1);
```

**Returns**

A string containing the text of the latest error message that resulted from a system call. Do not FREE this string.

**Parameters**

*int param1* is reserved, and should always have the value 0.
See Also
"system_fopenRO" on page 204, "system_fopenRW" on page 204, "system_fopenWA" on page 205, "system_lseek" on page 209, "system_fread" on page 205, "system_fwrite" on page 206, "system_fwrite_atomic" on page 207, "system_flock" on page 203, "system_ulock" on page 210, "system_fclose" on page 203

system_fclose

The system_fclose function closes a specified file descriptor. The system_fclose function must be called for every file descriptor opened by any of the system_fopen functions.

Syntax
int system_fclose(SYS_FILE fd);

Returns
0 if the close succeeded, or the constant IO_ERROR if the close failed.

Parameters
SYS_FILE fd is the platform-independent file descriptor.

Example
SYS_FILE logfd; system_fclose(logfd);

See Also
system_errmsg, system_fopenRO, system_fopenRW, system_fopenWA, system_lseek, system_fread, system_fwrite, system_fwrite_atomic, system_flock, system_ulock

system_flock

The system_flock function locks the specified file against interference from other processes. Use system_flock if you do not want other processes to use the file you currently have open. Overusing file locking can cause performance degradation and possibly lead to deadlocks.

Syntax
int system_flock(SYS_FILE fd);

Returns
The constant IO_OKAY if the lock succeeded, or the constant IO_ERROR if the lock failed.
Parameters
SYS_FILE fd is the platform-independent file descriptor.

See Also
system_errmsg, system_fopenRO, system_fopenRW, system_fopenWA, system_lseek,
system_fread, system_fwrite, system_fwrite_atomic, system_flock, system_ulock, system_fclose

system_fopenRO

The system_fopenRO function opens the file identified by path in read-only mode and returns a valid file descriptor. Use this function to open files that will not be modified by your program. In addition, you can use system_fopenRO to open a new file buffer structure using filebuf_open.

Syntax
SYS_FILE system_fopenRO(char *path);

Returns
The system-independent file descriptor (SYS_FILE) if the open succeeded, or 0 if the open failed.

Parameters
char *path is the file name.

See Also
system_errmsg, system_fopenRO, system_fopenRW, system_fopenWA, system_lseek, system_fread,
system_fwrite, system_fwrite_atomic, system_flock, system_ulock, system_fclose

system_fopenRW

The system_fopenRW function opens the file identified by path in read-write mode and returns a valid file descriptor. If the file already exists, system_fopenRW does not truncate it. Use this function to open files that will be read from and written to by your program.

Syntax
SYS_FILE system_fopenRW(char *path);

Returns
The system-independent file descriptor (SYS_FILE) if the open succeeded, or 0 if the open failed.
**Parameters**

char *path is the file name.

**Example**

SYS_FILE fd; fd = system_fopenRO(pathname); if (fd == SYS_ERROR_FD) break;

**See Also**

system_errmsg, system_fopenRO, system_fopenWA, system_lseek, system_fread, system_fwrite, system_fwrite_atomic, system_flock, system_ulock, system_fclose

---

**system_fopenWA**

The system_fopenWA function opens the file identified by path in write-append mode and returns a valid file descriptor. Use this function to open those files to which your program will append data.

**Syntax**

SYS_FILE system_fopenWA(char *path);

**Returns**

The system-independent file descriptor (SYS_FILE) if the open succeeded, or 0 if the open failed.

**Parameters**

char *path is the file name.

**See Also**

system_errmsg, system_fopenRO, system_fopenRW, system_lseek, system_fread, system_fwrite, system_fwrite_atomic, system_flock, system_ulock, system_fclose

---

**system_fread**

The system_fread function reads a specified number of bytes from a specified file into a specified buffer. It returns the number of bytes read. Before system_fread can be used, you must open the file using any of the system_fopen functions (except system_fopenWA).

**Syntax**

int system_fread(SYS_FILE fd, char *buf, int sz);
Returns
The number of bytes read, which may be less than the requested size if an error occurred or the end of the file was reached before that number of characters were obtained.

Parameters
SYS_FILE fd is the platform-independent file descriptor.
char *buf is the buffer to receive the bytes.
int sz is the number of bytes to read.

See Also
system_errmsg, system_fopenRO, system_fopenRW, system_fopenWA, system_lseek,
system_fwrite, system_fwrite_atomic, system_flock, system_ulock, system_fclose

system_fwrite
The system_fwrite function writes a specified number of bytes from a specified buffer into a specified file.

Before system_fwrite can be used, you must open the file using any of the system_fopen functions (except system_fopenRO).

Syntax
int system_fwrite(SYS_FILE fd, char *buf, int sz);

Returns
The constant IO_OKAY if the write succeeded, or the constant IO_ERROR if the write failed.

Parameters
SYS_FILE fd is the platform-independent file descriptor.
char *buf is the buffer containing the bytes to be written.
int sz is the number of bytes to write to the file.

See Also
system_errmsg, system_fopenRO, system_fopenRW, system_fopenWA, system_lseek,
system_fread, system_fwrite_atomic, system_flock, system_ulock, system_fclose
**system_fwrite_atomic**

The `system_fwrite_atomic` function writes a specified number of bytes from a specified buffer into a specified file. The function also locks the file prior to performing the write, and then unlocks it when done, thereby avoiding interference between simultaneous write actions. Before `system_fwrite_atomic` can be used, you must open the file using any of the `system_fopen` functions, except `system_fopenRO`.

**Syntax**

```c
int system_fwrite_atomic(SYS_FILE fd, char *buf, int sz);
```

**Returns**

The constant `IO_OKAY` if the write/lock succeeded, or the constant `IO_ERROR` if the write/lock failed.

**Parameters**

- `SYS_FILE fd` is the platform-independent file descriptor.
- `char *buf` is the buffer containing the bytes to be written.
- `int sz` is the number of bytes to write to the file.

**Example**

```c
SYS_FILE logfd; char *logmsg = "An error occurred.";
system_fwrite_atomic(logfd, logmsg, strlen(logmsg));
```

**See Also**

`system_errmsg`, `system_fopenRO`, `system_fopenRW`, `system_fopenWA`, `system_lseek`, `system_fread`, `system_fwrite`, `system_flock`, `system_ulock`, `system_fclose`

---

**system_gmtime**

The `system_gmtime` function is a thread-safe version of the standard `gmtime` function. It returns the current time adjusted to Greenwich Mean Time.

**Syntax**

```c
struct tm *system_gmtime(const time_t *tp, const struct tm *res);
```
Returns
A pointer to a calendar time (tm) structure containing the GMT time. Depending on your system, the pointer may point to the data item represented by the second parameter, or it may point to a statically-allocated item. For portability, do not assume either situation.

Parameters
time_t *tp is an arithmetic time.
tm *res is a pointer to a calendar time (tm) structure.

Example
time_t tp;struct tm res, *resp;tp = time(NULL);resp = system_gmtime(&tp, &res);

See Also
system_localtime, util_strftime

system_localtime
The system_localtime function is a thread-safe version of the standard localtime function. It returns the current time in the local time zone.

Syntax
struct tm *system_localtime(const time_t *tp, const struct tm *res);

Returns
A pointer to a calendar time (tm) structure containing the local time. Depending on your system, the pointer may point to the data item represented by the second parameter, or it may point to a statically-allocated item. For portability, do not assume either situation.

Parameters
time_t *tp is an arithmetic time.
tm *res is a pointer to a calendar time (tm) structure.

See Also
system_gmtime, util_strftime
system_lseek

The system_lseek function sets the file position of a file. This affects where data from system_fread or system_fwrite is read or written.

Syntax

```
int system_lseek(SYS_FILE fd, int offset, int whence);
```

Returns

The offset, in bytes, of the new position from the beginning of the file if the operation succeeded, or -1 if the operation failed.

Parameters

SYS_FILE fd is the platform-independent file descriptor.

int offset is a number of bytes relative to whence. It may be negative.

int whence is one of the following constants:

SEEK_SET, from the beginning of the file.

SEEK_CUR, from the current file position.

SEEK_END, from the end of the file.

See Also

system_errmsg, system_fopenRO, system_fopenRW, system_fopenWA, system_fread, system_fwrite, system_fwrite_atomic, system_flock, system_ulock, system_fclose

system_rename

The system_rename function renames a file. It may not work on directories if the old and new directories are on different file systems.

Syntax

```
int system_rename(char *old, char *new);
```

Returns

0 if the operation succeeded, or -1 if the operation failed.
Parameters
char *old is the old name of the file.
char *new is the new name for the file.

system_ulock
The system_ulock function unlocks the specified file that has been locked by the function system_lock. For more information about locking, see system_flock.

Syntax
int system_ulock(SYS_FILE fd);

Returns
The constant IO_OKAY if the operation succeeded, or the constant IO_ERROR if the operation failed.

Parameters
SYS_FILE fd is the platform-independent file descriptor.

See Also
system_errmsg, system_fopenRO, system_fopenRW, system_fopenWA, system_fread, system_fwrite, system_fwrite_atomic, system_flock, system_fclose

system_unix2local
The system_unix2local function converts a specified UNIX-style path name to a local file system path name. Use this function when you have a file name in the UNIX format (such as one containing forward slashes), and you need to access a file on another system such as Windows. You can use system_unix2local to convert the UNIX file name into the format that Windows accepts. In the UNIX environment this function does nothing, but may be called for portability.

Syntax
char *system_unix2local(char *path, char *lp);

Returns
A pointer to the local file system path string.
**Parameters**

char *path is the UNIX-style path name to be converted.

char *lp is the local path name.

You must allocate the parameter lp, and it must contain enough space to hold the local path name.

**See Also**

system_fclose, system_flock, system_fopenRO, system_fopenRW, system_fopenWA, system_fwrite

**systhread_attach**

The systhread_attach function makes an existing thread into a platform-independent thread.

**Syntax**

SYS_THREAD systhread_attach(void);

**Returns**

A SYS_THREAD pointer to the platform-independent thread.

**Parameters**

none

**See Also**

systhread_current, systhread_getdata, systhread_init, systhread_newkey, systhread_setdata, systhread_sleep, systhread_start, systhread_timerset

**systhread_current**

The systhread_current function returns a pointer to the current thread.

**Syntax**

SYS_THREAD systhread_current(void);

**Returns**

A SYS_THREAD pointer to the current thread.
Parameters

none

See Also

systhread_getdata, systhread_newkey, systhread_setdata, systhread_sleep,
systhread_start, systhread_timerset

systhread_getdata

The systhread_getdata function gets data that is associated with a specified key in the current thread.

Syntax

void *systhread_getdata(int key);

Returns

A pointer to the data that was earlier used with the systhread_setkey function from the current thread, using the same value of key if the call succeeds. Returns NULL if the call did not succeed. For example, if the systhread_setkey function was never called with the specified key during this session.

Parameters

int key is the value associated with the stored data by a systhread_setdata function. Keys are assigned by the systhread_newkey function.

See Also

systhread_current, systhread_newkey, systhread_setdata, systhread_sleep,
systhread_start, systhread_timerset

systhread_newkey

The systhread_newkey function allocates a new integer key (identifier) for thread-private data. Use this key to identify a variable that you want to localize to the current thread, then use the systhread_setdata function to associate a value with the key.

Syntax

int systhread_newkey(void);
Returns
An integer key.

Parameters
none

See Also
systhread_current, systhread_getdata, systhread_setdata, systhread_sleep,
systhread_start, systhread_timerset

systhread_setdata
The systhread_setdata function associates data with a specified key number for the current
thread. Keys are assigned by the systhread_newkey function.

Syntax
void systhread_setdata(int key, void *data);

Returns
void

Parameters
int key is the priority of the thread.
void *data is the pointer to the string of data to be associated with the value of key.

See Also
systhread_current, systhread_getdata, systhread_newkey, systhread_sleep,
systhread_start, systhread_timerset

systhread_sleep
The systhread_sleep function puts the calling thread to sleep for a given time.

Syntax
void systhread_sleep(int milliseconds);
Returns

void

Parameters

int milliseconds is the number of milliseconds the thread is to sleep.

See Also

systhread_current, systhread_getdata, systhread_newkey, systhread_setdata, systhread_start, systhread_timerset

systhread_start

The systhread_start function creates a thread with the given priority, allocates a stack of a specified number of bytes, and calls a specified function with a specified argument.

Syntax

SYS_THREAD systhread_start(int prio, int stksz, void (*fn)(void *), void *arg);

Returns

A new SYS_THREAD pointer if the call succeeded, or the constant SYS_THREAD_ERROR if the call did not succeed.

Parameters

int prio is the priority of the thread. Priorities are system-dependent.

int stksz is the stack size in bytes. If stksz is zero (0), the function allocates a default size.

void (*fn)(void *) is the function to call.

void *arg is the argument for the fn function.

See Also

systhread_current, systhread_getdata, systhread_newkey, systhread_setdata, systhread_sleep, systhread_timerset

systhread_timerset

The systhread_timerset function starts or resets the interrupt timer interval for a thread system.
Most of the systems do not allow the timer interval to be changed, this should be considered a suggestion, rather than a command.

**Syntax**

```c
void systhread_timerset(int usec);
```

**Returns**

```c
void
```

**Parameters**

`int usec` is the time, in microseconds

**See Also**

`systhread_current, systhread_getdata, systhread_newkey, systhread_setdata, systhread_sleep, systhread_start`

---

**USE_NSAPI_VERSION**

Plugin developers can define the `USE_NSAPI_VERSION` macro before including the `nsapi.h` header file to request a particular version of NSAPI. The requested NSAPI version is encoded by multiplying the major version number by 100 and then adding this to the minor version number. For example, the following code requests NSAPI 3.2 features:

```c
#define USE_NSAPI_VERSION 302 /* We want NSAPI 3.2 (Web Server 6.1) */
#include "nsapi.h"
```

To develop a plug-in that is compatible across multiple server versions, define `USE_NSAPI_VERSION` to the highest NSAPI version supported by all of the target server versions.

The following table lists server versions and the highest NSAPI version supported by each:

**Table 7-2 NSAPI Versions Supported by Different Servers**

<table>
<thead>
<tr>
<th>Server Version</th>
<th>NSAPI Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>iPlanet Web Server 4.1</td>
<td>3.0</td>
</tr>
<tr>
<td>Server Version</td>
<td>NSAPI Version</td>
</tr>
<tr>
<td>---------------------------------------</td>
<td>---------------</td>
</tr>
<tr>
<td>iPlanet Web Server 6.0</td>
<td>3.1</td>
</tr>
<tr>
<td>Netscape Enterprise Server 6.0</td>
<td>3.1</td>
</tr>
<tr>
<td>Netscape Enterprise Server 6.1</td>
<td>3.1</td>
</tr>
<tr>
<td>Sun Java System Application Server 7.0</td>
<td>3.1</td>
</tr>
<tr>
<td>Sun Java System Web Server 6.1</td>
<td>3.2</td>
</tr>
</tbody>
</table>

It is an error to request a version of NSAPI higher than the highest version supported by the `nsapi.h` header that the plug-in is being compiled against. Additionally, to use `USE_NSAPI_VERSION`, you must compile against an `nsapi.h` header file that supports NSAPI 3.2 or higher.

**Syntax**

```c
int USE_NSAPI_VERSION
```

**Example**

The following code can be used when building a plug-in designed to work with iPlanet Web Server 4.1 and Sun Java System Web Server 6.1:

```c
#define USE_NSAPI_VERSION 300 /* We want NSAPI 3.0 (Web Server 4.1) */
#include "nsapi.h"
```

**See Also**

“NSAPI_RUNTIME_VERSION” on page 173, “NSAPI_VERSION” on page 174

**util_can_exec**

**UNIX Only**

The `util_can_exec` function checks that a specified file can be executed, returning either a 1 (executable) or a 0. The function checks if the file can be executed by the user with the given user and group ID.

Use this function before executing a program using the `exec` system call.

**Syntax**

```c
int util_can_exec(struct stat *finfo, uid_t uid, gid_t gid);
```
Returns

1 if the file is executable, or 0 if the file is not executable.

Parameters

stat *finfo is the stat structure associated with a file.

uid_t uid is the UNIX user id.

gid_t gid is the UNIX group id. Together with uid, this determines the permissions of the UNIX user.

See Also

util_env_create, util_getline, util_hostname

util_chdir2path

The util_chdir2path function changes the current directory to a specified directory, where you can access a file.

When running under Windows, use a critical section to ensure that more than one thread does not call this function at the same time.

Use util_chdir2path when you want to make file access a little quicker, because you do not need to use a full path.

Syntax

int util_chdir2path(char *path);

Returns

0 if the directory was changed, or -1 if the directory could not be changed.

Parameters

char *path is the name of a directory.

The parameter must be a writable string because it isn’t permanently modified.

util_cookie_find

The util_cookie_find function finds a specific cookie in a cookie string and returns its value.
Syntax
char *util_cookie_find(char *cookie, char *name);

Returns
If successful, returns a pointer to the NULL-terminated value of the cookie. Otherwise, returns NULL. This function modifies the cookie string parameter by NULL terminating the name and value.

Parameters
char *cookie is the value of the Cookie: request header.
char *name is the name of the cookie whose value is to be retrieved.

util_env_find
The util_env_find function locates the string denoted by a name in a specified environment and returns the associated value. Use this function to find an entry in an environment.

Syntax
char *util_env_find(char **env, char *name);

Returns
The value of the environment variable if it is found, or NULL if the string was not found.

Parameters
char **env is the environment.
char *name is the name of an environment variable in env.

See Also
"util_env_replace" on page 219,"util_env_str" on page 220,"util_env_free" on page 218,
util_env_create

util_env_free
The util_env_free function frees a specified environment. Use this function to de-allocate an environment you created using the function util_env_create.
**Syntax**

```c
void util_env_free(char **env);
```

**Returns**

`void`

**Parameters**

- `char **env` is the environment to be freed.

**See Also**

"util_env_replace" on page 219, "util_env_str" on page 220, "util_env_find" on page 218,
util_env_create

---

**util_env_replace**

The `util_env_replace` function replaces the occurrence of the variable denoted by a name in a specified environment with a specified value. Use this function to change the value of a setting in an environment.

**Syntax**

```c
void util_env_replace(char **env, char *name, char *value);
```

**Returns**

`void`

**Parameters**

- `char **env` is the environment.
- `char *name` is the name of a name-value pair.
- `char *value` is the new value to be stored.

**See Also**

"util_env_str" on page 220, "util_env_free" on page 218, "util_env_find" on page 218,
util_env_create
util_env_str

The `util_env_str` function creates an environment entry and returns it. This function does not check for non-alphanumeric symbols in the name (such as the equal sign “=”). You can use this function to create a new environment entry.

**Syntax**

```c
char *util_env_str(char *name, char *value);
```

**Returns**

A newly allocated string containing the name-value pair.

**Parameters**

- `char *name` is the name of a name-value pair.
- `char *value` is the new value to be stored.

**See Also**

“util_env_replace” on page 219, “util_env_free” on page 218, “util_env_find” on page 218, `util_env_create`

util_getline

The `util_getline` function scans the specified file buffer to find a line feed or carriage return/line feed terminated string. The string is copied into the specified buffer, and NULL-terminates it. The function returns a value that indicates whether the operation stored a string in the buffer, encountered an error, or reached the end of the file.

Use this function to scan lines of a text file, such as a configuration file.

**Syntax**

```c
int util_getline(filebuf *buf, int lineno, int maxlen, char *line);
```

**Returns**

- 0 if successful; `line` contains the string.
- 1 if the end of file was reached; `line` contains the string.
- -1 if an error occurred; `line` contains a description of the error.
Parameters

`filebuf *buf` is the file buffer to be scanned.

`int lineno` is used to include the line number in the error message when an error occurs. The caller is responsible for making sure the line number is accurate.

`int maxlen` is the maximum number of characters that can be written into `l`.

`char *l` is the buffer in which to store the string. The user is responsible for allocating and deallocating `l`.

See Also

"util_can_exec" on page 216, `util_env_create`, "util_hostname" on page 221

util_hostname

The `util_hostname` function retrieves the local host name and returns it as a string. If the function cannot find a fully-qualified domain name, it returns NULL. You may reallocate or free this string. Use this function to determine the name of the system you are on.

Syntax

```c
char *util_hostname(void);
```

Returns

If a fully-qualified domain name was found, returns a string containing that name else returns NULL.

Parameters

none

util_is_mozilla

The `util_is_mozilla` function checks whether a specified user-agent header string is a Netscape browser of at least a specified revision level, returning a 1 if it is, and 0 otherwise. This function uses strings to specify the revision level to avoid ambiguities such as 1.56 > 1.5.

Syntax

```c
int util_is_mozilla(char *ua, char *major, char *minor);
```
Returns
1 if the user-agent is a Netscape browser, or 0 if the user-agent is not a Netscape browser.

Parameters
char *ua is the user-agent string from the request headers.
char *major is the major release number (to the left of the decimal point).
char *minor is the minor release number (to the right of the decimal point).

See Also
"util_is_url" on page 222, "util_later_than" on page 223

util_is_url
The util_is_url function checks whether a string is a URL, returning 1 if it is and 0 otherwise. The string is a URL if it begins with alphabets followed by a colon (:).

Syntax
int util_is_url(char *url);

Returns
1 if the string specified by url is a URL, or 0 if the string specified by url is not a URL.

Parameters
char *url is the string to be examined.

See Also
"util_is_mozilla" on page 221, "util_later_than" on page 223

util_itoa
The util_itoa function converts a specified integer to a string, and returns the length of the string. Use this function to create a textual representation of a number.

Syntax
int util_itoa(int i, char *a);
>Returns
The length of the string created.

>Parameters
int i is the integer to be converted.

char *a is the ASCII string that represents the value. The user is responsible for the allocation and deallocation of a, and it should be at least 32 bytes long.

>utilLater_than
The utilLater_than function compares the date specified in a time structure against a date specified in a string. If the date in the string is later than or equal to the one in the time structure, the function returns 1. Use this function to handle RFC 822, RFC 850, and ctime formats.

>Syntax
int utilLater_than(struct tm *lms, char *ims);

>Returns
1 if the date represented by ims is the same as or later than that represented by the lms, or 0 if the date represented by ims is earlier than that represented by the lms.

>Parameters
tm *lms is the time structure containing a date.

char *ims is the string containing a date.

>See Also
"utilStrftime" on page 226

>utilSh_escape
The utilSh_escape function parses a specified string and places a backslash (\) in front of any shell-special characters, returning the resultant string. Use this function to ensure that strings from clients won’t cause a shell to do anything unexpected.

The shell-special characters includes space and the following characters:
&;=":*?<>~{}[]$\!
Syntax
char *util_sh_escape(char *s);

Returns
A newly allocated string.

Parameters
char *s is the string to be parsed.

See Also
"util_uri_escape" on page 227

util_snprintf

The util_snprintf function formats a specified string, using a specified format, into a specified buffer using the printf-style syntax and performs bounds checking. It returns the number of characters in the formatted buffer.

For more information, see the documentation on the printf function for the runtime library of your compiler.

Syntax
int util_snprintf(char *s, int n, char *fmt, ...);

Returns
The number of characters formatted into the buffer.

Parameters
char *s is the buffer to receive the formatted string.
int n is the maximum number of bytes allowed to be copied.
char *fmt is the format string. The function handles only %d and %s strings. It does not handle any width or precision strings.
... represents a sequence of parameters for the printf function.

See Also
util_sprintf, "util_vsnprintf" on page 229, "util_vsprintf" on page 230
util_sprintf

The `util_sprintf` function formats a specified string, using a specified format, into a specified buffer, using the `printf`-style syntax without bounds checking. It returns the number of characters in the formatted buffer.

Because `util_sprintf` doesn’t perform bounds checking, use this function only if you are certain that the string fits the buffer. Otherwise, use the function `util_snprintf`. For more information, see the documentation on the `printf` function for the runtime library of your compiler.

Syntax

```c
int util_sprintf(char *s, char *fmt, ...);
```

Returns

The number of characters formatted into the buffer.

Parameters

- `char *s` is the buffer to receive the formatted string.
- `char *fmt` is the format string. The function handles only `%d` and `%s` strings. It does not handle any width or precision strings.
- `...` represents a sequence of parameters for the `printf` function.

Example

```c
char *logmsg; int len; logmsg = (char *) MALLOC(256); len =
util_sprintf(logmsg, "%s %s %s\n", ip, method, uri);
```

See Also

“util_snprintf” on page 224, “util_vsnprintf” on page 229, “util_vsprintf” on page 230

util_strcasecmp

The `util_strcasecmp` function performs a comparison of two alphanumeric strings and returns a -1, 0, or 1 to signal which is larger or that they are identical.

The comparison is not case-sensitive.

Syntax

```c
int util_strcasecmp(const char *s1, const char *s2);
```
Returns
1 if s1 is greater than s2.
0 if s1 is equal to s2.
-1 if s1 is less than s2.

Parameters
char *s1 is the first string.
char *s2 is the second string.

See Also
"util_strncasecmp" on page 227

util_strftime

The util_strftime function translates a tm structure, which is a structure describing a system time, into a textual representation. It is a thread-safe version of the standard strftime function.

Syntax
int util_strftime(char *s, const char *format, const struct tm *t);

Returns
The number of characters placed into s, not counting the terminating NULL character.

Parameters
char *s is the string buffer to put the text into. There is no bounds checking, so you must make sure that your buffer is large enough for the text of the date.

const char *format is a format string, a bit like a printf string in that it consists of text with certain %x substrings. You may use the constant HTTP_DATE_FMT to create date strings in the standard Internet format. For more information, see the documentation on the printf function for the runtime library of your compiler. Refer to Chapter 10, Time Formats for details on time formats.

const struct tm *t is a pointer to a calendar time (tm) structure, usually created by the function system_localtime or system_gmtime.

See Also
system_localtime, system_gmtime
**util_strncasecmp**

The `util_strncasecmp` function performs a comparison of the first `n` characters in the alphanumeric strings and returns a -1, 0, or 1 to signal which is larger or that they are identical. The function’s comparison is not case-sensitive.

**Syntax**

```c
int util_strncasecmp(const char *s1, const char *s2, int n);
```

**Returns**

-1 if `s1` is greater than `s2`.

0 if `s1` is equal to `s2`.

-1 if `s1` is less than `s2`.

**Parameters**

- `char *s1` is the first string.
- `char *s2` is the second string.
- `int n` is the number of initial characters to compare.

**See Also**

`util_strcasecmp`

**util_uri_escape**

The `util_uri_escape` function converts any special characters in the URI into the URI format (%XX, where XX is the hexadecimal equivalent of the ASCII character), and returns the escaped string. The special characters are %?#:+&"<> space, carriage return, and line feed.

Use `util_uri_escape` before sending a URI back to the client.

**Syntax**

```c
char *util_uri_escape(char *d, char *s);
```

**Returns**

The string (possibly newly allocated) with escaped characters replaced.
Parameters

char *d is a string. If d is not NULL, the function copies the formatted string into d and returns d. If d is NULL, the function allocates a properly sized string and copies the formatted special characters into the new string, then returns d.

The `util_uri_escape` function does not check bounds for the parameter d. Therefore, if d is not NULL, it should be at least three times as large as the string s.

char *s is the string containing the original unescaped URI.

See Also

`util_uri_escape`, `util_uri_parse`, `util_uri_unescape`

`util_uri_is_evil`

The `util_uri_is_evil` function checks a specified URI for insecure path characters. Insecure path characters include //, ./., ..// and ../. (also for Windows.//) at the end of the URI. Use this function to see if a URI requested by the client is insecure.

Syntax

```c
int util_uri_is_evil(char *t);
```

Returns

1 if the URI is insecure, or 0 if the URI is OK.

Parameters

char *t is the URI to be checked.

See Also

`util_uri_escape`, `util_uri_parse`

`util_uri_parse`

The `util_uri_parse` function converts //, ./, and */../ into / in the specified URI (where * is any character other than /). You can use this function to convert a URI’s bad sequences into valid ones. First use the function `util_uri_is_evil` to determine whether the function has a bad sequence.

Syntax

```c
void util_uri_parse(char *uri);
```
Returns
void

Parameters
char *uri is the URI to be converted.

See Also
util_uri_is_evil, util_uri_unescape

util_uri_unescape
The util_uri_unescape function converts the encoded characters of a URI into their ASCII equivalents. Encoded characters appear as %XX, where XX is a hexadecimal equivalent of the character.

Note - You cannot use an embedded NULL in a string, because NSAPI functions assume that a NULL is the end of the string. Therefore, passing unicode-encoded content through an NSAPI plug-in doesn’t work.

Syntax
void util_uri_unescape(char *uri);

Returns
void

Parameters
char *uri is the URI to be converted.

See Also
util_uri_escape, util_uri_is_evil, util_uri_parse

util_vsnprintf
The util_vsnprintf function formats a specified string, using a specified format, into a specified buffer using the vprintf-style syntax. The function performs bounds checking and returns the number of characters in the formatted buffer.
For more information, see the documentation on the printf function for the runtime library of your compiler.

**Syntax**

```c
int util_vsnprintf(char *s, int n, register char *fmt, va_list args);
```

**Returns**
The number of characters formatted into the buffer.

**Parameters**
- char *s is the buffer to receive the formatted string.
- int n is the maximum number of bytes allowed to be copied.
- register char *fmt is the format string. The function handles only %d and %s strings; it does not handle any width or precision strings.
- va_list args is an STD argument variable obtained from a previous call to va_start.

**See Also**
util_sprintf, util_vsprintf

---

**util_vsprintf**

The `util_vsprintf` function formats a specified string, using a specified format, into a specified buffer using the vprintf-style syntax without bounds checking. It returns the number of characters in the formatted buffer.

For more information, see the documentation on the printf function for the runtime library of your compiler.

**Syntax**

```c
int util_vsprintf(char *s, register char *fmt, va_list args);
```

**Returns**
The number of characters formatted into the buffer.

**Parameters**
- char *s is the buffer to receive the formatted string.
register char *fmt is the format string. The function handles only %d and %s strings. It does not handle any width or precision strings.

va_list args is an STD argument variable obtained from a previous call to va_start.

**See Also**
util_snprintf, util_vsnprintf

---

**vs_alloc_slot**

The vs_alloc_slot function allocates a new slot for storing a pointer to data specific to a certain VirtualServer*. The returned slot number may be used in subsequent "vs_set_data" on page 236 and "vs_get_data" on page 231 calls. The returned slot number is valid for any VirtualServer*.

The value of the pointer (which may be returned by a call to "vs_set_data" on page 236) defaults to NULL for every VirtualServer*.

**Syntax**

```c
int vs_alloc_slot(void);
```

**Returns**

A slot number on success, or -1 on failure.

**See Also**

"vs_get_data" on page 231, "vs_set_data" on page 236

---

**vs_get_data**

The vs_get_data function finds the value of a pointer to data for a given VirtualServer* and slot. The slot must be a slot number returned from "vs_alloc_slot" on page 231 or "vs_set_data" on page 236.

**Syntax**

```c
void* vs_get_data(const VirtualServer* vs, int slot);
```
Returns
The value of the pointer previously stored via "vs_set_data" on page 236, or NULL on failure.

Parameters
const VirtualServer* vs represents the virtual server to query the pointer for.
int slot is the slot number to retrieve the pointer from.

See Also
"vs_set_data" on page 236, "vs_alloc_slot" on page 231

vs_get_default_httpd_object
The vs_get_default_httpd_object function obtains a pointer to the default (or root) httpd_object from the virtual server's httpd_objset (in the configuration defined by the obj.conf file of the virtual server class). The default object is typically named default. Plug-ins may only modify the httpd_object at VSInitFunc time (see "vs_register_cb" on page 235 for an explanation of VSInitFunc time).

Do not FREE the returned object.

Syntax
httpd_object* vs_get_default_httpd_object(VirtualServer* vs);

Returns
A pointer the default httpd_object, or NULL on failure. Do not FREE this object.

Parameters
VirtualServer* vs represents the virtual server for which to find the default object.

See Also
"vs_get_httpd_objset" on page 233, "vs_register_cb" on page 235

vs_get_doc_root
The vs_get_doc_root function finds the document root for a virtual server. The returned string is the full operating system path to the document root.

The caller should FREE the returned string when done with it.
Syntax

char* vs_get_doc_root(const VirtualServer* vs);

**Returns**
A pointer to a string representing the full operating system path to the document root. It is the caller's responsibility to FREE this string.

**Parameters**
const VirtualServer* vs represents the virtual server for which to find the document root.

**vs_get_httpd_objset**

The vs_get_httpd_objset function obtains a pointer to the httpd_objset (the configuration defined by the obj.conf file of the virtual server class) for a given virtual server. Plugins may only modify the httpd_objset at VSInitFunc time (see “vs_register_cb” on page 235 for an explanation of VSInitFunc time).

Do not FREE the returned objset.

**Syntax**

httpd_objset* vs_get_httpd_objset(VirtualServer* vs);

**Returns**
A pointer to the httpd_objset, or NULL on failure. Do not FREE this objset.

**Parameters**
VirtualServer* vs represents the virtual server for which to find the objset.

**See Also**
“vs_get_default_httpd_object” on page 232, “vs_register_cb” on page 235

**vs_get_id**

The vs_get_id function finds the ID of a VirtualServer*.

The ID of a virtual server is a unique NULL-terminated string that remains constant across configurations. Note that while IDs remain constant across configurations, the value of VirtualServer* pointers do not.
Do not FREE the virtual server ID string. If called during request processing, the string will remain valid for the duration of the current request. If called during VSInitFunc processing, the string will remain valid until after the corresponding VSDestroyFunc function has returned (see “vs_register_cb” on page 235).

To retrieve a VirtualServer* that is valid only for the current request, use ”request_get_vs” on page 194.

**Syntax**

```c
const char* vs_get_id(const VirtualServer* vs);
```

**Returns**

A pointer to a string representing the virtual server ID. Do not FREE this string.

**Parameters**

`const VirtualServer* vs` represents the virtual server of interest.

**See Also**

“vs_register_cb” on page 235, ”request_get_vs” on page 194

---

**vs_get_mime_type**

The `vs_get_mime_type` function determines the MIME type that would be returned in the `content-type` header for the given URI.

The caller should FREE the returned string when done with it.

**Syntax**

```c
char* vs_get_mime_type(const VirtualServer* vs, const char* uri);
```

**Returns**

A pointer to a string representing the MIME type. It is the caller’s responsibility to FREE this string.

**Parameters**

`const VirtualServer* vs` represents the virtual server of interest.

`const char* uri` is the URI whose MIME type is of interest.
**vs_lookup_config_var**

The `vs_lookup_config_var` function finds the value of a configuration variable for a given virtual server.

Do not FREE the returned string.

**Syntax**

```c
const char* vs_lookup_config_var(const VirtualServer* vs, const char* name);
```

**Returns**

A pointer to a string representing the value of variable name on success, or NULL if variable name was not found. Do not FREE this string.

**Parameters**

- `const VirtualServer* vs` represents the virtual server of interest.
- `const char* name` is the name of the configuration variable.

---

**vs_register_cb**

The `vs_register_cb` function allows a plug-in to register functions that will receive notifications of virtual server initialization and destruction events. The `vs_register_cb` function would typically be called from an Init SAF in `magnus.conf`.

When a new configuration is loaded, all registered `VSInitFunc` (virtual server initialization) callbacks are called for each of the virtual servers before any requests are served from the new configuration. `VSInitFunc` callbacks are called in the same order they were registered; that is, the first callback registered is the first called.

When the last request has been served from an old configuration, all registered `VSDestroyFunc` (virtual server destruction) callbacks are called for each of the virtual servers before any virtual servers are destroyed. `VSDestroyFunc` callbacks are called in reverse order; that is, the first callback registered is the last called.

Either `initfn` or `destroyfn` may be NULL if the caller is not interested in callbacks for initialization or destruction, respectively.

**Syntax**

```c
int vs_register_cb(VSInitFunc* initfn, VSDestroyFunc* destroyfn);
```
Returns
The constant REQ_PROCEED if the operation succeeded.
The constant REQ_ABORTED if the operation failed.

Parameters
VSInitFunc* initfn is a pointer to the function to call at virtual server initialization time, or NULL if the caller is not interested in virtual server initialization events.

VSDestroyFunc* destroyfn is a pointer to the function to call at virtual server destruction time, or NULL if the caller is not interested in virtual server destruction events.

vs_set_data
The vs_set_data function sets the value of a pointer to data for a given virtual server and slot. The *slot must be -1 or a slot number returned from vs_alloc_slot. If *slot is -1, vs_set_data calls vs_alloc_slot implicitly and returns the new slot number in *slot.

Note that the stored pointer is maintained on a per-VirtualServer* basis, not a per-ID basis. Distinct VirtualServer*s from different configurations may exist simultaneously with the same virtual server IDs. However, since these are distinct VirtualServer*s, they each have their own VirtualServer*-specific data. As a result, vs_set_data should generally not be called outside of VSInitFunc processing (see "vs_register_cb" on page 235 for an explanation of VSInitFunc processing).

Syntax
void* vs_set_data(const VirtualServer* vs, int* slot, void* data);

Returns
Data on success, or NULL on failure.

Parameters
const VirtualServer* vs represents the virtual server to set the pointer for.
int* slot is the slot number to store the pointer at.
void* data is the pointer to store.

See Also
"vs_get_data" on page 231, "vs_alloc_slot" on page 231, "vs_register_cb" on page 235
vs_translate_uri

The vs_translate_uri function translates a URI as though it were part of a request for a specific virtual server. The returned string is the full operating system path.

The caller should FREE the returned string when done with it.

Syntax

char* vs_translate_uri(const VirtualServer* vs, const char* uri);

Returns

A pointer to a string representing the full operating system path for the given URI. It is the caller’s responsibility to FREE this string.

Parameters

const VirtualServer* vs represents the virtual server for which to translate the URI.

const char* uri is the URI to translate to an operating system path.

write

The write filter method is called when output data is to be sent. Filters that modify or consume outgoing data should implement the write filter method.

Upon receiving control, a write implementation should first process the data as necessary, and then pass it on to the next filter layer; for example, by calling net_write(layer->lower, . . . ). If the filter buffers outgoing data, it should implement the “flush” on page 158 filter method.

Syntax

int write(FilterLayer *layer, const void *buf, int amount);

Returns

The number of bytes consumed, which may be less than the requested amount if an error occurred.
Parameters

FilterLayer *layer is the filter layer in which the filter is installed.

const void *buf is the buffer that contains the outgoing data.

int amount is the number of bytes in the buffer.

Example

```c
int myfilter_write(FilterLayer *layer, const void *buf, int amount)
{
    return net_write(layer->lower, buf, amount);
}
```

See Also

“flush” on page 158, “net_write” on page 168, “writev” on page 238

writev

The writev filter method is called when multiple buffers of output data are to be sent. Filters that modify or consume outgoing data may choose to implement the writev filter method.

If a filter implements the write filter method but not the writev filter method, the server automatically translates net_writev calls to "net_write" on page 168 calls. As a result, filters interested in the outgoing data stream do not need to implement the writev filter method. However, for performance reasons, it is beneficial for filters that implement the write filter method to also implement the writev filter method.

Syntax

```c
int writev(FilterLayer *layer, const struct iovec *iov, int iov_size);
```

Returns

The number of bytes consumed, which may be less than the requested amount if an error occurred.

Parameters

FilterLayer *layer is the filter layer the filter is installed in.

const struct iovec *iov is an array of iovec structures, each of which contains outgoing data.

int iov_size is the number of iovec structures in the iov array.
Example

```c
int myfilter_writev(FilterLayer *layer, const struct iovec *iov, int iov_size)
{
    return net_writev(layer->lower, iov, iov_size);
}
```

"flush" on page 158, "net_write" on page 168, "write" on page 237
NSAPI uses many data structures that are defined in the nsapi.h header file, which is in the directory server-root/plugins/include.

The NSAPI functions described in Chapter 7, NSAPI Function Reference Before directly accessing a data structure in nsapi.h, check to see if an accessor function exists for it.

For information about the privatization of some data structures in Sun Java System Web Server 4.x, see “Privatization of Some Data Structures” on page 242.

The rest of this chapter describes public data structures in nsapi.h. Note that data structures in nsapi.h that are not described in this chapter are considered private and may change incompatibly in future releases.

This chapter has the following sections:

- “Session” on page 242
- “pblock” on page 243
- “pb_entry” on page 243
- “pb_param” on page 243
- “Session->client” on page 243
- “Request” on page 244
- “stat” on page 244
- “shmem_s” on page 245
- “cinfo” on page 245
- “sendfiledata” on page 245
- “Filter” on page 246
- “FilterContext” on page 246
- “FilterLayer” on page 246
- “FilterMethods” on page 246
Privatization of Some Data Structures

In Sun Java System Web Server 4.x, some data structures were moved from nsapi.h to nsapi_pvt.h. The data structures in nsapi_pvt.h are now considered to be private data structures, and you should not write code that accesses them directly. Instead, use accessor functions. We expect that very few people have written plug-ins that access these data structures directly, so this change should have very little impact on customer-defined plug-ins. Look in nsapi_pvt.h to see which data structures have been removed from the public domain, and to see the accessor functions you can use to access them from now on.

Plug-ins written for Enterprise Server 3.x that access contents of data structures defined in nsapi_pvt.h will not be source compatible with Sun Java System Web Server 4.x and 6.x, that is, it will be necessary to #include "nsapi_pvt.h" to build such plug-ins from source. There is also a small chance that these programs will not be binary compatible with Sun Java System Web Server 4.x and 6.x, because some of the data structures in nsapi_pvt.h have changed size. In particular, the directive structure is larger, which means that a plug-in that indexes through the directives in a dtable will not work without being rebuilt (with nsapi_pvt.h included).

We hope that the majority of plug-ins do not reference the internals of data structures in nsapi_pvt.h, and therefore that most existing NSAPI plug-ins will be both binary and source compatible with Sun Java System Web Server 6.1.

Session

A session is the time between the opening and closing of the connection between the client and the server. The session data structure holds variables that apply throughout the session, regardless of the requests being sent, as shown here:

typedef struct {
    /* Information about the remote client */
    pblock *client;

    /* The socket descriptor to the remote client */
    SYS_NETFD csd;

    /* The input buffer for that socket descriptor */
    netbuf *inbuf;

    /* Raw socket information about the remote */
    /* client (for internal use) */
    struct in_addr iaddr;
} Session;
The parameter block is the hash table that holds pb_entry structures. Its contents are transparent to most code. This data structure is frequently used in NSAPI. It provides the basic mechanism for packaging up parameters and values. There are many functions for creating and managing parameter blocks, and for extracting, adding, and deleting entries. See the functions whose names start with pblock_ in Chapter 7, NSAPI Function Reference. You should not write code that accesses pblock data fields directly.

typedef struct {
    int hsize;
    struct pb_entry **ht;
} pblock;

The pb_entry is a single element in the parameter block.

struct pb_entry {
    pb_param *param;
    struct pb_entry *next;
};

The pb_param represents a name-value pair, as stored in a pb_entry.

typedef struct {
    char *name,*value;
} pb_param;

The Session->client parameter block structure contains two entries:

- The ip entry is the IP address of the client machine.
- The dns entry is the DNS name of the remote machine. This member must be accessed through the session_dns function call:

```c
/** session_dns returns the DNS host name of the client for this* session
 and inserts it into the client pblock. Returns NULL if* unavailable.*/
char *
```
Under HTTP protocol, there is only one request per session. The request structure contains the variables that apply to the request in that session (for example, the variables include the client’s HTTP headers).

```
typedef struct {
    /* Server working variables */
    pblock *vars;

    /* The method, URI, and protocol revision of this request */
    block *reqpb;

    /* Protocol specific headers */
    int loadhdrs;
    pblock *headers;

    /* Server's response headers */
    int senthdrs;
    pblock *srvhdrs;

    /* The object set constructed to fulfill this request */
    httpd_objset *os;
} Request;
```

When a program calls the `stat()` function for a given file, the system returns a structure that provides information about the file. The specific details of the structure should be obtained from your platform's implementation, but the basic outline of the structure is as follows:

```
struct stat {
    dev_t st_dev;     /* device of inode */
    ino_t st_ino;     /* inode number */
    short st_mode;    /* mode bits */
    short st_nlink;   /* number of links to file */
    short st_uid;     /* owner's user id */
    short st_gid;     /* owner's group id */
    dev_t st_rdev;    /* for special files */
    off_t st_size;    /* file size in characters */
    time_t st_atime;  /* time last accessed */
    time_t st_mtime;  /* time last modified */
    time_t st_ctime;  /* time inode last changed*/
}
```

The elements that are most significant for server plug-in API activities are `st_size`, `st_atime`, `st_mtime`, and `st_ctime`. 
### shmem_s

typedef struct {
    void *data; /* the data */
    HANDLE fdmap;
    int size; /* the maximum length of the data */
    char *name; /* internal use: filename to unlink if exposed */
    SYS_FILE fd; /* internal use: file descriptor for region */
} shmem_s;

### cinfo

The cinfo data structure records the content information for a file.

typedef struct {
    char *type; /* Identifies what kind of data is in the file*/
    char *encoding; /* encoding identifies any compression or other */
    /* content-independent transformation that's been */
    /* applied to the file, such as uuencode)*/
    char *language; /* Identifies the language a text document is in. */
} cinfo;

### sendfiledata

The sendfiledata data structure is used to pass parameters to the net_sendfile function. The structure is also passed to the sendfile method in an installed filter in response to a net_sendfile call.

typedef struct {
    SYS_FILE fd; /* file to send */
    size_t offset; /* offset in file to start sending from */
    size_t len; /* number of bytes to send from file */
    const void *header; /* data to send before file */
    int hlen; /* number of bytes to send before file */
    const void *trailer; /* data to send after file */
    int tlen; /* number of bytes to send after file */
} sendfiledata;
Filter

The Filter data structure is an opaque representation of a filter. A Filter structure is created by calling “filter_create” on page 155.

typedef struct Filter Filter;

FilterContext

The FilterContext data structure stores context associated with a particular filter layer. Filter layers are created by calling “filter_insert” on page 156.

Filter developers may use the data member to store filter-specific context information.

typedef struct {
    pool_handle_t *pool; /* pool context was allocated from */
    Session *sn;        /* session being processed */
    Request *rq;        /* request being processed */
    void *data;         /* filter-defined private data */
} FilterContext;

FilterLayer

The FilterLayer data structure represents one layer in a filter stack. The FilterLayer structure identifies the filter installed at that layer and provides pointers to layer-specific context and a filter stack that represents the layer immediately below it in the filter stack.

typedef struct {
    Filter *filter; /* the filter at this layer in the filter stack */
    FilterContext *context; /* context for the filter */
    SYS_NETFD lower;        /* access to the next filter layer in the stack */
} FilterLayer;

FilterMethods

The FilterMethods data structure is passed to “filter_create” on page 155 to define the filter methods a filter supports. Each new FilterMethods instance must be initialized with the FILTER_METHODS_INITIALIZER macro. For each filter method a filter supports, the corresponding FilterMethods member should point to a function that implements that filter method.

typedef struct {
    size_t size;
    FilterInsertFunc *insert;
}
FilterMethods

FilterRemoveFunc *remove;
FilterFlushFunc *flush;
FilterReadFunc *read;
FilterWriteFunc *write;
FilterWritevFunc *writev;
FilterSendfileFunc *sendfile;
} FilterMethods;
Using Wildcard Patterns

This chapter describes the format of wildcard patterns used by the Sun Java System Web Server. These wildcards are used in:

- Directives in the configuration file obj.conf (see the *Sun Java System Web Server 6.1 SP10 Administrator’s Configuration File Reference* for detailed information about obj.conf).
- Various built-in SAFs (see the *Sun Java System Web Server 6.1 SP10 Administrator’s Configuration File Reference* for more information about these predefined SAFs).
- Some NSAPI functions (see Chapter 2, SAFs in the magnus.conf File.)

Wildcard patterns use special characters. If you want to use one of these characters without the special meaning, precede it with a backslash (\) character.

This chapter has the following sections:

- “Wildcard Patterns” on page 249
- “Wildcard Examples” on page 250

**Wildcard Patterns**

The following table describes wildcard patterns, listing the pattern and its use.

<table>
<thead>
<tr>
<th>Pattern</th>
<th>Use</th>
</tr>
</thead>
<tbody>
<tr>
<td>*</td>
<td>Match zero or more characters.</td>
</tr>
<tr>
<td>?</td>
<td>Match exactly one occurrence of any character.</td>
</tr>
</tbody>
</table>

TABLE 9-1  Wildcard Patterns
TABLE 9–1  Wildcard Patterns  (Continued)

<table>
<thead>
<tr>
<th>Pattern</th>
<th>Use</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>An or expression. The substrings used with this operator can contain other special characters such as * or $. The substrings must be enclosed in parentheses, for example, (a</td>
</tr>
<tr>
<td>$</td>
<td>Match the end of the string. This is useful in or expressions.</td>
</tr>
<tr>
<td>[abc]</td>
<td>Match one occurrence of the characters a, b, or c. Within these expressions, the only character that needs to be treated as a special character is ]; all others are not special.</td>
</tr>
<tr>
<td>[a-z]</td>
<td>Match one occurrence of a character between a and z.</td>
</tr>
<tr>
<td>[^az]</td>
<td>Match any character except a or z.</td>
</tr>
<tr>
<td>*~</td>
<td>This expression, followed by another expression, removes any pattern matching the second expression.</td>
</tr>
<tr>
<td>*</td>
<td>Match zero or more characters.</td>
</tr>
</tbody>
</table>

Wildcard Examples

The following table provides wildcard examples, listing the pattern and the result.

TABLE 9–2  Wildcard Examples

<table>
<thead>
<tr>
<th>Pattern</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>*.netscape.com</td>
<td>Matches any string ending with the characters .netscape.com.</td>
</tr>
<tr>
<td>(quark</td>
<td>energy).netscape.com</td>
</tr>
<tr>
<td>198.93.9[23].???</td>
<td>Matches a numeric string starting with either 198.93.92 or 198.93.93 and ending with any 3 characters.</td>
</tr>
<tr>
<td><em>.</em></td>
<td>Matches any string with a period in it.</td>
</tr>
<tr>
<td><em>-netscape-</em></td>
<td>Matches any string except those starting with netscape-.</td>
</tr>
<tr>
<td><em>.com-</em>.*.netscape.com</td>
<td>Matches any host from domain .com except for hosts from subdomain netscape.com.</td>
</tr>
</tbody>
</table>
### TABLE 9-2  Wildcard Examples  (Continued)

<table>
<thead>
<tr>
<th>Pattern</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>type=*-magnus-internal/*</code></td>
<td>Matches any type that does not start with <code>magnus-internal/</code>. This wildcard pattern is used in the file <code>obj.conf</code> in the catch-all <code>service</code> directive.</td>
</tr>
</tbody>
</table>
This chapter describes the format strings used for dates and times. These formats are used by the NSAPI function `util_strftime`, by some built-in SAFs such as `append-trailer`, and by server-parsed HTML (parse-html). The formats are similar to those used by the `strftime` C library routine, but not identical.

**Time and Date Strings**

The following table describes the symbols and their meanings.

<table>
<thead>
<tr>
<th>Symbol</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>%a</td>
<td>Abbreviated weekday name (3 chars)</td>
</tr>
<tr>
<td>%d</td>
<td>Day of month as decimal number (01-31)</td>
</tr>
<tr>
<td>%S</td>
<td>Second as decimal number (00-59)</td>
</tr>
<tr>
<td>%M</td>
<td>Minute as decimal number (00-59)</td>
</tr>
<tr>
<td>%H</td>
<td>Hour in 24-hour format (00-23)</td>
</tr>
<tr>
<td>%Y</td>
<td>Year with century, as decimal number, up to 2099</td>
</tr>
<tr>
<td>%b</td>
<td>Abbreviated month name (3 chars)</td>
</tr>
<tr>
<td>%h</td>
<td>Abbreviated month name (3 chars)</td>
</tr>
<tr>
<td>%T</td>
<td>Time &quot;HH:MM:SS&quot;</td>
</tr>
<tr>
<td>%X</td>
<td>Time &quot;HH:MM:SS&quot;</td>
</tr>
<tr>
<td>%A</td>
<td>Full weekday name</td>
</tr>
</tbody>
</table>
### Time Formats (Continued)

<table>
<thead>
<tr>
<th>Symbol</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>%B</td>
<td>Full month name</td>
</tr>
<tr>
<td>%C</td>
<td>&quot;%a %b %e %H:%M:%S %Y&quot;</td>
</tr>
<tr>
<td>%c</td>
<td>Date &amp; time &quot;%m/%d/%y %H:%M:%S&quot;</td>
</tr>
<tr>
<td>%D</td>
<td>Date &quot;%m/%d/%y&quot;</td>
</tr>
<tr>
<td>%e</td>
<td>Day of month as decimal number (1-31) without leading zeros</td>
</tr>
<tr>
<td>%I</td>
<td>Hour in 12-hour format (01-12)</td>
</tr>
<tr>
<td>%j</td>
<td>Day of year as decimal number (001-366)</td>
</tr>
<tr>
<td>%k</td>
<td>Hour in 24-hour format (0-23) without leading zeros</td>
</tr>
<tr>
<td>%l</td>
<td>Hour in 12-hour format (1-12) without leading zeros</td>
</tr>
<tr>
<td>%m</td>
<td>Month as decimal number (01-12)</td>
</tr>
<tr>
<td>%n</td>
<td>line feed</td>
</tr>
<tr>
<td>%p</td>
<td>A.M./P.M. indicator for 12-hour clock</td>
</tr>
<tr>
<td>%R</td>
<td>Time &quot;%H:%M&quot;</td>
</tr>
<tr>
<td>%r</td>
<td>Time &quot;%I:%M:%S %p&quot;</td>
</tr>
<tr>
<td>%t</td>
<td>tab</td>
</tr>
<tr>
<td>%U</td>
<td>Week of year as decimal number, with Sunday as first day of week (00-51)</td>
</tr>
<tr>
<td>%w</td>
<td>Weekday as decimal number (0-6; Sunday is 0)</td>
</tr>
<tr>
<td>%W</td>
<td>Week of year as decimal number, with Monday as first day of week (00-51)</td>
</tr>
<tr>
<td>%x</td>
<td>Date &quot;%m/%d/%y&quot;</td>
</tr>
<tr>
<td>%y</td>
<td>Year without century, as decimal number (00-99)</td>
</tr>
<tr>
<td>%%</td>
<td>Percent sign</td>
</tr>
</tbody>
</table>
The functions described in this chapter allow you to write a results caching plug-in for Sun Java System Web Server. A results caching plug-in, which is a Service SAF, caches data, a page, or part of a page in the web server address space, which the web server can refresh periodically on demand. An Init SAF initializes the callback function that performs the refresh.

A results caching plug-in can generate a page for a request in three parts:

- A header, such as a page banner, which changes for every request
- A body, which changes less frequently
- A footer, which also changes for every request

Without this feature, a plug-in would have to generate the whole page for every request (unless an IFRAME is used, where the header or footer is sent in the first response along with an IFRAME pointing to the body, in this case the browser must send another request for the IFRAME).

If the body of a page has not changed, the plug-in needs to generate only the header and footer and to call the `dr_net_write` function (instead of `net_write`) with the following arguments:

- header
- footer
- handle to cache
- key to identify the cached object

The web server constructs the whole page by fetching the body from the cache. If the cache has expired, it calls the refresh function and sends the refreshed page back to the client.

An Init SAF that is visible to the plug-in creates the handle to the cache. The Init SAF must pass the following parameters to the `dr_cache_init` function:

- RefreshFunctionPointer
- FreeFunctionPointer
The RefreshInterval value must be a PrIntervalTime type. For more information, see the NSPR reference at:

As an alternative, if the body is a file that is present in a directory within the web server system machine, the plug-in can generate the header and footer and call the fc_net_write function along with the file name.

This chapter lists the most important functions a results caching plug-in can use. For more information, see the following file:

server_root/plug-ins/include/drnsapi.h

This chapter has the following sections:
- “dr_cache_destroy” on page 256
- “dr_cache_init” on page 257
- “dr_cache_refresh” on page 258
- “dr_net_write” on page 259
- “fc_net_write” on page 262

**dr_cache_destroy**

The dr_cache_destroy function destroys and frees resources associated with a previously created and used cache handle. This handle can no longer be used in subsequent calls to any of the above functions unless another dr_cache_init is performed.

**Syntax**

```c
void dr_cache_destroy(DrHdl *hdl);
```

**Parameters**

DrHdl *hdl is a pointer to a previously initialized handle to a cache (see dr_cache_init).

**Returns**

void
Example

dr_cache_destroy(&myHdl);

dr_cache_init

The dr_cache_init function creates a persistent handle to the cache, or NULL on failure. It is called by an Init SAF.

Syntax

PRInt32 dr_cache_init(DrHdl *hdl, RefreshFunc_t ref, FreeFunc_t fre, CompareFunc_t cmp, PRUint32 maxEntries, PRIntervalTime maxAge);

Returns

1 if successful.

0 if an error occurs.

Parameters

The following table describes parameters for the dr_cache_init function.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>DrHdl hdl</td>
<td>Pointer to an unallocated handle.</td>
</tr>
<tr>
<td>RefreshFunc_t ref</td>
<td>Pointer to a cache refresh function. This can be NULL. See the DR_CHECK flag and DR_EXPIR return value for dr_net_write.</td>
</tr>
<tr>
<td>FreeFunc_t fre</td>
<td>Pointer to a function that frees an entry.</td>
</tr>
<tr>
<td>CompareFunc_t cmp</td>
<td>Pointer to a key comparator function.</td>
</tr>
<tr>
<td>PRUint32 maxEntries</td>
<td>Maximum number of entries possible in the cache for a given hdl.</td>
</tr>
<tr>
<td>PRIntervalTime maxAge</td>
<td>The maximum amount of time that an entry is valid. If 0, the cache never expires.</td>
</tr>
</tbody>
</table>
Example

if(!dr_cache_init(&hdl, (RefreshFunc_t)FnRefresh, (FreeFunc_t)FnFree, (CompareFunc_t)FnCompare, 150000, PR_SecondsToInterval(7200)))
{
    ereport(LOG_FAILURE, "dr_cache_init() failed");
    return(REQ_ABORTED);
}

The `dr_cache_refresh` function provides a way of refreshing a cache entry when the plug-in requires it. This can be achieved by passing NULL for the ref parameter in `dr_cache_init` and by passing DR_CHECK in a `dr_net_write` call. If DR_CHECK is passed to `dr_net_write` and it returns with DR_EXPIRED, the plug-in should generate new content in the entry and call `dr_cache_refresh` with that entry before calling `dr_net_write` again to send the response.

The plug-in may simply decide to replace the cached entry even if it has not expired (based on some other business logic). The `dr_cache_refresh` function is useful in this case. This way the plug-in does the cache refresh management actively by itself.

Syntax

```
PRInt32 dr_cache_refresh(DrHdl hdl, const char *key, PRUint32 klen, PRIntervalTime timeout, Entry *entry, Request *rq, Session *sn);
```

Returns

1 if successful.

0 if an error occurs.

Parameters

The following table describes parameters for the `dr_cache_refresh` function.
### Table 11-2  dr_cache_refresh parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>DrHdl hdl</td>
<td>Persistent handle created by the dr_cache_init function.</td>
</tr>
<tr>
<td>const char *key</td>
<td>Key to cache, search, or refresh.</td>
</tr>
<tr>
<td>PRUint32 klen</td>
<td>Length of the key in bytes.</td>
</tr>
<tr>
<td>PRIntervalTime timeout</td>
<td>Expiration time of this entry. If a value of 0 is passed, the maxAge value passed to dr_cache_init is used.</td>
</tr>
<tr>
<td>Entry *entry</td>
<td>The not NULL entry to be cached.</td>
</tr>
<tr>
<td>Request *rq</td>
<td>Pointer to the request.</td>
</tr>
<tr>
<td>Session *sn</td>
<td>Pointer to the session.</td>
</tr>
</tbody>
</table>

### Example

```c
Entry entry;
char *key = "MOVIES"
GenNewMovieList(&entry.data, &entry.dataLen); // Implemented by // plugin developer
if(!dr_cache_refresh(hdl, key, strlen(key), 0, &entry, rq, sn))
{
    ereport(LOG_FAILURE, "dr_cache_refresh() failed");
    return REQ_ABORTED;
}
```

### dr_net_write

The `dr_net_write` function sends a response back to the requestor after constructing the full page with hdr, the content of the cached entry as the body (located using the key), and ftr. The hdr, ftr, or hdl can be NULL, but not all of them can be NULL. If hdl is NULL, no cache lookup is done and the caller must pass DR_NONE as the flag.

By default, this function refreshes the cache entry if it has expired by making a call to the ref function passed to dr_cache_init. If no cache entry is found with the specified key, this function adds a new cache entry by calling the ref function before sending out the response. However, if the DR_CHECK flag is passed in the flags parameter and if either the cache entry has expired or the cache entry corresponding to the key does not exist, dr_net_write does not send any data out. Instead it returns with DR_EXPIR.
If ref (passed to dr_cache_init) is NULL, the DR_CHECK flag is not passed in the flags parameter, and the cache entry corresponding to the key has expired or does not exist, then dr_net_write fails with DR_ERROR. However, dr_net_write refreshes the cache if ref is not NULL and DR_CHECK is not passed.

If ref (passed to dr_cache_init) is NULL and the DR_CHECK flag is not passed but DR_IGNORE is passed and the entry is present in the cache, dr_net_write sends out the response even if the entry has expired. However, if the entry is not found, dr_net_write returns DR_ERROR.

If ref (passed to dr_cache_init) is not NULL and the DR_CHECK flag is not passed but DR_IGNORE is passed and the entry is present in the cache, dr_net_write sends out the response even if the entry has expired. However, if the entry is not found, dr_net_write calls the ref function and stores the new entry returned from ref before sending out the response.

**Syntax**

```c
PRInt32 dr_net_write(DrHdl hdl, const char *key, PRUint32 klen,
const char *hdr, const char *ftr, PRUint32 hlen, PRUint32 flen,
PRIntervalTime timeout, PRUint32 flags, Request *rq, Session *sn);
```

**Returns**

IO_OKAY if successful.

IO_ERROR if an error occurs.

DR_ERROR if an error in cache handling occurs.

DR_EXPIR if the cache has expired.

**Parameters**

The following table describes parameters for the `dr_net_write` function.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>DrHdl hdl</td>
<td>Persistent handle created by the dr_cache_init function.</td>
</tr>
<tr>
<td>const char *key</td>
<td>Key to cache, search, or refresh.</td>
</tr>
<tr>
<td>PRUint32 klen</td>
<td>Length of the key in bytes.</td>
</tr>
</tbody>
</table>
TABLE 11–3  dr_net_write parameters  (Continued)

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>const char *hdr</td>
<td>Any header data (which can be NULL).</td>
</tr>
<tr>
<td>const char *ftr</td>
<td>Any footer data (which can be NULL).</td>
</tr>
<tr>
<td>PRUint32 hlen</td>
<td>Length of the header data in bytes (which can be 0).</td>
</tr>
<tr>
<td>PRUint32 flen</td>
<td>Length of the footer data in bytes (which can be 0).</td>
</tr>
<tr>
<td>PRIntervalTime timeout</td>
<td>Timeout before this function aborts.</td>
</tr>
<tr>
<td>PRUint32 flags</td>
<td>ORed directives for this function (see the Flags table, below).</td>
</tr>
<tr>
<td>Request *rq</td>
<td>Pointer to the request.</td>
</tr>
<tr>
<td>Session *sn</td>
<td>Pointer to the session.</td>
</tr>
</tbody>
</table>

Flags

The following table describes flags for dr_net_write.

TABLE 11–4  Flags for dr_net_write

<table>
<thead>
<tr>
<th>Flag</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>DR_NONE</td>
<td>Specifies that no cache is used, so the function works as net_write does. DrHdl can be NULL.</td>
</tr>
<tr>
<td>DR_FORCE</td>
<td>Forces the cache to refresh, even if it has not expired.</td>
</tr>
<tr>
<td>DR_CHECK</td>
<td>Returns DR_EXPIR if the cache has expired, if the calling function has not provided a refresh function and this flag is not used, DR_ERROR is returned.</td>
</tr>
<tr>
<td>DR_IGNORE</td>
<td>Ignores cache expiration and sends out the cache entry even if it has expired.</td>
</tr>
<tr>
<td>DR_CNTLEN</td>
<td>Supplies the Content-Length header and does a PROTOCOL_START_RESPONSE.</td>
</tr>
<tr>
<td>DR_PROTO</td>
<td>Does a PROTOCOL_START_RESPONSE.</td>
</tr>
</tbody>
</table>

Example

if(dr_net_write(Dr, szFileName, iLenK, NULL, NULL, 0, 0, 0, DR_CNTLEN | DR_PROTO, rq, sn) == IO_ERROR)
{
    return(REQ_EXIT);
}
The fc_net_write function is used to send a header and/or footer and a file that exists somewhere in the system. The fileName should be the full path name of a file.

Syntax

PRInt32 fc_net_write(const char *fileName, const char *hdr, const char *ftr, PRUint32 hlen, PRUint32 flen, PRUint32 flags, PRIntervalTime timeout, Session *sn, Request *rq);

Returns

IO_OKAY if successful.

IO_ERROR if an error occurs.

FC_ERROR if an error in file handling occurs.

Parameters

The following table describes parameters for the fc_net_write function.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>const char *fileName</td>
<td>File to be inserted.</td>
</tr>
<tr>
<td>const char *hdr</td>
<td>Any header data (which can be NULL).</td>
</tr>
<tr>
<td>const char *ftr</td>
<td>Any footer data (which can be NULL).</td>
</tr>
<tr>
<td>PRUint32 hlen</td>
<td>Length of the header data in bytes (which can be 0).</td>
</tr>
<tr>
<td>PRUint32 flen</td>
<td>Length of the footer data in bytes (which can be 0).</td>
</tr>
<tr>
<td>PRUint32 flags</td>
<td>ORed directives for this function (see the Flags table, below).</td>
</tr>
<tr>
<td>PRIntervalTime timeout</td>
<td>Timeout before this function aborts.</td>
</tr>
<tr>
<td>Request *rq</td>
<td>Pointer to the request.</td>
</tr>
<tr>
<td>Session *sn</td>
<td>Pointer to the session.</td>
</tr>
</tbody>
</table>
Flags

The following table describes flags for fc_net_write.

<table>
<thead>
<tr>
<th>Flag</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>FC_CNTLEN</td>
<td>Supplies the Content-Length header and does a</td>
</tr>
<tr>
<td></td>
<td>PROTOCOL_START_RESPONSE.</td>
</tr>
<tr>
<td>FC_PROTO</td>
<td>Does a PROTOCOL_START_RESPONSE.</td>
</tr>
</tbody>
</table>

Example

```c
const char *fileName = "/docs/myads/file1.ad";
char *hdr = GenHdr(); // Implemented by plugin
char *ftr = GenFtr(); // Implemented by plugin

if(fc_net_write(fileName, hdr, ftr, strlen(hdr), strlen(ftr),
    FC_CNTLEN, PR_INTERVAL_NO_TIMEOUT, sn, rq) != IO_OKEY)
{
    ereport(LOG_FAILURE, "fc_net_write() failed");
    return REQ_ABORTED;
}
```
The Hypertext Transfer Protocol (HTTP) is a protocol (a set of rules that describes how information is exchanged) that allows a client (such as a web browser) and a web server to communicate with each other.

HTTP is based on a request-response model. The browser opens a connection to the server and sends a request to the server. The server processes the request and generates a response, which it sends to the browser. The server then closes the connection.

This chapter provides a short introduction to a few HTTP basics. For more information on HTTP, see the IETF home page at:

http://www.ietf.org/home.html

This chapter has the following sections:

- "Compliance" on page 265
- "Requests" on page 266
- "Responses" on page 267
- "Buffered Streams" on page 269

Compliance

Sun Java System Web Server 6.1 supports HTTP/1.1. Previous versions of the server supported HTTP/1.0. The server is conditionally compliant with the HTTP/1.1 proposed standard, as approved by the Internet Engineering Steering Group (IESG), and the Internet Engineering Task Force (IETF) HTTP working group.

For more information on the criteria for being conditionally compliant, see the Hypertext Transfer Protocol -- HTTP/1.1 specification (RFC 2068) at:

http://www.ietf.org/rfc/rfc2068.txt?number=2068
Requests

A request from a browser to a server includes the following information:

- “Request Method, URI, and Protocol Version” on page 266
- “Request Headers” on page 266
- “Request Data” on page 266

Request Method, URI, and Protocol Version

A browser can request information using a number of methods. The commonly used methods include the following:

- **GET** -- Requests the specified resource (such as a document or image)
- **HEAD** -- Requests only the header information for the document
- **POST** -- Requests that the server accept some data from the browser, such as form input for a CGI program
- **PUT** -- Replaces the contents of a server's document with data from the browser

Request Headers

The browser can send headers to the server. Most are optional.

The following table lists some of the commonly used request headers.

<table>
<thead>
<tr>
<th>Request Header</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Accept</td>
<td>File types the browser can accept.</td>
</tr>
<tr>
<td>Authorization</td>
<td>Used if the browser wants to authenticate itself with a server. Information such as the user name and password are included.</td>
</tr>
<tr>
<td>User-Agent</td>
<td>Name and version of the browser software.</td>
</tr>
<tr>
<td>Referer</td>
<td>URL of the document where the user clicked on the link.</td>
</tr>
<tr>
<td>Host</td>
<td>Internet host and port number of the resource being requested.</td>
</tr>
</tbody>
</table>

Request Data

If the browser has made a **POST** or **PUT** request, it sends data after the blank line following the request headers. If the browser sends a **GET** or **HEAD** request, there is no data to send.
Responses

The server’s response includes the following:

- “HTTP Protocol Version, Status Code, and Reason Phrase” on page 267
- “Response Headers” on page 268
- “Response Data” on page 269

HTTP Protocol Version, Status Code, and Reason Phrase

The server sends back a three-digit numeric status code. The five categories of status codes are:

- 100-199 a provisional response.
- 200-299 a successful transaction.
- 300-399 the requested resource should be retrieved from a different location.
- 400-499 an error was caused by the browser.
- 500-599 a serious error occurred in the server.

The following table lists some common status codes.

<table>
<thead>
<tr>
<th>Status Code</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>200</td>
<td>OK, request has succeeded for the method used (GET, POST, HEAD).</td>
</tr>
<tr>
<td>201</td>
<td>The request has resulted in the creation of a new resource reference by the returned URI.</td>
</tr>
<tr>
<td>206</td>
<td>The server has sent a response to byte range requests.</td>
</tr>
<tr>
<td>302</td>
<td>Found. Redirection to a new URL. The original URL has moved. This is not an error and most browsers will get the new page.</td>
</tr>
<tr>
<td>304</td>
<td>Use a local copy. If a browser already has a page in its cache, and the page is requested again, some browsers (such as Netscape Navigator) relay to the web server the “last-modified” timestamp on the browser’s cached copy. If the copy on the server is not newer than the browser’s copy, the server returns a 304 code instead of returning the page, reducing unnecessary network traffic. This is not an error.</td>
</tr>
<tr>
<td>400</td>
<td>Sent if the request is not a valid HTTP/1.0 or HTTP/1.1 request. For example HTTP/1.1 requires a host to be specified either in the Host header or as part of the URI on the request line.</td>
</tr>
<tr>
<td>401</td>
<td>Unauthorized. The user requested a document but didn’t provide a valid user name or password.</td>
</tr>
</tbody>
</table>
TABLE 12–2 Common HTTP Status Codes  (Continued)

<table>
<thead>
<tr>
<th>Status Code</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>403</td>
<td>Forbidden. Access to this URL is forbidden.</td>
</tr>
<tr>
<td>404</td>
<td>Not found. The document requested isn’t on the server. This code can also be sent if the server has been told to protect the document by telling unauthorized people that it doesn’t exist.</td>
</tr>
<tr>
<td>408</td>
<td>If the client starts a request but does not complete it within the keep-alive timeout configured in the server, then this response will be sent and the connection closed. The request can be repeated with another open connection.</td>
</tr>
<tr>
<td>411</td>
<td>The client submitted a POST request with chunked encoding, which is of variable length. However, the resource or application on the server requires a fixed length—a Content-Length header to be present. This code tells the client to resubmit its request with content-length.</td>
</tr>
<tr>
<td>413</td>
<td>Some applications (e.g., certain NSAPI plug-ins) cannot handle very large amounts of data, so they will return this code.</td>
</tr>
<tr>
<td>414</td>
<td>The URI is longer than the maximum the web server is willing to serve.</td>
</tr>
<tr>
<td>416</td>
<td>Data was requested outside the range of a file.</td>
</tr>
<tr>
<td>500</td>
<td>Server error. A server-related error occurred. The server administrator should check the server’s error log to see what happened.</td>
</tr>
<tr>
<td>503</td>
<td>Sent if the quality of service mechanism was enabled and bandwidth or connection limits were attained. The server will then serve requests with that code. See the “quality of service” section.</td>
</tr>
</tbody>
</table>

Response Headers

The response headers contain information about the server and the response data.

The following table lists some common response headers.

TABLE 12–3 Common Response Headers

<table>
<thead>
<tr>
<th>Response Header</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Server</td>
<td>Name and version of the web server.</td>
</tr>
<tr>
<td>Date</td>
<td>Current date (in Greenwich Mean Time).</td>
</tr>
<tr>
<td>Last-Modified</td>
<td>Date when the document was last modified.</td>
</tr>
<tr>
<td>Expires</td>
<td>Date when the document expires.</td>
</tr>
<tr>
<td>Content-Length</td>
<td>Length of the data that follows (in bytes).</td>
</tr>
</tbody>
</table>
TABLE 12-3 Common Response Headers  (Continued)

<table>
<thead>
<tr>
<th>Response Header</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>content-type</td>
<td>MIME type of the following data.</td>
</tr>
<tr>
<td>WWW-Authenticate</td>
<td>Used during authentication and includes information that tells the browser software what is necessary for authentication (such as user name and password).</td>
</tr>
</tbody>
</table>

**Response Data**

The server sends a blank line after the last header. It then sends the response data such as an image or an HTML page.

**Buffered Streams**

Buffered streams improve the efficiency of network I/O (for example, the exchange of HTTP requests and responses), especially for dynamic content generation. Buffered streams are implemented as transparent NSPR I/O layers, which means even existing NSAPI modules can use them without any change.

The buffered streams layer adds the following features to the Sun Java System Web Server:

- **Enhanced keep-alive support:** When the response is smaller than the buffer size, the buffering layer generates the `Content-Length` header so that the client can detect the end of the response and reuse the connection for subsequent requests.

- **Response length determination:** If the buffering layer cannot determine the length of the response, it uses HTTP/1.1 chunked encoding instead of the `Content-Length` header to convey the delineation information. If the client only understands HTTP/1.0, the server must close the connection to indicate the end of the response.

- **Deferred header writing:** Response headers are written out as late as possible to give the servlets a chance to generate their own headers (for example, the session management header `set-cookie`).

- **Ability to understand request entity bodies with chunked encoding:** Though popular clients do not use chunked encoding for sending `POST` request data, this feature is mandatory for HTTP/1.1 compliance.

The improved connection handling and response length header generation provided by buffered streams also addresses the HTTP/1.1 protocol compliance issues, where absence of the response length headers is regarded as a category 1 failure. In previous Enterprise Server versions, it was the responsibility of the dynamic content generation programs to send the length headers. If a CGI script did not generate the `Content-Length` header, the server had to close the connection to indicate the end of the response, breaking the keep-alive connection.
mechanism. However, it is often very inconvenient to keep track of response length in CGI scripts or servlets, and as an application platform provider, the web server is expected to handle such low-level protocol issues.

Output buffering has been built in to the functions that transmit data, such as “net_write” on page 168 (see Chapter 7, NSAPI Function Reference stream buffering, which are described in detail in the chapter “Syntax and Use of magnus.conf” in the Sun Java System Web Server 6.1 Administrator’s Configuration File Reference.

- UseOutputStreamSize
- ChunkedRequestBufferSize
- ChunkedRequestTimeout

The UseOutputStreamSize, ChunkedRequestBufferSize, and ChunkedRequestTimeout parameters also have equivalent magnus.conf directives, see “Chunked Encoding” in the chapter “Syntax and Use of magnus.conf” in the Sun Java System Web Server 6.1 Administrator’s Configuration File Reference. The obj.conf parameters override the magnus.conf directives.

**Note** – The UseOutputStreamSize parameter can be set to zero (0) in the obj.conf file to disable output stream buffering. For the magnus.conf file, setting UseOutputStreamSize to zero has no effect.

To override the default behavior when invoking an SAF that uses one of the functions “net_read” on page 166 or “netbuf_grab” on page 171, you can specify the value of the parameter in obj.conf, for example:

```
Service fn="my-service-saf" type=perf UseOutputStreamSize=8192
```

netbufbuf2sd API function, 168-169
netbuf_close API function, 169
netbuf_getbytes API function, 170-171
netbuf_getc API function, 171
netbuf_grab API function, 171-172
netbuf_open API function, 172
network I/O routines, 86
nondefault objects, processing, 38-39
NSAPI
alphabetical function reference, 143-239
CGI environment variables, 91-93
data structure reference, 241-247
filter interface, 96
function overview, 84-88
### NSAPI filters
- Interface, 96
- Methods, 96-99
- nsapi.h, 241
- nsapi_pvt.h, 242
- nt-console-init function, 66

### O
- obj.conf
  - Adding directives for new SAFs, 82-83
  - Case sensitivity, 46
  - Client tag, 34-36
  - Comments, 47
  - Directive syntax, 27
  - Directives, 27-31
  - Directives summary, 28-31
  - Flow of control, 37-44
  - Object tag, 32-34
  - Order of directives, 45-46
  - Parameters for directives, 46
  - Predefined SAFs, 23
  - Processing other objects, 38-39
  - Server instructions, 27-31
  - Standard directives, 23
  - Syntax rules, 45-47
  - Use, 23-47
- Object tag, 32-36
  - Name attribute, 32
  - Ppath attribute, 32
- Object type
  - Forcing, 40-41
  - Setting by file extension, 39-40
- Objects, processing nondefault objects, 38-39
- ObjectType
  - Example of custom SAF, 117-118
  - Flow of control, 39-41
  - Requirements for SAFs, 88-91
  - Summary, 29
- Opt parameter, 51
- Order
  - Of directives in obj.conf, 45-46
  - Of filters in filter stack, 99-100
- Output, 26

### P
- Param_create API function, 174-175
- Param_free API function, 175
- Parameter block
  - Manipulation routines, 84-85
  - SAF parameter, 74-75
- Parameters
  - For obj.conf directives, 46
  - For SAFs, 74-76
- PATH_INFO environment variable, 92
- Path name, converting UNIX-style to local, 210-211
- Path names, 47
- PATH_TRANSLATED environment variable, 92
- PathCheck
  - Example of custom SAF, 114-117
  - Flow of control, 39
  - Requirements for SAFs, 88-91
  - Summary, 29
- Patterns, 249-251
- Pb_entry NSAPI data structure, 243
- Pb_param NSAPI data structure, 243
- Pb SAF parameter, 74-75
- Pblock, NSAPI data structure, 243
- Pblock_copy API function, 175-176
- Pblock_create API function, 176
- Pblock_dup API function, 177
- Pblock_find API function, 177
- Pblock_findval API function, 178
- Pblock_free API function, 178-179
- Pblock_ninsert API function, 179
- Pblock_nvinsert API function, 179-180
- Pblock_pb2env API function, 180-181
- Pblock_pblock2str API function, 181
- Pblock_pinsert API function, 181-182
- Pblock_remove API function, 182
- Pblock_str2pblock API function, 182-183
Index

perf-init function, 66-67
PERM_FREE API function, 184
PERM_MALLOC API function, 183-184, 184-185, 185-186
PERM_STRDUP API function, 186
pfx2dir function, 38
plug-ins
  compatibility issues, 74, 242
  creating, 73
  example of new plug-ins, 107-136
  instructing the server to use, 82-83
  loading and initializing, 81-82
  private data structures, 242
pool-init function, 67-68
pool parameter, 65
ppath attribute
  in obj.conf objects, 32
  in objects, 33-34
predefined SAFs in obj.conf, 23
prepare_nsapi_thread API function, 187
private data structures, 242
processing nondefault objects, 38-39
product support, 21
profiling parameter, 69
protocol_dump822 API function, 187-188
protocol_set_finfo API function, 188
protocol_start_response API function, 188-189
protocol_status API function, 189-190
protocol_uri2url API function, 190-191 191
protocol utility routines, 85
pwpfile parameter, 64

R
read API function, 98, 192
REALLOC API function, 193
reference
  data structure, 241-247
  NSAPI functions, 143-239
register-http-method function, 68
relink_36plugin file, 81
REMOTE_ADDR environment variable, 92
REMOTE_HOST environment variable, 92
REMOTE_IDENT environment variable, 92
REMOTE_USER environment variable, 92
remove API function, 97-98 193-194
replace.c, 119
REQ_ABORTED response code, 76
REQ_EXIT response code, 77
REQ_NOACTION response code, 76
REQ_PROCEED response code, 76
reqpb, field in request parameter, 76
request
  NSAPI data structure, 244
  SAF parameter, 75-76
request_get_vs API function, 194
request-handling process, 88-91
  flow of control, 37-44
  steps, 25-26
request_header API function, 194-195
request headers, 266
REQUEST_METHOD environment variable, 92
request-response model, 265
request_stat_path API function, 195-196
request_translate_uri API function, 196
requests
  directives for handling, 26-27
  how server handles, 24-27
  HTTP, 266
  methods, 24
  steps in handling, 25-26
requirements for SAFs, 88-91
  AddLog, 91
  AuthTrans, 89
  Error directive, 91
  Init, 89
  Input, 90

Q
qos.c file, 130
quality of service, example code, 130-136
QUERY environment variable, 92
QUERY_STRING environment variable, 92
queueSize parameter, 70
quotes, 46
requirements for SAFs (Continued)
NameTrans, 89
ObjectType, 90
Output, 90
PathCheck, 90
Service, 90-91
responseheaders, 268-269
responses, HTTP, 267-269
resultcodes, 76-77
results caching plug-in, 255
important functions used by, 256
rotate-access parameter, 59
rotate-callback parameter, 59
rotate-error parameter, 59
rotate-interval parameter, 59
rotate-start parameter, 59
rotating logs, 58-59
rq->headers, 76
rq->reqpb, 76
rq->svrhdrs, 76
rq->vars, 75
rq SAF parameter, 75-76
rules, for editing obj.conf, 45-47

S
s, 243
SAFs
  compiling and linking, 78-81
  creating, 73-93
  examples of custom SAFs, 107-136
  in magnus.conf, 49-71
  include directory, 79
  interface, 74
  loading and initializing, 81-82
  parameters, 74-76
  predefined, 23
  result codes, 76-77
  return values, 76
  signature, 74
  testing, 84
SCRIPT_NAME environment variable, 92
search patterns, 249-251
sendfile API function, 99 197
sendfile data NSAPI data structure, 245
separators, 46
server
  flow of control, 37-44
  initialization directives in magnus.conf, 49
  instructions for using plug-ins, 82-83
  instructions in obj.conf, 27-31
  processing nondefault objects, 38-39
  request handling, 24-27
SERVER_NAME environment variable, 92
server-parsed HTML tags
  creating custom, 137-142
  more information, 137
SERVER_PORT environment variable, 92
SERVER_PROTOCOL environment variable, 92
SERVER_SOFTWARE environment variable, 92
SERVER_URL environment variable, 93
server.xml, variables defined in, 36-37
Service
  default directive, 43-44
  directives for new SAFs (plug-ins), 83
  example of custom SAF, 125-127
  examples, 42-43
  flow of control, 42-44
  requirements for SAFs, 88-91
  summary, 30
session
  defined, 242
  NSAPI data structure, 242
  resolving the IP address of, 197-198, 198
Session->client NSAPI data structure, 243
session_dns API function, 197-198
session_maxdns API function, 198
session SAF parameter, 75
shared library, loading, 65
shell expression
  comparing (case-blind) to a string, 199
  comparing (case-sensitive) to a string, 199-200,
  200-201
  validating, 201
shexp_casecmp API function, 199
shexp_cmp API function, 199-200
shexp_match API function, 200-201
shexp_valid API function, 201
